Additionally, Cisco objects to Alcatel's use of the word "selected" in its proposed construction. In this regard, Cisco argues that, while not all input data streams of the entire data processing system are part of the "multiplexed output data stream," all input data streams multiplexed onto a particular output port are part of the "multiplexed output data stream." Alcatel does not disagree with this assessment, and in fact notes that "[d]eleting the word 'selected' in Alcatel's proposed construction would still accurately reflect the clear meaning of the phrase." Alcatel's '052 Responsive Brief, at 3. Thus, the dispute over this term does not appear material, since neither party disagrees that not all input data streams are necessarily part of the "multiplexed output data stream," but all input data streams selected to be multiplexed onto an output of the system are part of that "multiplexed output data stream."

Therefore, the Court construes the term "multiplexed output data stream" as "a data transmission sent out from the data processing system made up of data from input data streams."
such as QAM or MDPSK. The Court construes the term "the information is multiplexed over a number M of levels" to mean "the information is multiplexed over a number M of levels, where M is the number of levels each symbol can take using differential modulation."

N-Data and National argue that these terms should be given their plain and ordinary meaning. N-Data also submits alternative definitions, should the court determine they need construction. Similar to above, the court believes that the jury would find construction of the terms assistive.

The central issue regarding these terms is whether they should be limited, as Dell suggests, to devices capable of receiving at least two inputs. N-Data argues that such limitation excludes a preferred embodiment. N-Data points to Figure 2 of the '216 patent in support of their contention. N-Data argues that a multiplexer can have one input and there is no requirement that each multiplexer have at least two inputs. Specifically, N-Data asserts that "multiplexer," as used in the patents in the context of "time division multiplexing," refers to the time placement of data in frames and not to the selection of inputs. Dell points to extrinsic sources and ordinary usage of the term for their definition of "multiplexer."

The court agrees with N-Data. Figure 2 of the '216 patent discloses two situations in which there is one input. In Node 1, the multiplexer has only one input and one output. Similarly, in the demultiplexing direction, there is one input and one output. Node 3 presents the same situation. Although N-Data's proposed definition may contradict the standard definition of multiplexer, the court must define the disputed term in light of the specification and claim language. Here, the court finds that the patentee disclosed multiplexers having only one input.

Dell proposes the same construction for "time-multiplexed data" and "time-division multiplexing data;" however, it does not provide intrinsic evidence in support of their multiple limitations.

In light of the above discussion, the court defines "multiplexer" as "circuitry for processing data from one or more inputs into a repeating series of frames or templates."

The court defines "time-multiplexed data" as "data that has been processed into a repeating series of frames or templates."

The court defines "time-division multiplexing data" as "processing data into a repeating series of frames or templates according to time intervals."

Multi-Tech next challenges the district court's construction of the claim term "multiplexing" in claim 1 of the '649 patent and claim 11 of the '532 patent. Multi-Tech argues that the court improperly imported limitations from the specification into the claims by requiring that voice data have priority over computer data and that computer data be substituted for detected and discarded silence packets.

Microsoft responds by pointing out that the parties agreed that Multi-Tech acted as its own lexicographer in defining the term "multiplexing." Therefore, Microsoft argues, the specification's definition of the term "multiplexing" to include the prioritization of voice packets, the detection and discarding of silence packets, and the transmission of computer data during periods of silence is the proper one.

We again begin our analysis with the claim language. Claim 1 of the '649 patent simply requires "multiplexing" outgoing voice and computer data packets and "demultiplexing" incoming voice and computer data packets. '649 patent, col. 47, ll. 3128-
14-25. Claim 11 of the '532 patent similarly requires "multiplexing" and "demultiplexing" voice and video data packets. '532 patent, col. 49, ll. 4-13. At the very least then, the plain language of the claims defines the term "multiplexing" as the combining of voice and computer data packets. The parties also agree that Multi-Tech acted as its own lexicographer in defining the term "multiplexing" to mean "dynamic multiplexing," or the combining of voice and computer data packets for transmission through the same channel by dynamically changing the time allocations for transmission of each type of data. That interpretation is supported by the specification. See, e.g., '289 patent, col. 3, l. 2; id. at col. 7, ll. 39-42.

The parties disagree, however, as to the propriety of the district court's inclusion of two additional limitations in its interpretation of the term "multiplexing." First, we agree with Microsoft that the court properly interpreted the term "multiplexing" to require the prioritization of voice data over computer data. In its discussion of multiplexing, the specification provides that voice data have higher priority than computer data "to ensure the integrity of the real-time voice transmission." Id. at col. 35, ll. 57-58. Because maintaining the integrity of the voice data is central to the functioning of the claimed inventions, we read Multi-Tech as having defined the term "multiplexing" to require the prioritization of voice data over computer data.

However, we agree with Multi-Tech that the court improperly construed the term "multiplexing" to require the detection and discarding of silence packets and the transmission of computer data packets during periods of silence. The specification's references to those limitations are nothing more than disclosures of a preferred embodiment. Although those features may be desirable, nowhere does the specification indicate that they are necessary for the multiplexing function. Moreover, the method of detecting and discarding silence packets and transmitting only computer data packets during periods of silence is separately claimed in the dependent claims. '649 patent, col. 47, ll. 26-35; '532 patent, col. 49, ll. 14-23; see Comark Communications, 156 F.3d at 1187 (recognizing that the doctrine of claim differentiation, although not a hard and fast rule of claim construction, creates a presumption that each claim in a patent has a different scope). We therefore conclude that the term "multiplexing" does not include the limitations of detecting and discarding silence packets and transmitting computer data packets during periods of silence.

E. The Johnson Patent

The parties ask the Court to construe the phrase "multiplexing address signals being transferred to said second bus by said access means and said controller means, together with data signals being transferred to said second bus" in Claim 55 of the Johnson patent. Joint Statement at 7. The parties agree that in the abstract "multiplexing" by itself can refer to (1) selecting one of two sets of data from an input for transmission to an output and (2) interleaving the two sets of data in time for sequential transmission to an output n3. AMD's Opening Markman Brief at 23; Oki's Response to AMD's Opening Markman Brief at 25. However, Oki argues that in the context of the Johnson patent, multiplexing requires interleaving two sets of data for transmission to an output. Oki's Response to AMD's Opening Markman Brief at 24. Thus, the Court must determine whether multiplexing as used in the Johnson patent requires interleaving. It does.

--- Footnotes ---

n3 Oki's expert describes interleaving with a useful analogy. One might imagine a two lane road on which cars travel side by side. If the cars each represents a unit of data, this two-lane road would allow parallel transmission. However, if the two-lane road merges into a single lane, the cars will have to enter the single lane "in an alternating manner, one at a time, to avoid collision." This merger is analogous to interleaving. Oki's Response to AMD's Opening Markman Brief, Ex. 16 ("Oklobdzija Decl.") at P 5.

--- End Footnotes ---

1. The Claims of the Johnson Patent

Claim 55 describes a method for transferring data back and forth between a computer's CPU and peripheral devices such as printers. "[H]igh performance devices including at least one" CPU are connected to a "first bus." 672 Patent col.49 ls.43-45. "[L]ower performance devices" are connected to a "second bus." Id. at ls.46-47. A "direct memory access means" transfers
data between the two buses. Id. at ls.49-50. The "direct memory access ["DMA"] means" includes "at least one direct memory access channel means." Id. at ls.50-52. When the DMA means transfers data between the two buses, the "direct memory access channel means" isolates the CPU (and other high performance devices) from the lower performing devices. Id. at ls.53-57. A second "means,"an "input/output ["I/O"] controller means," also transfers data between the two buses. Id. at ls.58-59. The I/O controller means includes "at least one address mapped input/output port means." Id. at ls.59-61. When the input/output controller means transfers data between the two buses, the address mapped input/output port means isolates the CPU (and other high performance devices) from the lower performing devices. Id. at ls.62-66. As the DMA means and the I/O controller means transfer address signals and data signals to the second bus, Claim 55 requires "multiplexing [of the] address signals . . . together with [the] data signals." Id. at col.49 ls.66-67; col.50 ls.1-2.

The claims standing alone are not conclusive on the meaning of multiplexing. However, the claims provide two hints whose implications become fully clear when the claims are read in light of the specification. First, whatever multiplexing is, Claim 55 only requires it as data travels in one direction. Claim 55 refers to data that travels in two directions: from the high performance devices on the first bus to the low performance devices on the second bus, and vice versa. Id. at col.49 1.43. However, Claim 55 only requires multiplexing as data is being transferred to the second bus. Id. at col.49 ls.66-67; col.50 ls.1-2. The second hint is the plain language of the claims themselves. The claims do not require multiplexing address signals and data signals. The claims require "multiplexing address signals . . . together with data signals." Id. at col.49 ls.66-67; col.50 ls.1-2. The implications of these hints will become clear as the Court delves into the specification.

2. The Specification of the Johnson Patent

The specification ties together the loose strings left by Claim 55. Two references to multiplexing prove informative. The first occurs in the description of a specific embodiment of the invention. In this embodiment, the bus connected to the high performance devices is actually composed of "two 32 bit wide buses referred to as the Address Bus' and Data Bus." Id. at col.1 ls.35-36. The Johnson patent refers to these two buses collectively as the Local Bus. Id. at 36-38. Address signals travel into a data transfer controller ("DTC") on the data bus. Id. at fig.3. Data signals travel into the DTC on the data bus. Id. These signals travel either to the input/output ports or the DMA channels. Id. Specifically, the address bus feeds address signals into both the I/O ports and the DMA Channels. Id. Likewise, the data bus feeds data signals into both the I/O ports and the DMA Channels. Id. At this point, then, both the I/O Ports and the DMA Channels are each ready to send a pair of address and data signals traveling in parallel to the remote bus. AMD argues that the multiplexing that Claim 55 refers to is selecting which of the pairs of signals to send to the Remote Bus. AMD's Opening Markman Brief at 23.

However, that's not what the specification says. The pairs of signals coming from the local bus to which the high performance devices are connected contain 64 bits of information. Id. at col. 1 ls.34-35. However, in the preferred embodiment, the Remote Bus onto which the data must be sent is only 32 bits wide n4. Id. at col. 8 1.43. Thus, the address signals and the data signals must be interleaved if they are to transfer to the 32 bit Remote Bus. The specification describes this interleaving as the multiplexing: "Fig. 3 goes on to show multiplexing and transceiver circuits . . . to indicate that address signals and data signals are interleaved when output to or received from the Remote Bus." Id. at col. 11 ls.60-64. The specification does not describe multiplexing as choosing between data from the I/O ports and the DMA channels. Thus, the specification indicates that multiplexing, as used in Claim 55, does require interleaving.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n4 This is analogous to cars traveling onto a 64 lane highway merging into a 32 lane highway.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Now, the first hint from the claims make sense. Multiplexing only needs to occur when data is transferred in one direction because data only needs to be interleaved as it is transferred from the faster 64 bit bus onto the 32 bit remote bus n5. This is borne out by the second important reference to multiplexing in the specification: the "Remote Address/Data Bus . . . is a bidirectional, Input/Output; asynchronous/synchronous, three state bus. The signals on this bus are multiplexed address/data signals for Remote Bus 120." Id. at col.8 ls.43-46. The phrase multiplexed address/data signals, like the words together with, invokes the notion that the data have been combined, or interleaved together. However, when describing the data on the Local Bus, the specification does not describe the data as multiplexed. This is so because, as Claim 55 indicates, multiplexing only needs to occur as data is being transferred from the Local Bus to the Remote Bus.
n5 Of course, the invention is not limited to a device in which the first and second busses are 64 and 32 bits wide. But the requirement imposed by multiplexing does envision a first bus with a greater data width than the second.

The second hint from Claim 55 also reveals its import when read in light of the specification. The words "together with" suggest that the address signals and data signals are somehow being combined. AMD's construction of the word multiplexing does not comport with this suggestion. According to AMD, two address-data pairs present themselves to the multiplexer. The multiplexer then chooses which of the two pairs to send on to the Remote Bus. Because each address-data pair arrives in parallel and leaves in parallel, no combination ever occurs. This, however, contradicts the notion that address signals must be multiplexed together with data signals. Interleaving, on the other hand, gives full meaning to the phrase "together with." According to the correct construction of Claim 55, paired address-data signals present themselves to the multiplexer. The multiplexer then breaks up the data pairs and sends them in time interleaved fashion. This allows address and data signals that arrived on two separate lines to leave the multiplexer on one single line, i.e. the remote bus. Construing multiplexing as interleaving gives full meaning to the words of Claim 55.

Another part of the specification reveals that the multiplexing as it is used in Claim 55 does not refer to selecting whether to send a pairs of signals from the I/O ports or the DMA channels to the Remote Bus. In a section explaining the function of the I/O ports, the specification explicitly refers to process AMD alleges constitutes multiplexing. "If a request from an I/O port for the Remote Bus occurs at the same time as a request from a DMA channel, the I/O has priority." Id. at col.25 ls.21-23. Unlike interleaving, the specification does not call this process multiplexing. The specification does not state that this activity is conducted by a multiplexer. Thus, while the patentee contemplated that the invention would make this decision between pairs of signals, he did not call it multiplexing.

AMD suggests that a reference to multiplexing in the specification's description of Figure 8 impacts the Court's construction of multiplexing in Claim 55. AMD's Opening Markman Brief at 24. The Court disagrees. Figure 8 of the specification depicts a block diagram of a DMA channel described by Claim 14. Compare id. at col.30 ls. 11-23 with col.44 ls.49-68. Claim 14 refers to multiplexing that takes place within the DMA channel. Both parties agreed at oral argument that this type of multiplexing does not require interleaving. Instead, this multiplexing does what AMD wishes the multiplexing in Claim 55 would do: it selects between two inputs that must be presented one at a time to a single output. Id. at col.44 ls.52-57. While this use of multiplexing does reveal that the patentee knew that the word multiplexing, in the abstract sense, could have many meanings, it does not inform the interpretation of Claim 55. Both the language of Claim 14 and the portion of the specification describing this multiplexing use different terminology than Claim 55. Claim 14 depends from Claim 13, which describes a data transfer controller that has a "queue means for buffering data being sent between the first and second bus." Id. at ls.45-46. Claim 14 then goes on to add the further limitation that the device set forth in Claim 13 have "(a) first multiplexing means for selectively transferring word length data input to [the] access means from [the] first bus and for selectively transferring packed data, input to [the] access means from said packing and funneling network means, into [the] queue means." Id. at col.44 ls.52-57. Two important differences between Claim 14 and Claim 55 are apparent. When the patentee uses multiplexing to describe the selection of one of two pieces of data, the claim explicitly describes that choice. Furthermore, Claim 14 does not state that the invention multiplexes "word length data" together with "packed data." Instead, the Claim uses language that indicates that the device is selectively choosing between them. Thus, the construction of multiplexing in Claim 55 is not altered by the fact that other claims indicate that the invention multiplexes in different ways.

The construction of Claim 55 in the Johnson patent reveals how the world of claim construction has changed since the Federal Circuit issued its landmark decision in Phillips. Prior to that decision, claim construction would begin with the various definitions of multiplexing the parties have offered. Phillips, 413 F.3d at 1319. Then, a court would attempt to look for an explicit indication in the patent that these definitions fell outside its scope. Id. Were the Court to engage in this method of claim construction, it might construe multiplexing to include interleaving and selecting between pairs of data since there is no explicit statement in the Johnson patent that this cannot be so. However, the Federal Circuit has rejected this method of claim construction. Id. at 1320. Instead of beginning with broad dictionary definitions, the Court begins with the language of the Johnson patent itself, allowing the claims and the specification to define the scope of the term multiplexing. See id. This method ensures that the Court does not construe multiplexing in an overly expansive way. See id.
3. Construction of Disputed Terms in the Johnson Patent

Based upon the foregoing considerations, the Court construes the phrase "multiplexing address signals being transferred to said second bus by said access means and said controller means, together with data signals being transferred to said second bus" in Claim 55 of the Johnson patent as follows: Address and data signals are being transferred to the second bus by the access and controller means. In this step, those address and data signals are combined for transmission over the second bus.

2801

2. "Multiplexor"

The court shall apply the ordinary definition of the word "multiplexor" in the relevant art. The term "multiplexor" shall be construed to mean "a device that allows the interleaving of two or more signals to a single line." 6

6 IEEE Standard Dictionary of Electrical and Electronics Terms, 430 (2d ed. 1978); see also F. Hill & G. Peterson, Introduction to Switching Theory & Logical Design 196 (3d ed. 1981) (a multiplexor "select[s] one of several inputs to connect to a single output line."); M. Mano, Digital Design 173 (2d ed. 1991) ("A digital multiplexor is a combinational circuit that selects binary information from one of many input lines and directs it to a single output line.").

D. "multiplicity"

This term appears in each of the patents, in a total of nine claims. A representative usage of "multiplicity" is:

19. An audio/video transceiver apparatus as in claim 17 in combination with a video library, coupled via a communication link with said audio/video transceiver apparatus, said video library storing a multiplicity of items of audio/video source information in said time compressed representation for selective retrieval, in said associated burst time period over said communications link.

The court construes "multiplicity" as "two or more; usually a fairly large number." Although Burst argues that claim construction is unnecessary for "multiplicity," the parties cite to extrinsic evidence indicating that the understandings of the average person and one of ordinary skill in the art may differ. Burst's definition from a standard dictionary reads: "a large number." American Heritage Dictionary 822 (2d College ed. 1982). Apple's definition, however, reads: "two or more; usually a fairly large number." Robert C. Faber, Landis on Mechanics of Patent Claim Drafting App. D-14 (5th ed. 2006). While the difference appears minimal, it embodies the parties' dispute regarding "multiplicity" and indicates that jurors would benefit from direction regarding the use by one skilled in the art.

The patents employ "multiplicity" in two different ways; both contexts support Apple's construction. In one instance, the term describes a "multiplicity of video frames collectively representing at least one full motion video program." '705 Patent at 12:38-40. In another instance, the term is used in connection with a "video library storing a multiplicity of items of audio/video source information. . . ." '995 Patent at 13:7-8. Apple's definition of multiplicity is supported by the claim language, since a video library constructed by a user may only include a limited number of items. Defining "multiplicity" as "two or more; usually a fairly large number" is also consistent with the usage in the '705 Patent, where the "frames collectively representing at least one full motion video program" indicates that they are numerous. '705 Patent at 12:38-40.
Thus, the court accepts Apple's construction of "multiplicity."

12. "Multiplicity": "A large number." This construction is consistent with: (1) the ordinary, dictionary definition of the term (D.I. 387, ex. 132 (THE CONCISE OXFORD DICTIONARY OF CURRENT ENGLISH (9th ed. 1995) ("a great number")), ex. 133 (OXFORD DICTIONARY OF ENGLISH (2nd ed. 2006) ("a large number or variety"); (2) the specification at col. 8, ll. 25-27 ("an order of magnitude"); and (3) the specification's separate use of "multiplicity" (see col. 8, ll. 4-13) and "plurality" (see claims 6 and 16).

Plaintiff advocated a definition of "more than one," a definition more consistent with "plurality."

12. "[A] multitasking operating system" 15 is an operating system that permits the user to execute two or more application programs at the same time. This construction is consistent with the claims, as well as the specification: col. 3:63-4:2; col. 27:59-65; col. 30:1-4; col. 31:10-31; col. 35:43-48.

MULTITHREADING

Plaintiff contends that "multithreading" should be given its common and ordinary meaning, within the field of computer programming. Citing a Microsoft publication, plaintiff asserts that "multithreading" means: "Supporting more than one thread within a single process." Pl Br (Doc # 331) at 18.

Plaintiff explicitly defined "multithreading" within both patents, although somewhat differently in each. The '603 patent reads:

The term "multithreading" is used in this application in its ordinary generally understood sense to mean the concurrent time-sliced preemptive execution of a plurality of threads of instructions located within the same single operator-selected application program, whereby during execution of the program each thread may have at various times direct access to the same program address space, and with at least one thread invoked by a periodic clock-activated interrupt service routine which upon each activation asynchronously and preemptively takes control of the central processing means away from an executing thread at a repetition rate sufficiently fast so that even where the system contains only a single central processor the concurrent threads appear to execute effectively simultaneously and are so perceived by the user.

'603:1:24-37.

The '604 patent reads:

The term "multithreading" is used in this specification in its ordinary generally understood sense to mean the concurrent asynchronous preemptive time-sliced execution of a plurality of threads of instructions located within the same software
program, controlled by a clock or timer which periodically activates the interrupt operation of the central processor.

An explicit definition of a claim term within the specification is given considerable weight in claim construction. See e.g., E. I. Du Pont, 849 F2d at 1433. The difference in the phrasing between plaintiff's definitions of multithreading in the two patents creates an ambiguity. Specifically, although plaintiff has provided an explicit definition of a claim term in each patent, it is not immediately apparent whether or not plaintiff intended to work with different definitions of multithreading in the two patents. It would be permissible for plaintiff to employ two different definitions of multithreading, but his statement in each patent that he is using multithreading "in its ordinary generally understood sense" suggests that plaintiff intended multithreading to have but a single meaning. In the '603 patent, multithreading is defined to include a periodic clock-activated interrupt service routine, but is apparently not limited to periodic preemption, as this definition implies that not all threads must be controlled by a periodic clock interrupt service routine. The definition in the '604 patent, however, states that preemption is "controlled" by a clock or timer, which activates the interrupt operation "periodically."

Looking at plaintiff's description of the illustrative embodiment, which is the same for both patents, does not resolve this ambiguity. Plaintiff's embodiment, as discussed above, is the invention disclosed in his 1982 application: the four-part-editor-compiler. As described in the patents, the compiler executes continuously in the background and is interrupted, not by a clock, but when the "programmer strikes a key on the console keyboard." '603:4:14-15. Plaintiff's detailed description of his preferred embodiment is nearly entirely devoted to a description of a system that does not rely on a clock activated interrupt. Indeed, in the patents' detailed description only a single brief paragraph, the same paragraph in each patent, mentions a clock or timer:

Furthermore, the interrupt which causes control of the CPU to pass from the compiler to the editor may be activated by a timer or clock instead of by a keyboard ** *. That is, the compiler may be periodically interrupted and the input port polled to test if a key has been struck. If not, the interrupt is terminated and control returns to the compiler. If polling the port reveals that a key has been struck then the interrupt service routine editor takes control and is executed in the manner described above. For most applications clock interrupts at intervals of about every 10 to 30 milliseconds should be frequent enough to keep up with the keys stroked at the keyboard.

'603:13: 8-20; '604:10:3-14.

Aside from summary sections, this paragraph is the only mention of a clock activated interrupt form of multithreading in the detailed description section of the patents in dispute. The claims of both patents, however, discuss plaintiff's invention only in terms of periodic preemption based on timeslices assigned to the threads. This apparent disconnect between the detailed description of plaintiff's preferred embodiment and the patents' claims may well raise serious 35 USC § 112 validity questions. For the purposes of claim construction, however, the court is obliged to interpret "what the patentee has chosen to claim as his invention." SSIIH Equipment SA v US Int'l Trade Comm, 718 F2d 365, 378 (Fed Cir 1983). Valid or not, plaintiff's clear intent is to claim the invention of a form of multithreading that operates pursuant to a periodic clock activated preemption.

The parties disagree whether the patents' version of multithreading excludes multithreading wherein the assignment of which thread may execute after the executing thread is interrupted is governed by the relative priority of threads. The patents do not discuss any method of assigning priority to threads; nor do the patents indicate that so assigning priority would be a possibility or, in fact, desirable. Plaintiff argues that the source code compiler embodiment is priority driven because the editor operates in the foreground and the compiler operates in the background. In this embodiment, however, only two threads operate and, therefore, it is never necessary to choose which thread operates next when one is interrupted, accepting for the moment plaintiff's contention that the editor may be interrupted. Plaintiff does not discuss an embodiment which operates with more than two threads; nor does his specification specifically discuss how the chain of execution will be determined.

Clearly plaintiff's claimed invention does not require a feature that assigns priority to threads. Nevertheless, the court thinks it premature to determine whether a form of multithreading that operates pursuant to the patents' description, but includes a method for assigning priority amongst threads would infringe plaintiff's patents. If as the litigation proceeds it becomes necessary further to clarify the court's construction of multithreading, the court will undertake that task. It is likely, however,
that this determination will take place as part of a fact-laden infringement analysis and not claim construction, which is a matter of law.

If there is any material difference between the explicit definitions of multithreading given in the patents, it relates to whether the '604 definition, which provides that multithreading is "controlled" by a clock or a timer, is limited to preemptive multithreading. As the court has decided that it is premature to make this determination, there is currently no need to choose between the explicit definitions of multithreading given in each patent. Accordingly, the court determines that multithreading shall be construed in each patent as explicitly defined in that patent. To the extent there is any material difference between these definitions, the patents shall be considered to be working with different definitions of multithreading.

A. "multivariate negotiation system"

As to this term, this Court ordered the following claim construction:

A system of hardware and software that enables participants to perform multiple rounds of bargaining over multiple terms. The multiple rounds of bargaining (i.e., the "negotiation") must allow for an offer and multiple counteroffers between two participants where each round is related to prior rounds and is more than a simple bid submission system.

Tr. 26:11-23; 31:10-17.

"A music device controlled by a computer" and "computer responsive music device" appear in claim 1, and "computer controlled music device" appears in claim 2. The parties agree that all three terms refer to the same device and have the same meaning, but disagree as to that meaning. Contois proposes that the terms be construed as "a device capable of playing music that is controlled by and responsive to a computer." Apple proposes that the terms be construed as "a device with a computer interface that plays music under control of computer music commands." Apple's proposed construction adds a limitation that is not part of the claim language: that the music be played under control of computer music commands. Neither claim recites any requirement that the music device play music under control of computer music commands.

n1 Claim 2 recites:

[the process of claim 1, wherein the step of playing the selected song item comprises: a) activating a play button located on the computer screen; b) sending a data stream from the computer to the computer controlled music device in response to step a) for controlling the playing of the selected song; c) receiving the data stream by the computer controlled music device from the computer; and d) playing the selected song item on the computer controlled music device.

Id. col. 14:66-15:8.

Although the specification discusses a preferred embodiment that operates using MIDI (Musical Instrument Digital Interface) to play a music device such as a player piano, the specification also makes clear that its discussion of MIDI is included purely for background. See '868 Patent col. 6:47-7:14. The specification also emphasizes that the user interface
software may be used "on any media playing device," and gives as examples devices that play back recorded music, as well as devices that produce music in response to computer commands. See id. col. 13:43-50; 14:2-3. Apple has supplied no persuasive reason for the Court to diverge from the ordinary and customary meaning of the phrase. The term is construed as "a device capable of playing music that is controlled by and responsive to a computer."

2808

1. "Mutual Fund" means "a Company that Pools Money from Many Investors and Invests the Money in a Group of Securities of other Companies."

All of the patent claims are directed toward "mutual funds." The '116 Patent and its prosecution history, however, failed to define "mutual fund," or use the term in a specialized way. "Mutual fund" is a term that is readily discernible by investment professionals and is defined by Webster's Dictionary as "an open-end investment company that invests money of its shareholders in a usually diversified group of securities of other corporations."

The '116 Patent used the term "mutual funds" in a manner consistent with its ordinary meaning:

There are approximately 9,000 mutual fund companies. These companies invest in approximately 50,000 United States Corporations that are traded on stock and bond exchanges and NASDAQ (National Association of Securities Dealers Automated Quotations) in America.

(SUF P 44.) Moreover, Boyle specifically categorized his term "Cross-Fund" in a similar manner, as "a simultaneous offering of a mutual fund in America and an overseas country." (Id. P 46.) Accordingly, the term "mutual fund" has a generally understood meaning, which is entirely consistent with the common sense definition of the term. Therefore, the Court will construe "mutual fund" to mean: "a company that pools money from many investors and invests the money in a group of securities of other companies."

2809

1. Claim Construction

a. "NSM-packet signal"

Asserted independent claims 36, 39, 132, 140, and 146 describe the transmission of "the multiplicity of NSM-packet signals as an RCN-packet signal." A threshold question is how the term "NSM-packet signal" should be interpreted. Citing to the deposition testimony of plaintiff and defendant experts and a technical dictionary, Itron contends that "NSM" denotes only the source of the packet signal and does not alter what it claims is the common, ordinary sense of the term "packet signal": a discrete chunk of data.

However, the court cannot adopt this broad, generic interpretation of "NSM-packet signal." As CellNet points out, Itron's immediate reference to extrinsic evidence violates a basic rule of claim construction. In interpreting claim terms, a court must first examine evidence intrinsic to the patent. See Vitronics, 90 F.3d at 1582. This is especially critical where the disputed language involves a coined phrase like "NSM-packet signal." Reliance on extrinsic sources when interpreting a coined phrase would run the risk of producing an arbitrary construction. Itron argues that "NSM-packet signal" has no special meaning within the context of the patent, and that, therefore, immediate reference to dictionary definitions and expert testimony is entirely appropriate. This is a surprising argument, especially considering Itron's later assertion, in resisting CellNet's motion for summary judgment on the issue of invalidity, that the term "network service module" is a term of art that can only be understood in light of the specification.
However, even if the court were to agree that "NSM-packet signal" and "packet signal" are synonymous, CellNet has submitted ample extrinsic evidence that "packet signal" is commonly understood to have a definition more specific than what Itron claims it does. As one communications textbook explains, "The essential idea of packet switching is to encapsulate data messages into fixed length blocks. Addressing as well as other overhead information is added to these blocks to form a packet." See Jeremiah F. Hayes, Modeling and Analysis of Computer Communications Networks 32 (1984) (CellNet Exh. Q). Further, at one point in his deposition, Itron's expert, Dr. Hulina, seemed to agree with this more specific definition: "The complete NSM-packet signal consists of a preamble, an opening frame, air detection, closing frame. Those are all digital, it's all digital data," Deposition of Dr. Paul T. Hulina, at 74 (CellNet Ex. E). In short, even if the court relies on extrinsic evidence, a substantial portion of it supports the construction the court draws from the patent's specification in the discussion below.

Here, the intrinsic sources clearly demonstrate that "NSM-packet signal" does not mean, as Itron argues, any discrete amount of data transmitted from an NSM. First, Claim 36 makes separate mention of "NSM data" and "NSM-packet signal," showing that the patent intends a conceptual distinction between the two terms. Second, the specification clearly articulates the difference between "NSM data" and "NSM-packet signal":

The NSM transmitter 318 transmits at a first carrier frequency the respective NSM data from the physical device in a brief message packet called an NSM-packet signal …. The NSM-packet signal transmitted by the NSM transmitter 318 follows a generic or fixed format; and a representative message packet is illustrated in FIG. 3. Included in the message is: preamble; opening frame; message type; message identification; service module type; message number; service module address; data field; error detection; and closing frame.

'094 Patent, Col. 8, ll. 2-13. Thus, as expressly defined by the specification, an "NSM packet-signal" includes more than just "NSM data"; it also includes a header, footer, and message identifier information.

While Itron argues that the specification describes a representative or preferred "NSM-packet signal" only, the language of the specification admits of little design flexibility, dictating a "fixed or generic format" made up of a number of information elements. The specification is "representative" merely in the sense that the exact combination of elements in the footer, header, and data structure illustrated in Figure 3 may vary. That is, although the precise structure may change, an "NSM packet-signal" must contain some kind of identifier information beyond the cumulative consumption data gathered by the NSM. Viewed within the larger context of the patented system, this requirement makes perfect sense. Without receiving message identifier information, the RCNs would be incapable of deleting redundant NSM-packet signals, as required in many of the claims in the '094 patent. Equally important, without receiving message identifier information, the utility implementing the system would never know which customer is responsible for what energy consumption data.

2 The court is well aware that extraneous limitations should not be imported from the specification into patent claims. Here, however, the court is not adding a limitation to the relevant claims but merely interpreting coined terminology that appears within it.

In short, because the inventors have chosen to be their own lexicographers with regard to the term "NSM-packet signal," the court must adopt their definition.

2. "Nx1 Switch" and "Nx1 Optical Switch"

For the following reasons, this court construes the claim term "Nx1 switch" in claim 19 and "Nx1 optical switch" in claims 2 and 9 to mean:
A device to receive an optical signal from one of N inputs and route the optical signal to one output, or to receive an optical signal from one input and route the optical signal to one of N outputs.

The claim language "N x 1 switch" and "N x 1 optical switch" works to narrow the previously construed term, an "optical switch." For example, in claim 19, the claim states that "the optical switch is an N x 1 switch." (772 patent, col. 10:22-23.) The term "N x 1 optical switch" is used in claims 2 and 9 in a similar manner: "wherein the optical switch is an N x 1 optical switch." (772 patent, col. 7:18-19; col. 8:17-18.) Therefore, both an "N x 1 switch" and an "N x 1 optical switch" are optical switches and should be construed in the same manner.

Moreover, the specification explains that an "N x 1 switch" is designed to receive a wavelength from the opposite direction and "provide the wavelength to a multiplexer/demultiplexer to be multiplexed with the other received wavelengths." (772 patent, col. 3:29-43.) The specification also contains a flow chart of the steps performed by a controller to control various types of optical switches. (772 patent, col. 3:40-43; see Fig. 2.) In introducing the flow chart, the specification specifically refers to a "1 x N switch" and references both a "1 x N switch" and an "N x 1 switch," thus equating the two switches. Id. This is understandable because an "N x 1 switch" is simply a "1 x N switch" operating in the opposite direction. As the specification explains, a "1 x N switch" is "used to send/receive a wavelength to/from one of N-1 peer OLTs or a client apparatus." (772 patent, col. 3:22-29.) Therefore, an N x 1 optical switch is a device that can receive an optical signal from one of N inputs and route the optical signal to one output, or can receive an optical signal from one input and route the optical signal to one of N outputs.

Vonage challenges the district court's construction of four terms in these patents. First, Vonage complains about the district court's failure to limit the term "translation" in asserted claims 26 and 27 of the '574 patent and claims 15 and 20 of the '711 patent. The district court instructed the jury that the term "name translation request" means "a query for translation of a name into routing information for a public packet data network." J.A. at 6622. Vonage argues that the district court erred in failing to define the claim term "translating," to require that the system "directly convert a higher level protocol identifier of a node to a different lower level protocol." J.A. at 2726. In its Markman decision, the district court rejected Vonage's interpretation and noted that "[a]lthough several examples appear in the specification demonstrating a translation from a higher to a lower level protocol, such limitations are not properly read from the specification into the claims." Verizon Servs. Corp. v. Vonage Holdings Corp., No. 06-0682 at 14 (E.D.Va. Feb. 12, 2007) ("Markman Order").

We see no error in the district court's construction. Vonage points to nothing, and we can find nothing, in the claim language or the specification that would support Vonage's proposed definition. The mere fact that the specification's examples of translation may involve a change in protocol from a higher to a lower level protocol does not establish that such a limitation should be imported into the claims. See Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005) (en banc) (cautioning against importing limitations from the specification into the claims); Texas Instruments, Inc. v. U.S. Int'l Trade Comm'n, 805 F.2d 1558, 1563 (Fed. Cir. 1986) ("This court has cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification."). Contrary to Vonage's argument, there is also no evidence that the ordinary meaning of translation in the art means a change in protocol from a higher-level to a lower-level protocol. 2

--- Footnotes ---

2 Vonage alternatively argues that the district court should have instructed the jury that translation requires a change in protocol, and that the extraction of a telephone number that the Vonage system performs is not a change in protocol. Vonage also argues that a mere extraction cannot be a translation. These arguments were not even raised in Vonage's claim construction briefs in connection with the Markman hearing. There is nothing in the specification or prosecution history that would compel Vonage's interpretation. Vonage offers no supporting dictionary definition of the term "translation." Under these circumstances one might have expected Vonage to provide expert testimony that those skilled in the art would understand the term "translation" to have the meaning that Vonage urged. But Vonage has not called our attention to any such testimony. On the other hand Verizon's expert did testify that one skilled in the art would understand extraction to constitute translation. We see no error in the district court's failure to include Vonage's interpretation in the jury charge.

--- End Footnotes ---
2. Narrow Band Transmission Medium

A narrow band transmission medium is an information channel capable of handling a relatively low bandwidth or data rate with respect to the information being sent across the medium.

4. Natural Concurrences/determining natural concurrences/determine the natural concurrencies

The next group of terms in dispute use the phrase "natural concurrences." These terms appear in claims 11-13, 20-22, and 26 of the '755 patent as well as in claims 1, 3, 6, 15, 28, and 35-37 of the '945 patent. Biax argues that the term "natural concurrences" means "attributes of instructions that enable the instructions to be executed in parallel with other instructions." Intel and ADI argue that the term means "mutually independent instructions that can be executed in parallel and do not rely on one another for any information nor do they share any hardware resources in other than a read only manner."

The specification resolves this claim construction dispute. In the specification, the patents state:

Clearly, mutually independent instructions can be executed in parallel and are termed 'naturally concurrent.' Instructions that are independent can be executed in parallel and do not rely on one another for any information nor do they share any hardware resources in other than a read only manner.

'755 patent, col. 9,11. 16-18. In light of this passage from the specification, the court defines "natural concurrences" to mean "mutually independent instructions that can be executed in parallel."

1. "a navigational receiver for providing a location of the remote unit"

The parties dispute the construction of the phrase: "a navigational receiver for providing a location of the remote unit." There are four aspects to the dispute: (a) whether the language should be construed as a means-plus-function limitation; (b) whether any construction of "navigational receiver" is necessary and (c) if so, what construction should be given to that phrase; and (d) what construction should be given to the phrase "for providing a location of the remote unit."

a. The subject phrase is not a means-plus-function limitation.

The subject claim language discloses a component of an apparatus claim and recites a function of the component, namely, "for providing a location of the remote unit."

A claim limitation to a component of an apparatus that recites a function but which does not recite definite structure for performing the recited function is subject to being considered a means-plus-function limitation to be construed in accordance with 35 U.S.C. § 112 P 6. B. Braun Medical, Inc. v. Abbott Laboratories, 124 F.3d 1419, 1424 (Fed. Cir. 1997). When construing a claim limitation under § 112 P 6, the first step in the analysis is to identify the particular claimed function. Micro Chem., Inc. v. Great Plains Chem. Co., 194 F.3d 1250, 1258 (Fed. Cir. 1999). The second step in the analysis is to look to the specification and identify the corresponding structure for performing that function. Id. The use of the word "means" in a limitation creates a rebuttable presumption that § 112 P 6 applies; similarly, the absence of the word "means" in a limitation creates a rebuttable presumption that § 112 P 6 does not apply. Personalized Media Communications, LLC v. International Trade Com'n, 161 F.3d 696, 703-04 (Fed. Cir. 1998). The presumption against the application of § 112 P 6 may
be overcome when a claim limitation does not use the word "means" but, nonetheless, employs functional language. Massachusetts Institute of Technology and Electronics For Imaging, Inc. v. Abacus Software, 462 F.3d 1344, 1353-54 (Fed. Cir. 2006). However, § 112 P 6 does not apply when the claim recites sufficient structure for performing that function. Id.

In this case, the inventors did not use the word "means" in the subject phrase. Thus, there is a rebuttable presumption that § 112 P 6 does not apply. Although the inventors use functional language in the limitation, one of ordinary skill in the art would understand the phrase "navigational receiver" to be a recitation of definite structure which is capable of performing the claimed function. Accordingly, the Court finds that the subject limitation is not a means-plus-function limitation.

b. Whether construction of "navigational receiver" is necessary

The second issue is whether the phrase "navigational receiver" needs construction. The Court looks first to the claim language itself. The phrase "navigational receiver" is a commonly used phrase meaning a "receiver which receives navigational information." This definition is simply restating the words of the phrase. However, the embodiments of receivers which are discussed in the '770 Patent refer to "global positioning satellites" ("GPS") only. Therefore, the Court considers whether the phrase as used in Claim 55 should be construed to be a GPS receiver. 3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
3 The meaning of "navigational information" is disputed within the context of Claim 11 of the '390 Patent and Claims 14 and 17 of the '889 Patent. The Court defers construction of the term until such time as it considers the terms of those patents that are in dispute.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

c. "navigational receiver"

The specification provides:

The navigational receiver . . . receives navigational information, as for example from global positioning satellites.

('770 Patent, Col. 11:28-30.)

The navigational receiver . . . is connected to an antenna . . . for receiving navigational information, such as from global positioning system satellites.

('770 Patent, Col. 12:14-16.)

[T]he navigational receiver . . . receives navigational information from global positioning system satellites.

('770 Patent, Col. 15:56-58.)

Notwithstanding the reference to GPS receivers as examples of "navigational receivers," there is nothing else in the specification, including the claims, which indicates explicitly or implicitly, that the inventors intended to limit "navigational receiver" to a GPS receiver. At this time, the Court has not been presented with any extrinsic evidence that one of ordinary skill in the art reading the patent documents would have understood "navigational receiver" to be limited to a GPS receiver. Thus, in the construction below, the Court declines to limit the phrase "navigational receiver" to a GPS receiver.

d. "for providing a location of the remote unit"

The functional phrase "for providing a location of the remote unit" is not subject to § 112 P 6. However, the language is a functional limitation on the "navigational receiver," i.e., it must be "for providing a location of the remote unit."

In the specification, the inventors disclose an embodiment which gives meaning to this function:

The navigational receiver 304 converts the navigational information into the location of the remote unit 302 and outputs...
the location 338 to the radio transmitter 314 for transmission to the base station 318.

("770 Patent, Col. 11:28-29.) Thus, although the invention in Claim 55 is not limited to the embodiment discussed in Col. 11:28-29, there are aspects of that embodiment which assist in defining the "for providing a location" function. First, since the preamble to Claim 55 and the subject phrase disclose a "remote unit," inherent in the claim is that the navigational receiver be located in a remote unit of a system which includes a base station. Without a base station, there is no meaning to the word "remote." Second, other language of Claim 55 explicitly provides that the receiver provide "a location." 4 Finally, the radio transmitter limitation, discussed below, limits the recipient of the "location" to "a radio transmitter." Therefore, the navigational receiver must be capable of providing the location of the remote unit to a "radio transmitter."

--- Footnotes ---

4 The parties have stipulated to the definition of location. The Court defers consideration of whether it will adopt the parties' stipulation. The Court notes that in the specification the inventors distinguish between providing a "location," which is required by Claim 55 (See e.g., "770 Patent, Col. 12:14-18.) and providing "raw navigational information" from which location can be "calculated." (See e.g., "770 Patent, Col. 16:39-47.)

--- End Footnotes ---

Accordingly, the Court construes the phrase "a navigational receiver for providing a location of the remote unit" as used in Claim 55 of the '770 Patent to mean: a receiver in a remote unit that receives navigational information, and that provides a location of the remote unit, to a radio transmitter.

2815

14. negative optical anisotropy ('412 patent)

CEA's proposed construction is "a characteristic of birefringent material wherein an ordinary index exceeds the extraordinary index."

Samsung's proposed construction is "a characteristic of a birefringent material wherein the values of two of the three principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) is less than the other two."

Samsung's proposed construction is supported by the specification 42 and is adopted by the court: "a characteristic of a birefringent material wherein the values of two of the three principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) is less than the other two."

--- Footnotes ---

42 "See '412 patent, 5:3-5 ("Compensating plate 16 is a negative optical anistropy uniaxial medium, the extraordinary index Ne1 of said medium being below its ordinary index No1.")."

--- End Footnotes ---

GO BACK

2816

The other disputed term in the '806 patent is the phrase "negative voltage with respect to." All the parties agree on the meaning of "voltage"; the only dispute concerns the meaning of "negative with respect to." The claims recite a second power supply that is at a negative voltage with respect to a first power supply. As we noted above, the district court construed "negative with respect to" to mean negative with respect to ground, i.e., an absolute negative voltage. NeoMagic argues, and we agree, that the district court's construction was in error. The plain language of the claim recites relative voltage rather than absolute voltage. As NeoMagic notes, if the inventors had meant to claim an absolute negative voltage, they need not have used the words "with respect to"; "negative" would have sufficed. Indeed, "negative with respect to said
first power supply" is inconsistent with a description of absolute voltage, because absolute voltage is relative to ground.

Because the plain language of the claim compares the second power source to a first power source with an output that need not be at ground, it is referring to relative voltage. As discussed above, one point can be negative with respect to another without being negative with respect to ground. Thus, the appropriate construction of "negative with respect to" is simply that the second power supply must have a voltage that is less positive than that of the first power supply. The second power supply need not have a voltage output that is negative with respect to ground, however, to meet this limitation.

The definition we adopt today is completely consistent with the specification. The invention described and claimed in the '806 patent is the isolation of a capacitor in an n-well on a p-substrate, where the p-n junction between the n-well and p-substrate is reverse-biased. Reverse-biasing simply requires that the voltage applied to the p-substrate be negative relative to that applied to the n-substrate. It does not require that an absolute negative voltage be applied to the p-substrate. In context, the "negative with respect to" language in the '806 patent clearly refers to reverse-biasing the claimed p-n junction. And, because only relative negative voltage (not absolute negative voltage) is required to reverse-bias the junction, the claims naturally use the words "negative with respect to" to recite the required conditions for reverse-biasing. Thus, the proper definition of "negative with respect to" requires only that the voltage supplied by the second power supply be negative relative to that provided by the first power supply.

"neighbor" is construed to mean "two nodes are neighbors when they have a link between them; a link is a bi-directional communication path that terminates at a single node on either end." The Court adopts as its construction the definition of the terms "neighbor" and "link" in the 4,466,060 Riddle patent ("the '060 patent"), which is incorporated by reference in the '607 patent. (D.I. 389, App. 29 ('060 patent) at 1:20-24.)

Lucent contends that the term "neighbor" means "two nodes are neighbors when they are connected by a bi-directional communication path that terminates at each of the two nodes at either end of the path." (D.I. 396 at 35.) Extreme contends that this term means "a node directly connected by a link, with no intervening nodes." (D.I. 395 at 34.) Foundry contends that this term should be construed such that "a node A is a neighbor of another node B if and only if node A is directly connected to node B by a communication link in the network, that communication link having no intervening network nodes between node A and node B." (D.I. 385 at 32.)

The Court finds that all three proposed constructions are modifications of the definition of "neighbor" set forth in the Riddle patent that is incorporated by reference in the specification of the '607 patent. Thus, the Court adopts a construction of the term "neighbor" that more closely reflects the definition of the term "neighbor" in the '060 Riddle patent, which is incorporated by reference in the '607 patent.

"nematic liquid crystal layer in its homeotropic structure" (‘412 patent)

CEA's proposed construction is "nematic liquid crystal layer having molecules substantially oriented in a homeotropic direction."

As with the other disputed claim terms including the phrase "homeotropic direction," Samsung agreed at oral argument to accept CEA's proposed construction because the court is separately defining "homeotropic direction" which will have the same meaning in all disputed claim terms of the patents-in-suit. 34 Therefore, the court adopts CEA's proposed construction: "nematic liquid crystal layer having molecules substantially oriented in a homeotropic direction."

--- Footnotes ---
34 D.I. 1053 at 98.
1. Construction of "Net Position Error"

In both its claim construction orders, this Court has consistently interpreted "net position error" to mean "attitude error arising after a modulated firing of a thruster pair, and is indicative of a difference between an estimated disturbance torque and an actual disturbance torque." Given the description of "net position error" in step [c] of claim 1, the Court continues to believe that this interpretation is the most sensible. See '375 patent, col. 9, lines 25-28 (describing "net position error" in step [c] as "being indicative of a difference between said estimated disturbance torque and said actual disturbance torque"). Moreover, the Federal Circuit appears to have accepted this definition. See Riley Decl., Exh. 4 at 6 ("[Dr. Kaplan] explained that only after the firing maneuver starts does net position error exist."). Thus, the Court declines to revisit its construction of "net position error."

Lockheed argues that the Court should change its construction of "net position error" because the current construction renders a portion of step [b] superfluous. Specifically, Lockheed contends that the phrase "without initially detecting said net position error" has no meaning under the Court's current construction, given that "net position error" as currently defined cannot exist until after the thrusters fire.

The Court disagrees with Lockheed's reading of step [b]. Lockheed reads the quoted language in isolation, and as a concrete limitation on the modulation process of step [b] that prohibits the measurement of "net position error" before the first modulation takes place. Under this interpretation, it is indeed superfluous to explicitly bar "net position error" from being measured before net position error can exist. Rather than reading the language as an explicit bar, however, the Court believes that the language is best read in the abstract and in connection with the preceding phrase, as a statement of the purpose of the first modulating step. Thus, the Court believes the disputed language is best interpreted as follows: "[The first modulating step is performed] in order to minimize a net position error without initially detecting said net position error." Read in this way, the language serves to make clear the manner in which the claimed invention differs from the prior art - the prior art minimized net position error by detecting it and reacting to it, while the current invention initially minimizes net position error without detecting it. This interpretation of the disputed language gives the most sensible meaning to net position error without rendering any portion of the patent's claims superfluous.

J. a netlist defining the hardware cells which are needed to perform the desired function of the integrated circuit

Ricoh contends that the term means "a description of the hardware components (and their interconnections) needed to manufacture the ASIC as used by subsequent processes, e.g., mask development, foundry, etc." Aeroflex states that the term means "producing a list of the needed hardware cells by eliminating any mapped hardware cells that are redundant or otherwise unnecessary, producing a custom controller type hardware cell for providing the needed control for those other hardware cells, and producing the necessary structural control paths and data paths for the needed hardware cells and the custom controller." '432 patent, col. 5:38-46.

Ricoh's proposed construction also relies heavily upon language in the specification. Specifically, Ricoh notes that the specification states that "[t]he list of hardware cells and their interconnection requirements may be represented in the form of a netlist. From the netlist it is possible using either known manual techniques or existing VLSI CAD layout systems to generate the detailed chip level geometrical information (e.g. mask data) required to produce the particular application specific integrated circuit in chip form." '432 patent, col. 2:42-49. The specification also states that "[t]he netlist provides all the necessary information required to produce the integrated circuit. Computer-aided design systems for cell placement and routing are commercially available which will receive netlist data as input and will lay out the respective cells in the chip, generate the necessary routing, and produce mask data which can be directly used by the chip foundry in the fabrication of integrated circuits."
Aeroflex also relies heavily upon the patent's specification to support its proposed construction. Aeroflex initially argues that the claim language "generating for the selected … hardware cells, a netlist defining the hardware cells which are needed to perform the desired function of the integrated circuit" requires that this step eliminate any selected hardware cells that are not needed. See '432 patent, col. 13:59-66. Aeroflex also contends that the patent's specification defines the "interconnection requirements" for the necessary hardware cells defined in the netlist as "data and control paths." See '432 patent, cal. 5:30-35. Finally, Aeroflex contends that a system controller must be generated to provide the netlist. In support of its argument, Aeroflex cites language from the preferred embodiment that states "[t]he netlist includes a custom generated system controller, all other hardware cells required to implement the necessary operations, and interconnection information for connecting the hardware cells and the system controller." '432 patent, col. 4:39-43. Additionally, Aeroflex asserts that the requirement that a controller be generated is also supported by the patent's file history. Specifically, Aeroflex argues that the file history limits the input specification to exclude register-transfer level descriptions that would define the control for the hardware cells of the ASIC, and thus a controller must be generated to provide necessary control for the ASIC.

The Court agrees with Ricoh that Aeroflex's arguments regarding "eliminating any mapped hardware cells that are redundant or otherwise unnecessary" and "producing a custom controller type hardware cell for providing the needed control for those other hardware cells" bear no relationship to a plain reading of claim 13. Additionally, contrary to Aeroflex's assertion, a review of the patent file history does not reveal that a controller must be generated in claim 13. Furthermore, while claim 10 expressly includes the generation of a controller, claim 13 includes no such language. See '432 patent, col. 16:1-4 ("The system as defined in claim 9 additionally including control generator means for generating a controller and control paths for the hardware cells selected by said cell section means.").

The Court also finds that claim 13 does not restrict the interconnection requirements of the hardware cells to "data and control paths." To be certain, "data and control paths" are the types of interconnections disclosed in the patent's preferred embodiment. But, the Court should not "limit[] the claimed invention to preferred embodiments or specific examples in the specification." Ekchian, 104 F.3d at 1303. Moreover, while claim 15 expressly includes the generation of control paths, claim 13 includes no such language. See '432 patent, col. 17:1-3 ("A process as defined in claim 13 including the further step of generating data paths for the selected integrated circuit hardware cells."). For these reasons, the Court agrees with Ricoh's proposed construction of the term. The Court defines "a netlist defining the hardware cells which are needed to perform the desired function of the integrated circuit" as a description of the hardware components (and their interconnections) needed to manufacture the ASIC as used by subsequent processes, e.g., mask development, foundry, etc.

2821

J. "network"

The term "network" is found in the '414 patent, claim 1: "A method of managing access to a plurality of media assets comprising the steps of: . . . authorizing over a network a plurality of media player devices with the user account . . . ." Networks are discussed in the following section from the specification: "The portal [] communicates with media player devices [] via communication network [] that may consist of the Internet and/or a combination of wireless communication networks, such as cellular networks, PCS networks, etc." (704 patent, 3:48-51). Figure 2 also depicts "network(s)" as including 56KB, Cable, DSL, Satellite, and Wireless. Zapmedia's proposed definition is "the Internet alone or in combination with one or more communication networks." According to Apple, "network" means "a group of two or more computer systems linked together."

Zapmedia argues that the Internet is a necessary component of the "network," although other communications networks may be used in addition to the Internet. According to Zapmedia, the term "network" must include the Internet, as that is the only means for the portal to communicate with back-end systems and servers. But the claim language uses network in the context of communications between the media player devices and the portal / server, not between any other components of the invention. (E.g., '414 patent, Fig. 2; claim 1 ("authorizing over a network a plurality of media player devices"); claim 4 ("a server application accessible over a network and capable of recognizing a plurality of media player devices"). Thus, there is no need to construe the term to require use of the Internet. As such, the court construes "network" to mean "one or more wired or wireless communication networks."

The primary dispute regarding "network" and/or "communications network" is whether the "service providing network accessible node (SPNAN)" and the "first network accessible node" are separate and distinct from the network as Defendants contend or are included in the network as Beneficial contends.

The term "network" is used in claim 1 of the '366 patent and the term "communications network" is used in claim 53 of the '702 patent. The parties agree that the terms "network" and "communications network" should be given the same meanings. While the Court adopts essentially the same construction for each term, the Court construes the terms slightly different because the Court's construction depends on the slightly different language used in the different claims. In particular, claim 1 uses the terms "network," "service providing computation system," and "node of the network," whereas claim 53 uses the terms "communications network," "service providing network accessible node (SPNAN)," and "first [or second] network accessible node." The Court finds that the claims expressly identify three separate entities: the network accessible node / node of the network, the communications network / network, and the service providing network accessible node / service providing computation system. The Court finds that in some instances the typical understanding of the term "network" or "communications network" may be interconnected computers or devices, but the claim language is clear in this case that the network is separate from and between the "SPNAN" and "first network accessible node" in claim 53 and the "service providing computational system" and "node of the network" in claim 1. For example, it is clear from claim 53 that the "network accessible node" can be connected and disconnected from the communications network. Further, the Court finds that the claims expressly require a "network interface" that separates the user's computer and the service providing computer from the network and allows the user computer and service providing computer to communicate with one another. Claim 1 describes transmitting combined data from the nodes "via" the network, and claim 53 describes transmitting between the nodes and the SPNAN first information and receiving first responsive information "via" the network. Further, the parties agree that the phrase "first network accessible node" means "a user's device that can be accessed via the communications network." In the context of the claims and specification, one of ordinary skill in the art would consider a node as being connected or connectable to a network, but not as part of the network as that term is used in the claims. The Court finds that the communications network, as used in the claims and illustrated throughout the specification, exists separate and apart from the "network accessible node" and the "SPNAN." Likewise, the Court finds that the network, as used in the claims and
illustrated throughout the specification, exists separate and apart from the "node of the network" and the "service providing computation system." This interpretation is consistent with dependent claim 54, which provides certain additional limitations "when the network is the Internet," implying that the user's computer and the SPNAN are not part of the network.

The Court rejects Beneficial's argument, even if true, that Defendants' construction would exclude an embodiment in the specification and therefore should not be adopted. First, the Court's construction does not exclude all disclosed embodiments. Second, the Court finds that neither asserted claim covers the embodiment that this construction allegedly excludes. Third, every claim does not need to cover every disclosed embodiment of a patent. See Helmsderfer v. Bobrick Washroom Equipment, Inc., 527 F.3d 1379, 1383 (Fed. Cir. 2008) ("It is often the case that different claims are directed to and cover different disclosed embodiments."); Sinorgchem Co., Shandong v. International Trade Com'n, 511 F.3d 1132, 1138-39 (Fed. Cir. 2007) (claims can be construed to exclude embodiments where multiple embodiments are disclosed). This is particularly true in this situation where there are multiple patents with numerous claims covering various aspects of the disclosed specification. Thus, the Court construes the term "communications network" to mean "interconnected computers or devices that transfer and exchange information between the service providing network accessible node ("SPNAN") and the first and second network accessible nodes." The Court construes the term "network" to mean "interconnected computers or devices that transfer and exchange information between the service providing computational system and the node of the network."

The term "network" is well-known to those in the art. According to the Microsoft Computer Press Dictionary, the ordinary meaning of "network" is "a group of computers and associated devices that are connected through communication facilities." See MICROSOFT PRESS COMPUTER DICTIONARY (3d ed. 1997). Thus, the definition of "network" has two elements: connecting and communicating.

The parties agree that a network must include a system or group of interconnected computers. Defendants assert that, in the context of the 290 patent, no other limitations are necessary. The Court disagrees with Defendants, since this definition ignores the communication element. MyMail asserts that the group of interconnected computers must also be uniquely identified, since according to the specification, after logging on to the network, a user receives an IP address to uniquely identify itself on the network. See Col. 7:10-19. The Court also disagrees with MyMail. The specification does discuss unique identification, but the unique identification simply serves as a means of establishing the interconnected computers' ability to communicate. Unique identification is not necessarily required. What is required is that ability to communicate. The Court therefore defines "network" as a "system of interconnected computers that have the ability to communicate."

IBM proposes the term means "a group of computers and peripheral devices connected together so that they can communicate with each other." SuperSpeed proposes the term means "communication facilities that link points at which computers or devices may be connected." SuperSpeed's construction was the agreed construction in the Oracle Litigation, and was adopted by Judge Gilmore in her Claim Construction Ruling. There is nothing in the intrinsic record that supports IBM's proposed construction. As SuperSpeed points out, computers or peripheral devices may be "connected to" or put "on" a network. See, e.g., '226 claim 27 ("a computer connected to the network . . ."); '013 claim 4 ("proving a plurality of computers on the network . . ."). In the context of this patent, however, the devices or peripherals themselves do not comprise the network.

IBM heavily relies on claim 1 of the '767 patent: "a computer network that comprises: one or more I/O devices on which data may be stored in files; and multiple computers coupled together." That reliance is misplaced, however, because
"computer network" is different from "network" as used alone in the other claims. 3

3 Id. see also, e.g., "A caching system comprising: a network; . . ." [244 Patent, cl. 15, 25]; A caching system comprising: a network; a first computer . . ." [244 Patent, cl. 25]

There is no support for deviating from Judge Gilmore's construction. In the context of this patent, the court construes "network" to mean "communication facilities that link points at which computers or devices may be connected."

2. Network

Citec defines a "network" as a "network card" connected to a "storage device." Romtec argues that Claims 1, 8, and 13 expressly define a network as "comprising said computer coupled to a . . . network card and a . . . data storage means." Claims 1, 8, 13. Romtec also argues that Citec's use of the term "storage device" rather than "data storage means" is an attempt to circumvent 35 U.S.C. § 112, ¶ 6. The Court agrees that the term "network" must be construed by reference to its component parts, as identified in the claims, that is, a "computer," a "network card," and a "data storage means." Romtec contends that the phrase should be construed to require that, for each network, the network card and data storage means be connected to the computer, and not directly to each other. In support of its position, Romtec refers the Court to the preferred embodiment, which depicts two network cards being installed on the motherboard of the computer and two different hard drives being connected to the motherboard via a hard drive ribbon cable. See Col. 2, l. 62-Col. 3, l. 1; Fig. 1.

Citec also refers the Court to the specification, which indicates that "[t]he computer is coupled to each of two different network cards, each of which is in turn connected to a separate storage device, such as a hard drive." Col. 2, ll. 5-7. "Each combination of a network card connected to a storage device constitutes a network." Col. 2, ll. 7-9.

The Federal Circuit has repeatedly cautioned against limiting the scope of a claim to the preferred embodiments described in the specification. See, e.g., Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998); Intervet America, Inc. v. Kee-Vet Laboratories, Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989). Accordingly, the Court declines to read Romtec's desired embodiment into the claims. Moreover, the Court does not find that the words and grammatical structure of the claims preclude the connection of the network card directly to the data storage means, as long as that combined device is connected to the computer. Accordingly, the term "network" is construed to mean a combination of a network card and data storage means in some manner connected to a computer, but not necessarily connected independently to the computer.

(2) data communication network, network

Dell and National agree and assert that these terms should be construed to require at least two computers interconnected to exchange information. N-Data argues to the contrary. Again, Dell and National point to Figure 2 of the various patents for support. As discussed above, the court is not persuaded that the network requires two or more computers.

As such, the court defines "network" as follows: "an interconnected set of devices which communicate with each other."

The court gives "data communication network" its plain and ordinary meaning in light of the other construed terms.
a. "Network": A collection of software and/or hardware interconnected by communication links for sharing information.

"Network"

Cisco's proposed construction for this term is "distinct set of interconnected elements used to communicate data among devices. Not limited to ATM networks or standards." Alcatel's proposed construction is "distinct set of interconnected elements used to communicate data in accordance with the asynchronous transfer mode (ATM) standards."

Cisco argues primarily that the plain meaning of the claim language supports its construction. Both parties agree, as is evident from their respective constructions, that a network comprises a "distinct set of interconnected elements used to communicate data." 8 Alcatel seeks to limit the network in this patent, however, to solely an ATM network. In the patent, the term network is explicitly used in claims 1, 3, 5, 6, 9, 12, 13, and 17. However, only claims 3, 5, 9, 13, and 17 specifically refer to an ATM network. Therefore, as Cisco contends, when a claim was intended to be limited specifically to an ATM network, it was so stated in the claim language. Moreover, claims 3 and 17 are dependent on claims 1 and 14, respectively, and those independent claims do not require the data to come from an ATM network. Therefore, the principles of claim differentiation instruct this Court, in general, not to read limitations into an independent claim when such limitations are expressly called for in another claim. See Karlin Tech., 177 F.3d at 971-72 (noting that, while not a rigid rule, the doctrine of claim differentiation "normally means that limitations stated in dependent claims are not to be read into the independent claim from which they depend"); Envtl. Designs, 713 F.2d at 699. Additionally, Cisco argues that construing "network" to refer solely to an ATM network would make the language referring to ATM networks in claims 3, 5, 9, and 17 mere surplusage. See Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d at 1444 (discouraging the construction of a claim that would "render the contested terms surplusage"); Texas Instruments, Inc. v. U.S. Int'l Trade Comm'n, 988 F.2d 1165, 1171 (Fed. Cir. 1993); see also Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987) ("There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant.").

However, Alcatel argues that interpreting the term "network" to reference only ATM networks would not render the contested term surplusage. According to Alcatel, claims 3, 5, 9, and 17, where an ATM network is explicitly referenced, there is also reference to "frames of data formatted according to the frame relay protocol in addition to ATM cells received from the ATM network, and indicate that the incoming ATM cells must be reassembled into frames prior to transmission to the customer premises equipment." Alcatel's Responsive Markman Brief on Claim Construction Regarding United States Patent No. 5,765,032 (Valizadeh) ("Alcatel's '032 Responsive Brief"), at 11. 9 Therefore, because each claim has an additional limitation other than the reference to an ATM network, each claim has a different scope than every other claim and therefore complies with the requirements of claim differentiation. See Tate Access Floors, Inc. v. Maxcess Techs., Inc., 222 F.3d 958, 967 (Fed. Cir. 2000) (holding that claim differentiation "does not mean that every limitation must be distinguished from its counterpart in another claim, but only that at least one limitation must differ" (quoting Kraft Foods, Inc. v. International Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000)); Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) (recognizing that the presumption of a different meaning and scope when different words or phrases are used in separate claims is intended to avoid making a claim superfluous).
To the extent that Cisco is arguing that every word in every claim must be construed to have different meaning, such interpretation is not required by the rules of claim construction. In addition to the cases cited above, the Federal Circuit has previously held that "two claims which read differently can cover the same subject matter." Tandon Corp., 831 F.2d at 1023. "That a patentee chose several words in drafting a particular limitation in one claim, but fewer (though similar) words in drafting the corresponding limitation in another, does not mandate different interpretations of the two limitations, since defining a state of affairs with multiple terms should help, rather than hinder, understanding." Kraft Foods, Inc., 203 F.3d at 1368. Furthermore, the claim language should not be construed to enlarge the claim beyond what the inventor has described as the invention. See Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001) ("Although the specification need not present every embodiment or permutation of the invention and the claims are not limited to the preferred embodiment of the invention, neither do the claims enlarge what is patented beyond what the inventor has described as the invention. 'Claim construction' is the judicial statement of what is and is not covered by the technical terms and other words of the claims." (citations omitted)).

Nevertheless, Cisco argues that the use of the term network in the specification comports with its proposed construction. In particular, Cisco points out that the term network is used in every major section of the specification to refer to networks generally (see, e.g., Valizadeh Supp., col. 1, ll. 5-10; col. 2, ll. 10-11, 46-48, 60-67 (hereinafter Valizadeh, at 1:5-10, 2:10-11, 2:46-48, 2:60-67)), and the specification clearly states "ATM" when discussing this specific type of network as a preferred embodiment (see, e.g., Valizadeh, at 1:13-39, 3:10-16). Accordingly, Cisco contends that by construing the term "network" in the claims to refer only to ATM networks, the Court would be improperly limiting the claims based on the preferred embodiment of the invention. See Dow Chem. Co. v. Sumitomo Chem. Co., Ltd., 257 F.3d 1364, 1378 (Fed. Cir. 2001) ("It is axiomatic that '[c]laims, not the specification embodiments, define the scope of protection.'" (citation omitted)).

In response, Alcatel contends that where Cisco points to portions of the specification referring to network in the general sense, that is misleading. More specifically, Cisco refers to column 2, lines 46-48, which describes Figure 1 as including simply a "common carrier network." However, in looking at Figure 1 itself, the common carrier network is actually referred to as a "Common Carrier ATM Network." Likewise, the term network is often used when describing a communications controller connected to a "network." As discussed below, Alcatel argues that a communications controller is defined in the patent as an end node to an ATM network, and therefore, if its argument holds, any reference to a network in connection with a communications controller would naturally be referring to an ATM network in particular.

Contrary to Cisco's arguments, Alcatel argues that when the term "network" was used in the claims, it was always referring to an ATM network. In support of this contention, Alcatel puts forth several arguments. First, Alcatel claims that the only common carrier network disclosed in the specification is an ATM network. Second, the "Statement of Reasons for Allowance" issued by the Patent Examiner indicates that these claims were permitted because they were limited to an ATM network. Third, although the term "network" generally does not imply a specific type of network, when the patent applicant chooses to be his own lexicographer, as Alcatel submits is the case here, the applicant's definition of a term controls over the term's ordinary meaning. Finally, Alcatel contends that when discussing the source of egress traffic (hence, the network), the specification uses terms such as "channels," "per-VC queuing," and "virtual circuits," which are all terms associated with ATM networks.

Furthermore, Alcatel points out that the phrase "network," when not specifically referring to ATM networks in the claims, is always used as part of the phrase "egress traffic of a network" (in claims 1 and 12) or "egress traffic directed from a network" (in claim 6). Alcatel argues below that "egress traffic" is always referring to traffic coming from an ATM network to the CPE, and therefore, were that the proper interpretation of "egress traffic," it would support their proposed construction of "network" here.
However, it is apparent that Alcatel is essentially attempting to limit the term "network" as comprising only an ATM network based on the examples given in the preferred embodiment, when the language used in the claim itself is not so limiting. "Particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." Rhine, 183 F.3d at 1346 (quoting Electro Med. Sys. S.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054 (Fed. Cir. 1994)). Although the preferred embodiments only involve ATM networks (see Valizadeh, at 3:11-12 ("According to the presently described embodiments, the network is an ATM network . . .")), the specification does contain language explicitly affirming that such embodiments are to be regarded as "illustrative rather than . . . restrictive." Id. at 5:37-43.

Nevertheless, Alcatel argues, that "non-restrictive" language does not mention the possibility of other networks applying to this patent, and thus, were the use of the term "network" in the patent understood to mean ATM network, this language would not dispel that interpretation. Moreover, Alcatel asserts that the above language indicating that the specification is non-restrictive is merely "boilerplate" language that should not be regarded as evidence that the network was intended to be anything other than an ATM network. See Les Traitements des Eaux Poseidon, Inc. v. KW! Inc., 135 F.Supp.2d 126, 135 (D. Mass. 2001) ("[The patentee] points to boilerplate language in the specification asserting that the general description is 'non-restrictive.' This general language carries little weight however. It is not possible to have an 'essential' structural feature also be 'non-restrictive.'"). However, in this case, unlike Poseidon, there is no evidence wherein Cisco explicitly states that it is "essential" under the patent for the network to be an ATM network.

Notwithstanding the absence of the word "essential", there is evidence in the patent history that could be interpreted as requiring that the network be an ATM network in order to distinguish this invention from the prior art. Alcatel argues that the patent examiner found, in the "Statement Of Reasons For Allowance," that ATM was the element of the invention not found in the prior art, and therefore the claims were allowed because they were limited to ATM configurations. 10 Cisco disagrees with this interpretation. Instead, Cisco contends that the examiner found that "the use of two sets of queues, each with its own service algorithm and set of queuing parameters" was the missing element in the prior art. See Cisco's Responsive Brief Re: Interpretation of the Claims of U.S. Patent No. 5,765,032 Responsive Brief ", (Valizadeh) ("Cisco's '032 at 5. In light of the conflicting interpretations, and based upon the Court's reading of the relevant passage, it is difficult to determine with certainly what the examiner found to be missing in the prior art, whether it was the use of the ATM network or the use of the the two sets of queues, each with its own service algorithms and queuing parameters, or both.

10 The text of the relevant passage is as follows: "Although the prior art of record disclose several claimed limitations, none of the references fairly teach or suggest a method and an arrangement for queuing and servicing egress traffic of a network, ATM network and traffic directed from a network to customer premise equipment, wherein each of the provided channel queues and port queues controlled by two service algorithms and two distinct set of queuing parameters, respectively, as recited in independent claims 1, 3, 5, 9 & 15 and the corresponding communications controller as recited in claim 16. Therefore, claims 1, 3, 5, 7, 9, 15 & 16, and their respective remaining dependent claims 10-12, 6 & 21, 8 & 22, and 17-20, are allowable over the prior art of record." Lumish Supp. Decl., Ex. F, at 3.

Regardless, Cisco points out that the terms "channels," "per-VC queuing," and "virtual circuits," which Alcatel claims to be terms used in connection with ATM networks, can be used in connection with other networks. In support of this statement, Cisco refers the Court to Alcatel's web site, in which Alcatel discusses frame relay and uses the terms "channel" and "virtual circuit" in connection with networks other than ATM networks. See Lumish Supp. Decl., Ex. H. Additionally, Cisco references a text on virtual private networking, which also uses the term "virtual circuit" in connection with other networks. See id., Ex. G.

Moreover, Cisco disputes Alcatel's contention that the applicant was his own lexicographer and therefore the Court should adopt his definition of "network" over the ordinary or accustomed meaning of the term. In order to establish that the applicant is his own lexicographer, the special meaning must appear with reasonable clarity and precision in the patent or its prosecution history. See Hockerson-Halberstadt, 222 F.3d at 955; Northern Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1295 (Fed. Cir. 2000). In this instance, Cisco argues that Alcatel has failed to demonstrate, other than by reference to the ATM network as the network used in the preferred embodiment, that the patentee had "an express intent to impart a
novel meaning.” Elekta Instrument S.A. v. O.U.R. Scientific Int'l, Inc., 214 F.3d 1302, 1307 (Fed. Cir. 2000); see also
Johnson Worldwide Assocs. v. Zebco Corp., 175 F.3d 985, 991 (Fed. Cir. 1999) (noting that the varied use of a term
generally shows that the term has a broad, not a limited, meaning).

Essentially, the proper construction of the term "network" turns on whether the entire patent is limited to only, as Alcatel
suggests, egress from ATM networks, or if an ATM network is simply used as a continuous example in the patent, but the
invention actually claims application to any type of network, as Cisco suggests. In a plain reading of the background section
of the patent, it is clear that the problem that this patent sought to solve was related to the prior configuration of egress
queues that would allow a busy virtual circuit to clog up an output port from a common carrier ATM network to the CPE.
See Valizadeh, at 1:12-2:2. However, merely because the patent was developed in response to problems related to ATM
networks, that does not preclude construing the claims as applying to other types of networks, if the claims are written in
such a manner, and the patent examiner had accepted such claims.

In sum, Alcatel argues that where the claim term network appears separately from the term ATM, the claim is still referring
to an ATM network. This is because it is used in connection with the terms "egress traffic of a network" and "egress traffic
directed from a network," which Alcatel contends, as discussed below, must necessarily mean traffic moving from an ATM
network to customer premise equipment. Nonetheless, Alcatel's argument regarding the "egress traffic" terms is essentially
the same as its argument for "network" - that because the patent proposed to solve a problem associated with a particular
type of network, the patent is necessarily limited to claiming application only to that network, despite the absence of such a
limitation in the claim language. The plain meaning in the claim language, however, indicates that "network" was not
intended to refer to solely an ATM network. Moreover, Alcatel has not demonstrated that the intrinsic evidence is sufficient
to require such a limited construction, and overcome the presumption that the term be given its ordinary meaning.

Therefore, the Court adopts the agreed upon language between the parties, and construes "network" as "distinct set of
interconnected elements used to communicate data."

3. Network/ networked/ networking

Several claims of the '864 patent recite the terms "network," "networked," and "networking." Foundry urges the court to
adopt the ordinary meanings of the disputed terms. Lucent, on the other hand, contends that "network" should be construed
to mean "a series of interconnected communication devices that use a single communication protocol." The court finds that
Lucent's proposed construction, which requires the use of "a single communication protocol," is too limiting. The court
therefore construes "network," "networked," and "networking," consistently with their ordinary meaning - "a series of points
1997).

2. "computer network" (claims 1 & 7) and "network" (claim 4)

The plaintiff proposes that "computer network" and "network" mean "a public computer network, such as the Internet,
comprised of two or more computers interconnected by communication channels." The defendant proposes that "computer
network" and "network" mean "the World Wide Web." The parties disagree about the breadth of the network. Defendant
argues that the terms should be construed solely to the World Wide Web, which is described in the preferred embodiment.

Defendant argues that its proposed claim construction is proper largely based on the preferred embodiment described in the
written description. Plaintiff does not dispute that the World Wide Web fits within the claimed invention, but argues that the
breadth of the terms "computer network" or "network" includes public networks other than the World Wide Web. The court
is persuaded that Plaintiff is correct. The written description states that the server site is connected to a computer network
"such as the 'Web or a Wide Area Network (WAN) other than the Web.'" 3:65-67. Accordingly, the court construes these
terms to mean "any public computer network comprised of two or more computers interconnected by communication
channels.

### 2831

#### 3. Computer network

The Court's Construction: An Ethernet network, asynchronous transfer mode network, or any other kind of network using two or more computers, including the internet. Markman Tr. 28:22-24.

RealNetworks agreed with the Court's construction of this term. Id. 20:12-14. Ethos objected to defining "network" as potentially being comprised of only two computers. According to Ethos, "[t]wo computers connected together by a wire don't constitute a network in the sense of the '892 [patent] or [the] '709 patent[;] . . . [t]he network is something different from either the client computer or the server computer." Id. 19:1-8.

The specification states:

The computer network may be an ethernet, an asynchronous transfer mode network, or any other kind of network.

'892 patent col.5 11.2-4; '709 patent col.5 11.10-12 (emphasis added).

Ethos admits that "[t]here's no question," that two or more computers connected together are "sometimes loosely referred to as a network in the technology." Markman Tr. 18:21-24. The question then is whether the intrinsic evidence revealed that the scope of this term as commonly understood was narrowed in the context of this invention. Ethos argued that the claim language suggests such a narrowing, by teaching the sending of data "over a computer network connecting the client computer to the server computer." Id. 19:4-5 (quoting '892 patent, claim 7, col.14 11.2-4). Ethos asserted that this language requires the court to construe the term "computer network" as "something different from either the client computer or the server computer[,] [s]o that you have a client computer, you have a server computer, and a network in between connecting them." Markman Tr. 19:7-10. The Court did not read this language as requiring such an interpretation. The language relied on by Ethos is altogether ambiguous as to whether the computer network must be independent from the server and client computer. The Court, therefore, rejected Ethos' argument and adopted the commonly understood meaning of the term.

### 2832

#### 7. "network access manager/module"

The plaintiff contends that this term means "a device, process or algorithm for controlling the assignment of synchronous and packet data portions on a TDM bus, and for passing data between the bus and a network." The defendants argue that the court should not construe this term. They add that the plaintiff's proposed construction is confusing because it describes functions from the "distributed packet manager." The plaintiff, on the other hand, contends that the specification discusses two functions of the network access manager and that a construction consistent with the specification would help the jury understand the functions of the network access manager.

A review of the specification demonstrates the propriety of the plaintiff's proposal. The specification states that the network access module "controls time-slot allocation among the synchronous modules and the packet modules." '858 patent, 5:12-13. The network access module also "provides the interface between the TDM bus and network facility." '858 patent, 3:46-47. The plaintiff's proposed construction captures a definition of the network access manager in essentially these terms. The court construes the term to mean "a device, process or algorithm for controlling the assignment of synchronous and packet data portions on a TDM bus, and for passing data between the bus and a network."
3. Network Card

The term "network card" is not defined in the claims or specification and should therefore be given its ordinary meaning to one skilled in the art. Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580 (Fed. Cir. 1995) ("[T]he words of a claim will be given their ordinary meaning to one of skill in the art unless the inventor appeared to use them differently."). The preferred embodiment supports such a construction when it describes "identical, conventional network cards" which "can be connected to separate external network systems." Col. 2, ll. 62-65. Citec seeks to define the term primarily in the context of its location or function within the system, because the specification describes the connection of a network card to a data storage means. Romtec seeks to limit both the function of the network card and its location within the patented system. Specifically, Romtec argues that the network card does not connect with a data storage means for purposes of the transfer of data, because the data storage means connects with the computer's motherboard through a hard drive ribbon cable. For the reasons outlined in the preceding section, the Court declines to read Romtec's functional and structural limitations into the claims. Accordingly, the Court construes the term "network card" to mean an electrical interface that couples a data storage means with a computer and may, but need not, interface with an external network system.

VI. "[N]etwork client"

The term "network client . . . appears in all of the claims of the '563 [P]atent and in claims 1-15 of the '882 [P]atent." (R&R at 152.) The term also appears in the specifications of the patents in suit. See, e.g., '493 Patent col. 8, ll. 7-13 (stating that the term "network client" includes web browsers); '563 Patent col. 4, ll. 26 - 27 (stating that the term "network client" includes customized web browsers). As further discussed below, the issue in construing the term "network client" turns on whether it can be defined as a web browser or a customized web browser.

A. The Special Master's Recommendation

The Special Master laid the foundation for his analysis of the term "network client" with a thorough dissection of claim 6 of the '563 Patent. (R&R at 154-56.) He then determined that a "network client" in accordance with the '493, '563, and '882 Patents resides within a personal computer, receives content from the Internet and processes it to produce a content manifestation environment which contains a window object. (Id.) According to the Special Master, these functions are akin to those performed by a web browser that has been customized by the subject matter claimed in the '493, '563, and '882 Patents. Having summarized the Special Master's reasoning, the Court will explain his analysis of the relevant claim language in greater detail.

According to the Special Master, a "network client" is a web browser. Specifically, the relevant claim language starts out with a web browser and then customizes it to create a "customized web browser." (Id. at 158; see also '563 Patent Cl. 6.) In order to facilitate his analysis, the Special Master formatted claim 6 of the '563 Patent as shown below.

6. A network client configured [1] to operate within a data processing system and [2] to receive content from a remote server system [3] to facilitate a windowed content manifestation environment therein, comprising:

[A] a content retrieval module configured to receive content from a network server system via an electronic data network; and

[B] a processing engine [i] coupled to said content retrieval module [ii] configured [(a)] to instantiate a content manifestation environment within the data processing system, [(b)] to process said content to produce at least corresponding window object within said content manifestation environment, [(c)] to process said content to produce at least corresponding window object within said content manifestation environment, [(d)] to process said content to produce at least corresponding window object within said content manifestation environment, [(e)] to process said content to produce at least corresponding window object within said content manifestation environment, [(f)] to process said content to produce at least corresponding window object within said content manifestation environment, [(g)] to process said content to produce at least corresponding window object within said content manifestation environment, [(h)] to process said content to produce at least corresponding window object within said content manifestation environment, [(i)] to process said content to produce at least corresponding window object within said content manifestation environment, [(j)] to process said content to produce at least corresponding window object within said content manifestation environment, [(k)] to process said content to produce at least corresponding window object within said content manifestation environment, [(l)] to process said content to produce at least corresponding window object within said content manifestation environment, [(m)] to process said content to produce at least corresponding window object within said content manifestation environment, [(n)] to process said content to produce at least corresponding window object within said content manifestation environment, [(o)] to process said content to produce at least corresponding window object within said content manifestation environment, [(p)] to process said content to produce at least corresponding window object within said content manifestation environment, [(q)] to process said content to produce at least corresponding window object within said content manifestation environment, [(r)] to process said content to produce at least corresponding window object within said content manifestation environment, [(s)] to process said content to produce at least corresponding window object within said content manifestation environment, [(t)] to process said content to produce at least corresponding window object within said content manifestation environment, [(u)] to process said content to produce at least corresponding window object within said content manifestation environment, [(v)] to process said content to produce at least corresponding window object within said content manifestation environment, [(w)] to process said content to produce at least corresponding window object within said content manifestation environment, [(x)] to process said content to produce at least corresponding window object within said content manifestation environment, [(y)] to process said content to produce at least corresponding window object within said content manifestation environment, [(z)] to process said content to produce at least corresponding window object within said content manifestation environment,
corresponding window object to be controlled as a result of performing at least one of [1] a moving operation, [2] a resizing operation, [3] a minimizing operation, or [4] a maximizing operation within said content manifestation environment without requiring said content manifestation environment to be refreshed.

(R&R at 154-55 (quoting '563 Patent Cl. 6 with the addition of clarifying text within brackets).) 22 According to the Special Master, claim 6 covers and starts out with a "network client," comprised of a "content retrieval module" coupled to a "processing engine," that is then configured to "perform three functions, namely, [1] to operate within a data processing system and [2] to receive content from a remote server system [3] to facilitate a windowed content manifestation environment therein." (Id. at 155 (brackets in original).) The Special Master then pointed out that the "content retrieval module" is simply defined as being configured to receive content from a network system over an electronic data network. (Id.) Next, the Special Master described the "processing engine," as configured "[(a)] to instantiate a content manifestation environment within the data processing system, [and (b)] to process said content to produce at least [one] corresponding window object within said content manifestation environment." (Id. (brackets in original) (emphasized text added).) According to the Special Master, claim 6 further provides that the window object must have at least one "control attribute" capable of affecting its manifestation ". . . within said content manifestation environment" via "the network client . . . . " (Id. at 156 (discussing '563 Patent Cl. 6).) In essence, the Special Master explained and examined each element of claim 6 of the '563 Patent to show that a network client is a web browser that is customized, as described by the claim language, to provide a windows based content manifestation environment according to the patents in suit. Having discussed the Special Master's analysis of the relevant claim language, the Court now turns to his analysis of the specifications of the patents in suit as well as the relevant objective extrinsic evidence. (See id. at 156-57.)

--- Footnotes ---

22 The bracketed text was added by the Special Master to: (1) help organize claim 6 into its base elements and (2) make an analysis of the relevant claim language easier to follow. As can be seen, the Special Master's reasoning directly parallels the relevant claim language because the focus of claim construction, as always, starts with the plain language of the claim.

Innova/Pure Water, Inc., 381 F.3d at 1115.

--- End Footnotes ---

According to the Special Master, the specifications of the patents in suit and relevant objective extrinsic evidence indicate that the term "network client" be defined as a web browser. The Special Master found that "network client" is an open ended term, which according to the specifications of the patents in suit can include a web browser or a customized web browser. (Id. (citing '493 Patent col. 6, l. 53 - col. 7, l. 9).) According to the Special Master, the specifications of the '493, '563, and '882 Patents indicate that a web browser is just one example of a "network client." (Id.) The Special Master then concluded that the "patentees appear to have used the term 'network client' in the subject claims according to its ordinary and customary meaning in the context of client-server network architecture." (Id. at 157.)

As further support for his recommended construction, the Special Master used technical dictionaries to construe the term "network client." (See id. at 157-58 (citing Computer & Internet Dictionary (3d ed. 1999); Microsoft Computer Dictionary (4th ed. 1999))). Finding that the term "network client" was not "per se" defined, the Special Master construed the term by defining the words "network" and "client" separately, as shown below. (Id. at 157-58.)

A "network" is, for example, "a group of two or more computer systems linked together." See COMPUTER & INTERNET DICTIONARY at 374. See also MICROSOFT COMPUTER DICTIONARY at 308 ("A group of computers and associated devices that are connected by communications facilities."). A "client" is "[t]he client part of a client-server [network] architecture," e.g., "an application that runs on a personal computer or workstation and relies on a server to perform some operations." See COMPUTER & INTERNET DICTIONARY at 94. See also MICROSOFT COMPUTER DICTIONARY at 88 ("3. On a local area network or the Internet, a computer that accesses shared network resources provided by another computer (called a server).")

The term "network client" per se thus appears to have a readily-discerned ordinary and customary meaning, and connotes a range of applications possible within the client-server network architecture. The term "network client" per se does not connotate a "customized WWW browser." Additional attributes and requirements of the "network client," though, are expressly set out in the claims. Those additional requirements may make the "network client" as defined by the claim...
language as a whole a "customized web browser."

(1d.) Consistent with his interpretation of the claim language and the specifications of the patents in suit, the Special Master found that a "network client" is best construed as a web browser that can be customized. Having detailed the Special Master's reasoning and recommended construction, the Court will summarize CA's objections and Simple's corresponding counter arguments.

B. CA's Objections and Simple's Counter Arguments

According to CA, the relevant claim language and portions of the specifications indicate that a "network client" can only be a customized web browser. CA argues that: (1) the use of the term "network client" in the claim language of the '563 and '882 Patents indicate that it should be defined only as a "web browser designed to provide window objects without requiring the download of a software system for that purpose"; and (2) a "network client" is not a web browser because claims 1 and 6 of the '563 Patent merely require that "content" be downloaded to enable a content manifestation environment featuring window objects, as opposed to the "software system" referred to in claim 1 of the '493 Patent. (See CA's Claim Construction Objections at 11-13.) According to CA, since the specifications of the '563 Patent consistently use the term "network client" to refer to a customized web browser, the Special Master's recommended construction has no basis in the '563 Patent. (Id. at 13-16.) CA also objects to what it calls the Special Master's inappropriate use of extrinsic evidence when constructing the term "network client." (Id. at 16-17 ("Stringing Together Dictionary Definitions Cannot Trump The Consistent Teaching Of The Specification").)

CA also argues that "network client' has a different meaning in the '882 patent than it does in the '563 [P]atent" because of "sloppy patent prosecution." (Id. at 17-19.) In "the first application that was filed in the prosecution of the '882 [P]atent, claims 1-13 were identical to claims 1-13 of the '493 [P]atent." (Id. at 18 (comparing '882 Prosecution History (Dkt. No. 366), Ex. 3 at SIM-007016-18 with '493 Patent, Cls. 1-13).) The first 13 claims of application number 09/843,130, which matured into the '882 Patent, were then canceled since they had already issued in the '493 Patent. (Id. (citing '882 Prosecution History at SIM-007244).) In their place, the patentees inserted claims that were "substantially identical to" those found in the '563 Patent, "as claims 1 through 15 of the '882 patent." (Id.) In light of this prosecution history, CA concluded that the Special Master incorrectly interpreted the term "network client" so as to preserve the validity of the '882 Patent, which failed to meet the written description requirement of 35 U.S.C. § 112 P 1. (Id. at 18.)

In response, Simple argues that the Special Master correctly construed a "network client" as a web browser. (Simple's Reply to CA's Objections at 12.) According to Simple, the Special Master's recommended construction was properly based on the claims of the '563 and '882 Patents, which "strongly imply that the customization of the 'network client' . . . [was] not an inherent feature." (Id. at 13 (citing Phillips, 415 F.3d at 1309-10 (for the proposition that the "claim language 'steel baffles' strongly implies baffles are not inherently made of steel").) Simple further argues that the Special Master's proposed construction is supported by the specifications of the '563 and '882 Patents as well as relevant extrinsic evidence. (Id.) Finally, Simple argues that CA "did in fact agree that the 'network client' could be construed as a web browser." (Id. at 14 (quoting Markman Tr. at 230:8-19).) Having summarized the parties' objections and counter arguments, the Court will conduct its analysis of the disputed term.

C. Analysis

The Court's analysis of the term "network client" will entail: (1) constructing the term based upon a review of the claim language and the specifications of the patents in suit and (2) addressing the arguments raised by the parties.

1. The Claim Language of the Patents in Suit Indicates That a "network client" is a Web Browser, Capable of Being Customized

Quite simply, the relevant claim language of the '563 and '882 Patents, starts out with a "network client" or web browser and then custom configures it to facilitate a windows based content manifestation environment. As such, concluding that a "network client" is already customized would make the associated claim language redundant. The Court's analysis of the relevant claim language leads to the same conclusion reached by the Special Master, namely that a "network client" is a web browser that can be customized according to the relevant claim language of the patents in suit. Accordingly, the Court adopts the Special Master's proposed construction of the term "network client" and directly incorporates his reasoning as it
pertains to the intrinsic evidence before the Court. (See generally R&R at 156 ("With the foregoing in mind, it is difficult to see what further 'construction' of 'network client' is necessary.").) The Special Master correctly concluded that, though a "network client" should be construed as a web browser, a "network client" as refined by the relevant claim language becomes a customized web browser. (Id. at 158; see also, e.g., '563 Patent Cl. 6.) In other words, a customized web browser is still a web browser. Having discussed the relevant claim language, the Court's analysis turns to the specifications of the patents in suit.

2. The Specifications of the Patents in Suit Indicate That the Term "network client" Should Be Broadly Construed as a Web Browser

According to the specifications of the patents in suit, a "network client" is broadly defined as a web browser. The specifications of the '493, '563, and '882 Patents use the open ended phrase "such as" when stating that a "network client" can be a web browser or a customized web browser. Innova/Pure Water, Inc., 381 F.3d at 1117 ("claims will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction.") (internal quotations omitted). For example: (1) the '493 and '882 Patents provide: "Client system 108 is configured to operate in accordance with an operating system such as MICROSOFT WINDOWS 98 . . . which may be operated in accordance with a network client application such as Internet Explorer version 4.x, Netscape Communicator 4.x, etc." and (2) the '563 Patent describes "a network client, such as a customized WWW browser client or application, which is configured to operate within a data processing system and to receive content from a remote server system to facilitate a windowed content manifestation environment." '493 Patent col. 8, ll. 7-13; '882 Patent col. 8, ll. 7-13; '563 Patent col. 4, ll., 24-30 (emphasis added). Accordingly, the specifications of the '493, '563, and '882 Patents indicate that the term "network client" should be defined as a web browser, which, as the patents in suit clearly indicate, can be customized.

The '493 and '882 Patents teach that a network client such as a web browser can be customized to provide the claimed invention. In the following excerpt, the '493 and '882 Patents list a WWW/web browser as an example of a network client that can use files downloaded over an electronic data network to facilitate a windows based content manifestation environment.

Such files are generated in accordance with the present invention to facilitate a windows based content manifestation environment on or within network clients such as WWW browsers that may be used to download the same and to display content therein.

At a client side . . . a client system 108 is outfitted with appropriate network client software to access an electronic data network . . . . Accordingly, client system 108 is configured to access and download HTML documents such as HTML documents and other related files 106 which may be generated and stored in data store 104.

Indeed, as the '493 and '882 Patents go on to point out, the aforementioned HTML files are subsequently loaded onto the network client/web browser to "facilitate a windows based content manifestation environment." E.g., '882 Patent col. 7, ll. 9-12 (stating "It is the HTML documents and the related files as discussed herein which facilitate a windows based content manifestation environment within a client system such as within client system 108."). Since the intrinsic evidence at hand is sufficient to define a "network client," the Court finds it unnecessary to refer to technical dictionaries in defining the term.

3. "[N]etwork client" Defined

The intrinsic evidence before the Court indicates that a "network client" is a web browser. This construction comports with: (1) the claim language of the patents in suit, which starts out with a web browser and then customizes it; (2) the portions of the specifications of the patents in suit which state that a network client can be a web browser or a customized web browser; and (3) the fact that a web browser, whether customized, enhanced or reconfigured, is still a web browser. Having construed the term "network client," the Court turns to CA's objections.

4. CA's Proposed Construction of "network client" Ignores the Relevant Intrinsic Evidence
CA's objections to the Special Master's recommended construction of the term "network client" inappropriately focus on narrowly limiting a "network client" to the end product of the relevant claim language found in the '563 and '882 Patents and ignoring the specifications of the '882 Patent. The Court has already stated that the relevant claim language of the '563 and '882 Patents starts out with a "network client" that is merely a conventional web browser and then proceeds to customize it according to claim elements therein. This point has been well discussed by the Special Master and need not be analyzed again.

CA seeks to improperly limit the construction of the term "network client" by selectively using language found in the specifications of the '563 Patent and ignoring the '493 and '882 Patents. (See CA's Claim Construction Objections at 13-16.) CA cites the following portion of the '563 Patent specification as proof that a network client must be a "customized WWW browser client." (Id. at 14.)

Accordingly, the present invention solves the aforementioned problems to deliver the above-described benefits by providing a network client, such as a customized WWW browser client, which is configured to operate within a data processing system and to receive content from a remote server system to facilitate a windowed content manifestation environment (CME).

(Id. (citing '563 Patent col 4, ll. 24-30).) CA then argues that the specification of the '882 Patent, which directly contradicts its own proposed construction, should be ignored since it is merely the product of "sloppy" prosecution. (Id. at 17-18.) Both arguments fail to account for the fact that the phrase "such as" does not connote an exclusive relationship. Rather, the foregoing passage merely conveys that a customized WWW browser is one example of a network client. This is consistent with the finding that, a network client can be both a web browser and a customized web browser since a web browser remains a web browser even after it is customized. See, e.g., '882 Patent col. 8, ll. 7-13. CA's argument, that the specifications of the '882 Patent should be ignored, fails if one were to construe a "network client" to be a web browser. This is because CA's argument that the '882 Patent is invalid and its specifications should be ignored hinges on construing a network client as a customized web browser. Accordingly, the Court is unpersuaded by CA's arguments. The Court now turns to CA's objection to the Special Master's use of extrinsic evidence.

CA's assertion that the Special Master inappropriately applied extrinsic evidence when constructing the term "network client" is incorrect. (CA's Claim Construction Objections at 16-17.) Although the Special Master augmented his analysis with extrinsic evidence, he defined "network client" according to intrinsic evidence found in the '493, '563, and '882 Patents. Indeed, the Special Master indicated that, after his analysis of claim 6 of the '563 Patent, it was "difficult to see what further 'construction' of 'network client' was necessary. (R&R at 156.) Having addressed the deficiencies in CA's objections, the Court will address Simple's counter arguments.

5. Simple's Counter Arguments

Simple correctly agrees with the Special Master's recommended construction of a "network client" as a web browser and seems to endorse much of his logic. However, Simple also argued that CA agreed with the Special Master "that the 'network client' could be construed as a web browser." (Simple's Reply to CA's Objections at 14 (quoting Markman Tr. at 230:8-19).) The Court is underwhelmed by this argument since reference to the Markman Transcript clearly shows that this was not the case. (Markman Tr. at 231-37.) Having addressed the parties' arguments, the Court will issue its ruling on the term "network client."

D. The Court's Ruling on the Term "network client"

CA's objection to the Special Master's recommended construction of the term "network client" is denied. Rather, the Court adopts the Special Master's recommended construction and rules that a "network client" is a web browser. The intrinsic evidence before the Court shows that the term "network client" includes a web browser as well as a customized web browser. See, e.g., '493 Patent col. 8, ll. 7-13 (stating that the term "network client" includes web browsers); '563 Patent col. 4, ll. 26-27 (stating that the term "network client" includes customized web browsers). Specifically, the relevant claim language of the '563 and '882 Patents shows that a "network client" is a web browser capable of being customized to produce a content manifestation environment featuring window objects. E.g., '882 Patent Cl. 1; '563 Patent Cls. 1, 6. Indeed, the entire purpose of claim 6 of the '563 Patent is to start out with a web browser, and then customize it.
I. "A Network Code That Identifies a Network Element to Provide Egress From the Packet Communication System"

Claim 1 of the '561 patent recites the phrase "a network code that identifies a network element to provide egress from the packet communication system." Sprint contends that this phrase should be construed to mean information that identifies a network element that provides an exit from a packet communication system (wherein the phrase "to provide egress from the packet communication system" modifies the "network element" and not the "network code"). Vonage contends that the phrase should be construed to mean a logical address identifying a network element that provides an exit from a packet communication system.

The primary dispute between the parties for this claim element is the meaning of the phrase "network code." In support of Sprint's proposed claim construction, Sprint contends that "it cannot be disputed that a 'network code' is 'information' for identifying a network element." This argument, however, is not based on any evidence in the intrinsic record that would allow the specific claim term "network code" to be construed so broadly so as to encompass any "information." Vonage, on the other hand, relies on an excerpt from the '561 patent specification which states that "[n]etwork codes are the logical addresses of network elements." '561 Patent at 12:47-53. Sprint asks the court to discount the significance of this claim language because it is contained in a portion of the specification which discusses one embodiment of the invention. While the court certainly recognizes that it would be improper to read an example from the specification into the claims, here the language from the specification contains no indication that the meaning given to "network codes" is in any way limited to any particular embodiment. It states simply, clearly, and unequivocally that network codes "are" the logical addresses of network elements. And, this is consistent with the claim language which recites "a network code that identifies a network element." Consequently, the court will construe the claim language "network code" to have the meaning set forth in the specification, as argued by Vonage.

The parties agree that the fact that the network element "provide[s] egress" from the packet communication system means that it "provides an exit" from the system. And, Sprint correctly points out that the court previously noted in its summary judgment ruling that the claim phrase "to provide egress from the packet communication system" modifies the phrase "network element" and not the "network code." In order to clarify this, then, the court construes the phrase "a network code that identifies a network element to provide egress from the packet communication system" to mean a logical address identifying a network element which network element provides an exit from a packet communication system.

2. "network facility"/"network communications facility"

The court next addresses the terms "network facility" and "network communications facility," which appear in 037 Patent in claims 2 and 8, respectively. 037 Patent 55:61, 56:49. The parties agree that the two terms are used interchangeably in the 037 Patent to refer to a type of peer-level facility. However, plaintiff argues that the court should construe both terms as "a facility for performance of network communications," while defendant contends that "network facility" and "network communications facility" refer to "the peer-level facility that consists of the NFS stack and its associated multi-tasking interface function."

For the reasons stated in its discussion of the term "operating system peer-level facility," the court declines to adopt the "multi-tasking interface function" limitation as part of the construction of the network facility term. Thus, what remains of the parties' dispute centers on the whether a network facility must consist of an NFS stack. Here too, the court's preceding discussion resolves the parties dispute. In the preferred embodiment of the invention, an NFS stack is defined as a series of communication protocol layers that provides a link between the "virtual file system" ("VFS") of the Unix kernel and representation (i.e., XDR) protocol layer. Id. at 7:42-46. As the court noted above, the claims of the 037 Patent are not limited to this preferred embodiment.
Nonetheless, defendant argues that the prosecution history of the 885 Application and the prior art file server depicted in the 037 Patent require the court to read the limitation "NFS stack" into the claims. With respect to the former, defendant does little more than repeat the previously quoted passage of prosecution history, noting that Auspex defined the term "primary peer-level facility" in response to the examiner's rejection of claim 1 of the 885 Application for indefiniteness. However, the cited passage does not mention the term "network communications facility." Indeed, the definition of peer-level facility on which defendant relies makes it clear that any component of a Unix operating system would merely relate to the preferred embodiment of the invention rather than to the scope of the claims. The court cannot arbitrarily select one such component, the NFS stack, to limit the scope of the network facility term.

As to prior art, defendant argues that Figure 1 of the 366 Patent depicts a prior art operating system that would anticipate the invention unless the network communications facility shown in the figure includes an NFS stack. It is true that "claims should be read in a way that avoids ensnaring prior art if it is possible to do so." Harris, 114 F.3d at 1153. Nonetheless, the Federal Circuit has recognized that "claim limitations may, and often do, read on the prior art." Intel Corp. v. United States Int'l Trade Comm'n, 946 F.2d 821, 842 (Fed. Cir. 1991). Simply put, there is nothing in the claims of the 037 Patent to indicate that a network communications facility must include an NFS stack. Because the court lacks the power to rewrite the claim to insert such a limitation, see Becton Dickinson & Co., 922 F.2d at 799 n.6, defendant's argument must be rejected.

Having rejected defendant's arguments for the reasons stated above, the court concludes that the ordinary meaning of the term "network communications" adequately describes the function performed by a network communications peer-level facility. Accordingly, the court construes "network communications facility" (or "network facility") as "a peer-level facility for the performance of network communications."

G. "Network Control Computer"

The term "network control computer" appears in claim 2 of the '943 patent. WebEx contends that "network control computer" should be defined identically to "remote system controller" and, therefore, suggests the following definition: "a computer or controller that checks validity of logon commands and interfaces signals between the local portion/computer unit and the remote computer unit to operate the remote computer unit, but excluding devices that forward packets without regard for content and websites." 198 ABC argues that the claim language and specification of the '943 patent make clear that the terms "remote system controller" and "network control computer" are not synonymous, and asserts that the definition of "network control computer" must account for the differences. 199 ABC contends that the proper definition for "network control computer" is "one or more computational devices that maintain a list of access codes for individuals authorized to use the remote computers and facilitate the connection between the remote and local computers upon receiving a valid logon command." 200

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

1. "Computational Devices" or "Computer or Controller"

ABC contends that a network control computer is composed of "one or more computational devices." ABC, however, presents no evidence that supports this assertion. ABC makes the conclusory argument that the claim language and specification support this aspect of its definition, but does not point to any mention of "computational devices." Nor does ABC explain why the singular form of the word "computer" was employed by the patent drafter if the term was intended to refer to multiple devices.

- 3159 -
The extrinsic evidence cited by ABC does not support this aspect of its definition. Although the word "network" is defined in a technical dictionary cited by ABC as "[a] group of computers and associated devices that are connected by communications facilities," 201 this does not suggest that a network control computer is made up of multiple computers or devices. Instead, it more likely suggests that the network control computer is a single computer that controls a "network" of multiple computers.

WebEx asserts that a network control computer is "a computer or controller." But this aspect of WebEx's proposed definition is not consistent with the specification of the patent, which cites a network control computer as a possible embodiment of a remote system controller. 202 The court has defined, consistent with the specification, 203 a remote system controller as "a computer or controller." Because the term "network control computer" includes the specific word "computer," the network control computer most logically falls into the first potential category of remote system controller -- computer -- rather than the later category -- controller. Accordingly, the court concludes that a network control computer is a single computer.

2. Functions of a Network Control Computer

ABC asserts that the network control computer "maintain[s] a list of access codes for individuals authorized to use the remote computers" and "facilitate[s] the connection between the remote and local computers upon receiving a valid logon command." WebEx asserts that the network control computer "checks the validity of logon commands" and "interfaces signals between the local portion/computer unit and the remote computer unit to operate the remote computer unit."

a. Maintaining a List of Access Codes

ABC asserts that the network control computer "maintain[s] a list of access codes for individuals authorized to use the remote computers." ABC bases this assertion on the only sentence in the specification of the '943 patent that mentions a network control computer: "For example, the remote system controller can be a network control computer which stores a list of access codes for individuals authorized to use the remote computer units." 204

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
204 '943 patent, col.5 ll.19-21.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

The cited sentence appears within a two-paragraph description of the function and possible embodiments of a remote system controller:

The remote system controller 26 communicates with the telephone network controller 14 and the television network
controller 18 via respective communication links 27a and 27b and also communicates with the remote computer units 24a and 24b via respective communication links 28a and 28b. The remote system controller 26 can be any type of computer or controller which is capable of receiving signals transmitted from at least one local portion 12 of the split personal computer system 10 and supplying such signals to at least one of the remote computer units 24 to permit bidirectional communication therebetween.

For example, the remote system controller 26 can be a network control computer which stores a list of access codes for individuals authorized to use the remote computer units 24. The remote system controller can also include a billing program which counts the time periods in which an individual utilizes at least one of the remote computer units . . . . 205

205 '943 patent, col.5 ll.8-28 (emphasis added).

Viewed in context, the underlined sentence suggests that a network control computer may fall within the definition of and is one possible embodiment of a remote system controller. 206 But the sentence, standing alone, does not clearly convey whether (1) all network control computers qualify as remote system controllers and store a list of access codes, or (2) only certain network control computers store a list of access codes, and thereby qualify as remote system controllers.

206 WebEx agrees, based on this sentence, that a network control computer "is a type of remote system controller." WebEx's Brief, Docket Entry No. 156, at 9. ABC's expert witness also asserts, citing this sentence, that "a Network Control Computer is a subset of a Remote System Controller." Affidavit of Ivan Zatkovich, P 28 (May 28, 2009) (included in ABC's Response, Docket Entry No. 165, at Exhibit A). ABC, however, attempts to argue the converse in its response brief, suggesting that a remote system controller that stores a list of access codes is a subcategory or type of network control computer. See ABC's Response, Docket Entry No. 166, at 25 ("[A] network control computer is not necessarily a remote system controller, although one device can perform functions of both elements. A network control computer 'stores a list of access codes for individuals authorized to use the remote computer units.' A remote system controller is a network control computer if it performs this function." (citations omitted)). This argument, besides being inconsistent with ABC's own expert witness testimony, is not supported by the particular sentence from the specification relied upon by ABC, when viewed in context.

Although both interpretations are plausible, the court concludes that the first interpretation of the sentence -- i.e., that all network control computers store a list of access codes and are remote system controllers -- is correct. Under this interpretation the difference in scope between claim 1 and claim 2 is much more clearly defined. 207 See Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1366 (Fed. Cir. 2000) ("Under the doctrine of claim differentiation, two claims of a patent are presumptively of different scope."). Under the first interpretation, claim 2 of the '943 patent is narrower than claim 1 because claim 2 is limited to operating a particular embodiment -- i.e., a network control computer -- of the broader category of devices allowed by claim 1 -- i.e., remote system controllers. This would not be the case under the second interpretation because under that interpretation some network control computers might not qualify as remote system controllers.

207 The primary difference between claims 1 and 2 of the '943 patent is that claim 1 requires a remote system controller while claim 2 requires a network control computer.

Additionally, if the court were to adopt the second interpretation, the court would need to include the limitation regarding storing a list of access codes in the definition of remote system controller -- something neither party has advocated --
because the presence of that limitation would be a characteristic necessary to qualify as a remote system controller, not as a network control computer. Under the first interpretation, however, storing a list of access codes is a unique feature that network control computers must have and, therefore, belongs in the definition of that term.

The court also notes that although WebEx's proposed definition does not include this limitation, WebEx offers no evidence or argument to counter ABC's argument that network control computers necessarily store a list of access codes. 208 Accordingly, the court concludes that a network control computer stores a list of access codes for individuals authorized to use the remote computer units. 209

------------------------------------------ Footnotes ------------------------------------------
208 See WebEx's Response, Docket Entry No. 166, at 6-8 (failing to address ABC's contention that the network control computer maintains a list of access codes).
209 The court uses the term "stores" instead of "maintains" and the term "remote computer units" instead of "remote computers" because these are the terms used in the specification.

------------------------------------------ End Footnotes ------------------------------------------

b. Checking the Validity of Logon Commands

WebEx contends that the network control computer checks the validity of logon commands and faults ABC's proposed definition for omitting this function. ABC contends that the network control computer need not necessarily be able to check the validity of logon commands. In support of its position, ABC offers the affidavit of a purported expert witness who attempts to differentiate the functions performed by the remote system controller and the network control computer. He asserts that

[the primary difference between these two structures is that a remote system controller validates logon commands and a network control computer maintains a list of access codes or login IDs for individuals authorized to use the remote computers. This means the Network Control Computer does not necessarily validate a login command but can identify the authorized users. Whereas, the Remote System Controller does in fact perform validation of the login command. 210

------------------------------------------ Footnotes ------------------------------------------
210 Affidavit of Ivan Zatkovich, P 30 (May 28, 2009) (included in ABC's Response, Docket Entry No. 165, at Exhibit A).

------------------------------------------ End Footnotes ------------------------------------------

The court finds ABC's argument illogical and unpersuasive. Claim 2 of the '943 patent explicitly states that the network control computer "check[s] the validity of a valid logon command." 211 In fact, during the reexamination of the '943 patent, ABC specifically added the phrase "and checking the validity" to claim 2 to make explicit that the network control computer was capable of that function. 212

------------------------------------------ Footnotes ------------------------------------------
211 '943 patent, claim 2 (as amended by Supplemental Amendment).

------------------------------------------ End Footnotes ------------------------------------------

Moreover, ABC's expert witness admits that "a Network Control Computer is a subset of a Remote System Controller." 213
ABC and its expert also admit that a remote system controller, by definition, checks the validity of logon commands. 214 If a network control computer is indeed a "subset" of the broader category of remote system controllers -- which, by definition, must be capable of checking the validity of logon commands -- then a network control computer must necessarily be able to check the validity of logon commands. Otherwise, it would not fit within the definition of a remote system controller.

--- Footnotes ---
213 Affidavit of Ivan Zatkovich, P 28 (May 28, 2009) (included in ABC's Response, Docket Entry No. 165, at Exhibit A).
214 See ABC's Brief, Docket Entry No. 154, at 19 (proposing a definition for "remote system controller" that includes the phrase "validating logon commands"); Affidavit of Ivan Zatkovich, P 30 (May 28, 2009) ("[A] remote system controller validates logon commands . . . ") (included in ABC's Response, Docket Entry No. 165, at Exhibit A).

The function of storing a list of access codes and checking the validity of logon commands are not mutually exclusive. Indeed, storing a list of access codes may be the feature of a network control computer that enables it to validate logon commands. Accordingly, the court concludes that a network control computer checks the validity of logon commands and will include this function in the definition.

c. Interfacing the Local Computer Unit with the Remote Computer Unit

ABC asserts that a network control computer "facilitate[s] the connection between the remote and local computers . . . ." ABC's proposed definition for the term remote system controller is remarkably similar in this regard, stating that the remote system controller "facilitat[es] communication between a local and remote computer . . . ." WebEx asserts that both a network control computer and a remote system controller "interface[] signals between the local portion/computer unit and the remote computer unit . . . ." In light of these proposed definitions, the parties apparently agree that a network control computer and a remote system controller perform the same function with respect to the local and remote computer units.

Claim 2 of the '943 patent states that the network control computer "connect[s] the remote computer unit to the local computer unit . . . ." 215 Claim 1 of the same patent describes the corresponding function of the remote system controller as "interfacing . . . the local computer unit with the remote computer unit . . . ." 216

--- Footnotes ---
215 '943 patent, claim 2 (as amended) (emphasis added).
216 '943 patent, claim 1 (as amended) (emphasis added).

Although claim 2 describes the network control computer as "connect[ing] . . . to" and claim 1 describes the remote system controller as "interfacing . . . with," the court concludes, as the parties do, that the functions are no different. Several dictionaries define the verb "interface" using the term "connect." 217 Moreover, the court has already concluded that a network control computer is a subset or type of remote system controller. Therefore, a network control computer must be able to perform the same functions as a remote system controller. Accordingly, the court will use the same language to describe this common functionality of the network control computer and the remote system controller. The network control computer interfaces the local computer unit with the remote computer unit.

--- Footnotes ---
217 See, e.g., Random House Webster's College Dictionary (1999) (defining "interface" as "to bring together; connect or mesh" (emphasis added)); Merriam Webster's Collegiate Dictionary (10th ed. 1996) (defining "interface" as "to connect by means of an interface").
d. Operating the Remote Computer Unit

WebEx's proposed definition states that the remote system controller validates logon commands and interfaces the local computer unit with the remote computer unit "to operate the remote computer unit." ABC's proposed definition does not include any such phrase to explain the purpose of validating logon commands and interfacing the local computer unit with the remote computer unit.

Claim 2 explicitly states that the network control computer "connect[s] the remote computer unit to the local computer unit permitting the local computer unit to operate the remote computer unit upon receipt and checking the validity of a valid logon command . . . ." 218 Moreover, the court's definition of remote system controller -- a category of devices of which network control computers are a subset -- explains that the purpose of validating logon commands and interfacing the local and remote computer units is "to permit the local . . . computer unit to operate the remote computer unit." Accordingly, the court's definition of network control computer will recognize that a network control computer validates logon commands and interfaces the local and remote computer units to permit the local computer unit to operate the remote computer unit.

218 '943 patent, claim 2 (as amended) (emphasis added).

3. Exclusions

As it did with regard to the term remote system controller, WebEx asserts that ABC disclaimed two categories of devices from the scope of the term network control computer during the prosecution of the '943 patent and that these exclusions should be reflected in the court's definition of the term. The underlying facts and arguments are identical. Accordingly, for all the same reasons stated above in the court's discussion of the term remote system controller, the court concludes that ABC clearly and unmistakably disavowed passive devices that merely forward data packets without regard for their content from the scope of the term network control computer. ABC, however, did not clearly and unmistakably disavow websites. The court's definition will so reflect.

4. Conclusion

A "network control computer" is "a computer that stores a list of access codes for individuals authorized to use the remote computer units, checks the validity of logon commands, and interfaces the local computer unit with the local computer unit to permit the local computer unit to operate the remote computer unit, but excluding passive devices that merely forward data packets without regard for their content."

2838

1. "network for data communications"

The district court construed the phrase "network for data communications" to mean "establishing data communications between every pair of processor systems in the distributed computer system using any kind of network." Seachange, 115 F. Supp. 2d at 482. The district court reasoned that the claim language does not command a specific type of network, that claim differentiation doctrine favors a broad interpretation, that the written description does not require a narrow construction, and that the prosecution history does not show clear disavowal. Id. at 478-81.

Claim 37 does not suggest that the claimed "network" is limited to networks employing direct, point-to-point interconnections. The language specifies only that each processor system be interconnected to each other processor system. Moreover, the technical dictionary definition of "network" does not suggest the point-to-point limitation; indeed, it implies
that a "network for data communications" can employ direct or indirect interconnections. See The New IEEE Standard Dictionary of Electrical and Electronics Terms 842 (5th ed. 1993) (hereinafter "IEEE").

Seachange agrees with this assessment and asks that we apply the doctrine of claim differentiation. The doctrine of claim differentiation stems from "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999). Although the doctrine is at its strongest "where the limitation sought to be 'read into' an independent claim already appears in a dependent claim," Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004), there is still a presumption that two independent claims have different scope when different words or phrases are used in those claims, Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1365-69 (Fed. Cir. 2000); see also Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). However, the doctrine "only creates a presumption that each claim in a patent has a different scope; it is not a hard and fast rule of construction." Kraft, 203 F.3d at 1368 (internal quotations omitted). "The doctrine of claim differentiation can not broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence.... Claims that are written in different words may ultimately cover substantially the same subject matter." Multiform Desicants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1480 (Fed. Cir. 1998).

Claim 1 of the '312 patent requires "interconnecting each one of said processor systems in a point-to-point two way channel interconnection with each other one of said processor systems." '312 patent, col. 17, ll. 54-56. Claim 37 is identical to claim 1, except that claim 37 requires only that the interconnection be through a "network for data communications." The doctrine of claim differentiation creates a presumption that these limitations in claim 1 and claim 37 are of different scope and suggests that claim 37 does not require point-to-point, two-way channel interconnections. However, that presumption is not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history. Kraft, 203 F.3d at 1368.

As to the written description, C-COR argues that Seachange limited the scope of "network for data communications" to point-to-point networks by implication. C-COR asserts that the written description discloses only point-to-point interconnections and establishes that the point-to-point interconnections achieve a necessary objective of the invention. C-COR adds that the written description eliminates embodiments incompatible with point-to-point wiring. C-COR cites several cases in support of its arguments. E.g., Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1351-52 (Fed. Cir. 2004) (construing claim to require feature that was "central to the functioning of the claimed invention"); Alloc, Inc. v. ITC, 342 F.3d 1361, 1369-70 (Fed. Cir. 2003) (construing claim to include limitation because "very character of the invention" required that the limitation be part of every embodiment); Watts v. XL Sys., Inc., 232 F.3d 877, 882-83 (Fed. Cir. 2000) (construing claim to include limitation, in part, because specification limited invention to embodiments with that feature); Bell Atl. Network Servs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001) (construing claim to reflect inventor's consistent usage of claim term in specification); Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1300-01 (Fed. Cir. 1999) (construing claim to require a particular configuration where specification described the importance of the configuration and did not disclose others).

Seachange responds that the written description does not show a clear disavowal or a redefinition. Seachange argues that the type of network connection used is not important to the invention and that the invention resides in RAID Squared. Seachange explains that the text of the specification contains little disclosure of the types of network interconnections covered by the patent because that was not significant. Seachange asserts that a patentee is entitled to claims that are broader than embodiments described and that C-COR seeks to erroneously import a limitation from a preferred embodiment.

We agree with C-COR that the written description consistently refers to the network interconnections as point-to-point, e.g., '312 patent, col. 3, ll. 30-34; col. 4, ll. 36-43; col. 2, ll. 15-25; Abstract; col. 5, ll. 1-4, 52-58; col. 6, ll. 7-9, and suggests an upper limit on the number of processor systems compatible with point-to-point wiring, id., col. 5, ll. 58-61; col. 8, ll. 30-38 ("More or less processor systems can be used, although a practical upper limit may be between nine and thirteen. ... When more cluster members are employed, the point to point wiring becomes progressively more difficult and expensive. Indeed, nine cluster members would require thirty-six interconnecting channels while thirteen cluster volumes would have 78 interconnecting channels.")). Furthermore, point-to-point interconnections achieve an object of the invention in that they increase read and write bandwidth. See id., col. 2, ll. 7-9; col. 7, ll. 63-67. However, it is unclear whether these references to point-to-point are simply the consistent description of one possible embodiment or a description of the invention itself. In all of the cases cited by C-COR, the conclusion compelled by the written description is that the limitation in issue is a
limitation on the invention, not just a feature of a possible embodiment. The issue is unresolved with certainty from the written description in this case. We turn next to the prosecution history for guidance.

On October 24, 1995, Mann et al. ("Applicant") filed the application which matured into the '312 patent. In a September 30, 1996, Preliminary Amendment ("Preliminary Amendment"), Applicant added thirty-six claims, including claim 37, which was numbered as claim 40 throughout examination ("claim 37 (40)"). Applicant also added claims 68-72, and 74, which included a limitation directed to an "interconnecting data communications network." Id. at 11-13. Applicant stated that it added claims "to more fully cover the scope of the invention." Preliminary Amendment at 13.

In a December 12, 1996, Office Action ("First Action"), the Examiner rejected claims 1-75. The Examiner grouped claims 1, 37 (40), and others, and rejected them under 35 U.S.C. § 103 as unpatentable over Morita et al., U.S. Patent No. 5,502,980 ("Morita"), in view of Benner et al., U.S. Patent No. 5,072,371 ("Benner"). First Action at 3. In a June 12, 1997, Amendment ("Amendment"), Applicant's attorney stated:

With respect to the various prior art rejections, the Examiner grouped various claims and rejected the grouped claims. Applicant submits that with respect to each group of claims that certain of the claims in the group add further patentably distinct features to the invention and thus are further patentably distinct over the applied references. For simplicity, however, Applicant will in general treat a single claim as being representative of the group of claims but reserves its right to later argue that additional ones of the claims are patentably distinct over the combination of references. Amendment at 29-30. Applicant's attorney then argued:

As an illustrative claim in this grouping, Applicant's claim 1 ... recites a method in which at least three processor systems are interconnected using a point-to-point two-way channel interconnection with each one of the other processor systems. That is, any one processor system can communicate directly with any one of the other processor systems. The claim also recites that data is stored at each of the processor systems which also stores a portion of a redundant representation of the data. Neither the point to point two-way channel interconnection nor the arrangement of stored data and redundant data is suggested by the combination of Morita and Benner.

Morita, as the Examiner, [sic] admits does not describe at least three processor systems in a distributed computing system and also does not describe a point to point interconnection. Applicant submits that Morita also does not describe or suggest that the processor system stores data in the manner recited in claim 1. ...

Benner describes a parallel computing system of the hypercube type. As such, although Benner does describe more than two processor systems, Benner does not describe that each of the processor systems are interconnected in a point to point two-way channel interconnection with each one of the other processor systems as recited in Applicant's claim 1. The Examiner indicates, however, that Benner suggests such an arrangement. ... Although Benner ... describes his connections as "point to point" paths, Benner does not suggest that each of the processors in the hypercube arrangement are coupled to each one of the other processors in the hypercube arrangement as recited in claim 1. Rather, Benner teaches away from such an interconnection scheme ...

... Accordingly, in view of the fact that neither Morita nor Benner whether taken separately or in combination suggest the above-mentioned elements of Applicant's invention and furthermore since the combination of Morita and Benner does not appear to be suggested from the references nor appear to be logical, it is submitted that the rejection has been overcome by argument.
Therefore, claim 1 and claims 9-12, 19, 20, 23-27, 40, 48-51, 53-55 and 63-66 are all patently distinct over Morita in view of Benner.

Id. at 29-35. In this amendment, Applicant did not separately argue that claim 37 (40) was patently distinct on any other basis.

In the same December 12, 1996, First Action, the Examiner also grouped claims 68-72 and 74 and rejected them under 35 U.S.C. § 103 as unpatentable over Morita in view of Benner and Madonna, U.S. Patent No. 5,544,163 ("Madonna"). First Action at 14. The Examiner employed reasoning similar to what he employed in rejecting the grouping that included claim 37 (40), except that the Examiner relied on Madonna for disclosure of a "switching system" which was not a limitation in claim 37 (40). Id. at 14-15. In response, applicant's attorney argued:

Applicant's claim 68 which is representative of this group of claims is patently distinguished over the art of record since the references neither describe nor suggest ... at least three processor systems ... interconnecting data communications network ... and data storage control as recited in claim 68 as argued previously with respect to the Morita and Benner references.

Amendment at 46-47.

In a September 16, 1997, Office Action ("Allowance"), the Examiner allowed claims 1-28 and claims 32-75. Allowance at 1. His statement of reasons for allowance noted that "the prior art of record fail to teach storing data input at any one of the processor systems according to a distributed redundant storage process with data stored at each of the processor systems and a portion of the redundant representation of the data stored at each of said processor systems." Id. at 3.

On November 26, 1997, after the Examiner had concluded his examination and issued his notice of allowance, a protest petition ("Protest") was filed. In that Protest, the protester argued that Gardner anticipated claims 1-28, 36-67, and 72-75. Protest at 2. The protester asserted that claims 29-35 and 68-71 were obvious over Gardner in view of Madonna and other references. Id. at 3. The protester emphasized that Gardner taught the use of RAID-5 at the system level and asserted that such feature could not be the point of novelty. However, the protester conceded that "if there exists a difference between [Gardner] and [Seachange's application], the difference may relate to the selected network." Id. at 3-4.

In a November 26, 1997, protest response, the Examiner requested that Applicant respond to the protest. On May 4, 1998, Applicant responded by asserting that "nowhere in [Gardner] does the patentee describe or suggest a store/retrieve two-way point-to-point configuration." Protest Response at 2 (internal citation omitted). The response further argued that Gardner "actually recites ... a network which may, for example, comprise an Ethernet TM , Fiber Distributed Data Interchange (FDDI), Asynchronous Transfer Mode (ATM), a small computer system interface (SCSI) or any other network used for transporting data amongst the media service." Id. (internal quotation omitted). Applicant's attorney added that Gardner "relates to an allocation scheme for a plurality of media servers connected in a conventional client-server computer network." Id. at 3. The attorney asserted that Gardner does not not suggest "interconnecting each of the processors in a point to point configuration (claims 1-15); ... [or] interconnecting each one of said processor systems through a network for data communications with each other one of said processor systems (claims 40-54) ...." Id. at 3-4. The Examiner then allowed the claims to issue.

C-COR argues that Applicant's arguments made during prosecution narrowed the scope of the "network for data communications" limitation in claim 37 (40) to cover only a point-to-point network. Seachange counters that Applicant's arguments did not amount to a clear and unambiguous disclaimer of claim scope. We agree with C-COR.

"The prosecution history constitutes a public record of the patentee's representations concerning the scope and meaning of the claims, and competitors are entitled to rely on those representations when ascertaining the degree of lawful conduct, such as designing around the claimed invention." Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 957 (Fed. Cir. 2000). Thus, in construing the claim, we consider the prosecution history to determine "whether the patentee disclaimed or disavowed subject matter, narrowing the scope of the claim terms." Nystrom v. Trex Co., 374 F.3d 1105, 1113 (Fed. Cir. 2004) (internal quotation omitted). In doing so, we examine the entire prosecution history, which includes amendments to claims and all arguments to overcome and distinguish references. Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1326 (Fed. Cir. 2002); Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 979 (Fed. Cir. 1999). Where an applicant argues that a claim possesses a feature that the prior art does not possess in order to overcome a prior art rejection, the argument may
serve to narrow the scope of otherwise broad claim language. Rheox, Inc., 276 F.3d at 1325 ("Explicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations ...."); Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1304 (Fed. Cir. 1997) ("Since, by distinguishing the claimed invention over the prior art, an applicant is indicating what the claims do not cover, he is by implication surrendering such protection."). A disclaimer must be clear and unambiguous. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323-25 (Fed. Cir. 2003).

The Examiner grouped several claims together, including claims 1 and 37 (40), and rejected them as a group as being obvious over Morita in view of Benner. First Action at 4. Applicant responded, stating, inter alia, that applicant will in general treat a single claim as being representative of the group. Amendment at 29. Applicant then selected claim 1 as "an illustrative claim" and argued that Morita and Benner do not suggest connecting each processor to each other processor via point-to-point, two-way channel interconnections. Id. at 30-32. Applicant also argued that Morita and Benner do not disclose "the arrangement of stored data and redundant data" required by claim 1. Id. at 30-31. Applicant concluded that "in view of the fact that neither Morita nor Benner ... suggest the above-mentioned elements of Applicant's invention...., it is submitted that the rejection has been overcome by argument. Id. at 35. Even though Applicant "reserved its right to later argue that additional ones of the claims are patently distinct over the combination of references," id. at 29-30, Applicant made no separate patentability argument for claim 37 (40). Because Applicant provided "clear notice of the linkage" between claim 1 and claim 37 (40) for the purpose of its argument to overcome the prior art rejection on the basis of the "point-to-point" and "redundant storage" limitations, it would be improper to now broadly construe claim 37 (40) not to contain those limitations. See Elkay, 192 F.3d at 980 (holding that arguments made with respect to a claim during the prosecution of an earlier patent applied to a claim in a later patent where the claims were "affirmatively linked" by the applicant); Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1347 (Fed. Cir. 1998) (holding that a general statement distinguishing prior art applied to all claims linked to the statement).

Seachange argues that Applicant made two arguments to overcome Morita and Benner, and because the "point-to-point" argument relates directly to the "point-to-point" language of claim 1 rather than the "network for data communications" language of claim 37 (40), and because the "redundant storage" argument relates to all claims of the grouping, the public was on notice that claim 37 (40) did not necessarily contain the "point-to-point" feature. Seachange buttresses this argument by citing the notice of allowance in which the Examiner allowed all claims based only on the "redundant storage" feature. However, the conclusion that Seachange would have us reach -- that Applicant responded to the First Action and distinguished claim 37 (40) over Morita and Benner based only on the "redundant storage" feature, and not based on the point-to-point feature -- is unwarranted. Nothing in the prosecution history suggests that the point-to-point argument did not apply to all of the grouped claims. Applicant did not indicate that the "point-to-point" argument applied only to claim 1. Instead, the natural reading of Applicant's statements suggests that the "point-to-point" argument applied to each claim in the grouping.

The conclusion that Applicant narrowed the meaning of the word "network" as used in claim 37 (40) to require point-to-point interconnections is consistent with similar treatment of claims 68-72 and 74. Claims 68-72 and 74 each recite an "interconnecting data communications network" in language that Seachange admits is "almost identical" to the "network for data communications" language of claim 37 (40). In arguing for patentability of claims 68-72 and 74 (of which claim 68 was representative), Applicant stated that "the references neither describe nor suggest ... interconnecting data communications network ... and data storage capacity as recited in claim 68 as argued previously with respect to the Morita and Benner references." Amendment at 46-47. Applicant's only previous argument relevant to the "data communications network" limitation was the argument in response to the rejection of the group of claims including claims 1 and 37 (40) that Morita and Benner did not disclose that each of the processor systems are interconnected in a point-to-point two-way channel interconnection with each other one of the processor systems. See id. at 28-48. By arguing for patentability in both groups of claims based upon an interpretation of "network" as requiring point-to-point interconnections, the "inescapable conclusion" is that claims 68-72 and 74, and likewise, claim 37 (40), must be so limited. See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1342-45 (Fed. Cir. 2001) (drawing the "inescapable conclusion," from reading together portions of the intrinsic record, that the inventor disavowed claim scope and that a claim term has a narrow meaning).

We find unpersuasive Seachange's argument that the Examiner cited the "redundant storage" feature as the reason for allowance. The fact that the Examiner did not indicate reliance on the point-to-point distinction is of no consequence. An applicant's argument made during prosecution may lead to a disavowal of claim scope even if the Examiner did not rely on the argument. Microsoft, 357 F.3d at 1350.

PUBPAT
Seachange further argues that to distinguish Benner, Applicant needed only to argue that claim 1 requires each processor be interconnected to each other processor, and did not need to argue that each processor be interconnected to each other processor by point-to-point connections. Seachange asserts that Applicant's "as argued previously" statement referred only to the argument that Benner did not disclose a system in which each processor system was interconnected to each other processor system. However, Applicant did not argue that claim 1 was patentable merely because it featured a system in which each processor system was interconnected to each other processor system. Applicant argued that Benner does not describe that each of the processor systems are interconnected in a point-to-point two-way channel interconnection with each other one of the processor systems as recited in Applicant's claim 1. Amendment at 32. Applicant made no separate patentability argument for claim 37 (40) at that time. Consequently, Seachange cannot now rewrite the prosecution history to distinguish claims 37 (40), 68-72 and 74, based only on the limitation that each processor be interconnected to each other processor, and thereby erase the requirement that all connections be point-to-point. Hockerson-Halberstadt, 222 F.3d at 957 (explaining that an argument "that would erase from the prosecution history the inventor's disavowal of a particular aspect of a claim term's meaning" is "inimical to the public notice function provided by the prosecution history").

Seachange also argues that the file wrapper shows that Applicant added claim 37 (40) "to more fully cover the scope of the invention," Preliminary Amendment at 13, and that Applicant would not have added claim 37 (40) if it was of the same scope as claim 1. However, Seachange inappropriately emphasizes Applicant's subjective intent. Courts must "view[] the prosecution history not for ... applicant's subjective intent, but as an official record that is created in the knowledge that its audience is not only the patent examining officials and the applicant, but the interested public." Biogen, Inc. v. Berlex Labs., Inc., 318 F.3d 1132, 1139 (Fed. Cir. 2003).

Seachange's final argument is that Applicant's response to the protest shows that claim 1 is of different scope than claim 37 (40). Protest Response at 3-4. On the one hand, Applicant stated that Gardner did not disclose either a point-to-point network as in claim 1 or a network for data communications as in claim 37 (40), implying a difference in the scope of claim 1 and claim 37 (40). On the other hand, Applicant distinguished over Gardner based on the "network" element and contended that Gardner disclosed a number of different types of networks -- Ethernet TM, FDDI, ATM, and SCSI networks used for transporting data among the media -- but did not disclose "a store/retrieve two-way point-to-point configuration." Id. at 2. C-COR cites to Digital Biometrics for the proposition that this global statement limits claim 37 (40) to point-to-point networks. In Digital Biometrics, the applicant made a global statement distinguishing its invention from the prior art and applying specifically the remarks to "all of the pending claims [that] stand rejected under 35 USC 102(b) or 35 USC 103." 149 F.3d at 1347 (internal quotation omitted). Although the applicant then distinguished each claim on narrower grounds, we held that the argument with respect to individual claims did not "eliminate [the import] of global comments made to distinguish applicants' claimed invention' from the prior art." Id.

In the final analysis, the Protest Response does not alter our conclusion that the statements Applicant made in responding to the First Action and in distinguishing over Morita and Benner inescapably narrowed the meaning of the data communications network in claim 37 (40) to a point-to-point network. Applicant's response to the First Action was "a deliberate surrender of claim scope, unmistakable in its effect because it is not suitable to multiple interpretations." Omega Eng'g, 334 F.3d at 1327. The Protest Response addressed Gardner, did not alter the bases upon which the Applicant distinguished Morita and Benner, and did not undo this disclaimer already made. See Hockerson-Halberstadt, 222 F.3d at 957.

The district court erred in construing the "network for data communications" element of claim 37 (40) and the claims dependent therefrom. The presumption attendant to claim differentiation doctrine is rebutted. The phrase "network for data communications" is limited to networks in which every processor system is connected to every other processor system via direct, point-to-point, two-way channel interconnections.

Network device; network accessing device

MyMail asserts that the definition of both terms is a "general purpose computer and associated software capable of connecting to a network." Defendants argue that a "network device" is "a device communicating with a network" and that a
"network accessing device" is "a device using the resources of a network." The Court adopts elements of each proposed definition, and construes both terms to mean "a device capable of communicating with the network."

According to both the Microsoft Press Computer Dictionary and Webster's Dictionary of Computer Terms, "device" is a broad and generic term that can refer to virtually any piece of computing equipment, so the Court concludes no definition of "device" is necessary. See MICROSOFT PRESS COMPUTER DICTIONARY 141 (3d ed. 1997); WEBSTER'S NEW WORLD DICT. OF COMP. TERMS 144 (6th ed. 1997). What makes a generic device a "network device" or "network accessing device" is the capability of communicating with the network. The specification explains such devices supply "the basic capabilities needed to successfully connect the user" to the network. Col. 9:17-18. The device need not be continuously connected, as Defendants assert, but must only provide the capabilities needed to establish a connection. Indeed, Claim 1 states that the user connects, disconnects, and is reconnected. However, the specification makes it apparent that only devices with the ability to communicate with the network, after a connection is established, are network devices or network accessing devices, so the terms must be defined in the context of communications, not connections.

2840

6) "network management site" (claim 16)

STV Asia proposes that this term be construed to mean "location of network management system." Defendants argue that the term means "a central location where the network management system is located." While the parties dispute whether the word "central" should be included in the Court's construction, the issue that divides the parties is really whether or not the term refers to a single location or rather, allows for multiple locations. Defendants concede that nothing in the language of claim 16, where this claim term is found, requires that the "network management site" must consist of a single location. They assert, however, that the specification describes an invention that has only one network management site and nothing in the specification permits or suggest that the invention encompasses a video distribution network with multiple network management sites.

The Court has addressed this dispute in its discussion of the term "network management center," in which it concluded that the network management system is located in the distribution center and that there is no indication in the specification that there may be multiple distribution centers across which the network management system may be spread. For the same reasons, the Court concludes that the "network management cite" is limited to one location in the distribution center.

The Court construes this term as follows: "a single location from which the network is managed."

2841

2) "network management system" (claims 1, 15)

STV Asia proposes that this claim term be construed to mean "a program trafficking scheme for selecting and scheduling audiovisual material." Defendants argue that this term means "a combination of interacting hardware and software components centrally located in the distribution center that manages the network." The parties' proposed constructions reflect two areas of dispute.

First, there is disagreement about where the network management system is located. Defendants assert that STV Asia's use of the word "scheme" in its proposed construction suggests that the network management is merely a construct rather than a thing with a physical location. According to Defendants, such a construction is inconsistent with the specification, which indicates that the network management system is located in the network distribution center. STV Asia responds that a "scheme" can be a thing with a location but asserts that there is no support in the specification for Defendants' proposed construction to the extent that it requires the network management system to be "centrally" located in the distribution center. Further, STV Asia asserts that the network management system could be spread out over more than one location.

Second, Defendants assert that STV Asia's proposed construction impermissibly limits the network management system to
the narrow activity of "selecting and scheduling" audiovisual material when in fact, the specification describes the network management system as performing a broader array of functions. STV Asia appears to concede that the network management system does more than just "selecting and scheduling" material but asserts that its construction should be adopted because it will "assist the trier of fact." Reply at 9.

STV Asia stipulated at oral argument that it does not dispute Defendants' use of the phrase "a combination of hardware and software components" in their proposed construction.

With respect to the first disputed issue -- the location of the network management system -- the Court concludes that the network management system is based in the distribution center and that there is only one distribution center. The section of the specification that describes the network management system does not directly address where it is located. See '069 patent, col. 9, l. 31 - col. 10, l. 67; col. 10, ll. 32-35. However, Figure 1 of the '069 patent shows the network management center -- as well as the technical operation center and the earth station -- inside the distribution center. See also '069 patent, col. 5, ll. 25 - 29 ("In the preferred embodiment, as illustrated in Fig. 1, the distribution network includes a distribution center 100 (technical operation center 200, earth station 234 and network management 261) and a receiving site (receiving system 254)"). Further, the Summary of Invention, which describes the invention as including "a network management system which forms playlists for each of the receiving sites in response to inputs from a user," specifies that "the user [is] located in the distribution center." '069 patent, col. 2, ll. 44-49; see also '069 patent, col. 5, ll. 8-11 ("In the preferred embodiment, users enter the desired playlists for each receiving site into the system from the technical operation site"); '069 patent, col. 5, ll. 25 - 29 ("In the preferred embodiment, as illustrated in Fig. 1, the distribution network includes a distribution center 100 (technical operation center 200, earth station 234 and network management 261) and a receiving site (receiving system 254)"); '069 patent, col. 9, ll. 27-30 ("The network management software allows the user located in the technical operation center to make quick modifications based on the actual product movements in each of the stores"); '069 patent, col. 9, ll. 32-43 ("The network management system determines what is to be displayed at each of the retail stores along with when it is displayed. Moreover, the network management system monitors which clips are located in each receiving site and which additional clips are required in each receiving site to display the desired programs. This information is then used to determine which clips will be sent from the distribution center to each receiving site"). Finally, claim 15 supports the conclusion that the network management system is based in a single distribution center: that claim calls for a "distribution center for transmitting video program segments to a plurality of receiving sites" and states that "the network management system control[s] which video program segments are sent to each of the receiving sites."

With respect to the function of the network management system, the Court declines to adopt STV Asia's proposed construction to the extent it describes the function of the network management system as "selecting and scheduling audiovisual material." While it is true that this is the main function of the network management system, it does not encompass all of the functions served by the network management system and therefore is too narrow.

The Court construes this claim term as follows: "a combination of interacting hardware and software components that manage the network from a single distribution center."

16. Network management system; a control system common to the downstream and upstream channels

The term "network management system" appears in claim 119 of the '845 patent, and the term "a control system common to the downstream and upstream channels" appears in claim 16 of the '727 patent. The plaintiff proposes "a device that provides active management of both upstream and downstream channels" as a construction for each of the above terms. The defendants counter with "a common network management system that is separate and apart from upstream and downstream routers for controlling paths in both the upstream and downstream channels of hybrid interfaces" as a construction. The relevant portions of the specification and the drawings in the patent counsel the court to conclude that the network management system is a control system that is separate and apart from the upstream and downstream routers. As a result, upon consideration of the parties' arguments, the court adopts the defendants' construction.
K. Network Members: Defendants seek to limit network members by defining the term 'network member" as follows:

A person or entity that has applied for membership to the network by completing a registration application or by contacting quotation system offices or by other means and has received password information or other means necessary to access and use the quotation system.

The specification defines a network member: "A network member is anyone or any company which has registered as a user by completing an application..." (Col. 4, ll. 1-4). The specification also provides an example of methods of applying for membership and access to and use of the quotation system, but this illustrative example cannot be construed as a straight jacket defining network members. The definition of network member is as stated in the specification.

2. "Network monitors": n1 Software and/or hardware that can collect, analyze and/or respond to data.

n1 All patents, multiple claims.

The above limitation has been construed broadly, as the words used are words well known in the art and it does not appear from the specification n2 that the patentees were acting as their own lexicographers. The court recognizes, consistent with defendants' proposed construction, that the specification does describe the network monitors as using "the same monitor code-base" to provide a "reusable software architecture" that accommodates "[c]ustomizing and dynamically configuring" the monitors. (‘203 patent, col. 10, ll. 29-36) However, the disputed claim language does not track the language of the specification and the court declines to read further limitations into the claims.

n2 Because this limitation is included in all the patents in suit and in multiple claims, and because the specifications of all the patents in suit are substantially similar, the court will refer to the specification of the '203 patent unless otherwise indicated.
enhanced node from changing from one communication protocol to another."

Once again, Datapoint's basic argument that the communication need not be heard network-wide fails, for the reasons stated above. As for the argument that network operational activity may be fleeting or transitory, we agree with the Master's conclusion that the purpose of the network operational activity is for "all nodes [to] sense something occurring on the network and respond accordingly," essentially to keep them from timing out. The last limitation of 879 patent claim 1 makes clear that the network operational activity is more than simply signals, and serves some additional purpose other than communicating information: "the signals are applied in predetermined patterns to create network operational activity in both protocols while simultaneously communicating information . . . ."

This conclusion is fully supported by the 879 patent specification, which demonstrates, in the words of the Master, that the network operational activity is tied to "persistence and consistency." See, e.g., 879 patent, col. 17, lines 14-16 ("Several time-out intervals in the basic link level protocol (discussed below) depend on detection of network activity . . ."); 879 patent, col. 17, lines 36-43 ("[The] periodic guarantee of basic signal activity prevents any basic nodes from forcing network reconfiguration due to apparent inactivity during enhanced frames. In configurations using active hubs as part of the physical media, this periodic guarantee of basic signal activity prevents any hubs from dropping into idle state due to apparent inactivity during enhanced frames."); 879 patent, col. 22, lines 14-22 ("In order to prevent the basic nodes from timing out and initiating a network reconfiguration, each basic node must detect network activity . . . within its activity time-out period (78.4 [mu] sec for standard ARCNET). In order to eliminate the small possibility that the middle of an enhanced frame could be misinterpreted as the beginning of a basic frame, each basic node must detect network activity every 4.4 [nanoseconds]."). Our de novo review satisfies us that the Master's claim construction of "network operational activity" is supported by the intrinsic evidence.

1. Network Page

The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiff</th>
<th>Defendant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page on the Internet, private corporate network, intranet, local area network or other network.</td>
<td>All files, data, and information presented when a network address is accessed, including any text, audio, advertising, images, files, graphics, or graphical user interface.</td>
</tr>
</tbody>
</table>

The parties' dispute over this term revolves around whether the term "page" needs to be separately defined. The parties do not dispute the meaning of "network." The patent claims clearly distinguish "network page" from "material on a page" and "material on the network page." (14:15-50.) At oral argument, counsel for the plaintiff conceded that an image on a "page" did not constitute a "page." The parties then agreed that the term "page" did not need to be further defined.

Therefore, the term "page" needs no further construction, and the court concludes that the term "network page" means "Page on the Internet, private corporate network, intranet, local area network or other network."

2. ASP and NSP

Two new terms, Access Service Provider ("ASP") and Network Service Provider ("NSP"), are coined by the patentee to claim the invention in the 290 patent. In the lexicon of the 290 patent, an ASP performs many of the same log-in and authentication functions performed by the disclosed prior-art Internet Service Providers ("ISPs"), and an NSP acts similar to
prior-art Network Access Providers ("NAPs"), providing the physical connection between the customer and internet. However, the coined terms are not completely analogous to their well-known prior art counterparts. Indeed, these coined terms help delineate the 290 patent's claimed invention from prior art internet access systems, such as those using Remote Authentication Dial-In User Service ("RADIUS") servers for authentication management.

The term "ASP" (or variation thereof) appears in every asserted claim of the patent-in-suit. "NSP" appears in all asserted claims except independent Claim 3 and dependent Claims 4 and 5. MyMail asserts that ASP should be defined as "a party that offers network access service to the user via one or more NSPs" and NSP should be defined as "a party other than the ASP that provides the actual connection to the network." Defendants' propose defining ASP as "an ISP broker including a server that (1) has a public Internet address, (2) maintains ISP-specific user IDs and passwords for multiple ISPs, and (3) transmits to the user's computer a user ID and password for a particular ISP selected by the broker based on the user's location and the user's preference for a type of Internet service (such as lowest cost service, highest reliability service, and most available service)" and NSP as "a provider of network services (such as an ISP) that (1) authenticates its customers for access to its services (such as Internet access, email, etc.) based on user IDs and passwords that are specific to the provider, and (2) grants its customers Internet access directly from a modem bank."

To properly define these coined terms, the Court first looks to the ordinary meaning of each component word in ASP and NSP. See Bancorp Servs., 359 F.3d at 1372. That however provides little insight into the meaning of either coined term, so the Court next looks to the specification. See Goldenberg, 373 F.3d at 1164. Although the definitions proposed by both MyMail and Defendants find some support in the specification, when construing terms like NSP and ASP that lack an accepted meaning in the art, the Court must construe the terms as broadly as provided for by the patent itself. Irdeto Access, Inc. v. EchoStar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004). The Court thus rejects both sets of definitions since both import unnecessary limitations and neither reflect the breadth provided in the specification, figures, and claims.

Figure 1 of the 290 patent provides that a user dials into an NSP, is authenticated, and then connects to the internet. The user next communicates, over the internet, with an ASP. The ASP again authenticates the user and (re)assigns him to an appropriate NSP, which provides internet access for the rest of the session. The specification teaches that the ASP offers network access via multiple NSPs, see Col. 8:32-34, but Claim 8 establishes that an ASP works with either a single NSP or multiple NSPs. Accordingly, the Court defines NSP as "a party that provides a connection to the network and authenticates users for access to the network" and ASP as "a party that provides authenticated access information to a user through the network to enable the user to access one or more NSPs."

III

On the merits, MyMail first argues that the district court wrongly construed the patent to require the NSP to perform authentication. Both parties agree that the term NSP is a coined term, without a meaning apart from the patent. As construed, all the asserted claims involve communicating with the ASP through a connection established by the NSP. We therefore look to the specification to determine what the NSP must do when establishing that communication link. See Phillips v. AWH Corp., 415 F.3d 1303, 1316-17 (Fed. Cir. 2005) (en banc).

An examination of the specification reveals that the invention requires the user to be authenticated before being given access to the internet. When describing the initial steps of the inventive method, the specification states that, "[t]o begin the process of the present invention," the user is provided a telephone number, a user ID, and a password associated with an ISP to allow the user to gain access to the internet. '290 patent, col. 6, ll. 32-46. Additionally, much of the invention is concerned with giving users new IDs and passwords, items described as "necessary" to allow an ISP to grant access to a user. E.g., '290 patent, col. 8, ll. 22-27; col. 7, ll. 55-59; col. 9, ll. 55-58. The IDs and passwords described would serve no function if the user did not have to be authenticated before being connected to the internet.

The specification also indicates that the ISP (and therefore the NSP) is the entity performing the authentication. In addition to stating that the ID and password are "ISP specific," '290 patent, col. 2, ll. 21-24, the specification states that, "[u]pon receipt of the access information, the ISP 'authenticates' the user" and, if the access information is valid, the user is then connected to the internet. Id. col. 6, ll. 40-46, 66-67 & col. 7, ll. 10-19 (figure references omitted).
The specification shows that the ASP cannot perform the required authentication. Besides explicitly stating that the ISP performs the authentication, the specification describes the authentication and connection steps as being completed before the ASP becomes relevant. See '290 patent, col. 7, ll. 32-33. With the exception of the unclaimed embodiment discussed below, nothing in the specification suggests that the ASP assists in the connection process. Moreover, part of the ASP's function is to distribute the "necessary" IDs and passwords to users. E.g., id. col. 8, ll. 22-27; col. 7, ll. 55-59; col. 9, ll. 55-58. That distribution function would not be required if the ASP performed the authentication; one ID and password combination would suffice because only one entity would ever need to evaluate it. A major function of the claimed invention would thus be obviated if the ASP authenticated users for access to the internet. Accordingly, we interpret the specification as requiring the NSP to perform the authentication function.

MyMail argues that the specification discloses authentication by the ASP because the specification describes an embodiment in which it is required that "all user (client) authentication for all ISPs happens at the [ASP] (i.e., all authentication for all ISPs is centralized) or at a centrally located database point." '290 patent, col. 23, line 67, through col. 24, line 4. That embodiment, however, is part of the so-called "multi-dial subfunction" embodiment that MyMail has conceded to be part of an unclaimed invention.

In the multi-dial subfunction embodiment, authentication must be centralized to allow one user ID and password combination to be used for multiple ISPs. In that system, the user may be assigned to an ISP without requiring the user to disconnect and reconnect using new login information. '290 patent, col. 24, ll. 7-16. No such functionality is contemplated in the claimed invention, however. In fact, the added functionality is disclosed as the advantage of the unclaimed embodiment over the claimed invention. See id. col. 24, ll. 14-17. Because the identity of the entity performing authentication was dictated by a functional improvement over the claimed invention, the multi-dial subfunction embodiment does not speak to which entity performs authentication in the claimed invention. See LG Elecs., Inc. v. Bizcom Elecs., Inc., 453 F.3d 1364, 1378 (Fed. Cir. 2006) (finding specification language relating to additional functionality in an unclaimed invention irrelevant to the claimed invention).

Moreover, before the district court MyMail agreed that the patent contemplates that the NSP will perform the authentication function. During the Markman hearing, MyMail's counsel stated the following:

The Court asked a number of real-world questions of [defendants' counsel] about how [the defendants do] authentication and where it happens and so forth. There is no dispute between the parties that it is part of what the NSP does to serve as an authentication gatekeeper. When the user dials into the network service provider, there has to be some authentication. That is one of the things that the network service provider [NSP] does.

The claims, however, do not address where the database for that authentication is maintained... So the specification tells us that the location of that database is not really important. It is important that the NSP has to do it, but it is clearly a remote database.

The context makes clear that counsel's statement refers to the scope of the claims; counsel acknowledged that under the patent the "NSP has to do [authentication]" but disagreed about whether a remote database would satisfy that requirement.

Defendants' counsel referenced that point later in the hearing, prompting the district court to ask about the extent of the parties' disagreement as to the required function of the NSP. In response, MyMail's counsel reviewed the proposed claim construction, which referred to "a provider of network services that authorizes users for access to its services based on user IDs and passwords." MyMail's counsel read the proposed language aloud, accepting or objecting to various portions as he went along. The following exchange occurred when he reached the authentication requirement:

[MyMail's counsel]: That authorizes user's access to its service. Okay. Based on user ID and passwords those limitations are not contained in the claims. The specification makes it clear that it is login and authentication information not limited to user ID, not limited to password, and certainly not making appropriate the conjunctive "and" that you have to have both.

The Court [addressing defendants' counsel]: Do you have a problem... with taking out the part about the passwords and
that part of the further definition of what authentication means?

In that statement, as in the earlier one, MyMail's counsel agreed as to the entity that had to perform authentication but disagreed as to the method of authentication, i.e., what information was employed to authenticate the user. Having agreed to that construction before the district court, MyMail "cannot now argue against that claim construction simply because it resulted in an adverse ruling on summary judgment." LizardTech, Inc. v. Earth Res. Mapping, Inc., 424 F.3d 1336, 1341 (Fed. Cir. 2005). In light of the specification's teachings and MyMail's admissions below, the district court's claim construction must be affirmed.

2849

10. Network that is further connected to the gateway computer

This term is used in the '201 patent. The court rejects both parties' proposed constructions. The court defines "network" to mean "a plurality of computers that are interconnected so they can exchange information." The balance of the phrase needs no construction.

2850

1. "network-wide program" or "network-wide video program" (claims 1, 9, 38, 38)

STV Asia asserts that this claim term should be construed as "system distributed material." Defendants, however, contend that STV Asia's proposed construction is too broad, reading out of the claim term the limitations requiring that the program be distributed network-wide, that is, to all the locations in the network. Defendants also assert that the word "material" is inconsistent with the patentee's use of the term "video program," encompassing not only audiovisual materials but also things that do not constitute video programs, such as text files and pictures. Defendants' proposed construction is: "a preassembled video program that is received in every retail location in the media distribution network, and that may then be shown as it is received or customized for specific locations in the network."

The Court addresses first the question of whether the term requires that the program be received at every location in the network. The Court concludes that it does. First, consistently throughout the specification, the "network-wide program" is described as the default programming, played at each location, into which the market-specific programming is inserted. The Abstract states that ":[t]he distribution network provides automatic insertion of custom, store specific video segments . . . into a general, network-wide video program without the need for operational involvement of personnel at the receiving site . . . ." Similarly, in describing the specific embodiments, the inventors consistently describe a technology that provides a means of "customizing" the programs shown at the individual receiving sites by allowing insertion of market-specific segments into the network-wide program. See, e.g., '416 patent, col. 4, ll. 33-41.

The claims also describe a system in which "customized programs" are created by inserting "market-specific segments" into a "network-wide program." See, e.g., '416 patent, claim 1 (claiming an invention in which the "network-wide video program" is to be transmitted to "a plurality of receiving sites in stores" and in which there is a means to insert the "market-specific segments into the network-wide video program," resulting in the creation of a "customized program" to be displayed "in said stores"). If a network-wide program were sent to only some locations, the distinction between the network-wide program and the market-specific segments would be lost and the inventor's scheme for creating customized programming would no longer make sense.

Further, in the patent prosecution, the inventors made clear that programming was tailored to the needs of the specific receiving sites by inserting market-specific material into a more general program that is received by all the locations. In particular, in seeking to overcome a rejection based on prior art, the inventors explained that in prior art, in order to "have the advertising be market or store specific, different tapes [had to] be mailed to the various store." Declaration of Shane Brun in Support of Defendants' Response to Plaintiff's Opening Brief on Claim Construction ("Brun Decl."), Ex. 4 (May 9, 1994 Amendment) at 6. They argued that the invention described in the '416 patent overcame these problems:
by providing a central location which transmits a network-wide program and market-specific segments to the participating stores. The market-specific segments are provided with an appropriate address. The stores play only those market-specific segments for which it/they have been addressed. This results in a fully tailored program being sent to each participating retail store.

Id. at 7.

The Court rejects STV Asia's assertion that a network-wide program need only be distributed to some retail locations. STV Asia relies on a single line in the specification in which the inventor states that the invention describes a "distribution network for transmitting . . . from a distribution center to a multitude of receiving sites, typically retail stores. " '416 patent, col. 4, ll. 23-27 (emphasis added). While read in isolation, this statement might be read as allowing for transmission of "network-wide programs" to less than all of the receiving sites, such a reading is not supported by consideration of the patent specification as a whole. In particular, nowhere in the patent is there any indication that the inventor sought to describe a network-wide program that would be distributed to only some of the receiving centers. Nor has STV Asia cited anything in the patent history that would support such a construction.

STV Asia's proposed construction would seem to allow for situations in which a receiving center would receive only the market-specific material, in which case, the invention would no longer involve the insertion of market-specific material into a network-wide program to customize the program. This is not the invention described in the specification. Alternatively, STV Asia's proposed construction might allow for several "network-wide programs," such that each receiving center receives one of the network wide programs in addition to market-specific segments. In this scenario, the customization would result not only from insertion of the market-specific segments but also the choice of which network-wide program the receiving center received. Again, this is not the invention described in the patent, which draws a clear distinction between the market-specific segments used to "customize" and the network-wide material. There is simply no suggestion in the patent that the network-wide material is itself customized.

Finally, the dictionary definition of the word "wide" when used in the form used in the disputed claims of the '416 patent supports the conclusion that the term "network-wide" requires distribution to the entire network. In particular, Merriam-Webster's Collegiate Dictionary includes the following definition: "extending throughout a specified area or scope -- usu. used in combination <nationwide> <industry-wide>." This usage is consistent with the inventor's description in the specification and the patent prosecution history. The Court concludes that the term "network-wide program" requires distribution of the program to every store location in the network. n2

--- Footnotes ---

n2 At oral argument, the parties stipulated that the receiving sites in the '416 patent may be described as "stores."

--- End Footnotes ---

1. "network-wide program" or "network-wide video program" (claims 1, 9, 38, 38)

STV Asia asserts that this claim term should be construed as "system distributed material." Defendants, however, contend that STV Asia's proposed construction is too broad, reading out of the claim term the limitations requiring that the program be distributed network-wide, that is, to all the locations in the network. Defendants also assert that the word "material" is inconsistent with the patentee's use of the term "video program," encompassing not only audiovisual materials but also things that do not constitute video programs, such as text files and pictures. Defendants' proposed construction is: "a preassembled video program that is received in every retail location in the media distribution network, and that may then be shown as it is received or customized for specific locations in the network."

The Court addresses first the question of whether the term requires that the program be received at every location in the
network. The Court concludes that it does. First, consistently throughout the specification, the "network-wide program" is described as the default programming, played at each location, into which the market-specific programming is inserted. The Abstract states that "[t]he distribution network provides automatic insertion of custom, store specific video segments . . . into a general, network-wide video program without the need for operational involvement of personnel at the receiving site . . . ." Similarly, in describing the specific embodiments, the inventors consistently describe a technology that provides a means of "customizing" the programs shown at the individual receiving sites by allowing insertion of market-specific segments into the network-wide program. See, e.g., '416 patent, col. 4, ll. 33-41.

The claims also describe a system in which "customized programs" are created by inserting "market-specific segments" into a "network-wide program." See, e.g., '416 patent, claim 1 (claiming an invention in which the "network-wide video program" is to be transmitted to "a plurality of receiving sites in stores" and in which there is a means to insert the "market-specific segments into the network-wide video program," resulting in the creation of a "customized program" to be displayed "in said stores"). If a network-wide program were sent to only some locations, the distinction between the network-wide program and the market-specific segments would be lost and the inventor's scheme for created customized programming would no longer make sense.

Further, in the patent prosecution, the inventors made clear that programming was tailored to the needs of the specific receiving sites by inserting market-specific material into a more general program that is received by all the locations. In particular, in seeking to overcome a rejection based on prior art, the inventors explained that in prior art, in order to "have the advertising be market or store specific, different tapes [had to] be mailed to the various store." Declaration of Shane Brun in Support of Defendants' Response to Plaintiff's Opening Brief on Claim Construction ("Brun Decl."), Ex. 4 (May 9, 1994 Amendment) at 6. They argued that the invention described in the '416 patent overcame these problems:

. . . by providing a central location which transmits a network-wide program and market-specific segments to the participating stores. The market-specific segments are provided with an appropriate address. The stores play only those market-specific segments for which it/they have been addressed. This results in a fully tailored program being sent to each participating retail store.

Id. at 7.

The Court rejects STV Asia's assertion that a network-wide program need only be distributed to some retail locations. STV Asia relies on a single line in the specification in which the inventor states that the invention describes a "distribution network for transmitting . . . from a distribution center to a multitude of receiving sites, typically retail stores." '416 patent, col. 4, ll. 23-27 (emphasis added). While read in isolation, this statement might be read as allowing for transmission of "network-wide programs" to less than all of the receiving sites, such a reading is not supported by consideration of the patent specification as a whole. In particular, nowhere in the patent is there any indication that the inventor sought to describe a network-wide program that would be distributed to only some of the receiving centers. Nor has STV Asia cited anything in the patent history that would support such a construction.

STV Asia's proposed construction would seem to allow for situations in which a receiving center would receive only the market-specific material, in which case, the invention would no longer involve the insertion of market-specific material into a network-wide program to customize the program. This is not the invention described in the specification. Alternatively, STV Asia's proposed construction might allow for several "network-wide programs," such that each receiving center receives one of the network wide programs in addition to market-specific segments. In this scenario, the customization would result not only from insertion of the market-specific segments but also the choice of which network-wide program the receiving center received. Again, this is not the invention described in the patent, which draws a clear distinction between the market-specific segments used to "customize" and the network-wide material. There is simply no suggestion in the patent that the network-wide material is itself customized.

Finally, the dictionary definition of the word "wide" when used in the form used in the disputed claims of the '416 patent supports the conclusion that the term "network-wide" requires distribution to the entire network. In particular, Merriam-Webster's Collegiate Dictionary includes the following definition: "extending throughout a specified area or scope -- usu. used in combination <nationwide> <industry-wide>.") This usage is consistent with the inventor's description in the specification and the patent prosecution history. The Court concludes that the term "network-wide program" requires distribution of the program to every store location in the network. n2
Next, the Court addresses whether a "network-wide program" or "network-wide video program" allows for STV Asia's use of the term "material" in its proposed construction. The Court concludes that it does not. The inventor used the term "video program" and explained in the specification that "[w]hile the term 'video' is used herein unaccompanied by the word 'audio' the term 'video' is intended to refer to recorded audio-visual media as in common usage." '416 patent, col. 5, ll. 14-18. As the inventor has provided a straightforward explanation for the term "video program," the Court finds no justification for adopting the more vague term proposed by STV Asia, which might arguably include formats that do not fall into the category of a video program.

The Court therefore construes the terms "network-wide program/network-wide video program" as follows: "a preassembled audiovisual program that is sent to every store location in the media distribution network."  

The Court declines to include in its construction the phrase proposed by Defendants, "that may then be shown as it is received or customized for specific locations in the network." Defendants explained at oral argument that they included this language (which relates to other claim terms) in order to make their construction of the term easier for a jury to understand.

B. Claim 2 of the '092 Patent

Claim 2 provides:

The process of claim 1 wherein values for said updated secret cryptographic value are never recreated more than a fixed number of times when said step (b) is repeated a large number of times.

Claim 2 depends from Claim 1. Specifically, Claim 2 is a limitation on step (b) of Claim 1. The parties dispute the meaning of two phrases in Claim 2: "never recreated more than" and "a fixed number of times."

1. "never recreated more than"

In the process disclosed in Claim 2, the inventor used the word "never." The word "never" is a commonly used word which means "not ever; not at any time; under no circumstances." See Webster's New Twentieth Century Dictionary, 1208 (2d ed. 983). The phrase "never recreated" refers to values for the "updated cryptographic value" disclosed in Claim 1(b). Claim 2 limits the transformation operation to "never" recreate the same secret cryptographic value "more than a fixed number of times."

2. "fixed number of times"

The dispute over "fixed number of times" centers around whether the limit on the recreation of the "values" is predetermined. The plain ordinary meaning of the phrase "fixed number" is a number which is "established or set." See Webster's New Twentieth Century Dictionary, 694 (2d ed. 1983). The inventor used the phrase with its plain ordinary meaning:

Using methods that will be described in detail below, such update functions are applied by the client in a sequence that
assures that any single secret value is never used or derived more than a fixed number of times (for example, three).

('092 Patent, Col. 2:62-65.)

On the face of Claim 2, the parameters and cryptographic operations which determine the limit and impose the "no further re-creation of values" limitation are part of the cryptographic algorithm of Claims 1 and 2.

The Court construes the entire phrase of Claim 2, "values for said updated secret cryptographic value are never recreated more than a fixed number of times" to mean: identical secret cryptographic values are never recreated more than a fixed number of times. The number of times is determined by the transformation operation algorithm and the initial parameters.

3. next-line

OPTi's construction for "next-line" is "the line immediately following the line being transferred." nVidia proposes that "next-line" be construed as "the line immediately following the line of secondary memory being received by the bus master."

The only dispute between the parties regarding the term "next-line" is whether, during a transfer, the memory can be in transit to the bus master or whether it has already arrived at the bus master. nVidia asserts that a line is the "next-line" only when it is "the line . . . immediately following the line . . . being received by the bus master" instead of simply being the next line in sequence. For example, if line 1 were in transit from the target to the master, the "next line" to be transferred -- i.e., the next line in sequence -- and, the next line to be snooped, would be line 2. This is true regardless of whether any of the data units of line 1 had arrived at their destination or not.

nVidia's proposed construction for this term is based on a construction of the limitation from the perspective of the bus master or PCI bus. The Court has rejected that approach. Accordingly, "next-line" is construed to mean "the line immediately following the line being transferred."

(b) Next Operation Information

Cisco contends that "next operation information" should be construed as "information added by a network forwarding device that specifies the particular type of operation to be performed by that device in forwarding a packet. Examples of such types of operation are routing, transparent bridging, and source route bridging." See Cisco's Claim Construction Illustratives, Exh. 42. StorageTek argues that "next operation information" as used in claim 1 is "information that specifies the particular type of operation to be performed downstream on the PDU. The information is added to the media header information and must include information to accomplish forwarding of the PDU in the communications network to reduce the subsequent processing of the PDU by the forwarding device." See JCC at 5.

3 Cisco's proposed construction presented in the parties' Corrected Joint Claim Construction Brief ("JCC") was "information that specifies the particular type of operation to be performed by the network forwarding device in forwarding a packet. Examples of such types of operation are routing, transparent bridging, and source route bridging." See JCC at 5.

The first issue in contention between the parties on this element is StorageTek's use of the word "downstream" in its proposed claim construction. Within claim 1, next operation information is used with reference to the "protocol data unit.
forwarding device." The claim specifically requires that the preprocessor modification means must add next operation information, including at least one encoded instruction to the forwarding device for accomplishing forwarding of the data unit. See 170 Patent claim 1. Therefore, while it appears from the claim language that the forwarding device acts subsequent to the preprocessor adding the next operation information to the media header information of the PDU, there is no indication that the forwarding device is "downstream" of the preprocessor, as that term is commonly understood by those skilled in the art.

For example, Cisco's expert states that use of the word "downstream" in construing this element of claim 1 would be inappropriate and misleading because the term downstream generally refers to "downstream" within a communication network. See Smith Decl. at 2. However, as discussed above, the preprocessor adds the "next operation information" to the media header of the PDU for use by the forwarding device. Therefore, the changes to the PDU occur within the same device. Use of the term "downstream" in the patent would be misleading because the operation does not occur "downstream" in the network, but within the same device.

StorageTek does not dispute Cisco's position that the "next operation information" added by the preprocessor and used by the forwarding device does not leave the forwarding device or that "downstream" is typically used to describe an event that occurs further on in the network, not later within the same device. See id. at 2-3; 170 Patent Col. 9, In. 63 -- Col. 10, In. 1; Col. 10, In. 6-10. StorageTek does argue that the discussion of whether the preprocessor modification claimed in claim 1 occurs within one device or can be applied to a larger network is a "tangential" issue that concerns Cisco's alleged infringement. In a brief submitted after the claim construction hearing, StorageTek argues that Cisco is improperly attempting to read into the claim language the "forwarding device" limitation from the preamble to claim 1. See, e.g., Cisco's Claim Construction Illustratives, Exh. 43. StorageTek contends that the preamble of claim 1 cannot be used to import a limitation -- that the protocol data unit preprocessor claimed is for use in a protocol data unit forwarding device -- into the claim language because the preamble only limits an invention where the preamble serves to "give meaning to a claim to properly define the invention,' not when the preamble merely states a purpose or intended use of the invention." Apple Computer, Inc. v. Articulate Systems, Inc., 234 F.3d 14, 22 (Fed. Cir. 2000) (citing DeGeorge v. Bernier, 768 F.2d 1318, 1322 n.3).

StorageTek argues that while the forwarding device is mentioned in claim 1 subpart (c) in connection with the next operation information, the reference to "forwarding device" is "merely peripheral to the purpose of the invention, which is to reduce subsequent processing of the protocol data unit as compared to subsequent processing otherwise necessary." StorageTek's Supplemental Memorandum at 3. However, this assertion contradicts a statement made during the prosecution of the 170 patent. Specifically, in the 1/17/96 Amendment and Response, the patentee amended claim 1 in response to the PTO's § 112 rejection of the claim for indefiniteness to "further clarify the nature of the reduction in subsequent processing required by a forwarding device as a result of the added next operation information." See Declaration of Thomas A. Lewry in Support of StorageTek's Proposed Claim Construction, Exh. 3, 1/17/96 Amendment and Response at 4. The prosecution history clearly links the use of the next operation information to the forwarding device recited in both the preamble and the claim.

--- Footnotes ---

4 The patentee, in distinguishing prior art, also asserted that "there is no teaching or suggestion [in the prior art] of providing a preprocessor, separate from the processor which actually forwards a protocol data unit . . . so as to decrease the amount of processing that would otherwise be required to be performed by the primary processor in the forwarding device." 1/17/96 Amendment and Response at 6-7.

--- End Footnotes ---

The prosecution history, therefore, confirms that the "protocol data unit forwarding device" recited in the preamble is not simply a "descriptive name" for the set of limitations provided in claim 1, see IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1434 (Fed. Cir. 2000), but gives meaning to the claim to properly define the invention of claim 1. See Apple Computer, 234 F.3d at 22. Because the invention claimed in claim 1 of the 170 patent is limited to a preprocessor for use in a protocol data unit forwarding device, the next operation information is not related to "operations to be performed downstream" as that term is normally understood by one of ordinary skill in the art and the Court will not use that phrase.
The second issue in contention is whether examples of "types of operations" to be performed by the forwarding device should be included in the definition of this element. Cisco asserts that examples of the types of operations, including routing, transparent bridging and source route bridging, should be included in the definition. See Cisco's 170 Responsive Claim Construction Brief at 20, n. 11 ("Cisco's 170 Response"). StorageTek responds that the examples are unnecessary and would only serve to confuse the jury into believing that the operations in claim 1 are limited to those examples, as StorageTek admits they are in claim 2. The Court agrees with StorageTek and finds that the definition of "next operation information" in claim 1 should not include the examples suggested by Cisco.

Therefore the Court construes "next operation information" for claim 1 as follows:

"next operation information" means information that specifies the particular type of operation to be performed by the network forwarding device. The information is added to the media header information and must include information to accomplish forwarding of the PDU in the communication network.

Guardian's Position

Guardian argues that there are seven relevant claim terms in dispute. Guardian's interpretations are listed below.

Heated Treated Coated Article: a coated article that has been heated to a temperature for a sufficient period of time to enable thermal tempering, bending or heat strengthening of the articles.

Layer: a region of material having a thickness and the composition of which is chosen to provide desired properties.

Oxidation Graded: having a change in the relative oxygen content in a region such that one portion contain more oxygen than another portion.

Progressively More Oxidized: having a trend of increased relative oxygen content.

More Oxidized at a Location Further From the Layer Comprising Ag Than at a Location Closer to the Layer Comprising Ag: these precise words do not appear in the asserted claims of the patents-in-suit, and therefore, they do not require interpretation.

Metal or Metal Nitride Contact Layer: metal or metal alloy, contact lawyer means a layer contacting another layer, metal nitride is a material including both metal and nitrogen.

More Metallic: having more relative metal content in a region compared to reactive non-metals such as oxygen or nitrogen.

AFG's Claim Interpretations

AFG groups the terms in dispute into four categories: (1) coated article claim elements; 2) layer claim elements; (3) oxidation graded claim elements; and (4) nitride claim elements.

Coated Article: all of the coated article definitions ("heat treated coated article," "coated article," and "after being heat treated (HT) said coated article") should be interpreted as: "an article which has been coated" with either: a) "and has been heated to a temperature sufficient to enable thermal tempering, bending, or heat strengthening"; or b) "with a heat treatable coating."

Layer: "a thickness of material having a function and chemical composition bounded on each side by an interface with another thickness of material having a different function and/or chemical composition."

Oxidation Graded: all of the oxidation graded claims ("oxidation graded," "is more oxidized at a location further from the [first] layer comprising Ag than at a location closer to the [first] layer comprising Ag," "is more metallic at a location closer to the silver inclusive layer than at another location further from the silver inclusive layer," and "is more metallic at a
location closer to the metal or metal nitride contact layer than at another location further from the metal or metal nitride contact layer") should be interpreted as, "a layer that is progressively more or less oxidized through its thickness" with the appropriate variations in language used in the different claims.

Nitride layer: all of the nitride layer ("nitride layer," "comprises silicon nitride," "layers which comprises a nitride," and "layer comprises Si-rich Si[x]N[y] where x/y is from .76 to 1.5") is "a layer containing a silicon nitride compound, and not containing oxygen."

* * *

Nitride:

With regard to the disputed term "nitride," the difference between the parties proposed interpretations is whether the interpretation should include the limitation "not containing oxygen." The claims and the specifications say nothing about requiring the nitride or silicon-nitride layer to be oxygen free nor do they state that they contain oxygen. The question is whether someone skilled in the art of "stacking" would understand that the term nitride or silicon-nitride layer to possibly allow for oxygen to be present.

The patents' claims and specifications often refer to the silicon-nitride layer by its periodic formula designation, Si[x]N[y]. According to AFG, if this were meant to include any degree of oxygen the term would be referred to as a silicon oxynitride and its equation Si[x]O[y]N[z]. The term "silicon oxynitride" is used separately in specifications for patent '349 Col. 7, lines 24-35, which states:

Fifth dielectric layer may be of or include tin oxide in certain embodiments of the invention. However, other dielectric materials may be used for layer 23 including but not limited to silicon nitride, titanium dioxide, niobium oxide, silicon oxynitride, zinc oxide or the like. Protective overcoat dielectric layer 25 is provided at least for durability purposes, and may be of or include silicon nitride (e.g. Si3N4) in certain embodiments of this invention. However, other dielectric materials may be instead used for layer 25, including but not limited to titanium dioxide, silicon oxynitride, tin oxide, zinc oxide, niobium oxide, SiZRN, or the like.

In this instance, the two substances are treated as two separate substances. This supports AFG's proposed definition which specifically states that the layer compound cannot include oxygen.

Conversely, the '608 patent's claims specifically states that, "[t]he coated article of claim 1, where in the contact layer is substantially free of oxygen." Col. 8, lines 34-35. In this case, the patent delineates when the layer is to be substantially, and even still not completely, free of oxygen. Nowhere else are these words uttered in the claim specifications. This cuts in favor of Guardian's interpretation since the patent would claim that the nitride layer was free of oxygen.

What steers this court's decision is the patents' claims use of the word "comprise[.]" For example, the '050 patent claims describes the coating as containing "at least one dielectric layer comprises Si-rich Si[x]N[y] where x/y is from .76 to 1.5." Col. 20, lines 49-50. The Federal Circuit refers to claim terms like "composed of or 'comprised of' as 'transition phrases.'" AFG Indus. v. Cardinal IG Co., 239 F.3d 1239, 1244-45 (Fed. Cir. 2001). The Federal Circuit "has consistently held that the word 'comprising' is an open transition phrase. In contrast, 'closed' transition phrases such as 'consisting of' are understood to exclude elements, steps or ingredients not specified in the claim." Id. at 1245 (citations omitted).

The patents' claims use the word "comprise" when describing the composition of the nitride or silicon nitride layers. '349, col. 26, lines 62-63; '349 col. 27, line 29; '349, col. 28, lines 1, 11-13, 38-39; '050, col. 20, lines 49-50; '050, col. 21, lines 7-11, 35-36; '050, col. 22, lines 8-10, 25-26; '608, col. 7, lines 16-17, 34, 36. Moreover, the file history of the '349 and '050 patents state that the amount of oxygen which can diffuse from the nitride layer into the NiCr inclusive layer is reduced but not eliminated. Feb 14, 2003 Amendment p. 13. Therefore, Defendant's proposed interpretation which includes the phrase "not containing oxygen" will not be adopted. Plaintiffs' interpretation of the disputed term "nitride layer" is adopted.

GO BACK

2856 - 3183 -
3. "Node"

Defendants assert "node" should be construed to mean "a processor or computer with a memory." Defendants' construction is based on the description of "node" in the Detailed Description of Certain Embodiments in the specification: "[e]ach node can be a processor with a main memory. Alternatively, each node can be a computer with a main memory." Col. 7, lines 31-35. Plaintiff contends this term is entitled to its ordinary meaning, but if the Court deems construction necessary, "node" should be construed to mean "a processor or computer on which runs a SQL-compatible or other relational database."

The parties' constructions are similar in that they construe "node" to mean a processor or computer. Similar to the above analysis of "database," there is nothing in the intrinsic evidence requiring a "node" to be a processor or computer "on which runs a SQL-compatible or other relational database." See Renishaw, 158 F.3d at 1249 (explaining the court may not "add a narrowing modifier before an otherwise general term that stands unmodified in a claim").

Therefore, the Court construes "node" to mean "a processor or computer with a memory." A "node" is not limited to a processor or computer "on which runs a SQL-compatible or other relational database."

2857

2. "node"

This term appears in claims 1, 2, 5, 6, 8, 10, 11, 12, 14 and 17. Claim 1 is representative (the disputed term is in boldface):

1. A method of forming a long distance communication channel between two telephone devices each of which are connected to a PSTN, said method comprising

   a user of one of said telephone devices initiating and establishing a telephone communication with a first commercial access provider node of INTERNET and providing thereto a telephone address,

   using INTERNET to establish a communication channel between said first commercial access provider node and a second commercial access provider node of INTERNET and providing said telephone address to said second commercial access provider node,

   said second commercial access provider node using said telephone address and a telephone dial out capability of said second commercial access provider node to establish a communication with a telephone device at the telephone address using a PSTN, and

   using the INTERNET communication channel to link said telephone devices and form a real time voice communication between said telephone devices.

a) The Parties' Proposed Constructions

The parties propose the following constructions:

<table>
<thead>
<tr>
<th>eBay</th>
<th>IDT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection points within the system, such as computers or other hardware and/or software.</td>
<td>A point of connection into a network, such as a computer.</td>
</tr>
</tbody>
</table>

*2*See Doc. No. 99 at 33 (JCCC Exhibit 1 at 31)

eBay urges that "[t]he commercial access provider computer system includes 'nodes,' which are simply connection points within the system, such as computers or other hardware and/or software." (Doc. No. 82 at 17).

IDT urges that "[e]ach independent claim makes clear that the nodes are entry points into a network," (Doc. No. 86 at 6), pointing to claim 1 calling for "initiating and establishing a telephone communication with a first . . . node of INTERNET."
IDT also points to Fig. 5 and the accompanying specification illustrating and describing a "UniPost Access Node" as an entry point to a network. (Doc. No. 86 at 6-7). IDT further relies, inter alia, on NEWTON'S TELECOM DICTIONARY, 8th ed., 1994 at 707, defining "node" as "a point of connection into a network." With respect to eBay's proposed construction, IDT acknowledges that a "node" can be a connection point "within" a network. However, IDT argues that is not how the term is used in the '350 patent. According to IDT, "[e]ach part of the specification that eBay contends supports its definition of 'node' describes a node as a 'commercial access providing computer' into a network, or a point of access into the network, not a connection point within a network." (Doc. No. 86 at 8).

eBay in its reply asserts that the '350 patent also describes "nodes" that are "within" the system. eBay points to the disclosure at col. 7, lines 24-31 and lines 47-56. eBay urges that "a user traveling to Tokyo calls a node in Tokyo to retrieve messages stored on a node in Toronto," and "[t]he Tokyo node connects to the Toronto node over the Internet, the user's messages are transmitted from the Toronto node to the Tokyo node, and the user then retrieves her messages over her telephone connection directly with the Tokyo node." (Doc. No. 91 at 7). eBay says that in that embodiment, "there is a single connection point into the system -- the Tokyo node," and the "Toronto node is an internal connection point for data transmission within the system, although it is still a 'node.'" Id. eBay urges that the dictionary definitions IDT relies on should be disregarded because they contradict the teachings of the '350 patent. Id.

b) Discussion

As IDT and eBay both agree, the term "node" may refer to a junction point "within" a network. See e.g., MCGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNICAL TERMS (5th ed. 1994) at 1349 defining "node" in the field of electronics as "[a] junction point within a network." eBay is also correct that in the embodiment described in col. 7, the Toronto "node" is "within" the system -- while the Tokyo "node" provides access "into" the system. But the embodiment described in column 7 is the messaging embodiment of Fig. 3. IDT is correct that in the embodiment of Fig. 5, the "nodes" 6 provide access "into" the network.

In the context of claim 1:

   a user of one of said telephone devices initiating and establishing a telephone communication with a first commercial access provider node of INTERNET and providing thereto a telephone address,

   . . .

   said second commercial access provider node using said telephone address and a telephone dial out capability of said second commercial access provider node to establish a communication with a telephone device at the telephone address using a PSTN, and

both "nodes" are clearly providing points of connection into a network -- in this case the Internet. The same is true for the remainder of the asserted claims.

Although there is a presumption that same term bears the same meaning throughout a patent, that is not always true. It depends on the context in which the term is used. See e.g., Yingbin-Nature (Guangdong) Wood Indus. Co. v. U.S. Int'l Trade Comm'n, 535 F.3d 1322, 1338 (Fed. Cir. 2008)("the ALJ had no trouble correctly distinguishing, in context, between the patentee's use of the term 'clearance' in claim 5 to describe an internal void in coupled panels, and in claim 17 to describe the indentation of an uncoupled panel that defines an internal void upon coupling.").

c) Conclusion

In view of the foregoing, the Court concludes that:

   The term "node," as used in the asserted claims of the '350 patent, means "a point of connection into a network, such as a computer."
a first node and a second node

Claims 1, 4, 6, 7, and 8 contain the term "node." The parties address "node" in the context of the claimed "a first node" and "a second node." Lonestar argues that "a first node" means "one of two 'opposing nodes' of the 'capacitor structure,' all portions of which are connected to each other in such a way as to enable them to be at the same voltage when the capacitor is operating, which voltage is different from that of the second and opposing node; the 'first node' is not electrically connected to the 'second node.'" Lonestar argues that "a second node" carries the same construction as "a first node" with the modification that the second node's "voltage is different from that of the first and opposing node; it is not electrically connected to the 'first node.'" Nintendo proposes that "a first node" means "a common conducting structure," and "a second node" is "a common conducting structure different than the first node." Lonestar asserts that the nodes are the strips themselves and objects to Nintendo's construction as requiring the nodes to be a separate structure from the strips. Nintendo contends that because the claim recites that the strips and nodes are "connected," the nodes and strips must be separate structures.

The Court construes "a node" to mean "a conductor or conductors commonly connected." Claim 1 states, "conducting strips alternately connected to a first node and a second node." Col. 7:6-7 (emphasis added). Furthermore, the specification states, "[a]ll the strips 24A of the first layer and the strips 26A of the second layer are connected to form a common node," Col. 2:40-42 (emphasis added); "[t]here is also a capacitance between the strips connected to the nodes A and B and the substrate," Col. 2:58-60 (emphasis added); and "the strips which are connected to the opposite nodes." Col. 6:41-42 (emphasis added). These references in the specification thus refer to strips both as being "connected to form a common node" and being "connected to nodes." In one instance, this language seems to treat a strip as being a part of a node, and in the other instance, it treats the strips as being separate. For the conducting strips to be "connected to the nodes," the nodes and structures must be regarded as not being one in the same structure. If the strips were the same structures as the nodes, there would be no reason to state that there is a connection between the strips and the nodes.

While the nodes may be different from the strips, this does not preclude a node from including the strip. Neither the claims nor the specification create such a limitation. Thus, as described in the specification a strip may be a sub-structure of a node. This means that a strip that is connected to a node can also be a part of the common conducting structure that forms the node. This applies to "a first node," "a second node," "said first and second nodes form two opposing nodes," and "alternately connected to a [said] first node and a [said] second node." Accordingly, the Court construes "a node" to mean "a conductor or conductors commonly connected."

b. "node"

The parties dispute the meaning of the term "node." Intel's proposed construction for the term "node" is a data processing device that can communicate on a communication system, and, by definition, includes, but is not limited to, devices such as a computer, a file server, a gateway, a co-processor, a modem server, memory, or a printer. In support of its construction, Intel points to the written description, which states:

As used herein, a "node" is a computer, file server, bridge, gateway, co-processor, modem server, memory, printer or other data processing device ("DPD") coupled to the communication medium though an interface.Col. 1:9-13.

Broadcom argues that the definition of the term "node," should include the limiting language in the written description that requires the node to be a device that is "coupled to the communication medium through an interface." The term coupled is a term of art in patent parlance that means electrically (or otherwise) connected to allow the transfer of signals.

It is clear from the specification's language above, in which the inventors expressly define the term "node" as used in the patent, that the inventors have chosen to be their own lexicographer with respect to this term and have stated their special
definition of the term in the patent specification. Vitronics, 90 F.3d at 1582. The court therefore adopts the meaning of node from the specification. A "node" is a computer, file server, bridge, gateway, co-processor, modem server, memory, printer or other data processing device ("DPD") coupled to the communication medium through an interface. The parties, however, dispute whether the phrase "coupled to the communication medium through an interface" modifies and thus limits each term in the list above and hence modifies the definition of "node" itself or only modifies the term "other data processing device," the last term in the list above.

The more natural reading of the phrase is to read the phrase "coupled to the communication medium through an interface" as modifying the definition of the term "node" itself. This reading is consistent with the use of the term "node," throughout the specification. For example, when referring to the algorithms that it discloses regarding the selection, the specification states that "the selection can be executed by the node's interface circuitry or software." Col. 5:33-35. This reading is also consistent with the ordinary meaning of the term node. Therefore, the court finds that the term "node" is any data processing device, including, but not limited to, a computer, a file server, a bridge, a gateway, a co-processor, modem server, memory, or printer, that includes a network interface, through which it is coupled to the communication medium.

For the sake of clarity, it should be noted that the term "node" is used in a phrase in the claim that recites "a plurality of nodes coupled to said communication medium for a transfer of data between said nodes." Reading the phrase as a whole, one could argue that being coupled to the communication medium is not part of the intrinsic meaning of "node," because if it were, the use as "coupled to said communication medium" as a modifier in the claim, arguably would be redundant. Therefore, the court holds that while a node must be a device that includes a network interface, it does not as part of its own definition have to be coupled, or electronically connected, to the communication medium.
Data node

Claims 1, 2, and 6 of the '930 Patent contain the term "data node." Network-1 contends that the term means "Ethernet switch or hub," 2 while Defendants contend that it means "data switch or hub." The parties disagree whether or not the term "data node" is limited to an Ethernet environment.

Footnotes
2 This construction of "data node" was adopted by the Court in the D-Link case. However, in that case, the construction was agreed on by the parties, and the Court did not resolve whether or not the term was limited to an Ethernet environment.

Network-1 asserts that the specification repeatedly describes an Ethernet limitation, which makes it a requirement of the claim scope. Defendants counter that the claims do not recite an Ethernet limitation, and that although the preferred embodiment is in the context of an Ethernet system, the specification does not characterize the invention as a whole to include an Ethernet limitation. Defendants also argue that restricting the term to the preferred Ethernet embodiment improperly imports a limitation from the specification.

The '930 Patent does not describe the Ethernet as a feature of the present invention as a whole, which is required to limit the scope of the claimed invention. See Honeywell Int'l., Inc. v. ITT Indus., 452 F.3d 1312, 1318-19 (Fed. Cir. 2006); Scimed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1343 (Fed. Cir. 2001). The specification more broadly refers to a variety of telecommunications and data communications equipment and a desire to remotely power data network devices from a centrally powered system during power outages. '930 Patent, col. 1:22-40. Additionally, the specification sets forth a general objective of determining if remote equipment is capable of accepting remote power followed by a specific objective of delivering power over switched Ethernet segments in accordance with IEEE 802.3 standards. See id. at 1:41-48. The Summary of the Invention implies that Ethernet power is in accordance with only the specific objective, not the general objective. See id. at 1:51-59. The scope of the invention as a whole is not limited to Ethernet power, and other network topologies do not preclude use of the claimed invention. Accordingly, Ethernet is not a proper limitation, and the Court adopts Defendants' construction and construes the term "data node" to mean "data switch or hub."

"First, second and third nodes"

This term appears in Claim 36 of the '280 patent, which describes: "A network for carrying data and power signals, said network comprising: first, second and third nodes, each of said nodes containing at least one power consuming circuit . . ." SercoNet argues that this term means "three distinct communication entities designated 1st, 2nd and 3rd" whereas NetGear construes it as "First, second and third SICs." However, at the hearing, the parties agreed that the plain meaning of the term node means any addressable entity -- in other words, an entity that has its own identity to the network. Printers and computers are examples of nodes. NetGear, however, argues that the specification limits the term "node" to SICs rather than its plain meaning.

Starting with the claim language, the claim itself does not define the term node. The inventor, however, specifically used the term SIC many times in other claims in the related patents, but did not do so here. The claim language, therefore, indicates that "node" is not synonymous with SIC.

Turning to the specification, the specification also refers to the term SIC many times, yet the claim uses the broader term "node". Furthermore, the abstract notes that the invention is a serial intelligent cell and a connection topology for local area
networks, noting that the network can be configured by a plurality of SICs, which can be connected to one or more data terminals, computers, telephones, sensors, etc. In other words, the specification shows that both SICs and other addressable entities are connected to the network. Figures 7 and 8 also show both computers and SICs connected together in a network. While the computers are referred to as "data terminal equipment units" in the figures, and while the claim language separately refers to data terminal equipment units, there is nothing indicating that "nodes" does not encompass both data terminal equipment units and SICs. The specification, therefore, does not indicate that all entities in the network are SICs.

In addition, the patent prosecution history also supports a conclusion that the term "nodes" was used according to its normal usage. The information disclosure statement filed with the USPTO disclosed the '517 patent, which in turn referred to nodes as LAN devices such as computers, printers and modems. See '517 patent at 3:34-36.

Finally, NetGear's own proposed construction of other terms repeatedly uses the term "device," which itself is a broader term that it seems to use interchangeably with nodes, peripherals, and entities. For example, defendant proposes that an SIC itself is a device arranged in a certain way with certain types of connections, and that a LAN is a configuration of "devices" arranged in a serial fashion. Yet in the patent itself, the term "devices" refers more broadly to data terminals, computers, telephones, sensors, etc. See '510 patent at Abstract.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "First, second and third nodes" with the modifications discussed at the hearing and construes the term as: "3 addressable or identifiable entities designated 1st, 2nd, and 3rd."

Noise

The Court adopts ST's proposed construction of "noise" and construes the term as "unwanted electrical signals." The Court finds that ST's construction matches the appropriate dictionary definition and represents the understanding of one skilled in the art. Webster's New Collegiate Dictionary, at 772 (1980); see also Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002) (holding that dictionaries are reliable sources of information regarding the understanding of those skilled in the art). Although Motorola also derives its proposed construction 10 from a relevant dictionary, the Court rejects Motorola's construction because it introduces an ambiguity. Motorola would have the Court construe "noise" to be only that which "produce[s] undesirable effects," but Motorola does not indicate what constitutes an "undesirable effect."

1. "in accordance with a noise model"

Plaintiffs' construction: in accordance with a representation of noise used to predict noise

Defendant's construction: in accordance with a model that predicts noise statistics, including the average noise level and probability distribution of noise

The parties' fundamental dispute about this term relates to the term "noise model." Although they appear to agree that a "model" in this context is a construct that is used for the purpose of prediction and that, in this case, a noise model predicts noise statistics, the parties disagree whether the '859 patent describes a particular method for predicting noise statistics.
Defendant contends that the meaning of "noise model" is unclear from the language of the claims and is limited by the patent specification. Not surprisingly, plaintiffs take the position that "noise model" should be construed broadly, if at all. At the claim construction hearing, plaintiffs indicated that they believed no construction was necessary. Transcript, dkt. # 80, at 35, ln. 24 and 36, ln. 1.

In support of its argument that the patent specification limits the definition of the term "noise model," defendant cites several portions of the patent specification: "the noise model can be used to predict the exact noise statistics (mean and probability distribution)" '859 pat. col. 2, lns. 42-43; "A noise model is used to predict the mean noise level in each kernel," id. at col. 2, lns. 50-51; "parameter values are input to the noise model to predict the mean noise level in each kernel of the grid," id. at col. 6, 34-36.

Defendant's argument has two flaws. First, the portion of the specification on which defendant's construction relies most heavily, column 2 at lines 42 and 43, is included in a discussion of the preferred embodiment of the invention. Nowhere else in the patent is there any indication that this embodiment represents the noise model used in the invention as a whole. As the Court of Appeals for the Federal Circuit has cautioned repeatedly, it is error to apply to the invention as a whole limitations that relate to a preferred embodiment only. Acumed LLC v. Stryker Corp., 483 F.3d 800, 805 (Fed. Cir. 2007) (citing Phillips, 415 F.3d at 1323 (warning against confining claims to preferred embodiments)).

The second problem with defendant's argument is the absence of any indication that any of these references in the specification were intended to narrow the kind of noise models that might be used as part of the claimed invention. In each instance they describe a type of noise model that may be used, but there is no indication that these references describe the only types of noise models. Therefore, it would be incorrect to adopt defendant's limitation when construing the term "noise model."

Although defendant's proposal is unpersuasive, I find plaintiffs' initial construction perplexing and unhelpful at best. I conclude that both proposed constructions are flawed and will decline to adopt either construction.

Dependent claim 29 recites the step of "painting with an electronic brush said first control image, said electronic brush having a shape in one or both of intensity and color to paint in inherently non-aliased strokes." Adobe contends that this phrase means painting in the manner taught by the '755 patent. Adobe points out that, although the term "inherently non-aliased strokes" does not appear in the '529 specification or the patent's prosecution history, it does appear in the abstract of the '755 patent, and the '529 patent refers to the '755 patent in describing its paint strokes. In addition, the '529 specification described in substantial detail the '755 painting process.

As Quantel observes, however, Adobe once again improperly seeks to import a limitation from the specification into a claim. The claim itself does not refer to the painting process of the '755 patent. And the specification expressly notes that a blending effect "can be provided by utilizing techniques derived from modified arrangements to those disclosed" in the '755 patent, thereby suggesting that "inherently non-aliased strokes" may be achieved in another manner. Indeed, Mr. Taylor testified as much. See Tr. at 96. Because claim terms are to be given their ordinary and customary meaning where the patentee does not explicitly provide a special meaning, Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996), the court shall construe "inherently non-aliased strokes" in a manner based on the parties' usage: natural-appearing lines that blend smoothly into a background image in the process of being created.

Liquidnet proposes that "non-binding indications" be construed to mean "non-binding offers to buy or sell a security." 94
ITG/Pulse adds a further limitation -- that the non-binding purchase or sale offers "allow[] traders to enter into negotiations to trade the securities, which cannot be executed without a further, affirmative action by a trader." 95 Because it is supported by the intrinsic evidence, I adopt ITG/Pulse's construction.

The word negotiation appears throughout the specification. In one of those instances, a portion of the specification states that, "[b]ased on these indications, traders at one institution can enter into negotiations with traders at other institutions[]" 96 Thus, according to the specification, traders use non-binding indications to enter into negotiations with one another. Moreover, during prosecution of the patent, the patent applicant confirmed this interpretation of the patented method -- telling a PTO examiner, "[a]s pointed out in the specification . . . , the indications provide information to allow traders to enter into negotiations to ultimately trade the securities." 97

Liquidnet objects to this interpretation of the term "non-binding indications" on the ground that it requires a limitation to be read from the specification into the claim. 98 A district court must be careful not to read language into a patent claim without appropriate justification. Accordingly, earlier in this Opinion, I declined to construe several terms in claim one to require automation even though the specification described the patented method as occurring automatically." 99 However, the relevant distinction between those terms (e.g., sending), and the term "non-binding indications," is that the word "non-binding" is an ambiguous term that requires further clarification. 100 The term "non-binding" reveals that these indications alone are insufficient to constitute trader authorization, and that at least one further step must take place before a trade is executed. The specification and prosecution history make clear that this extra step is negotiation.

Accordingly, I adopt ITG/Pulse's construction of the term "non-binding indications" to mean "non-binding purchase or sale offers that allow traders to enter into negotiation to trade securities, which cannot be executed without a further, affirmative action by a trader." However, I emphasize that negotiation need not be an in-depth process. It can be as basic as each party assenting to the terms of the other party's non-binding indications.
Sun's construction                      NetApp's construction
In such a way that the [data and] redundant information can be placed in locations within the stripe
within the stripe in any order. that are not known in advance.

--- Footnotes ---

8 At the hearing, Sun agreed to omit the words "data and" from its proposed construction.

--- End Footnotes ---

The parties dispute whether the term "non-fixed pattern" has a physical or a temporal connotation. Sun's construction takes into account the order and location of the placement of the information, while NetApp's construction focuses on when the locations are known.

Representative claim 1 requires that "the at least one unallocated block used to store the redundant information is located in any disk." Claim 1 at 12:18-20. While NetApp argues that this language means that the location of redundant information (also referred to as parity, which is a subset of redundant information) is not known in advance, the plain meaning of "located in any disk" refers to location -- more specifically, that the parity can be stored in any disk. This language does not support a temporally-oriented construction. In addition, the claim language separately contains a timing component, as the claims require that the parity be dynamically allocated in a non-fixed pattern before each write request is completed for each stripe. See, e.g., Claim 1 at 12:22-24. This claim language further supports Sun's construction, which refers to the physical location of the parity, rather than NetApp's, which refers to when the location is known.

Turning to the specification, Sun first notes that the abstract states that any available block in a stripe can be used to store parity, and that the location of parity is assigned arbitrarily within the stripe:

In response to a request to store (write) data on the array, the file system determines which disks contain free blocks in a next allocated stripe of the array. There may be multiple blocks within the stripe that do not contain file system data (i.e., unallocated data blocks) and that could potentially store parity. One or more of those unallocated data blocks can be assigned to store parity, arbitrarily. According to the dynamic parity distribution technique, the file system determines which blocks hold parity each time there is a write request to the stripe. The technique alternately allows the RAID system to assign a block to contain parity when each stripe is written.

'305 patent abstract (emphasis added). The "Summary of the Invention" repeats the same language. Id. at 3:61-4:3. The arbitrary selection of the parity location is recited again in the context of the present invention. Id. at 6:24-37 ("In accordance with the present invention, the dynamic parity distribution system and technique distributes parity across disks of the array . . . There may be multiple blocks within the stripe that do not contain file system data (i.e., unallocated data blocks) and that could potentially store parity . . . One or more of those unallocated data blocks can be assigned to store parity, arbitrarily.").

The above language, which clearly applies to the invention as a whole, supports both parties' constructions. The specification confirms that any unallocated data block can be used to store parity, and that the location of parity is assigned arbitrarily within the stripe. It also confirms that the file system waits to determine which unallocated block will hold the parity until there is a write request to the stripe. 9 However, as noted above, the latter timing component is already contained in the claim language, which states that the information is allocated before each write request is completed for each stripe. See, e.g., Claim 1 ("is dynamically allocated in a non-fixed pattern by the storage module before each write request is completed for each stripe."). In addition, this existing claim language is clearer than NetApp's proposed construction, which, in reciting "in advance," does not explain "in advance" of what.

--- Footnotes ---

9 As NetApp notes, Figure 2 also illustrates this timing component via an order of steps. Figure 2 is a "flowchart illustrating
a sequence of steps for distributing parity among disks . . "$ The figure demonstrates that the first step in assigning parity is to determine which disks contain free blocks, the system then reserves as many free blocks as are required for the parity, identified the reserved blocks, and then assigns the parity to the reserved blocks. See '305 patent at Figure 2. While this flowchart supports NetApp's construction, the order of steps is discussed elsewhere in the claim.

In addition, in the context of one embodiment, the specification notes that any available block within a stripe is a suitable candidate for either data or parity: "In the illustrative embodiment, the file system maintains at least one unallocated block per stripe for use by the RAID system. During block allocation, the file system provides an indication to the RAID system of the unallocated block(s) to be used to store parity information. All unallocated blocks on the disks of the array are suitable candidates for file system data or parity. Notably, the unallocated block(s) used to store parity may be located in any disk and the location(s) of the unallocated block(s) can change over time." Id. at 4:4-12 (emphasis added). The specification then states that the location of parity within a stripe is determined arbitrarily, can vary from stripe to stripe, and is not determined by the RAID configuration. Id. at 6:16-23. The specification repeats several times that any unallocated block within a stripe can be selected to hold parity:

According to the inventive technique . . . During block allocation, the file system provides an indication to the RAID system of the unallocated block(s) to be used to contain parity information. All unallocated blocks on the disks of the array are suitable candidates for file system data or parity. Notably, the unallocated block(s) used to store parity may be located in any disk and the location(s) of the unallocated block(s) can change over time. Moreover, all blocks in a RAID group are available for potential allocation, since parity is not held in fixed locations. In practice, this means that all blocks, including those that were "hidden" in the parity disk are available to the file system 160 for allocation in volume block number space.

Id. at 8:37-49 (emphasis added). This portion of the specification specifically contains the "fixed" location language. It strongly indicates that fixed location implies a physical location, i.e., that the data or parity can be placed in any unallocated block in the stripe. This language supports Sun's construction and indicates that the term means something more than NetApp's construction, which fails to state that the redundant information could be placed anywhere, so long as it is in an unoccupied block.

While NetApp argues that the "fact that parity is permitted to be stored in any location within a stripe, does not mean that in every system, at all times, parity must be stored on all of the disks," NetApp Opp. at 5-6, Sun's construction does not include such a requirement. Rather, Sun proposes that the parity "can be placed within the stripe in any order," not that it must be. In so arguing, NetApp concedes that parity may be stored in any location within the stripe. Its construction, however, omits this limitation, because it allows the claims to read on systems in which parity cannot be placed on any unallocated disk in the stripe. Sun gives the example that if a system permitted parity to be stored on disk 1 or 2, but not disks 3, 4, or 5, but did not know in advance if the parity would be stored on disk 1 or 2, then such a system would satisfy NetApp's proposed construction, but would vitiate the patent's central teaching that parity may be stored on any disk. While NetApp argues that such a rule could not exist in the context of this patent, because the patent claims themselves require that the parity be able to be placed on "any disk," this language is not contained in all of the patent claims. See, e.g., Claims 36 and 42.

NetApp also argues that the non-fixed pattern does not refer to data or redundant information. However, as Sun notes, the claims themselves specifically refer to the arrangement of redundant information and data. For example, claim 23 provides for "the system of claim 1, wherein the non-fixed pattern is created by the redundant information being stored in any block remaining after the data is allocated to blocks of the stripe." The "non-fixed" pattern refers to relative placement of data and redundant information within a stripe. Sun's original proposed construction, however, implied that the data blocks themselves are ordered arbitrarily like the redundant information, which is not supported by the patent. In fact, Sun itself concedes that its construction "does not require arbitrary data block assignments," but rather "simply refers to the relationship between redundant information and data blocks -- without requiring a particular ordering of blocks within a stripe." Sun Reply at 4-5. According to the patent, the parity is distributed in a non-fixed pattern which depends upon placement of the preexisting data, as the parity is only placed in unallocated blocks. A more accurate construction, therefore, would refer to placement of redundant information "in such a way that the redundant information can be placed within the stripe on unallocated blocks in any order."
At the hearing, NetApp articulated its argument in a new way, stating that the pattern is non-fixed with regard to the system as a whole, i.e., the patterns across the stripes, but the pattern need not be arbitrary within a stripe. 10 NetApp argued, as an example, that the invention would encompass an algorithm which would store parity in every third free block of the system. However, NetApp's expert Dr. Gregory Ganger conceded that when applied to an empty system, this algorithm would yield a system-wide non-random pattern. Only after time, according to Dr. Ganger, would this pattern become random, because the previously stored data itself would be changing and would exist in a random pattern. But the patent requires that parity be permitted to be stored in any location within a stripe, as NetApp concedes in its brief. Opp. at 5:27-28. The patent does not limit this requirement to a mature system. Yet in the above example of an immature system, under NetApp's proposal, parity would be located in a fixed pattern across the stripes, which the patent disavows.

10 NetApp also argued that the system is designed to balance the load (see, e.g., '305 patent at 9:41-45) and that a completely random placement of parity does not make sense in the context of this invention, but Sun's construction does not require a completely arbitrary assignment.

As to the prosecution history, Sun argues that the applicants stated four separate times to the PTO that the invention permits the placement of parity and data in any order in a stripe. First, after the PTO rejected certain claims as being anticipated by the Patterson reference, NetApp contrasted Patterson by stating that the applicant's invention stores parity data in the unallocated blocks in a stripe, and that the "unallocated blocks can change with each stripe and do not follow a constant pattern." Williamson Decl., Ex. E (May 22, 2006 response to PTO) at 14. The PTO again rejected certain claims as being anticipated by Patterson, and NetApp responded by adding the "dynamically allocated" claim language and argued that "the storage operating system then selects at least one unallocated block of the stripe to store redundant information. This allows for the redundant information to be placed in any order, varying from stripe to stripe." Id., Ex. F (Oct. 23, 2006 response to PTO) at 13-14. In contrast, according to the applicant, Patterson described a RAID system where parity information is stored in a rotating pattern. The PTO again rejected claims as being anticipated, and NetApp responded on February 5, 2007. NetApp responded by adding the "in a non-fixed pattern" language to the claims and argued:

In further detail, Applicant's invention allows the at least one unallocated block used to store the redundant information is dynamically allocated by the storage module before each write request for each stripe in a non-fixed pattern. Before each stripe is written across each disk, the storage module determines at least one unallocated block to use for redundant information. Each unallocated block is selected from the one or more blocks that are not already allocated to data blocks. The storage operating system then selects at least one unallocated block of the stripe to store redundant information. This allows for the redundant information to be placed in any order, varying from stripe to stripe because there is no fixed pattern.

Williamson Decl., Ex. G (Feb. 5, 2007 response to PTO) at 13-14 (emphasis in original). The PTO rejected the claims again as being anticipated, and NetApp moved the location of the "a non fixed-pattern" language in the claims and argued that the invention allows "the at least one unallocated block used to store the redundant information is dynamically allocated in a non-fixed pattern by the storage module before each write request is completed for each stripe." Williamson Decl., Ex. H (June 28, 2007 response to PTO) at 16-17.

The PTO issued its Notice of Allowance on September 7, 2007, and in his reasons for allowance, the Examiner stated: "The prior arts . . do not teach . . a method, system, program and an apparatus that in which at least one block is dynamically assigned/allocated in a non-fixed pattern (in any disk) for storing the parity/redundant information/data before completing each write request for each stripe." Williamson Decl., Ex. I (Sept. 7, 2007 Notice of Allowance) at 5 (emphasis in original).

The Notice of Allowance, therefore, shows that the Examiner expressly identified as a point of novelty that the redundant information is stored in a non-fixed pattern that can be on any [unallocated] disk on which the stripe is written in any order. The Examiner also identified as a point of novelty that this dynamic assignment/allocation occurs before each write request for each stripe is completed. However, as discussed above, this latter timing requirement is already included in the claim language.
In response to this prosecution history, NetApp argues that the applicants' statements to the PTO must be read in context. But the prosecution history cited above includes the portions relied upon by NetApp and teaches that redundant information may be placed in any order on any disk. The prosecution history, therefore, supports Sun's construction.

In sum, Sun's construction, with minor adjustments, is more appropriate. NetApp's construction only addresses the timing of when locations in the stripe are known, which is already addressed by other parts of the claim language, and fails to discuss the physical placement of the redundant information. For these reasons, the Court construes "non-fixed pattern" as "in such a way that the redundant information can be placed within the stripe on unallocated blocks in any order."

"Non-information-bearing optical signal" means "an optical signal which has not been modulated."

A. "non-interactive electronic message"

The term "non-interactive electronic message" is found in the preamble of claim 26: "[a] method for processing a non-interactive electronic message using a computer." Non-interactive electronic messages are described in the following passage from the specification:

"[I]n the instant invention the data of the electronic message 11 is delivered to the automatic message interpreting and routing system 1 in a non-interactive manner. Specifically, the customer 50 transmits a non-interactive electronic message 11 to the system 1. This non-interactive transmission of electronic messages 11 prescribes that the customer 50 need not later provide additional input to assist the system 1. It is noted that defining an electronic message 11 as being non-interactive prescribes only that the message content need not be supplemented. Thus, as described in more detail below, the form of the non-interactive electronic message 11 may be altered by the system 1 after the customer 50 sends it; however, the customer 50 is not required to provide supplemental information to assist the system 1."

('947 patent, 4:58-5:4) (emphasis added). Bright Response asserts that this term means "an electronic message not requiring additional input or supplementation from the sender." The defendants contend that "non-interactive electronic message" is insolubly ambiguous and thus indefinite.

The defendants argue that "non-interactive electronic message" is insolubly ambiguous because neither the claim nor specification provides any guidance as to which of the many possible interpretations of this term is correct. According to the defendants, neither the claims nor the specification explain what a non-interactive message is or how to determine if a message is non-interactive. As to Bright Response's proposed construction, the defendants contend that one cannot determine from the message itself whether it requires additional input or supplementation from the user.

One of ordinary skill in the art reading the specification would understand that the transmission and processing of the message must be non-interactive. The specification explains that "the data of the electronic message 11 is delivered . . . in a non-interactive manner" and refers to "[t]his non-interactive transmission of electronic messages." ('947 patent, 4:58-61, 62-63). This non-interactive transmission and processing is consistent with the preferred embodiment, E-mail messages, in that the sender provides no further input or interaction once the message is received. The specification sufficiently explains what is meant by "non-interactive," and this term is not insolubly ambiguous.

Bright Response asserts that additional user input or supplementation is allowed, but not required, for a non-interactive message. In support of this construction, the plaintiff cites the following text from the specification: "This non-interactive transmission . . . prescribes that the customer 50 need not provide later input . . . [D]efining an electronic message 11 as being non-interactive preserves only that the message content need not be supplemented." ('947, 4:62-5:1). But, read as a whole, the patent does not support Bright Response's argument. Construing "non-interactive electronic message" to allow interaction would contradict the plain meaning of "non-interactive." Therefore, the court construes "non-interactive"
electronic message" to mean "an electronic message in which the sender does not provide any additional information after the message has been received."

4. "Non-Linear Phase Domain Video Signal"

Comark argues that the term "non-linear phase domain video signal" means "a video signal which is distorted in a non-linear way and fed to a phase modulator in order to phase modulate another signal." Harris contends that the term means "a video signal that has itself been 'phase modulated' in a non-linear manner, i.e., intentionally distorted in phase."

The term "non-linear phase domain video signal" appears throughout the '904 patent, including Claims 1 and 14. The term "non-linear phase domain video signal" is not commonly used by persons with expertise in the field of television transmitter circuitry. (Tr. 10/18/96 at 87.) Claim 1 is clear that the amplitude and phase modulator receives the aural signal and amplitude and phase modulates that signal using the non-linear amplitude domain video signal and the non-linear phase domain video signal, respectively. (See Ex. DMX-1 at col. 6, lines 34-38.) The specification does not define the term. Rather, it describes its function by stating that

the non-linear amplitude domain video signal 29 amplitude modulates the IF aural signal 33. The independently inputted non-linear phase domain video signal 31 then phase modulates the IF aural, to produce the modified IF aural signal 28 added to the visual signal at adder 21.

Id. at col. 3, lines 50-55. The use of the word "modulates" in these two locations suggests that the non-linear video signals generated in the non-linear amplifier are not modulated, but instead modulate the IF aural signal as they are inputted to the amplitude and phase modulator. See id. at Fig. 1.

The patent, however, is inconsistent in at least three places. Claim 15 recites: "A method according to Claim 14, wherein the aural signal added to the amplitude modulated non-linear amplitude domain video signal and the phase modulated non-linear phase domain video signal is an IF aural signal." Id. at col. 8, lines 23-27. Similarly, claim 18 describes a non-linear phase domain video signal that is modulated separately from the non-linear amplitude domain video signal. Id. at col. 8, lines 34-37.) Claim 19 describes "[a] method according to Claim 14, wherein the amplitude modulated non-linear amplitude domain video signal and the phase modulated non-linear phase domain video signal are added to the aural signal separately." Id. at col. 8, lines 38-42. The use of the word "modulated" in the past tense is evidence that the non-linear phase domain video signal already has been modulated before it is added to the IF aural signal.

Because the court cannot determine the meaning of the term "non-linear phase domain video signal" from the intrinsic evidence, it must examine the extrinsic evidence, such as expert testimony, to construe the term.

Modulation means varying one signal by means of another, so that any device with only one signal as input does not qualify as a modulator. (Tr. 10/21/96 at 83.) The non-linear amplifier has only one signal as input; there is no second IF signal that could turn the amplifier into a modulator. Id. Therefore, the "non-linear phase domain video signal" that is generated in the complementary non-linear amplifier is not modulated. Rather, the signal is used to modulate the IF aural carrier in the amplitude and phase modulator.

This conclusion is supported by a diagram of the complementary non-linear amplifier. (Ex. DMX-1, Fig. 3.) A person of ordinary skill in the art would recognize the diagram as illustrating a non-linear amplifier that contains twin circuits that are clipping, stretching, and inverting the video signal, and not modulating it. (Tr. 10/21/96 at 86.) If the amplifier were modulating the video signal, there would be a third external unit to indicate what is being modulated. Id. at 85.

If the non-linear amplifier were to modulate the video signal, the invention described in the '904 patent would not work. Id. at 87. This is because it would be unable to compensate a signal that has been phase modulated and then subsequently phase modulate an aural carrier with it. Id. at 88-89. A video signal should not be phase modulated before it is applied as a non-linear signal used to modulate the aural IF carrier. Id. at 56. Thus, if the non-linear phase domain video signal is interpreted as having been phase modulated, then the corrector will not perform the necessary correction. Id.
The court will adopt Comark's proposed construction.

*

The term "non-linear phase domain video signal" in Claims 1 and 14 means a video signal which is distorted in a non-linear way and fed to a phase modulator in order to phase modulate another signal.

2872

A. Non-personalized cardholder name

I conclude that the term "non-personalized cardholder name" as used in claim 1 of the '181 patent means a name that does not identify the purchase card as belonging to a specific cardholder and that is used by a retailer to complete a purchase transaction. Plaintiff contends that "non-personalized cardholder name" does not need to be defined because it is readily understood to refer to "a name that is never associated with a specific cardholder." Plt.'s Br., dkt. 41, at 7. I disagree.

It is proper to begin by placing the term in context:

wherein each of the purchase cards is a bearer instrument having an associated account number issued by a major branded credit card organization, an expiration date and a non-personalized cardholder name selected by the purchase card provider printed thereon, wherein the purchase card does not include information identifying the specific perspective cardholder[.]

'181 Pat., col. 6, lns. 32-38. (Emphasis added.) The ordinary meaning of "non-personalized cardholder name" in context of the claim language is "a name that does not identify the card as belonging to a specific cardholder." This meaning of "non-personalized" is proper in light of the ordinary definition of "personalized" which is to "make (something) identifiable as belonging to a particular person, esp. by marking it with their name or initials: [as adj.] (personalized) personalized license plates." New Oxford American Dictionary 1269 (2d ed. 2005).

The purpose of the patented method further supports this construction of non-personalized. According to the specification, the "primary objective" of the patented method is to "create a non-traceable means to transact a purchase over the Internet." '181 Pat., col. 2, lns. 65-67. Thus, the non-personalized cardholder name must not be linked to the identity the specific cardholder. If the name on the card does not identify the card as belonging to the specific cardholder, then the card would not be traceable to the cardholder using the name on the card. Moreover, the specification's examples of non-personalized names supports construing "non-personalized" as "a name that does not identify the card as belonging to a specific cardholder." Id., col. 3, lns. 15-16 ("a non-personalized cardholder name 43 (such as the name of the purchasing intermediary)"), col. 5, lns. 16-19 ("they simply insert the cardholder name, for example the name of the purchasing intermediary or an alias such as 'John Smith' as provided on the card.").

Plaintiff's concern over using the word "identify" as opposed to "associate" is unfounded. Plaintiff contends that a card with a faux name chosen by the consumer would be a "non-personalized cardholder name" under a construction using the term identify. First, the claim states that a non-personalized cardholder name must be "selected by the purchase card provider," '181 Pat., col. 6, ln. 36, which makes plaintiff's concern about a consumer choosing a "personalized" faux name a non-issue. Further, the issue raises a distinction without a difference. The definition of "identify" includes use of the word "associate:" "associate (someone) closely with; regard (someone) as having strong links with." New Oxford American Dictionary 839, # 2 (2d ed. 2005). However, use of the word "identify" helps provide a smoother connection between the purpose of the patented method, that being, engaging in a transaction in an anonymous manner, and the purpose of providing a non-personalized cardholder name, that being, providing "pseudo purchase transactional information to the consumer." '181 Pat., col. 5, ln. 12.

Plaintiff also challenges the second portion of the construction: "that is used by a retailer to complete a purchase transaction." Plaintiff contends that construing "non-personalized cardholder name" to include this additional limitation improperly imports a limitation from the specification into the claim. Again, I disagree. Although plaintiff is correct in noting that it is improper to read a limitation from the specification into the claims, the court's construction does impose
such a limitation. Microsoft Corp. v. Multi-Tech Systems, Inc., 357 F.3d 1340, 1347 (Fed. Cir. 2004). Instead, the construction follows the rule that "'[c]laims must be read in view of the specification, of which they are a part.'" Id. (alteration in original) (quoting Markman, 52 F.3d at 979).

It is true that claim 1 does not provide any function for the "non-personalized cardholder name." As the claim is written, the term serves no function and appears to be nothing more than an aesthetic limitation. However, the presence of a purely aesthetic limitation in a method claim doesn't quite jive. If the "non-personalized cardholder name" serves no functional purpose, as plaintiff contends, then the term is superfluous to the patented method. In fact, if the term serves no functional purpose, the method's purpose, anonymous internet transactions, would be best served using a card with no name at all. This leads to the logical conclusion that the term must serve some purpose in the patented method. A look at the specification and patent history helps clear up the ambiguity regarding the term's purpose.

Turning to the specification, it is clear that the "non-personalized cardholder name" does serve a functional purpose under the patented method. The "non-personalized cardholder name" is a necessary component for conducting an anonymous transaction with a retailer over the internet, which is the patented method's "primary objective." '181 Pat., col. 2, lns. 65-67. Simply put, the non-personalized name is used when the cardholder is prompted by the retailer's application or web-site to provide a name in completing a purchase. Id., col. 5, lns. 15-17. The specification is clear that "[t]he account number, cardholder name and expiration date are [ ] used by the retailer's application to complete the purchase transaction with the consumer in a manner known in the art." Id., col. 5, lns. 21-24. Another portion of the specification explains that

The purchasing card 40 includes a unique and non-traceable Master Card or Visa credit account number 42, a non-personalized cardholder name 43 (such as the name of the purchasing intermediary) and an expiration date 44 which allows the consumer the ability to make a purchase(s) over the Internet or in other "bricks and mortar" retail establishments.

In light of those clear statements, the patented method requires not merely a non-personalized name but a non-personalized name that allows the consumer to make anonymous purchases over the internet by permitting a retailer to use the name to complete a purchase transaction. Cf. SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) ("Where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question.").

The prosecution history for the '181 patent further supports limiting the term to a non-personalized name used by a retailer to complete a purchase transaction. "'[A] court should also consider the patent's prosecution history, if it is in evidence. . . . Like the specification, the prosecution history provides evidence of how the [Patent Office] and the inventor understood the patent.'" Ultimax Cement Manufacturing Corp. v. CTS Cement Manufacturing Corp., 587 F.3d 1339, 1347 (Fed. Cir. 2009) (alterations in original) (quoting Phillips, 415 F.3d at 1317). According to the prosecution history for the '181 patent, the patentee understood the patented method to require that the non-personalized cardholder name be used by a retailer in completing an anonymous internet transaction.

During prosecution of the patent, the patentee, represented by his attorney, argued that a novel feature of patented method, which was not disclosed in the prior art, was providing a non-personalized cardholder name and an account number to a retailer to complete a transaction. Spaccarotella Decl., dkt. 39, exh. F at AXPR0016376. The patent examiner rejected the patentee's argument because the "non-personalized cardholder name" had no function in the patented method. Id. The examiner suggested that the prior art could be overcome if there was an amendment to the specification which specify[sic] that the purchase transaction is based upon the account number and the non-personalized information associated with the purchase card and that the specification also provides other details which defines the personalized information in order to facilitate the claim interpretation and how it relates [to] the purchase transaction process.

Id.

The patentee filed an amendment that added "a non-personalized cardholder name 43" to the list of items in the
specification that allowed the consumer to complete a purchase with a retailer over the internet, id., exh. G at AXPR0014212, and the portion of the specification explaining that the account number, non-personalized name and expiration date are used by a retailer to complete the purchase transaction, id., at AXPR0014215. Additionally, the patentee reworded the "transacting" step in the claims to require use of the account number and the non-personalized cardholder name to complete a purchase. Id. at AXPR0014216. In the patentee's remarks regarding the amendments, he noted that the examiner had "requested that the specification more clearly state that a purchase is transacted based upon the account number and the non-personalized cardholder name associated with the purchase card." Id. at AXPR0014219. He also explained that he had "made minor amendments to the specification in accordance with the Examiner's suggestions" and he confirmed "that such amendments merely serve to clarify the present invention, but do not constitute new matter to the application." Id. at AXPR0014219.

Limitation of the scope of a claim using the patent's prosecution history requires a clear statement in the history that shows "reasonable clarity and deliberateness" in creating the limitation. University of Pittsburgh of Commonwealth System of Higher Education v. Hedrick, 573 F.3d 1290, at 1296 (Fed. Cir. 2009). The statements by the inventor along with the amendments to the patent's specification are just such clear, deliberate statements. They unambiguously reflect the patentee's understanding that the patented method requires that the non-personalized cardholder name be used by retailers to complete transactions.

Plaintiff contends that there was no clear limitation of the patented method because the alteration of the "transacting" step in the actual claim language was eventually eliminated before the patent was issued. However, this change in the claim language does not change what the patentee expressed as his understanding and clarification of the "present invention." Further, the clarifications in the specification regarding the function of the non-personalized cardholder name were never eliminated from the patent. The patentee's explanation that a novel feature of the patented method was using the non-personalized cardholder name to complete a purchase transaction with a retailer and memorialization of that explanation in the specification clearly confirm the limitation. Therefore, the court cannot construe the term without the limitation that the "patentee itself regarded as comprising its inventions and represented to the PTO." Microsoft Corp., 357 F.3d at 1349.

A. "Non-public Personal Information" (’783 Patent)

"Non-public personal information" appears in every independent claim (claims 1, 18, and 20) of the ’783 patent. In Yodlee v. Block Financial Corp., the court adopted H&R Block's proposed construction of the term, construing it to mean "information/data that is specific to an end user and requires verification and access data for retrieval." Yodlee Exh. V at 6-7. Yodlee now seeks to have this construction apply in the instant case. CashEdge argues that this Court should construe the phrase as "information that is personal to a specific end user and not accessible to the general public." The Court agrees with CashEdge that its definition is more consistent with the patent's language; nowhere does the patent limit "non-public" to "requir[ing] verification and access data for retrieval." The Block court imposed that construction only because it agreed with H&R Block that "personal information" was specific to an end user, not because anything in the patent or prosecution history required "verification and access data." Accordingly, the Court adopts CashEdge's proposed construction of "non-public personal information."

--- Footnotes ---

n4 The Block court rejected Yodlee's proposal that the phrase be given its ordinary and customary meaning, because it found that during prosecution of the patent Yodlee had included "non-public" to specify that the information was specific to a given end-user.

--- End Footnotes ---
3. "non-regulated" / "non-regulating" / "without regulation" (’190, ’083, and ’702 patents)

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>SynQor's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;non-regulated, isolated DC output&quot;</td>
<td>&quot;an [isolated DC] output that is approximately proportional to the input voltage during normal operation even when faced with variations in input voltage and output current&quot;</td>
<td>&quot;does not control an output towards a predefined value&quot;</td>
</tr>
<tr>
<td>&quot;non-regulating&quot;</td>
<td>&quot;producing a non-regulated output during normal operation even when faced with variations in input voltage and output current&quot;</td>
<td>Same as above.</td>
</tr>
</tbody>
</table>
| "without regulation" | See construction of "regulation."
|                      |                                 | Same as above. |

There are two primary issues in dispute between the parties as to these terms. The first issue is whether the construction of the non-regulated terms should include the phrase "during normal operation." The parties primarily rely on the same arguments as previously presented in regards to the "regulated" terms, and the Court will not rehash their arguments. The second issue is whether the non-regulated terms should be defined negatively as the Defendants propose or affirmatively as SynQor proposes. SynQor argues that the specification affirmatively describes a non-regulated output as being proportional to the input voltage. See ’190 patent, 5:13-24; 15:4-11. SynQor argues that the term "approximately" is not indefinite and is supported by the specification. Defendants argue that the terms, "non-regulated," "non-regulating," and "without regulation" simply mean not "regulated." Because the parties have essentially agreed that the term regulated means "controlling an output towards a predefined value," Defendants argue that these terms mean the opposite, i.e., "does not control the output towards a predefined value." Defendants argue that SynQor agrees with this logic because for the term "without regulation" it merely proposes the opposite of regulation. Defendants further argue that the term "approximately" is not supported by the specification and there is no guidance as to the bounds of the term.

Consistent with previous terms and for the same reasons, the Court rejects SynQor's attempt to add "during normal operation" to this term when there is no basis for it in the claims or the specification. The claims consistently use "regulation" terms and also "non-regulation" terms. The claims, the specification, and the terms themselves imply that the meanings of these terms are opposites. The Court does not find any support in the specification for SynQor's "approximately proportional" language, and thus rejects SynQor's attempts to add limitations that are not present. The Court notes that SynQor agrees that "without regulation" means no "regulation" or the absence of "regulation" as previously defined, but argues that the terms "non-regulated" and "non-regulating" mean something different. The Court is not persuaded by SynQor's arguments. The Court finds that "without regulation" and "no regulation" and "non-regulated" have the same meanings as implied in the claims and the specification. The Court agrees with the Defendants and finds that these terms are the opposite of the "regulation" terms. Thus, similar to its constructions for the "regulation" terms, the Court adopts the following constructions:

"non-regulated output" means "an output that is not controlled towards a predefined value;"

"non regulated, isolated DC output" means "an isolated DC output that is not controlled towards a predefined value;"

"non-regulating" means "not controlling an output towards a predefined value;" and

"without regulation" means "the act of not controlling an output towards a predefined value."
C. Non-Single Crystal Semiconductor Material

In the context of plaintiff's summary judgment motion, the parties dispute the meaning of "non-single crystal semiconductor material" in claims 1 and 5. Although plaintiff's motion is limited to those claims, this term appears in claims 1, 5, 12 and 13. Specifically, the patent claims disclose "source and drain regions comprising a non-single crystal semiconductor material doped with a recombination center neutralizer." Plaintiff would have the court adopt the definition provided in the specification and adopted by the court in Acer for the '941 patent: "a semi-amorphous semiconductor, an amorphous semiconductor or a mixture thereof." Defendants contend that the term should be limited to semi-amorphous semiconductor material.

The patent specification is explicit in defining "non-single crystal semiconductor material" as including amorphous or semi-amorphous semiconductor material or a mixture of the two. Defendants argue that the court should disregard this instruction because the specification explains that amorphous semiconductor materials cannot be used for the source and drain regions, explicitly describes only semi-amorphous semiconductor material, disparages amorphous and other semiconductor materials and fails to disclose a single embodiment of source and drain materials made of amorphous or other semiconductor materials. The crux of defendants' argument is that the specification teaches only a method of manufacturing a semi-amorphous semiconductor and identifies the non-single crystal semiconductor as the starting material, preventing the patent from covering products consisting of amorphous semiconductors.

According to the only embodiment contained in the specification, the starting material undergoes a structural change that is induced by localized heating (the step depicted in Figure 6G) and results in a final product (the source and drain regions) made of semi-amorphous semiconductor material. Defendants assert that because the specification indicates that this process can be used where the non-single crystal semiconductor is amorphous or some other semiconductor material, the final product is always semi-amorphous semiconductor material, necessitating that the "non-single crystal semiconductor material" be semi-amorphous semiconductor material. I disagree.

The specification illustrates the formation of a thin film transistor in which starting semiconductor material is converted into semi-amorphous semiconductor material through the application of a current. However, the specification states explicitly that the process described clarifies "the manufacturing method of the present invention and its advantages in the case where the non-single crystal semiconductor is the semi-amorphous semiconductor." This leaves open the possibility that the non-single crystal semiconductor could be a different type of semiconductor.

Defendants point out that the specification goes on to state that

Also in the case where the non-single crystal semiconductor 7 is an amorphous semiconductor or a mixture of the semi-amorphous semiconductor material and the amorphous semiconductor, it can be formed by the above-described method.

The specification later states:

Even if the non-single crystal semiconductor 7 is the amorphous semi-conductor or the mixture of the semi-amorphous and the amorphous semiconductor, the semi-amorphous semiconductor S2 is formed to have the same construction as in the case where the non-single crystal semiconductor 7 is the semi-amorphous semiconductor.

I agree that the second statement seems to imply that amorphous or mixed semiconductor material results in a final semi-amorphous semiconductor. However, the patent abstract describes the invention as

A semiconductor device which has a non-single crystal semiconductor layer formed on a substrate and in which the non-single crystal semiconductor layer is composed of a first semiconductor region formed primarily of non-single crystal semiconductor and a second semi-conductor region formed primarily of semi-amorphous semiconductor. The second semiconductor region has a higher degree of conductivity than the first semiconductor region so that a semi-conductor element [sic: may] be formed.
The resulting semiconductor regions, including the more conductive region, are not limited to semi-amorphous semiconductor material. Therefore, there is no ground for limiting the meaning of non-single crystal semiconductor to semi-amorphous semiconductor. Various statements in the specification emphasize the point that a non-single crystal semiconductor can be an amorphous or a semi-amorphous one or a combination of the two. It seems implausible that the specification would define non-single crystal semiconductor material initially as including a variety of materials but later intend that term to refer to only one type of semiconductor material. If plaintiff had intended to describe the source and drain regions in the patent claims as limited to semi-amorphous material, it would have said so, rather than using the broader definition of the term "non-single crystal semiconductor material."

Equally unpersuasive are defendants' arguments that plaintiff disavowed a broad definition of the claim term by including only one embodiment disclosing a final semi-amorphous semiconductor product or making disparaging remarks about the properties of amorphous semiconductors. At most, these factors indicate plaintiff's strong preference for semi-amorphous semiconductors. However, as plaintiff notes, preferred embodiments cannot be used to limit claim language intended to have a broader effect. Innova/Pure Water, Inc. v. Safari Water Filtration Systems, 381 F.3d 1111, 1117 (Fed. Cir. 2004) (even when patent describes only single embodiment, otherwise broader claims will not be read restrictively unless patentee has demonstrated clear intention to limit claim scope in that manner.)

Because I construe non-single crystal semiconductor material to mean "a semi-amorphous semiconductor, an amorphous semiconductor or a mixture thereof," it is irrelevant whether the accused products contain semi-amorphous or only amorphous semiconductor material. Therefore, plaintiff is entitled to summary judgment on the question whether defendants' products satisfy the non-single crystal semiconductor element of claims 1 and 5.

A. Non-telephone actuation signal

The first claim term in dispute in the '184 Patent is the term "non-telephone actuation signal." The defendants contend that the claim term should be construed to mean "a one-way activation signal sent outside standard telephone system signaling channels." The plaintiff contends that the term means "a broadcast activation signal sent via something other than a telephone system." The parties agree that an actuation signal is an "activation signal." The core disagreement is over the construction of "non-telephone."

After reviewing the intrinsic record, the court construes the term "non-telephone actuation signal" to mean an "activation signal sent over something other than a telephone system." Although Eicon suggests that the claim term could include a signal sent outside "standard telephone system signaling channels," this definition is, in the court's view, too vague. Eicon does not suggest what these channels include or whether, for instance, a non-telephone actuation signal could include a signal sent via non-standard telephone system signaling channels.

The plaintiff's definition is also not appropriate. Brooktrout contends that the court should limit the definition to a "broadcast signal," because the preferred embodiment of the invention discloses an airborne activation signal transmitted from a broadcast facility. The Federal Circuit has warned district courts not to impose limitations appearing in the preferred embodiments of inventions when the claim language supports a broader claim scope. E.g., Nystrom v. Trex Company, Inc., 374 F.3d 1105, 2004 WL 1432247 *7 (Fed. Cir. 2004). The court observes that the claim language itself simply uses the term "non-telephone," implying that the patentee intended to claim all methods of actuation other than through the telephone system. Had the patentee intended to restrict the scope of the claim to broadcasted signals, the claim language would have used the phrase "broadcast actuation signal" or similar terms.

In addition, the written description states:

Preferably, an actuation signal is immediately sent out over the local broadcast facility indicated as 22 with the computer logic 30, which includes broadcast receiving capability, of the facsimile machine 18 effectively listening for an actuation signal received by the associated antenna 20 connected thereto. This arrangement is described in U.S. Pat. No. 4,713,837 incorporated herein by reference.
'184 Patent, Col. 2, ll. 58-65. The language of the specification suggests that the broadcast example described is not the only method of supplying a non-telephone actuation signal. Moreover, in the '837 patent, the patentee discloses that "[i]t can be appreciated that the antenna 6 could be replaced with a connection to a broadcast carried over a cable network as but one alternative." By this language, the patentee is attempting to illustrate additional ways of transmitting the actuation signal. Accordingly, the court construes the term "non-telephone actuation signal" to mean "an activation signal sent via something other than the telephone system."

2877

1. "Non-transmissive, radiation reflecting optical structure" 7

7 Defendants state that the term requiring construction is simply "non-transmissive" without the additional qualifying language supplied by Philips.

This term is at the heart of the dispute. It is found in Claim 1, which recites

[a] record carrier containing information which is readable by a beam of radiation, said record carrier comprising a disc-shaped, radiation-transmitting substrate having a pair of planar surfaces on opposite sides thereof, a non-transmissive, radiation reflecting optical structure on one of said planar surfaces of said substrate . . . .

'846 Patent, Col. 5, ll. 61-66 (emphasis added). 8 Defendants urge the court to read this term as meaning that the optical structure "does not transmit radiation such as light. For example, light can not be seen through the disc." 9 Philips, on the other hand, contends that the term should not be construed to convey a property of the optical structure itself (its relative translucence). Rather, Philips argues that the term should be understood as characterizing the method by which the disc is read (in reflection mode as opposed to transmission mode). Philips proposes that the term be construed as "[a]n optical structure that reflects radiation for reading the information but does not also transmit radiation for reading the information."

The '846 Patent does not provide a definition of "non-transmissive." Therefore, the court will first look to the teachings of the specification and claim language. A stated object of the invention disclosed in the '846 Patent was to improve on the prior art by

provid[ing] a record carrier in which the optical structure is protected against dust particles and damage without the use of a protective layer which is required to satisfy stringent requirements. For this purpose the record carrier according to the invention is characterized in that the optical structure is a radiation-reflecting structure and the carrier substrate is radiation-transmitting, the surface of the carrier substrate more remote from the optical structure forming both the entrance face and the exit face for the read radiation. In this record carrier the carrier substrate itself ensures that dust particles are sufficiently spaced away from the optical structure.

'846 Patent, Col. 2, ll. 8-21 (emphasis added).

The specification describes prior art disclosed in the "Journal of the S.M.P.T.E." in November of 1979. This prior art used a protective layer on top of the optical structure that allowed the device to be read only in transmission mode. As the beam
had to pass through the protective layer to reach the detector, the protective layer had to meet stringent quality standards. See id., Col. 2, ll. 6-7.

10 In addition to meeting precise thickness requirements, the protective layer in the prior art was required to "intimately engage" the optical structure in order to prevent the occurrence of local air bubbles between the optical structure and the protective layer. '846 Patent, Col. 1, ll. 59-65.

Claim 1 specifies that the substrate under the optical structure is "radiation transmitting", id., Col. 5, l. 63, and that the convergent beam of radiation used to read the disc enters the substrate and passes through it to a focused point on the optical structure. Id., Col. 6, ll. 8-11. The use of the word "transmitting" in conjunction with the word "radiation" signifies that the substrate allows light to pass. From this, defendants argue, it follows that only a non-transmissive optical structure will do the opposite; that is, not allow light to pass through and reach the additional layer that covers the optical structure.

The specification further discloses that

[t]he faces of the optical structure have been made highly reflecting, for example in that after the structure has been pressed in the substrate a metal layer is deposited on it from vapour. The thickness of this metal layer is not of importance. Id., Col. 3, ll. 29-34 (emphases added). 11 Of more than passing significance, this language discloses that the optical structure need only be "highly reflecting." It does not require that it be impervious to light. This interpretation finds support in the later statement that the thickness of the metal layer deposited by vaporization is of no critical significance. If, as defendants argue, the invention disclosed was concerned with prohibiting light from passing through the optical structure altogether, the thickness of the reflective layer on the optical structure would have been crucial to the task.

11 This layer is referred to in Claim 1 as a "reflective layer extending over [the] intermediate areas and [the] depressions [in the optical structure] . . . ." '846 Patent, Col. 6, ll. 6-7.

It is clear (and also undisputed) that the reduction, and preferably the elimination, of dust interference was a goal of the '846 Patent.

By making the optical structure radiation-reflecting and the substrate radiation-transmitting, whilst the surface of the substrate more remote from the optical structure forms both the entrance face and the exit face for the read radiation, and by coating a surface of the optical structure more remote from the substrate with an additional layer, a simple record carrier is obtained which is well protected against dust particles and damage.

Id., Abstract. This in turn is supported by the language of Claim 1, which recites, in part,

the diameter of the beam is sufficiently larger than the diameter of said spot [on the optical structure] so that dust particles, scratches and the like on said other surface, do not interfere with the readout of information by the convergent beam focussed to said spot on said optical structure . . . .

Id., Col. 6, ll. 20-25.

Defendants point in particular to two statements in support of their contention that light does not pass through the optical structure. First, the specification discloses that

[t]he optical structure is read in reflection mode, which means that the read beam is modulated by reflection at the optical
structure. The additional layer is not traversed by the read beam and is only required to protect the optical structure from damage. Hence this layer need not satisfy exacting requirements. It need not be radiation-transmissive and need not have a constant thickness throughout its surface. In addition, it need not accurately engage the optical structure.

Id., Col. 2, ll. 28-36 (emphasis added). Second, defendants make note of the statement that

the record carrier may be read in a non-dustfree room, for example a living room, for dust particles deposited on the layer 10 have no effect, because the read beam does not pass through this layer.

Id., Col. 4, ll. 21-24 (emphasis added). 12 Because the specification and claim language provide no clear answer, the court will turn next to the prosecution history.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

12 In response to a question at his deposition about whether in 1971 and 1972 it was a matter of concern whether or not the read beam passed through the information layer (optical structure), Kramer responded, "I don't know. We couldn't care less. We couldn't care less. It's just that it should reflect enough that we have a good signal." Kramer Dep. at 120.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The original applied-for claim recited a disc-shaped record carrier with a "radiation-reflecting" optical structure. The Examiner rejected this claim over three patents issued to Feinleib: U.S. Patent Nos. 3,665,425 ('425 Patent); 3,696,344 ('344 Patent); and 3,696,386 ('386 Patent) (collectively, Feinleib). Unlike the invention in the '846 Patent, where information is permanently pressed into the disc and cannot be erased or rewritten, Feinleib's invention contained amorphous material that was recordable and rewritable, that is, actively recorded, erased, and rewritten by a light beam. The '386 Patent explains that the memory is read in the transmission mode, where the light source and the detector are positioned on opposite sides of the disc and the detector reads the differences in the intensity of the light. 13

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

13 The '425 Patent notes that the disc can also be read in the reflection mode.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

In response to the rejection over Feinleib, Philips argued that "[a]pplicant's information structure is totally reflecting and therefore cannot pass light," contrasting the prior art by arguing that in Feinleib, the light "would tend to pass through the information structure." Pros. Hist. (PH) 0387 (emphasis added). Philips continued that

[a]pplicant achieves dust immunity of the information structure with respect to both the entering and exiting beam by selecting a totally reflecting information structure and a transparent substrate of sufficient thickness that a converging beam focussed as a cone of light on the information structure has a diameter at the entry surface of the substrate that is larger than the dust particles and a diameter at the information structure that is smaller than such dust particles. The exit cone of light thereby has the same diameter at the surface of the substrate.

Feinleib is totally unconcerned with dust immunity, since in all of the embodiments shown in the drawings Feinleib locates his transparent information structure near the upper surface of the record carrier, thereby bringing the dust accumulating on the upper surface close to the focus of the radiation beam used for reading. Furthermore, . . . the information structure of his non-preferred embodiment is alternately reflecting and transmitting radiation in accordance with the recorded information. Thus, in his reflecting embodiment, d[i]scussed but not shown in Feinleib, the light focussed on the portions of the information structure between reflecting areas would tend to pass through the information structure to the
upper surface of the disc and would thereafter reflect off dust particles on the surface, thereafter propagating back through
the information layer and disturbing the reading of the recorded information. Applicant's information surface, however, is
totally reflecting and therefore cannot pass light to the nearby dust containing upper surface.

PH 0386-0387 (emphases added). According to Philips, dust immunity could only be achieved "by a proper combination of

The Examiner, however, maintained the rejection, responding that "as far as the Examiner knows nothing is totally
reflective." Philips subsequently replaced the words "totally reflecting" with the disputed term "non-transmissive,"
responding that

[o]bviously, the read beam does not pass through the layer 10 because it does not permeate the non-transmissive character
of the information layer prevents radiation from interacting with either dust or bubbles trapped between the protective layer
10 and the information layer 9 that would in the Feinleib apparatus scatter or reflect the light passing between reflective
portions of Feinleib's reflecting and transmitting areas of his information structure.

It is only by the non-transmissive nature of the information structure in the embodiment of Fig. 2 that permits Applicant
to avoid interference by dust particles and also permits Applicant to cover the reflective structure with a protective layer 10
to guard against scratching without the necessity for avoiding bubbles trapped between the information structure and the
protective layer. Such bubbles would in all probability form light reflecting and scattering [sites] for scattering or reflecting
light passing through the permeable areas of the reflective Feinleib information structure and passing back through that
structure to interfere with the reading of the information.

PH 0393. Philips further stated,

[t]he importance of the non-transmissive carrier of the information structure in applicant's disc is that after the beam
passes through the substrate and is intercepted by the information structure it can not thereafter continue through the
information structure to the backside of the record carrier where dust particles may also deposit.

PH 0492 (emphasis added).

Philips attempts to deflect these seemingly conclusive statements by putting the blame on its (prior) prosecuting attorney
who, according to Philips, did not fully understand the technology. However, later in the prosecution, after the Examiner
rejected the application yet again (on grounds of indefiniteness), Philips' new attorney argued that

[a]pplicant does not see how one can state more clearly that the "optical structure" does not transmit radiation incident on
it than by saying that it is "non-transmissive" in the manner specified in the claims. Nor can applicant understand how it
could be seriously contended that a man skilled in the art would not be able to determine the meaning of that expression.

PH 0621-0622. Philips defined the invention by explaining that

[t]he information (such as an audio or video signal) is contained in a plurality of depressions (a) spaced apart in the track
direction by intermediate areas (b). A reflective layer (9) extends completely over the intermediate areas (b) and the
depressions (a), rendering the entire optical structure reflective and non-transmissive to the incident radiation of the read
beam.

PH 0744.

Philips attempted to differentiate its invention by emphasizing that it read only in reflection mode, a matter that was given
scant attention by Feinleib. 14

The second function performed by the substrate is to maintain dust particles, scratches and the like sufficiently far from
the plane of the optical structure so that they do not interfere with the read-out of the information. This "dust immunity"
results from the fact that in applicant's construction the optical structure is reflective and is disposed on the surface of the
substrate which is remote from the source of the beam, so that the exterior surface (8) of the substrate defines both the
entrance plane for the incident beam and the exit plane for the reflected modulated radiation.

PH 0745.

14 The Federal Circuit, in reviewing two decisions of the Board affirming the rejection of the application for obviousness, noted that although Feinleib separately suggested (1) a device that employs an optical structure comprised of depressions formed in a substrate, and (2) an optical structure that operates in the reflective mode, there was no "teaching which would lead one skilled in the art to use those alternatives together." In re Kramer, 1991 U.S. App. LEXIS 682, 1991 WL 3392, at *2. The Federal Circuit therefore concluded that it was error for the Examiner to reject the application as obvious over Feinleib. Id.

Perhaps the most telling statement by Philips was made in an attempt to directly distinguish its invention from Feinleib.

In essence, the only similarity between the memory unit [in Feinleib] and the record carrier defined in [applicant's disc] is that they are both optical storage media. There the similarity ends. In applicant's disc the optical structure is non-transmissive and reflective. Feinleib's entire memory unit is transmissive (he recovers the information by detecting intensity variations of the light after it has passed through the medium).

PH 0751 (emphases in original). Here, Philips used the word "transmissive" to describe the manner in which Feinleib's memory unit (information structure)functioned, that is, that it read the information in transmission mode.

As the intrinsic evidence does not provide a definitive answer to the dispute, the court will finally turn to the extrinsic evidence. 15 As previously emphasized, "[i]n construing claims, the courts focus on what one of ordinary skill in the art at the time of the invention would have understood the term to mean." Mass. Inst. of Tech. v. Abacus Software, 462 F.3d 1344, 1353 (Fed. Cir. 2006) (citation omitted). Therefore, the court must determine what a person with an undergraduate degree (or the equivalent) in electrical engineering, physics, or optics would have understood the term "non-transmissive optical structure" to mean in 1972.

15 Courts are not prohibited from "examining extrinsic evidence, even when the patent document itself is clear. . . . Rather, [courts merely cannot] rely on extrinsic evidence in claim construction to contradict the meaning of the claims discernible from thoughtful examination of the claims, the written description, and the prosecution history -- the intrinsic evidence." Pitney Bowes, Inc. v. Hewlett Packard Co., 182 F.3d 1298, 1308 (Fed. Cir. 1999) (emphasis in original).

According to defendants' expert, Dr. Schlesinger, one of ordinary skill in the art in 1972 would have read the '846 Patent and the prosecution history to unequivocally state that the optical structure does not transmit light. Schlesinger Decl. P 6. More specifically, Dr. Schlesinger testified that the hypothetical person skilled in the art in 1972 would have understood that the optical structure should be made "as non-transmissive as possible and practical and that while theoretically and even actually some photons may pass this is irrelevant as they are not seen or detected on the other side of the structure." Id. P 7.

16 Dr. Schlesinger's testimony has particular force because he took care to contrast the technology available in 1972, before the CD was invented, to the present-day technology, which is at issue. With this in mind, Dr. Schlesinger noted that,

[b]ecause in 1972, each spot on an optical disk directly represented an increment of sound, as did each spot in the groove of a vinyl record, if the optical structure was transmissive then reflections from bubbles and dust over it would have been heard as crackles and pops as was the case for dust or scratches on the surface of a vinyl record. If the optical disk contained video information the result would have been "snow" or speckles on the screen as was the case with Laserdisc throughout the 1970s.
16 The court understands from Dr. Prucnal's testimony that a fundamental principle of optics states that "when light passes from one material to another, some of the light is reflected, some of the light is transmitted, and some of the light is absorbed." Prucnal Decl. P 6. Therefore, it follows that nothing can be absolutely 100 percent non-transmissive.

According to Dr. Schlesinger, the problems associated with dust and bubbles were obviated in 1980 when Sony announced (and patented) an interleaving and error correcting technology that eliminated the misreading of adjacent spots on the disc that resulted from bubbles, dust, or scratches on the surface. The patent teaching the "Sony solution" was included as an essential licensed patent in the CD licenses granted by Philips. See id. PP 17-22. According to Dr. Schlesinger, the Sony solution made it unnecessary after 1980 to incorporate in the CD-ROM an optical structure that did not transmit light. In post-1980 discs, the optical structure was able to "harmlessly transmit [a fraction of the beam] without the ill effects that were the concern of the '846 [P]atent back in 1972 and 1973." Id. P 24.

CONCLUSION

Giving due consideration to the testimony of the witnesses (including Kramer), the court construes the term "non-transmissive" to mean "an optical structure that reduces the transmission of radiant light to the greatest degree practicable consistent with the intended purpose."

2878

D. Non-Volatile Configuration Memory

The module of Claim 1 includes "a non-volatile configuration memory," the meaning of which is in dispute. Digi asserts that "non-volatile configuration memory" should be construed as "data storage (either internal or external to the module) for configuration data which persists after the module is powered down." Lantronix maintains that this term should be construed as "a computer memory device, located within the module, that does not lose its memory when power to the memory is turned off. Claim 1 requires that such a memory contain configuration information and instructions for implementing an API specific to the device." The parties agree that a non-volatile memory is one that retains its stored data after power is shut down. The dispute arises over whether the data storage needs to take place within the module, or if it may exist outside the module.

In support of its proposition that the non-volatile configuration memory can be located either internal or external to the module, Digi cites to language in the patent specification that describes different embodiments of the patent. Specifically, Digi points to the following language:

A configuration memory 86 on the chip provides a flash or other non-volatile memory which may be programmed by the user with configuration data, byte code data, and other information specific to a particular application or device. Alternatively, an EEPROM interface 88 allows this data to be stored on an external non-volatile device, such as an EEPROM.

(Id. at c. 16, 11: 15-22.)

For example, the same chip is used in a small digital camera as is used in a large industrial machine, the only difference being the specific data and/or instructions stored in the configuration memory 86 and/or in an external EEPROM. For example, the configuration memory 86 and/or the external EEPROM might store an application specific applet customized for the device.

(Id. at c. 16, 11: 30-36.)
In the case of automatic configuration, the chip is initialized using configuration data stored in an internal configuration memory and/or in an external memory (e.g., EEPROM) connected directly to the network interface chip. (Id. at c. 16, 11: 59-63.)

Lantronix, on the other hand, asserts that the alternative, EEPROM embodiment is not supported by the claim language. Specifically, Lantronix points to the language of Claim 1, which claims a "single self-contained and autonomous module . . . wherein the module comprises . . . a non-volatile configuration memory." (Id. at c. 18, 11: 41-53.) Lantronix contends that in order for the module to be "self-contained," the memory must be on or within the module.

The Court agrees, in part, with Lantronix's construction. The Court finds that the claim language requires that the memory be either on or within the confines of the module. In order to give full meaning to the terms "self-contained," "wherein," and "comprises," and to remain consistent with the Court's construction of the term "self-contained," the Court must read Claim 1 to require memory that is contained within the confines of the module.

The Court does not agree with Lantronix, however, that the EEPROM embodiment is inconsistent with the language of Claim 1. The specification describes two alternate embodiments of the patent, one with internal memory and another with EEPROM memory that is "connected directly to the network interface chip." (‘192 Patent at c. 16, 11: 59-63.) This is not inconsistent with the requirement that the module, including its non-volatile configuration memory, be self-contained. In the manner described in the EEPROM embodiment, the main network interface chip has the EEPROM directly attached to it. This EEPROM is still inside the same physical confines of the module and thus still consistent with the language of Claim 1.

With these considerations in mind, the Court construes "non-volatile configuration memory" to mean "data or memory storage, located within the module, that persists when the module is powered down."

1. "Non-volatile Memory."

Consistent with the intrinsic evidence and plain meaning of the term, "non-volatile memory" shall mean "memory that retains stored information in the absence of power."

"[S]ectors" (claims 1 & 10)

As a starting point, both SanDisk and Ritek agree that a "sector" is the "basic unit of erase." The Federal Circuit endorsed this interpretation. SanDisk Corp v Memorex Prods, Inc, 415 F3d at 1281. Judge Breyer also adopted this construction in the Lexar litigation. In full, Judge Breyer's construction was:

A "non-volatile memory sector" is the basic unit of erase for the non-volatile memory. It is not limited to 512 bytes of user data and 64 bytes of overhead data.

SanDisk Corp v Lexar Media, Inc, 1999 U.S. Dist. LEXIS 2682, 1999 WL 129512, 3 (ND Cal 1999). The parties agree with this construction as far as it goes, but this does not end their dispute.

The dispute is whether the construction of "sector" should include some reference to size or number of memory cells. JCC (Doc # 371), Ex A at 6. SanDisk proposes that the court adopt Judge Breyer's construction and add that a sector is "further
understood to refer to a substantial number of memory cells." Id. Ritek contends that SanDisk is playing "fast and loose with the courts" since they previously argued that "sector" was not limited to the size recited above. Ritek Br (Doc # 148) at 15.

SanDisk's position in Lexar (that size was not limited to a specified value) was essentially arguing that the example provided in the specification should not be read into the claim. See Lexar, 1999 U.S. Dist. LEXIS 2682, 1999 WL 129512, 3; Berta Reply Decl (Doc # 397-2), Ex A at 8-12. This is consistent with arguing that size must be a certain minimum number of cells, i.e., more than an insubstantial number. Ritek's judicial estoppel argument lacks merit.

Ritek also argues that inserting SanDisk's proposed language is incorrect because the specification refers to "Flash EEprom" and traditional (non-flash) "EEprom." Ritek argues that since the invention did not exclude EEprom, and in fact refers to EEprom, that the invention relates to both flash EEprom and traditional EEprom. This distinction is significant, Ritek argues, because traditional EEprom memories would only allow sectors to contain small units of memory.

The court need not visit the issue whether the invention relates to flash EEprom only or both flash and traditional EEprom because it is unnecessary to insert SanDisk's proposed addition ("further understood to refer to a substantial number of memory cells") in the court's construction. Nothing in the construction which the parties agree to ("the basic unit of erase") precludes the size of the "basic unit of erase" from being a "substantial," according to one having ordinary skill in the art, "basic unit of erase." The court reaches this conclusion without deciding whether Ritek's argument, that the invention is not limited to flash EEprom memories, has merit. The court also reaches this conclusion without deciding whether SanDisk's arguments that one having ordinary skill in the art would understand the invention to relate only to flash EEprom memories.

Since Ritek does not argue, as Lexar did, that a sector was limited to a described embodiment in the specification (512 bytes of user data and 64 bytes of overhead data), it is unnecessary to include that clarification here.

Accordingly, the court adopts the following construction for "sector" means:

The basic unit of erase.

2881

SynQor argues that operation in "normal" mode means how the device usually operates, and that it is proper to define the term in affirmative ways rather than negative ways. Thus, SynQor construes the term as "the mode in which the device usually operates when it is on." Defendants argue that the language "in which the device usually operates" proposed by SynQor has no support in the specification and adds confusion, not clarity, to the definition. Defendants also argue that it would render the claim indefinite because one would not know whether a system was covered by the patent until one monitored the system for a long enough time to determine what "usually" happened. Defendants argue that the specification only defines non-normal operation is exclusory terms, such as excluding start-up and fault conditions, whereby "normal operation" should be everything else.

The parties agree that during normal operation excludes "start-up and fault conditions such as over-current conditions." Further, the parties agree that it also excludes "shutdown" conditions. The "during normal operation" language, and any differences between "normal" and other modes, is only found in the '021 patent. Regarding the term "during normal operation," the parties agree when it is not normal operation, but disagree as to when the isolation stage is affirmatively in normal operation. The Court rejects the "usually operates" language proposed by SynQor because there is no support for such language and it is ambiguous. However, the '021 patent references both the "normal state of operation" and the "normal mode of operation." See '021 patent 4:37, 5:60. The Court finds that affirmatively stating that it is a "normal mode of operation," rather than just "a mode" of operation conforms to the language of the specification. Thus, the Court construes the term "normal operation" to mean "a normal mode of operation that excludes start-up, shutdown, and fault conditions such as over-current conditions."
F. "The normal operation . . . is interrupted to convey"

I adopt the following definition, based on the plain meaning of the words in the phrase: "the regular, standard, or natural function or working . . . is stopped so that it can be resumed at a later time, in order to convey . . ."

In several claims, the patent purports to describe a method of notifying an account holder about a pending transaction, not via direct communication over a telephone or computer network, but rather through some form of broadcast medium such as a "television, radio, car radio, computer, etc." '725 Patent, Col. 41:35-37. Such a transmission would reach the television, radio, or other device and "interrupt" its "normal operation" to convey the message which the Central Processing Computer wished to send (presumably, a message that the holder's account was being debited).

This phrase is not defined in the patent, and neither party suggests that these words are a term of art in any industry related to the invention. The phrase describes a process by which any one of a list of common broadcast devices -- a "television, radio, car radio, computer, etc." -- can be used to notify the end user of a transaction involving their account. It is common knowledge that such consumer devices communicate over a number of broadcast media: radio waves, television signals, computer networks, cable networks, satellite communications, and so forth. Since the patent does not specify how this process of interrupting a broadcast would work technically, I conclude that the phrase does not have a technical meaning, but rather embraces any means of interrupting a broadcast signal.

Defendants offer:

the standard functioning of the communications device is suspended while the information and/or message to the account holder of the signal being sent to the communications device is substituted for the functioning of the communications device simultaneously with the execution of the transaction by the central processor or upon the occurrence of the triggering event.

I would have to reject that definition simply because it is overly cumbersome and redundant. For example, they include a requirement that an interruption take place "simultaneously with the execution of the transaction... or upon the occurrence of the triggering event," although neither the plain meaning of the words nor their context imposes such a requirement.

Plaintiffs offer:

The regular, standard, or natural function or working... is disrupted, the normal flow of the operation is broken and can be resumed at a later time or is stopped so that it can be resumed, in order to convey...

This definition is far more direct. The parties seem to agree that "normal operation" means the standard functioning of the device. They further agree that the word "convey" does not need to be construed.

Plaintiffs' unwieldy interpretation of "interrupted," -- "is disrupted, the normal flow of the operation is broken and can be resumed at a later time or is stopped so that it can be resumed," -- is overly verbose, and is apparently based on a technical definition of the word "interrupt" from the world of computer science. The phrase, "stopped so that it can be resumed at a later time" is sufficient.

Therefore, "the regular, standard, or natural function or working... is stopped so that it can be resumed at a later time, in order to convey..." is the definition I adopt.
1454 (Fed. Cir. 1998) (en banc). In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

PC Connector accuses the district court of having improperly construed the terms "normally connectible" and "conventional" in claim 1, and "traditionally connectable" and "standard" in claim 10, as fixing the peripherals and computer I/O ports described by such terms to be those in existence at the time of filing in 1988. According to PC Connector, the terms merely clarify the manner of connecting peripherals to a computer--i.e., through dedicated I/O ports typically clustered at the rear of the chassis-without imposing a time-based limitation on the I/O technologies involved. We disagree.

PC Connector essentially advances a construction that would require the words "normally," "conventional," "traditionally," and "standard" to be redefined as specifically referring to--or, depending on the context, synonymous with being connectable to--a dedicated computer I/O port. We conclude that the record is unable to support this departure from the ordinary meanings of those words, whose descriptive properties are implicitly time-dependent. A claim cannot have different meanings at different times; its meaning must be interpreted as of its effective filing date. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 986 (Fed. Cir. 1995) (en banc) ("The focus is on the objective test of what one of ordinary skill in the art at the time of the invention would have understood the term to mean."). We also find nothing in the written description that amounts to a clear attempt by the patentee to impart any special meaning to the words "normally," "conventional," "traditionally," or "standard." Likewise, in the prosecution history, we do not read the patentability arguments that were made specifically to distinguish a test fixture as having effected the particular redefinition now advanced on appeal. As a consequence, the terms "normally," "conventional," "traditionally," and "standard" are governed by their ordinary and customary meanings, and that, in view of their implicit time-dependence, the district court did not err in construing the literal scope of the claim limitations qualified by those terms as being limited to technologies existing at the time of the invention.

We find nothing in the written description that amounts to a clear attempt by the patentee to impart any special meaning to the words "normally," "conventional," "traditionally," or "standard." Likewise, in the prosecution history, we do not read the patentability arguments that were made specifically to distinguish a test fixture as having effected the particular redefinition now advanced on appeal. As a consequence, the terms "normally," "conventional," "traditionally," and "standard" are governed by their ordinary and customary meanings, and that, in view of their implicit time-dependence, the district court did not err in construing the literal scope of the claim limitations qualified by those terms as being limited to technologies existing at the time of the invention.

PC Connector's argument that the dictionary definitions of "normally," "conventional," "traditionally," and "standard" contain no explicit reference to a time limitation is not persuasive, as their time-related significance is implicit from their ordinary usage--just as other words are implicitly not time-related. A comparison of the words "conventional" and "dedicated" is instructive in this regard, as PC Connector's briefs appear to treat them as interchangeable and coterminous in claim scope, when, in fact, they are not. To illustrate, a present-day USB port may be described as a "dedicated" I/O port within the ordinary meaning of "dedicated" as that word would be used to characterize the I/O ports found on a computer built in 1988, yet it would not be considered "conventional" back then, even though it is "conventional" today. (Martin Aff. P11; J.A. 264). Thus, unlike the word "dedicated," the word "conventional" necessarily has a meaning specific to the time of filing. Accordingly, the district court did not err in its claim construction.

19. "transformer that is not driven into saturation" ('083 and '702 patents)

SynQor's Proposed Construction
"transformer connected in a power converter in a manner and configuration such that the transformer's magnetic flux density level is less than its

Defendants' Proposed Construction
INDEFINITE for system claims.
This term is also subject to a motion for summary judgment of indefiniteness filed by some of the Defendants. See Dkt. No. 432. Defendants argue that the term is indefinite in apparatus claims because the claim limitation describes a method of use of the transformer. Defendants rely on the Federal Circuit case of IPXL Holdings, L.L.C. v. Amazon, Inc., 430 F.3d 1377, 1384 (Fed. Cir. 2005) (holding that the claim language of "the user uses the input means" is indefinite). In that case, the Federal Circuit held that an apparatus claim cannot claim a particular use of an apparatus because determination of infringement of an apparatus claim should be determinable at the time the apparatus is made and sold. See id. In other words, claims that mix method and apparatus limitations are indefinite because they present a lack of clarity as to when the subject matter claim would be infringed. See id. Defendants argue that driving or not driving a transformer into saturation is an act which may or may not occur during the use of a product. Defendants argue that there is nothing inherent to the structure disclosed in the specification or the claim that would guarantee that the transformer would not saturate. Defendants argue that a transformer might or might not be driven into saturation, depending on how the transformer is used, and thus, there would be no way to predict if the product when sold will eventually infringe this limitation. Defendants argue that if the claim had stated "cannot be driven into saturation," or "adapted to" or "capable of," as opposed to "is not driven into saturation," then it would not be indefinite. Defendants argue that even though an accused power converter's transformer may be capable of being driven into saturation, the power converter meets the limitation if when actually used it "is not driven into saturation" during certain types of uses. Defendants argue that SynQor's addition of the term "during normal operation" makes the claim even more problematic, because then one has to watch how the product operates in a particular environment to see how the product is used.

SynQor argues that the IPXL case is narrow and rarely applied. SynQor argues that many courts have rejected attempts to invalidate claims by IPXL on claims containing functional language. SynQor argues that IPXL does not apply to functional language that is used by the patentee to describe the functions of, or to further elaborate on capabilities of, the underlying claimed apparatus. SynQor argues that the language at issue is clearly used to describe the structure and capabilities of the claimed apparatus and is not a method step. SynQor argues that it was well-known in the art that the structure of the transformer, as well as related circuitry, could vary depending on whether it was designed to be driven into saturation or not. SynQor argues that the claim language is part of a description of comparable structure in the claims which describe the functions performed by the control circuitry in combination with the other structural elements of the "non-regulating isolating step-down converter." SynQor argues that the specification describes the structural aspects of the circuit that cause the transformer not to be driven into saturation. SynQor argues that the claimed language is clearly not a method step but describes how the "control circuitry" and related power components, such as the transistor and the transformer, are configured to be capable of operating in a particular way, i.e., "not driven into saturation."

The Court agrees with numerous other courts in that the holding in the IPXL case is very limited. For the instant dispute the Court finds that the IPXL case does not apply because the single claim does not improperly cover both an apparatus and a method of use of that apparatus. Claim 1 of the '083 patent, illustrative of the disputed term, claims "[a] non-regulating isolating step-down DC-DC power converter . . . comprising: 1) at least one isolating step-down transformer that is not driven into saturation, . . . " The Court finds that the language "is not driven into saturation" does not describe a method step and instead is used to describe the structure and capabilities of the claimed apparatus. Such use of language in the claims is not improper. See Microprocessor Enhancement Corp. v. Texas Instruments, Inc., 520 F.3d 1367, 1375 (Fed. Cir. 2008). Further, the specification provides that it is well-known in the art "to keep the lengths of the two halves of the cycle well balanced to avoid imposing an average voltage across the core and driving it into saturation." '083 patent, 15:40-44. The Court finds that one of ordinary skill in the art would understand the specification to describe structural aspects of the circuit that insure that the transformer does not saturate. Still further, SynQor offers various prior art references, including references cited during prosecution of the patents-in-suit, providing support for the proposition that it is well known in the art that transformers and related circuitry in a power converter can be designed to not saturate. This Court agrees and finds that one of ordinary skill in the art would understand that power converters are designed to insure that the transformer does not saturate. The Court rejects Defendants' arguments to the contrary. Thus, the Court finds that one of ordinary skill in the art would understand that the claimed language describes the structure and capabilities of the claimed apparatus and is not merely a method step.

Finding that the term is not indefinite, the Court must next construe the term. Defendants have provided no competing construction to SynQor's proposed construction. Consistent with previous terms and for the same reasons, the Court rejects
SynQor's attempt to add "during normal operation" to this term when there is no basis for it in the claims or the specification. SynQor argues, without any dispute from Defendants, that saturation is a phenomenon that occurs when the magnetizing current flowing through a transformer exceeds a certain threshold, at which point the magnetic material no longer amplifies the applied magnetic field and an increase in the applied external magnetizing field cannot increasethesaturation of the transformer. The court finds that one of ordinary skill in the art would understand the term saturation in the context of the claims to generally mean the concept advanced by SynQor. 

The Court construes "transformer that is not driven into saturation" to mean "transformer that is connected in a manner such that the transformer's magnetic flux density level is less than its saturation flux density level."

2885

C. "Optical Demultiplexer Through Which the First Optical Line Interface Is Not Optically Coupled To the First Transponder"

For the following reasons, this court construes the claim term "optical demultiplexer through which the first optical line interface is not optically coupled to the first transponder" in claims 1 and 6 to mean:

The first optical line interface does not send optical information to the first transponder through the optical demultiplexer. Alternatively, the first optical line interface does not receive optical information from the first transponder through the optical demultiplexer.

Both claims 1 and 6 of patent '772 require that the first optical line interface and the first optical transponder are coupled. Claim 1 reads, "a first optical interface optically coupled to a first transponder." Claim 6 reads, "a first transponder optically coupled to the first optical line interface." Applying the definition for "optically coupled to," stated in A, supra, claims 1 and 6 become "a first optical line interface sends optical information to a first transponder and/or a first optical line interface receives optical information from a first transponder." With this rephrasing, the ordinary language of the term dictates that the first transponder and the first optical line interface do not send or receive optical information between each other through the optical demultiplexer.

Patent '772's specification supports this interpretation of the term by presenting a clear illustration of the situation contemplated by the language "optical demultiplexer through which the first optical line interface is not optically coupled to the first transponder" at Figure 3. Specifically, Figure 3 shows an optical line interface labeled 202 coupled to a transponder labeled T in the lower right hand corner of the illustration. The optical line interface and the transponder transmit optical information between each other via the following path: from input/output line interface 202 along line 320 to multiplexer/demultiplexer 204, then along line 214 to multiplexer/demultiplexer 216, and finally to transponder T. (See '772 patent, Fig 3.) Figure 3 also shows an optical multiplexer labeled 208 that is not situated along the transmission path that couples the optical line interface and the transponder. (Id.) The illustration at Figure 3 therefore shows that the first optical line interface does not send optical information to the first transponder through the optical demultiplexer. Alternatively, the first optical line interface does not receive optical information from the first transponder through the optical demultiplexer.

2886

G. "whereby said caller is not required to be within a particular network for making calls"

Stanacard argues that this term should be given its plain and ordinary meaning or, in the alternative, be construed to mean "whereby the caller is not required to use any particular type of network such as private branch exchange, landline, mobile, or Internet."

Rebtel argues that this claim language is insolubly ambiguous, and therefore invalid, on the grounds that the '156 Patent fails to define with sufficient specificity what constitutes a "network." As a result, Rebtel argues, a party cannot know whether or not it is "within a particular network for making calls."
The point of this claim limitation, however, is not to require that a caller be situated within a particular type of network. Rather, it states the opposite – that what is claimed is an open system that does not restrict the caller to any specific network when calling into the claimed system. See '156 Patent, col. 1:29-31 ("In addition, a calling card caller is typically able to utilize any telephone within a general geographic area to complete the telephone call . . ."). This is consistent with Stanacard's arguments before the patent examiner, in which it distinguished the claimed invention over the Bedingfield reference by noting that the claimed invention did not require that the caller be within a particular network for making calls. See '156 Patent File History, Comments on Stmt of Reasons for Allowance, Jan. 11, 2008, at 1. Moreover, the specification makes clear that this claim limitation refers to events occurring prior to the caller's connection with the claimed system and does not encompass the utilization of either Stanacard or Rebtel's "networks." See, e.g., '156 Patent, col. 2:22-26 ("The environment includes an electronic device 111 (e.g. a land line telephone, a cellular telephone, a satellite telephone, and the like), a caller interface 115, a network 120 (e.g., a local area network, a home network, the Internet, telephone network) . . . ."); Fig. 1.

The claim language, read in the context of the specification's disclosure, establishes that this limitation excludes from claimed material any system that restricts the caller to a specific network, of any type, when dialing the assigned incoming telephone number and placing a call into the claimed system. Because the claim language conveys the meaning of this limitation, no construction is required and "whereby said caller is not required to be within a particular network for making calls" is given its plain and ordinary meaning.

Trilogy contends that these terms mean "a relationship that cannot be put into effect." Selectica contends that these terms mean "a relationship is notActivatable if the selection of certain left-hand side items results in an invalid configuration state." The patents explain that "configuration system 212 also ensures that no relationship that will put the configuration into an invalid state can become active. . . . If a relationship will make a configuration invalid, it is made notActivatable." 651 patent, col. 13, 11. 11-16. The court construes the term "NotActivatable/making said relationship NotActivatable" to mean "a relationship in which the selection of certain left-hand side items results in an invalid configuration state."

"Notification Alert System" ('910 Patent)

The '910 patent includes the term "notification alert system" in independent claim 1. The revised joint claim construction brief requests the Court to determine whether the term, which also does not use the word "means," is subject to means-plus-function analysis, and Yodlee's brief argues the point. However, neither CashEdge's brief nor its expert address this term. There is also no admission from Yodlee's expert that this term was coined, as there is for "gatherer." See Papakonstantinou Decl. PP 9, 18. Thus, there is no evidence before the Court that would rebut the presumption against means-plus-function construction. Accordingly, the Court finds that this term is not subject to 35 U.S.C. § 112 P 6.

A. "A set of notification rules"

Independent claims 13 and 23 both recite a step of "defining a set of notification rules for the subscriber rental queue." Plaintiff contends that the term "a set of notification rules" should simply be construed as "a set of rules relating to notifications sent to the subscriber." Defendants contend that this term is indefinite and cannot be construed, or alternatively, to the extent that the term is amenable to construction, it should be construed to mean "a set of rules governing the transmittal and content of notifications about queue status sent to the subscriber."
1. Indefiniteness

A patent specification must "conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. "[T]he purpose of the definiteness requirement is to ensure that the claims delineate the scope of the invention using language that adequately notifies the public of the patentee's right to exclude." Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005) (citation omitted). The definiteness requirement "does not compel absolute clarity. Only claims not amenable to construction or insolubly ambiguous are indefinite." Id. (citation omitted). "Thus, the definiteness of claim terms depends on whether those terms can be given any reasonable meaning." Id. "If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." Exxon Research & Engineering Co. v. United States, 265 F.3d 1371, 1375 (Fed Cir. 2001). "By finding claims indefinite only if reasonable efforts at claim construction prove futile, we accord respect to the statutory presumption of patent validity . . . and we protect the inventive contribution of patentees, even when the drafting of their patents has been less than ideal." Id.; see also Halliburton Energy Services, Inc. v. M-I LLC, 514 F.3d 1244, 1249-50 (Fed. Cir. 2008) (holding that an accused infringer must show by clear and convincing evidence that "a skilled artisan could not discern the boundaries of the claim based on the claim language, the specification and the prosecution history, as well as her knowledge of the relevant art area").

The Court finds that defendants have not met their burden of providing clear and convincing evidence that the term "a set of notification rules" is not amenable to construction or is insolubly ambiguous. Defendants argue that while the asserted claims describe "notification rules" and "replenishment control rules" as separate sets of rules, the specification fails to define the scope of these terms so that it is impossible, even for one of ordinary skill in the art, to discern which features described in the specification correspond to "notification rules" and "queue replenishment control rules." Defendants note that the "queue control options," "threshold options," "notification options," "queue monitoring parameters," "queue replenishment parameters," and "queue management options" recited in the detailed description ('243 patent, 6:41-65, 8:27-36, 9:34-64, 10:41-11:7) appear to be related to the "notification rules" and the "queue replenishment control rules" of the claims. However, defendants contend that the specification fails to distinguish the various "options" and "parameters" associated with "notification rules" from those associated with "queue replenishment control rules" so that the specification confuses rather than clarifies the meaning of these terms. For example, defendants point out that in Figure 2 of the '243 patent, while the user interface screen 230, showing various notification options that can be selected by a user, appears to correspond to "notification rules," the option "No notice--autoship" does not relate to "notification rules" and instead relates to "queue replenishment control rules" because under this option, a queue would be automatically replenished without any notification to the user. Thus, defendants argue that the specification does not provide any guidance for a person skilled in the art to discern the respective boundaries of "a set of notification rules" and "a separate set of queue replenishment control rules."

Plaintiff argues that one of ordinary skill in the art will be able to understand from the description of user options and parameters displayed on the user interface screens of Figure 2, the underlying notification rules and queue replenishment control rules defined by the system operator. Plaintiff specifically notes that although the interface screen 230 with the notification options may relate to both notification rules and queue replenishment control rules depending on the option selected, one of ordinary skill in the art can easily distinguish the underlying notification rules and the queue replenishment control rules based on the notification options. For example, if the option "No notice--autoship" is selected, the notification rule will be to send no notice, and the queue replenishment control rule will be to select and add a new title to the corresponding subscriber queue. Although the drafting of the '243 patent has been less than ideal and the task of construing the claim terms may be formidable, defendants have not provided clear and convincing evidence that the claim terms are insolubly ambiguous. In other words, reasonable efforts at claim construction would not prove futile and one of ordinary skill in the art would be able to discern the boundaries of what is being claimed based on the claim language, the specification, the prosecution history, and his or her knowledge of the relevant art. Accordingly, the Court finds that the term "a set of notification rules" is amenable to construction.

2. Claim Construction

As for the construction of the claim term, plaintiff proposes that "a set of notification rules" be construed to mean "a set of rules relating to notifications sent to the subscriber," whereas defendants propose that it be construed to mean "a set of rules
governing the transmittal and content of notifications about queue status sent to the subscriber." Plaintiff argues that
defendants are attempting to unnecessarily narrow the scope of the asserted claims by adding extraneous limitations that the
notification rules (1) govern the transmittal of notifications, (2) govern the content of notifications, and (3) require the
notifications to be about queue status. Plaintiff contends that the notification rules need not necessarily "govern" the
transmittal and the content of the notification. Plaintiff explains that the notification rules may simply "relate to" whether or
d to send a notification, the type of notification to be sent, or the content of the notification. In sum, plaintiff argues that
the definition of "a set of notification rules" should not be limited by any language that is not explicitly recited in the
asserted claims.

Defendants contend that construing "a set of notification rules" as "a set of rules relating to notifications sent to the
subscriber" will obscure the difference between notification rules and queue replenishment control rules because virtually
all aspects of media queue rental systems have some relation to notifications. First, defendants point out that the term "rule"
is commonly defined as "a prescribed guide for conduct or action." 4 Thus, the notification rules must do more than "relate
to" notifications, and must actually "govern" the notifications sent to the subscriber. Defendants argue that such construction
is fully supported by the specification. Specifically, defendants note that the detailed description recites that "the subscriber
identifies specifically what type of policies/rules should be employed--i.e., what notice and action should be sent to
him/her." 423 patent, 15:41-44. Defendants also note that both claims 13 and 23 require that the notification rules be used to
determine when it is necessary to send a notification. Id. 27:36-39, 28:26-29.

Second, defendants argue that the notification rules must govern notifications about the status of the subscriber's queue, not
just any notification. Defendants assert that construing the notification rules as otherwise would be inconsistent with the
claim language and the descriptions in the specification. Particularly, defendants note that both claims 13 and 23 recite in
their preambles "[a] method of electronically notifying a subscriber to a content provider of activity in a subscriber rental
queue associated with the subscriber," 5 and further specify in the claim body that the notification rules are "for the
subscriber rental queue" and are used to "monitor the subscriber's queue." Id. 27:15-19, 28:14-18. Defendants also note that
the summary of the invention states one of its objectives as providing "a notification system that alerts and informs

Third, defendants contend that the claimed notification rules should be limited to rules governing the transmittal and content
of notifications sent to the subscriber. Specifically, defendants assert that the scope of the claimed notification rules is not
clear from the plain meaning of the claim language so that it should be construed in light of relevant descriptions in the
specification and the prosecution history. Defendants rely on the descriptions of Figures 2, 3A, and 3B showing illustrative
features of the claimed invention for prompting a subscriber to select a desired notification option from plural notification
options. Defendants assert that the subscriber's selection of a notification option determines how and when a notification
should be sent to the subscriber as well as what should be included in the notification. '243 patent, 9:34-45. Defendants also
rely on the fact that during prosecution of the '243 patent, the patent examiner described the notification rules as rules "that
will notify the subscriber when the ordering of the queue has been changed by the monitoring queue." First Office Action 6,
The Court finds that while plaintiff's construction is overly broad, defendants' construction is too narrow. Defendants correctly argue that the notification rules cannot be construed as merely "relating to" notifications sent to a subscriber and must actually govern or constrain some aspect of the notifications. Also, it is evident from the claim language and the intrinsic evidence that the notification rules are about the subscriber's queue status, and not any notification. Further, since a notification by its plain meaning implies the transmittal or communication of information, the Court finds it appropriate to construe the term "notification rules" to at least govern the transmittal or communication of the notifications to the subscriber. However, the Court is not persuaded by defendants' argument that the intrinsic evidence requires construing the notification rules to govern the content of notifications. Although defendants point to Figures 3A and 3B of the '243 patent to demonstrate how the content of notifications can vary depending on the notification option selected by the subscriber, plaintiff correctly argues that this constitutes improperly "reading a limitation into the claim from the specification." See Comark, 156 F.3d at 1187; Phillips, 415 F.3d at 1323. Therefore, the Court shall construe "a set of notification rules" to mean "a set of rules governing the transmittal of notifications about queue status sent to the subscriber."

H. Independent Claim 1 - "notifying"

As to the disputed term "notifying" in independent claim 1, the magistrate judge recommended that the word "notifying" be construed as: "Giving notice to." First Report at 7, 12. No objections have been filed with respect to the magistrate judge's proposed construction. After careful review of the magistrate judge's findings and conclusions, record, legal briefing, and applicable law, the court determines that the magistrate judge's proposed construction of "notifying" in independent claim 1 is correct, and it is hereby accepted as the court's construction of "notifying."

5. notifying completion (claim 9)

Plaintiff's construction: "providing notice that the formatting process is complete, when in actuality it is not"

Defendants' construction: "outputting a message to the host computer that the formatting process is complete, when in actuality it is not"

The dispute is whether it is the "host computer" that must be notified. Defendants say "yes"; plaintiff says that it does not matter who or what gets notified so long as someone or something is notified. For this term, the claim language supports plaintiff because there is no indication in the claim itself that the host computer, or any other particular entity, must receive the notification.

Defendants make several related arguments why a "host computer" limitation should be read into the claim. First, they say that when the specification addresses the issue of notification, it is always notification to the host computer. Each of these references is nearly the same: "the controller 9 outputs . . . a message to a host computer so as to notify a user (the host computer) that the formatting process has been completed." '955 Patent, col. 8, Ins. 7-10, 33-35; col. 9, Ins. 3-6, 54-58; col. 10, Ins. 33-37; col. 11, Ins. 39-43. However, as plaintiff points out, each of these references is in the context of a discussion of a preferred embodiment, which cannot be used to limit the claim. In arguing to the contrary, defendants cite Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1367 (Fed. Cir. 2007), in which the court held that particular "statements are not descriptions of particular embodiments, but are characterizations directed to the invention as a whole." Anderson does not help defendants because, in that case, the specification included statements that were not limited to particular embodiments but discussed a restriction that was "require[d]" by the invention as general matter. Id. That is not the case here.

Second, defendants say that the purpose of the invention suggests that it is the host computer being notified in claim 9.
Defendants write: "If the notification is not provided to the host computer, the host computer will believe that the drive is busy formatting and will not accept read or write requests, defeating the purpose of the invention." Dkt. # 183, at 10-11. As I understand defendants' argument, it is that (1) the host computer decides whether to "accept" a read or write request; (2) the host computer cannot accept such a request unless it knows that drive is finished formatting; and therefore (3) if the host computer does not receive notice of completion of formatting, it cannot read or write a disk.

In my view, this argument falls apart at its second premise. The point of the invention is to allow other, higher priority processes to be performed even after formatting has started. Thus, the host computer does not need notice that formatting has finished in order to accept another request. If defendants intended to make a different argument, they have not made it clear.

In addition, plaintiff disputed the accuracy of defendants' first premise at the hearing, saying that it is not necessarily the case that the host computer controls the reading and writing process; it could be a network, a controller or a program on the drive. Dkt. # 186, at 51. Defendants disputed this claim, saying that "any request to the drive would have to come through a host computer." Dkt. # 186, at 60. Defendants may be correct as a matter of fact and they may present evidence on this question at the summary judgment stage if they believe it is relevant to an issue of infringement or invalidity. However, defendants point to nothing in the claim itself that requires the host computer either to control the recording process or to receive notification that formatting is complete. Accordingly, I conclude that it would be incorrect to read in a "host computer" limitation into claim 9 as a matter of claim construction.

Both parties include in their proposed constructions the phrase "when in actuality it is not" for the idea that the notification occurs before formatting is actually complete. Again, this part of the construction is redundant because this idea is communicated by the claim itself. '955 Patent, col. 13, Ins. 47-49 ("notifying completion of the formatting process before the formatting process is completed"). Because this phrase is unnecessary and redundant, it should not be part of the construction.

This reduces plaintiff's construction to "providing notice that the formatting process is complete," but this does no more than restate the claim using a few additional words. (Defendants replace "notifying" with "outputting a message," but they provided no argument why that phrase was preferable. In any event, I do not think, that the phrase adds any clarity to the claim.) Accordingly, I conclude that the term "notifying completion" does not require any construction.

**Court's construction: No construction needed.**

2. Nullifying Decoded Data (Claim 1)/Nullify Decoded Data (Claim 8)

Matsushita argues "nullifying decoded data"/"nullify decoded data" should be construed as "rendering decoded data null as data." Mediatek argues "nullifying decoded data"/"nullify decoded data" should be construed as "eliminating data from frame buffer memory by replacing it with a null value not used for display, and setting flags indicating that there is no data in the corresponding memory to be displayed."

The Court finds, for the reasons stated by Matsushita, that "nullifying decoded data"/"nullify decoded data" is properly construed as "rendering decoded data null as data rather than skipping data yet to be decoded." 4

4 The additional clarifying language is derived from the prosecution history, wherein Matsushita distinguished the instant invention over prior art. (See Huang Decl. Ex. E at MTK1109352) ("While [the prior art reference] skips data to be decoded … to nullify the same when a reproduction speed is varied, it does not delete a decoded memory data utilized for a display …") (emphasis in original).

Construing the Disputed Limitations of Claim 1

As far as claim construction is concerned, our task is to identify the claimed function and the corresponding structure of each of the three disputed limitations of claim 1. We begin with the first of the three disputed limitations: "means for assigning a plurality of numbers representing said angular positions of said reel, said plurality of numbers exceeding said predetermined number of radial positions such that some rotational positions are represented by a plurality of numbers."

This limitation contains the terms "angular positions," "radial positions," and "rotational positions." The district court construed each of these terms to refer to stop positions of the reel. Neither party challenges that construction.

The claimed function of the "means for assigning" limitation is "assigning a plurality of numbers representing said angular positions of said reel, said plurality of numbers exceeding said predetermined number of radial positions such that some rotational positions are represented by a plurality of numbers." In other words, the claimed function is assigning a plurality of numbers to stop positions, where the plurality of numbers exceeds the number of stop positions and some stop positions are represented by more than one number.

In regard to the disclosed corresponding structure of the "means for assigning" limitation, WMS and IGT stipulated--and the district court accepted the stipulation--that the Telnaes patent discloses a microprocessor, or computer, to control the operation of the slot machine, including the operation of the machine in the assignment of numbers to reel stop positions. n2 The algorithm that controls the assignment of numbers to stop positions is disclosed in Figure 6 of the Telnaes patent. Figure 6 illustrates an algorithm in which a plurality of single numbers are assigned to stop positions such that: 1) the range of single numbers exceeds the number of stop positions; 2) each single number is assigned to only one stop position; 3) each stop position is assigned at least one single number; and 4) at least one stop position is assigned more than one single number. The prosecution history reinforces the teachings of Figure 6. The prosecution history indicates that each number must correspond to a stop position, but that several numbers may correspond to the same stop position. In response to an Office Action, Telnaes stated, "the applicant has disclosed a machine which utilizes a standard mechanism but on which the odds can be changed substantially infinitely. The only guidelines are that there must be a symbol for each symbol indicator in virtual memory but there can be many positions in the virtual memory for each symbol on the reel."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n2 Although we fail to find anything in the Telnaes patent that limits the "means for assigning" limitation to a microprocessor or computer, where, as here, the parties agree to a claim construction that is adopted by the district court, and neither party disputes that construction on appeal, we decline to raise an issue sua sponte that the parties have not presented. See Seal-Flex, Inc. v. Athletic Track & Court Constr., 172 F.3d 836, 842, 50 U.S.P.Q.2D (BNA) 1225, 1228 (Fed. Cir. 1999).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

The district court construed the "means for assigning" limitation of claim 1 to cover "any table, formula, or algorithm for determining correspondence between the [randomly selected] numbers and rotational positions of the reel." WMS argues that this construction was overly broad. It contends that the "means for assigning" limitation should have been defined by the corresponding structure, material, or acts described in the patent specification, or their equivalents, and should have been further limited by the prosecution history. IGT responds that the court properly construed the claim.

We agree with WMS that the district court's construction of the "means for assigning" limitation was overly broad. The written description of the Telnaes patent is almost completely devoid of any structure to support this limitation of the claim. The district court apparently took this lack of disclosure to indicate that the limitation reads on any means for performing the recited function. However, this construction is at odds with the requirements of 35 U.S.C. § 112. See Valmont Indus., 983 F.2d at 1042, 25 U.S.P.Q.2D (BNA) at 1454 (holding that section 112, P 6, permits the use of means-plus-function language in claims, but with the proviso that the claims are limited to the structure, material, or acts disclosed in the specification and their equivalents).
The district court determined that the structure disclosed in the specification to perform the claimed function was "an algorithm executed by a computer." While this finding accurately reflected the parties' stipulation, the court erred by failing to limit the claim to the algorithm disclosed in the specification. The structure of a microprocessor programmed to carry out an algorithm is limited by the disclosed algorithm. A general purpose computer, or microprocessor, programmed to carry out an algorithm creates "a new machine, because a general purpose computer in effect becomes a special purpose computer once it is programmed to perform particular functions pursuant to instructions from program software." In re Alappat, 33 F.3d 1526, 1545, 31 U.S.P.Q.2D (BNA) 1545, 1558 (Fed. Cir. 1994) (en banc); see In re Bernhart, 57 C.C.P.A. 737, 417 F.2d 1395, 1399-1400, 163 U.S.P.Q. (BNA) 611, 615-16 (CCPA 1969) ("If a machine is programmed in a certain new and unobvious way, it is physically different from the machine without that program; its memory elements are differently arranged."). The instructions of the software program that carry out the algorithm electrically change the general purpose computer by creating electrical paths within the device. These electrical paths create a special purpose machine for carrying out the particular algorithm. n3

n3 A microprocessor contains a myriad of interconnected transistors that operate as electronic switches. See Neil Randall, Dissecting the Heart of Your Computer, PC Magazine, June 9, 1998, at 254-55. The instructions of the software program cause the switches to either open or close. See id. The opening and closing of the interconnected switches creates electrical paths in the microprocessor that cause it to perform the desired function of the instructions that carry out the algorithm. See id.

In a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm. See Alappat, 33 F.3d at 1545, 31 U.S.P.Q.2D (BNA) at 1558. n4 Accordingly, the structure disclosed for the "means for assigning" limitation of claim 1 of the Telnaes patent is a microprocessor programmed to perform the algorithm illustrated in Figure 6. In other words, the disclosed structure is a microprocessor programmed to assign a plurality of single numbers to stop positions such that: 1) the number of single numbers exceeds the number of stop positions; 2) each single number is assigned to only one stop position; 3) each stop position is assigned at least one single number; and 4) at least one stop position is assigned more than one single number.

n4 In State Street Bank & Trust Co. v. Signature Financial Group, Inc., 149 F.3d 1368, 47 U.S.P.Q.2D (BNA) 1596 (Fed. Cir. 1998), cert. denied, 525 U.S. 1093, 142 L. Ed. 2d 704, 119 S. Ct. 851 (1999), the patented invention related generally to a system that allowed an administrator to monitor and record financial information flow and make all calculations necessary for maintaining "a partner fund financial services configuration." 149 F.3d at 1371, 47 U.S.P.Q.2D (BNA) at 1598. We pointed out that claim 1 of the patent, which was drafted in section 112, P 6 format claimed "a machine, namely, a data processing system for managing a financial services configuration of a portfolio established as a partnership, which machine is made up of, at the very least, the specific structures disclosed in the written description and corresponding to the means-plus-function elements (a)-(g) recited in the claim." Id. at 1372, 47 U.S.P.Q.2D (BNA) at 1600. The structures corresponding to the means-plus-function elements recited in claim 1 in State Street were "a personal computer including a CPU" (element (a)), "a data disk" (element (b)), and "arithmetic logic circuits" configured to perform various functions (elements (c)-(g)). Id. at 1371-72, 47 U.S.P.Q.2D (BNA) at 1599.
will not disturb the district court's claim construction.

Finally, we consider the third disputed limitation of claim 1: "means for stopping said reel at the angular position represented by said selected number." n5 The claimed function is stopping the reel at the stop position that corresponds to the random number selected by the "means for randomly selecting" limitation. The disclosed structure is a brake. Neither of these points is in dispute.

--- Footnotes ---

n5 The construction of this limitation is actually disputed only in the sense that it turns on the construction of the two claim limitations just discussed.

--- End Footnotes ---

As just seen, the functions of the three disputed limitations of claim 1 are: 1) assigning a plurality of numbers to stop positions, where the plurality of numbers exceeds the number of stop positions and at least one stop position is represented by more than one number; 2) randomly selecting one of the numbers assigned to stop positions; and 3) stopping the reel at the stop position that corresponds to the selected number. Referring to the means for selecting and means for stopping limitations, WMS argues that selecting "one" number and stopping the reel at the stop position represented by "said selected number" indicates that claim 1 is limited to assigning and selecting single numbers rather than combinations of numbers. The district court concluded, however, that: "there is nothing in the claim that limits the generated numbers to be a single number." WMS Gaming, slip op. at 26. We agree with WMS on this point. The plain meaning of "selecting one of said . . . numbers" is selecting a single number, not a combination of numbers. See Insituform Techs., Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1105, 40 U.S.P.Q.2D (BNA) 1602, 1607 (Fed. Cir. 1996) (determining that the claim term "a cup" suggests the use of only one cup). In addition, the last limitation of the claim refers to "said selected number." This reference to "number" in the singular sense bolsters the interpretation that "selecting one of said . . . numbers" is limited to selecting a single number. Nothing in the written description, drawings, or prosecution history indicates that the phrases "one of said . . . numbers" or "said selected number" should be given anything other than their ordinary meaning. See York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996) ("Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning."). Therefore, the term "number(s)," as used in claim 1, refers to single numbers, as opposed to combinations of numbers, and the recited function of claim 1 is limited to assigning and selecting single numbers.

---

d. Claim term five

"number(s) [of consecutive first values]" (claims 1, 4, 6, and 10)

The parties' dispute with respect to term five also concerns whether the '672 patent necessarily includes runlengths of zero length. However, there is essentially no substantive difference between the constructions proposed by the parties. Plaintiff proposes that term five be construed as: "The non-negative integers 0, 1, 2, 3, . . . ." While Plaintiff may intend by this definition to incorporate the requirement that there are runlengths of zero length, it is not clear that this language would have that effect. The claim construction offered by Plaintiff includes the entire set of non-negative integers beginning with zero, which is an infinite set. Accordingly, unless Plaintiff intends to mean that the patent covers only those embodiments in which every non-negative integer is included (which seems impossible), this proposed construction must necessarily be interpreted as providing the set of possible integers. Thus, the construction offered by Plaintiff essentially is identical to the construction proposed by Defendants, that term five be construed as: "A count of consecutive first values-i.e., a run length." A "count" similarly would include zero as a possible, but not required, number. Because the Court is reluctant to imply that a runlength of zero length is necessarily included, even though Plaintiff's definition probably would not require it, the construction proposed by Defendants is preferable. Accordingly, the Court will construe "number(s) [of consecutive first values]" as "A count of consecutive first values-i.e., a run length."
5. "objectionable interference or distortion"

The plaintiff argues that "objectionable interference or distortion" means the modification to a signal during scrambling." Joint Claim Construction Brief, Exh. B. The defendants argue that the term means the modification to the analog signal that results in the signal being scrambled. I have rejected the construction that limits scrambling to analog signals.

I construe the term "objectionable interference or distortion" to mean the modification made to a signal during scrambling.

The DIRECTV defendants argue that the term "objectionable" is indefinite under 35 U.S.C. § 112, P 2. Defendant DIRECTV . . . Principal Opening Brief On Claim Construction, at pp. 60-61. According to these defendants:

There is no standard set forth in the specification, nor test in the art, to allow one skilled in the art to determine what amount of interference or distortion is "objectionable."

Id. at 60.

"The definiteness inquiry focuses on whether those skilled in the art would understand the scope of the claim when the claim is read in light of the rest of the specification." Union Pacific Resources Co. v. Chesapeake Energy Corp., 236 F.3d 684, 692 (Fed. Cir. 2001).

The specification of this patent provides that the "signal scrambling circuit modifies the signal in accord with predesigned parameters so as to render the signal unusable upon reception by a receiver not containing a corresponding decoding circuit." '066 Patent, co. 2, lines 9-12 (emphasis added). Consequently, one skilled in the art reading the claim in the light of the entire specification would understand that interference is "objectionable," as that term is used in claim 9, if it is of an amount sufficient to "render the signal unusable" to anyone without a decoding circuit. The term "objectionable" is not indefinite.

Obligation

Plaintiff advances a construction of the term "obligation" as "an amount owed by a merchant that is independent of any costs or fees arising out of the use of customer identifiers as payment." Defendants, on the other hand, originally asserted that "obligation" should be construed according to its ordinary meaning but then stated in their responsive briefing that the term should account for transactional costs and fees. Defendants argue that the term should exclude only certain enumerated fees and costs (e.g., discount rate, interchange fees and network fees), but not other fees and costs normally associated with the typical transaction processing environment. Thus, Defendants propose a construction of: "amount owed by merchant other than the processing fees, i.e., discount rate, interchange fee, and network fee."

The '281 specification describes a number of fees and costs that are usually incurred by a merchant, including merchant processor fees, discount rates or surcharges, interchange fees, network fees, card service fees, transaction fees, and card issuer fees. Col. 4, line 21 - Col. 5, line 3. However, the term "obligation," as used in the context of the '281 patent consistently refers to an amount owed by the merchant that is independent of any particular purchase and outside of any of the fees and/or costs normally imposed on the merchant for a typical processing transaction. The '281 specification provides an example of the kinds of fees that are incurred in a typical transaction processing environment:

The merchant processor 300 thus pays the merchant 20 some amount less than what the merchant 20 would receive in the [typical transaction processing environment described in relation to FIGS. 1A and 1B]. For example, carrying on with the example introduced above with reference to FIGS. 1A and 1B, instead of paying $98.10 to the merchant 20 on a $100 original card purchase, the merchant processor 30 might send $88.10 to the merchant 20 and the other $10.00 to the
When read in the context of authorization and settlement of a customer payment for goods or services, it is clear from the illustrations that the "obligation" recited in the claims of the '281 patent does not include any of the fees or costs deducted for using the typical transaction processing environment, i.e., the "overhead" amounts that are incurred as a result of merely handling the customer payment using a customer identifier, not just the discount rate, interchange fees and network fees as Defendants claim. To limit the "overhead" amounts exclusion to just those things specifically enumerated in the '281 patent specification would amount to expanding the scope of the claim language beyond the restrictions fairly articulated in the '281 patent specification.

Plaintiff also directs the Court to the prosecution history of the '281 patent, and notes that during the prosecution, the Applicant articulated that "[t]he existence of the loan in the present invention is independent of and unrelated to the consummation of any particular purchase [by a customer]." '544 Patent File History, 1/20.99 Am. and Resp., p. 3.

Defendants assert that this portion of the prosecution history can be ignored because it was made "during prosecution of a different patent and with respect to a different term in a different claim" Defs.' Resp. Claim Construction Br., p. 8. However, the prosecution history of a parent patent is part of the prosecution history of the child patent. See Goldenberg v. Cytogen, 373 F.3d 1158, 1167 (Fed. Cir. 2004)(holding that the prosecution history of the parent application is treated "as part of the intrinsic evidence" of the child application when construing claim terms). The '281 Patent is a continuation of the '544 Patent, and as Plaintiff points out, both patents contain identical disclosures. Thus, the statements made during the prosecution of the '544 Patent apply to the construction of "obligation" in the '281 Patent.

Accordingly, the Court construes the term "obligation" as "an amount owed by a merchant that is independent of any costs or fees arising out of the use of customer identifiers as payment."

5. oblique observation ('028 and '412 patents)

CEA contends that this term does not require construction, but provides a proposed construction of: "an observation other than in the homeotropic direction."

Samsung's proposed construction is: "an observation made at an angle other than in the homeotropic direction, which direction is perpendicular to the glass plates of the cell."

The specification defines "oblique observation": "oblique observation (as opposed to an observation made in the homeotropy direction.)." 19 The parties' proposed constructions are substantially identical, with Samsung's proposed construction adding a definition of "homeotropic direction." At oral argument, Samsung agreed to CEA's proposed construction--with the same caveat concerning the construction of "a liquid crystal layer which can have a homeotropic structure," above, that "homeotropic direction" will be construed by the court and have the same meaning in both patents-in-suit. 20

Therefore, the court adopts CEA's proposed construction: "an observation other than in the homeotropic direction."
TERM # 17: "observer's computer" - In this dependent claim, although the parties purport to dispute the meaning of the term "observer's computer" it appears as though they are really once again revisiting the definition of "auction process", which this court already addressed on summary judgment, and will not address again. Defendants seek to distinguish their product by arguing that it does not perform the communicating and displaying steps while the auction is ongoing. However, we have already rejected imposing a temporal limitation on the term "auction process" in the context of the summary judgment motion. The disputed term means: "A computer used by a non-bidding party to view an electronic auction."

9. "obtain access"

In addition to the control program limitation, claim 1 of the 037 Patent recites "[a] processor . . . coupled to [a] memory store to obtain access to said control program." 037 Patent, 55:33-35. As with the term "control program," plaintiff maintains that "obtain access" need not be construed by the court. Defendant proposes the construction "locate a unit of code or memory and use it in a process."

Defendant's proposed construction relies on the first definition of "access" in the AP Dictionary. See id. at 14. However, this definition, like each of the other four in the AP Dictionary, suffers from the flaw that it refers to the verb "to access" rather than the noun "access." In contrast, "access," when used as a noun, means "permission, liberty, or ability to enter, approach, communicate, or pass to and from." Webster's Third International Dictionary at 11. In fact, the ability to "enter, approach, [or] communicate" aptly describes the "access" to the control program that is being obtained by the processor in claim 1 of the 037 Patent. In other words, the 037 Patent's use of the term "obtain access" is consistent with its ordinary meaning, as evidenced by the non-technical dictionary definition cited above.

Defendant nonetheless argues that Auspex disclaimed the ordinary meaning of "obtain access" in the course of prosecution of the 885 Application, a parent application of the patent in suit. The prosecution history reveals that Auspex initially claimed a "storing means to permit the transfer of instructions and data." Grewal Decl., Exh. K at 433. The examiner rejected this language as indefinite under 35 U.S.C. § 112 P 2, noting, among other things, that "it is not entirely clear what is encompassed by the limitation permitting the transfer of programs and data." Id. at 421. In response, Auspex amended the limitation "to permit the transfer of instructions and data" to claim "to obtain access to said control program." Id. at 433.

Defendant argues that this amendment compels the court to impose a narrower construction on the term "obtain access." However, the examiner's rejection of the initial claim was based on the indefiniteness of the term "permit the transfer of instructions and data" rather than the phrase "to obtain access to said control program," which is found in both the amended claims of the 885 Application and claim 1 of the patent in suit. As the Federal Circuit noted in Inverness Medical Switzerland GmbH v. Warner Lambert Co., 309 F.3d 1373 (Fed. Cir. 2002), "[i]t is inappropriate to limit a broad definition of a claim term based on prosecution history that is itself ambiguous." Id. at 1382. Although the cited claim amendment would certainly preclude plaintiff from asserting that "obtain access to said control program" should be construed as "permit the transfer of data and instructions," the court need not address that issue to conclude that "obtain access" should be construed according to its ordinary meaning. Because the ordinary meaning of the disputed term as it is used in the claims is the term itself -- i.e., "obtain access" -- the court declines to construe the term.

F. "Obtain . . . information about the data structure . . . [by] accessing content of information."

The parties did not agree on the precise wording of this disputed term. However, the briefing focuses on the term put forward by ProClarity ("obtain . . . information about the data structure . . . [by] accessing content of information . . ."). This term appears in all claims of the '511, '382, and '617 patents. It also appears in claims 10-15 and 19-25 of the '392 patent, as
well as claims 5, 11, and 19-23 of the '694 patent. This term includes several other disputed terms discussed earlier, including "information," "data structure," and "content of information." As a result, the court's construction of this term essentially turns on its construction of the other disputed terms.

Timeline's proposed construction of the term is "accessing the information in a data source to obtain information about the logical organization of the data in the source." ProClarity's proposed construction is "the computer program derives, via intelligent interrogation, the organizational scheme between content of information by accessing that content alone."

Timeline's proposed construction flows from its proposed constructions of the disputed terms "information," "content of information," and "data structure." Because the court has largely adopted Timeline's proposed constructions of those terms, the Court also adopts Timeline's proposed construction of this term.

Therefore, the court construes the term "obtain . . . information about the data structure . . . [by] accessing content of information" to mean "accessing the information in a data source to obtain information about the logical organization of the data in the source."

a. "obtaining a current position of at least a part of a seat on which the occupant is situated"

The parties agree that the court should construe this phrase to be "detecting the . . . of at least a part of the seat on which the occupant is situated with respect to a reference position." (Chart at 19.) However, Plaintiff argues that no additional construction is required for "current position," whereas Defendant suggests the best construction to be "quantity of movement." (Id.) Plaintiff argues that Defendant's construction narrows Plaintiff's claim, requiring a discrete, numerical determination. In response, Defendant argues that the specification itself calls for "detecting the quantity of movement": "The seat portion 2 is provided with a seat track position-detecting sensor 10. The seat track position detecting sensor fulfills a role of detecting the quantity of movement of the seat 1 which is moved from a back reference position, indicated by the dotted chain line." '516 Patent col. 10 l.26-30.

As Defendant correctly notes, the phrase "detecting the quantity of movement" does not require the identification of a discrete, numerical unit of movement because the act of "detecting" does not require a calculation or an actual determination; rather, it can mean "to discover or ascertain the existence, presence, or fact of." Dictionary.com, The American Heritage Dictionary of the English Language, 4th Ed., available at http://dictionary.reference.com/browse/detect (last visited Jul. 7, 2009). Furthermore, while the specification uses the phrases proposed by both parties, the court finds no requirement by the specification to use one proposed construction over another. "The written description part of the specification itself does not delimit the right to exclude. That is the function and purpose of the claims," Markman, 52 F.3d at 980, and the court will therefore use Plaintiff's construction of the phrase "current position," see id. Moreover, the limitation in the claim of "with respect to a reference position" will preserve for Defendant the notion that a comparison is made when this procedure occurs. Use of "quantity of movement," or similar phrase, could circumscribe Plaintiff's claim by implying measurement of an action rather than determination of a static state. Finally, the court will also include the explanatory phrase, "In other words, detecting how far forward or backward the seat is' in order to render more clearly for the jury what is being detected, as shown by Figure 1 of the '516 Patent. See Embrex, Inc., 216 F.3d at 1347.

The court will therefore construe "obtaining a current position of at least a part of a seat on which the occupant is situated" as "detecting the current position of at least a part of the seat on which the occupant is situated with respect to a reference position. In other words, detecting how far forward or backward the seat is."

11. "obtaining a measure of the magnetic field variation as a function of time" ('326 patent, claim 73)

AVID argues that this term means "obtaining a measure of the variation in the magnetic field as a function of time."
maintains that the patent specification at 3:3-11 and 9:3-13 unambiguously describes detecting the variation in amplitude of the reversing magnetic field and indicates that the detected variation is a measure of the power absorbed by the tag. The Defendants contend that the term should be construed as a step-plus function limitation pursuant to 35 U.S.C. § 112 P 6. In support of their step-plus-function argument, the Defendants assert that the element does not recite the acts necessary for obtaining a measure of the magnetic field variation. According to the Defendants, the corresponding structure is first and second pairs of capacitors 120, 125 coupled in series with coil 110, a SPDT switch 130 coupled in series with capacitors 120, 125, and a double-ended balanced coil driver 135 coupled to SPDT switch 130. The Defendants argue that these elements perform the acts necessary for obtaining a measure of the magnetic field variation as recited in claim 73.

AVID disputes the Defendants' assertion that the term should be construed as a step-plus-function limitation. According to AVID, the absence of the signal "step for" raises the presumption that a method claim is not in step-plus-function form. Furthermore, the claim preamble describes a method "comprising the steps," which AVID asserts is different from the "steps for" language that characterizes step-plus function claims. AVID also disputes the Defendants' argument that no acts are mentioned in the term. According to AVID, the claim requires the act of obtaining a measure of the magnetic field variation and further indicates that the measure is obtained as a function of time. Thus, the acts relates to the function of detecting magnetic field variations caused by a tag. After carefully considering the parties' proposed constructions and the "326 patent, the Court adopts the Plaintiff's proposed construction. The absence of the signal "step-for" creates a presumption that a method claim is not in step-plus-function form. Cardiac Pacemakers, Inc. v. St. Jude Med., Inc., 381 F.3d 1371, 1382 (Fed. Cir. 2004). The Defendants have not overcome this presumption. AVID's construction is therefore adopted.

D. Terms Related to Calibration

The parties dispute a number of terms that relate to the calibration of the transmitter/receiver pair. Much of the debate regarding these claims focuses on the difference between "one-point" and "two-point" calibration. A brief background will be helpful in the analysis below. Succinctly stated, one point calibration is a simple technique in which the transmitter and receiver are placed at a known distance apart (which can be calculated with something as simple as a tape measure), the strength of the electromagnetic field is measured, allowing for the calculation of a "proportionality constant" ("k") using the equation:

\[ B = \frac{k}{d} \]

where \( B \) is the measured magnetic field strength and \( d \) is the distance between the transmitter and receiver. In the HDD context, that constant can then be used to calculate the distance between the transmitter and receiver based on measured magnetic field strengths as the boring tool is moved from place to place through the ground. Problems arise when environmental conditions affect the measured field strength. Distance measurements calculated using the original "k" will therefore be inaccurate if the perceived "B" has been so affected.

Two-step calibration, on the other hand, is an ingenious technique in which new and updated "k" constants can be calculated whenever desirable during the course of an HDD operation. This technique takes advantage of the mathematic formula above, but goes a step further. As would be typically done during an HDD operation, the boring tool with its transmitter would be in the ground and the "locator" with its receiver would be above ground. A field strength measurement would be taken at one position, such as with the locator on the ground, directly above the transmitter. At this point, only "B" would be known in the above equation. The locator is then moved to a precisely known distance above the ground, designated "d," and another field strength measurement "B" is taken. These measurements can be designated \( B[1] \) and \( B[2] \). The three unknowns "k," "d[1]," and "d[2]," can then be solved for by relatively simple algebra using the three equations:

\[ B[1] = \frac{k}{d[1]} \]
\[ B[2] = \frac{k}{d[2]} \]

Thus, even if the perceived "B" measurements are affected by environmental conditions, a new "k" and distance measurements can be calculated at any given time during the operation.

Claim terms 16 and 18 directly relate to the calculation of the proportionality constant. The disputed terms are as follows:
16. "obtaining distance and electromagnetic signal field strength measurements (i) based on said positional relationship between the transmitter and receiver and (ii) based on the transmission and reception of said constant signal by said transmitter and receiver, respectively, and using those measurements, establishing a proportionality constant"

18. "obtaining a proportionality constant"

The Court sets forth once again the language of Claim 4 of the ‘258 Patent so that the language of claim term 16 may be taken in its proper context:

4. In a method for locating a boring tool that moves through the ground from a first point to a second point, said method using (1) a given transmitter . . . and (2) a receiver . . . whereby to determine the location of the boring tool, the improvement comprising the steps of:

(a) providing a specific positional relationship between said transmitter and receiver and, while maintaining that positional relationship, transmitting a CONSTANT electromagnetic signal with time from said transmitter and receiving said CONSTANT signal from said receiver;

(b) obtaining distance and electromagnetic signal field strength measurements (i) based on said positional relationship between the transmitter and receiver and (ii) based on the transmission and reception of said constant signal by said transmitter and receiver, respectively, and using those measurements, establishing a proportionality constant k of said dipole FOR SAID GIVEN TRANSMITTER AND RECEIVER, which said proportionality constant relates to the cube root of the magnetic field strength of said dipole; and

(c) thereafter, using said proportionality constant and a CONSTANT electromagnetic signal with time, causing said receiver to determine the depth of said boring tool.

Plaintiff DCI proposes a construction for claim term 16 that reads: "Calculating a proportionality constant based on the signal strength of a detected, non-degrading, and recurrent electromagnetic signal at a known distance." Defendant meanwhile asserts that this term should mean "one distance and two field strength measurements are taken after the transmitter is placed below ground and the receiver is placed above ground in two different locations." In this instance, based solely on the clear language in claims 4 and 9 of the '258 Patent, the Court finds that plaintiff's construction is closer to the mark. The claim language in claims 4 and 9 of the '258 Patent clearly describe a one-step calibration technique. The steps of the improvement in the Jepson claim include (a) placing the transmitter and receiver at a known distance apart, (b) taking a magnetic field strength measurement to calculate a proportionality constant (using the above first equation as verbally described in the claim language), and (c) "thereafter" using the proportionality constant to obtain the depth of the boring tool during HDD operations. Thus, this term means calculating a proportionality constant based on the strength of a constant electromagnetic field strength at a known distance.

The Court does not see this claim term as being limited in a spatial sense as defendant suggests. The Jepson claim format, while defining the context and scope of the prior art and the invention itself, does not impose such a limitation in this instance. The improvement described after the preamble is discussing a method of calibrating the transmitter/receiver pair to be used in the method for locating a boring tool as described in the preamble. Thus, the improvement is not limited by the below-ground transmitter / above-ground receiver configuration described therein. It is also clear that these claims do not describe two-step calibration by taking one distance and two field strength measurements as argued by the defendant.

Nevertheless, the Court notes that the specification does not specifically describe a one-step calibration method. To show this, the Court quotes heavily from the relevant specification text:

The aforementioned factors and parameter relationships indicate, and the prior art has recognized, that the distance between transmitter and receiver can be obtained using magnetic field strength measurements alone once the proportionality constant has been determined.
The proportionality constant depends upon a variety of parameters, such as soil characteristics, tool body attenuation and battery strength. As a result, locator/monitors of the present invention should be calibrated (i.e. the proportionality constant should be determined) before use under new conditions or after a substantial period of continual use. Since calibration is required often, a simple procedure therefor, as provided by the present invention, is desirable.

A method to accurately determine the proportionality constant in an antennae separation-insensitive manner is to measure the magnetic field strength at two position using a "single antenna location" device (e.g. two orthogonal antennae dispose in close spatial proximity), such as the locator/monitor of the present invention. In such a device, the single antenna location is moved between two measurement positions by an operator. Consequently, the spacing between the two measurement positions can be much larger than that of a spatially separated two-antennae device, since packaging requirements do not limit the distance between measurements positions in locator/monitors of the present invention.

In the practice of the present invention, the magnetic field strength \( B[1] \) is measured by the orthogonally disposed antennae at a first position that is located a distance \( d_1 \) from transmitter. Similarly, magnetic filed strength \( B[2] \) is measured at a second position that is vertically displaced from the first position and located a distance \( d_2 \) from transmitter. If the distance \( d \) between the first and second positions is known, the variables \( k \), \( d[1] \) and \( d[2] \) may be calculated by solving the following equations:

\[
B[1] = \frac{k}{d[1]}
\]

\[
B[2] = \frac{k}{d[2]}
\]

\[
\]

An important feature of this process is that \( d \) is accurately ascertainable. As a result, an accurate independent measurement system is incorporated into receiver of locator/monitors of the present invention, so that the distance between the two measurement positions can be determined. The independent distance measuring means could also be separate from the receiver, but such a configuration is not preferred.

'589 Patent, Col.12:1-49. This description does not encompass a simple one step calibration followed by depth measurements taken during operation. Rather, it discussed the two-step calibration method using two field strength measurements and a known distance between measurement positions. As a matter of claim construction, the Court will not use the specification language to give the claim language a different meaning than is plainly obvious. Whether this has implications regarding the "enablement" requirement of the specification, however, is an issue for another day.

While the above revelation may not immediately affect the Court's construction of claim term 16, it does significantly influence the construction of claim term 18. This claim term is found solely in Claim 10 of the '258 Patent:

10. In a method for locating a boring tool that moves through the ground from a first point to a second point during which time at least the roll orientation of the boring tool changes, said method using: (1) a given transmitter defining an axis and power supply carried by the boring tool within an electrically conductive housing for transmitting by means of a dipole field to an above ground location an electromagnetic signal containing information which is used in obtaining the location of the boring tool and (2) a given receiver located at said above ground location for receiving and processing said electromagnetic signal, whereby to determine the location of the boring tool, the improvement comprising the steps of:

(a) obtaining a proportionality constant for said given transmitter and said given receiver;

(b) thereafter, using said given transmitter [as the boring tool moves] . . .

(c) causing said given receiver to receive and process [the signal] . . .

(d) monitoring and displaying the depth of said boring tool as it moves through the ground from said first point to said second point using the signal processed by said receiver.

(emphasis added). Defendant argues that this claim element should be read as a "step plus function" limited claim element.
While it is true that the preamble does not contain the so-called magic words "steps for" and is therefore rebuttably presumed to not be in step plus function format, the Court agrees that the phrase "obtaining a proportionality constant" itself provides no information as to how this step is to be carried out. In short, this claim element contains no "acts." This is in direct contrast to Claim 4 of the same patent, which verbally describes the use of the field-strength proportionality equation within the claim language, and Claim 9's description using the equation itself. Therefore, the Court reads this to be a step plus function claim element, and the phrase "obtaining a proportionality constant" must be limited to the acts described in the specification for achieving the function of the step.

As noted above, the only description of calibration contained in the specification is that quoted above. The acts described are a two-point calibration technique as described above. Two field strength measurements are taken at two different distances from the transmitter, the difference in the distances being known. A proportionality constant is then calculated via the three equations above, and the depth of the boring tool can be calculated during the HDD operation.

2. "obtains a buffer"

TiVo argues this claim term is newly raised by EchoStar after the claim construction hearing and believes no construction is needed. 6/7/05 Joint Claims Construction Chart at 9. EchoStar argues "obtains a buffer" means "obtains a set of buffer memory addresses into which it can write data." See '389 patent at cols. 7:47-50, 8:9-18; 8:38-65, & Fig. 8; EchoStar's Opening Br. at 23-25; EchoStar Slide Presentation at 127-28. The Court, however, finds "obtains a buffer" requires no construction, as persons of ordinary skill in the art readily understand its meaning as written in claims 31 and 61.

The Court finds that, although the term "buffer" has a plain and ordinary meaning to persons of skill in the art, it requires additional construction for clarification. Because neither party has offered a stand-alone construction for this term in their papers, and is not defined in the '389 patent, the Court turns to extrinsic evidence in order to assist its understanding of the term. Phillips, 415 F.3d 1303, 2005 WL 1620331 at *15. In this instance, the Court turns to technical dictionary published by the Institute of Electronic and Electrical Engineers, the IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS (6th ed. 1997), which defines "buffer" as: "(5)(A) A device or storage area used to store data temporarily to compensate for differences in rates of data flow, the time occurrence of events, or amounts of data that can be handled by the device or process involved in the transfer or use of the data." IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS at 113 (6th ed. 1997). The Court notes that EchoStar's expert witness, Dr. Rhyne, has acknowledged that the IEEE dictionary this is a widely accepted technical dictionary in the electrical engineering field. Rhyne Decl. at 45. On the basis of the use of the term in the '389 claims, and on the basis of its IEEE dictionary definition, "buffer" will be construed as "memory where data can be temporarily stored for transfer." This definition is further consistent with the definition provided by counsel during the claims construction hearing. 5/23/05 Hr. Tr. 58:11-13.

The claim phrase as a whole, "obtains a buffer" is therefore construed as "obtains memory where data can be temporarily stored for transfer."

9. "[A] display screen occupying substantially an entire broad side of the processing module" 11 is a display screen that occupies the entire surface of the largest face, except for a small border, as shown in figure 9. This construction is consistent with the specification: col. 24:23-35; figure 2; figure 7; figure 9.

7. Step (D): Odds Having a Range of Outcomes

We find that the meanings of the terms "odds" and "odds having a range of outcomes" are inter-dependent, and thus we will address them together in this section.

Defendants suggest that "odds" means: "the inverse of the probability of winning a particular progressive prize." (Def. Resp. at 11.) For example, if the probability is 1/1000, the inverse probability is a single number, 1000. Plaintiff suggests that "odds" means "the ratio of two [undefined] numbers." (Pl. Resp. at 17.) In the Joint Claim Construction and Pre-Hearing Statement (#87), Plaintiff's proposed construction of "odds" is "the ratio of the probability of a progressive award event occurring to that of a non-progressive prize award event occurring."

We first look to the claim terms for guidance for construing the meaning of "odds." See Phillips, 415 F.3d at 1312; Vitronics, 90 F.3d at 1582. In the case of "odds," Steps (D) and (E) provide substantial guidance:

(D) computing the odds of a handle pull generating a prize award event using the total wager amount and the amount of the wager, the odds having a range of outcomes, the prize winning number being within the range of outcomes;
(E) generating a random number within the range of outcomes;

First, Step (D) describes computing odds by using the total wager amount and the amount of the wager. However, the step does not indicate exactly how those amounts should be used to compute the odds, and we must look to the specification for guidance in that capacity. Nevertheless, the rest of the steps provide guidance as to the purpose of the odds.

When read by itself, the phrase, "the odds having a range of outcomes," could mean that there are a range of outcomes for the odds. If this meaning were to be adopted, we still would not know whether the outcome was intended to be a single number or a ratio. However, when examined in conjunction with step (E) of Claim 11, we see the phrase, "generating a random number within the range of outcomes." With this phrase in mind, a more sensible reading of "the odds having a range of outcomes" would be "the odds providing a range of outcomes to be used to generate the random number." This construction gives the odds a purpose within the claim: creating a range of numbers from which the generated random number is chosen. Without this purpose for Step (D), there is no other range of outcomes in the claim from which to generate the random number. This purpose provides substantial support for the proposition that "odds" should be construed to encompass a relationship between two numbers, as a range cannot exist within one number alone.

For the most part, this construction is supported by the specification. The specification provides an equation "for creating a set of numbers for the random number generator." (‘460 Patent, col. 16 at 12-13.) MR = PT/WG, where MR = the maximum number for the range of random number selection, PT = prize's total wager amount, and WG = wager made as a multiple of the lowest monetary unit. (Id. at 16-24.) The specification does not describe this equation as a means for calculating odds, however, it certainly appears related to the odds calculation and purpose set forth in the claims, as it uses the wager and the total wager amount to create a set of numbers for the random number generator.

In discussing this equation further, the specification states "the computed odds, represented by the maximum number for range of random numbers." Defendants argue that this sentence indicates that the computed odds must be a single number, the inverse of the probability of winning a particular prize. However, such a construction appears to contradict the purpose of odds as set forth in the claims: to provide a range of numbers (outcomes) from which to generate a random number. This poses the question, then, can the odds be "represented by" a single number and yet be more than one number - or a relationship between numbers - which thus creates a range of numbers.

We find that it can, and that a construction of "odds" as the mathematical relationship of two numbers, wherein the total wager amount is divided by the individual wager, and the resulting figure provides a ratio of two numbers, which in turn provides a range of numbers from which to generate a random number, is the construction most supported by the claim terms, the overall meaning of the specification, and common understandings of the term. While portions of the specification occasionally refer to the odds as a single number, say 14, 285, 715 (col. 3 at 3 (in discussion of prior art) ) we find that such
usage can also imply a relationship between two numbers, i.e. 14,285,715 divided by 1. Any other understanding would obfuscate the purpose of the odds: to provide a range of numbers. Indeed, the testimony of both parties' experts did not provide any basis for a finding that one of ordinary skill would commonly understand the meaning of "odds" to be a single number. Defendants' expert, Mr. Bertram, indicated that such usage was unusual, though not unheard of; and Plaintiff's expert, Mr. Ladner, indicated that such usage would imply a relationship between two numbers, the number provided and one.

We are cognizant that the construction proposed by Defendants is a form of a relationship between two numbers - an inverse probability represented by a single number. Such a construction does find support in the specification. However, we find such a construction's emphasis on the singularity of the number, when taken to the extreme, could potentially invalidate the patent by obfuscating the purpose of the odds - creating a range of numbers for random number generation. In addition, we reject the second portion of Defendants' proposed construction as the specification and claim terms do not discuss "odds" in relation to the probability of winning a prize award, but rather focus on the relationship of the total wager amount and the wager, and the use of these figures for creating a range of numbers.

Nevertheless, Plaintiff's proposals are not more helpful. Plaintiff's first proposed construction is overly broad, as it emphasizes that the numbers are undefined. While we recognize that a purpose of the invention is to allow for diverse odds and wagers, and we do not want to adopt a construction which would interfere with that purpose, we find that some mention of the claim's parameters for the odds would be helpful. In addition, Plaintiff's second proposed construction, "the probability of a progressive prize award event occurring . . ." is not clearly supported by the claim terms or the specification. The odds may relate to the probability of winning, but the specification does not discuss this enough to warrant its inclusion as a limitation of the claim.

However, the Plaintiff's use of the term "ratio," while not used specifically in the specification, does support the meaning of the equation discussed above, wherein one figure is divided by another. Use of the term, "ratio" is well-supported by extrinsic evidence. One dictionary definition of "odds" is "[t]he ratio of the probability of an event's occurring to the probability of its not occurring." The American Heritage Dictionary (4th Ed. 2004). In turn, a dictionary definition of ratio is: "The relation between two quantities expressed as the quotient of one divided by the other." Id. Because such a meaning is not contradicted by the specification (even a singular number is a ratio between that number and one), our seeking guidance from this extrinsic evidence is appropriate. See Phillips, 415 F.3d at 1317-18. Therefore, we adopt the following construction for "odds": a ratio of two numbers, represented by the total wager amount divided by an individual wager, creating a range from which a random number may be generated.

E. "Offer(s)"

The final two steps of the process described in Claim 11 involves "locating financial card offers" and "presenting said financial card offers to" the eligible applicant. The word is used in a similar manner in Claim 22. Defendant contends the word should be defined to mean "proposal of material terms for a financial card that, if accepted, would form a binding contract." Plaintiff proposes the word be defined as "an invitation to accept a financial card." The parties' arguments establish that the point of contention essentially is whether a binding contract is made (1) when the customer clicks on the offer and starts the processing of the application or (2) when the financial institution processes the application and decides to send a financial card to the applicant. The Court holds the latter is the more accurate description and therefore adopts Plaintiff's definition.

Defendant emphasizes the patented process' ultimate objective is to form a contract, and therefore equates "offer" with
"offer to form a contract." While Defendant correctly identifies the ultimate objective, it does not necessarily follow that the contract must be formed at the time the applicant selects the offer he or she deems suitable. It is equally plausible for the contract to be formed once the financial institution accepts the application. The presentation of a set of financial card terms to an applicant would constitute an "offer to apply," acceptance of which does not form a binding contract. This view is more consistent with both the extrinsic and intrinsic evidence.

The intrinsic evidence demonstrates the applicant's data is forwarded to the financial institution once an offer is accepted, yet Defendant's definition would obligate the financial institution to issue a card even if the applicant's data is false. This outcome makes no sense. Moreover, as discussed in connection with the definition of "financial card," the process described by the '645 Patent is intended to replace direct mail solicitations. An applicant filling out a direct mail solicitation would not thereby form a binding contract; the application would be reviewed by the financial institution and a card would be issued if that review confirmed the applicant's eligibility. One would expect the replacement process described by this process to follow a similar approach.

Defendant correctly observes there is no real opportunity for the applicant to negotiate with the financial institution, but incorrectly concludes this means acceptance of the offer must result in a binding contract. One has nothing to do with the other, and this narrow view fails to consider the possibility of an offer to apply for a financial card with given terms. This omission is significant given the stated parallels with an offer delivered via direct mail: an applicant filling out the solicitation understands he or she is applying for a credit card, not entering a binding contract obligating the financial institution to issue a card.

In addition to the real world considerations discussed above, the Court notes the '645 Patent describes the person entering data in an attempt to procure a financial card as an "applicant" -- that is, someone who is applying for something. An application may be accepted or rejected, so the applicant's efforts are not guaranteed to result in the issuance of a card. The '645 Patent does not describe the person entering data as an "acceptor" or by any other term indicating a contract is formed at the moment the data is submitted.

**2910**

1. "office machine system"

The first disputed term in this category is "office machine system" which appears in Claims 57 to 60 of the '554 Patent. In line with Ricoh's position described above, Ricoh offers the following construction for "office machine system."

A modular business device that includes an intelligent engine that has its own microprocessor and its own communication capability that enables it to communicate with other modules of the office machine system or with other devices. Each module of the office machine system has its own microprocessor and its own interface unit. The intelligent modules
communicate with each other using an intelligent protocol. Moreover, the modularity of the office machine system allows interchangeability of modules between models and products. The engine of the office machine system carries out the mechanical operations of the office machine system.

(Chart at 1). In sharp contrast, Pitney contends that the term should be construed as "[a] business office device, such as a copier, printer or facsimile, connected to but separate from an external operation panel." (Id.) (emphasis added).

Based on the parties' proposed constructions, the parties clearly dispute more than the "physical separation" issue. Rather, the parties disagree on the basic definition for the term. The Court first notes the parties' agreement that the "office machine system" includes the copier engine 10 and the operation panel 20 in Figures 1 and 2 of the patent. (Chart at 1). This part of the construction finds support in the prosecution history of the '554 Patent wherein the inventor stated: "Claim 14 does not recite a copier machine but generically recites a business office machine system. Such a system corresponds to elements 10 and 20 illustrated in Figures 1 and 2." ('554 Prosecution History, Apr. 24, 1995, Prelim. Amendment at 16).

The written description, however, clarifies that element 10 is not limited to a copier engine. Specifically, in describing Figure 1, the written description provides:

FIG. 1 illustrates a preferred embodiment of the present invention including a copier engine 10, operation panel 20, and remote diagnostic station 30. However, the present invention is not limited to copier devices, and can be applied to other business equipment devices, such as a printer or facsimile, which has means which are described below.

In the following illustration, the target device in FIG. 1 is a copier engine 10. The target device 10 includes means to store Static State Data 107, which does not change over the life of the device, such as the model number, serial number, model characteristics and the like.

'554 Patent, col. 2, ll. 39-53 (emphases added). In this excerpt, the inventor uses the terms "copier engine," "business equipment device," and "target device" interchangeably. As such, the patent provides that the "office machine system" is not limited to a copier engine, but generally includes a "business equipment device" or "target device." The first part of Pitney's proposed construction reflects this conclusion.

Turning to the additional limitation that the business office device is "connected to but separate from" the operation panel, Pitney argues that the intrinsic evidence mandates this conclusion. In contrast, Ricoh contends that the term "office machine system," when read in the proper context of the specification, does not require the operational panel to be physically apart from the business office device.

The Court finds Pitney's argument to be more persuasive. Figures 1 and 2 of the '554 Patent illustrate that the business office device, in this case a copier, and the operation panel are separate components of the system. These figures further illustrate that the operation panel and the business office device are connected by a communication media line 12. Moreover, in both the Abstract and the written description, the patentee describes the present invention as one that allows "an external device or devices to access the state of the target device(s), to communicate with the target device(s) and to control the target device(s)." '554 Patent, col. 1, ll. 60-64 (emphasis added); see id., Abstract ("The present invention communicates and controls various modules of business devices which allow an external device such as an operation panel to access the state of a target device, such as a copier, printer or facsimile."). (emphasis added). Thus, the patentee used the specific term "external" to describe the system. This indicates that the operation panel is separate from, or external to, the target device and connected by a communication line which accords with Pitney's proposed construction.

Ricoh argues that the prosecution history of the '554 Patent actually provides support for its position that the claim does not require physical separation between the operation terminal and the target device. (Tr. of Markman Hr'g at 29:14-30:12). Based on an examination of the '554 Patent prosecution history, however, Ricoh misreads the patentee's statements. During prosecution, the patentee sought allowance for a number of claims, including Application Claims 39 and 40. n2 ('554 Patent Prosecution History, Sept. 13, 1995 Amendment at 2-4). Although the Examiner initially allowed these claims, he subsequently withdrew the allowance in light of the parent application which issued as the '779 Patent, another patent owned by the patentee. (Id., Oct. 18, 1995 Examiner's Action at 1; Jan. 4, 1996 Examiner's Action at 1-2). The Examiner concluded that Application Claims 39 and 40 of the '554 Patent application claimed the same invention as Claims 32 and 33 of the '779 Patent, and thus rejected the application claims on double patenting grounds. (Id., Jan. 4, 1996 Examiner's Action at 2-4).
at 2). In response to the rejection, the patentee argued that the subject matter of the claims were not identical. (Id., Feb. 1, 1996 Response at 1-3).

Further, application Claims 39 and 40 . . . recite communication between an office device and a remote terminal. A remote terminal must be remote from the office device. To the contrary, patent Claim 32 [of the '779 Patent] recites communication between an office device and an operation terminal. There is no requirement in patent Claim 32 for the operation terminal to be remote from the office device. It may be possible for the operation terminal to be mounted within the same housing as the office device and therefore, the operation terminal will not be remote from the office device. To the contrary, application Claims 39 and 40 require a remote terminal and not simply an operation terminal and this is a clear difference between the claims. n3

(Id. at 6) (emphasis added and in original).

n2 Application Claims 39 and 40 initially depended on Claim 37 which was rejected on anticipation grounds. (Id., July 26, 1995 Examiner's Action at 3). The claims were subsequently amended as independent method claims. (Id., Sept. 13, 1995 Amendment at 2-4).

n3 These claims were ultimately allowed and issued as Claims 1 and 5 of the '554 Patent. (Id., Apr. 1, 1996 Notice of Allowability at 1-3).

At the hearing, Ricoh relied on these statements in asserting that the patentee did not intend to require a remote operation panel. (Tr. of Markman Hr'g at 30:6-8) (“The examiner in that case said, well, the operation panel needs to be remote, and Ricoh said, no, it either could be remote, or it couldn't be remote.”). The Court disagrees with Ricoh's interpretation of these statements. These statements during prosecution clearly reveal the patentee's intent that the operation panel "must be remote from the office device," or more specifically, that Claims 39 and 40 of the '554 Patent application must include a remote terminal that is not housed or mounted in the same housing as the office device - a feature that was not claimed in the previously issued '779 Patent. As such, the Court rejects Ricoh's argument, and concludes that the '554 Patent prosecution history provides additional support for the conclusion that the claim requires physical separation between the business office device and the operation panel.

Ricoh also argues that Pitney's construction should not be adopted because it fails to capture the essence of the claimed invention. Ricoh, however, fails to convince the Court that the patentee intended to include all of the limitations appearing in Ricoh's rather lengthy proposed construction. Although Ricoh's construction may generally describe the invention, the Court does not find, nor does Ricoh provide, a basis for interpreting the specific term "office machine system" in the manner urged by Ricoh.

In contrast, the Court finds clear support in the intrinsic evidence for Pitney's proposed construction as discussed above. Consequently, the Court adopts Pitney's construction as it reflects an appropriate interpretation of the claim term. Accordingly, "office machine system" means "[a] business office device, such as a copier, printer or facsimile, connected to but separate from an external operation panel."

B. "OLAP server" and "for use with any one of a plurality of different OLAP servers"

"OLAP server" appears in claims 1, 2, 6, 7, 12 and 13 of the '544 patent and "for use with any one of a plurality of different OLAP servers" appears in claim 1 of that patent. Although the parties briefed these terms separately, the court construes them at the same time. Hyperion contends the term "OLAP server," while known in the art, is indefinite because "HyperRoll * * * elected to use two separate and contradictory definitions of 'OLAP Server' in the '544 Patent." Hyperion Br at 14. Hyperion further contends that "for use with any one of a plurality of different OLAP servers" means "capable of being used
concurrently with more than one OLAP Server." Id at 13.

HyperRoll instead asserts that one of ordinary skill in the art would know that the "OLAP server" is the OLAP server of the prior art, i.e., a "system or program that accesses data stored in data stores to provide decision support." HyperRoll Br at 10. HyperRoll asserts that "for use with any one of a plurality of different OLAP servers" means "capable of being used with different OLAP servers." Joint Cl Const at 57.

The dispute between the parties on these terms boils down to two issues: (1) Is the term "OLAP server" indefinite? (2) Does "for use with any one of a plurality of different OLAP servers" require the stand-alone data aggregation server to be capable of being used concurrently with more than one OLAP server?

First, Hyperion asserts that the conventional, prior art use of an OLAP server is a server that performs aggregation functions. Hyperion Reply Br at 14. Hyperion contends that the patent uses this definition for OLAP server in the background section, but then the patent "describe[s] an embodiment where the aggregation functionality is moved from the OLAP server to a stand-alone data aggregation server. This removes what is considered to be the essential functionality of an OLAP server from the OLAP server. * * * [O]nce the aggregation functionality is removed from an OLAP server, it is no longer an OLAP server, it is something else." Hyperion Br at 23.

Hyperion is correct that the patent uses the term "OLAP server" both to refer to the prior art server that included aggregation functionality and the present invention in which the aggregation functionality is moved to a separate, stand-alone data aggregation server. But this does not render the term indefinite. Contrary to Hyperion's contention, the prior art OLAP server as described in the patent could perform some functions other than aggregation. See, e.g., FIG 1B (showing a prior art "multidimensional OLAP server" containing an "aggregation access and retrieval module," an "application logic module" and a "presentation module"). A person of ordinary skill in the art, having read the patent and the claims, would conclude that the "OLAP server" as described in claim 1 retains at least some of these other functions, even if the aggregation functionality had been "outsourced" to the data aggregation module. Accordingly, the term "OLAP server" as used in the claims and explained in the specification is not "insolubly ambiguous" and therefore is not indefinite. See Invitrogen Corp. v. Biocrest Mfg., L.P., 424 F.3d 1374, 1383 (Fed Cir 2005).

Next, Hyperion argues the term "for use with any one of a plurality of different OLAP servers" means that the stand-alone data aggregation server must be "capable of being used concurrently with more than one OLAP server." But the intrinsic evidence does not support this construction.

First, the plain language of the term does not suggest that the aggregation server must be capable of being used with more than one OLAP server concurrently. The natural meaning of "for use with any one of a plurality of different OLAP servers" is that the aggregation server could be used with any one of the servers, but not necessarily with more than one server at the same time.

Hyperion also relies on HyperRoll's amendments to the drawings and claims, contending that these amendments illustrate that the stand-alone data aggregation server must be capable of operating concurrently with a plurality of different OLAP servers. Hyperion Br at 22. But Hyperion misreads the prosecution history. The patent examiner stated in a summary of an October 16, 2001, interview, "The applicants agreed to provide numbering of the figures, and to resolve an inconsistency between Figures 6B and 7A and also showing a plurality of OLAP servers[] and display a plurality of OLAP servers." Doc # 197, Ex B at 1. Plaintiffs subsequently filed an amendment on October 23, 2001, adding, inter alia, FIG 6E and noting in the specification:

[FIG 6E shows] "the Aggregation Server can be plugged into (e.g., interfaced to) OLAP Servers (two shown as 605' and 605") of different users and vendors. As shown, the Aggregation Server 603 is operably plugged into (e.g., interfaced to) OLAP Server 605' of one user or vendor, yet it is also capable of being operably plugged into OLAP server 605" of another user or vendor, as indicated by the dotted lines. This dramatic move discontinues the restricting dependency of aggregation from the analytical functions of OLAP * * * .

The patent never says anything about requiring the aggregation server to be capable of connecting to the two OLAP servers concurrently. If anything, the dotted line in FIG 6E suggests that although one could switch the OLAP server to which the aggregation server connects, the aggregation server in that embodiment does not connect to more than one OLAP server at
a time. This interpretation is consistent with the claim language and with HyperRoll's proposed construction.

Accordingly, the court rejects Hyperion's contention that "OLAP server" is indefinite and its proposed construction for the term "for use with any one of a plurality of different OLAP servers." The court adopts HyperRoll's construction for this term: "capable of being used with different OLAP servers." The court declines to construe further the term "OLAP server" given that its meaning is clear in the relevant claims.

4. On

a. Depositing a Titanium Film Containing Nitrogen Atoms on a Semiconductor Substrate

The titanium film containing nitrogen atoms must be deposited directly on a semiconductor substrate.

b. Forming a Titanium Nitride Film on the Semiconductor Substrate

The titanium nitride film must be directly on the titanium silicide film, which in turn must be directly on the semiconductor substrate.

Claim Construction: "Single Screen"

The parties vigorously dispute the meaning of claim 1's "single screen" limitation. Both parties recognize that this limitation is emphasized in both the specification and the Prosecution history as a defining feature of the '055 invention. Indeed, in distinguishing the '055 invention from the prior art during prosecution, the "single screen" limitation was repeatedly cited and characterized by the patentee.

The parties dispute, however, both the type of information that must be displayed on the "single screen" and the nature of the "single screen" in relation to the system as a whole. With respect to the information displayed on the single screen, Amazon contends that the claim requires the presentation of a transaction type, a plurality of transaction parameters, and an additional transaction parameter. IPXL contends that only a transaction type and a plurality of transaction parameters must be displayed on the "single screen."

With regard to the nature of the screen and how it fits into the claimed system, Amazon contends that the "single screen" limitation does not preclude previous screens entirely, but that the limitation precludes the display of information entered by users on previous screens. IPXL contends that the "single screen" is the system's only screen and that the user must be able to specify the desired transaction or transaction parameters without first navigating a series of transaction entry screens. For the following reasons, the Court adopts neither party's position.

The complete limitation at issue incorporates already construed claim limitations. Specifically, "the processor causing the display to display on a single screen stored transaction information," incorporates the "transaction information" limitation (at least one user defined transaction and at least one user defined transaction parameter) already construed in conjunction with the "means for storing user defined transaction information" limitation. As such, no further construction is required to determine the nature of the information that is displayed on the "single screen."

A question remains, however, as to whether the claim requires the "single screen" to be the only screen presented to the user, or alternatively, whether other screens may precede the "single screen." Nothing in the language of claim 1 suggests that the "single screen" must be the only screen presented to the user. To the contrary, claim 1's preamble dictates that the claim covers a "system" which, as described in the specification, may present multiple screens to the user. For instance, the specification clearly describes a system that first identifies and verifies a user. Col. 6, 11. 65-66. Likewise, in disclosing the
preferred embodiment, the specification contemplates preliminary steps that would require preliminary screens:

Therefore, upon insertion of the ID card 30 into the reader/writer 13, information stored on the ID card 30 is read (other preliminary steps may also be performed in a known manner, such as entering a PIN, etc.) and a number of menu choices are displayed on the display 15.

Col. 7, ll. 20-24. Furthermore, the specification's flowcharts detail the flow of actions and operations associated with the system. The flow charts support the Court's conclusion that preliminary screens disclosing preliminary "start" and/or "identify user" boxes are encompassed within claim 1. Figs. 2, 5, 6. Although the system of claim 1 is not limited to a single and only screen, the specification and the prosecution history make clear that transaction information is to be entered exclusively on the "single screen" and may not be entered on preliminary or additional screens. In other words, as stated in the plaintiff's claim construction brief:

The '055 specification and prosecution history clearly demonstrate that the only reasonable construction of "single screen" is a screen presented to the user, which the user uses to specify the desired transaction for execution or to specify one or more transaction parameters without first navigating a series of transaction entry screens.

... From Amazon's claims charts, it appears that Amazon will argue that "single screen" may be a summary screen where transaction information is presented to the user after the user has proceeded through a series of consecutive screens to select a transaction type and/or transaction parameters. This, however, frustrates the very purpose of the '055 invention, which was to avoid the series of consecutive screens (which the specification calls "annoying," "time consuming," and "inefficient"). IPXL Cl. Constr. Br. at 19, 21). The Court adopts plaintiff's argument that the "single screen" must exclusively display, and allow the user to modify, stored transaction information. That conclusion is clearly supported by the patentee's comments during the prosecution of the '055 patent. For instance, in response to the examiner's May 16, 1997, office action setting forth an objection to the specification and a rejection under 35 U.S.C. 112(1), the patentee explained:

... one aspect of the present invention involves using a single display screen for selection of an ATM transaction. Currently known systems typically require a user to go through a series of screens and make a single selection per screen. For example, one screen may seek selection of the transaction type, the next screen may ask for the user to select an account, another may ask for the amount of the transaction, etc. None of the prior art of record appears to disclose providing a single screen for multiple selections. (IPXL 00089). Again, in distinguishing prior art references following the examiner's January 6, 1999, office action setting forth an obviousness rejection under 35 U.S.C. 103, the patentee explained:

For example, with respect to ATM machines, a user typically must enter transaction information by selecting one transaction parameter per screen. Madan, even if it were to be considered analogous, does not disclose this.

Neither Madan nor Martino discloses an ATM that enables a user to select from a single screen transaction type and transaction parameters.

(IPXL 00105-106). Consistent with these remarks, in a supplemental response to the examiner's January 6, 1999, office action, the patentee reiterated the nature of the "single screen" limitation when distinguishing additional prior art references:

Neither Anderson or Coutts disclose at least displaying transaction information on a single screen as claimed by Applicant. Anderson and Coutts do not appear to relate to the various novel aspects of the present invention including those pertaining to presenting transaction information on a single screen.

(IPXL 00110). These remarks during the prosecution of the patent confirm that regardless of the nature of the preliminary screens involved in the system, a single screen must eventually present exclusive stored transaction information that may be selected exclusively on the "single screen."
The specification of the '055 also supports such an interpretation of the "single screen" limitation. For example, the specification explains that:

The need to manually enter or select the transaction type and each or many of the transaction parameters each time a user desires to perform a transaction can be annoying and time consuming.

Col. 2, ll. 4-7.

It is another object of the invention to provide an ATM system with a single display screen from which a user can select a transaction type and one or more of the transaction parameters necessary to define the selected transaction.

Col. 3, ll. 1-4.

Unlike conventional ATMs, which use a series of consecutive menu screens to enable the user to, select the transaction type and transaction parameters, the GUI according to one embodiment of the present invention provides a single screen from which the user can select the transaction type and all or some of the transaction parameters necessary (or desired) to define the selected transaction.

Col. 14, ll. 29-36. Read in light of claim 1 as a whole, the '055 specification, and the '055 prosecution history, the Court concludes, that "the processor causing the display to display on a single screen stored transaction information" requires:

The presentation of stored transaction information to a user on one screen, without the user having to first encounter any preliminary screens that would require the user to select a transaction type or a transaction parameter.

C. "On and [in] contact with" ('715 patent, claim 1; '419 patent, claim 1).

Ixys and APT agree that the definition of this claim term should begin with the sentence "In a layered device formed on a substrate, above and touching or in immediate proximity to." While Ixys' construction ends there, APT inexplicably urges this court to add that "On or in contact may impose different requirements, depending on the types of layers involved and how the layers interact." APT is surely aware that claim language is construed within the context of the claims in which it arises, and hence that the same words may, in some limited cases, take on different meanings when applied to different technologies or materials in different claims. Here, however, the court is asked to interpret the language "On and [in] contact with" in the context of only two claims, both of which reference "an insulating layer" in contact with "said first metallization layer." Whatever "different requirements" APT may envision, they are certainly not relevant here.

According to the parties' agreement on the first part of the definition for this term, the court construes this claim language to mean: "In a layered device formed on a substrate, above and touching or in immediate proximity to."

2915

C. Anticipation…that depends on what "ON" is.

Unitrode's first argument for summary judgment in its favor is that Claim 1 of the '098 Patent is invalid for lack of novelty because it reads on the prior art of Carsten. In order for a patent claim to be anticipated by prior art under 35 U.S.C. § 102, a "device or method, having all of the elements and limitations contained in the claims, [must be] described in a single prior art reference." ATD Corp. v. Lydall, Inc., 159 F.3d 534, 545 (Fed. Cir. 1998). The first step in any analysis of invalidity is claim construction, which is an issue of law. See Rockwell Int'l Corp. v. United States, 147 F.3d 1358, 1362 (Fed. Cir. 1998).

In construing the disputed terms of a claim, "the court should look first to the intrinsic evidence of record, i.e., the patent
itself, including the claims, specification and, if in evidence, the prosecution history. "Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (citing Markman v. Westview lnstr., Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc), aff'd 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996)). "Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Id.

While the Federal Circuit has "made strong cautionary statements on the proper use of extrinsic evidence" (like expert and inventor testimony, dictionaries and learned treatises), "trial courts generally can hear expert testimony for background and education on the technology implicated by the presented claim construction issues, and trial courts have broad discretion in this regard." Key Pharms. v. Hercon Labs., Inc., 161 F.3d 709, 716 (Fed. Cir. 1998). The Court properly relies on expert testimony in cases where the intrinsic evidence (i.e., the patent record) does not resolve the dispute. "What is disapproved of is an attempt to use extrinsic evidence to arrive at a claim construction that is clearly at odds with the claim construction mandated by the claims themselves, the written description, and the prosecution history, in other words, with the written record of the patent." Id. Among the extrinsic evidence which the Federal Circuit has sanctioned in interpreting claims are dictionaries and reference books. EMI Group N. Am., Inc. v. Intel Corp., 157 F.3d 887, 892 (Fed. Cir. 1998), cert. denied, 526 U.S. 1112, 143 L. Ed. 2d 788, 119 S. Ct. 1756 (1999).

The construction of a single word or phrase in a patent claim is often the dispositive issue. Attorneys therefore marshal impressive arsenals of legal precedent, technical exegesis, record citations, canons of construction, extrinsic evidence, and--above all--the most clever reasoning to persuade a judge that a word such as "as," "or," or "is" isn't what she thought it might be. Here, the able counsel for Vicor and Unitrode have taken aim at the single word "ON," as the fate of both their arguments ride on its meaning.

On these motions for summary judgment, Claim 1 of the '098 Patent is chiefly at issue. 4 It reads:

In a single ended forward converter in which energy is transferred from a primary winding to a secondary winding of a transformer during the ON period of a primary switch, circuitry for recycling the magnetizing energy stored in said transformer to reset it during the OFF period of said primary switch, comprising:

a storage capacitor;

an auxiliary switch connecting in series with said storage capacitor;

a switch control circuit operating said auxiliary switch in accordance with a control logic such that (a) said auxiliary switch is opened prior to the ON period of said primary switch, (b) said auxiliary switch remains open throughout the ON period of said primary switch, (c) said auxiliary switch is closed after the ON period of said primary switch.

Col. 8, ll. 52-67 (emphasis added). The important question in construing this language is whether the "ON period" is defined in terms of voltage across the primary switch (Unitrode's proposed construction) or in terms of that switch's capacity to carry current (Vicor's proposed construction). If defined in terms of voltage, 5 the ON period would begin when the voltage across the switch drops to zero. In a real-life solid state transistor switch, the voltage does not drop to zero the instant current begins to flow across the switch. Indeed, the voltage in such switches will not drop to its lowest until some point in time after the current has begun to flow at its maximum rate. Thus, a voltage-based definition would not necessarily require a switch-timing delay, since Claim 1 could read on a device such as Carsten's in which the auxiliary switch remains engaged while current is flowing through the primary switch.

--- Footnotes ---

4 Claims 3 and 5, dependent claims of Claim 1, are also at issue in Unitrode's motions for summary judgment. Claim 3 reads, "The transformer resetting apparatus of claim 1 wherein said circuitry is connected in parallel with said primary winding." Col. 9, ll. 4-6. And Claim 5 reads, "The transformer resetting apparatus of claim 1 wherein the auxiliary switch is a MOSFET transistor with an integral reverse diode." Id. at ll. 11-13. However, both parties agree that the validity of these dependent claims is entirely contingent on the construction given to Claim 1.

5 In lay terms, voltage is a measure of the electrical force or potential energy across the switch. At oral arguments both parties likened voltage to the water pressure inside a water tank, while the current was likened to the flow of water from the...
tank's faucet.

By contrast, under a current-based definition, the ON period would begin at the moment the primary switch is capable of carrying a current. Thus defined, Claim 1 would require some period of switch delay between the opening of the auxiliary switch and the flow of current through the primary switch—a novel element unanticipated by prior art.

6 There will always be some amount of current "leakage" across a switch that cannot be prevented. Both parties agree, however, that such current leakage should not factor into the Court's claim construction.

1. Unitrode's proposed claim construction

In support of its proposed voltage-based definition of ON, Unitrode places great emphasis on the following Figure 4b from the '098 Patent:

The figure above "considers a sequence of two ON periods separated by an OFF period. . . . The figure displays, as functions of time, idealized waveforms defining the state of the [primary] switch 10 [and] the voltage V across it. . . ." Col. 5, ll. 55-57. Unitrode insists this portion of the specification explicitly defines ON period in terms of voltage. As a result, Unitrode contends that the Court is required to adopt its voltage-based definition of "ON" in construing the patent claims. See Vitronics, 90 F.3d at 1582 ("Usually, [the specification] is dispositive; it is the single best guide to the meaning of a single term."). For additional support, Unitrode points to references in the specification where voltage and the state of the primary switch are mentioned in tandem. See, e.g., col. 5, ll. 61-62 ("During [the "ON"] period, the voltage V across the primary switch and the current I through the auxiliary switch vanish."). As Unitrode points out, the specification and the drawings of the patent never show the current flowing through the primary switch.

To bolster its proposed claim construction Unitrode also relies on the interpretive maxim of claim differentiation. That doctrine, "which is ultimately based on the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope, normally means that limitations stated in dependent claims are not to be read into the independent claim from which they depend." Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999) (citations omitted). While the claim differentiation doctrine is "not a hard and fast rule of construction, it does create a presumption that each claim in a patent has a different scope." Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998).

Unitrode argues that, by proposing a current-based definition for ON, Vicor is attempting to read into Claim 1 all of the limitations found in unasserted dependent Claims 22, 23 and 24. Claim 22 contains the limitation that the ON period begins "a small delay period after the opening of the auxiliary switch." Col. 10, ll. 1-3. Claim 23 contains the limitation that the small delay period "accommodates charging and discharging of capacitances" in the converter. Id. at ll. 4-6. And Claim 24 contains the further limitation that the capacitances "comprise parasitic capacitances." Id. at ll. 7-8. According to Unitrode, each of the limitations in these dependent claims would be rendered superfluous by a construction of Claim 1 that would, in effect, require a "small delay" between the opening of the auxiliary switch and initiation of the ON period that would "accommodate the charging and discharging of capacitances" that are "parasitic capacitances."

2. Vicor's proposed claim construction

Vicor argues that Unitrode's voltage-based definition of the ON period is inconsistent with the language and purposes of the '098 Patent and that ON should instead be defined in terms of the point at which the primary switch is enabled to conduct current. In support of this definition, Vicor places great emphasis on the following passage from the specification:
a delay between the opening of the auxiliary switch 21 and the closing of the primary switch 10 represents dead time. For this reason, it is efficient to keep such a delay to a minimum, consistent with the requirement to avoid overlap between switches. However, a small delay is useful to allow the magnetizing current to charge and discharge parasitic capacitances associated with the switches and windings.

Col. 7, ll. 4-11. According to Vicor, the above language explicitly recites the function and purpose of the claimed invention. As such, the construction given to ON period must accord with "a full understanding of what the inventor[] actually invented and intended to envelop with the claim." Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998) (citing Markman v. Westview Instruments, Inc., 517 U.S. 370, 389, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996)).

In Vicor's view, this portion of the specification militates in favor of a current-based definition because it states that the purpose of opening the auxiliary switch "prior" to the closing of the primary switch is to allow the discharge of the switch's parasitic capacitance. By contrast, adopting a voltage-based definition of ON would not require a "delay" or "dead time" between the opening of the auxiliary switch and closing of the primary switch so as to "allow the magnetizing current to charge and discharge parasitic capacitances associated with the switches and windings." Moreover, according to Vicor, adopting a voltage-based definition would violate the patent's requirement to "avoid overlap between switches." If the terms of a claim must be read in accordance with the purpose of the invention, Vicor asserts that a current-based construction of ON is the best way to achieve that goal.

3. The Court's construction

Although the question is close, I conclude that Vicor's interpretation is the better.

To start with, the "ON period" is nowhere defined in terms of either the current or the voltage across the switch. Instead, the specification states: "at time t[1], the auxiliary switch 21 is opened and the primary switch 10 is closed, initiating the first ON period." Col. 5, ll. 59-60. See also col. 4, ll.3-4 (referring to the converter's "ON period" as "when the primary switch is closed.") Thus, the beginning of the ON period is described as the moment the primary switch is "closed." Because the word "closed" is not defined, this definition only moves the analysis a mini-step ahead.

The Court must construe the claim in the context of the whole patent, with analysis rooted in the words of the specification. See Renishaw, 158 F.3d at 1250. The current-based definition is consistent with the specification which describes in plain terms that the patent contemplates "dead time" when the reset mechanism is not operational. Col. 7, ll. 4-6. Although "dead time" is not defined in the patent, Mr. Carsten, who is now an expert for Unitrode, agreed in his deposition that "dead time" in the patent is time during which neither switch is carrying current. (See Vicor Statement of Undisputed Facts ("SUF") (Docket No. 81), Ex. 10.)

In addition, the text describes the useful properties for allowing such a delay, namely, that the reversed flow of magnetizing current can be used to "discharge the parasitic capacitances of the switches and windings." Col. 7, ll. 10-11. A current-based definition supplies a reading of the claims that preserves this purpose stated in the specification. Mr. Carsten's deposition testimony is consistent with Vicor's definition:

Q. Okay. And what are these multiple interpretations of "ON" and "OFF" that you think are possible?

A. It is on when it has at least close to the lowest possible voltage while carrying conducting current [Unitrode's definition]. Anything in between is a linear operation.

Q. So that's one possible definition?

A. That's one possible meaning of the term. Another possible meaning of the term is that a device is on when it's conducting any current at all above and beyond the normal leakage current.

Q. Which of the two definitions would you say is most relevant to using delays to discharge the parasitic capacitance non-dissipatively?

A. In that context, the definition is closer to the second one where any current at all is a conduction.
(Vicor SUF, Ex. 4.) By contrast, a voltage-based definition would permit the harmful dissipative discharge of the parasitic capacitances when current passes through the primary switch because, by Carsten's own admission during deposition, the primary switch may be carrying its maximum current before the initiation of the "ON period." (See id., Ex. 16.)

Unitrode argues that this Court should not rely on a single passage in the patent that references discharging parasitic capacitance because the patent never states that the process must be non-dissipative. However, it is immaterial that the text does not specify whether the discharge of the parasitic capacitances is dissipative or non-dissipative in nature. If there is a residual capacitance in the switch and winding, it will ultimately be discharged in one manner or another. It either can be discharged as heat (i.e., dissipatively), or it can be discharged as energy flowing into the transformer core (i.e., non-dissipatively). Only the latter result, however, could be considered "useful" as required by the specification. Col. 7, ll. 4-11.

The specification also asserts a "requirement to avoid overlap between switches." Id. at ll. 8-9. The current-based definition of ON would forbid simultaneous conduction of current across the primary and auxiliary switches, making that definition more compatible with this requirement. On the other hand, under Unitrode's definition of ON, current could continue to flow through the primary switch and into the transformer core while the auxiliary switch remains engaged and conducting current. This simultaneous conduction of current would be inconsistent with the requirement to avoid overlap between switches.

The current-based definition is also consistent with the extrinsic evidence, although not mandated by it. "Absent an express definition in the specification of a particular claim term, the words are given their ordinary and accustomed meaning; if it is a term of art, it is given the ordinary and accustomed meaning as understood by those of ordinary skill in the art." Zelinski v. Brunswick, 185 F.3d 1311, 1315 (Fed. Cir. 1999). Because there is no intrinsic express definition of the word "on" or "closed," the key to the dispute may be the expert testimony on the background of the technology. See Key Pharms., 161 F.3d at 716. Plaintiff's expert Paul Horowitz, a professor of Physics at Harvard University, conceded in his expert report that the terms "on" and "off" did not have a single accepted meaning in connection with electronic switches. However, he states that there is an ordinary and accustomed meaning for closing a switch: "A 'switch' is a device, such as a relay or transistor, that can be enabled to conduct current, or disabled from conducting current." He noted, "When a switch is enabled to conduct current, the switch is said to be 'closed.' When the switch is enabled to block current (or disabled from conducting current), it is said to be 'open.'" (Vicor SUF, Ex. 27, p. 4.) See Random House Unabridged Dictionary (2d ed. 1993) (defining "switch" to include: "5. Elec. A device for turning on or off or directing an electronic current or for making or breaking a circuit."). Plaintiff's expert Nathan Sokol also opined that in the context of the patent "closed" means "the action which is taken to make the switch do something" and "that action results in the switch being enabled to conduct current." (Unitrode Aff. of D. Massa (Docket No. 104), Ex. 2.)

Defendant's expert, Dr. James K. Roberge, a professor of Electrical Engineering at MIT, states: "Transistor switches do not turn on and off instantaneously; they have ON periods and OFF periods and transition states between those two periods." (Aff. of J. Roberge (Docket No. 91), P12.) He relies on a textbook, R. Ralph Benedict, Electronics for Scientists and Engineers, 212-214 (1967) to prove his point: "The textbook indicates that the ON period begins when the voltage across the switch falls to a voltage close to zero, even though current has already begun to flow in the switch prior to that time . . . . Current can begin to flow in a switch even though the switch is not yet in its ON period." Roberge adds: "Although in some usages, the ON period of a switch is defined in terms of current flow, it is not generally defined as occurring when "on" or "off" or "current" or "any measurable" current, and rather when 90 percent of the saturation or maximum current flow is reached." (Roberge Aff., P12; see also Unitrode Aff. of W. Stoner (Docket No. 92), Ex. 2 (Vinciarelli stating in deposition, "I guess every device has a transition state between an on and off. That's correct.").) The Roberge-Horowitz debate highlights the complexity of defining "ON" in the context of transistors which have this transition on-off state. However, because the specification provides that the word "closed" demarcates the start of the "ON" period (T[1]) it cuts against a voltage based definition because no action is taken at the moment the voltage hits zero. In contrast, an action is taken at the moment the switch is enabled to carry current.

Although Unitrode's arguments have some persuasive weight, they cannot be sustained when the patent is read as a whole. For several reasons, Figure 4b and the accompanying text cannot be accepted as an explicit voltage-based definition of ON period. First, the waveforms depicted in Figure 4b are idealized, not real waveforms. The patent recognizes this when it states that "the first ON period is given by the time interval between t[1] and t[2] [referring to Fig. 2b]. During this interval, the voltage V across the switch 10 vanishes. . . ." Col. 1, ll. 59-61; see also col. 5, l. 61-62 ("During this [ON] period, the
voltage V across the primary switch and the current I through the auxiliary switch vanish.") Significantly, the patent does not state that voltage drops to zero at t[1], but only that it vanishes "during" the ON period between t[1] and t[2]. "During" can mean either "throughout the duration of" or "at a point in the course of." Webster's 9th New Collegiate Dictionary, p. 289 (1986). It is not defined to mean at the start of. The use of the term "during" suggests that voltage does not drop to zero at t[1], the start of the ON period.

--- Footnotes ---

7 This discussion applies to the idealized waveforms in Figure 2b and 3b as well.

--- End Footnotes ---

Second, these idealized waveforms do not show the real-life details of current flowing across a solid-state transistor. Without some reflection of the reality that voltage across a transistor switch does not drop instantly to zero, the idealized waveforms are equally consistent with both parties' definitions and do not provide the strong guidance urged by Unitrode.

Third, although Unitrode has argued that Figure 4b would be "useless" if it did not serve to define the ON period in terms of voltage across the switch, that simply is not the case. Although the figure does little or nothing to describe the fine switch-timing properties of the invention, it provides a useful illustration of the operation of the magnetizing current mirror as a whole. The '098 Patent can best be understood as a whole document by acknowledging that, in 1981, Dr. Vinciarelli was under the mistaken impression that his patent was the only known manifestation of a magnetizing current mirror device. The thrust of the patent's specification was the description of the core reset mechanism itself, while comparatively minor attention was given to the fine switch-timing properties that are the subject of this suit.

Fourth, the patent explicitly disclaims any relation between Figure 4b and the aspects of the invention dealing with the discharge of the primary switch's parasitic capacitance. See col. 5, ll. 44-51 ("neglecting … parasitic effects including the ones associated with … the capacitance of non-ideal hardware realizations of the primary switch 10 …, the operation of the magnetizing current mirror as a reset mechanism is illustrated by an example in 4b."). It is therefore less plausible that the inventor would rely on this figure to define the invention's switch-timing properties.

Finally, Unitrode presses an argument based on claim differentiation for adopting a voltage-based definition for ON period. See Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) (holding "the scope of a particular claim can often be determined on inspection of other claims."). The doctrine of claim differentiation is a presumption, not a hard and fast rule. See Comark Communications, 156 F.3d at 1187. And, in some circumstances, if a claim will bear only one interpretation, a certain amount of "similarity [between claims] will have to be tolerated." Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) (quoting Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 404 (Ct. Cl. 1967)).

In connection with this argument, Unitrode also emphasizes the statutory mandate that the claims of a reissued patent cannot be broader than the original claims. See 35 U.S.C. § 251. ("No reissued patent shall be granted enlarging the scope of the claims of the original patent unless applied for within two years from the grant of the original patent.") Section 251 is the statutory basis for correction of "error." In re Weiler, 790 F.2d 1576, 1579 (Fed. Cir. 1986) "The statute is remedial in nature, based on fundamental principles of equity and fairness, and should be construed liberally." Id. However, it prohibits broadening reissue claims after two years, whether or not the broader claims are supported in the specification. See Reiffin v. Microsoft Corp., 214 F.3d 1342, 1348 (Fed. Cir. 2000) (Newman, J. concurring) (citing, as an example, Carbide & Carbon Chem. Co., 315 U.S. 668, 86 L. Ed. 1105, 62 S. Ct. 839 (1942)).

By its usage of the word "prior," Claim 1 requires some delay between the "ON period" of the auxiliary switch and "ON period" of the primary switch. The claim does not, however, specify the length of delay. Claim 21 and its dependent Claims 22 and 23 require that the switch delay be a small delay. Vicor argues that "some delay" is broader than "small delay."

The history of the reissue proceeding is helpful here. The Supplemental Reissue Declaration states:

Applicant also noted that the notion (disclosed and claimed in the '146 patent) of using a switching delay to charge and discharge circuit capacitances did not appear in any of the references until the 1990 Carsten article and that applicant's
Disclosure of this feature predated Carsten's discovery by at least eight years.

(Massa Aff., Ex. 4, P18.) The Interview Summary by the patent examiner states:

Applicant's attorney was informed that the above two references [Carsten and Polikarpov] even if they were earlier art wouldn't anticipate or wouldn't have been obvious over claims 1 and 18, nor do the reference [sic] disclose the switch timing.

(Vicor SUF, Ex. 7.) One wonders, then, why Vicor felt compelled to add the new claims which substantially track the specification in the original patent. In any event, Vicor's argument that the reissued claim (specifying a small delay) is narrower than the original specification (specifying "delay") is strained in the context of this patent where all switching delays are fractions of seconds. However, as I've construed Claim 1 to encompass a current-based definition, the new claim is at worse redundant and certainly not broader than Claim One as construed.

As a back up, Unitrode argues that certain references define the ON period of a switch as commencing when current flow through the switch has reached 90% of its maximum value. This contention was corroborated by the testimony of Vicor's own expert, Professor Horowitz. (Stoner Aff., Ex. 11.) If "ON" were defined this way, the Carsten devices would anticipate the claims. This definition suffers from the same flaws inherent in the voltage-based definition because it does not avoid "overlap between the switches" or provide "dead time."

Two final considerations bolster the Court's current-based claim construction. First, the original Vinciarelli patent underwent a reexamination proceeding in which the PTO upheld the validity of Claim 1 despite the existence of much of the same prior art presented by Unitrode in this proceeding. In such circumstances, the burden on the party seeking invalidity is made even heavier. See Custom Accessories, Inc. v. Jeffrey-Allan Indus., Inc., 807 F.2d 955, 961 (Fed. Cir. 1986). Second, due to the patent's presumption of validity under 35 U.S.C. § 282, any remaining ambiguity should be resolved in favor of Vicor. See Modine Mfg. Co. v. U.S. Int'l Trade Comm., 75 F.3d 1545, 1557 (Fed. Cir.) ("When claims are amenable to more than one construction, they should when reasonably possible be interpreted so as to preserve their validity."), cert. denied, 518 U.S. 1005 (1996).

In sum, based on the specification, I conclude that Vicor's proposed current-based definition is better because it is consistent with the goal of achieving the non-dissipative discharge of parasitic capacitance. Unitrode's motion for summary judgment on the ground that the patent claims are anticipated by prior art under 35 U.S.C. § 102 must therefore fail as a matter of law.

2916
e. a source electrode and a drain electrode on a said semiconductor layer

LGD contends that "a source electrode and a drain electrode on said semiconductor layer" means "a source electrode and a drain electrode above and in contact with the semiconductor layer." D.I. 376 at Exh. C-17.

AUO contends that there is ambiguity as to what layer is referred to as "said semiconductor layer" in the claim language. AUO contends that one of ordinary skill in the art would understand that the electrodes would need to be above and in contact with an impurity-doped semiconductor layer in order for the TFT to function. AUO contends that LGD's position ignores what is commonly understood as "above and in contact with," and ignores the construction of "source electrode," which requires that the conductive material be formed over the source region. D.I. 1429 at 13. Thus, AUO's proposed construction for the phrase "a source electrode and a drain electrode on said semiconductor layer" is "the source electrode and the drain electrode above, supported by, and in contact with the semiconductor layer." D.I. 376 at Exh. C-17. CMO's construction of this phrase is identical to LGD's proposed construction. Id.

The Court adopts the claim construction proposed by LGD and CMO. This construction is consistent with the Court's definition of the term "on," and with the plain claim language and the requirements of the specification. '449 patent, col. 1, ll. 40-51; col. 1, l. 61 - col. 2, l. 4; col. 2, ll. 37 - col. 3, l. 15; col. 3, l. 50 - col. 4, l. 5, col. 4, l. 65 - col. 5, l. 15, Figs. 1-3. Accordingly, the phrase "a source electrode and a drain electrode on said semiconductor layer" means "a source electrode and a drain electrode above and in contact with the semiconductor layer."
a first layer of conducting strips parallel to each other on said substrate

 Claim 1 contains the term "a first layer of conducting strips parallel to each other on said substrate." Lonestar contends that "first layer of conducting strips" is "any layer of two consecutive layers of conducting strips that is nearer to the semiconductor substrate than the consecutive layer selected as the 'second' layer, it need not be the layer most near to the semiconductor substrate, so long as it is more near to it than the 'second layer.'" Lonestar then contends that "on said substrate" means "positioned directly or indirectly above said semiconductor substrate." Nintendo contends that "a layer of conducting strips" means "a layer in which the spacing of the conducting strips and the width of the conducting strips are set to the critical dimensions of the manufacturing process." Nintendo then contends that "the 'first' layer of conducting strips 'on said substrate' is the first deposited layer of conducting strips positioned above and capacitively coupled to the substrate." The parties disagree as to whether "first layer" indicates a sequence limitation, whether the "first layer of conducting strips" must be directly and capacitively coupled to the substrate, and whether the specification limits the claimed invention to "critical dimensions."

 As to the dispute on whether "first layer" indicates a sequence limitation, in light of the specification and the claim language itself, "first" indicates that the "first layer" is closer to the semiconductor substrate than the "second layer." See Col. 6:67-7:5; see Figure 2; see Col. 5:40; see Col. 5:54-57. With regard to other possible layers, the intrinsic record does not require that the "first layer" must be the layer closest to the semiconductor substrate. Claim 1 applies "comprising" language, which "creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unreicted elements." See Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1372 (Fed. Cir. 2005) (citing Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001) ([T]he transition 'comprising' creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unreicted elements')). Nintendo does not rebut this presumption.

 However, Nintendo believes that any additional layers of strips that are deposited cannot be placed closer to the semiconductor substrate than the "first layer." Nintendo argues that the specification does not suggest that a layer of conducting strips could be inserted between the substrate and the first layer. Nintendo in essence suggests that if the specification does not disclose an embodiment, then that embodiment is not allowed for by the patent. This position is not supported by case law. See Envtl. Designs, Ltd. v. Union Oil Co. of Cal., 713 F.2d 693, 699 (Fed. Cir. 1983) ("The claim, not the specification, measures the invention") (citation omitted); see Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) ("the claims define the scope of the right to exclude; the claim construction inquiry, therefore, begins and ends in all cases with the actual words of the claim") (citation omitted). While claims are read in view of the specification, Phillips, 415 F.3d at 1314, this does not mean that the specification must disclose every potential embodiment for such embodiments to be covered by the patent. Cf. Envtl. Designs, 713 F.2d at 699. Furthermore, Nintendo's citations to the specification do not support Nintendo's position. See Col. 1:37-45; see Col. 5:29-57; see Col. 2:19-55; see Col. 6:18-42. Nintendo's citations instead show that the patentee described the "first layer" relative to the "second layer" while not specifying "first" in relation to the semiconductor substrate. See, e.g., Col. 2:27-30 ("Above and separated from the first layer of conducting strips 24A and 24B by an insulating layer (not shown), is a second layer of conducting strips 26A and 26B"). There is no express or implied restriction in the claims or specification on a layer existing between the first layer and the semiconductor substrate. Thus, "first" does not disallow a layer of conducting strips to be placed between the semiconductor substrate and the first layer.

 Concerning the dispute about whether the first layer of conducting strips must be directly and capacitively coupled to the substrate, the Court construes "on said substrate" as "positioned directly or indirectly above said semiconductor substrate." The claim language does not require that the first layer be capacitively coupled to the substrate, and the specification shows that the first layer can be directly or indirectly above the substrate. Figure 2 shows a first layer of conducting strips that is separated from the "substrate 10" by an "insulating layer 11." Col. 2:19-22; see Figure 2. The strips are positioned above the substrate but not directly on the substrate. Also, while the specification makes reference to the first strips being capacitively coupled to the substrate, it does not do so to define the first layer as Nintendo's proposed construction suggests. See Col. 5:5-12. Instead, the specification refers to the strips of various layers being connected to A and B nodes, and the A and B nodes being equally capacitively coupled to the substrate. See id. The specification states, "Since the present invention has
an equal number of strips in each layer connected to the A and B nodes, the A and B nodes are equally capacitively coupled to the substrate 10. … Likewise, the total capacitance of the A and B strips in the second layer to ground are also equal." Id. This language does not define the first layer as capacitively coupled to the substrate. Rather, nodes A and B are described as both being capacitively coupled to the substrate. In addition, the claim language in question is clear. Nintendo has not provided sufficient support in the intrinsic record to require the capacitive coupling limitation to be added to the first layer of strips, particularly when such requirement may be more confusing than the relatively clear claim language. Thus, the Court does not construe "on said substrate" as directly on the substrate or capacitively coupled to the substrate.

GET DRAWING SHEET 1 OF 2

In regard to "critical dimensions," Nintendo's proposed construction states that the width of the conducting strips are set to critical dimensions. Claim 1 does not explicitly limit the capacitor structure to "critical dimensions" or even provide other guidance as to the dimensions. "A critical dimension is the smallest distance in a structure or separation between structures which can be controlled in a process." Col. 2:68-Col. 3:3. In contrast, dependent claim 3 provides specific guidance as to the width, height, and depth of the strips by stating, "the relationship between w, h, and d being w&t;2&t; &t; 2hd." Col. 7:25-28. When a dependent claim adds a limitation to an independent claim, it is presumed that the independent claim does not include that limitation. Phillips, 415 F.3d at 1314-15. In line with this rule, the dimension limitation of dependent claim 3 and the absence of this limitation in independent claim 1 suggests that claim 1 does not include a "critical dimension" limitation because there are not any dimension limitations provided in claim 1 and such limitations exist in claim 3. In light of this reasoning and the additional evidence below showing no "critical dimension" limitation in the specification, Nintendo's arguments fail.

The specification does not limit the capacitor structure to critical dimensions. Table A shows several values for the variable "w" that would satisfy the conditions for making the disclosed invention. Col. 4:55-62. Furthermore, the specification states that "the performance of the present invention is enhanced with each with each [sic] expected dimensional improvement in semiconductor processing technology," implying that the invention may exist in a state that is not the most enhanced state. Col. 5:1-4. This would allow the invention to be made with different dimensional settings. While the invention may be best enhanced with critical dimensions used with each improvement in semiconductor processing technology, this does not mean that enhancement is not achieved with something less than critical dimensions. Further, as shown in Table A and described in the specification reference to Table A, differing dimensional values (as opposed to only the critical dimensions) may still provide "an enhanced capacitor structure." Col. 4:51-5:4.

While the specification states that "the width and spacing of the conducting strips 24A and 24B are set to critical dimensions," Col. 5:43-45, it does so to teach "enhanc[ing] the side-wall capacitances," Col. 5:45-46, and no one set of dimensions is specified. Any further specification description is mentioned as an example: "i.e., the strips and spacing between the strips are as narrow as possible." Col. 5:46-47. Thus, the claims themselves and the specification both provide support for rejecting the "critical dimension" limitation, and the Court accordingly does not add such a limitation to its construction.

Accordingly, the Court construes "on said substrate" to mean "positioned directly or indirectly above said semiconductor substrate." In light of the Court's resolution of the parties' additional disputes, the rest of the language in the claim term does not require construction.

2918

In the Court's opinion and order dated November 8, 1999, I asked the parties to supplement their initial presentations concerning the meaning of the phrase "one address element" in connection with my construction of disputed element iii in Claim 1 of Patent No. 5,212,773 (the '773 patent), so that I might test my preliminary conclusion that the word "one" encompassed both a single address element and a plurality of address elements. Once again, the parties have provided me with extremely lucid and helpful letters, for which I tender my thanks. It is a pleasure to work on what would otherwise be frighteningly complex issues with lawyers who extend every effort to make them comprehensible.

The meaning of the ubiquitous word "one" continues to trouble me, and I fear that the Federal Circuit's latest opinion on claim relinquishment, Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 52 U.S.P.Q.2D (BNA) 1109 (Fed. Cir. 1999) --
Inconveniently decided after our Markman hearing -- does not really clarify matters, since it can be read to support both parties' point of view.

In Elkay, the District Court had construed a claim limitation containing the words "an upstanding feeding tube . . . to provide a hygienic flow path for delivering liquid from said inverted unpressurized container . . . and for admitting air . . . into said container" to encompass both a single tube that performed both functions and two tubes that performed the functions separately. The Federal Circuit reversed. The panel acknowledged (1) that the articles "a" and "an" are not necessarily limited to the singular, and also (2) that the written description, if qualified as a preferred (as opposed to the sole) embodiment, does not conclusively establish that the use of such articles was meant to exclude the plural. However, the appellate court concluded that such a restriction was mandated by the prosecution history of plaintiff's patent.

To understand what the Federal Circuit meant by its ruling, a fairly detailed review of this portion of the opinion is in order. The Court of Appeals started from the proposition that, as a matter of law, the prosecution history "limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Elkay, 52 U.S.P.Q. (BNA) at 1112-13. It then noted that the Examiner had rejected the original claims corresponding to those in issue based on a prior patent (Krug) in view of yet another prior patent (Savage). The Krug patent described a beer dispensing apparatus with two separate feed tubes, one for pressurized air and one for beer. Savage described an apparatus that allowed a liquid feed tube to be connected to a collapsible bag so that air could not be introduced into the bag as the connection was made. Thus, it seemed clear that the Examiner's rejection of Elkay's application was squarely grounded in Elkay's possible use of multiple tubes. Elkay responded to this rejection by distinguishing Krug on the ground that, inter alia, Elkay claimed "a flow path . . . for delivering liquid . . . and admitting air" whereas Krug taught the use of separate tubes to perform those two functions. Elkay did not amend the language of its claim, but its argument emphasized the singular nature of the article "a" as used in its application.

The Federal Circuit discounted the fact that Elkay had not filed an amendment to its claim. The court found that the argument Elkay made to overcome the Examiner's objections was entitled to equal weight as amended language, and that this argument precluded Elkay from contending that its patent covered a device with more than one tube. Moreover, the Federal Circuit ruled that it was "irrelevant whether Elkay emphasized this argument at the time, or indeed whether Elkay had to relinquish an interpretation of the feed tube limitation that could cover more than one flow path for liquid and air." Id. As long as Elkay made the argument in order to overcome the rejection, it necessarily conceded the point. Finally, the Court noted:

Elkay's argument that its statement distinguishing Krug on the basis of Krug's use of separate feed tubes was insignificant is particularly unpersuasive in view of the Examiner's response to that statement. In the Examiner's Statement of Reasons for Allowance, dated March 30, 1993, the Examiner wrote that he allowed claim 22 (i.e., claim 7 in the '531 patent) because he understood the claim to describe a single feed tube with a single flow path for both liquid and air: [Examiner's Statement omitted].

As noted above, both parties find comfort in the Federal Circuit's reasoning. IBM argues that Elkay stands for a relatively simple and straightforward proposition: once TM amended the claim language, which originally read "at least one message element," to read "one message element," it was precluded from taking the position that the word "one" meant "one or more than one." For a neophyte like myself, there is considerable appeal to this argument. If I could read Elkay to preclude me from relying on anything in the file wrapper except amended language where an amendment is made, I would find that IBM was correct without further analysis.

But the Elkay court carefully stated that "It is the totality of the prosecution history that must be assessed, not the individual segments of the presentation made to the Patent and Trademark Office by the applicant" Id. (emphasis added). There is much in the file wrapper that seems to support TM's position.

The Examiner originally rejected the claims that eventually became the '773 patent by Office Action sent June 22, 1991. The Examiner relied on three grounds: first, the claims were indefinite (under 35 U.S.C. § 112 (b)); second, certain claims (including independent Claims 2 and 8, which, in their amended version, are in suit here) were anticipated by prior art, namely the Lawrence patent (under 35 U.S.C. § 102); and third, those claims that were not anticipated were obvious in light of Lawrence. This last objection appears to be directed particularly at Claims 3 and 9 or the original patent application, which are not in suit before me.
In response to the rejection, TM did two things: it amended its claim language in multiple respects (including the substitution of "one" for "at least one" in the claims here in suit), and it submitted an argument to the Examiner. It appears that much of the amended language was designed to overcome the Examiner's complaint about indefiniteness, which he made as to all the claims. TM's argument, however, distinguished Lawrence, and it did so by doing precisely what TM did at the Markman hearing -- it contrasted Lawrence's use of a store-and-forward process with TM's use of wormhole routing. Unlike the applicant in Elkay, TM did not focus at all on the difference between "at least one" (as used in its original independent claim) and "one" (as used in the amended claim). Rather, it argued that the difference between the two patents was how much of a message the router node in TM's computer system needed to receive before it could forward the message to the next point. TM emphasized that the store-and-forward system disclosed in Lawrence required arrival of the entire message before it would route the message to the next node, while TM's "wormhole routing" scheme would start the message on its way as soon as it decoded "enough of a message" to recognize where the message ought to go. (A 2110.)

As I noted in my original opinion, the Examiner specifically relied on this concept of forwarding a message as soon as the node switch received "enough of a message" to recognize its destination when it allowed the claim. Indeed, the Examiner stated that he viewed TM's argument as "persuasive." (A. 2113) In Elkay, an Examiner's response to a patentee's argument in its Statement of Reasons for Allowance was deemed a particularly persuasive piece of evidence. See id. Since the Examiner in this case responded by finding TM's argument compelling, I cannot think of why I ought not do so. Clearly, the patent was allowed because of the difference between store-and-forward and wormhole routing, not because of the change from "at least one" to "one." This interpretation of the claim history explains why, when TM amended its claim language, it did not also change the embodiment described in the specifications, which all parties agree would be read out of the patent if IBM's literal reading of the word "one" were to prevail.

Unfortunately, I cannot stop yet. For there is other language on this one page of the Elkay decision that would seem to favor IBM's position. The Elkay panel stated that it was irrelevant whether Elkay could have obtained its patent without relinquishing the two-tube interpretation of its claim: if in fact that claim was relinquished, it is gone. See id. IBM contends that TM relinquished the claim to "at least one" simply by deleting that language from its revised claims and substituting therefor the singular word "one." While it may have done so without needing to, IBM argues, TM did it and must live with the consequences. As I noted in my original decision, that argument is clear, simple and logical, and therefore quite persuasive -- even in the patent context, where the singular can sometimes encompass the plural.

TM counters with two arguments. First, it claims that Elkay concerns only the effect of arguments made to the Patent Office, as opposed to claim amendments. I find this contention less than persuasive. The Elkay court opinion includes the following statement: "Arguments made during the prosecution of a patent application are given the same weight as claim amendments." Id. (emphasis added). If an applicant can relinquish a claim by arguing that the claim language does not encompass it, he can just as easily relinquish a claim by amending his claim language to eliminate it.

TM's other point has more merit. TM reminds this Court that in York Products Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1575 (Fed. Cir. 1996), the very same Federal Circuit held, "Unless altering claim language to escape rejection, a patent applicant only limits claims during prosecution by clearly disavowing claim coverage." It argues that the change in language simply eliminated excess verbiage in a "comprising" claim -- i.e., one that "includes" the specifically listed limitations and nothing else. Therefore, the language change cannot be read as a clear disavowal of the plurality claim.

This argument, too, has a certain elegance and appeal. In Elkay, the patentee's emphasis on the singularity of the article "a" in his argument necessarily implied that he was relinquishing any claim to a two-tube system. Ours, unfortunately, is not a case where the patentee's intention to relinquish is similarly clear. Given patent law's unusual "singular-encompasses-the-plural (sometimes)" rule, eliminating words of plurality may not necessarily indicate the patentee's intention to abandon plurality claims -- especially where, as here, other evidence in the file wrapper (especially the preferred embodiment) suggests that the patentee is not relinquishing such claim.

IBM responds that the change in language must have been made to overcome the prior art as disclosed in Lawrence, because Celeritas Techs Ltd. v. Rockwell Int'l Corp., 150 F.3d 1354 (Fed. Cir. 1998), cert. denied, 525 U.S. 1106, 142 L. Ed. 2d 774, 119 S. Ct. 874 (1999), held that a claim is anticipated if (and only if) "each and every limitation is found either expressly or inherently in a single prior art reference." Id. at 1361. IBM notes that original Claims 2 and 8 required that, for each message (which includes a series of message elements including at least one address element and at least one data
element), the switch decodes at least one address element to identify an output circuit for that message. Those claims were rejected "as being clearly anticipated by" Lawrence '892. To IBM, that means the Examiner rejected TM's claims because the Lawrence patent either expressly or inherently disclosed a switch that decoded at least one address element of a series of message elements (including at least one address element and at least one data element) in order to route the message.

However, IBM's reasoning does not really address TM's argument, at least as this Court understands TM's argument. TM does not disagree that both patents disclose a switch that decodes at least one message element in order to route a message -- Lawrence at the specification at column 18, line 11-63 of the patent and Figure 15 (A. 2172, 2183) and TM in its specification. 1 But there is a critical difference between the two patents: Lawrence will not transmit the message to its destination until the entire message is received at one point in the system, while '773 will transmit the message without waiting for the tail end to catch up to the front. That is what makes '773 a significant improvement over the prior art. Nothing in Celeritas or any other case that has been brought to the Court's attention precludes patentability when an old concept (decoding address elements in order to forward a message within a massively parallel processor) is carried out in a new and materially improved way (wormhole routing as opposed to store and forward). This, while IBM is correct that "Anticipation under Section 102 can be found only when the reference discloses exactly what is claimed . . . ." Titanium Metals Corp. of America v. Banner, 778 F.2d 775, 780 (Fed. Cir. 1985), it is wrong in supposing that TM could not overcome the Examiner's literalist approach to anticipation by pointing out where the critical distinction between the two routing systems lay. Focusing only on the literal terms of the two computer systems, the Examiner found anticipation because he did not understand the difference between store and forward (Lawrence) and wormhole routing (773). Once he understood that difference, he had no difficulty concluding that '773 represented a significant and patentable improvement over Lawrence -- regardless of the number of address elements that had to be decoded under each patent in order to identify a message's destination.

1 The Court finds it interesting that neither party disclosed the decoding of multiple address elements in its claim limitations, but relied on that particular feature only in describing the preferred embodiment.

TM also calls the Court's attention to another portion of the file wrapper, one that was not addressed in the parties' initial submissions. When the Examiner rejected Claims 2 and 8 on the ground that Lawrence anticipated them (discussed above), he also rejected dependent Claims 3 and 9, where messages had only one address element. (A. 2097) IBM correctly points out that Claims 3 and 9 were not rejected on the ground of anticipation, but rather on the ground of obviousness. 2 After reviewing the Examiner's reasons for rejection, I cannot say that either TM's argument derived from same or IBM's response to that argument adds anything to the equation.

2 I wish that TM had never brought this section to my attention, because deciphering it has caused the Court no end of grief. As far as I can determine, the Examiner concluded that a message could only have one address element if it were in a two-processor system -- in which case, there would only be one place for the message to go. Indeed, the Examiner repeated several times that the situation disclosed in Claims 3 and 9 could only arise in a two-processor computer system -- a fact that obviously bothered him no end. I do not think that his rejection sheds any light whatever on the present problem.

The Court has taken a stream of consciousness approach to this question, but it was the best way to arrive at an answer. And the answer is that I was correct in the first instance. I might wish that TM had not made the particular verbiage change that has given me and the parties so much agida, and I suspect TM wishes it had not done so as well. However, looking at the entire file wrapper (as Elkay instructs), I am constrained to conclude that the language change from "at least one" to "one" -- viewed (1) in the context of a "comprising" claim, (2) in light of the disclosed specification, and (3) in view of the distinction between '773 and Lawrence that was argued by TM and accepted by the Examiner -- was not made to overcome prior art and does not preclude a finding that the phrase "decoding one address element" includes "decoding at least one address element.

- 3250 -
The parties next dispute the claim language concerning "one first capacitor" and "one second capacitor." This language also appears in claim 41 of the '364, quoted above, and in claim 71 of the '934 Patent, which discloses:

71. A revenue meter for measuring the delivery of electrical energy from an energy supplier to a consumer through an electric circuit, said meter comprising:

- a draw-out chassis coupled with said meter and operative to fit within a switchboard enclosure;
- terminals disposed on said chassis for engaging matching terminals within said enclosure;
- a display;
- a meter cover operative to enclose said meter and said display within said enclosure;
- a seal connected with said meter cover and operative to prevent removal of said meter cover and indicate tampering with said meter;
- a first power supply coupled with said electric circuit and operative to provide power to said meter from said electric circuit under normal operating conditions; and
- a second power supply operative to provide power to said meter when a power quality event occurs on said electric circuit, said second power supply including:
  - at least one first capacitor coupled with said electric circuit and operative to store electrical energy from said electric circuit;
  - at least one second capacitor coupled with said at least one first capacitor and said meter and operative to store electrical energy from said electric circuit;

said first and second capacitors further operative to provide said energy to said meter when said power quality event occurs.

Claim 72, which depends from claim 71, also discusses the first and second capacitors; it discloses "[t]he revenue meter of claim 71 wherein said at least one second capacitor has a higher capacitance than said at least one first capacitor." U.S. Patent 7,006,934 B2, col. 50, line 39 - col. 51, line 3. Claim 42 of the '364 Patent, which depends from claim 41 of the '364 Patent, is identical. See U.S. Patent No. 6,792,364 B2, col. 43, lines 46-48.

Square D argues that this language means "a first capacitor operative to store electrical energy, and a second capacitor operative to store electrical energy." EI contends that the "first capacitor" language should be construed to mean "a low energy capacitor bank to provide dc ripple filtering energy storage sufficient to meet the energy requirements of the meter electronics for event detection and data storage;" and that the "second capacitor" language should be construed to mean "a high energy capacitor bank to provide dc ripple filtering and energy storage sufficient to meet the energy requirements of the meter electronics for event detection and data storage."

To support its proposed construction, EI argues that the distinction between the one low energy capacitor bank and the second high energy capacitor bank is "fundamental to the successful operation of the revenue meter." Opening Claim construction Brief, p. 25 (quoting U.S. Patent No. 7,006,934, col. 18, lines 36-38; U.S. Patent No. 6,792,364, col. 14, lines 42-44. And, to be sure, there is language in the specification to this effect. The specifications of both patents state that "[t]he division of energy storage into two separate high and low energy capacity banks 930 and 935 is fundamental to the
successful operation of the revenue meter, particularly when the meter is being powered by the end use in calibration test
fixtures as is typically done in utility company meter shops." U.S. Patent No. 6,792,364 B2, col. 14, lines 42-47; U.S Patent
No. 7,006,934 B2, col. 18, lines 36-41. But the specification also makes clear that this language refers to the power supply
of the preferred embodiment, and that it need not be true of all embodiments. Accordingly, it would be inappropriate to read
this limitation into the claims.

The doctrine of claim differentiation bolsters this conclusion. This doctrine, which is admittedly more a guide than a rigid
rule, instructs that "the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the
limitation in question is not present in the independent claim." Phillips, 415 F.3d at 1315, quoted in Halliburton Energy
Services, Inc. v. M-I LLC, 514 F.3d 1244, 1252 n.3 (Fed. Cir. 2008)(citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d
898, 910 (Fed. Cir. 2004)). Claims 42 and 72, which depend, respectively, from claims 41 and 71, disclose a second
capacitor with a "higher capacitance" than the first capacitor. This is strong evidence that no limitation concerning
capacitance should be read into the independent claims. Accordingly, the Court adopts Square D's construction of "one first
capacitor . . . and one second capacitor . . . ."

5. "one of a selection of formats"

The plaintiff contends that the term "one of a selection of formats" means one of a plurality of types of data. The defendants
assert that the term means that each record includes an indicator determining a single way of multiple available ways to
display the record on the television screen.

The term is found in each of the four claims at issue, as follows:

Claim 8: "the database having individual first records, each first record comprising one of a selection of formats, at least
one of the first records comprising executable program code or an object. . . ."

Claim 15: "the users database comprising individual records comprising records recovered from the data stream, the
individual records comprising one of a selection of formats and at least one record comprising executable program code or
an object broadcast from the first records. . . ."

Claim 22: "the user records recovered from the broadcast database records comprising one of a selection of formats and
at least one record comprising executable program code or an object broadcast from the first records. . . ."

Claim 29: "a database having individual first records, each first record comprising one of a selection of formats, at least
one of the first records comprising executable program code or an object. . . ."

The dispute is linked to the definition of "record" and whether a record must be displayable. In the present setting, the issue
is whether a selection of formats is limited to how data is arranged on a display screen or whether it includes also how data
is arranged in a record, data file, or storage device. I already have construed "records" to include both displayable records
and records which are not displayed.

The defendants advanced the definition of "format" contained in the McGraw-Hill Dictionary of Scientific and Technical
Terms (5th ed. 1994). Defendants Joint Opening Claim Construction Brief for the '094 Patent, at p. 28. The plaintiff
endorsed that definition at the Markman hearing. Record, at p.43. The McGraw-Hill Dictionary defines "format" as "the
specific arrangement of data on a printed page, display screen, or such, or in a record, data file, or storage device." Id. at
792.

I adopt the ordinary meaning of the term "format" advanced by all of the parties and construe the term to mean the specific
arrangement of data on a printed page or display screen or in a record, data file, or storage device.

Selection also has an ordinary meaning. "Select" means "to choose from among several. . . ." The American Heritage
Dictionary of the English Language, at 1177.
Combining the ordinary meanings of the two words, I construe the term "one of a selection of formats" to mean one of several arrangements of data on a printed page or display screen or in a record, data file, or storage device.

I reject the defendants' argument that each record must include "an indicator" determining the format. See Defendants Joint Opening Claim Construction Brief for the '094 Patent, at p. 29. Any such construction would improperly import into the claims a limitation from an embodiment of the patent. Texas Digital, 308 F.3d at 1204("Consulting the written description and prosecution history as a threshold step in the claim construction process, before an effort is made to discern the ordinary and customary meanings attributed to the words themselves, invites a violation of our precedent counseling against importing limitations into the claims"). There simply is nothing in the language of the claims that requires each record to have "an indicator."

"only a single tournament game is playable for each sequence"

Dependent claim 5 contains the next disputed phrase:

(5) A system according to claim 1 wherein only a single tournament game is playable for each sequence within the at least one sequence of tournament games.

JVL argues that "only a single tournament game is playable for each sequence" means "each sequence of tournament games consists of two or more repetitions of the same tournament game." Def.'s '887 Presentation at 30. This interpretation builds upon JVL's construction of "sequence of tournament games" offered with respect to claim 1(b). JVL's construction was not fully adopted. Rather, as discussed above, "sequence of tournament games" means "one or more type(s) of tournament game(s) played at least times in succession."

Merit's proffered construction is "only a single tournament game is playable in a sequence of tournament games." It argues that construing "only a single game" to mean "two or more repetitions of the same tournament game," as JVL does, is "plainly wrong" and has "no basis" in the patent. However, JVL has not simply equated a "single" game with "two or more." Its argument here is consistent with its argument with respect to claim 1, namely, that a sequence of tournament games, as claimed in claim 1(b), must include at least two games.

There is a difference between playing a single type of game, such as Solitaire, one time, and playing Solitaire more than once. JVL's construction captures this distinction. Referring back to claim 1, claim 5 states that each sequence includes the play of only a single tournament game. JVL points out that while claim 1 does not say what tournament games are included in the sequence, claim 5 specifically requires that the same tournament game is repeated in sequence. Claim 5 provides a further limitation on claim 1, by requiring that the sequence be made up of only one type of game. It does not indicate that a sequence consists of one play of a single type of game. Accordingly, JVL's construction, "each sequence of tournament games consists of two or more repetitions of the same tournament game," is adopted.

"Only Four Elements"

The district court provided the jury with the following construction of "only four elements":

"Only four elements" is another illustration of the advantages of the patented thing, but unnecessarily dividing a single component into two does not necessarily keep a five-part thing from infringing.

While a five-part component might be equivalent to a four-part component, they never can be literally the same. It is not clear from the instruction whether the district court was directing this explanation to the doctrine of equivalents. However,
at the trial the experts for both sides, and counsel in argument, drew this distinction and explained it to the jury.

While prosecuting the application that led to the '482 patent, the applicants not only added "only four elements" to the preamble of what became claim 6, but also argued that the simplicity of this construction made it novel and nonobvious over the cited references, none of which showed such an easily manufactured packaged component. Consequently, we find this prosecution history important in determining the effect of the "only four elements" portion of claim 6. The applicants were clearly arguing that these words were significant to the claim. Since to literally infringe claim 6 an accused device must have only four elements, no reasonable jury could have found infringement.

6. Only if

In prior cases, the court has not defined the term "only if." Samsung contends that the court should adopt a construction for the term in this case to mean "at no time other than when." The court rejects this construction and remains persuaded that this term needs no construction and will be understood by a jury.

4. only if said electrical condition is outside a predetermined range

The court rejects Rohm's argument and concludes that this term needs no construction.

This case comes before the court for construction of a claim term pursuant to a remand from the United States Court of Appeals for the Federal Circuit. See O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351 (Fed. Cir. 2008). Pursuant to that court's mandate, this court must construe the "only if" limitations in the asserted patents. Claim 1 of the '615 patent is illustrative of the relevant claim language. It provides, with the pertinent portion italicized, as follows:

A DC/AC converter circuit for controllably delivering power to a load, comprising an input voltage source; a first plurality of overlapping switches and a second plurality of overlapping switches being selectively coupled to said voltage source, said first plurality of switches defining a first conduction path, said second plurality of switches defining a second conduction path; a pulse generator generating a first pulse signal; a transformer having a primary side and a secondary side, said primary side selectively coupled to said voltage source in an alternating fashion through said first conduction path and, alternately, through said second conduction path; a load coupled to said secondary side of said transformer; and a feedback control loop circuit receiving a feedback signal indicative of power being supplied to said load, and adapted to generate a second signal pulse signal for controlling the conduction state of said second plurality of switches only if said feedback signal is above a predetermined threshold; and drive circuitry receiving said pulse signal and controlling a conduction state of said first and second plurality of switches based on said first and second pulse signals, wherein, said drive circuitry alternating the conduction state of said first and second plurality of switches, controlling the overlap time of the switches in the first plurality of switches, and controlling the overlap time of the switches in the second plurality of switches, to couple said voltage source to said primary side. '615 Patent, claim 1 (emphasis added).

The parties dispute whether the "only if" limitation allows for exceptions. The plaintiff asserts that the limitation applies solely to the steady state operation of the circuit. The defendants argue that the limitation is drafted in exclusive terms and therefore applies at all times the circuit is operating, with no exceptions, to include the start-up, steady state, and shut-down phases of the device.

Using claim 1 of the '615 patent as an example, the plaintiff's proposed construction is:
when the feedback control loop circuit is receiving a feedback signal indicative of power being supplied to the load, the feedback signal must be above a predetermined threshold for the second pulse signal to be controlling the conduction state of the second plurality of switches.

The defendants' proposed construction, which would apply to all of the asserted claims, is:

In the context of the disputed claims, "only if" means that, during all times including start-up and shut-down of the device, the feedback circuit must not be active unless the feedback signal is above the predetermined threshold or outside the predetermined range and must cease being active immediately and without delay when the feedback signal stops being above the threshold or outside the range.

The court has first considered the language of the claims. See Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). The "only if" language is drafted in exclusive terms. Under the language of the claims, the feedback control loop circuit controls the conduction state of the second plurality of switches "only if" said feedback signal is above a predetermined threshold. In other words, if the feedback signal is not above a predetermined threshold, then the feedback circuit does not control the conduction state of the second plurality of switches.

Second, because "the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification," the court has also considered the specification. Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005) (en banc). In the embodiment disclosed in Figure 2 of the patent, the feedback signal does not control the conduction state of the second plurality of switches during start-up. Instead, a predetermined amount of power is supplied to the switches to increase the power to the load until the lamp strikes. Once the lamp strikes, current flows through the feedback circuit, and power is then controllably delivered to the lamp by using the feedback signal to control the conduction state of the second pair of switches. '615 patent, col. 7:5-26. The specification is thus consistent with the defendants' view that the claim language applies at all times. The claim language, read in light of the specification, persuades the court that the "only if" limitation applies during the start-up, steady state, and shut-down modes of the circuit.

The defendants overreach, however, with their proposed construction. The cited portion of the prosecution history relating to Henry falls short of establishing a prosecution history disclaimer. Similarly, the court is not persuaded that the patentee's statements regarding the Rohm reference require the additional limitations proposed by the defendants.

Accordingly, using claim 1 of the '615 patent as an example, "only if" means that, during all times, including start-up, steady state, and shut-down of the device, the feedback circuit must not control the conduction state of the second plurality of switches unless the feedback signal is above a predetermined threshold. If the feedback signal is not above the predetermined threshold, then the feedback circuit must not control the conduction state of the second plurality of switches.

A. Claim Language

Claims 1 and 11 of the '920 patent are "means-plus-function" claims. 35 U.S.C. § 112 P 6 enables the drafter of the claims to describe the function, or functions, performed by a means described in the specification. Means-plus-function claims must be construed to cover the structure disclosed in the specification and its equivalents. U.S. v. Telectronics, 857 F.2d 778 (Fed. Cir. 1988).

Claim 1 reads:

1. An overvoltage protection circuit used with a pair of telephone lines comprising: first voltage clamping means for clamping voltage signals on said lines at a first predetermined voltage potential;

 second voltage clamping means for clamping voltage signals on said lines at a second predetermined voltage potential; and
filter means responsive to said second voltage clamping means for filtering noise or transients signals from said voltage signals only when said voltage signals exceed said second predetermined voltage potential. [Emphasis added]

Claim 11 reads:

11. An overvoltage protection apparatus used with first and second conductors connected to a telephone system or other similar communications source for protecting a subscriber station, said overvoltage protection apparatus comprising:

first means connected between the first and second conductors for conducting current while at a voltage greater than or equal to a first breakdown voltage and for blocking current while at a voltage below said first breakdown voltage;

second means coupled between first and second conductors for conducting current while at a voltage below said second breakdown voltage; and

means connected in series between said first and second means for filtering noise or transients signals from said first and second conductors only while said second means is at a voltage greater than or equal to said second breakdown voltage. [Emphasis added]

To resolve this dispute the court must first examine the words of the claims. Vitronics, 90 F.3d at 1582. In both claims, there are three elements. The dispute is focused on the third elements of claim 1 and claim 11. The third element in claim 1 is a "filter means responsive to said second voltage clamping means for filtering noise or transients signals from said voltage signals only when said voltage signals exceed said second predetermined voltage potential." The third element in claim 11 is a "means connected in series between said first and second means for filtering noise or transients signals from said first and second conductors only while said second means is at a voltage greater than or equal to said second breakdown voltage." Plaintiff argues that the "only when" and "only while" limitations apply solely to this third element. Defendant, on the other hand, argues that this restriction applies to the entire claim and thus the whole device depicted in the '920 patent.

If plaintiff's argument succeeds, the '920 patent covers all devices that incorporate a low pass filter with a TVS, thereby creating a filter that does not operate unless a predetermined voltage is reached. This construction would include devices that have an additional ability to filter the incoming signal when the threshold voltage has not been reached. In other words, the presence of two filters, one operating at all times and another using the low pass filter/TVS combination, would not be immune from infringement. If defendant's argument succeeds, the '920 patent's scope is restricted to entire devices that will not in any way filter the signal if the threshold voltage is not reached. Under this construction, any device that filters when the voltage is below the threshold voltage cannot infringe. To determine which argument is valid, the court must examine the language of the claims, the language of the specification, and the prosecution history.

Words in the claim are generally given their ordinary and customary meaning. Id. However, the patentee may "chose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as it is clearly stated in the patent specification." Id. A precursory review of the specification shows no such special definition of "only." Thus, at this stage in the analysis, the limiting phrase, "only when said voltage signals exceed said second predetermined voltage potential" is given its ordinary meaning.

A grammatical analysis supports a construction that the "only when" phrase should be limited solely to the "filter means." Claim 1, as issued in the '920 patent, has a preamble phrase and three supporting phrases. As a matter of grammar, if the limitation was intended for the whole device, the limiting phrase should have been in the preamble. See Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620-21 (Fed. Cir. 1995)(holding that words appearing in the preamble of a patent claim can provide a limitation applied to the claim as a whole). The presence of the "only when" language as part of a separate supporting phrase implementing a distinct element required in the claimed invention establishes that the limitation of operation applies solely to the filter means, not the entire device.

While this grammatical approach appears plausible, the esoteric nature of patent law leaves open the possibility that patent claims are not to be construed according to these guidelines. Two Federal Circuit cases, however, support the grammatical analysis. In a case involving electric furnaces, the Federal Circuit decided whether the limiting language "consisting of" located in a clause and not the preamble should be applied only to the element in that clause or rather to the claim as a whole. Mannesmann Demag Corp. v. Engineered Metal Products Co., 793 F.2d 1279, 1282 (Fed. Cir. 1986). In
Mannesmann, the court held that the correct reading was to apply the limitation solely to the clause in which it was located.

The second case involved similar claim language to that in dispute. In Lewmar Marine, Inc. v. Barient, Inc., the Federal Circuit reversed the district court's finding of invalidity due to anticipation. 827 F.2d 744 (Fed. Cir. 1987). Lewmar involved a patent covering sailboat winches. Id. The claim language included a limiting phrase in means-plus-function claims. 2 Id. at 747 n.1. In Lewmar, the court held that the "only upon" restriction applied to the "means automatically to disconnect the disconnectable drive means" precluded any other method of shifting gears in the winch beside reversing the direction of cranking. Id. at 750. Defendant argues that this precedent bars plaintiff's claim construction because the Federal Circuit applied this restriction to the entire device. While Lewmar definitively enforces the use of "only" as an absolute limitation in claim language, it does not mandate application of a limiting phrase to claim language external to the clause in which the phrase is located. See Id. at 749-50. Even though not explicitly stated by the Federal Circuit, its holding in Lewmar is a logical extension of applying this restriction solely to the element in which it was located.

Footnotes

2 One claim at issue in Lewmar was claim 1, which read:

1. A winch in which there are more than two drive trains between a drive shaft and the winch drum offering respectively different drive ratios of drive of the drum in one sense of rotation,

   at least one of the drive trains having a disconnectable drive means, the ratios being successively engageable by successively opposite directions of rotation of the drive shaft,

   a preselector operable to determine which one of two of the said drive ratios engageable upon a given said direction of rotation of the drive shaft will be engaged,

   the reselector being thus operable by causing connection or disconnection of the disconnectable drive means in one of the said drive trains, and means automatically to disconnect the disconnectable drive means only upon reversal of the drive shaft from the given said direction of rotation.

End Footnotes

While the two cases support the elemental limitation interpretation, they did not do so merely by examining the grammar of the claims at issue. Rather, both cases additionally examined the specification and the prosecution history to determine whether their grammatical constructions correctly defined the scope of the invention. The court now proceeds to examine the specification of the '920 patent.

The specification acts as a dictionary when it defines terms in the claims; either expressly or implicitly. Vitronics, 90 F.3d at 1582. It is the "single best guide to the meaning of a disputed term." Id. The use of "only" must be read in light of inventor's description and purpose of the invention. Lewmar, 827 F.2d at 750. An examination of the '920 patent specification fails to present any reason why filtering below the threshold voltage should be precluded.

The detailed description of the invention asserts that "in normal operation data signals are unaffected by the frequency response of the filter comprised of resistor 14 and capacitor 22." Since the resistor and capacitor cited constitute the filter means in this embodiment, this statement provides the best insight into the meaning of the "only when" limitation. This phrase explicitly states that the data signals are unaffected by the specific filter means disclosed, not unaffected by any filtering at all.

The summary of the invention also supports this interpretation. The importance of the device is repeatedly stated as the ability to eliminate transient signals above the data signal voltage and below the ring voltage. The importance of preventing any additional filtering is not mentioned anywhere in the patent. Rather, the focus is on enabling a specific method of filtering which is dependant on both voltage and frequency. The inclusion of this specific method of filtering does not
exclude the use of any other filtering method to remove undesirable signals from a telephone line.

Plaintiff additionally asserts that defendant's interpretation cannot be correct because it would prevent the embodiment in the patent from being covered by its own claims. A claim interpretation that would exclude the patentee's device is rarely the correct interpretation. Modine Manufacturing Co. v. U.S. Inter. Trade. Com., 75 F.3d 1545, 1550 (Fed. Cir. 1996). When such an interpretation is viable there must be "highly persuasive evidentiary support." Id. Plaintiff states that any TVS device has a certain amount of inherent capacitance that will cause the circuit to attenuate high frequencies even when the signal voltage is below the threshold voltage. Consequently, plaintiff's embodiment itself has an inherent low pass filter which operates even below the threshold voltage.

Plaintiff is correct; it would be incorrect to interpret the claims to exclude its embodiment. As the U.K. decision found, there is inherent filtering in plaintiff's device due to the inherent capacitance of the TVS. However, this does not mandate agreement with either plaintiff's or defendant's claim interpretation. The inherent filtering implicit in plaintiff's device is not mentioned in the '920 patent because it will filter out only very high signals which are typically of no concern. Thus, the inherent filtering is of no consequence. To be correct, defendant may be in arguing that any inherent filtering or additional filtering does not negate infringement. On the other hand, defendant could argue consistently with plaintiff's embodiment that any intentionally designed filtering added into the circuit is free from infringement. Thus, defendant's suggested interpretation of the limitation clause can be reconciled to include plaintiff's disclosed embodiment by acknowledging the relevant frequency range and lack of filtering in this range by plaintiff's device. The inherent filtering argument does not lend itself to resolution of the claim construction other than to identify the practical nature of the devices utilized.

C. Prosecution History

The prosecution history sheds the most light on this dispute. The prosecution history consists of the communications between the patent examiner and the patent attorney prosecuting the patent application, including any express representations made concerning the scope of the claims. Vitronics, 90 F.3d at 1582. If any interpretation was disclaimed during the prosecution, the prosecution history excludes that interpretation from the claim construction. Id. at 1583.

The patent application that eventually issued as the '920 patent was initially rejected as obvious in light of an earlier patent known as the Standler patent. This rejection was resolved in a conversation with the patent examiner on November 17, 1987. The claims overcome the rejection when the patent attorney agreed to add the "only" clauses. Defendant argues that this addition requires that if there is a series inductor or if a device filters all the time, it cannot infringe the '920 patent.

By examining the Standler patent, one can see that there are both TVS devices and a low pass filter arrangement. Yet, in the Standler patent, the TVS and the low pass filter operate independently of each other. Neither the filter means nor the TVS was novel. What made plaintiff's device patentable was the joining of the two to create a new filtering apparatus dependant on both frequency and voltage.

In the communications to the examining attorney in the Patent Office, the attorney prosecuting the patent application stated that plaintiff's device was patentable over this prior art because the transient voltage did not have to be greater than the ring voltage to be eliminated. This statement supports that necessity for a co-dependence between the TVS and the low pass filter components to correctly eliminate the undesired signals. The office action rejecting the initial patent application restricted the claims construction to a device in which the TVS and low pass filter operate together to eliminate unwanted signals. The '920 patent cannot claim devices that solely use a TVS and low pass filter independently.

Defendant's argument that there cannot be a series inductor is clearly without merit. Nowhere in the prosecution history does the examiner or the patent attorney refer to the inductor as barring patentability of plaintiff's device. An inductor in series with a resistor operates as a low pass filter. Nowhere in the prosecution history, specification, or claim language is the use of other types of low pass filters abandoned.

Defendant's other argument, that the Stander prior art eliminates all-the-time filtering, is also tenuous. Filtering all the time is a gelatinous phrase. It may apply to the filter means or the entire device. Prosecution history estoppel bars recapture of only that subject matter actually surrendered during prosecution. Litton Systems, Inc. v. Honeywell, Inc., 140 F.3d 1449, 1455 (Fed. Cir. 1998). The claim amendment prevents the patentee from recovering the subject matter that the applicant had
to abandon in order to obtain a patent. Id. at 1456. During prosecution, claims are to be given their "broadest reasonable interpretation." In re Donaldson, 16 F.3d 1189, 1194 (Fed. Cir. 1994). Thus, it follows that any additions to overcome prior art were made with the intention of narrowing the claim coverage as little as possible. There is no evidence in the prosecution history supporting a need to prevent overall filtering solely on the basis of frequency.

In the instant case, the patent attorney had to overcome the presence of a TVS and a low pass filter in another patented device. To do this, the "only when" language was added. As a result, a new filter apparatus was patented which was dependent both on frequency and voltage. Thus, the "filter means" was in operation only when a certain threshold voltage was reached.

D. The Meaning of the Limitation Clause

Due to the lack of any evidence demonstrating the need to limit filtering to that effectuated by the "filter means" disclosed in the '920 patent, it is difficult to find support for defendant's argument that the limitation clauses in claims 1 and 11 should be applied to the whole claim and not the individual elements. The location of the limitation clauses in the supporting phrases rather than in the preamble of the claim, the focus on the ability to filter below the ring voltage in the specification, and the scope of the prior art cited in the prosecution history all support plaintiff's position.

Claims are construed to be interpreted by a hypothetical person skilled in the art at the time of filing of the patent application. Loctite Corp. v. Ultraseal Ltd., 781 F.2d 861, 867 (Fed. Cir. 1985). No evidence has been presented as to why a person skilled in the art would perceive a benefit from barring any additional filtering that operates independent of voltage. The court cannot find any evidence to counter the plain meaning of the claims viewed in light of the specification and prosecution history of the '920 patent. The "only" limitation clauses are applicable only to the elements described in the phrases in which they are placed. Thus, only the "filter means," as described in claim 1, or the "means connected in series," as described in claim 11, are restricted to operate only when the voltage exceeds a predetermined threshold voltage. Since the intrinsic evidence clearly resolves the ambiguity, it would be incorrect to continue to examine extrinsic evidence. Vitronics, 90 F.3d at 1583.

E. "Comprising"

Both claims 1 and 11 complete their preambles with the word "comprising." "Comprising" is a term of art in patent claim drafting that means "the named elements are essential, but other elements may be added and still form a construct within the scope of the claim." Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 500 (Fed. Cir. 1997). In other words, the term "comprising" signifies inclusiveness. One cannot avoid infringement by adding elements if each element recited in the claims is found in the accused device. A.B. Dick Co. v. Burroughs Corp., 713 F.2d 700, 703 (Fed. Cir. 1983). All the elements must be found in the accused device. If these elements are found, the accused device infringes.

Defendant asserts the patentability of its invention over the '920 patent. Patentability and infringement are not mutually exclusive. Thus, the additional of any elements to what is covered in the '920 patent, even if sufficient to become patentable, does not absolve the new invention from infringing. If the elements of the '920 patent are present, the device infringes.

F. Conclusion on Claim Construction

The claim language in dispute in the '920 patent is construed in accordance with the plaintiff's arguments. The third element, the filter means, is read as operated by a voltage-controlled on/off switch. Additional elements may be added so as to filter the relevant range of frequencies regardless of the voltage. However, these are additions. So long as the frequency response of the alleged device changes when the threshold voltage of the second element in the claim is reached so as to attenuate, or increase attenuation, of the undesired high frequencies within the relevant frequency range, the device incorporates the third element of claim 1 or claim 11.
mean "a category for which a category label is displayed and individual item labels are displayed for every item in the category."
Both parties agree than an "open category" is, at least, a category for which item labels are displayed for every item in the category. The essential dispute, however, is whether a category label is displayed for both open and closed categories. For the reasons stated earlier, the claim language does not require the display of category labels for opened categories. Sklar specifically left out this requirement from the claim language. Therefore, the Court accepts Sklar's proposed construction.

2928

1. Open lamp condition.

Several claims of the '129 patent include the term "open lamp condition." n1 Samsung seeks a construction of "open lamp" to mean "a situation in which the lamp is not connected to the converter." O2 suggests that the term needs no construction, but should be given its ordinary meaning. In any event, O2 contends that an "open lamp condition" is broader than Samsung proposes and includes situations where the lamp has failed or is broken.

n1 For example, claim 13 claims "a circuit as claimed in claim 1, wherein said predetermined range indicates an open lamp condition."

The court holds that one of ordinary skill in the art, reading the claim language in light of the specification, would apply Samsung's definition. Various claims of the '129 patent use the term "open lamp condition." Still others use the term "short circuit condition." Compare '129 patent, claims 21 and 22. Although the specification is somewhat ambiguous, it appears to use the term "open lamp condition" to refer to the condition in which the CCFL lamp has been removed or is not connected to the converter. Column 9 of the '129 patent describes a time-out sequence designed to shut off the circuit in the case of an open lamp condition. The relevant passage states:

'Drive pulses are disabled once the time-out is reached, thus providing safe-operation of the converter circuit. That is, circuit 60 provides a sufficient voltage to ignite the lamp, but will shut off after a certain period if the lamp is not connected to the converter, so that erroneous high voltage is avoided at the output. This duration is necessary since a non-ignited lamp is similar to an open-lamp condition.'

'129 patent, col. 9, ll. 8-15. Read in light of this passage of the specification, the term "open lamp condition" means "a condition in which the lamp is not connected to the converter."

2929

3. "Open orders"

ITG/Pulse proposes that the term "open orders" be construed to mean "firm orders, i.e., binding purchase or sale offers that can be executed without a further affirmative action by the trader; not contemplated or completed orders." 77 Liquidnet proposes that the term should be construed to mean "instructions to buy or sell a quantity of a security not yet placed elsewhere (i.e., where the total order size exceeds the quantity, if any, committed to another broker or other execution venue)." 78 The major distinction between the parties' constructions is whether an order's "open" status means that it has already been placed in another venue -- besides the ETM contemplated by the patented method -- for execution. ITG/Pulse argues that the "open" status of an order indicates that it has already been placed in another venue for execution but has not yet been executed. 79 Liquidnet, in contrast, argues that the "open" status indicates that the order has not yet been placed elsewhere for execution, and that a trader has only indicated internally to others within his or her investment firm that a
While the claim language and the specification do not explicitly define the term "open orders," these sources of intrinsic evidence most directly support Liquidnet's definition of the term. The claim states that the OMS contains records of orders -- including a field identifying "the total order size" and a field describing the "quantity of the security placed elsewhere." 81 According to the specification, in a preferred embodiment, "the ETM uses the values of these two fields to determine a quantity of the security if any, that are [sic] available to be transacted to the ETM." 82 The specification, therefore, contemplates at least one embodiment of the invention wherein the term "open orders" (i.e., those orders that are accessed and ultimately transmitted to the ETM) refers to the subset of orders that have not been placed elsewhere for execution. Furthermore, step (ii) of claim one states that the non-binding indications generated from the "open orders" indicate the "available quantity" of the security as "determined by the accessed records." 83 This claim language in step (ii) does not require, but is consistent with, Liquidnet's construction -- as the "available quantity" described in the claim would be determined by subtracting the quantity of a security placed elsewhere from the total order size (both of which can be determined by reference to the accessed records).

ITG/Pulse, obviously, objects to this definition, and provides evidentiary support for its view. Its most persuasive, but ultimately unavailing, argument is that Liquidnet disclaimed its construction of the term "open orders" during its prosecution of Patent '834. 84 In late 2004, Liquidnet, in arguing that its claims were not encompassed by prior art, told the PTO that its patented method "reflect[s] a conversion from firm orders to non-binding indications; from the proverbial 'apples' to 'oranges.'" 85 According to ITG/Pulse, this statement shows that the patented method involves the conversion of firm -- i.e., binding -- orders to non-binding indications, and that the original orders were binding because they had already been placed in another venue for execution. This statement, however, is not sufficiently unambiguous to constitute a prosecution disclaimer. 86 At the time the statement was submitted to the PTO, the claim language was different than it is now and referred to "orders" rather than "open orders." 87 Given that the specification identifies several different order statuses (e.g., open, contemplated, completed), it is apparent from the intrinsic evidence that the term "orders" is more inclusive than the subset described as "open orders." In addition, another portion of the prosecution history directly contrasts the patented method with a "system [in the prior art] that merely consolidates . . . bids and offers" already placed in other venues. 88 Accordingly, when the intrinsic evidence is considered "as a whole," the prosecution history statement describing the conversion of firm orders to non-binding indications is too ambiguous to constitute a prosecution disclaimer. 89

81 Patent '834 col. 12 ll. 62-63.
82 Id. col. 9 ll.42-45.
83 Id. col. 13 l. 4.
84 See Tr. at 5-6 (the proper construction "open orders . . . comes down to statements that were made by Liquidnet to the
Of course, the fact that this statement does not rise to the level of prosecution disclaimer does not eliminate its possible relevance. District courts use prosecution history to clarify claim language even when they are not applying the prosecution disclaimer doctrine. That said, because the prosecution history reflects an ongoing negotiation between the patent applicant and the PTO, it cannot be given precedence over the specification and the claims themselves, which reflect the final agreement between the parties. The specification and the claim language provide greater support to Liquidnet's definition. Accordingly, the term "open orders" means "instructions to buy or sell a quantity of a security not yet placed elsewhere."

2930

An opening to expose the channel and via

The Court construes the phrase "an opening to expose the channel and via" in claim 11 of the '339 patent and claim 3 of the '442 patent as "an opening in the second soft mask where the channel and via are to be formed." Samsung argues that no construction is necessary because "via" and "channel" are described elsewhere in the patent and the remainder of the phrase is clear. However, the claims describe how the second soft mask covers the insulating layer and exposes the areas where the channel and via will be after the second etch is applied. This construction clarifies that the phrase refers to the area that is eroded by the second etch to form the channel and via.

MEI's construction--"an open portion of the second soft mask that is aligned with the region to form the channel and via such that substantially no portion of the second soft mask is in that region"--requires a high degree of precision that is not specified in the patent. Furthermore, this construction would likely require further construction to define what "substantially no portion" means.

13. Operable to perform unique operations on each component symbol

The plaintiff proposes that "operable to perform unique operations on each component symbol" should be construed to mean "capable of performing a distinct operation on each component of a data unit." The defendants urge that the disputed
phrase means "able to simultaneously perform different operations on each partitioned item of data." At issue is the meaning of the term "unique." The plaintiff contends it is sufficient that the multi-precision execution unit performs the same, single chosen type of operation (e.g., multiply) on each component symbol, albeit in different, separate, and distinct instances. See Plaintiff's Reply Brief at 33. The defendants insist, however, that the plaintiff's construction should be rejected because it does not reflect the definition of the term "unique." After considering the submissions of counsel, the court concludes that the plaintiff is correct. The court defines this term to mean "capable of performing a distinct operation on each component of a data unit."

C. "Operably connecting"

The term "operably connecting" first appears in claim 1 of the '611 patent, and again in claim 9. Virtually identical language appears in claim 18, the third independent claim, where it states "operably connect." Callpod contends that term means "connecting in a manner that allows a signal to flow from one point to another point." Defendants propose that the term should be construed as "physically connecting."

The language of the claims themselves supports Callpod's position. Claim 18 has an added limitation not present in the two other independent claims: "a wireless telephone interconnect cable adapted to operably connect. . . ." (JA, Ex. 1, '611 Patent, cols.5 ll.16-17.) The fact that the claim mentions a physical cable as a requirement to be adapted for the operable connection suggests that the previous claims that do not include the cable limitation are broader. See Intamin, Ltd. v. Magnetar Techs., Corp., 483 F.3d 1328, 1334-35 (Fed. Cir. 2007) (stating that where a later claim includes a limitation not present in an earlier claim, the earlier claim impliedly includes embodiments that do not include that limitation).

Defendants claim that the specification precludes such a broad reading of the claims for the specification refers solely to physical connections. Callpod argues that references in the specification concerning physical connections do not limit the scope of the patent but merely describe the preferred embodiment. The detailed description of the invention in the patent falls under the heading, "Detailed Description of the Preferred Embodiment." (JA, Ex. 1, '611 Patent, at 1:60-61.) The fact that the claim mentions a physical cable as a requirement to be adapted for the operable connection suggests that the previous claims that do not include the cable limitation are broader. See Intamin, Ltd. v. Magnetar Techs., Corp., 483 F.3d 1328, 1334-35 (Fed. Cir. 2007) (stating that where a later claim includes a limitation not present in an earlier claim, the earlier claim impliedly includes embodiments that do not include that limitation).

Defendants claim that the specification precludes such a broad reading of the claims for the specification refers solely to physical connections. Callpod argues that references in the specification concerning physical connections do not limit the scope of the patent but merely describe the preferred embodiment. The detailed description of the invention in the patent falls under the heading, "Detailed Description of the Preferred Embodiment." (JA, Ex. 1, '611 Patent, at 1:60-61.) The fact that the claim mentions a physical cable as a requirement to be adapted for the operable connection suggests that the previous claims that do not include the cable limitation are broader. See Intamin, Ltd. v. Magnetar Techs., Corp., 483 F.3d 1328, 1334-35 (Fed. Cir. 2007) (stating that where a later claim includes a limitation not present in an earlier claim, the earlier claim impliedly includes embodiments that do not include that limitation).
Claim 3 provides as follows: "The system of Claim 1 in which the actuating mechanism is operated remotely by sending signals from a communication device." Graham-White contends that the italicized phrase should be construed as "the actuating mechanism receives signals from a communication device that is not in contact with the actuating mechanism." Ellcon argues that Claim 3 is limited to wireless remote control. This court agrees with Graham-White's construction and therefore construes the phrase as follows: the actuating mechanism receives signals from a communication device that is not in contact with the actuating mechanism.

3. Operating Data

Lectrolarm proposes that "operating data" should be construed to mean:

the data inputted by the user through the control pad, buttons, and switches on the operating panel that direct the automatic reciprocating motion of the camera between defined points. The operating data must include at least position data (represented by angles of rotation, polar coordinates, or any other suitable units) and stopping interval data. Operating data may also include data specifying speed of rotation, pan and tilt at the discretion of the user.

The Defendants would interpret "operating data" to mean:

information that the controlling means uses to control the automatic operation. Operating data is not necessarily input directly by the user, but can be derived from the manner in which the user uses the system.

The plain language of Claim 2, P 2 requires that "operating data" be data that 1) is input using the structure of the input means and 2) that directs the automatic operation of the camera. U.S. Patent 4,974,088, Column 10:43-45.

The definition of "operating data," however, must be narrowed from the plain language of the claim. The patent describes two different types of automatic operation. The first is "rectilinear motion [of the camera] between two points A and B. . . ." U.S. Patent No. 4,974,088, Column 5:57-59. The second type involves automatically directing the camera to a pre-set home position when an alarm is triggered. U.S. Patent No. 4,974,088, Column 6:28-40. Claim 3, P 2 describes "home position data used for making said rotating camera base rotate to prescribed home positions during automatic operation." U.S. Patent No. 4,974,088, Column 8:61-64. To give separate meaning to the terms "operating data" and "home position data," "operating data" cannot be the data used in all types of automatic operation, but must only refer to the data used during automatic rectilinear motion of the camera base between points A and B.

Lectrolarm would like the court to include the language "the data inputted by the user through the control pad, buttons, and switches on the operating panel" in its definition of "operating data." That language is not appropriate. First, there is no need to recite the structure of the input means, which has already been defined. Second, the specification does not describe the user as "inputting" the "operating data." It describes the user as "setting" the operating data. U.S. Patent No. 4,974,088, Column 3: 59-60; 5:22-24.

Lectrolarm would also like the court to include the language "the operating data must include at least position data (represented by angles of rotation, polar coordinates, or any other suitable units) and stopping interval data. Operating data may also include data specifying speed of rotation, pan and tilt at the discretion of the user" in its definition of "operating data." There is no basis in the patent for the court to include this language. The patent does not speak to the nature of the data saved, but provides only that it is saved through use of the input means.

The court also declines to accept the Defendants' proposed definition because it is overly broad. The Defendants propose
stating that "operating data is not necessarily input directly by the user, but can be derived from the manner in which the user uses the system." The claims and specification make clear that the operating data is set through use of the input means. The Defendants proposed construction opens the door for use of structures other than the input means to set the operating data stored in the system.

Based on the patent claims and the specification, the court defines operating data as "data that controls the automatic operation of the camera base, and that is set through use of the structure of the input means."

C. "Wireless communication system/network operating in accordance with the GSM standard"

WiAV proposes that the term means: a wireless system/network that, consistent with the GSM standard, includes a paging channel that indicates the presence of pending telephone calls or paging messages and uses a time slot that is less than 1 ms and represents fewer than 128 bits. The Defendants propose the construction: system/network that transmits data between a mobile station and a base station over a 200 kHz radio channel using time division multiple access according to the Global System for Mobile communications specifications existing as of October 29, 1997.

1. Words of the Claim

Claims 1 and 2 of '920 Patent claim a method of operating a mobile station, comprising

scanning broadcast information in a wireless communication network for a short page channel;

receiving a single time slot of said short page channel containing one group of call alert data, said wireless communication network operating in accordance with the GSM standard, said single time slot being less than one millisecond in duration and representing less than 128 data bits; and

processing said one group of call alert data and determining from said group of call data alert whether a pending telephone call or paging message may have been directed to the mobile station.

receiving a short page channel transmitted by a wireless communication system operating in accordance with the GSM standard;

extracting paging data from a time slot of said short page channel;

determining from said paging data in said time slot that a telephone call or paging message may have been directed to said mobile stations, said time slot being less than one millisecond in duration and representing less than 128 bits; and

receiving four time slots of a paging channel and responsively determining whether the mobile station is an intended recipient of a telephone call or paging message.

Id. at 26:1-16 (emphasis added).

The focus of the interpretive dispute is the meaning of the phrase "in accordance with." WiAV contends that the phrase means consistent with the GSM standard. The Defendants argue that WiAV's proposed construction broadens the claim by removing the requirement that the system/network operate "in accordance with the GSM standard" and allowing merely a system/network that is "consistent" with the GSM standard.

The words "consistent with" are not used in the claims. The term, "in accordance with," is given no special meaning in the patent and nothing in the patent suggests that the words should receive any meaning other than their general usage meaning.
However, the text of the claims does not instruct further.

2. Specification

The parties' reading of the specification raises two issues. The parties first disagree over the general focus of this claim term. While the Defendants' construction focuses on transmission under the GSM standard, WiAV focuses on the general use of a paging system under the GSM standard. Both constructions find some support in the specification.

The Defendants' proposed construction finds ample support in the specification as well as the Redl textbook that is incorporated by reference in the specification. First, the specification states that GSM depends on "time division multiple access wherein mobile stations are allocated very short time periods within which to communicate." '920 Patent at 1:51-55. Additionally, the specification explains that mobile stations and base stations in a GSM system communicate using radio frequency channel with a width of 200 kHz. Id. at 7:35-36; see also Pl. Ex. F at WIA V0006012 ("...the GSM channel spacing is 200 kHz.") Finally, the specification provides that the "GSM specification provides eight time slots (or physical channels) in each 200 kHz radio channel." '920 Patent at 7:43-45. Thus, the specification shows that a wireless communications system operating in accordance with the GSM standard would be limited to a 200 kHz radio channel and would use TDMA, as argued by the Defendants.

WiAV argues that the use of a 200 kHz radio channel and TDMA are "incidental to the invention. Rather, WiAV argues, the claim term at issue refers to the receipt and processing of a paging channel. The specification explains that, when scanning for telephone calls or paging messages, "[e]ach alerted mobile station 106 then examines standard paging channel (PCH) information according to standard GSM specifications to determine whether the telephone call or paging message is intended for the respective mobile station 106." '920 Patent at 10:51-55. The specification also provides that, "[i]n accordance with the GSM standard, the mobile station 106 receives and processes standard paging channel 218 PCH information approximately every 0.5 to 2 seconds." Id. at 15:36-38. Thus, the specification also shows that the GSM standard referred to in the claim term is linked to the process of receiving and processing the paging channel information.

The second key point of contention between the parties is whether the claim term requires limitation to the GSM standard as of the date of filing, October 29, 1997. Generally, a claim's meaning "must be interpreted as of the filing date" because a "claim cannot have different meanings at different times." PC Connector Solutions v. SmartDisk Corp., 406 F.3d 1359, 1363 (Fed. Cir. 2005). Thus, the focus of the claim construction inquiry is "what one of ordinary skill in the art at the time of the invention would have understood the term to mean." Markman, 52 F.3d at 986.

The Defendants argue that the claim term must be limited to the GSM standard as of October 29, 1997. WiAV, on the other hand, argues that the term cannot require compliance with the GSM standard of October 29, 1997 because, at that time, the standard did not include short paging, which is essential to the claimed invention. WiAV argues that the Patent describes an improvement over the October 29, 1997 GSM standard. '920 Patent at 11:45-53 ("According to existing GSM-based wireless communications systems, mobile stations receive, store and process four time slots of a paging channel (PCH) to determine whether a telephone call or paging message is pending. Under the present invention, a mobile station 106 in standby mode (waiting for a telephone call or paging message) need never process more than a single time slot to detect the possibility that a telephone call or paging message has been directed to mobile station 106.") And, WiAV asserts that a person of ordinary skill in the art would have understood the invention as such and thus, would not have limited it to the October 29, 1997 GSM standard. Finally, WiAV argues, such a limitation would exclude all the preferred embodiments because they contain short-paging channels, which did not exist as part of the 1997 GSM standards. See Vitronics Corp., 90 F.3d at 1583 (an interpretation that excludes a preferred embodiment is "rarely, if ever, correct" and requires "highly persuasive evidentiary support.")

In response, the Defendants assert that the system must merely use the GSM transmission protocols existing as of October 29, 1997, the date the patent was filed. Those requirements, the Defendants argue, do not impact the use of a short paging channel or exclude the preferred embodiments. Thus, under the Defendants' construction the wording "in accordance with the GSM standard" does not preclude use of short paging channels, but instead requires only that the short paging channels be implemented in a network using the pre-existing GSM transmission protocols as set forth in the patent and the Redl textbook.

Use of a short paging channel clearly was not a requirement of the 1997 GSM standard. Thus, when reading the patent, one
of ordinary skill in the art would understand that a limitation to the transmission protocols under the GSM standard as of October 29, 1997 would not exclude the use of a short paging channel, which is an improvement in the GSM standard. Those transmission protocols are made clear in the specification, and it is appropriate to limit the term to the GSM transmission protocols existing as of October 29, 1997.

3. Prosecution History

WiAV argues that the correct meaning of the disputed term is clarified by an understanding of how it came to be part of the claim and the Patent. During prosecution of the '069 Patent, the parent patent, the applicant added the following limitation to claim 1: "said wireless communication network operating in accordance with the GSM standard, said single time slot less than 1 millisecond in duration and representing less than 128 data bits." (Pl. Ex. 5 at 2.) During prosecution, the applicant equated the GSM standard with the length of the time slot: "Applicant amended Claim 13 to clarify that the recited short page channel time slot is one in accordance with the GSM standard, and thus, is of less than one (1) millisecond in duration and represents less than 128 bits." (Id. at 9.) The limitation remained in the claims of the application that became the '920 Patent. Thus, says WiAV, the only relevant aspect of the GSM standard that the applicant sought to disclose during the prosecution was the length of the time slot. While the applicant did specifically limit the time slot, there is no evidence that the length of the time slot was the only relevant part of the GSM standard to which the disputed text referred.

The Defendants assert that, during prosecution, the applicant expressly disclaimed non-TDMA technologies, and thus, it is essential to the construction of the term that it include limitation to TDMA. "[W]here the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Omega Eng'g Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). This doctrine protects the public's reliance on the applicant's statement and "precludes patentees from recapturing through claim interpretation specific meanings disclaimed during prosecution." Id. at 1323-24.

Here, the applicant attempted to distinguish prior art for which a claim was rejected by stating that "Kunkel provides a solution to the channel-scanning problem for non-TDMA technologies such as CDMA and FDMA and thus teaches away from the use of its technology when dealing with TDMA networks." (Def. Ex. F at WIAV0005902.) At the Markman hearing, it was clarified that the GSM standard utilizes both FDMA and TDMA, and that FDMA is considered to be the starting point for the GSM system but that the hallmark of a GSM system is the use of TDMA in addition to FDMA.

4. Proper Construction of "Wireless communication system/network operating in accordance with the GSM standard"

Overall, there is some support for both of the parties' constructions, but the Defendants' construction is more consistent with the intrinsic record. Certainly, the specification makes clear that the GSM system uses a 200 kHz radio channel and that it utilizes TDMA. And, the prosecution history shows that the applicant attempted to distinguish prior art based on the invention's use of TDMA. Thus, use of these aspects of the GSM standard in defining the term is appropriate.

Additionally, the Plaintiff's construction has very little meaning, especially when stripped of its redundant limitation of the time slot to less than 1 millisecond and representing fewer than 128 bits. Indeed, without this redundant limitation, the Plaintiff's construction says very little about the GSM standard under which the wireless system must operate.

The construction proposed by the Defendants is further supported by the fact that the term "in accordance with" is used throughout the patent consistently with its ordinary and plain meaning. The Merriam-Webster online dictionary defines "accordance" as "agreement" or "conformity." Merriam-Webster Online Dictionary, http://www.merriam-webster.com/dictionary/accordance (last visited March 15, 2010). No definition equates "in accordance with" and "consistent with," the meaning urged by WiAV. Thus, given the ordinary meanings of the words of the claim, one of ordinary skill in the art would understand that the wireless system or network would operate in conformity or agreement with the GSM standard.

Therefore, the term will be construed as: system/network that transmits data between a mobile station and a base station over a 200 kHz radio channel using time-division multiple access (TDMA) in accordance with the Global System for Mobile communications specifications existing as of October 29, 1997.
"Operating mode" terms

Operating modes

Defendants argue that the term "operating mode" cannot be construed. Defendants contend it is unclear whether "operating mode" refers to a functioning status of the controller, which the user can control, or to external factors over which the user has no control. Defendants provide a general dictionary definition for each of the term's components: "operate" is "to perform a function; work" and "mode" is "a given condition of functioning; a status." See AM. HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (4th ed. 2000). Citing instruction manuals and the descriptions of prior art game surveillance cameras, Defendants argue that "operating mode" refers to a user-selected status of the camera during which certain functions are performed. Defendants contend that "operating mode" must include user selectivity and some change in the controller's function.

In the Summary section, the specification describes the controller as having at least two "operating modes." Col. 1:44. In the first operating mode, the controller activates the camera mechanism when the controller receives a triggering signal from the motion detector. Col. 1:44-47. In the second operating mode, the controller activates the activity counter and does not activate the camera mechanism when a triggering activity occurs. Col. 1:47-50. The Detailed Description states that in "one operating mode," the activity counter can increase and a picture can be taken when the signal is received. Col. 8:23-24. In "another operating mode," the controller can be set so that only the activity counter increases, and a picture is not taken. Col. 8:24-27. Another example of this mode is when the film runs out while pictures are being taken and the camera automatically-without user input-takes no pictures. Col. 8:27-30. This mode is described as the "activity counting mode." Col. 8:39-40.

The claims describe three operating modes. In claim 7, the controller has at least two operating modes. Col. 13:19. In a first mode, the controller activates the camera mechanism when the controller receives a triggering signal from the motion detector. Col. 13:19-22. In a second mode, the controller increases the number of the activity counter and does not activate the camera mechanism when the controller receives a triggering signal from the motion detector. Col. 13:22-26. In claim 8, which depends from claim 7, in the first mode the controller activates the camera mechanism and increases the activity counter when a triggering activity occurs. Col. 13:27-30. A third mode is described in claim 9, which depends from claim 7, in which the controller activates a test light and does not activate the camera mechanism when a triggering activity occurs. Col. 13:31-34. Claims 20, 23, and 26 contain the same description of "operating modes" as claim 7.

The specification clearly provides that an operating mode can be switched automatically or by the user. An "operating mode" is not defined by the manner in which it is selected. Defendants argue that an "operating mode" must be selected by the user but this construction is not supported by the specification. The specification provides that the camera can switch from "first mode" to "second mode" by the user's input or automatically when the film runs out. User input or selection is not a necessary element of an operating mode. The specification supports defining "operating mode" as a functional status of the controller irrespective of whether the user controls selection. Defendants argue there is no difference between the "first mode" and "second mode" because the controller does not change its functioning state at all. The specification states that when the film runs out, the activity counter can increase while no pictures are taken. Col. 8:26-29. It is implicit from the language that when the film runs out, the controller will not activate the camera mechanism. Thus, the functional status of the controller changes from the "first mode" to the "second mode." Defendants' contention that the controller does not change its functioning state is without merit. The Court construes "operating mode" to mean "a functional status which the controller can be placed in by the user or automatically without user intervention."

XVII. "Operating range"

The Court next construes the term "operating range" from claim 11 of the '925 patent.
A. The Parties' Proposed Constructions

Black & Decker proposes construing the term "operating range" as a "range typically required to operate radio." Bosch argues that the term "operating range" means "the voltage at which the radio operates."

B. The Court's Construction

The Court agrees with Black & Decker's proposed construction. Although the parties' proposed constructions are similar, substituting Bosch's proposed construction into the claim language would render the claim nonsensical because it would require a "voltage within the nominal voltage at which the radio operates." Based on the surrounding claim language, the term "operating range" must reflect a range, or some other disbursement of voltages, within which the claimed voltage can exist. Accordingly, the Court construes the term "operating range" as the "range typically required to operate the radio."

D. Operating Session

The parties agree that the term "operating session" refers to communications between the subscriber client computer and the server. Their main point of disagreement is over when it begins and ends.

Plaintiff contends that the language of Claims 1 and 24 provides that an operating session begins when the subscriber client computer's identity data is forwarded to the clearinghouse. (D.I. 266, pg. 27). Plaintiff contends that a subscriber is authenticated during an operating session, and authentication cannot be completed without identity data. Id. Plaintiff further contends that the inventors intended "beginning" to have its conventional meaning of "the time or place of starting." (Id. citing Webster's New Twentieth Century Dictionary (1983)).

Defendants contend that Plaintiff's proposed construction is overly broad, in that an "operating session" would inappropriately cover communications that never result in a successful log in or never grant access to the requested protected content. (D.I. 268). Defendants point to the patent abstract, which states that user/subscriber authentication is completed before an operating session occurs. (See '416 Patent, Abstract). Defendants note that the patent uses the terms "operating session" interchangeably with the terms "session" and "active session," to discuss something that is not started until after successful authentication. (D.I. 268, pg. 18-19 citing '416 Patent 7:48-53, 8:27-30, 10:17-21 and Figs. 17, 18). Finally, Defendants contend that an "operating session" ends when the user logs off or when the website forcibly logs the user off for lack of use. Id. at 19:26-37 and Figs 20, 22.

Reviewing the claim language in light of the specification, the Court concludes that "Operating Session" means "a period of communication between the subscriber client computer and the first server computer that follows successful initial authentication and ends upon termination of authorized access, such as upon a log-out or time-out due to prolonged inactivity."

Plaintiff does not contest Defendants' assertion that "session" and "active session" are used synonymously throughout the specification to refer to what the claim language calls an "operating session." Instead, Plaintiff relies upon Figure 18 to support its position that an operating session begins when identity data is transmitted during a login attempt. (D.I. 207, pg. 19). However, the description of Figure 18 refers to login, authentication and session initiation as three distinct, sequential, phases of a single process. (416 Patent, 3:20-22). Moreover, the figure details that a user must input its identity data, which is encrypted before being sent to the login enforcer. The login enforcer then sends the encrypted identity data and an "Initiate Session" message to the Session Initiator. (416 Patent, Fig. 18). At this point, with no session yet begun, the Session Initiator sends an "authenticate login" message to the clearinghouse, and the clearinghouse authenticates the login parameters. Id. It is only after the user's login parameters are authenticated that the "User Authentication Server" sends a successful "Authentication Response" to the Session Initiator, prompting the Session Initiator to create a new active session with a unique session ID. Id. Moreover, the specification states several times, "[i]f the login is successful, the subscription access server initiates a session[.]") (416 Patent, col 7, ll. 48-53; see also Abstract ("The clearinghouse authenticates the subscriber and server computers before an operating session begins.").
which builds sessions for every valid subscriber”), col. 8 ll. 27-30 (“When the CGIs get the login parameters sent by the subscriber software, they send a request to the session manager to authenticate the subscriber and start a new session.”), col. 13, ll. 42-53 and col. 17, ll. 45-50. Further, the invention has several features, such as the usage server and the URL tracking server, that are set to track what protected content is visited during an active session, so that information providers can keep a record of how, when, and how often users are accessing the information that has been made available to them. (See e.g. ’416 Patent, col. 4, ll. 55-59).

Therefore, in light of the process described in Figure 18, the language of the specification, and the described purpose of the operating session, the Court disagrees with Plaintiff that an “operating session” includes the transmission of identity data. Moreover, Plaintiff does not dispute that an operating session ends when a user is no longer authorized to access protected content. Accordingly, the Court concludes that an operating session follows successful initiation, and ends upon termination of authorized access.

2940

1. "operating system peer-level facility"/"component facility"

The term "operating system peer-level facility" appears in independent claims 1 and 7 of the 037 Patent, 55:21-22, 56:37-38. Claim 11 of the 037 Patent includes the related term, "component facility," which both parties agree is synonymous with "operating system peer-level facility." Id. at 57:11-12. The court therefore construes the term "operating system peer-level facility" in lieu of addressing the two terms separately.

Plaintiff argues that "operating system peer-level facility" is simply "an independent software entity." In contrast, defendant proposes a lengthy definition, arguing that the court should construe the term to mean "a major functional subsystem of the operating system separate from a conventional Unix kernel, constituted as an independent, separately executed software entity including a unique, multi-tasking interface function (or multi-tasking interface subcomponent)." Defendant's proposed construction goes on to recite several examples of peer-level facilities: the network communications facility, the filesystem facility, and the storage facility.

To resolve the parties' dispute, the court first looks to the language of the claims. See Teleflex, 299 F.3d at 1324. Claim 1 states in relevant part:

A computer system employing a multiple facility operating system architecture, said computer system comprising . . .

a plurality of processor units provided to co-operatively execute a predetermined set of operating system peer-level facilities, wherein each of said processor units is associated with a respective different one of said operating system peer-level facilities and not another of said operating system peer-level facilities, and wherein each of said operating system peer-level facilities constitutes a respective separately executed software entity which includes a respective distinct set of peer-level facility related functions . . .

037 Patent, 55:18-29. Claims 7 and 10 also respectively claim, inter alia, a "plurality" of "[operating system] peer-level facility[ies] constituting [] respective software entit[ies] executed separately from [a] kernel," id. at 56:41-43, and "additional component facilities," each of which includes "a facility sub-component" that "defines the execution operation of [] one of said component facilities, coupled to a multi-tasking sub-component," id. at 57:10-15.

As previously noted, plaintiff argues that a peer-level facility is nothing more than "an independent software entity." Arguably, this definition could include any self-contained computer program. However, as the quoted claim language makes clear, the raison d'etre of the peer-level facilities is the segregation of the various operating system functions onto different processor units. For example, claim 1 states that each peer-level facility "includes a respective distinct set of peer-level facility related functions." Id. at 55:28-29. The specification similarly emphasizes this separation of function among the various peer-level facilities, noting that advantages of the invention include "provid[ing] for the implementation of multiple facilities, each instance on a respective processor, all within a single cohesive system while incurring little additional control overhead in order to maintain operational coherency." Id. at 3:57-60. In addition, each of the operating system peer-level facilities is described as "distinct" and "separately executed." Id. at 55:28-29. A second important feature of the peer-level-
facilities is operational independence. As the ordinary meaning of the word "peer" implies, each of the facilities are co-equal, no one facility being dominant or subordinate to the other. Accord Webster's Third New International Dictionary 1665 (1976) (defining peer as "one that is the same or equal standing . . . with another"). In short, there is little doubt that independence and segregation of operation system functions are important aspects of the claimed peer-level facilities.

Although these limitations are apparent from the plain meaning of the claim language, defendant seeks to introduce myriad other elements into the disputed term, citing the specification and the prosecution history. It is well-established that the prosecution history may limit the scope of claims "so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Teleflex, 299 F.3d at 1326. Moreover, "when two patents using the same claim term both stem from the same parent application, the prosecution histories of both are relevant to an understanding of the terms in both patents." Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1460 n.2 (Fed. Cir. 1998) (citing Jonsson v. Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990)).

In the instant case, defendant relies on the prosecution history of a predecessor application from which the 037 Patent claims priority, Application No. 404,885 (Sept. 8, 1989) (" 885 Application"). 4 Claim 1 of the 885 Application initially recited a computer system "employing a multiple facility operating system architecture, said computer system comprising [inter alia] . . . a plurality of processor units for implementing a pre-determined set of peer-level facilities wherein each of said peer-level facility [sic] includes a plurality of related functions." Grewal Decl., Exh. K at 433. The examiner rejected this claim for indefiniteness, pointing out that "the computer system of claim one is only vaguely defined by the claim language. . . . Applicants should particularly point out the functions performed by the processor units in response to executing [the instructions necessary to store programs and data and to pass messages]." Id. at 422.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Auspex filed the 885 Application in September 1989. Although this application was ultimately abandoned, Auspex filed Application No. 875,585 (" 585 Application") as a continuation of the abandoned 885 Application. Prior to abandoning the 585 Application in April 1994, Auspex filed another continuation application, Application No. 225,356 (" 356 Application"). The 037 Patent ultimately issued on May 16, 2000 pursuant to a divisional application based on the 356 Application. Thus, the 885 Application is parent application of the patent in suit.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

In response to the examiner's rejection, Auspex amended the phrase "a plurality of related functions" to read "a respective plurality of peer-level facility related functions" and replaced the gerund "implementing" with "executing." Id. at 433. Auspex's response also took issue with the examiner's characterization of claim 1 as inadequately defining the invention, arguing that "[r]eliance on the specification to provide definitions of terms utilized in a claim, where such terms do not otherwise have a conventional definition, is not improper. . . . Specifically, the specification [of the 885 Application] substantially defines the primary peer-level facilities as, in the context of the UNIX operating system, the major functional subsystems of the operating system constituted as [ ] separately executed software entities separate from a conventional UNIX kernel." Id. at 439.

As the quoted passage of the 885 Application's prosecution history makes clear, Auspex sought to overcome the examiner's rejection of claim 1 by expressly defining the term "primary peer-level facility" in the context of the Unix operating system. As the Federal Circuit has repeatedly emphasized, "[t]he prosecution history limits the interpretation of claim terms to exclude any interpretation that was disclaimed during prosecution. . . . Claims may not be construed one way in order to obtain their allowance and in a different way against accused infringers." Southwall Techs., 54 F.3d at 1579 (citations omitted). The broad construction that plaintiff now proposes is simply inconsistent with the Auspex's representations to the examiner during the prosecution of the 885 Application.

Plaintiff raises two objections to this line of reasoning. First, it notes that the quoted passage of the 885 Application's prosecution history defines the term "primary peer-level facility" rather than "operating system peer-level facility." However, there is little doubt that the primary peer-level facilities of the 885 Application are substantially identical to the operating system peer-level facilities of the 037 Patent. Although claim 1 of the patent in suit includes additional claim elements not present in the parent application -- presumably to avoid rejection on indefiniteness or anticipation grounds -- the disclosed structures and functions of the peer-level facilities are closely related to those in claim 1 of the 885.
Application. Compare Grewal Decl., Exh. K at 433 with 037 Patent, 55:18-58. Moreover, the adjective "primary," like the modifier "operating system," both limit the scope of the term "peer-level facility" to the major, functionally independent components that are described in the cited passage of the prosecution history. Accordingly, the court concludes that the definition of "primary peer-level facility" in the 885 Application should limit the scope of each claimed "operating system peer-level facility" in the 037 Patent.

Plaintiff's second objection is aimed at the "conventional Unix kernel" limitation in defendant's proposed construction of the operating system peer-level facility term. Plaintiff observes that the definition of primary peer-level facility in the 885 Application includes the caveat "in the context of the UNIX operating system" -- i.e., the operating system disclosed as part of the preferred embodiment of the present invention. See Grewal Decl., Exh. K at 439. By its own terms, this definition contemplates that peer-level facilities could function in contexts other than a conventional Unix operating system. Moreover, the specification of the 037 Patent expressly states that the Unix operating system is merely a preferred embodiment of the invention, noting that the invention is "applicable to a wide variety of primary, or full-function operating systems such as MVS and VMS." 037 Patent, 6:54-57. Accordingly, the court declines to adopt defendant's proposed "conventional Unix kernel" limitation as part of its construction of the operating system peer-level facility term.

Of course, this leaves open the question as to whether the "kernel" limitation should be included in the construction at all. Plaintiff argues that it should not, citing the preferred embodiment of the 037 Patent, which includes the Unix kernel itself as one of the operating system peer-level facilities. Id. at 8:46-48. Thus, plaintiff argues that limiting the functional subsystems covered by the definition of peer-level facility to those that are executed separately from the kernel would be illogical, noting that such a definition would require the kernel (itself a peer-level facility) to be executed separately from itself. The court agrees. While recognizing that the prosecution history of the 885 Application at least implicitly excludes the operating system kernel from its definition of "primary peer-level facility," the court must also heed the Federal Circuit's warning that it is rarely, if ever, correct to construe a term to exclude a preferred embodiment. Vitronics, 90 F.3d at 1583-84. Reading the "executed separately" limitation into the claim language would require the court to choose between one construction that is inconsistent with the preferred embodiment disclosed in the specification (i.e., one that excludes a Unix kernel from the scope of the claim language) and another that is simply irrational, given that the kernel cannot be executed separately from itself. Thus, the court holds that the limitation "separately from the kernel" should not be read into the term "operating system peer-level facility." 5

5 Similarly, the court notes that claim 11 of the 037 Patent recites an "operating system [that] includes a kernel and a plurality of additional component facilities executed separately from said kernel." 037 Patent, 57:9-11. The need to qualify the term "component facilities" with the adjective "additional" suggest that absent such a qualification, the term component facility would include the kernel.

Having thus far defined "operating system peer-level facility" as "a major functional subsystem of the operating system constituted as a separately executed software entity," the court turns to several additional limitations that defendant seeks to introduce to the disputed term. First, defendant argues that the terms should be construed to include a "multi-tasking interface function." However, this construction is inconsistent with the plain meaning of the claim language. For example, claim 7 states that each operating system peer-level facility "implements" a multi-tasking interface. 037 Patent, 55:43-44. Defendant's construction would require that the facility implement a part of itself, rendering the claim language redundant and circular. In any event, the multi-tasking interface is a separate element of the claimed invention, which the court declines to read into the peer-level facility term. 6 Defendant also requests that numerous examples of peer-level facilities be included in the claim language. However, even defendant's proposed construction does not suggest that this list is exhaustive. As a result, including these examples in the claim language does nothing to define the scope of the patent's terms, and ultimately, plaintiff's right to exclude. "The Federal Circuit has repeatedly cautioned courts from positing constructions that would contribute nothing but meaningless verbiage to the definition." Nikon Corp. v. ASM Litho. B.V., 308 F. Supp. 2d 1039, 1072 (quoting Harris Corp. v. Ixys Corp., 114 F.3d 1149, 1152 (Fed. Cir. 1997)). Accordingly, the court declines to construe the claim to include the proposed terms.
Because the court declines to read a multi-tasking interface limitation into the disputed terms, it need not address defendant's argument that this multi-tasking interface is "unique."

Thus, for the reasons stated above, the court construes "operating system peer-level facility" as "a major functional subsystem of the operating system constituted as a separately executed software entity."

4. Operation Code

a. Proposed constructions

The disputed term "operation code" is used in U.S. Patent Nos. 6,378,120 ("the '120 patent"), 6,378,020 ("the '020 patent"), 6,426,916 ("the '916 patent"), and 6,452,863 ("the '863 patent"). Rambus proposes that "operation code" be construed as "one or more bits to specify a type of action." Joint Claim Construction Statement ("JCCS") Ex. A at 8. Hynix submits that the term means "bits in a field within a packet or computer code instruction that identifies what type of action to be performed." Id. The dispute focuses on Hynix's attempt to limit the operation code to require that the action be performed "within a packet" or "within a computer code instruction." Hynix's proposed construction improperly broadens the scope of what could constitute an operation code.

b. Claim language

The claims teach that there are conceptually three types of operation codes. "The first operation code instructs the memory device to perform a read operation." '120 patent, cl. 1. "The second operation code instructs the memory device to perform a write operation." '120 patent, cl. 2. "The third operation code instructs the memory device to store the value [which is representative of a number of clock cycles of the external clock signal to transpire before the memory device outputs the data] in a programmable register on the memory device." '120 patent, cl. 12.

The dependent claims recite various properties the operation code may have. "The first operation code [may] 12 include[] precharge information." '120 patent, cl. 7 (which is dependent on claim 1). "The first operation code [may be] included in a request packet." '120 patent, cl. 8 (which is dependent on claim 1). "The block size information and the first operation code [may be] both included in the same request packet." '120 patent, cl. 9 (which is dependent on claim 1). This request packet may also include address information. '120 patent, cl. 10 (which is dependent on claim 8). Finally, the operation codes are issued by a memory controller ('863 patent, clss. 1, 3) and provided to the memory device via an external bus ('120 patent, cl. 2, dependent on cl. 15).

12 Throughout this paragraph "may" is inserted because these are dependent claims.
13 Hynix offers no specific explanation why "operation code" should be limited to fields within a "computer code instruction." Moreover, Hynix proffers no definition for a "computer code instruction." The patents use the term "computer" inconsistently, sometimes referring to a computer as a higher level or simply different device from the present invention. Therefore, Hynix has presented no persuasive evidence demonstrating that the limitation "within a computer code instruction" applies to "operation code."

The Federal Circuit faced a similar construction issue in Infineon II. 318 F.3d at 1095. There, the court reasoned that by claiming a "bus carrying device-select information without the need for separate device-select lines connected directly to individual semiconductor devices" (i.e. a bus that is multiplexed), Rambus showed it "did not redefine bus" in the specification to be a multiplexing bus." Id. Similarly, by specifying in certain dependent claims that the operation code is included in "a request packet," or simply "a packet," Rambus does not appear to limit "operation code" as used in other claims to bits in a field within a packet.

c. Ordinary meaning

The court looks to the relevant technical dictionaries to ascertain the ordinary and customary meaning of "operation code." Tex. Digital, 308 F.3d at 1202. The patents relevant to operation code were issued in 2001 and 2002, so the court looks to the 2001 edition of The Authoritative Dictionary of IEEE Standard Terms for guidance. "Operation code" has the following definition:

(1)(B) The code that represents or describes a specific operation. The operation code is usually the operation part of the instruction.

THE AUTHORITATIVE DICTIONARY OF IEEE STANDARD TERMS 769 (2001 ed.).

In light of the evidence presented, the court finds this definition to be the ordinary meaning of "operation code." Rambus's proposed construction is substantially similar to this definition, and therefore comports with the ordinary meaning of "operation code." Notably, the ordinary meaning of "operation code" does not connote that it be transmitted solely within a packet.

d. Specification

To rebut the presumption that one skilled in the art would have understood "operation code" to carry its ordinary meaning, Hynix argues the specification defined the claim term by implication to include the packet limitation. See Bell Atl. Network Servs. v. Covad Communications Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001) ("when a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term by implication"). Hynix observes that the sole support for the meaning of "operation code" in the specification is in the AccessType field in the preferred embodiment of the request packet.

In the preferred implementation, the operation code is part of the control information. '120 patent, cl. 9, 11. 39-41. The control information is contained within two 4 bit fields that constitute the first byte of a six byte request packet. '120 patent, cl. 9, 1. 25; Fig. 4. The preferred implementation labels the operation code in this packet "AccessType" (120 patent, cl. 9, 1. 35), which is depicted in Figure 4. AccessType is also depicted in additional types of packets in Figure 5 and Figure 6. The specification explains that AccessType is a field which "specifies whether the requested operation is a read or write and the type of access, for example whether it is to the control registers or other parts of the device, such as memory." 120 patent, cl. 9, 11. 43-46.

In Toro Co. v. White Consolidated Industries, Inc., the Federal Circuit explained that a limitation upon a claim term may be implied from its existence in the sole preferred embodiment when "no other broader concept was described as embodying the applicant's invention, or shown in any of the drawings, or presented for examination." 199 F.3d 1295, 1301 (Fed. Cir. 1999). The court construed "including" and "cover" as requiring that a restriction ring be permanently attached to the cover because "nowhere in the specification, including its twenty-one drawings, is the cover shown without the restriction ring attached to it" Id. Moreover, "the specification described the advantages of the unitary structure as important to the
invention." Id. Hynix concludes that since the sole use of "operation code" in the preferred implementation is as the AccessType field within a packet, the specification clearly implies that the construction of "operation code" should be limited to being within a packet. See Toro, 199 F.3d at 1301.

A weakness in Hynix's position is revealed when the preferred embodiment is viewed in light of Infineon II. 318 F.3d at 1095. The Federal Circuit held that Rambus's invention's use of a bus "is not limited to a multiplexing bus." Id. Stated another way, the scope of Rambus's invention includes operation on a non-multiplexed bus. The Infineon II court defined "multiplexing" as "the sharing of a single set of lines to send multiple types of information," such as address, data and control information. Id. at 1094. The preferred embodiment of AccessType being within a request packet is illustrated in Figure 4. The packet depicted in Figure 4 (as well as in Figures 5 and 6) requires the use of a multiplexed bus. For example, in Figure 4, the bus line carrying Access Type[0] would carry the first bit of the operation code on cycle 0, then the same bus line would carry address information on the remaining cycles. The packet depicted in Figure 6 requires the same bus line to carry control information (i.e., AccessType), address information, invalid request information, and request information over the course of 12 bus cycles. The critical fact is that these packets travel on a multiplexed bus and cannot operate on a non-multiplexed bus.

If the preferred embodiment of operation code requires the use of a multiplexed bus, but the Federal Circuit has found the invention may be operated on non-multiplexed bus, then the logical conclusion is that this cannot be the only possible embodiment of the "operation code." See SRI Int'l v. Matsushita Electric Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985) (the law does not require an applicant describe in the specification "every conceivable and possible future embodiment of his invention."). Consequently, Rambus's patents are distinguishable from the patents in Toro. See 199 F.3d at 1301. In implying a limitation from the preferred embodiment in Toro, the court found that "this is not a case of limiting the claims to a preferred embodiment' of an invention that has been more broadly disclosed." Id. In contrast, here the Federal Circuit has found that a broader invention has been disclosed, one in which the claims cover operation on both multiplexed buses and non-multiplexed buses. Infineon II, 318 F.3d at 1095. Therefore, a limitation absent in the claims or ordinary meaning of "operation code" cannot be inferred from a preferred embodiment that does not describe the full scope of the claimed invention's method of operation. See RF Del., Inc. v. Pac. Keystone Techs., Inc., 326 F.3d 1255, 1264 (Fed. Cir. 2003) (independent claims usually cover a scope broader than the preferred embodiment, especially when the dependent claims recite the precise scope of the preferred embodiment).

e. Prosecution history

Hynix's citation to Rambus's statements in the prosecution history of the '916 patent is similarly unavailing. Rambus's statements do not add any more context to the definition of "operation code" than what is disclosed in the specification.

f. Breadth

Hynix argues Rambus's definition of "operation code" improperly broadens the term to the point that "any input electrical signal with two possible voltage levels, for example, could qualify as an operation code' as long as some action ( on' or off') occurred in response." Hynix's Resp. CC Br. at 17. At first blush, this argument has some appeal. However, the claims themselves limit the practical effect of Rambus's proposed construction. For example, the theoretical input electrical signal that Hynix fears will be considered an operation code still must either "instruct the memory device to perform a read operation," ('120 patent, cl. 1), a "write operation" ('120 patent, cl. 2), or "to store the value in a programmable register on the memory device." ('120 patent, cl. 12). It must also be sampled synchronously with respect to the external clock signal. Id. Finally, it must include precharge information. 14 However, only certain claims, like dependent claim 8 of the '120 patent, require that the operation code be contained within a request packet.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

14 At the least the first such input signal would have to include this information.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

The court is satisfied that Rambus's construction sufficiently "assigns a fixed, unambiguous, legally operative meaning to the claim." Liquid Dynamics Corp. v. Vaughan Co., Inc., 355 F.3d 1361, 1367 (Fed. Cir. 2004). The claim language, the
specification, and the prosecution history do not suggest that the patent uses "operation code" in a manner inconsistent with its ordinary meaning. Therefore, the court finds "operation code" is properly construed as "one or more bits to specify a type of action."

The term "operation of a microprocessor" should be interpreted as follows: "execution of software/program code."

The next disputed term "operation panel" presents the same issue regarding physical separation. This term appears in Claim 2 of the '618 Patent. Ricoh contends that an "operation panel allows a user to specify a function to and display data from the business device engine." (Chart at 27). Pitney argues that the "operation panel" is "an input/output device that can input commands and display information that is separate and external from the business office device." (Id.). The Court notes that the parties agree that the terms "operation panel" and "operation terminal" should be construed in the same way. (Ricoh Br. at App. 4; Pitney Br. at App. 4).

Consistent with this Court's analysis and conclusion concerning "input/output device," the Court adopts Pitney's construction. During prosecution, the patentee stated that the "input/output device" corresponds to the "operation terminal." ('289 Patent Prosecution History, Dec. 22, 1995 Amendment at 25). Ricoh provides no additional support for an alternative construction. Consequently, "operation panel" means "an input/output device that can input commands and display information that is separate and external from the business office device."

"operational data for the scanhead" and "operational data unique to the transducer scanhead"

Plaintiffs' construction: data designed for specific applications such as cardiac analysis, neo-natal analysis, gynecology analysis and prostate analysis

Defendant's constructions: "operational data for the scanhead" means data that is used in the operation of the scanhead; "operational data unique to the transducer scanhead" means data that is collectively used in the operation of a particular model of the transducer scanhead

Plaintiffs contend that both terms mean the same thing: data designed for specific applications such as cardiac analysis, neo-natal analysis, gynecology analysis and prostate analysis. They argue that their proposed construction is supported by the patent specification. Not so. The portion of the patent specification on which they rely explains merely that "Memory 135 stores operational data unique to the specific transducer scanhead which may be designed for specific applications such as cardiac analysis, neonatal analysis, gynecology analysis and prostate analysis." '839 pat., col. 4, lns. 24-27 (emphasis added). Obviously, "may" does not mean "must."

Defendant's constructions have the advantage of being consistent with the claim terms, patent specification and common sense. E.g., '839 pat., col. 2, lns. 24-32. As discussed above, neither the patent language or the specification indicates that the claim language should be construed narrowly. In addition, it would be contrary to the holdings of the court of appeals to construe the two terms identically, when they use different wording and appear in two separate claims. Applied Medical Resources v. United States Surgical Corp., 448 F.3d 1324, 1333 n.3 (Fed. Cir. 2006) (affirming presumption that different terms have different meanings).

Court's constructions: "operational data for the scanhead" means data that is used in the operation of the scanhead;
"operational data unique to the transducer scanhead" means data that is used collectively in the operation of a particular model of the transducer scanhead.

As with other limitations related to a means/function limitation, defendants attempt to link the construction of this term to corresponding structure for the related means plus function term, "means for providing an operational state signal." Further, in this case, defendants argue that it should be limited to the output of just one of the multiple structures listed in specification. Defendants' proposed construction of the corresponding means is "A periodic output from a processor running special purpose software that drives an LED to blink at a specific rate." Once again, the Court rejects Ipsos's proposed construction as unnecessarily limiting.

Plaintiff's proposed construction is adopted as "a signal that indicates the operating state of device."

The third term from the Claims Involving Products Carrying Participation Numbers the parties have presented to the Court for construction is "operations of the interface." This term appears in the preamble of Claims 44 and 93 of the '707 patent and Claims 79 and 190 of the '863. The language containing this term varies slightly in the claims, but generally provides for "[a] process for controlling operations of an interface with a telephonic communication system." The term "operations of the interface" as it appears in the preamble is also referred to in the limitations of the claims, such as "to access said operations of the interface."

The defendants argue that "operations of the interface" is synonymous with "format." The plaintiffs contend that the term should be construed as "the set of processes or actions that effectuates interactive connection and that is part of the work performed by the system connected to the telephone network." (Pls.' App. at 68).

The claim language does not support the defendants' limited construction of this term. In the second limitation of Claim 37, upon which Claim 44 depends, the claim includes the step of "receiving said call data signals . . . to select a specific operating format from a plurality of operating formats of said operations of the interface." This claim recites both the terms "format" and "operations of the interface." The use of both terms separately in the same claim indicates that they have different meanings. In addition, the claim refers to selecting one of a plurality of operating formats of the operations of the interface, which shows that the operations of the interface includes more than one format. Further, the term "format" is not present in Claims 93 of the '707 patent or Claim 190 of the '863 patent, which indicates that the operations of the interface do not necessarily include a format.

The term "operations of an interface" is not discussed in the specification. The defendants point out that in Column 10, lines 32, 39, and 43, Katz refers interchangeably to "mail order operating format" and "mail order interface." From this portion of the specification, however, the Court cannot conclude that the operations of the interface can only include a format.

The Court concludes that there is no reason in the claim language or specifications to depart from the ordinary, common meaning of "operations of the interface." Based on the foregoing and consistent with the Court's construction of "interface structure," the Court concludes that the term "operations of an interface" means: the processes, activities, or functions of the interactive connection between the processors upon which the Katz system is running, the communication facility, and the callers. The term does not require that the Katz system be running a format, or specifically, one of the seven formats disclosed in the specifications.
With respect to "operational," Leviton focuses on the use of that term in claims 5 and 22 of the '112 patent by arguing that the district court improperly imported limitations from a preferred embodiment into the claims. Leviton's most coherent argument in this regard relates to claim 22, which reads in relevant part:

22. A circuit interrupting device comprising:

. . .

a circuit interrupter disposed within said housing, the circuit interrupter having an operational state and a non-operational state and configured to cause electrical discontinuity between said first and second conductors upon the occurrence of a predetermined condition;

. . .

a reset lock-out device that prevents reestablishment of electrical continuity between said first and second conductors if said third electrical conductor is not connected to a neutral line; and

wherein activation of the reset device activates the circuit interrupter to be in the operational state to move the reset lock-out device to a reset position.

'112 patent col.9 l.17-col.10 l.24 (emphasis added).

According to Leviton, the plain language of the second limitation reproduced above ("a reset lock-out device . . .") demonstrates that claim 22 only prevents reestablishment of electrical continuity if there is an open neutral condition, i.e., the third wire "is not connected to a neutral line." As such, the "operational state" of the circuit interrupter referenced in the "wherein" clause is satisfied so long as the circuit interrupter is able "to move the reset lock-out device to a reset position."

Although we agree that activation of the circuit interrupter to be in the operational state is necessary to move the reset lock-out position, the remainder of Leviton's argument is unpersuasive because it ignores the first limitation reproduced above ("a circuit interrupter disposed . . ."). which plainly ties the "operational state" of the circuit interrupter to the ability of the circuit interrupter to "cause electrical discontinuity. . . upon the occurrence of a predetermined condition." n6 The ability of the circuit interrupter to cause discontinuity requires, as Leviton admits, both the sensing circuitry and the trip mechanism to be working properly. Appellant's Br. at 3-4. Accordingly, "activat[ing] the circuit interrupter to be in the operational state" must also require both the sensing circuitry and the trip mechanism to be working properly. This requirement is not inconsistent with, and does nothing to eliminate, the additional requirement of claim 22 that the reset lock-out device must prevent reestablishment of electrical continuity in the event of an open neutral condition.

--- Footnotes ---

n6 Such "predetermined conditions" include ground faults, arc faults, appliance leakage faults, immersion faults, and test cycles. '112 patent col.2 ll.27-28. However, an open neutral condition is not a "predetermined condition" because an open neutral condition cuts off power to the trip mechanism of the circuit interrupter. See id. col.3 ll.44-54. And it is axiomatic that if the trip mechanism—which is "electro-mechanical," id. col.3 ll.8-9—has no power, it cannot cause electrical discontinuity. Thus, if an open neutral condition could be one of the "predetermined conditions," the circuit interrupter could not fulfill its stated purpose because it could not be configured to cause discontinuity in response to such a condition.

--- End Footnotes ---

Leviton attempts to draw an even finer linguistic distinction with respect to claim 5 of the '112 patent:
Claim 5 does not discuss a device in terms of "operational," it recites a device which will not allow itself to be reset if any one of its circuit interrupter components is "non-operational." Accordingly, there was no basis to limit the claim to a device that will allow reestablishment of electrical continuity only after a complete test of the system to show that it is fully operational.

Appellant's Br. at 25 (emphasis in original).

We disagree. There is simply no way for the device to know in advance which of its circuit interrupter components, if any, are not working properly. Therefore, the device must, as the district court held, be capable of testing both the sensing circuitry and the trip mechanism in order to determine whether the circuit interrupter is operational. To be sure, a situation may arise in which the first of those two components is found to be malfunctioning, thereby rendering a test of the second component unnecessary. That does not mean, however, that both components need not be tested before electrical continuity is reestablished.

Leviton further argues with respect to claim 5 that the doctrine of claim differentiation precludes the district court's construction of "non-operational" because dependent claims 12 and 13 respectively describe preventing the reestablishment of electrical continuity "if said trip mechanism is non-operational," and "if said sensing circuitry is non-operational." '112 patent col.7 l.66 - col.8 l.6. Thus, according to Leviton, independent claim 5 is actually narrower than dependent claims 12 and 13 under the district court's claim construction. See Appellant's Reply Br. at 9-11. "As this court has frequently stated, the presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). However, "that presumption can be overcome if the circumstances suggest a different explanation, or if the evidence favoring a different claim construction is strong." Id. Here, the presumption is clearly overcome because, as explained in the preceding paragraph, the device must be capable of testing both the sensing circuitry and the trip mechanism in order to determine whether the circuit interrupter is operational. If, as Leviton suggests, electrical continuity could be reestablished when only the trip mechanism is operational, or when only the sensing circuitry is operational, the circuit interrupter would remain non-operational and the device would not function properly, i.e., it would not cause electrical discontinuity upon the occurrence of a predetermined condition. Therefore, claim differentiation does not apply in this case.

Because we are not persuaded by Leviton's arguments, we see no need to disturb the district court's construction of "operational."

**2948**

f. "Relay having an operational position and a test position"

Claim 5 requires a "relay having an operational position and a test position." The court begins by construing "operational position" and "test position." As the parties agreed, the claimed relay is the element that separates the high voltage delivery system from the rest of the defibrillator. In one position, which is referred to in the specification as the "normally closed" or "closed" position ('374 Patent at 9:13-14, 10:24-25), the high voltage delivery system is capable only of self-tests in which it sends a current through a test load. 374 Patent at 11:30-42. In this position, the defibrillator cannot shock a patient. 374 Patent at 8:34-38.

In another position, which is referred to as "normally open" or "open," the high voltage delivery system can deliver a shock to a patient, as the parties agree. In addition, however, the defibrillator can conduct other self-tests with the relay in open position. E.g., 374 Patent at 9:4-21 (describing the "Defibrillator Connector/Relay self-test"), 10:14-22 (describing the "HV Isolation Relay self-test").

The "test position" of Claim 5 is the relay position in which the high voltage delivery system can only perform self-tests and cannot shock a patient. The "operational position" is the relay position in which the high voltage delivery system can deliver shock to the patient, although the defibrillator can perform other relay self-tests in this position as well.

The parties' dispute over this term centers on whether the relay may consist of a combination of relays and can have more than two positions, as Philips contends, or whether the relay is a single relay with only two positions, as Defibtech contends.
Philips can point to no intrinsic evidence that discloses more than one relay or more than two positions. Instead, it relies on three arguments: that the specification does not exclude such relays, that dictionary definitions of "relay" do not exclude such relays, and that the inventors' decision to claim a "relay having an operational position and a test position" is no different than using the open-ended terms "comprising" or "including."

The court finds Philips' first two arguments unavailing. The specification speaks only of a relay with two positions. n10 It does not state that such positions are preferred, and it does not suggest that a relay with more than two positions could have any function in this invention. As for Philips' dictionary definitions, the court declines to rely on them for the reasons stated in its prior order. October 25 order at 5.

--- Footnotes ---

n10 The specification also teaches that the relay may become stuck in a position between the open and closed position. 374 Patent at 10:26-28 (discussing possibility that relay could "fail[] to move completely to the normally closed position").

--- End Footnotes ---

As to Philips' third argument, the term "having" does not carry the presumption of open-ended interpretation that accompanies the term "comprising." Crystal Semiconductor Corp. v. Tritech Microelectronics Int'l, Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). Instead, a court must look to the specification to determine what the inventors intended. Lampi Corp. v. Am. Power Prods., Inc., 228 F.3d 1365, 1376 (Fed. Cir. 2000). As already noted, if the inventors intended "having" to be non-limiting, n11 they left no hint in the specification. The specification speaks uniformly of a single two-state relay. The court construes the term accordingly. A "relay having an operational position and a test position" is a single relay with only an operational position and a test position, where "operational position" and "test position" have the meanings the court provided above.

--- Footnotes ---

n11 As Defibtech noted at oral argument, the inventors used the term "having" only twice in the 73 claims of the 374 Patent, whereas they used the presumptively open-ended term "comprising" more than 60 times.

--- End Footnotes ---

5. "Operative": "Producing a designed effect." "Operative" is utilized in the specification to refer to a component achieving a specific result, e.g., "operative to download" (col. 2, ll. 6-10; col. 3, ll. 35-40) or "operative to embed [commands]" (col. 6, ll. 24-31). The claims also utilize "operative" to describe the visualization functionality as producing or providing a specific effect, e.g., "to embed commands to the web browser" (claims 13, 30, 35, 46) or "to delete executable content" (claim 34), as compared to merely being enabled to function (or as plaintiff asserts, "having the capability to" function).

--- End Footnotes ---

--- D. "Operatively connected" ---

The district court construed the claim term "operatively connected" to mean "joined or linked together to produce the designed effect." District Court Opinion at 20. The court also held that the "operatively connected" limitation, when read in light of the '041 patent specification, should be construed to mean "joined or linked together to produce the designed effect within the terminal." Id. at 21 (emphasis added).
Catalina challenges this construction, arguing that the district court improperly imported "within the terminal" into the "operatively connected" limitation. Catalina argues that the plain and ordinary meaning of the "operatively connected" limitation is not restricted to operative connections only within the coupon-dispensing terminal. We are not persuaded by Catalina's argument on appeal. The language of claim 1 itself describes "[a] system ...wherein each terminal comprises" the device recited by the claim 1 limitations. '041 patent col. 30, ll. 46-49 (emphasis added). It is within those limitations that the "operatively connected" term is used. Furthermore, the patent specification itself often refers to the disclosed invention as a "stand alone coupon dispensing terminal." See, e.g., '041 patent col. 2, ll. 5-7. Clearly, the language of the claims and the intrinsic evidence supports the district court's construction of the "operatively connected" term in claim 1.

Accordingly, the district court's construction of "operatively connected" is upheld.

As to the operatively connected limitation, this limitation appears in two of the '404 patent's three independent claims. Claim 1 is representative:

1. An interactive computer software system permitting a user to take a pre-selected computer course or access a pictorial data base, comprising:

   . . . .

   (c) a graphics computer sub-system operatively connected to said host computer sub-system, said graphics computer sub-
   system executing said course upon interrogation by said host computer sub-system wherein said course includes a series of
   interrelated pictures displayed by said graphics computer sub-system, said series of pictures defining a course responsive to
   input data from the user and interactively dialoguing with the user as the user progresses through said pre-selected course or
   data base;

   . . . .

'404 patent, col. 8, l. 49-col. 9, l. 3 (emphasis added). The district court construed the operatively connected limitation to
mean "the graphics computer subsystem communicates with the host computer subsystem through an unmediated
mechanism." Amended Claim Construction Order, slip op. at 1. To the contrary, the broad language "operatively connected"
do not require communication through an unmediated mechanism.

Claims 1 and 11 use the phrase "operatively connected" to describe the communications that take place between a graphics
computer sub-system and a host computer sub-system during operation. The claim language does not state or suggest,
however, that these communications must be done on a non-mediated communication mechanism. While the specification
does contemplate a non-mediated communication mechanism, see '404 patent, col. 4, ll. 58-59, the particular
communication mechanism in any given system has nothing to do with the '404 patent's improvement over the prior art. In
other words, the manner in which the host system and the graphics system communicate has no bearing on the modification
of one picture or screen without affecting the other screens. This feature was the '404 patent's key innovation as outlined in
the specification and prosecution history. Thus, this court agrees with IP Innovation that the operatively connected limitation
does not require communication over an unmediated communication mechanism.

B. Operatively connecting

Claim 1 of the '865 patent includes the following limitations:
first means for operatively connecting the first terminal of a selected one of said differential amplifiers to the first terminal of said sense amplifier, and

second means for operatively connecting the second terminal of a selected one of said differential amplifiers to the second terminal of said sense amplifier.

Claims 6, 7, and 8 of the '865 patent include limitations using similar language, as follows:

first means for operatively connecting the first terminal of the selected differential amplifier to said first input-output bus line, and

second means for operatively connecting the second terminal of said selected differential amplifier to said second input-output bus line.

These disputed claim elements are expressed in "means plus function" language, which, as noted, must be construed to cover the corresponding structure described in the specification or its equivalents. See 35 U.S.C. § 122, P 6; see also Sofamor Danek Group, 74 F.3d at 1220. The parties agree that the structures constituting the first and second means are the two switching gate transistors pictured as Q[4] and Q[4'] in Figure 5 of the '865 patent and that these two transistors must "operatively connect[]" the differential sense amplifier terminals with the output sense amplifier terminals and the input/output data bus lines. What is sharply disputed is the scope of the phrase "operatively connecting." NEC argues that this phrase requires a direct electrical connection between the differential sense amplifier and what is usually referred to as an output amplifier, but which is called a sense amplifier in the '865 patent. Hyundai counters that this phrase must be construed more broadly to include information transferred through a type of buffer circuit, called a "source follower," in which the output of the differential sense amplifier is used to operate a gate which, in turn, controls another signal generated from the power supply that controls the output sense amplifier, but which does not create any electrical connection between the two amplifiers.

The switching gate transistors Q[4] and Q[4'] pictured in Figure 5 of the '865 patent are configured so as to create a direct source-drain electrical connection between the two amplifiers when they are in their active state. Indeed, such a configuration would appear to be necessary to achieve the benefit of the patent: namely, comparing the actual outputs of the two sides of the differential sense amplifier in order to determine logic level, rather than merely comparing the signal on one side with a reference voltage on the other. Under Hyundai's construction, the first and second means elements of Claim 1 include a configuration in which there is no direct current path between the outputs of the differential sense amplifier to compare at the output sense amplifier. Such a construction is unpersuasive as it would frustrate the patent's purpose. Nor is there any doubt that the patent's purpose is a proper interpretive guide; the Federal Circuit has held that the purpose of the invention may guide claim construction since "the problem the inventor was attempting to solve, as discerned from the specification and prosecution history, is a relevant consideration" in construing claims. CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1160 (Fed. Cir. 1997); see also Applied Materials, Inc. v. Advanced Semiconductor Materials Am., Inc., 98 F.3d 1563, 1573 (Fed. Cir. 1996).

8 Figure 5 may be found at Appendix 4 to this opinion.
the output sense amplifier.

2953

(3) Operatively Coupled to Said Communication Pathway

Independent claim 1 includes the limitation "operatively coupled to said communication pathway." The parties propose the following meanings to this term:

<table>
<thead>
<tr>
<th>Braun's Proposed Construction</th>
<th>VMI's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected to the communication pathway to send and/or receive coded data on the signals on the communication pathway.</td>
<td>Connected to the communication pathway to send and receive signals on the communication pathway.</td>
</tr>
</tbody>
</table>

The parties arguments are similar to the ones regarding the meaning of the "communication pathway." Again, insofar as Braun insists that "door operation commands" are limited to only coded data signals, its reliance on that term for interpretation of other terms is wrong. The Court adopts VMI's proposed construction: "operatively coupled to said communication pathway" means connected to the communication pathway to send and receive signals on the communication pathway.

2954

2) "operator" (Claim 13)

The only dispute regarding this term is whether the operator must be a human being. I conclude that in the context of the written description, see id. at 1313, the ordinary person skilled in the art would recognize that this term implies human involvement. As the patentee has not "clearly set forth an explicit definition of the term different from its ordinary meaning," Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204 (Fed. Cir. 2002), I adopt the customary meaning of "operator."

I construe this term to mean: "a person who performs a function with the use of a device or process."

2955

a. “operator group”

Plaintiffs contend that “operator group” means “at least one multimedia box, where a multimedia box can be a jukebox.” Id. at 26. They base their proposed construction on the claim language that states that an “operator group” includes “at least one multimedia box” and the specification that alternatively describes the multimedia box as a jukebox. See e.g., id., Ex. 7 at 4:35-65. Defendants contend that “operator group” means “a group of one or more multimedia boxes operated by an operator.” Resp. Brief, Ex. E at 3. They base their proposed construction on language in the
specification stating that a certain number of jukeboxes is operated and serviced by one operating company in each case so that these jukeboxes represent one operator group 22. Each operator group 22 has a management station 30 allocated to it, which is linked in each case via ISDN line 3 in a star-shaped structure to the individual jukeboxes 20 of one operator group 22.

Opening Brief, Ex. 7 at 4:65-5:3. Defendants also point to a sentence in plaintiffs’ brief that defines “jukebox operator” as “an individual or company that typically owned a number of jukeboxes at various locations.” Id. at 2.

Neither parties’ proposed construction is particularly helpful. Plaintiffs’ proposed construction essentially construes “operator group” as one or more jukeboxes. Such a definition ignores the specification entirely. Defendants’ proposed construction, which utilizes the term it seeks to define, is confusing. Because “operator group” does not appear to have any particular meaning to a person of ordinary skill in the field, the Court must construe the term in light of the specification. The Court therefore construes “operator group” as “one or more jukeboxes managed and serviced by one entity.”

C.1.b. “operator terminal”

Verizon alleges that "operator terminal" means "hardware and software used by an operator to send and receive voice and data." Verizon Reply Brief at 21. According to Katz, "operator terminal" should be construed as "an input-output device (attended by a human communicating with a caller) designed to receive data in an environment associated with the job to be performed and capable of transmitting entries to and obtaining input from the system of which it is a part." Katz Brief at 77.

Both Verizon and Katz assert that their asserted interpretations are consistent with the plain meaning of "operator terminal" as understood by one of ordinary skill in the relevant art. See, e.g., Waite 1/14/03 Decl. PP 28-30; Hopenfeld 1/15/03 Decl. Ex. 3.

The term "operator terminal" means "an input-output device, for use by a human operator, capable of transmitting data to and obtaining input from the system to which it is connected." The Court's interpretation is consistent with the ordinary meaning of the claim language. Other language in claim 21 further limits "operator terminal." For example, the language of claim 21 requires that "operator terminal" have telephonic communication capabilities, see Col. 23:41-42 ("for use by a person to communicate through the telephone facility;") and that it have the ability to provide data to the central memory. See Col. 23:59-61 ("the operator terminal providing other data entries to the central memory to update data relating to the caller."). The specification of the 551 patent does not suggest a contrary definition. Indeed, the description of the structure and functions of the operator (interface) terminal in the 551 patent is somewhat sparse. However, the specification of the 551 patent informs us that an operator terminal, according to the disclosed embodiment, 1) is connected to the processing systems P1-Pn; 2) allows operators to directly communicate with callers; and 3) appears to allow operators to manually enter data during interactions with callers. See 551 Patent, Col. 4:37-40 ("the processing systems P1-Pn are interconnected with a command computer terminal CT, at least one interface terminal IT, and at least one printer PR."); Col. 5:18-24 ("In the disclosed embodiment, the processors PR1-PRn are connected collectively to the command computer terminal CT (incorporating a CRT display), the interface terminal IT, and the printer PR."); Col. 5:53-57 ("Either during the
data accumulation phase, or after the processing phase to isolate a subset, a distinct operation may involve actuating the interface terminal T1 \[sic\] for direct local communication between the caller and an operator at the terminal T1 \[sic\].

Col. 7:13-17 ("In an alternative mode, the processor PR1 may abort the interface and couple the interface terminal IT for direct personal communication with the caller. The interchange would then proceed, person-to-person."); Col. 10:43-50 ("Either before or after qualification, the caller might be advised that if he prefers to communicate directly with a person, or needs such contact at any point in the communication, he may accomplish it simply by pushing the asterisk button (*) at the terminal T1. Such action forms an abort signal that is detected by the processing unit 92 to transfer the communication to the interface terminal IT (FIG. 1).";)

Col. 11:6-10 ("Note that the caller may not be identified in the files of the mail-order house and in that event, the operation may be shifted to a manual operation to be continued through the interface terminal IT (FIG. 1) as explained above."); see also Col. 19:46-48 ("Thus, the format defines a subset then further selects a sub-subset of winners. In any of the various formats, the status of the analysis can be televised by selecting a camera focused on the interface terminal IT.").

2957

23. The method in accordance with Claim 1 further comprising presenting on said remote contribution accepting devices symbols representing operators for inducing the making of monetary contributions, said symbols comprising said request for a contribution data packet.

An "operator" is the device by which a person triggers the action, usually by means of a button, switch, or similar triggering device. The operator, in this case, has marks or symbols specifying contribution amounts.

2958

A. Court's Review of the Special Master's Report and Recommendation Regarding Definition of "Optical Arrangement."

In reviewing the Special Master's Report, this Court reviews de novo the findings of fact and conclusions of law objected to by the parties. Fed.R.Civ.P. 53(g)(3)&(4). All other findings of fact and conclusions of law may be reviewed de novo. See Fed.R.Civ.P. 53 advisory committee note on 2003 amendment.

The construction of patent terms is a question of law determined by the court. Markman v. Westview Instruments, Inc., 52 F.3d 967 (Fed.Cir. 1995). The Court must first look to the intrinsic evidence of the patent to determine the scope of the claims. Id. at 979. The intrinsic evidence includes the words of the claims themselves, the specification, and the prosecution history, if in evidence. Id. Where the use of intrinsic evidence alone will resolve the ambiguity in a disputed term consideration of extrinsic evidence is improper. Hockerson-Halberstadt, Inc., v. Avia Group, Int'l, Inc., 222 F.3d 951, 955 (Fed.Cir. 2000). However, the court may in its discretion receive extrinsic evidence to aid the court in coming to a correct conclusion as to the true meaning of language employed in the patent. Markman, 52 F.3d at 980. "Extrinsic evidence consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises." Id.

B. Erchonia's Objections to Special Master's Final Report and Recommendation.

Erchonia has set forth multiple bases in opposition to the Special Master's Final Report and Recommendation regarding his interpretation of the term "optical arrangement." Erchonia contends that Special Master's final recommendation is flawed because "optical arrangement" does not necessitate that there be two or more optical devices but rather that it can consist of a single lens or other optical device. However, in reviewing these objections it is clear that the Special Master properly considered the record before him and evidence presented to come to a logical conclusion regarding the meaning of "optical arrangement."

(1) The Parties Discussed The Definition of "Optical Arrangement" That is Proposed by the Special Master.

First, Erchonia argues that the modifications added by the Special Master to the definition of "optical arrangement" were improperly raised by REM in its Response to the Special Master's Draft Report and Recommendation. (Erchonia Objection,
p. 5). However, a review of the record simply does not support that argument. Rather, a review of the Markman Hearing transcript reveals that these modifications to the definition of "optical arrangement" were discussed by both parties and, at the very least, the parties were able to come to a common understanding of the meaning of "optical arrangement" at the Markman hearing. At the Markman hearing the following discussion took place:

Special Master Peterson: Okay, I am going to dictate slowly the definition for "optical system" taken from the McGraw-Hill Dictionary of Scientific and Technical Terms, and it is in the field of optics. It is, quote: A collection comprising mirrors, lenses, prism and other devices placed in some specified configuration which reflect, refract, disperse, absorb, polarize or otherwise act on light period, close quote. Now, my question, Mr. Brunelli, is what, if anything, in the specification or prosecution history would indicate that would incorrectly describe "optical arrangement"?

Mr. Brunelli: Okay. I've got two points. One, I read the definition as requiring at least -- Because of the word "collection," I read that as requiring at least two of these things. Is that how you're reading it, as well?

Special Master: Well, I hadn't gotten to that point yet, but all right.

Mr. Brunelli: So if there is -- I suppose you could read "collection" as requiring only one or more of these, as well, so there is an ambiguity there. If it's -- If it's not at least two, I think neither the Specification nor the file history support -- would support the reading. Second, I believe that a -- "other devices" is broad in that it may include things that are not optics such as mechanical elements, a mechanical mask, or an electromechanical element such as a motorized mirror. Those are clearly -- Those type of things are clearly not encompassed by the specification.

Special Master: Well, just a second. Let me -- We can solve that issue easily by changing "other devices" to "other optical devices."

Mr. Brunelli: Okay.

Special Master: And if we just make it clear, we say "a collection comprising two or more . . . ."

Mr. Brunelli: If we went with "a collection comprising two or more mirrors, lenses, prisms or other optical devices placed in some specified configuration which reflect, refract, disperse, absorb, polarize, or otherwise act upon light" and you're asking me if that would be a acceptable definition for "optical system," and clearly I think that would because it came out of the dictionary, as you just stated, and the next question becomes does "optical system" -- can optical system" be changed for "optical arrangement"? Am I following you?

Special Master: Well, no, you're changing the second question slightly. Is that an accurate definition of the term "optical arrangement" as it is used in the context of the patent and prosecution history of the case?

Mr. Brunelli: Well, I really think that the -- because of the way this patent was drafted, I really think that the patentee defined "optical arrangement" as being a particular thing.

Special Master: I understand.

Mr. Brunelli: But let's -- let's assume that argument is falling -- is falling short, in your opinion, and so I will argue in the alternative. If, in the alternative, "optical arrangement" is -- is not -- has not been defined, then I think the proposed definition that we've just run through would work in understanding what is meant by "optical arrangement" as used in the claims of the 096 Patent.

Special Master: All right. Mr. Schwartz, did you have anything to say in closing?

Mr. Schwarz: Well, I think those are good questions then. I will tell you that I think that -- seeing the file history, that there is -- that the examiner, at least, had the opinion that optical -- Well, he had a discussion about other optical arrangements as taught in Oshiro and Blum, kind of my interpretation of his -- what you stated, he had a long discussion about other optical arrangements that could be used, including light generating prisms and lenses and those things, and discussed that they were well-known in the art. So I would support your -- I support the contention that "optical"
"optical arrangement" is broader than just a line generating prism and a collimating lens. And I also, as I said earlier, believe "optical system" and "optical arrangement" are equivalent.

Special Master: All right. Let me -- Let me ask you, Mr. Schwartz, from that definition that we just discussed with Mr. Brunelli would that be acceptable from your standpoint?

Mr. Schwartz: I think that the definition you just read out of the McGraw-Hill Dictionary was extremely accurate. I don't have any concern what you've proposed as alternative language here other than making clear two things. When you say -- you had -- At one point in your discussion Mr. Brunelli said "comprising two or more." I'd like to make clear that it can be in combination. You could obviously have a lens and a prism, it doesn't have to be two lenses or two prisms, although I think that's what you intended anyway. (Emphasis added).

Special Master: Yes.

Mr. Schwartz: The only point where I disagree with Mr. Brunelli was he made a point of saying that a motorized mirror, he believed, would be a mechanical device. I think that a mirror, whether it's motorized or not, is an optical device, but I'm not sure we need to go that far for purposes of this discussion.

Special Master: All right. All right. Anything else, Mr. Schwartz?

Mr. Schwartz: No sir. I think that gives you a good flavor. I would just refer you, as I know you're fully familiar, to the briefs or anything that we didn't address during oral argument.

The above discussion demonstrates that both parties were given an opportunity to discuss and dispute the meaning of "optical arrangement" wholly consistent with the construction the Special Master recommends now. Additionally, a plain reading reveals that the parties seemed to be in general agreement that the proposed definition by the Special Master in his Final Report and Recommendation was appropriate.

(2) The Prosecution History and Prior Art Support the Special Master's Recommendation.

Second, the Special Master's Final Report and Recommendation soundly describes his determination that an "optical arrangement" calls for two or more optical devices. Despite Erchonia's argument to the contrary, the prosecution history and prior art supports the Special Master's recommendation that "optical arrangement" consist of two or more optical devices rather than just a single optical device as Erchonia contends.

Specifically, Erchonia contends that the Special Master failed to appreciate that the Patent Examiner of the 096 patent considered the possibility that "optical arrangement" could be made up of a single prism. Erchonia cites the Patent Examiner's statement in rejecting claim 5 of the 096 Patent that it would have been obvious "to modify the combined device of Ohshiro et al and Blum et al, with Itzkan to provide a line generating prism as an alternative, equivalent means for focusing the light onto the tissue in a line." (Draft Report and Recommendation p. 82, citing Office Action at 4). Erchonia contends that this statement shows that the Patent Examiner considered the possibility of a single prism acting as an optical arrangement on the 096 Patent, thus supporting its position that "optical arrangement" does not necessitate two or more such devices. However, as noted by REM, this argument has been addressed by the Special Master with sound reasoning. Most significantly, the Patent Examiner's statement, cited above, was made in the context of rejecting claim 5 of the original 096 application on the basis of obviousness in light of the prior art. Specifically, application claim 5 (ultimately patent claim 4) specified in pertinent part:

5. The device of claim 1 wherein said optical arrangement includes:

a. collimating lens; and

b. line generating prism, said collimating lens and line generating prism disposed in a serial relation to said generating means.
(Final Report and Recommendation, p. 118).

The Patent Examiner's rejection was based upon two optical devices, a "collimating lens" and "a line generating prism." Thus, it cannot be said that the Patent Examiner contemplated only one optical device.

Additionally, Erchonia's reliance Ohshiro et al., patent # 4,905,690, a prior art reference to the 096 Patent, for the proposition that "optical arrangement" may consist of only one optical device is not persuasive. As noted by the Special Master, the Ohshiro patent consists of a "series of lenses." (Final Report and Recommendation, p. 49, Exhibit 1 to REM's Response, abstract of Ohshiro et al.). Obviously, a "series of lenses" would suggest more than one lens or optical device.

Lastly, Erchonia's reliance on the Sousa et al, patent # 5,822,345, to lend support to its argument that "optical arrangement" does not necessitate "two or more" optical devices is not persuasive. As Erchonia points out, the Special Master noted that the Sousa et al specification relates that "optical system 13, . . . can be a focusing lens or other suitable optical arrangement . . ." (Draft Report and Recommendation, p. 89, Exhibit 2 to REM's Response, 345 patent, col. 7, ll. 19-22). However, the Sousa patent specification also possesses language suggesting that "optical arrangement" calls for two or more optical devices, or lenses. Specifically, in the same specification, the patent calls for a "series of lenses." (Exhibit 2, to REM's Response, 345 patent, col. 5-6, ll. 62-68).

Thus, the prosecution history of the 096 patent and the prior art addressing "optical arrangement" reasonably suggest that an "optical arrangement" would likely require at least two or more lenses or devices. At the very least, contrary to Erchonia's position, the prosecution history and prior art of the 096 Patent do not evidence that an ordinary person skilled in the art would equate "optical arrangement" with only one such device.

(3) The Special Master Did Not Improperly Apply The Preferred Embodiment Into The Claims.

Erchonia also argues that the Special Master improperly read claim limitations from the preferred embodiment when interpreting "optical arrangement" in the independent claims. Specifically, Erchonia relies on the Special Master's reference in the Final Report and Recommendation that the specific embodiment disclosed in the specification of the 096 Patent has at least two optical elements or devices; specifically the "collimating lens" and "line generating prism." (Final Report and Recommendation, p. 120). However, Erchonia's argument is not well taken as it even acknowledges that the Special Master did not relate that specific limitation from the preferred embodiment of a "collimating lens" and a "line generating prism" into the definition of "optical arrangement." (Erchonia's Objection to Final Report, p. 7-8). Rather, the definition of "optical arrangement" is broader in that it only requires "two or more . . . optical devices." Therefore, it is difficult to see how the Special Master improperly read the limitations of the preferred embodiment of the 096 into the definition of "optical arrangement."

This same line of reasoning also rebuts Erchonia's argument that the Special Master ran afoul of the doctrine of claim differentiation, which prohibits dependent claim limitations from being read into independent claims. See Curtiss-Wright Flow Control Corp. v. Velan, Inc. 438 F.3d 1374, 1380 (Fed. Cir. 2006). As discussed above, the Special Master's definition of "optical arrangement" requires only a collection of "two or more . . . optical devices." (Final Report and Recommendation, p. 123). Whereas, the limitations of the preferred embodiment, such as in dependent claim four, relate that the dependent claims involve a "collimating lens" and "a line generating prism" which are distinct types of "optical devices." (Final Report and Recommendation, p. 120). Therefore, because the independent claim is based upon the broad category of "optical devices" and the dependent claims involve specific types of "optical devices" it cannot be said the Special Master read the claim limitations into the independent claims.

(4) The Special Master Did Not Improperly Assign A Burden of Proof.

Lastly, Erchonia argues that the Special Master improperly assessed it a burden of proof in determining the meaning of "optical arrangement." Specifically, Erchonia cites the Special Master's determination that neither party had provided proof of the question of how one of ordinary skill in the art would interpret "optical arrangement." However, Erchonia's argument is not persuasive because the fact that the Special Master noted that both parties provided inadequate evidence in support of their purported interpretations of "optical arrangement" does not mean he assigned a burden of proof to either party. It simply demonstrates that the evidence presented by both parties was not helpful in making the ultimate determination.
Rather, the Special Master turned to other reliable means of interpretation such as other intrinsic and extrinsic evidence.

C. The Definition of "Optical Arrangement"

The Special Master followed proper procedure in formulating his final recommendation regarding the term "optical arrangement." He looked first to the intrinsic record to determine the proper definition of "optical arrangement." However, after reviewing the intrinsic record, including the claim language, prosecution history and specification it is unclear if one of ordinary skill in the art would determine if an "optical arrangement" can be made up of just one "optical device" or calls for at least two. (Final Report and Recommendation, pp. 120, 121).

Because of this uncertainty, it was appropriate for the Special Master and is appropriate for this Court to turn to available extrinsic evidence available. Here, the Special Master with the parties consent turned to the dictionary, to resolve any ambiguity. Phillips, 415 F.3d 1303 at 1318-19 (2005). Both parties generally agreed to the persuasiveness of the McGraw-Hill Dictionary of Scientific and Technical Terms (5th Ed. 1994) with its definition of "optical system."

First, as noted by the Special Master, the plain meaning of term "arrangement" connotes multiple parts. See Merriam-Webster's Collegiate Dictionary (10th Ed. 1999) at 64 (defining "arrangement" as "something made by arranging parts or other things together"). Thus, the term itself would call for at least two devices, not a single device as Erchonia contends.

Second, the technical definition of "optical system" as defined in the McGraw-Hill Dictionary of Scientific and Technical Terms (5th Ed. 1994) is, "a collection comprising mirrors, lens, prisms, and other devices, placed in some specified configuration, which reflect, dispense, absorb, polarize, or otherwise act on light. " (emphasis added). This definition speaks in terms of multiples and again indicates that "optical arrangement" would call for at least two or more devices.

Thus, when turning to plain language of the dictionary terms of "arrangement" and "optical system" it is apparent that the term itself indicates that more than one "optical device" is necessary. The Court in performing a review of the intrinsic record and extrinsic record agrees with the Special Master's final recommendation that "optical arrangement" as listed in independent claims 1 and 10 means:

A collection comprising two or more mirrors, lens, prisms, or other optical devices, placed in some specified configuration, which reflect, refract, dispense, absorb, polarize, or otherwise act on light. That definition allows for a combination of two or more different optical devices. Also, a mirror whether it is motorized or not, is an optical device.

Therefore, the Court adopts the Special Master's Final Report and Recommendation.

2959

Optical channel selector

The Court agrees with Ciena's proposed construction and construes the term as a "device that selects a single optical channel from a wavelength division multiplexing input signal." Nortel argues that the term should be construed as "an apparatus that selects a single wavelength from a wavelength division multiplexed optical signal and terminates the remainder of the wavelengths." Nortel argues the specification demonstrates that the optical channel selector terminates the wavelength. The specification states:

Channel selector 102 passes optical signals having wavelengths other than the channel wavelength to be processed by the remodulating channel selector. These non-selected channels pass through low reflectivity port 104 and exit the optical communication system. The low reflectivity port 104 may be an angled fiber cut, although any low reflectivity waveguide termination technique may be employed. The selected channel wavelength is reflected by channel selector 102 through splitter 103 onto optical path 106.

Col. 7:36-45. Nortel argues that because the signals that are passed by the channel selector 102 "exit the optical communication system," they are being terminated by channel selector 102. This embodiment of the invention indicates that if any structure performs the function of terminating wavelengths it is low reflectivity port 104, not optical channel selector 102. Channel selector 102 simply "passes optical signals having wavelengths" other than the optical signal to be processed.
Nortel’s construction would exclude this embodiment set out in the specification. “The Court must always read the claims in view of the full specification. A claim construction that excludes a preferred embodiment . . . ‘is rarely, if ever, correct.’” SanDisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005)(citing and quoting Vitronics, 90 F.3d at 1582-83). Furthermore, the specification specifically states that “an optical channel selector optically communicates with the optical input port to select a single optical channel from the [wavelength division multiplexing] input signal.” Col. 3:1-3. Accordingly, the Court construes “optical channel selector” as a “device that selects a single optical channel from a wavelength division multiplexing input signal.”

2. "An optical coupling means having an input, an input/output and an output" and "a first optical coupler having an input, an input/output and an output"

(a) Means Plus Function

As an initial matter, Pirelli contends that the language "optical coupling means" should not be construed using the "means-plus-function" formulation under 35 U.S.C. § 112, P6. Pirelli maintains that since optical couplers were known devices at the time of the filing of the patent application, the "optical coupling means" claim language recites predominantly structure. Therefore, Pirelli averes that "optical coupling means" is a structural element corresponding to an optical coupler and should not be limited to specific examples given in the specification. To further support for its position, Pirelli points to the prosecution history of claim 1 of the '459 Patent. There, Pirelli explains that the language use to be "optical coupler", but was amended for a reason unconnected to any means-plus-function determination. See Prosecution History, 71. Ciena disagrees.

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claims shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

Under section 112, paragraph 6, "an applicant can describe an element of his invention by the result accomplished or the function served, rather than describing the item or element to be used . . . ." Warner-Jenkinson v. Hilton Davis Chemical Co., 137 L. Ed. 2d 146, 117 S. Ct. 1040, 1048 (1997). "In determining whether to apply the statutory procedures of Section 112, P6, the use of the word "means" triggers a presumption that the inventor used the term advisedly to invoke the statutory mandates for means-plus-function clauses." York v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1574 (Fed. Cir., 1996). However, this presumption is not conclusive. See Sage Products, Inc. v. Devon Indust., Inc., 126 F.3d 1420, 1997 WL 578762, at *7 (Fed. Cir. 1997). "Merely because a named element of a patent claim is followed by the word 'means'. . . does not automatically make that element a 'means-plus-function' element under 35 U.S.C. § 112, P6." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir., 1996); see also York, 99 F.3d at 1574 ("Mere incantation of the word 'means' in a clause reciting predominantly structure cannot evoke section 112, P6.").

The Court must decide on an element-by-element basis, based upon the patent, whether § 112, P6 applies. See Cole, 102 F.3d at 531. "Where a claim used the word 'means', but specifies no corresponding function for the 'means', it does not implicate section 112." Sage, 1997 WL 578762, at *7 (citing York, 99 F.3d at 1574). Similarly, if a claim has sufficient structure within the claim itself which can perform the recited function, the language of the claim is not in means-plus-function format. See id. (citing Cole, 102 F.3d at 531).

In the case bar, the "optical coupling means" of Claim 1 employs the language "means" and thereby, presumptively implicate section 112, P6. That being said, there is no corresponding function for the "means". Although it is evident from other parts of the patent that the function of the optical coupling means is to separate different wavelengths, nowhere does
the claim language state that function. See York, 99 F.3d at 1574. Moreover, the Court is counseled by the fact the "optical coupling means" recites a definite structure, i.e., the optical coupler. See Cole, 102 F.3d at 531 (clause reciting predominately structure does not implicate § 112, P6). Finally, the Court need look no further than the nearly identical language of Claim 7 which refers to the same optical coupling device as a "first optical coupler", with the conspicuous absence of the word "means". See Col.9, line 14. Therefore, it is apparent that "optical coupling means" and "first optical coupler" are synonymous.

Thus, because there is a detailed recitation of structure and there is an absence of any mention of function in the claim, the Court finds the mean-plus-function limitations of section 112, P6, are not implicated in construing "optical coupling means". See Cole, 102 F.3d at 531.

A. Optical Devices

An optical device is a device that is capable of emitting light.

1. "Optical Demultiplexer"

For the following reasons, this court construes the claim term "optical demultiplexer" in claims 1, 4-6, 11-15, 17, 20, and 24 to mean:

A device that receives a plurality of wavelengths multiplexed together as an optical signal and outputs each of the plurality of wavelengths as at least one of the following: (a) individual wavelengths, (b) bands of wavelengths or (c) a combination of bands and individual wavelengths.

The specification for the '772 patents states that:

It is yet another aspect of the invention to utilize optical line terminals having a multiplexer/demultiplexer including one or more stages of inputting/outputting individual wavelengths or bands of a predetermined number of wavelengths, or a combination of bands and individual wavelengths.

('772 patent, col. 1:52-56.) In other words, an OLT can have a demultiplexer, which may have one or more stages for outputting (1) individual wavelengths or (2) bands of a predetermined number of wavelengths or (3) a combination of bands and individual wavelengths.

Figure 3 of the '772 patent specification shows a demultiplexer outputting a combination of bands and individual wavelengths in a two-stage process. ('772 patent, Fig. 3.) In the first stage, optical signals are demultiplexed and bands of wavelengths are output. ('772 patent, col. 4:7-42; see Fig. 3.) In the second stage, at least one of the bands is demultiplexed further and output as individual wavelengths. Id. The culmination of the two-stage process is the output of a combination of bands and individual wavelengths. ('772 patent, col. 3:61-4:6; see Fig. 3.) Thus, based on examination of the specification an "optical demultiplexer" is a device that receives a plurality of wavelengths multiplexed together as an optical signal and outputs each of the plurality of wavelengths as at least one of the following: (a) individual wavelengths, (b) bands of wavelengths or (c) a combination of bands and individual wavelengths.

2. "Optical Element in a Telescope"
The term "optical element" appears, in either singular or plural form, in claims 1, 10, 15, 18 and 20. As used in the '908 Patent, the term "optical element(s)" includes mirrors, lenses, or prisms.

Plaintiff argues that "optical element in a telescope" should be restricted to "mirrors." (Pl.'s Reply Br. at 2.) In contrast, defendant contends that the phrase "optical element" is much broader, and includes "lenses," "mirrors," and "prisms," thus comporting with its dictionary definition. (Pl.'s Reply Br. at 3, P2.)

As a threshold matter, the term "optical element" must include both lenses and mirrors because this Court's construction of the term "telescope" includes both reflecting and refracting telescopes. However, "optical element" includes both mirrors and lenses based on other intrinsic evidence as well.

Looking to the patent claims, there are several places in which the doctrine of claim differentiation indicates that the term "optical element(s)" is not limited to mirror(s). The clearest example of this point is a comparison of claims 15 and 16. Claim 15 is an independent claim that is nearly identical to claim 1. See '908 Patent at 7:3-8. It describes "[a] method of aligning an optical element in a telescope, comprising: (a) projecting a holographic image onto at least a portion of an optical element to be aligned; and (b) aligning the optical element in response to the projected holographic image." Id. Claim 16 is "the method of claim 15, further comprising employing a mirror as the optical element." Id. at 7:9-10. Since claim 16 is a dependent claim, which, by definition, must add a limitation, and the limitation it adds is that the optical element be a mirror, the doctrine of claim differentiation instructs that the term "optical element" is not limited to a mirror.

Claims 10 and 11 have a similar relationship. Claim 10, like claims 1 and 15, describes "[a] method of aligning an optical element in a telescope." Id. at 6:55 (emphasis added). Claim 11, which is dependent upon claim 10, is "the method of claim 10, further comprising employing a plurality of mirrors as the optical elements." Id. at 6:61-62 (emphasis added). If the only "optical element" in a "telescope" could be a "mirror," then claim 11 would be redundant in requiring a "plurality of mirrors as the optical elements," since the only optical elements in a telescope would be "mirrors." Based on the doctrine of claim differentiation, the claim language evinces an intent that "optical elements in a telescope" should include more than "mirrors."

Next, looking to the specification, the introduction states that "the present invention generally relates to the alignment of optical elements, and more specifically to the alignment of mirrors in a telescope." Id. at 1:6-8, 11. If the term "optical elements" were restricted to "mirrors" then the introduction to the specification would be redundant by using the phrase "the alignment of mirrors in a telescope." The presence of the second clause of the sentence indicates that the term "optical elements," alone, is not sufficient to specify mirrors. Moreover, as discussed supra, the specification asserts that the invention can be used with a "refracting telescope." See id. at 6:11, 19-21. Refracting telescopes contain lenses rather than mirrors. (See Markman Hearing, Def. Ex. A.) Accordingly, the meaning of "optical elements in a telescope" should at the very least, include both "mirrors" and "lenses."

Plaintiff might argue that the introduction to the specification is a disclaimer limiting "the present invention . . . more specifically to the alignment of mirrors in a telescope." Id. at 1:6-8, 11 (emphasis added). According to Phillips, "the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor. In that instance . . . the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive." 2005 U.S. App. LEXIS 13954, 2005 WL 1620331, at *8. However, as previously discussed, the plain language of the claims, as well as other parts of the specification, do not evince any attempt to limit the scope of the term "optical element." Given Phillips' insistence on maintaining the line "between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim," 2005 U.S. App. LEXIS 13954, [WL] at *15, language in the specification will not be used to limit claim scope unless that language conveys a clear intent to use the term narrowly. Given the amount of intrinsic evidence in this case demonstrating a broader definition, the introduction to the specification cannot be given such a preclusive effect. The term "optical elements" must be construed to include both "mirrors" and "lenses."

What is less clear is whether the phrase "optical elements in a telescope" should include "prisms." As discussed supra, the claims may be interpreted such that the disputed term includes other "optical elements" besides a "plurality of mirrors;" however, the specification neither mentions, nor provides a diagram demonstrating the invention's use with a telescope containing a prism. Phillips specifically warns against confining claims to specific embodiments of the invention described within the specification. See id. Therefore, a lack of intrinsic evidence is not dispositive. The issue is whether a person of
ordinary skill in the art would interpret the phrase "optical element in a telescope" to include "prisms." In ascertaining how a person of ordinary skill in the art understands a claim term, a court may look at extrinsic evidence where the intrinsic evidence is ambiguous. See 2005 U.S. App. LEXIS 13954, [WL] at *16. Both the prior art as well as technical dictionaries make it clear that a prism may be used as an "optical instrument" within a "telescope." (See Markman Hearing, Def. Exs. B, C; Def's Opp. Br. at 3, P2.) Therefore, this Court will not exclude "prisms" from the definition of "optical elements in a telescope." In sum, this Court rejects plaintiff’s definition limiting the term "optical elements in a telescope" to "mirrors," in favor of a broader definition which includes "mirrors," "lenses," and "prisms."

The Court agrees with Ciena that this term does not require construction. Nortel argues that the term should be construed as “the access point to an integrated module that receives wavelength division multiplexed optical signals.” Nortel does not introduce any support for its use of the words “access point.” In fact, Nortel does not present any support for its proposed construction of “optical input port” other than as it relates to its argument that the “remodulating channel selector” should be construed as an integrated unit. For the reasons discussed above, the Court does not define the term “remodulating channel selector” and, therefore, does not import a limitation that would require the “remodulating channel selector” to be an “integrated module.” Moreover, “optical input port” is a term that would be well understood in the art to mean the input port for an optical signal. The specification indicates that this is how the “optical input port” is understood in terms of the invention. See Cols. 2:64-67; 7:30-34. “Words of a claim ‘are generally given their ordinary and customary meaning.’” Phillips, 415 F.3d at 1312 (citing Vitronics, 90 F.3d at 1582). “[T]he ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention, . . . .” Id. at 1313. Accordingly, it is not necessary for the Court to construe the term.

1. "Optical Line Interface"

For the following reasons, this court construes the claim term "optical line interface" in claims 1, 3-8, 11-13, 17, 18, 20, 21, 23, and 24 to mean:

An interface that can carry a plurality of wavelengths multiplexed together as an optical signal.

The parties agree that an optical line interface can send or receive a plurality of wavelengths multiplexed together. Specifically, Fujitsu's proposed construction states, "an interface adapted for carrying wavelength division multiplexed (WDM) optical communication signals of the highest relative order" (Dkt. No. 90, Ex. C at 2), while Tellabs' proposed construction states, "an interface that can carry a plurality of wavelengths multiplexed together as an optical signal" (Dkt. No. 91, Ex. C at 1).

Patent '772's specification also supports the parties' agreed-upon construction. The specification establishes that the invention pertains to a "wavelength division multiplexed (WDM) optical communication system" ("772 patent, col. 1:14-22) and that a "WDM system employs plural optical signal channels, each channel being assigned a particular channel wavelength" ('772 patent, col. 1:28-29). With regard to an OLT, the specification states, "[t]he OLT has an input/output line interface which is connected to an external fiber facility and transmits/receives an optical signal having N optical wavelengths." ('772 patent, col. 2:40-42; see Fig. 1.)

The parties, however, dispute the inclusion of the phrase "highest relative order" in the construed meaning of the phrase "optical line interface." Fujitsu's proposed construction requires that the optical signals be of the "highest relative order." (Dkt. No. 90, Ex. C at 2.) Fujitsu's proposed construction improperly imports a limitation from a preferred embodiment in the specification. See Phillips, 415 F.3d at 1323 (explaining that courts generally should not limit patent claims to the preferred embodiments in the specification); Astrazeneca AB, 384 F.3d at 1340 (same). Patent '772's specification only uses...
the term "highest relative order" once as the specification describes Figure 4, and states that "[t]he line interface is adapted for wavelength division multiplexed (WDM) optical communication signals of the highest relative order." ('772 patent, col. 4:48-50.) To incorporate the requirement that the optical signal be of the 'highest relative order' would limit the claim to a preferred embodiment. The court therefore rejects the incorporation of the limitation "highest relative order" into the construction of "optical line interface."

2. "Bidirectional Optical Line Interface"

For the following reasons, this court construes the claim term "bidirectional optical line interface" in claims 14, 15, and 16 to mean:

An interface for sending and receiving a plurality of wavelengths multiplexed together as an optical signal.

In construing the term "bidirectional optical line interface," the court must consider that differences among other claims of the '772 patent can assist in the court's understanding of a term's meaning. See Phillips, 415 F.3d at 1314. Accordingly, the term "bidirectional optical line interface" must be construed consistent with the construction of "optical line interface" as explained above. However, the construction of "bidirectional optical line interface" will depart from the construction of "optical line interface" because the addition of the word "bidirectional" necessarily narrows the construction of the term "optical line interface." The word bidirectional requires that the optical line interface send and receive a plurality of wavelengths multiplexed together as an optical signal. Thus, while an "optical line interface" can send or receive a plurality of wavelengths multiplexed together, a "bidirectional optical line interface" must send and receive a plurality of wavelengths multiplexed together as an optical signal.

Tellabs' proposed construction appears to be consistent with this court's construction of "bidirectional optical line interface." (Dkt. No. 91, Ex. C at 2.) But Fujitsu's proposed construction is less clear.

Fujitsu presented two proposals for the meaning of the term "bidirectional optical line interface." For the purpose of independent claim 14, Fujitsu proposed the following construction: "optical line interface can transmit and receive wavelengths over a single optical fiber line to and from an external device." (Dkt. No. 90, Ex. C at 17.) For claim 15, which is dependent on claim 14, Fujitsu proposed: "an interface adapted for carrying bidirectional wavelength division multiplexed (WDM) optical communication signals of the highest relative order." (Dkt. No. 90, Ex. C at 21.) Fujitsu also proposes that claim 16, which is dependent on dependent claim 15, must be construed in the same manner as independent claim 14. (Dkt. No. 90, Ex. C at 22.)

Fujitsu's proposed construction of "bidirectional optical line interface" for claims 14 and 16 uses the conjunctive "and," making the construction of "bidirectional optical line interface" narrower than the construction of "optical line interface." But Fujitsu's proposed construction for claim 15 uses the word "bidirectional," and so the court finds Fujitsu's construction to be unclear. Additionally, Fujitsu's proposed construction for claim 15 contains the words "highest relative order," which as explained above, the court rejects as importing a limitation into the claim from a preferred embodiment.

N. Ref. No. 38 "Optically Readable."

This term is recited or referred to in Claims 82, 83, 84, and 85.

According to Plaintiff, the term "optically readable" means capable of being read by an optical scanner. Defendants counter that the definition of the term encompasses capable of being read by humans and by a mechanical device.

As noted by Plaintiff, the background portion of the '730 Patent describes the process of counting votes by optical scanning...
or mechanical scanning. (Col. 1, ll. 23-27.) The specification provides that the voting records may be stored in an electronically or optically readable media. (Col. 22, ll. 50-54.) The Claims in dispute each provide for specific voting information to be on printed paper that is "human readable and/or optically readable." Claims 82, 83, 84, and 85. These references in the specification and in the Claims meet the requirements of In re Wright, 866 F.2d at 425, because the term "optically readable" is clearly conveyed in the patent language and its specification. Moreover, this term is used throughout the patent description and in the patent specification. And, the ordinary meaning of the term is clearly conveyed by the Plaintiff's definition.

The Court construes the term "optical readable" as: "Capable of being read by an optical scanner."

Plaintiff argues that construction is not subject to 35 U.S.C. § 112 P 6, asserting that "the word 'reader' is structural and not purely functional." (D.I. 150 at 29) (citing TriMed, Inc. v. Stryker Corp., 514 F.3d 1256, 1260 (Fed. Cir. 2008); Phillips 415 F.3d at 1311; Watts v. XL Sys., Inc., 232 F.3d 877 (Fed. Cir. 2000)). Plaintiff fails to provide any evidence supporting this contention. The Federal Circuit, in TriMed, explained:

Use of the word "means" in claim language creates a presumption that § 112 P 6 applies. If, in addition to the word "means" and the functional language, the claim recites sufficient structure for performing the described functions in their entirety, the presumption of § 112 P 6 is overcome—the limitation is not a means-plus-function limitation. Sufficient structure exists when the claim language specifies the exact structure that performs the functions in question without need to resort to other portions of the specification or extrinsic evidence for an adequate understanding of the structure.

TriMed, Inc. v. Stryker Corp., 514 F.3d at 1259-60 (citations omitted). Here, "reader" does not provide sufficient structure for performing the function of effecting the input of optical information. As discussed below, it is necessary to resort to the specification to adequately understand the requisite structure. Therefore, plaintiff has failed to overcome the presumption that this term is subject to § 112 P 6.

The parties agree that a photoelectric sensor array is corresponding structure. (D.I. 180, ex. A at P 1.5) Plaintiff asserts that the limitation also includes a scanner or equivalents including a CCD or CMOS digital camera. (Id.) Defendant asserts that the limitation also includes bar code scanner module 212 and scanner tip 214, a light source, and decoding logic. (Id.)

A corresponding structure for purposes of 35 U.S.C. § 112, P 6 must be disclosed within the four corners of the patent or clearly within the intrinsic record. See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1208 (Fed. Cir. 2002) ("Structure disclosed in the specification is 'corresponding' structure only if the specification or prosecution history clearly links or associates that structure to the function recited in the claim.") (citation omitted) (emphasis added). The exact term "optical reader" is referenced only once in the specification:

Various optical type scanners are also of substantial utility for quick, easy and highly accurate input of existing printed data, e.g., bar codes, text, and graphical information. Instant type optical readers which may be integrated into a hand-held shell module according to the present invention are disclosed in a pending application of the present inventors U.S. Ser. No. 894,689 filed Aug. 8, 1986, (now U.S. Pat. No. 4,877,949 issued Oct. 31, 1989), and the disclosure including the drawings of this pending application are incorporated herein by reference in their entirety as illustrating arrangements which may be embodied in a peripheral shell such as indicated at 250 in FIG. 10.
(‘947 patent, col. 11:16-27) (emphasis added). 13 The specification teaches numerous examples of readers that use optical means in reference to reading and decoding bar codes. (See e.g. ‘947 patent, col. 11:18-19; col. 17:1-39; col. 18:12-36) Plaintiff argues that decoding is not a limitation; that "[t]he specification discloses corresponding structures that capture an image but do not decode it." (D.I. 150 at 30) (citing '947 patent, col. 18:38-44) Plaintiff ignores the paragraph immediately preceding the cited portion, which discusses digital signal processing used in decoding the image captured:

An image sensor has the advantage that it establishes an absolute dark signal as indicated at 331, FIG. 13A, and at 332, FIG. 13B, at the beginning of each reading operation. This allows the reader electronics the ability to always properly set up for detecting all bars and spaces of a label. . . . Digital signal processing according to the present embodiment will result in proper detection of a first black bar on a white background as illustrated in FIG. 13A and will not insert bars or spaces in the case of either FIG. 13A or FIG. 13B.

(‘947 patent, col.18:9-37) Plaintiff further argues that "[t]he specification also incorporates U.S. Patent 5,019,699 to Koenck, which discloses a device for capturing digital images of printed text for later Optical Character Recognition processing (i.e., decoding)." (D.I. 150 at 31) (citation omitted) (emphasis added) The mere inclusion of a patent by reference does not clearly link or associate that structure to the function recited in the claim.

Optical signal

Claim 18 of the ’714 Patent contains the term "unmodulated optical signal." The parties agree that an "unmodulated optical signal" is an optical signal that has not been processed by the array of optical signal processing devices, but disagree about the construction of the term "optical signal." Cheetah contends that the term means "light of more than one wavelength," while Mitsubishi contends that it means "light beam carrying information." The parties disagree whether the term "optical signal" requires the light to carry information.

Cheetah asserts that the ’714 specification teaches that the input signal light includes light having "a plurality of wavelength signals." ’714 Patent, col. 17:31-33. Cheetah also asserts that the United States Patent and Trademark Office ("Patent Office"), using the broadest reasonable interpretation in light of the specification, interpreted the term to include incandescent light emitted from a typical lamp used in projection systems. Mitsubishi counters that Cheetah's construction renders the term "signal" meaningless and would encompass, for example, sunlight within the meaning of "optical signal." Additionally, Mitsubishi argues that the ’714 specification supports a construction of light carrying information by citing to the Overview, which states that "[a]s optical systems continue to increase the volume and speed of information communicated, the need for methods and apparatus operable to facilitate high speed optical signal processing also escalates." ’714 Patent, col. 1:28-31 (emphasis added).

Cheetah's construction would reduce "optical signal" to merely light or a lightbeam. Although the Patent Office used the broadest reasonable interpretation in light of the specification, the Court must first focus on the claims and specification as a whole under the guidance of Phillips. Phillips, 415 F.3d at 1314-15 (stating with regard to the specification "[u]sually, it is dispositive; it is the single best guide to the meaning of a disputed term"). The specification is directed towards transmitting information optically and heavily emphasizes this functionality, and Cheetah's construction does not conform with this. See e.g. ’714 Patent, col. 18:61-67, col. 19:8-10, col. 20:14-19.

The use of the term "signal" itself also implies information. Cheetah argues that an optics dictionary defines the term "optical signal" as "a signal that (a) contains optical power and (b) may be transmitted (i) in an optical waveguide . . . or optical integrated circuit (OIC) or (ii) as a lightbeam in free space." Even this extrinsic evidence cited by Cheetah supports
the inclusion of "information," because the definition itself begins with "a signal" and states that this signal may be transmitted as a lightbeam. This definition does not define "optical signal" as merely a lightbeam, but as "a signal" that may transmitted as a lightbeam.

Even accepting Cheetah’s interpretation of the prosecution history, the specification of the '714 Patent gives clear guidance that the term "signal" has meaning that cannot be ignored under Phillips. See Phillips, 415 F.3d at 1314-15. When the intrinsic record is viewed as a whole, an "optical signal" is more than merely light or a lightbeam. Accordingly, the Court adopts Mitsubishi’s construction and construes the term "optical signal" to mean "light beam carrying information."

2970

1. "second optical signal laser transmitter"

To reiterate, the purpose of the '073 Patent was to create a universal adapter that receives optical signals emitted by a transmitter and adjusts their parameters to match those required by an EDFA optical line amplifier connected to the adapter output. The adapter operates by converting the optical signals received into electrical signals representative of the information carried by such input optical signals, and by reconverting those electrical signals back into output optical signals having the appropriate optical wavelength to be compatible with the EDFA optical line amplifier. The electrical signals are reconverted into outgoing optical signals by means of a "second optical signal laser transmitter".

The dispute between the parties boils down to whether the "second optical signal laser transmitter" is equivalent to a laser, or whether it should be construed as referring to a laser plus a modulated signal. Pirelli asserts that an optical communication transmitter is not just constituted of an optical source like a laser, but is instead made up of both an optical source and an information-bearing modulated signal. Ciena, on the other hand, contends that the "second optical signal laser transmitter" is just a laser. Extrinsic evidence will not be consulted in construing this language. 9

9 Pirelli during oral argument attempted to use extrinsic evidence in order to support its construction of the disputed language. Ciena objected saying that they thought there was an agreement not to use any extrinsic evidence. The Court declines to consider such extrinsic evidence. The Court is counseled by the fact, as will be discussed below, that the claim and the specification unequivocally describe the meaning and scope of the disputed language. As such, utilization of extrinsic evidence is improper. See Vitronics, 90 F.3d at 1583.

(a) The Claim Language

Because the claim language is of paramount importance in the construction of this disputed language, the Court starts with the language of the claim. In Claim 8 of the '073 Patent 10, the claim, in relevant part, reads: "a second optical signal laser transmitter connected to said first optical amplifier for supplying optical signals to said first optical amplifier . . . ." Col. 8, lines 40-42. It is Pirelli's position that the second optical transmitter does not just refer to the laser itself, but also refers to the modulating signal coming from the laser. Pirelli reaches this conclusion by arguing that the first and second optical signal laser transmitter must be construed identically because the same language has been used. Because a first optical signal laser transmitter supplies a modulated optical signal through the use of a laser, the second optical signal laser transmitter must also be interpreted as including both the laser and the modulated signal. Pirelli also advances the contention that it is black letter law that every word of a claim must be given meaning. Thus, the word "transmitter" must be interpreted as requiring a modulated optical signal. Ciena argues that the second optical transmitter is a laser and that the "first optical signal laser transmitter" is a completely different claim element.

10 Because the language "second optical signal laser transmitter" and all the other relevant language appear in Claim 8 of the '073 Patent, only this claim language will be referenced, although similar language appears in Claim 1, 3, 13, 14, 15 and...
(b) The Specification

Pirelli asserts that the "first optical signal laser transmitter" is described in the specification as supplying an optical signal that has been modulated with information. See Col.1, lines 9-12 ("an optical line transmitting apparatus provided with a laser"); Col.2, lines 31, 36 ("transmitting . . . apparatus"), 49 ("optical line transmitting apparatus"); Col.5, lines 62-63 ("transmitting . . . apparatus"); Col.6, lines 6-7 (same), 33, 46, 48, 54, 60, 61, 64 ("transmitter"). Further, Pirelli contends there is no indication that the second optical transmitter was to be construed differently from the first optical transmitter in the claim language. Therefore, a laser by itself cannot constitute an optical signal laser transmitter, but rather there must also be some modulated signal that emanates from the laser.

Ciena asserts that the second optical signal laser transmitter should not be confused with the first optical signal laser transmitter. Whereas the first optical transmitter is part of the terminal station equipment, the second optical transmitter is the laser in the claimed adapter that reconverts electrical signals into optical signals so that these optical signals are compatible with the optical amplifier. To support its conclusion, Ciena cites specification language that states that the claimed adapter is comprised of three components: (1) an optical-to-electric converter module, (2) a second adjustment module and (3) a laser. See Col.2, lines 54-62. Ciena argues that these three components correspond exactly to the three components of the adapter recited in Claim 8, with the laser corresponding to the "second optical laser transmitter". Further, Ciena cites specification language that supports its conclusion that the second optical transmitter is just a laser: "laser piloting circuit . . . actuates a laser in the adapter converting said electrical signal to an optical signal . . . ." Col.3, lines 57-59. Lastly, Ciena explains that in a "direct modulation" system, a laser piloting circuit directly acts upon a laser that then emits the proper optical signals that are compatible with the optical amplifier.

(c) Prosecution History

Ciena also avers that Pirelli had to define the "laser piloting means" and in response, told the PTO that it was merely a "laser modulating circuit". Prosecution History, p. 167. Ciena asserts that a laser modulating circuit is a circuit that directly controls a laser. That laser is represented in the claim by the "second optical signal laser transmitter". Therefore, in a "direct modulation" set-up, the laser modulating circuit must act on a laser.

(d) Claim Construction

The claim language refers to a "second optical signal laser transmitter" which supplies optical signals to an optical amplifier. However, the claim is ambiguous as far as whether the second optical transmitter has to be a laser or whether it can also include the modulated signal emitted by the laser. The specification is not helpful in that the "second optical signal laser transmitter" appears nowhere in the specification. Although as Ciena has pointed out, the preferred embodiment seems to contemplate using a laser, "references in the specifications to a preferred embodiment . . . do not limit the scope of the patent claim." See Specialty Composites, 845 F.2d at 987. Moreover, the specification does not require that a laser be used as a second optical signal laser transmitter. See id. ("Where the specification does not require limitation, that limitation should not be read from specification into claims of patent.").

That being said, the Court finds unconvincing that Pirelli’s contentions that the "second optical signal laser transmitter" is a laser plus a modulated signal and that the second optical signal laser transmitter should be construed identically to the "first optical signal laser transmitter." First, common sense dictates that having the definition of a "second optical signal laser transmitter" be a laser plus a modulated signal is incoherent. That's like saying a radio and the music that is emitted from it are what constitute a radio. But when the radio is turned off, the radio does not stop being a radio. Similarly, when the second optical signal laser transmitter is turned off, that does not mean that it stops being a second optical transmitter. The modulated signal is simply not a part of the laser transmitter; the modulated signal is what comes out of the laser transmitter.
This finding is not inconsistent with giving meaning to every word in the claim. As discussed above, the word "transmitter" cannot refer to a modulated signal emanating from the laser. The "second optical signal laser transmitter" remains a laser transmitter irrespective of whether a signal is being modulated.

Second, the Court is not persuaded by Pirelli's argument that identical language must be interpreted in the same manner in the claims and specifications of a patent. See Tandon Corp. v. U.S. Int'l Trade Comm., 831 F.2d 1017, 1023-24 (Fed. Cir. 1987). The first laser transmitter performs a very different function than the second laser transmitter. The first laser transmitter is part of the line terminal equipment and is responsible for sending down the fiber optic line the initially incompatible optical signal. On the other hand, the second laser transmitter is responsible for changing altered electrical signals into altered optical signals which are now compatible with the EDFA optical amplifier. The simple response to this argument is that identical phraseology has not been employed; hence a first optical signal laser transmitter and second optical signal laser transmitter.

Lastly, the Court is further counseled by the prosecution history cited by Ciena which clearly shows that Pirelli believed the laser piloting means to be a "laser modulating circuit". Because the laser piloting means actuates the second optical signal laser transmitter, a fortiori the second laser transmitter must itself be a laser.

Therefore, the Court finds that the "second optical signal laser transmitter" in the '073 Patent is a laser, and nothing more.

**2971**

d. "an optically absorptive refractory transition metal"

i. composition of the metal

One of the primary issues before the court is whether the term "an optically absorptive refractory transition metal," as claimed in the second element of claim 1, includes alloys. The court has determined that the term "metal," as used in the context of the metal interconnect layer, includes alloys. EMI urges that the court should construe the term "metal" similarly in this instance.

To interpret the meaning of this claim limitation, the court looks to the intrinsic evidence of the patent, which comprises the claims, the specification, and the prosecution history. See Pitney Bowes, 182 F.3d at 1309. Upon arriving at a claim construction based upon this intrinsic evidence, the court consults extrinsic evidence to verify that the claim construction under consideration is not inconsistent with widely held understandings in the pertinent technical field. Id.

A term appearing repeatedly in the same claim should be interpreted consistently. See Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1345 (Fed. Cir. 1998). The word "metal," however, is not a discrete claim term. In claim 1, the word "metal" has two different usages. The "metal interconnect layer" is distinct from the "optically absorptive refractory transition metal." These "metals" have different elemental compositions--the metal interconnect is made of an aluminum-based compound, while the metal absorptive layer comprises a transition metal. The "metals" also have different functions in the claimed method--the metal interconnect conducts electricity, while the metal absorptive layer absorbs laser light and transmits heat to the interconnect. Thus, the operative claim limitations are "a metal interconnect layer" and "an optically absorptive refractory transition metal," and the court is not bound by Digital Biometrics to interpret them consistently.

The specification does not provide grounds for finding that the term "an optically absorptive refractory transition metal" refers to alloys. The specification repeatedly distinguishes elemental metals from alloys. The specification recites that the interconnect may comprise "aluminum or aluminum alloys," and states that a diffusion barrier underneath the interconnect may comprise a "transition metal alloy." In the context of the absorptive layer, however, the specification only discusses the use of "a transition metal." Although the specification does not recite the use of a transition metal alloy in the absorptive layer, this alone is not fatal to EMI's proposed construction, as an applicant need not disclose every possible embodiment of his invention. See SRI International v. Matsushita Electric Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985).
The prosecution history, however, indicates that the scope of the claimed absorptive layer is limited to pure elemental metals. As originally submitted by the applicants, the claim recites a method for "forming a layer of optically absorptive material." When the PTO examiner rejected the claim in light of prior art references that employ blackened aluminum or silicon oxides for absorptive layers, the applicants amended their claims to recite "forming a layer of optically absorptive metal." In a second rejection, the examiner noted that the prior art already disclosed the use of molybdenum in a laser cutting process and stated that "even the use of a novel starting material would not necessarily render the process patentable." The applicants finally changed their claim by emphasizing the function of the absorptive layer in transferring laser energy to the interconnect, and as such amended their claim to read "using an optically absorptive refractory transition metal having a higher boiling point than the interconnect beneath it." Notably, the introduction of the word "an" to qualify the metal in the final amendment shows that the scope of the claims progressively narrowed from the use of any suitable material to the use of "an optically absorptive . . . metal."

The applicants clearly contemplated that pure elemental metals are sufficient to enable the invention. In his first rejection letter, the examiner rejected the claims under § 112 for failure to enable the invention, as he asserted that pure elemental transition metals were insufficiently absorptive to induce the claimed explosion. In reply the applicants stated that "titanium, tungsten, tantalum and molybdenum are optically absorptive metals, especially in relation to aluminum." The applicants discussed the physical properties of pure titanium that render it sufficiently absorptive to enable the claimed invention. They stated that "no further processing steps need be taken to prepare the materials optically absorptive." In this exchange with the examiner, the applicants relied on the physical properties of pure elemental metals to enable the device.

Having found no support in the intrinsic evidence to suggest that the claim limitation "an optically absorptive refractory transition metal" covers alloys, the court looks to extrinsic evidence to determine if a person of reasonable skill in the art would interpret the term "an optically absorptive refractory transition metal" to include alloys. Hawley's Condensed Chemical Dictionary defines the term "transition metal" equivalently as "transition element," and lists pure elements as fulfilling this definition. The dictionary clearly distinguishes between alloys and elemental metals, as the definition of "alloy" states that "the properties of alloys are often greatly different from those of the components." Because the dictionary definition of the term "transition metal" does not indicate that this term refers to alloys, and because nothing in the intrinsic evidence suggests otherwise, the court concludes that the term "an optically absorptive refractory transition metal" refers only to pure elemental metals, and does not include alloys. The court reserves the question as to whether the claim may cover alloys under the doctrine of equivalents.

ii. the relative absorptivity

The parties dispute the extent to which the transition metal layer must be optically absorptive with respect to the interconnect. Based on language in the specification, EMI asserts that the transition metal layer is "more absorptive of optical energy than the metal interconnect layer." Cypress advocates that no such limitation should be read into the claim, and that the claim should simply mean that the upper layer be "optically absorptive." Since the plain language of the claim suggests no limitation on the degree of absorptivity of the transition metal layer, the court declines to construe the specification's description of the high relative absorptivity of this layer as a claim limitation. See Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571 (Fed. Cir. 1988). No judicial interpretation is necessary for this limitation.

2972

A. "Optically Coupled To"

For the following reasons, the court construes the claim terms "optically coupled to" in claim 1, "is optically coupled to" in claims 3 and 11, and "optically couple . . . to" in claims 1, 6, and 7 to mean:

(Component A) can send optical information to (Component B) and/or (Component A) can receive optical information from (Component B).

The court arrived at this definition after considering the parties' respective positions as presented in their materials. As for Tellabs' '772 patent, Fujitsu identified a total of seven terms that use the language "optically coupled to," "is optically coupled to," or "optically couple . . . to" and provided an individual construction for each of the seven terms. (See generally
Dkt. No. 90, Ex. C.) Fujitsu's proposed seven constructions are all in the form "can send/receive optical information bi-directionally to from." In response, Tellabs argued that:

Several of the terms raised by Fujitsu are of the form 'A optically coupled to B,' 'A is optically coupled to B,' or 'optically couple A to B,' where A and B are different elements. For this reason, Tellabs proposes a single construction that would apply to each of these claim terms with the insertion of the appropriate A and B elements.

(Dkt. No. 91, Ex. C at 2.) The court agrees with Tellabs' proposition that a single construction should apply to all manifestations the "optically coupled to" language because each of the terms operate to establish that two separate components are optically coupled.

Patent '772's specification explains that optical line terminals (OLTs) are designed to send and receive optical signals:

[An] aspect of the invention to utilize optical line terminals having all-optical pass-through interfaces that provide for continued transmission of optical signals . . . and to connect two optical line terminals back-to-back . . . to provide an optical path from the line side interface of the first optical line terminal to the line side interface of the second line terminal.

('772 patent, col. 1:44-51, 61-2:11.) A single OLT "has an input/output line interface which is connected to an external fiber facility and transmits/receives an optical signal . . . on a single optical fiber which is multiplexed/demultiplexed by a multiplexer/demultiplexer [ ] which outputs demultiplexed wavelengths . . . on individual optical fibers." ('772 patent, col. 2:40-46.) In this manner, a wavelength can be "directly passed-through to a peer OLT rather than being sent to a client apparatus." ('772 patent, col. 2:18-21; col. 3:18-21.) Accordingly, the intrinsic evidence establishes that optical signals are sent and received between various components of one or more OLT. Therefore, "optically coupled to" requires that optical information can be sent or received between two different components.

GO BACK

H. "Is Optically Coupled To . . . Through At Least" and "Optically Couple . . . To . . . Through At Least"

For the following reasons, this court construes the '772 patent's claim terms using the language "is optically coupled to . . . through at least" in claims 4, 5, 12, and 13 and "optically couple . . . to . . . through at least" in claims 1 and 6 to mean:

(Component A) can send optical information to (Component B) through at least (Component C). Alternately, (Component A) can receive optical information from (Component B) through at least (Component C).

Fujitsu identified a total of six terms that use either "is optically coupled to . . . through at least" or "optically couple . . . to . . . through at least." In response, Tellabs argued:

Several of the terms raised by Fujitsu are of the form 'A is optically coupled to B through at least C' or 'optically couple A to B through at least C,' where A, B, and C are different elements. For this reason, Tellabs proposes a single construction that would apply to each of these claim terms with the insertion of the appropriate A, B, and C elements.

(Dkt. No. 91, Ex. C at 3.) The court agrees with Tellabs that a single construction should apply to each claim term using the operative language because both "is optically coupled to . . . through at least" and "optically coupled . . . to . . . through at least" operate to establish that two components are optically coupled through at least a third component.

GO BACK

Claim 1 of the '750 patent reads as follows (with added emphasis on the disputed terms):

[1] A bar code scanner which comprises a housing having a port through which a beam of light for illuminating the bar code passes out of said housing and light reflected from said code passes into said housing.

[2] a laser diode and **optics for forming said beam from the light from said laser diode.**
[3] a photodetector for receiving said reflecting light,

[4] means supporting said photodetector in said housing,

[5] a printed circuit board having circuits thereon connected to said diode and said photodetector, and

[6] means assembling said laser diode and optics in supported relationship upon said printed circuit board and together with each other as a unitary structure located in said housing.

--- Footnotes ---

1 The bracketed element numbers are not part of the claim, but were added by the district court for reference. We will continue to use them.

--- End Footnotes ---

The crux of the dispute over claim construction is whether the "optics for forming said beam" include only the collimating lenses necessary to reduce the diverging fan of laser light into a ray, or whether the term includes other optics involved in the propagation of the laser beam, including the beamsplitters which shape and direct the beam after it is created. According to the claim, the "optics for forming said beam" must be together with the laser diode as a unitary structure. PSC has argued consistently that the only optics encompassed in the patent claims are the optics that create the beam, the collimating lenses. Under PSC's construction, optics which shape or direct the beam after its creation are not "optics" within the meaning of the patent claim. Therefore, the claim requires, according to PSC, only that the collimating lenses be together with the laser diode as a unitary structure.

The district court disagreed with PSC. The district court held that the term optics as used in [6] is defined by [2] as the "optics for forming said beam." After consulting a dictionary, the court held that the "optics for forming" could include optics which shape and direct the beam, including the beamsplitters. More importantly, the district court found PSC's construction inconsistent with the specification, which states that the laser beam producing means and the beamsplitters are both part of the unitary structure. Thus, the court construed the claim as requiring the beamsplitters, which direct the beam and integrate the marker beam with the laser beam, to be part of the optics for forming said beam and concluded that they must be assembled together with the laser diode and the other optics as part of the unitary structure in [6]. The district court also found that its more limited construction was also supported by the fact that the invention claimed by the '750 patent is not a pioneering invention.

According to this construction, the district court held that Accu-Sort did not infringe because its Model 20 and 22 scanners both use mirrors which direct the laser beam after it is created. The court found that the mirrors were equivalent to the beamsplitters of the '750 patent (because both components change the direction of the beam) and concluded that there was no infringement because it was undisputed that Accu-Sort's mirrors were not integrated with the rest of the optics in a unitary structure.

--- Footnotes ---

2 Accu-Sort's mirrors, although present on the circuit board with the rest of the optics, are entirely separate from the laser diode assembly.

--- End Footnotes ---

II.

The district court correctly referred to the specification to define the means-plus-function language in claim 1. To literally infringe a means-plus-function claim, an accused device must employ a means that is identical to or the equivalent of the structures described in the specification. Valmont Indus. v. Reinke Mfg. Co., 983 F.2d 1039, 1042, 25 U.S.P.Q.2d (BNA) 1451, 1454 (Fed. Cir. 1993). The final inquiry as to whether an accused element is an "equivalent" is a question of fact. D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1575, 225 U.S.P.Q. (BNA) 236, 239 (Fed. Cir. 1985). The specification contains language which corresponds directly to the means-plus-function limitation in [6] and describes the means for accomplishing the function described in limitation [6] as follows: "The laser beam producing means 20, the marker beam producing means 54 together with the beam splitters 62 and 70, are mounted to each other and to a printed circuit board 68 . . . ." We agree with the district court that this language directly tracks the disputed claim language which provides: "means assembling said laser diode and optics [for forming] in supported relationship upon said printed circuit board and together with each other as a unitary structure located in said housing." Therefore, the proper construction of the terms "optics for forming" includes the collimating lenses and the beamsplitters or their equivalents.

During oral argument, PSC argued that the district court improperly found that all optics which change the shape or direction of the laser beam must be mounted together in a unitary structure. PSC argues that this claim construction is flawed because the collection lens, as described in the preferred embodiment for the '750 patent, is not part of the unitary structure. Therefore, PSC contends that the district court erred in construing the '750 patent claim in a manner which excludes the disclosed preferred embodiment. If PSC were accurately characterizing the district court's claim construction, this would be a persuasive argument. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2d (BNA) 1573, 1578 (Fed. Cir. 1996) (an interpretation of a patent claim which renders the disclosed preferred embodiment outside the scope of the claim is "rarely, if ever, correct and would require highly persuasive evidentiary support"); Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1581, 38 U.S.P.Q.2d (BNA) 1126, 1130 (Fed. Cir. 1996) ("We share the district court's view that it is unlikely that an inventor would define the invention in a way that excluded the preferred embodiment, or that persons of skill in this field would read the specification in such a way.").

However, no such situation arises in this case. PSC has mischaracterized the district court's claim construction. The district court did not, nor do we, construe the patent claim as requiring all optics which direct or shape the laser beam to be part of the optics for forming. The specification defines this means-plus-function limitation as including the beamsplitters, but not the collection lens. The specification states:

The laser beam producing means 20, the marker beam producing means 54 together with the beam splitters 62 and 70, are mounted to each other and to a printed circuit board 68 which contains a tone generator 78 and other analog circuitry for operating and controlling the laser diode 42 (the power control circuitry) and energizing lamp . . . . The board 68 is located in the bottom of the upper housing 14 which is substantially flat as is shown in FIGS. 2 and 3. The board is located by one of the mountings which supports the collection lens 32. . . . The entire unitary assembly 20 may then be inserted into the upper housing portion 14 and clipped in place.

The specification also explains that the "collection lens 32 is mounted against shoulders 36 and 38 of the housing in the beam port 28." Figure 1 of the patent also shows that the collection lens is not a part of the unitary structure. The specification and the figures support the conclusion that the optics for forming, which are ultimately a part of the unitary structure, include the collimating lenses and the beamsplitters, but do not include the collection lens. PSC would like us to construe the claims in a manner that is much broader than the specification permits. This, we cannot do. Therefore, we affirm the district court's construction of the '750 patent claims.

3 To the extent that PSC argues that the "together with each other" language in [6] does not require that the components be integrated as a unitary structure, but merely connected via the printed circuit board, we disagree. We agree with the district court's interpretation of these terms as requiring some integration of the components beyond their mere placement on the printed circuit board. The district court correctly refused to allow PSC to render this additional claim limitation meaningless. This construction is supported by the specification which states that the optics "are mounted to each other and to a printed circuit board."
I. "Optimization"

The term "optimization" appears in claim 1 of the '382 patent, claims 1-18 of the '392 patent, claims 11-26 of the '617 patent, and claims 19-22 of the '694 patent. The term is generally used in the following context: "... wherein said information about the data structure leads to optimization of said new database. ..." See, e.g., '382 patent, Col. 23:20-23 (emphasis added).

Timeline's proposed construction of the term "optimization" is "providing performance with respect to a given characteristic (e.g. speed or flexibility of output) that is superior to the performance of some other possible configuration with respect to that characteristic." Timeline argues that the term is defined in the specification for the '694 patent, which states:

[A] database is optimized for speed and/or flexibility of output if it provides speed or flexibility of output which is superior to the speed or flexibility of some other possible configuration. Thus, in this context, "optimized" does not necessarily require a mathematically precise optimization.

'694 patent, Col. 18:52-57 (emphasis added). Timeline notes that the definition of a term in a patent specification controls the interpretation of the term. See, e.g., Schoenhaus v. Genesco, Inc., 440 F.3d 1354, 1358 (Fed. Cir. 2006) (The patentee is free to act as his own lexicographer, and may set forth any special definitions of the claim terms in the patent specification or file history, either expressly or impliedly.)

ProClarity's proposed construction is "prepared for a particular purpose." In its briefing, ProClarity offers little if any support for this proposed construction. Instead, ProClarity argues that the term "optimization" is subjective and indefinite. However, ProClarity acknowledged at oral argument that its indefiniteness argument would be more appropriately presented in a summary judgment motion, rather than at the claim construction phase of the litigation.

Therefore, the court construes "optimization" to mean "providing performance with respect to a given characteristic (e.g. speed or flexibility of output) that is superior to the performance of some other possible configuration with respect to that characteristic."
does the specification require usage by the host system. This argument is similarly unpersuasive.

3Com objects to Realtek's language as too "absolutist." Doc # 340 (03-2177) at 14. 3Com argues that "each optimization step is simply an attempt to make the transmission of frames more efficient rather than a dynamic change * * * to make it as perfect, effective or functional as possible." Id at 15 (quotations omitted). When the term is viewed in context, there is no practical difference between these positions. More fully, claim ten recites "feedback for optimizing the threshold." The context of the term clarifies that "optimizing" merely indicates a direction of progress and that perfection need not be achieved. It is irrelevant whether the purpose of the feedback is to make transmission "more efficient" or to "make it as perfect, effective or functional as possible." Both formulations produce the same effect, so 3Com's "absolutist" fears are unjustified. 3Com's objection to Realtek's proposal is unpersuasive.

Aside from the issues noted above, the court finds D-Link's proposal otherwise acceptable. Accordingly, the court adopts the modified construction, "changing the threshold value to make it as perfect, effective or functional as possible."

GO BACK

2977

Optimizer for substantially matching the patient's heart rate to hemodynamic demand under conditions of physical activity and rest of the patient

The Court agrees with Alt that this claim limitation should not be construed as a means-plus-function limitation under 35 U.S.C. § 112, P 6. A claim term that does not use the word "means" gives rise to a rebuttable presumption that § 112, P 6 does not apply. Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002)). "The presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Id. The presumption can be overcome "if it is demonstrated that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Id. (citing CCS Fitness, 288 F.3d at 1369). Medtronic has not overcome this presumption. Claim 15 provides sufficient structure to perform the claimed function. The claim names "optimizer" as the structure that performs the recited function. See Col. 13:41-14:3. Furthermore, the claim goes on to indicate two structures that make up the optimizer, the "second sensor" and "signal processor," and how those structures act to perform the claimed function. See id. Therefore, the claim is not subject to § 112, P 6. See TurboCare Div. of Demag Delaval Turbomachinery Corp. v. Gen. Elec. Co., 264 F.3d 1111, 1120-21 (Fed. Cir. 2001) (holding that a term was not subject to § 112, P 6 because the claim identified two structures for achieving the claimed function and then described how those structures achieved the claimed function). Similarly, due to the claim language's thoroughness, the Court agrees with Alt that the term does not require construction.

GO BACK

2978

1. "option identifier"

Plaintiffs' construction: information that establishes the identity of the option

Defendant's construction: alphanumeric data representing the option to be activated

The parties agree about the purpose of an "option identifier"; it is data that allows specific options to be activated in an ultrasound imaging system. They disagree about what the patent discloses regarding the nature of this data (plaintiffs use the term "information" and defendant uses the term "alphanumeric data"). In their briefs, plaintiffs argue that defendant's original construction was too narrow because it included only "numeric data." In its reply brief, defendant altered its construction slightly, to include "alphanumeric" data. It is not clear whether this resolves the dispute regarding this term because plaintiffs did not have an opportunity to respond.

I presume that it does not, because the alteration does not address plaintiffs' primary argument in their opening brief, that the patent specification anticipates the verbal disclosure of information over the telephone. '294 pat., col. 2, Ins. 34-39. ("The present invention is a method and apparatus for configuring an ultrasound imaging system at a remote location by obtaining
an encrypted feature key from a central location (e.g., via telephone) and then inputting that feature key into the ultrasound imaging system using an operator interface (e.g., a keyboard). However, plaintiffs' argument is misplaced. The claim language itself explains that the option identifier is something that is entered by depressing a sequence of keys on a keyboard. Hence, it must be alphanumeric. The relevant language of claim 7 provides "decrypting means for outputting decrypted data in response to depression of a sequence of keys of said operator representing an encrypted feature key comprising an encrypted validation identifier and an encrypted option identifier." Therefore, I will adopt defendant's modified construction of this term.

Court's construction: alphanumeric data representing the option to be activated
(1) a rigid elongated handpiece having a proximal end and a distal end;

(2) a flexible cable having one end coupled to said proximal end and another end adapted for coupling to video imaging equipment;

(3) a housing removably coupled to said distal end of said rigid elongated handpiece;

(4) a sensor for sensing an image of a selected target, said sensor being coupled to said rigid elongated handpiece and said flexible cable, said sensor extending into said housing;

(5) opto-electric componentry extending from said sensor through said handpiece to said cable; and

(6) an objective element positioned in said housing and arranged to focus an image of a selected target upon said sensor when said housing is coupled to said rigid elongated handpiece.

The parties are now before the Court on cross-motions for partial summary judgment as to Claim 30, along with claim 32, which is based on Claim 30. The salient issue presented by the parties' motions is whether the AcuCam contains "opto-electric componentry extending from said sensor through said handpiece to said cable," as stated in Claim 30. The Court discusses this matter below.

4 Because the Court concludes that the AcuCam lacks the limitation regarding opto-electric componentry, the Court does not reach the issue of whether the AcuCam contains a "housing" as specified in Claim 30.

DISCUSSION

A. Legal Standard

Under Federal Rule of Civil Procedure 56, a court may properly grant a motion for summary judgment if the pleadings and materials demonstrate that there is "no genuine issue as to any material fact and the moving party is entitled to judgment as a matter of law." Celotex Corp. v. Catrett, 477 U.S. 317, 322, 91 L. Ed. 2d 265, 106 S. Ct. 2548 (1986). A dispute about a material fact is genuine "if the evidence is such that a reasonable jury could return a verdict for the nonmoving party." Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). A court may grant a summary judgment motion in a patent infringement case, as in any other case. Avia Group Int'l, Inc. v. L.A. Gear Cal., Inc., 853 F.2d 1557, 1561 (Fed. Cir. 1988).

There is a two-step analytical process to determine whether an accused device literally infringes on an existing patent. First, the Court must construe or interpret the scope of the patent claims; this determination is a matter of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 1995 WL 146983 at *11 (Fed. Cir., filed April 5, 1995). Second, the Court must then determine "whether the properly interpreted claims encompass" the accused product. ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988).

B. New Image's Definition of Opto-Electric Componentry is Correct

1. Overview of The Parties' Respective Positions
The threshold issue presented by the parties' motions is the proper construction of "opto-electric componentry extending from said sensor through said handpiece to said cable," as recited in Claim 30 of the '001 patent.

New Image argues that because the '001 patent and its prosecution history are silent as to the meaning of "opto-electric componentry," the Court should employ the ordinary meaning of the term as it is used by those persons skilled in the art. The ordinary meaning of "opto-electric componentry," argues New Image, is a device which converts optical power (photons) to electrical signals (electrons) or vice versa. In contrast, HTMI asserts that any wiring or circuitry between the sensor and the cables constitutes the opto-electric componentry. (Pl.'s Opp'n at 11.)

2. The Specification Provides No Guidance on the Meaning of Opto-Electric Componentry

In construing the meaning of a patent claim, the court should consider the claim itself, the specification, and the prosecution history. Markham, 1995 WL 146983 at *11. The Court, in its discretion, may also consider extrinsic evidence including "all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises." Id. However, "extrinsic evidence is to be used for the court's understanding of the patent, not for the purpose of varying or contradicting the terms of the claims." Id.

In the instant case, HTMI asserts that the specification of the '001 patent demonstrates that the term "opto-electrical componentry" should necessarily be equated with the interconnections between the sensor and the cable. (Pl.'s Opp'n at 11.) HTMI contends that this fact is "obvious" from the drawings and supported by the deposition testimony of New Image's own expert, Robert Fischer. These contentions are without merit.

First, the mere reference to drawings in the '001 patent is insufficient to construe the meaning of "opto-electric componentry." As the Federal Circuit explained in Markham, "any special definition given to a word must be clearly defined in the specification." 1995 WL 146983 at *11 (emphasis added). Even assuming that the definition ascribed by HTMI is present in the specification, such meaning is far from "clearly defined." Id. In short, the conclusion advocated by HTMI is not "obvious" to the Court.

Second, HTMI misconstrues Mr. Fischer's testimony. Although Mr. Fischer did state that the wires extending between the sensor and the cable correlated to opto-electrical componentry, (Sobon Decl. Ex. I at 141), he later clarified that he misunderstood plaintiff's counsel's, previous questions and that his prior response was incorrect. (Barone Reply Decl. Ex. 2 at 152). Thus, the deposition testimony cited by HTMI is of dubious value as support for its argument.

3. HTMI's Reliance on The File History is Misplaced

HTMI next argues that the file history of the '001 patent establishes the proper meaning of opto-electrical componentry, as it is used in Claim 30. Specifically, HTMI highlights certain passages in the amendment filed by HTMI's attorneys in connection with the patent reexamination proceedings. (See Pl.'s Opp'n at 11; Sobon Decl. Ex. J.) This text states:

The interior of the handle also remains sealed, for example, through the provision of the O-Rings. In this way, the endoscopic apparatus can be immersed in a sterilizing solution without affecting the electro-optical componentry or interconnections that extend through the handpiece to couple the camera to video imaging equipment.

(Sobon Decl. Ex. J at 9-10.) HTMI contends that this demonstrates that it intended the terms "electro-optical componentry" and "interconnections" to be used interchangeably.

The Court disagrees with HTMI's assertion that the file history explicitly equates opto-electrical componentry with the interconnections between the CCD sensor and the extension cables. The above passage cited by HTMI clearly uses the terms "electro-optical componentry" and "interconnections" in the disjunctive. While the word "or" can be used to signify words that are synonymous, it can also be used to indicate alternative choices. (See Black's Law Dictionary 1095 (6th ed. 1990).) However, it is unclear from the file history which interpretation of the word "or" was intended. Moreover, there is nothing explicit in the above file history statement which suggests that HTMI intended to equate "electro-optical componentry" with either the "interconnections" or the term "opto-electrical componentry." Thus, contrary to HTMI argument, the file history simply does not clearly define the meaning opto-electric componentry in the manner so construed by HTMI. 5
C. The Dictionary Definitions Provide the Ordinary Meaning of Opto-Electric

Because the specification and file history provide no decisive guidance in defining the term "opto-electronic componentry," this Court must determine the "ordinary meaning" of the claim at issue. Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 951 (9th Cir. 1994) ("Although a patentee can be his own lexicographer, . . . the words of a claim 'will be given their ordinary meaning, unless it appears that the inventor used them differently.'") (citations omitted).

The Court finds compelling the several definitions provided by New Image which were culled from various technical dictionaries. For example, The New IEEE Standard Dictionary of Electrical and Electronics Terms, (5th Ed. 1993), defines "optoelectronic" as: 6

Pertaining to a device that responds to optical power, emits or modifies optical radiation, or utilizes optical radiation for its internal operation. Any device that functions as an electrical-to-optical or optical-to-electrical transducer . . . .

(Fischer Decl. Ex. 4.; see also The Photonics Dictionary, (37th Ed. 1991) (identical definition).) From these definitions, it is evident that "opto-electric" components must, in some manner, convert optical power (photons) to electronic signal (electrons). See id. P 15 and Ex. 4 (copies of excerpts from technical dictionaries which define "optoelectronic.").

6 The term "optoelectronic" is synonymous with "opto-electrical." (Fischer Decl. P 16.)

HTMI does not controvert New Image's dictionary definitions. 7 Instead, HTMI asserts that these definitions are sufficiently broad such that "all the components that extend from the CCD sensor to the cable connector 'pertain to' the CCD sensor." (Pl.'s Opp'n at 15.) in essence, HTMI has defined opto-electric componentry as any device or part connected to an opto-electric device. However, such a construction would result in a definition of "opto-electric" based solely on the physical proximity of the component, as opposed to its actual function. Such a definition is so vague that it would effectively render the term "opto-electric componentry" meaningless. It is precisely for this reason that the Court, in its preliminary injunction order, seriously questioned whether HTMI would succeed on the merits on infringement based on Claim 30. 8

7 Tellingly, HTMI does not attempt to explain its interpretation of the "ordinary meaning" of opto-electric. Instead, HTMI ignores the applicable rules of infringement analysis and argues that New Image's own evidence and testimony demonstrate that the AcuCam possesses opto-electric componentry within the meaning of Claim 30.8 In the Court's preliminary injunction Order, this Court explained that:

HTMI, . . . assert[s] that the terms "opto-electric componentry" also encompass components which carry optical images in an electrical format, and as the AcuCam possesses such components between the CCD and the cable, it possesses this element of claim 30.

HTMI's description of opto-electrical componentry, however, overly stretches the ordinary meaning of the term as defined above. The CCD is the only component which the AcuCam possesses which fits within the plain meaning of the term opto-electric." Furthermore, HTMI conceded at oral argument that the CCD in the AcuCam corresponds to the sensor of claim 30, and not to the optoelectric componentry.

(Order Granting Pl.'s Mot. for Prelim. Inj. at 16 (emphasis added).)
Moreover, the dictionary definitions proffered by New Image clearly specify that "optoelectronic" relates to a device which "responds to optical power, emits or modifies optical radiation, or utilizes optical radiation for its internal operation." (Fischer Decl. Ex. 4 (emphasis added).). This definition is corroborated by the expert testimony adduced by New Image as well as by the technical articles authored by those skilled in the art. (E.g., Fischer Decl. P 15; Magen Decl. Ex. 1 (excerpts from deposition of Dominick Danna, an electrical engineer and endoscope designer) 9; Magen Decl. Ex. 2 (article by Hugo Vifian published in the Microwave Journal).) 10

9 In response to HTMI's attorney's questions, Mr. Danna testified at his deposition that an optoelectronic device is one which converts "photoenergy into electronic signals." (Sobon Decl. Ex. O at 124.) This is consistent with the various dictionary definitions discussed above and appended to the Fischer declaration.10 In this article, Mr. Vifian writes:

The final group is the optoelectrical components. This group includes lightwave detectors or receivers, and demodulator sensors. These components have optical input and electrical output ports, and are O/E [optical/electrical] components.

(Magen Decl. Ex. 2 at 68.) HTMI does not address the significance of this article in its opposition. Although HTMI raises an evidentiary objection to this article in its inappropriate and unauthorized surreply (see n.1), said objection is untimely, and therefore, is deemed waived.

HTMI does not proffer its own definition of opto-electric, other than to state that opto-electric componentry essentially means anything between the sensor and the cable. Instead, HTMI attempts--unsuccessfully--to attack the evidence offered by New Image. For example, HTMI attempts to undermine the significance of Mr. Danna's testimony by noting that he stated that there "possibly" were other definitions to "optoelectronic" other than that which he had previously given. Unfortunately, HTMI, for reasons not evident from the record, did not query Mr. Danna any further concerning the nature of those other possible definitions.

HTMI's citation to the deposition testimony of George Sutton, one of New Image's experts, is equally misplaced. (Pl.'s Opp'n at 15.) In his deposition, Mr. Sutton testified that the wires in the AcuCam "carried" images taken by the CCD. (Sobon Decl. Ex. E. at 47.) This testimony does not--as argued by HTMI-- establish that Mr. Sutton "thinks that all the components that extend from the CCD sensor to the cable connector 'pertain to' the CCD sensor." (Pl.'s Opp'n at 15.) Rather, Mr. Sutton simply acknowledged that the wires leading from the CCD act as a conduit for electrical signals produced by the CCD.

At bottom, the Court rejects HTMI's contention that either Claim 30 or its file history explicitly equate "opto-electric componentry" with the interconnections between the CCD sensor and the external cable. The Court agrees with New Image that the ordinary meaning of the term "opto-electric componentry," as it is used in Claim 30, relates to an optical-to-electrical or an electrical-to-optical transducer extending from the sensor to the cable. If the drafters of the '001 patent had envisioned something different, they "could have prevented this result through clearer drafting." Hoganas AB, 9 F.3d at 951.

Claim 30 of the '001 patent (with the disputed claim language emphasized) reads as follows:

A dental endoscopic apparatus comprising:

a rigid elongated handpiece having a proximal end and a distal end;

a flexible cable having one end coupled to said proximal end and another end adapted for coupling to video imaging equipment;
a housing removably coupled to said distal end of said rigid elongated handpiece;

a sensor for sensing an image of a selected target, said sensor being coupled to said rigid elongated handpiece and said flexible cable, said sensor extending into said housing;

**opto-electrical componentry** extending from said sensor through said handpiece to said cable; and an objective element positioned in said housing and arranged to focus an image of a selected target upon said sensor when said housing is coupled to said rigid elongated handpiece.

The district court construed the term "opto-electrical componentry" to mean "an optical-to-electrical or an electrical-to-optical transducer." High Tech, 1995 WL 381502, at *6. The court then determined that the AcuCam device did not meet the limitation of "opto-electrical componentry extending from said sensor through said handpiece to said cable" because it did not contain a transducer connecting the CCD sensor to the cable. See id. The court therefore granted New Image's motion for partial summary judgment. The district court did not construe any of the other limitations in claim 30.

II.

On appeal, HTMI argues that the district court erred in construing the term "opto-electrical componentry." HTMI contends that the term should be construed to mean an electrical component that conveys optical images in an electrical form. HTMI also argues that we should construe on appeal other claim terms such as "objective element" and "housing," which the district court did not address. In light of its proposed claim construction, HTMI urges us to hold that the AcuCam device infringes claim 30 of the '001 patent.

When interpreting a claim, the court should look first to intrinsic evidence: the claim itself, the specification, and the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996). If an ambiguity remains after considering intrinsic evidence, then the court may refer to extrinsic evidence, such as expert and inventor testimony. Id. at 1584, 39 USPQ2d at 1577. In addition, although technically considered extrinsic evidence, the court is free to consult technical dictionaries at any time in order to determine the ordinary meaning of claim terms. Id. at 1584 n.6, 39 USPQ2d at 1578 n.3.

In construing the term "opto-electrical componentry," the district court concluded that neither the claims, the specification, nor the prosecution history provided clear guidance for defining the term. Accordingly, the court looked to various dictionaries and technical articles, and to expert testimony for the ordinary meaning of the term. As noted, the court concluded that the ordinary meaning of the term "opto-electrical componentry" was an "optical-to-electrical or an electrical-to-optical transducer," and it adopted this meaning in its claim construction. The court then determined that the only component in the AcuCam device which had an opto-electrical function was the CCD camera, which corresponded to the "sensor" in claim 30. The court found that the components connecting the CCD sensor to the cable in the AcuCam device were resistors, capacitors, logic gates, transistors, diodes, voltage regulators, and wires. The court further found that none of these components were "opto-electrical" within the ordinary meaning of the term. The court therefore concluded that the AcuCam device did not possess "opto-electric [sic] componentry extending from said sensor through said handpiece to said cable," as recited in Claim 30. High Tech, 1995 WL 381502, at *6.

When construing a patent claim, terms should generally be given their ordinary and customary meaning. See Vitronics, 90 F.3d at 1581, 39 USPQ2d at 1576. However, we have stated that: "[a] technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and the prosecution history that the inventor used the term with a different meaning." Hoescht Celanese Corp. v. BP Chem. Ltd., 78 F.3d 1575, 1578, 38 USPQ2d 1126, 1129 (Fed. Cir.) (emphasis added), cert. denied, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996). We also have stated that courts may refer to technical dictionaries in construing claims, as the district court did in this case, "so long as the dictionary definition does not contradict any definition found in
or ascertained by a reading of the patent documents." Vitronics, 90 F.3d at 1584 n.6, 39 USPQ2d at 1578 n.3 (emphasis added). Although the term "opto-electrical componentry" does not appear anywhere in the written description, it is apparent that the patentee used the term "opto-electrical componentry" to refer to electrical components that carry an optical image in an electrical form. The written description states: "Camera 56 will have connected to it a number of lead wires 64 which travel through hollow regions 62 and 48, exit handpiece 12, and are ultimately connected to an image processing system 14." '001 patent, col. 6, ll. 6-10. These wires are the only structure disclosed that connects the sensor to the cable as required by claim 30 ("opto-electrical componentry extending from said sensor through said handpiece to said cable"). We therefore conclude that a person skilled in the art reading the patent document would understand that the term "opto-electrical componentry" referred to the indicated wires.

It also should be noted, we believe, that the claim construction we have adopted is appropriate because the ordinary meaning of the term "opto-electrical componentry" would not cover any of the disclosed embodiments of the invention claimed in the '001 patent. The Supreme Court has stated that the terms in a claim must be defined in a manner that fully comports with the instrument as a whole and that preserves the patent's internal coherence. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1395, 38 USPQ2d 1461, 1470, 134 L. Ed. 2d 577 (1996). Furthermore, a claim interpretation that does not cover a disclosed embodiment is "rarely, if ever, correct." Vitronics, 90 F.3d at 1583, 39 USPQ2d at 1578; see also Hoechst, 78 F.3d at 1581, 38 USPQ2d at 1130 ("it is unlikely that an inventor would define the invention in a way that excluded the preferred embodiment"); Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1550, 37 USPQ2d 1609, 1612 (Fed. Cir.) ("a claim interpretation that would exclude the inventor's device is rarely the correct interpretation"), cert. denied, 116 S. Ct. 2523 (1996). The ordinary meaning of "opto-electrical componentry," which forms the basis for the district court's claim construction, would require the presence of a second transducer in the device. However, there is no support for a second transducer in the specification or in the prosecution history because the only transducer described in the specification is the CCD camera.

For the foregoing reasons, we conclude that the term "opto-electrical componentry," as used in Claim 30, means electrical components that convey optical images in an electrical form. However, we are not prepared on the basis of the record before us to say that the AcuCam device contains "opto-electrical componentry extending from said sensor through said handpiece to said cable." We believe that the district court should make the appropriate factual determination as to whether this limitation of claim 30 is met in the accused device. In addition, we leave construction of the terms "objective element" and "housing" and determination of whether these limitations of claim 30 are met in the accused device to the district court in the first instance.

The decision of the district court is vacated, and the case is remanded for further proceedings consistent with this opinion.

Each party shall bear its own costs.

MAYER, Circuit Judge, dissents.

GO BACK

2982

With emphasis added to the words "or" and "either," on which the claim construction issue turns, independent claims 1, 16, and 20 recite:

1. A method of processing Doppler return information in a traffic radar comprising the steps of:

   [a] receiving Doppler return information containing at least one return signal derived from a target vehicle,

   [b] presenting said Doppler return information as digital data,

   [c] transforming said data into the frequency domain to provide a spectrum that includes frequency components corresponding to Doppler return signals contained in said information,

   [d] storing said components in a memory,
(Emphases and clause letters added.)

The district court construed the term "or" as used in claim clauses 1[e], 16[d], and 20[f] to mean "a choice between either one of two alternatives, but not both." This construction was the basis for the court's summary judgment of no infringement, and is the only aspect of the claim construction on appeal.

Kustom argues that "or" should not have been restricted to a search of either the fastest target data (frequency) or the strongest target data (magnitude) "but not both." Kustom states that the district court's construction contradicts the correct usage of the term "or." Kustom points to the Microsoft Press Computer Dictionary, 24, 344 (3d ed. 1997), which distinguishes among logical operators, defining "or" (which returns a "true" value when one or both values are true), "and" (which returns a "true" value if and only if both values are true), and "exclusive or" (which returns a "true" value when only one value is true). Kustom cites precedent which cautions against construing technical terms of the art at issue in accordance with non-technical dictionary definitions, instead of the technical usage of the field of the invention.

It is presumed that technical words in patent documents are used, and intended to be understood, as they would be used and understood by persons experienced in the field of the invention. See, e.g., Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1478, 45 U.S.P.Q.2D (BNA) 1429, 1433 (Fed. Cir. 1998); Hoechst Celanese Corp. v. BP Chemicals, Ltd., 78
However, whatever the meaning of "or" as a logical operator, it is quite clear from the patent documents that Kustom was not using "or" as a technical programming operator, but in its ordinary meaning as stating alternatives. If a divergent specialized usage were intended, the context was such that it was required to be clearly explained in the patent documents. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996) ("[A] patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history.").

The district court construed "or" and "either" in their common usage as designating alternatives. We agree with this construction, for there is no indication that Kustom used these words with a different meaning. Particularly, there is no basis whatsoever for believing that Kustom intended its usage of "or" somehow to embrace "and." The district court analyzed the detailed flowcharts in the '246 specification, which showed that only one search of memory is done for any one data set for either magnitude or frequency criteria. The '246 patent does not describe any embodiment that searches for and displays both modes.

Kustom's claim amendments and accompanying remarks, requiring the alternative "multi-mode" operation that is achieved by operator selection of either strongest or fastest mode, are consistent with this construction. As filed, all of the claims of the '246 patent application were rejected for obviousness over the Muni Quip MDR-1 radar device in combination with United States Patent No. 3,631,486 to Anders. Kustom then rewrote the claims to include the limitation to "magnitude or frequency." Original claim 1 did not include clauses 1[d], 1[e], and 1[f], instead reciting a spectrum validation process and the step of "determining the magnitude and frequency of each valid component." New clause 1[e] limited the memory search to "magnitude or frequency" (emphasis added). Similar changes were made to claim 16, which as filed included "means for determining the magnitude and frequency of each valid component and retaining the same in memory"; this clause was cancelled, and clause 16[d] was added, limiting the memory search to "magnitude or frequency." Original claim 20 as filed included clause 20[f] with its "either" and "or" limitations on operator selection and target identification. During prosecution Kustom explained to the examiner that "Claim [20] specifically calls for two search modes under operator selection." Kustom described its invention as having "multi-mode operation," whereby the desired mode, whether magnitude (strongest target) or frequency (fastest target) would be selected by the operator. It is apparent that the modes of search and display were intended, in the '246 invention, to be selected in the alternative. The prosecution history requires that "or" means the operator's choice between search for the strongest or fastest target speed, but not both. The district court's claim construction is affirmed.

The district court also erred in construing the language of the body of the claims. The body of claim 1 provides in relevant part:

receiving a definition of a second coordinate system for the digitizer, which second coordinate system allows specification of points specified in the digitizer's coordinate system but is not congruent with the digitizer's coordinate system because one of the following elements is different from the digitizer's coordinate system: location of the point of origin, or angle of rotation, or scale . . . .

'492 patent, col. 49, ll. 55-62 (emphasis added). 5 The district court construed the language in the body of the claim in light of the preamble:

The claims define three essential attributes of the digitizer coordinate system [i.e., a point of origin, angle of rotation, and scale]. Every data translation may not involve varying all three attributes, but the first computer system has to be capable of translating all three attributes."

Noninfringement Order at 5 (emphasis added). The district court thus effectively substituted the word "and" from the preamble for the word "or" used in the body of the claim. The district court concluded that "the language of the claims and their preambles indicates that 'and' is the appropriate designation" and that "Schumer's reliance on the term 'or' that appears later in the claims is misleading." Id. at 4-5 (emphasis added). Accordingly, the district court construed this language to require that "the claims define three essential attributes of the digitizer coordinate system [i.e., a point of origin, angle of
Every data translation may not involve varying all three attributes, but the first computer system has to be capable of translating all three attributes."

5 Similar language appears in the body of claims 6 and 9.

The district court's claim construction contradicts the plain meaning of the word "or" in the claims. The proper approach is to construe the claim language using standard dictionary definitions, because here, the claims have no specialized meaning. See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1206-1207 (Fed. Cir. 2002). Webster's Third International Dictionary defines "or" as follows: "used as a function word to indicate (1) an alternative between different or unlike things, states, or actions ... (2) choice between alternative things, states, or courses." Webster's Third New Int'l Dict. 1585 (1967).

We have consistently interpreted the word "or" to mean that the items in the sequence are alternatives to each other. In Brown v. 3M, 265 F.3d 1349, 1352, 60 USPQ2d 1375, 1377 (Fed. Cir. 2001), we upheld the district court's construction of the word "or" in the claim as meaning that the apparatus was capable of converting "'only two-digit, only three-digit, only four-digit, or any combination of two-, three-, and four-digit date-data,'" by finding that the interpretation of the word "or" involved a "plain reading of the claim text. These are not technical terms or art, and do not require elaborate interpretation." In Kustom Signals, Inc. v. Applied Concepts, Inc., 264 F.3d 1326, 1331, 60 USPQ2d 1135, 1138 (Fed. Cir. 2001), we agreed with the district court's construction of "or" as "designating alternatives." We noted that "there is no indication that Kustom used these words in a different meaning. Particularly, there is no basis whatsoever for believing that Kustom intended its usage of 'or' somehow to embrace 'and.'" Id.

Giving the term "or" its accepted definition, however, is not the end of the inquiry. A question remains as to whether the claims should be interpreted to mean that the method must be capable of translating each of the three alternative variables, i.e., point of origin, angle of rotation, and scale, as the district court apparently held.

If this were a product patent, the concept of capability would have relevance. So too it would have relevance if this process patent were tied to a "particular machine or apparatus." 6 But here we deal with a method claim which is not tied to a particular device but that "operates to change articles or materials to a 'different state or thing.'" Gottschalk v. Benson, 409 U.S. 63, 71, 34 L. Ed. 2d 273, 93 S. Ct. 253. Such a claim must be interpreted to cover any process that performs the method steps. Here in claim 1 the method is identified as "receiving a definition of a second coordinate system for the digitizer, which ... is not congruent with the digitizer's coordinate system because one of the following elements is different ..." '492 patent, col. 49, ll. 55-61. One of those elements is scale. Thus, for example, a method that translates from a device where only the scale is different is within the literal scope of the claim. The method is performed if any of the three features of a coordinate system is translated, and thus, infringement occurs if any one of these translations is performed.

6 In Gottschalk v. Benson, 409 U.S. 63, 71, 34 L. Ed. 2d 273, 93 S. Ct. 253 (1972), the Supreme Court reiterated the proposition that "a process patent must either be tied to a particular machine or apparatus or must operate to change articles or materials to a 'different state or thing.'" The Court referred to the well established definition of "process" stated in Cochrane v. Deener, 94 U.S. 780, 788, 24 L. Ed. 139, 1877 Dec. Comm'r Pat. 242 (1877), "A process is a mode of treatment of certain materials to produce a given result. It is an act, or a series of acts, performed upon the subject-matter to be transformed and reduced to a different state or thing."
overcome the Logan patent, Schumer is estopped by his prosecution history from discounting the importance of the angle of rotation limitation.” Noninfringement Order at 5.

It is well established that statements made during prosecution are used to interpret the scope and meaning of ambiguous claim terminology. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1577 (Fed. Cir. 1996) (“This [prosecution] history contains the complete record of all the proceedings before the Patent and Trademark Office, including any express representations made by the applicant regarding the scope of the claims. As such, the record before the [PTO] is often of critical significance in determining the meaning of the claims.”). There is no ambiguity here. But even where the claim language is not ambiguous, "the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 USPQ2d 1673, 1676 (Fed. Cir. 1995). Thus, the prosecution history limits even clear claim language so as to exclude any interpretation that was surrendered during prosecution, but only where the accused infringer can demonstrate that the patentee surrendered that interpretation "with reasonable clarity and deliberateness." Pall Corp. v. PTI Techs., Inc., 259 F.3d 1383, 1393, 59 USPQ2d 1763, 1769 (Fed. Cir. 2001) (quoting N. Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1294-95, 55 USPQ2d 1065, 1075 (Fed. Cir. 2000)), vacated on other grounds by PTI Techs., Inc. v. Pall Corp., 153 L. Ed. 2d 152, 122 S. Ct. 2324 (2002). There was no such clear surrender here.

The Examiner first rejected the claims that eventually issued as claims 1-10 as unpatentable over the Logan patent, U.S. Patent No. 4,821,029 ("Logan"), under 35 U.S.C. § 103(a). Logan disclosed a conventional prior art digitizer that allowed creation of regions, each with its own coordinate system. As to claim 42 (issued claim 1), the Examiner stated:

"It would have been obvious to one of ordinary skill in the art at the time the invention was made to realize Logan includes means for translating the coordinates of the digitizer's coordinate system (touch screen) into the coordinates of the second coordinate system (sub-area or chamber) when the pointer is located within the region so as to designate the sub-area on the touch screen."

In response, Schumer made a Preliminary Amendment in which he added the following emphasized language:

"outputting the position of the pointer on the surface in a coordinate system of the digitizer which coordinate system has a point of origin where the coordinates are 0,0 and has an angle of rotation such that the line from coordinate 0,0 to coordinate 0,5 defines an angle of rotation with respect to the digitizer and has a scale such that the distance from coordinate 0,0 to coordinate 0,5 is a certain physical length, comprising . . . ."

Preliminary Amendment of April 8, 1996, at 1 (Emphasis added). Schumer explained:

"The Applicant now has a greater understanding of the Examiner's concerns with respect to the meaning of the terms "origin," "scale," and "rotation" as used in the claims. To clarify that the limitations using this terminology create a nonobvious distinction over Logan, the claims have been amended to make this terminology much more specific."

". . . . Each of the coordinate systems in Logan uses a single point of origin . . . . In each of the different coordinate systems disclosed by Logan, the point of origin where the coordinates are 0,0 is the same. Similarly, the multiple coordinate systems in Logan all use the same angle of rotation . . . . In Logan, the multiple coordinate systems all have the same angle of rotation with respect to the digitizer.

". . . . Also, when the scale is defined to be a specific physical length from a point defined as another specific coordinate, for the multiple coordinate systems in Logan, the scale of each of the coordinate systems is the same."

Id. at 10-11 (Emphases added). Thus, Schumer explained that in Logan, the regions' coordinate systems did not have the ability to deviate from the coordinate system of the digitizer: the scale was always the same, the point of origin always had
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

to be in a corner of the region, and the angle of rotation was always the same. Schumer distinguished Logan on three
grounds: Logan could not translate to coordinate systems with different origins, with different scales, or with different
angles of rotation. Id.

The Examiner responded with a second office action, stating, "Applicant's arguments with respect to claims 42-51, 60-67
have been considered but are deemed to be moot in view of the new grounds of rejection." Office Action of April 3, 1997, at
3 (referring to the § 112 rejection discussed below).

The Examiner ultimately rejected claims 42-51 under 35 U.S.C. § 112, first paragraph, because "the specification does not
disclose which coordinate system has a point of origin where the coordinates are 0,0 . . . ." Id. at 2.

In response to the second office action, Schumer amended his claims to overcome the section 112 rejection by deleting the
following language: "where the coordinates are 0,0," "such that the line from coordinate 0,0 to coordinate 0,5 defines an
angle of rotation," and "such that the distance from coordinate 0,0 to coordinate 0,5 is a certain physical length." Schumer
explained: "Applicant has deleted the objected to language from claims 42, 46, and 50" to overcome the section 112
rejection "for including in the preamble language which is not found in the specification."

Thus, the examiner never substantively addressed Schumer's argument and amendment distinguishing the Logan prior art,
and instead declared those arguments "moot."

In summary, the prosecution history makes clear that Schumer distinguished the prior art Logan patent on the ground that it
did not disclose the ability to translate any of the three parameters. Schumer's proffered interpretation is not inconsistent
with what he argued during prosecution to obtain allowance. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570,

We conclude that the prosecution history does not compel a limitation of the claim language different from its plain
meaning, and we conclude that the correct construction requires that the device performing the claimed method need only
have the ability to translate one of the three attributes of the coordinate system.

2984

c. "OR Circuit Means"

Claim 1 of the '290 patent describes an "OR circuit means operative to generate an output signal substantially equal to the
greatest of any input signal." '290 patent, col.6, ll.23-26. Control argued that an "OR circuit means" is simply a circuit that
chooses between the greater of two signals. Markman Hr'g Tr. at 19:2-6; Pl.'s Mem. at 11. Delta countered that Control's
proffered definition was too broad and that it had abandoned the broader definition during the patent prosecution. Markman
Hr'g Tr. at 20:5-22. Delta noted that in response to a rejection by the examiner, Control amended the claim to include only a
limited variety of OR circuits. Id. According to Delta, the definition of "OR circuit means" must include the limitation that
the circuit generates an output signal that is substantially equal to the greater of the two input signals. Further, the two input
signals must correspond to a fixed level signal that is independent of temperature and a variable level signal that is
dependent on temperature.

After hearing oral argument and reviewing the claim language, the Court construed the claim term, in the form of a
proposed address to the jury:

An OR circuit is a circuit that makes a choice. In this case, it makes the choice whether to run the fan at a temperature, at
a fixed temperature speed or at a speed that is dependent on the temperature, that is, which runs faster as the temperature
rises, or slower as the temperature drops.

Now, look, look down further and you'll see that it says . . . they use the OR circuit to generate an output signal, that is,
the signal that drives the apparatus, substantially equal to the greatest of any input signal.

Markman Hr'g Tr. 26:19 to 27:5.
PROCEDURAL HISTORY

On Sept. 1, 1999, Brown filed this complaint pro se alleging that four major corporations installed or used a process that infringed on elements of claim 16 in the 824 patent and even after notice, refused to stop infringing and refused to obtain a license for Brown's patented process. These corporate defendants include 3M, Revlon Inc., Procter & Gamble, and Air Products & Chemicals Inc. Brown alleged that the defendants' use of a Y2K remediation system that was based on a process sold and licensed by TOCS infringed upon his patent.

2 Claim 16 states:

An apparatus for processing year-date data in a computer system, the apparatus comprising:

1) a CPU,
2) a bus coupled to the CPU,
3) a memory coupled to the bus,
4) a system clock coupled to the bus, wherein the system clock is set to an offset time wherein the offset time is a time other than the actual time,
5) at least one application program stored in the memory and being executed by the CPU,
6) at least one database file stored in the memory containing records with year-date data with years being represented by at least one of two-digit, three digit, or four-digit year-date representations, and
7) a mechanism for converting the year-date data representations in the database file to a two-digit year-date data representation.

3 Pfizer, Inc. was also a defendant, but it was later dismissed from the complaint pursuant to stipulation.

DISCUSSION

Summary Judgment

Summary judgment is proper when there is no genuine issue of material fact and the moving party is entitled to a judgment as a matter of law. Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 247-48, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). The burden is on the movant to demonstrate the absence of all genuine issues of material fact. Cooper v. Ford Motor Co., 748
Rule 56(c) of the Federal Rules of Civil Procedure provides for the granting of summary judgment motions "if the pleadings, depositions and admissions on file, together with the affidavits, if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law."

Invalidity and Non-Infringement

There is a rebuttable presumption of patent validity. 35 U.S.C. § 282. Defendants may overcome this presumption with clear and convincing evidence. See id; See also, Connell v. Sears, Roebuck & Co., 722 F.2d 1542, 1549 (Fed. Cir. 1983). When clear and convincing evidence exists, then the Court must find for the defendant. Martin v. Barber, 755 F.2d 1564, 1567 (Fed. Cir. 1985).

Infringement is generally a question of fact. Nicholl, Inc., v. Schick Dry Shaver, Inc., 98 F.2d 511, 513 (9th Cir. 1938); Dawn Equipment Co. v. Kentucky Farms Inc., 140 F.3d 1009, 1017 (Fed. Cir. 1998). However, when it appears that extrinsic evidence is not needed to explain the terms of art and a court is able to comprehend what the invention disclosed in a patent is and to determine whether one device infringes on another, the question of infringement or non-infringement is one of law. United States v. Esnault-Pelterie, 303 U.S. 26, 30, 82 L. Ed. 625, 58 S. Ct. 412 (1938); Kemart Corp. V. Printing Arts Research Laboratories, Inc., 201 F.2d 624, 627 (9th Cir. 1953). Where there is no evidence of infringement or where evidence establishes without conflict that there is no infringement, it is the duty of the court to find for the defendant. Martin v. Barber, 755 F.2d at 1567; McRoskey v. Braun Mattress Co., 107 F.2d 143, 147 (9th Cir. 1939).

The first step in deciding infringement of a patent is to determine the scope of the claims as indicated by the language of the claims, which is a question of law, Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 758 (Fed. Cir. 1984), after reading them and the specifications in light of the prior art. James P. Marsh Corp. v. United States Gauge Co., 129 F.2d 161, 164 (7th Cir. 1942). The next step is for the trier to judge whether the claims cover the accused device, which is typically a question of fact, Envirotech Corp., 730 F.2d at 758, except where it appears that no substantial dispute of fact is presented. United States v. Esnault-Pelterie, 303 U.S. at 30. When presented with issues of validity along with issues of infringement, the Court should decide both. Stratoflex Inc. v. Aeroquip Corp., 713 F.2d 1530, 1540 (Fed. Cir. 1983).

The first task for this Court is to construe independently the terms of a claim and any disputed claim terms. Claim construction is a matter of law. See Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1451 (Fed. Cir. 1998) (en banc); Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996).

The parties disagree with how the term "or" is used in claim 16 of the 824 patent. The defendants argue non-infringement and invalidity issues based on the ambiguousness of the term "or" in claim 16. They argue that Brown first alleged infringement based on the ability to convert solely two-digit date-data and now alleges infringement on the ability to convert a combination of formatted date-data. They argue that Brown must stick to one particular format and cannot replace or interchange "or" with "and." Brown argues that since the UPI process incorporates the ability to process two-, three- and four-digit date data, processing merely two-digit date-data was sufficient to infringe on the 824 patent.

In order to construe the terms in a claim, the Court must look to the intrinsic evidence and determine whether the inventor used the terms in a claim in accordance with their ordinary meaning. Markman v. Westview Instruments, Inc., 517 U.S. at 388.

The Court finds that the claim term "or" does not limit the date-data to one particular format and Brown is not replacing "or" with "and."

"Or" can be construed in various ways. "Or" is a function word that illustrates the difference between unlike things or actions. It may also be used to indicate a choice between alternative things or courses of action. "Or" can be inclusive, describing a list of alternative things in which one may choose one option or any combination of alternative options. It can also be exclusive, forcing one to choose only one option from the list of things that it conjoins.

"Or" as used in element 6 of claim 16 has always been inclusive, meaning that it was capable of converting only two-digit numbers, only-digit numbers, only four-digit numbers, or any combination of two-, three-, and four-digit numbers.
The evidence supports this interpretation. Nothing Brown alleged has contradicted this claim construction. Brown's allegations that the current defendants and TOCS infringed even though they only converted two-digit numbers, when UPI's process had the ability to process all of these formats, is consistent with this interpretation.

Furthermore, the diagrams in the patent also support the interpretation that "or" is inclusive. The diagram labeled Figure 7 in the patent teaches the ability of the method to convert a combination of formatted data. Each year goes through a conversion mechanism which changes the year into a two-digit year-date representation, regardless if it is in a two-, three- or four-digit format.

Thus, under these circumstances, "or" in element 6 of claim 16 must be construed to include the ability to convert only two-digit, only three-digit, only four-digit, or any combination of two-, three- and four-digit date-data. This interpretation of "or" is within the ordinary meaning of the term, and is further supported by the disclosures in the patent. Based on this interpretation of "or," the Court must find that the terms in claim 16 are unambiguous.

Dr. Brown's patent, filed on May 22, 1997, claims a system for setting the computer clock to an offset time, applicable to records with year date data in "at least one of two-digit, three-digit, or four-digit" representations. Claim 16 is in suit:

16. An apparatus for processing year-date data in a computer system, the apparatus comprising:

   a CPU;

   a bus coupled to the CPU;

   a memory coupled to the bus;

   a system clock coupled to the bus, wherein the system clock is set to an offset time wherein the offset time is a time other than the actual time;

   at least one application program stored in the memory and being executed by the CPU;

   at least one database file stored in the memory containing records with year-date data with years being represented by at least one of two-digit, three-digit, or four-digit year-date representations; and

   a mechanism for converting the year-date data representations in the database file to a two-digit year-date data representation.

(Emphasis added.) During prosecution Dr. Brown identified the TOCS patent (filed on November 14, 1995) as the closest reference.

The district court construed the word "or" in claim 16 as meaning that the apparatus was capable of converting "only two-digit, only three-digit, only four-digit, or any combination of two-, three-, and four-digit date-data." Slip op. at 9. We agree with this construction of the claim, for it is the plain reading of the claim text. These are not technical terms of art, and do not require elaborate interpretation. There is no basis in the specification or prosecution history for reading "or" as "and" -- nor does Dr. Brown request such a reading.
I would reverse. The court errs by reading the claim term "or" exclusively, while the district court appropriately read it inclusively when construing the claim. This is not a case of a species anticipating a genus, or of a combination claimed in the alternative. Instead, the Brown patent teaches an apparatus with additional functionality not disclosed in the allegedly anticipating TOCS patent.

Claim 16 of the Brown patent includes the following limitations:

- at least one database file stored in the memory containing records with year-date data with years being represented by at least one of two-digit, three-digit, or four-digit year-date data representations;

and

- a mechanism for converting the year-date data representations in the database file to a two-digit year-date data representation.

'T824 patent, col. 18, ll. 59-65.

The "mechanism for converting the year-date data representations in the database file" refers to "the" antecedent year-date data representations in the prior limitation. Such data representations may consist of only two-digit dates, only three-digit dates, only four-digit dates, or any combination or sub-combination thereof. Therefore, although the data may vary, the mechanism always must have the capacity to convert all of the possible data sets into two-digit year-date data representations. Moreover, the "mechanism for converting . . ." limitation is stated in means-plus-function format pursuant to 35 U.S.C. § 112, P 6, and must be interpreted by reference to the structure or acts disclosed in the specification. The preferred embodiment in the specification discloses a process for converting all such possible year-date combinations to two-digit representations, before further processing to offset the system clock. See '824 patent, col. 12, l. 5 - col. 13, l. 7. The presence of this disclosure mandates the construction of the "mechanism for converting . . ." limitation as one that requires the capacity to process two-, three- and four-digit dates, even if the full capacity of the device is not always utilized.

To invalidate a patent by anticipation, a prior art reference needs to disclose each and every limitation of the claim. Standard Havens Prods., Inc. v. Gencor Indus., Inc., 953 F.2d 1360, 1369, 21 U.S.P.Q.2D (BNA) 1321, 1328 (Fed. Cir. 1991). The TOCS patent teaches a mechanism for processing two-digit year-date representations by using an offset date other than an actual date. However, it does not disclose a mechanism for converting three- or four-digit year-date representations by using an offset date other than an actual date. Although its specification states that ". . . all date data is preferably converted prior to processing by the application so that the years are confined to a single century," id. at col. 4, ll. 18-20, it discloses no acts or structure to perform this conversion, and makes no mention of reducing three- or four-digit dates to two-digit dates. Therefore, the TOCS patent does not anticipate because it does disclose the "mechanism for converting the year-date data representations" limitation.

Similarly, the test for literal infringement under § 112, P 6 is first, whether the accused device performs an identical function to the one recited in the claim, and, if so, whether the accused device uses the same structure, materials or acts found in the specification, or their equivalents. Gen. Elec. Co. v. Nintendo Co., Ltd., 179 F.3d 1350, 1355, 50 U.S.P.Q.2D (BNA) 1910, 1913-14 (Fed. Cir. 1999). A system made in accordance with the TOCS patent would not literally infringe the '824 patent because it would not perform the function of converting three-digit and four-digit date representations. Therefore, because it would not infringe if later, it cannot anticipate though earlier.

The parties dispute the proper construction of "order" in claim 16 of the 067 patent. I Claim 16 of the 067 patent recites a
memory system, including a nonvolatile semiconductor memory device, comprising a "control means for writing data to said unused blocks on the basis of an order in which said unused blocks are arranged." Toshiba contends that the term "order" here is used in its ordinary sense and should be construed simply as "arrangement." Lexar, on the other hand, argues that Toshiba's proposed construction does not add any value or clarity to the meaning of the claim term and that the construction of "order" should refer to a "chain" arrangement.

--- Footnotes ---
1 The Court notes that Toshiba objects to the inclusion of "order" in the list of claim terms to be construed. According to Toshiba, Lexar originally included the term in its list but removed it; the parties did not discuss the term in the meet and confer process associated with the Joint Claim Construction Statement ("JCCS") and did not include the term in the JCCS. Moreover, according to Toshiba, Lexar only provided its proposed construction of the term two days before Toshiba's opening claim construction brief was to be filed. Toshiba claims that it was prejudiced because it did not have sufficient time to analyze the term or to adequately consider and respond to Lexar's proposed construction. Lexar contends, however, that it listed "order" in its 4-1 disclosures, as required by the Patent Local Rules, and that Toshiba had adequate time to consider and respond, particularly since Lexar offered Toshiba extra time to file its opening brief. The Court finds that Toshiba had adequate time to analyze the term and consider Lexar's proposed construction such that it was not unduly prejudiced.

--- End Footnotes ---

Lexar argues that the specification of the 067 supports its proposed construction because various preferred embodiments teach a chain arrangement. Generally speaking, it is improper to import a limitation from the specification into the claim construction. Markman, 52 F.3d at 980. However, as discussed supra, the Federal Circuit has recently found that where the specification consistently and clearly uses a claim term in a specific way, the claim term may be so limited. Alloc, 342 F.3d at 1368. Here, though, only the third preferred embodiment, described in the Summary of the Invention section, references pointers. ('067 patent 3:35-55.) The other embodiments described contain no such reference. ('067 patent 2:40-45, 3:17-34.) Therefore, the rule announced in Alloc does not apply here and Lexar's construction cannot be right.

Moreover, Lexar's prosecution history argument is equally unavailing. As Toshiba explains, the excerpts of the file history cited by Lexar refer to claims in the 067 that are dependent from claim 16 in which a chain arrangement of unused blocks is expressly disclosed. The excerpts do not read on the construction of "order" in independent claim 16.

Furthermore, Toshiba contends that the doctrine of claim differentiation prohibits referring to a chain arrangement in the construction of "order" in claim 16. Indeed, claim 17, dependent from claim 16, teaches a particular order of unused blocks in which the blocks are arranged in a chain. If the "order" in which the unused blocks, referenced in claim 16, are arranged the same way, there is no purpose for laying out the chain arrangement in claim 17. Elements recited in a dependent claim cannot be read into the broader, independent claim from which it depends. Tandon Corp., 831 F.2d at 1023. Therefore, Toshiba is right that "order" in claim 16 should not be limited to an arrangement of linking in a chain by pointers.

The Court finds, however, that Toshiba's proposed construction, "arrangement," is so simple as to fail to sufficiently explain what "order" means. "Arrangement," adds nothing to the understanding of "order" here. The Court notes that the term "order" refers to how the control means writes data to unused blocks. Therefore, the Court construes "order" in accordance with its ordinary meaning, but places it in the proper context of flash memory technology. "Order" is a logical or comprehensible arrangement of unused blocks.

--- End Notes ---

2. Order List

'172 Patent, Claim 1

ePlus asserts that "order list" needs no construction because it is used consistently with its plain and ordinary meaning. However, if construed, ePlus proposes the meaning: the list of items that you are going to order. Lawson proposes that the
term mean: a list of items derived from a list of selected matching items.

a. Words of the Claims

Claim 1 of the '172 Patent claims an electronic sourcing system comprising:

a database containing data relating to items associated with at least two vendors maintained so that selected portions of the database may be searched separately;

means for entering product information that at least partially describes at least one desired item;

means for searching for matching items that match the entered product information in the selected portions of the database;

means for generating an order list that includes at least one matching item selected by said means for searching;

means for building a requisition that uses data obtained from said database relating to selected matching items on said order list;

means for processing said requisition to generate purchase orders for said selected matching items.

b. Specification

The specification provides that "[o]ne Hit List 47 has been created by TV/2 search program 50, the user can view it and select particular ones of the located catalog items for Order List 48." '172 Patent at 10:22-24. However, the specification further states that, during a search, a "user may also add additional items to the Order List 48 being built in Shell 52 if desired, whether those additional items had been selected from the Hit List 47 or not." Id. at 12:39-41. This makes clear that Lawson's definition, which requires that items on an order list be derived from a list of selected matching items, or the Hit List 47, is incorrect. Rather, the specification shows that items can be added to an order list whether or not they are derived from a list of selected matching items.

Lawson disagrees with ePlus' proposed definition, asserting that an order list is merely an interim list of items that you may order. Lawson argues that construing an "order list" as "items that you are going to order" is incorrect because there are many additional steps that must be taken before the items are ordered and consequently, the items may not be ordered at all. For example, the specification states that an object of the invention is to create an order list and "transfer[] that order list to a requisition/purchasing system for generating a requisition." Id. at 3:1-6. That requisition is later transferred to a purchase order through an inventory sourcing process. Id. at 15:39-41. And, during the inventory sourcing process, the exact item found during a catalog search can be changed to a corresponding item from another vendor. Id. at 14:53-59 ("[A]n entry in an inventory-sourced Requisition Management screen may indicate for a requisitioned item a vendor and vendor catalog number that has been changed, from what was obtained from a catalog search, to a corresponding vendor and vendor catalog number for that item from another source."). Thus, Lawson correctly argues that the exact items on an order list may not be ordered at all.

The specification best describes the "order list" when it provides that it is an object of the invention to "provide an electronic sourcing system capable of creating an order list including desired catalog items located as the result of [] a database search." Id. at 3:1-4.

c. Proper Construction

The words of the claims and the specification make clear that neither of the party's proposed constructions are wholly consistent with the intrinsic evidence. Most significantly, Lawson's definition limits the items on an order list to items originally found on a Hit List. The specification demonstrates that items can be added to an order list whether or not they first appear on a Hit List. And, ePlus' definition suggests that the items on an order list will be ordered, notwithstanding that...
the specification outlines several steps that must take place, and may change the order list, before an actual order is placed. Instead, the specification describes the order list as, and it is construed to mean: a list of desired catalog items.

1. " -order"

Pulse argues no construction of " -order" is necessary apart from that for the " -order (low/high)-pass filter section" term, noting the term is never used apart from the entire filter section phrasing. Pulse therefore argues the term has no independent significance. Alternatively, Pulse proposes that " -order" "identifies the specific components as disclosed in the respective claim."

Unlike Pulse, Mascon parses out this term for a separate construction and alleges the term is indefinite under 35 U.S.C. § 112, second paragraph. In the alternative, Mascon submits the term means "the largest exponent of the transfer function relating the magnitude of the output of a filter in response to an electrical signal applied to the input of the filter" or "the highest exponent of the frequency term in the denominator of the filter's transfer function." 3

3 Contrary to the Patent Local Rules, Mascon offered the latter construction for the first time in its Opening Claim Construction Brief.

When read in the context of the claims and specification, the term " -order" is not indefinite but rather serves to identify the components of the various filter sections. Mascon's proposed constructions have no basis in the patent claims or specifications. While Mascon explained the technical underpinnings of its proposed constructions during the tutorial and oral arguments, employing either one would go beyond the intrinsic evidence. A construction which relies on additional terms, unmentioned in the specification or claims, would merely create potential for confusion for the jury. In addition, construing this term separately "will add no further clarity" as to how one skilled in the art would understand it as used.

The court therefore concludes the term " -order" has no independent significance and does not require specific construction by the court.

Finally, we turn to "trade order." In the '132 patent, patentee claims "displaying an order entry region...for receiving commands from the user input devices to send trade orders..." and "selecting a particular area in the order entry region...to set a plurality of additional parameters for the trade order and send the trade order to the electronic exchange." The '304 patent claims "displaying an order entry region comprising a plurality of locations for receiving commands to send trade orders..." and "in response to a selection of a particular location of the order entry region by a single action of a user input device, setting a plurality of parameters for a trade order relating to the commodity and sending the trade order to the electronic exchange." We construe "trade order" as "a single, electronic message in executable form that includes at least all required parameters of a desired trade." Plaintiff's main concern is with the term "executable." Plaintiff argues that use of "executable" is inconsistent with Figure 1, which shows how a system can be configured to allow for trading in multiple exchanges simultaneously. The figure shows how a user's computer is hooked up to the exchange through a series of routers and gateways. Further, the written description states that "[w]hen the system is configured to receive data from multiple exchanges, then the preferred implementation is to translate the data from various exchanges into a simple format" ('132, 4:28-32; '304, 4:32-35). Plaintiff asserts that a trade order in executable form would be contrary to the translation function. We disagree. First, we note that the patents use the term "execute" throughout the written description. For example, "These embodiments, and others described in greater detail herein, provide the trader with improved efficiency and versatility in placing, and thus executing, trade orders for commodities in an electronic exchange" ('132, 3:21-24; '304, 3:25-28). Second,
we note that the term "executable," as used in this construction, must be viewed from the perspective of the user, not the computer. Once the trader has selected an area in the order entry region, and sent the trade to the market, the user need do nothing further to execute the order. Thus, from the perspective of the trader, the trade has been executed, and must have been in executable form. As with the constructions of "single action" and "order entry region," however, if the computer must perform additional steps or route the order through a router or gateway, such would still fall within the ambit of "trade order," as construed herein.

Order Entry Region

Both patents use the term "order entry region" in claim 1. During the preliminary injunction phase we construed the term to mean "an area comprising a plurality of locations where users may enter commands to send trade orders, and that each location corresponds to a price level along the common static price axis." We see no reason to depart from that construction now.

Along with the debate over "single action of a user input device" (see below), the parties' dispute centers on whether a pop-up window is covered under plaintiff's patents. While that is clearly a question for another day, it can offer context for our construction analysis. See Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1326-27 (Fed.Cir. 2006) ("While a trial court should certainly not prejudge the ultimate infringement analysis by construing claims with an aim to include or exclude an accused product or process, knowledge of that product or process provides meaningful context for the first step of the infringement analysis, claim construction").

Like plaintiff's patents as a whole, "order entry region" should be viewed from perspective of the user, not the computer. With that in mind we accept defendants' argument that "order entry region" is a location within the trading display where a user sends and not simply initiates an order. The patents' written descriptions consistently state that a selection within the order entry region does more than simply initiate an order, it sends or executes the order (see, e.g., '304, 3:9-10; '132, 3:5-6 ("The 'Mercury' display and trading method of the present invention ensure fast and accurate execution of trades . . ."); '304, 3:26-28; '132, 3:22-24 (". . . provide the trader with improved efficiency in placing, and thus executing, trade orders for commodities in an electronic exchange"); '304, 10:34-39; '132, 9:63-67 ("A left click on the IS in the BidQ column will send an order to market to buy 17 lots...of the commodity at a price of 89")). The prosecution history further reveals that patentee originally envisioned claim language that included "[a] method of-initiating placement of a trade order of the commodity through a single action of the user input device with a pointer of the user input device positioned over an area in said dynamic displays of bids and asks" (certified file history for U.S. Patent No. 6,772,132, eSpeed claim construction, cxh. C, at eS64874). Over a year later, the patentee changed the focus of that claim, removing the language "initiating placement" and amending it to read, "method comprising...selecting a particular area in the order entry region through a single action of the user input device with a pointer of the user input device positioned over the particular area to set a plurality of additional parameters for the trade order and send the trade order to the electronic exchange" (id. at cS65203). Thus, from the perspective of the user, selection of an area in the order entry region is the final step in the trader's placement of an order at the market. In other words, the user need not do anything more before the order is entered at the market. If, however, the computer or the exchange had to perform additional steps before the order was actually filled at the exchange, such would still fall within the ambit of "order entry region," as construed herein. n7

n7 Defendant eSpeed again attempts to insert the term "matched" into its construction. As we noted in our preliminary injunction analysis, "[t]he words 'aligned' and 'corresponding' do not mean 'unambiguously matched'" (Trading Technologies I., 370 F.Supp.2d at 700), nor do they mean "matched." As noted above, we construe both terms to mean "in relationship with," which is a broader construction than "matched."
38. The second point of disagreement is the meaning of the terms "fulfill" and "order fulfillment component" in claims 6 and 9, and in particular whether "fulfill" or "fulfillment" refer to computer or physical processes. Though the patent specification does not explicitly define the phrase, order "filling" and "fulfillment" is discussed at length at column 8 and figure 7 in the context of Amazon.com's order consolidation algorithm. That discussion and the entire specification describe only computer processes and an order is defined to be filled "when all its items are currently in inventory (i.e. available) and can be shipped." In addition, Amazon.com's expert Mr. Mulligan testified that an "order fulfillment component" of a "server system" as required by claim 9 is "the software that takes the information provided by the database of the user information and the inventory database and combines those into a shipment order . . . and then notifies that the order is ready for shipment." (Tr. at 165:7-12).

39. Mr. Mulligan's above definition of "order fulfillment component" as a computer program is consistent with the out of court statements by Barnesandnoble.com's Chief Information Officer, Mr King, regarding Barnesandnoble.com's "fulfillment application" in a recent interview with an industry trade press. (See Ex. 8). During cross-examination Mr. King testified that "fulfillment application" was a commonly used term in the industry to refer to computer programs associated with the fulfillment process. (Tr. at 432:25-433:8). The Court therefore finds that "order fulfillment component" as used in claim 9 refers to order fulfillment application software described by Mr. Mulligan and Mr. King.

40. Similarly, the Court finds that the term "fulfill" as used in claim 6 in the phrase, "so that the server system can fulfill the generated order," refers to processes performed by the order fulfillment component of (or order fulfillment application running on) the server system and does not include the physical steps of handling or packing tangible items.

B. "Ordered List."

The term "ordered list" was used in each independent claim of the '381 patent. For example, claim 14 recited (col. 13:64-14:17):

14. A computer-implemented method for renting movies to customers, the method comprising:

   providing electronic digital information that causes one or more attributes of movies to be displayed;

   establishing, in electronic digital form, from electronic digital information received over the Internet, a movie rental queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer.

   causing to be delivered to the customer up to a specified number of movies based upon the order of the list, wherein the customer is not required to return the movies within a specified time associated with delivery;

   in response to one or more delivery criteria being satisfied, selecting another movie based upon the order of the list and causing the selected movie to be delivered to the customer; and

   in response to other electronic digital information received from the customer over the Internet, electronically updating the movie rental queue.

Netflix proposes that the term "ordered list" should mean a "list specifying the customer's desired rental order" while Blockbuser contends that it should mean "names or other representations of two or more items, arranged so that one or more of the items is before or after one or more other items."

Like all the other disputed terms, "ordered list" has a commonly-understood meaning. Any juror, having likely done grocery shopping in his or her life, is familiar with a list: a series of items. The term "ordered" indicates that the arrangement of
items on the list is dictated by some logic, rule, or governing principle. Taken by themselves, these terms are easily understood by the layperson. They need no clarification.

The question now becomes whether or not the use of the term "ordered list" in the claims and specification indicates the customer's desired rental order. This order holds that it does not. First, the use of the term within the claims is instructive. As shown above, claim 1 recited "a movie rental queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer." The ordered list is a component of the queue that has its own sequence. Second, as mentioned above, reading the limitation that the ordered list must be according to the customer's desired order would render claim 6 of the '381 patent redundant.

Patent terms must be construed in light of the invention's purpose. Nystrom v. TREX Co., Inc., 424 F.3d 1136, 1144 (Fed. Cir. 2005). Netflix argues that it would defeat the invention's purpose if any order other than the one specified by the customer were used in the ordered list. The '450 patent stated that the invention's purpose was to ensure that "the greatest number of customers are provided with their most preferred items. For example, customers may specify priorities for the items indicated by the item selection criteria" (col. 11:17-21). This purpose, however, does not absolutely demand that the only sequence in the ordered list is that specified by the customer. The use of the term "may" indicates that the customer has the ability, but is not required, to rank the items in the ordered list in his or her preferred sequence. Indeed, items in the ordered list may merely appear in some computer-assigned default order such as the chronological order in which they were added to the list.

Netflix, in its responses to the tentative claim-construction ruling, argues that the ordered list may include items arranged by some default order, however, the items in the list only have an order once the customer looks at them. The customer can either rearrange the items according to his or her preference, or adopt the order in which the items already appeared. Only then after the customer has approved the sequence, Netflix argues, is the "ordered list" truly the claimed ordered list. The specification of the '381 patent does not teach how the customer handles or interacts with the "ordered list;" it only addresses the queue. This gloss on the Court's definition of "ordered list" lacks support and will not be adopted.

The prosecution history of the '381 patent also supports this construction. The examiner rejected all pending claims for not meeting the statutory subject matter requirement under 35 U.S.C. 101 . The applicants overcame the examiner's rejection by arguing that the useful, tangible result of their invention was to rent movies to customers based on the order of the customer's preference. That result brought the invention within the scope of the technological arts (Ramani Decl. Exh. 11). As discussed below, plaintiffs distinguish between the use of the term "based on" an "in" when ordering items. Again, the use of the phrase "based on" indicates that the ordered list may reflect the customers preferences exactly, but need not necessarily do so.

Finally, Blockbuster argues at length that Netflix's proposed definition of this term conflates it with the term "movie/item rental queue." Netflix's proposed definition of "movie/item rental queue" is "sequence of items/movies used by a rental provider to determine which items/movies to deliver." Both terms refer to a grouping of items placed in some kind of sequence or order. The rental queue reflects the provider's priorities in addition to customer preferences, while the ordered list includes items for possible rental to the customer, the order of which is determined at least in part by the customer, but may be based on some default order.

To borrow from the example Blockbuster used in its brief, the provider could automatically add all adventure movies starring Harrison Ford to the rental queue based on the customer's selected criteria ('450 patent, col. 8:54-60). The customer can then see that these movies were added to her rental queue and decide that she prefers The Empire Strikes Back to Indiana Jones and the Temple of Doom. Accordingly, she can place one ahead of the other within the queue set up by the system, resulting in her "ordered list." She might choose to put them in some order with respect to her other selections. She might also choose to leave Patriot Games, another selection added to her queue, in the order in which the provider added it. The provider, in selecting a movie to rent, may discover that it has no copies of Empire Strikes Back, a and will accordingly rearrange the queue to select another movie to rent to the customer.

This order holds that the term "ordered list" will be given its plain meaning. The ordered list may be, but is not required to be, ordered precisely according to the customer's preferences; it could also include some other default order.

GO BACK
An ordered sequence of process steps

The parties now appear to be in agreement on the proper construction of "an ordered sequence of process steps." In its bench book for the Markman hearing, ITI concedes that either parties' proposal can be used. Defendants' proffered construction involves specifying the order in which each process step must take place. In its bench book, ITI proposes a construction with slight variations: specifying the order in which process steps take place. The Court agrees with ITI that the words "each" and "must" are unnecessary; in fact, including "must" runs counter to the concept that the order of the steps can change as a result of manufacturing plant conditions, as the portion of claim 34 immediately following this limitation provides. The Court therefore construes the limitation to mean specification of the order in which process steps take place.

C. Ordering

<table>
<thead>
<tr>
<th>Leader's Construction</th>
<th>Facebook's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Organizing</td>
<td>Placing into a fixed sequence</td>
</tr>
</tbody>
</table>

The term "ordering" is recited in Claim 17. Leader proposes that "ordering" be construed to mean "organizing" because the terms are used interchangeably in the computer science field when referring to data stored on a computer. (D.I. 179, at 9.) Further, Leader contends that its proposed construction comports with the plain language used in the Claim, and is consistent with the specification. Facebook also contends that its proposed construction, "placing into a fixed sequence," is what one of ordinary skill in the art understands "ordering" to mean. (D.I. 191, at 31.) Facebook argues that the surrounding language in Claim 17 "clearly implies a relationship between environments that is based on placement into a fixed sequence." (Id. at 32.) Moreover, Facebook contends that the specification supports its proposed construction because Claim 17 is discussed in the context of a routing algorithm which defines sequential arrangements. (Id.)

The Court concludes that Facebook's proposed construction reads in a limitation not supported by either the language of Claim 17 or the specification, and thus, will adopt Leader's construction. In relevant part, Claim 17 claims:

17. A computer-implemented method of managing data, comprising computer-executable acts of:

   generating a plurality of user environments in a web-based system;

   ordering two or more of the plurality of user environments according to different arrangements of the user environments;

   storing in a storage component ordering information related to the ordering of the two or more of the plurality of user environments;

   traversing the different arrangements of the user environments with one or more of the applications based on the ordering information to locate the data associated with the user environment.

'761 patent, col. 22:12-34 (emphasis added). As Facebook alleges, the claim language surrounding the term "ordering" does imply a relationship between user environments. The Claim consistently specifies the manner in which the relationship between user environments is achieved: "according to different arrangements of the user environments." Id. However, nothing in the literal claim language suggests that the "ordering" of the user environments according to "different arrangements" necessarily means that the user environments are placed in a fixed sequence.

The parties do not agree on which portion of the specification applies to Claim 17. Facebook directs the Court's attention to
a portion of the specification describing Figure 4B. In Figure 4B, "there is illustrated board/web relationship diagram 402." '761 patent, col. 8:18-19. This embodiment teaches that "[b]oards can exist in any number of webs," and that "[t]he web represents a certain view of the relationship among boards." '761 patent, col. 8:19-22. Further,

[t]he disclosed system has associated therewith a routing algorithm, referred to herein as a 'webslice'. A webslice is a relationship rule that defines a relationship between a web and one or more boards of that web. If a web changes (e.g., a board is added), and meets the criteria of the rule, the content will be on the new board as well.

'761 patent, col. 8:59-64. Facebook contends that this routing algorithm defines the sequential arrangements in which the user environments may be placed, but upon review of the specification as a whole, the Court disagrees.

The Summary of the Invention states that "[w]hen a user logs in to the system that employs the tool, the user enters into a personal workspace environment. This workspace is called a board, and is associated with a user context." '761 patent, col. 3:32-35. Further, the Summary of the Invention states that "[t]wo or more boards (or workspace environments) can be grouped as a collection of boards, also called a web." '761 patent, col. 3:64-66. These terms, "workspace environment" and "board" appear to be used consistently throughout the '761 patent. Understood as such, the routing algorithm (or webslice) defines the relationship between a web (or collection of boards) and one or more boards (or workspace environments) within that web. By its terms, the routing algorithm does not define the relationship between user environments within the web, and thus, does not support Facebook's proposed limitation. Accordingly, the Court concludes that "ordering" means "organizing."

Claim 20 describes a method for storing the analog and digital signals involving "converting," "formatting," "ordering," and "compressing." The parties dispute the proper construction of the "converting," "formatting" and "ordering" steps.

The specification describes the process of converting and formatting the information:

When the information from identification encoder 112 is digital, the digital signal is input to the digital input receiver 124 where it is converted to a proper voltage. A formatter 125 sets the correct bit rates and encodes into least significant bit (lsb) first pulse code modulated (pcm) data. Formatter 125 includes digital audio formatter 125a and digital video formatter 125b. The digital audio information is input into a digital audio formatter 125a and the digital video information, if any, is input into digital video formatter 125b. Formatter 125 outputs the data in a predetermined format.

When the retrieved information from identification encoder 112 is analog, the information is input to an analog-to-digital converter 123 to convert the analog data of the retrieved information into a series of digital data bytes. Converter 123 preferably forms the digital data bytes into the same format as the output of formatter 125.

('992 Patent, Col. 7:1-18.)

In the July 12 Order, the Court construed the phrase "ordering means for placing the formatted data into a sequence of addressable data blocks" as a means-plus-function element. In a means-plus-function claim, the claims specify the function and the specification details the structure. The Court identified the "time encoder" (FIG. 2a 114) and its equivalents as the corresponding structure.

Claim 20 is not a means-plus-function claim. Thus, importing limitations from the specification is not appropriate. In Claim 20, the phrase "ordering into ... a sequence of addressable data blocks" is a very broad limitation which could include time encoding, as well as other ways of generating addressable data blocks. The parties have requested that the Court construe the word "addressable" as it applies to the data blocks. The specification contains the following with respect to the phrases "address" and "addressability."

Stored items are preferably accessed in compressed data library 118 through a unique address code. The unique address
code is a file address for uniquely identifying the compressed data items stored in the compressed data library section of a library system. This file address, combined with the frame number, and the library system address allow for complete addressability of all items stored in one or more compressed data libraries.

(‘992 Patent, Col. 10:46-57.) It is clear that there are multiple uses of the phrases "address" and "addressable." The ordering step in Claim 20 follows the conversion and formatting steps, and precedes the compression step. The claim element requires that the formatted and converted data be ordered into a sequence of addressable data blocks. The term "addressable" in the context of Claim 20 refers to the addressability of portions of the information within a file, and is not physical storage addresses.

The Court construes "ordering the converted analog signals and the formatted digital signals into a sequence of addressable data blocks" as follows:

In a distribution method in which a transmission system stores the information, "ordering the converted analog signals and the formatted digital signals into a sequence of addressable data blocks" means "in the transmission system placing the converted analog signals and the formatted digital signals into a sequence of data blocks, such that the ordering of the data blocks permits the retrieval of portions of information from items." "Addressable" does not refer to physical storage locations, but rather to positions relative to the beginning of a file containing information.

2998

TERM # 21: "ordering the interest cost values associated with said inputted data." - Defendants claim that the ordering must occur prior to the "transmitting" step. On this point, we agree with defendants. Although we recognize that we need not require that the steps in a process occur in the same order that they appear in a claim, in this case, we find evidence from the claim language itself that the interest cost values can only be transmitted after they are put in some order. The transmitting step refers back to "said interest cost values". At least one interest cost value is "automatically computed" and interest cost values are then ordered. The first time that plural interest cost values are required is in the ordering step. The transmitting step speaks to previously mentioned plural interest cost values. These values must come from the ordering step. For this reason, based on the structure of the claim, we agree with defendants on this issue. This phrase means: "placing the interest cost values in some order before transmission to the issuer's computer".

2999

B. Pricer Patents

Trilogy's second group of patents are referred to as the Pricer patents. There is only one non-means-plus-function term remaining in dispute—"organizational groups." Trilogy contends that the term "organizational groups" means "one or more entities grouped together." Selectica contends the term means "a group of purchasing organizations where each group has a characteristic."

The 400 patent provides:

The invention operates under a simple paradigm of WHO (the purchasing organization) is buying WHAT (the product). In the invention the WHO is defined by creating an organizational hierarchy of purchasing organizations. A "purchasing organization" (also referred to as a customer) may be a single person. . . . A purchasing organization may also be a larger entity, such as a company. One or more customers (i.e. purchasing organizations) may be members of each organizational group and each customer may be a member of more than one organizational group. Similarly, one or more products may be members of each product groups and each product may be a member of more than one product group.

‘400 patent, col. 6, 11. 3-16. In addition, the patent states:
In the invention the WHO is defined by creating an organizational hierarchy of organizational groups, where each group represents a characteristic of the organizational group.

'400 patent, col. 3, 11.24-25 (emphasis added). The specification explains that the invention "allows pricing rules to be based on characteristics of each organizational group instead of basing the rules on a per-customer basis." 400 patent, col. 3, 11. 35-38 (emphasis added). Thus, considering the claim language in the context of the specification, the court adopts Selectica's construction and construes "organizational groups" to mean "groups of purchasing organizations where each group has a characteristic." See Selectica's Response Brief, at 31 (offering revised construction).

3000

c. "Originating Processor" and "Originated Information"

The parties dispute the construction of the term "originating processor" recited in the claims of the '960, '670, and '592 patents n6 and "originated information" recited in the claims of the '960, '670, '592, and '451 patents. n7 Claim 1 of the '960 patent, from which claim 15 ultimately depends, again is exemplary and states in pertinent part:

1. A system for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising:

   at least one gateway switch in the electronic mail system, one of the at least one gateway switch receiving the originated information and storing the originated information prior to transmission of the originated information to the at least one of the plurality of destination processors;

   a RF information transmission network for transmitting the originated information to at least one RF receiver which transfers the originated information to the at least one of the plurality of destination processors;

   at least one interface switch, one of the at least one interface switch connecting at least one of the at least one gateway switch to the RF information transmission network and transmitting the originated information received from the gateway switch to the RF information transmission network; and wherein

   the originated information is transmitted to the one interface switch by the one gateway switch in response to an address of the one interface switch added to the originated information at the one of the plurality of originating processors or by the electronic mail system and the originated information is transmitted from the one interface switch to the RF information transmission network with an address of the at least one of the plurality of destination processors to receive the originated information added at the originating processor, or by either the electronic mail system or the one interface switch ...

'960 patent, col. 49, ll. 2-38 (emphases added).

--- Footnotes ---

n6 This term appears in all of the asserted claims of the '960 and '670 patents, and in parent claim 25 of asserted claim 40 of the '592 patent. A variation, "originating device," is used in claims 40, 150, 278, 287, 653, and 654 of the '592 patent. "Originating device" was separately construed by the district court and that construction has not been appealed.

n7 This term appears in all of the asserted claims of the '960 and '670 patents. A variation, "originating electronic mail," is used in claims 313 and 317 (both depending from independent claim 311) of the '451 patent. A slightly different variation, "originate the electronic mail," is used in claims 40 (depending from independent claim 1), 150, 278, and 287 of the '592 patent. We treat these variations as being of identical scope and meaning to the term "originating information" as discussed in our opinion.

--- End Footnotes ---
The district court construed "originating processor" as "any one of the constituent processors in an electronic mail system that prepares data for transmission through the system." Claim Construction Order, slip op. at 5. The court construed "originated information" as "the message text of an electronic mail message." Id., slip op. at 6 (noting an exception for the term as used in a patent which is not disputed on appeal).

RIM argues that "originating processor" is correctly construed to mean a processor that initiates or starts the transmission of data through the system, thereby excluding any of the "constituent processors" in the system which subsequently handle the data. It argues that "originated information" is the electronic mail message generated by an "originating processor." RIM argues that its constructions are supported by dictionary definitions of the term "originating" and "originate" which impose an "initiating" requirement on the claims. RIM argues that the '960 patent specification supports this construction, because it describes an "originating processor" as a processor at which an electronic mail message is composed by a person or inputted by a machine.

NTP responds that this dispute centers on whether an "originating processor" can include gateway switches. Before the district court, NTP urged that "originating processor" be construed to include not only "that processor upon which the sender types the message," but also "all of the constituent processors in an electronic mail system that run electronic mail programming to format and initiate transmission of electronic mail messages." NTP's Claim Construction Mem. at 37. NTP argues that RIM's proposed construction is erroneous because it ignores language in the written description specifying that a gateway switch can originate information, and thus would exclude embodiments in the written description. NTP argues that a construction which limited "originating processor" to only processors upon which senders actually type the electronic mail message is not required by RIM's dictionary definitions.

As we shall explain, we conclude that the district court erred in its claim construction of the term "originating processor." The term "originating processor" is properly construed as "a processor in an electronic mail system that initiates the transmission of a message into the system." We do not hold that the "originating processor" is always the processor on which text of the email message was created. As a practical matter this will probably be the case. However, there could be a situation where someone composes an email message on one processor, then perhaps transfers the message from the creating processor to the "originating processor" that initiates the message into the electronic mail system; e.g., by copying onto a disk.

Further, we conclude that the district court did not err in construing "originated information" as "the message text of an electronic mail message." RIM focuses its argument on the term "originating processor." Indeed, RIM presents no independent argument that "originated information" means anything other than the text of an electronic mail message to be transmitted in the electronic mail system. We see no reason to disturb the district court's claim construction of the term "originating information."

We begin with the language of the claims. See PSC Computer Prods., Inc. v. Foxconn Int'l, 355 F.3d 1353, 1359 (Fed. Cir. 2004). Claim 1 of the '960 patent recites:

1. A system for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising: ... at least one gateway switch in the electronic mail system ...

   at least one interface switch ...

'960 patent, col. 49, ll. 2-19 (emphases added). Construing "originating processor" to mean the processor that is the origin of the email message text comports with the goal of the system--to move "originated information" from the processor where the email message text originated to the processor(s) where it is intended to be received. Moreover, that construction is consistent with the overall context of the claim language. Claim 1 of the '960 patent contains a number of limitations relating to devices that process data, including, inter alia: "a plurality of originating processors," "at least one gateway switch," and "at least one interface switch." See '960 patent, col. 49, ll. 2-25. Nothing in the claim suggests that "a plurality of originating processors" defines a genus which includes the claimed "gateway switch" or "interface switch" as a species. Instead, these limitations are used as three separate, independent limitations to describe the various constituent components in an electronic mail system that prepares and transmits electronic mail messages. There is no antecedent basis in the claim.
language to signify that "at least one gateway switch" conceptually is contained within "a plurality of originating processors." See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1119 (Fed. Cir. 2004) ("While not an absolute rule, all claim terms are presumed to have meaning in a claim.").

In addition, as claim 1 above recites, the "originated information" originates from the "originating processor." '960 patent, col. 49, ll. 2-3. Thus, the plain language of the claims indicates that "originating processor" is not referring to every component that initiates data. Rather the "originating processor" is, more precisely, the processor that is the source of the "originated information"--the text of the electronic mail message.

Also, the claim language shows how a gateway switch is not included within the larger term "originating processor," but is rather a separate component from an "originating processor." That is because the "originated information" is transmitted from an "originating processor" to a gateway switch. Indeed, the "originating processor" and the gateway switch initiate different types of data. "Originated information"--the electronic mail message--originates with the "originating processor." By contrast, the gateway switch is never described as being the origin of the "originated information." Rather, it merely "receives" the "originated information" from the "originating processor." See, e.g., id. at col. 49, ll. 8-9; '611 patent, col. 19, ll. 60-63, col. 47, ll 52-54. A gateway switch may sometimes add or initiate address information such as an address of an interface switch to the "originated information" that it receives from the "originating processor." See, e.g., '960 patent, col. 49, ll. 26-37. However, a gateway switch is not the origin of the "originated information" itself. According to the language of the claims, gateway switches are components that receive "originated information" from an "originating processor" and then sometimes append additional data to the information received from an "originating processor."

The written description is consistent with this interpretation and reveals that two different types of information are "originated" and transmitted within the claimed invention. First, there is "originated information." As the district court correctly held, "originated information" refers to the text of the electronic mail message being transmitted. One could analogize this to the contents of a physical letter one mails to a recipient via the postal system. Second, in the claimed invention there is also what one might call address information or destination information. This refers to an identifier of the intermediate components and/or the destination processor(s) to which the electronic message text should be delivered. See, e.g., '960 patent, col. 24, ll. 31-46 (discussing "address of the interface switch" and "identification number of the RF receiver"). Address information originated from a gateway switch or interface switch is never described as itself the "originated information" or the "other originated information." Rather, it is described as separate information which is added to the "originated information" which came from an originating processor. See, e.g., id. at col. 21, ll. 54-56 (text notes that the address of the interface switch can be added "to the information originating from the originating processor"); id. at col. 22, ll. 24-26 (text notes that the destination address can be "added to the information from the originating processor"); id. at col. 26, ll. 39-41 (text notes adding information to the "information from the originating processor"); id. at col. 49, ll. 27-29 (claims describe "adding" address information to "originated information"); id. at col. 50, ll. 7-10 (text describes movement of both "originated information" and identification number in the RF transmission network); id. at col. 54, ll. 49-51 (text notes identification number "added to the originated information"). This address information can be analogized to the address contained on the outside of an envelope that one mails with the post office, as well as information added by the post office, such as a barcode, which may direct the envelope through the myriad routes in the postal system. Thus, just as one physically mails a letter with two types of information--the text of the actual letter itself within the envelope and the address information on the outside of the envelope--the claimed invention "originates" two types of information.

From the written description, one skilled in the art would understand an "originating processor" to refer to a processor where "originated information"--the electronic mail message text--is introduced into the electronic mail system. In some cases, this "originating processor" is the point at which some or all of the second type of information, the address information, is added. In other cases, after the "originating processor" sends the "originated information" to a gateway switch, the gateway switch then "originate" and appends additional address information onto the "originated information." A user typing at the originating processor does need to provide at least some address destination information--for example, that the email message is intended for "John Doe." See, e.g., id. at col. 24, ll. 29-30. However, the user need not know precisely through which switches the email message needs to travel within the system to get to John Doe (or even whether John Doe's destination processor is a wireless or wireline processor). In the "most user friendly form" of the invention, the user need only indicate the intended recipient, and the proper address information can be added to the text of the electronic mail message either by the originating processor itself or by later components in the electronic mail system, such as gateway switches and/or interface switches. See, e.g., id. at col. 24, ll. 25-30. This is analogous to how, in the postal system, one need only indicate a destination address, and the postal system sometimes adds barcode information to envelopes which help
The term "originating processor" does not encompass every constituent processor that initiates data into the system. "Originating processor" refers more precisely to the processor that initiates the electronic message text into the system. It is correct to conclude that other components besides an "originating processor" "originate" information. For example, components such as the gateway switches originate some of the address information to get the electronic message from the "originating processor" to the proper destination processor(s). However, there is nothing in the written description to suggest that one skilled in the art would blur the distinction between a component such as a gateway switch that sometimes "originate" address information, and an "originating processor," which is a separately labeled and separately claimed component than a gateway switch or an interface switch.

Referring specifically to the written description, Figure 1 of the '960 patent discloses a prior art electronic mail system in which the "originating processor" is depicted as the processor which originates the email message, which is separate and distinct from other constituent components such as gateway switches:

[SEE PRIOR ART IN ORIGINAL]

The specification states that Figure 1 shows "communications between an originating processor A-N, which may be any of the processors within the groups of associated processors # 1-# 3 or processor # N and a destination processor A-N are completed through the public switch telephone network 12 to one or more gateway switches ..." 960 patent, col. 2, ll. 23-28 (emphases added). This passage explains that the electronic mail message originates from the "originating processor" and then moves "to" an associated gateway switch. Thus, the "originating processor" is not a generic term referring to all data-generating constituent processors in a system, but more precisely refers to a processor that is separate from the gateway switches. Moreover, the written description repeatedly refers to the "originating processor" where the electronic mail message text is generated. See, e.g., id. at col. 3, ll. 12-21 ("Finally, the message or message text must be entered which is the information that is inputted by the person or machine which is originating the message at the originating processor A-N. Upon completion of the message text, the user ...enters a series of commands or keystrokes on the originating processor to transmit the message to the gateway switch ....") (emphasis added); id. at col. 19, ll. 29-30 (explaining how, in the claimed invention, the "originating processor" might be associated with "an icon driven display" and a computer "mouse" for the user). There is no corresponding discussion of the electronic mail message text being generated with, or the use of "an icon driven display" with, a gateway or interface switch.

Components other than an "originating processor" can initiate data. The written description describes how, for example, "the identification of the RF receiver 119 and the address of the interface switch may be implemented by the originating processor A-N of one of the computing systems # 1-# N, a gateway switch 14 or an interface switch 304 ...." Id. at col. 24, ll. 42-46. This shows that three different components can initiate address information: (1) an "originating processor" A-N; (2) a gateway switch 14; or (3) an interface switch 304. However, simply because the "originating processor" is but one of three separate, differently named and labeled components that can serve as the initiator of address information, does not mean that the term "originating processor" covers all of these different components. If "originating processor" referred to all three components, then the specification would simply read "the identification of the RF receiver 119 may be implemented by an originating processor."

The specification makes clear that it may take several processors in Campana's claimed invention to successfully initiate an electronic mail message. As Campana teaches in his written description, to initiate an electronic mail message, the message text must be entered, then the addresses of various interface switches and the receiving destination processor must be entered and appended to the message. See id. at col. 19, ll. 26-39. The written description also teaches that entering the addresses of the interface switches, RF receivers, and destination processors may be accomplished by various components, including the originating processor or a gateway switch. See id. at col. 21, ll. 54-56, 65-66 (noting that the address of the receiving interface switch may be added by the originating processor or a gateway switch); id. at col. 22, ll. 10-15, 24-26 (noting that the address of the destination processor may be added by "the originating processor by an operator or a machine using the originating processor" or the gateway switch). However, the mere fact that a constituent component may tack on destination address information to the "originated information" coming from the "originating processor" does not turn that constituent processor into an "originating processor." Gateway switches are separate components from the "originating processor" that can also add address information after receiving the message text from the "originating processor." This is why Campana asserts that the invention is "user friendly" because only a "minimum amount of information ...must be
provided to initiate the transmission of electronic mail from an originating processor to at least one destination processor." Id. at col. 19, ll. 20-25.

The written description further describes how either the "originating processor," "gateway switch," or "interface switch" can be used to add information needed to transmit the electronic mail message, such as addressing data. See id. at col. 22, ll. 24-26 ("The address of the destination processor may also be added to the information originated by the originating processor by the gateway switch."). Figure 11 of the '960 patent visually demonstrates various steps by which the "originating processor," "gateway switch 14," and "interface switch 304" could operate together to add address information to the text of the electronic mail message, i.e., the "originated information":

* * *

See '960 patent, col. 28, ll. 10-13 ("Figure 11 summarizes electronic mail message entry methods for messages (information) originating from originating processors within an electronic mail system." (emphasis added)). The arrows show the flow of the "originated information" from the "originating processor," the first processor in the system where the information is originated, to a gateway switch 14, and then to an interface switch 304. Campana describes the flow of data in the various entry methods. For example, in "entry method 1" the "originating processor" itself adds the appropriate destination address data. Id. at col. 28, ll. 13-17. When the "originated information" then reaches a gateway switch 14, the gateway switch takes no action, because all of the address data necessary at that point has already been added by the "originating processor." By contrast, in "entry method 3," a gateway switch, after receiving the "originated information" from the "originating processor," adds the wireless destination address. Id. at col. 28, ll. 24-29. Although under the various methods enumerated in Figure 11 either the "originating processor," "gateway switch," or "interface switch" may add address information to the electronic mail message, the gateway and interface switches do not initiate the message text of an electronic mail message and, thus, are not "originating processors."

This shows how the "originating processor" merely refers to the first (initiating) processor of the "originated information." A gateway switch is not an "originating processor." While the gateway switch serves as an initiator of address information, as in entry methods 3, 4, and 5, a gateway switch only does this after it gets the "originated information" from the "originating processor." "Originating processor" is not an umbrella term referring to all of the processors that add data into the system, but rather would be understood to one skilled in the art to be the first processor, or the initial source of the "originated information" or email message text. All three different components in Figure 11, an "originating processor," a "gateway switch," and an "interface switch," are initiating address information. "Originating processor" refers to one of these components—the first processor, and not all three. Thus, the "originating processor" is the sole processor that initiates the transmission of the electronic mail message text into the electronic mail system and is separate from the gateway or interface switches.

3001

c. "Originating Processor" and "Originated Information"

The parties dispute the construction of the term "originating processor" recited in the claims of the '960, '670, and '592 patents n6 and "originated information" recited in the claims of the '960, '670, '592, and '451 patents. n7 Claim 1 of the '960 patent, from which claim 15 ultimately depends, again is exemplary and states in pertinent part:

1. A system for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising:

   at least one gateway switch in the electronic mail system, one of the at least one gateway switch receiving the originated information and storing the originated information prior to transmission of the originated information to the at least one of the plurality of destination processors;

   a RF information transmission network for transmitting the originated information to at least one RF receiver which transfers the originated information to the at least one of the plurality of destination processors;
at least one interface switch, one of the at least one interface switch connecting at least one of the at least one gateway switch to the RF information transmission network and transmitting the originated information received from the gateway switch to the RF information transmission network; and wherein

the originated information is transmitted to the one interface switch by the one gateway switch in response to an address of the one interface switch added to the originated information at the one of the plurality of originating processors or by the electronic mail system and the originated information is transmitted from the one interface switch to the RF information transmission network with an address of the at least one of the plurality of destination processors to receive the originated information added at the originating processor, or by either the electronic mail system or the one interface switch...

960 patent, col. 49, ll. 2-38 (emphases added).

--- Footnotes ---

n6 This term appears in all of the asserted claims of the '960 and '670 patents, and in parent claim 25 of asserted claim 40 of the '592 patent. A variation, "originating device," is used in claims 40, 150, 278, 287, 653, and 654 of the '592 patent. "Originating device" was separately construed by the district court and that construction has not been appealed.

n7 This term appears in all of the asserted claims of the '960 and '670 patents. A variation, "originating electronic mail," is used in claims 313 and 317 (both depending from independent claim 311) of the '451 patent. A slightly different variation, "originate the electronic mail," is used in claims 40 (depending from independent claim 1), 150, 278, and 287 of the '592 patent. We treat these variations as being of identical scope and meaning to the term "originating information" as discussed in our opinion.

--- End Footnotes ---

The district court construed "originating processor" as "any one of the constituent processors in an electronic mail system that prepares data for transmission through the system." Claim Construction Order, slip op. at 5. The court construed "originated information" as "the message text of an electronic mail message." Id., slip op. at 6 (noting an exception for the term as used in a patent which is not disputed on appeal).

RIM argues that "originating processor" is correctly construed to mean a processor that initiates or starts the transmission of data through the system, thereby excluding any of the "constituent processors" in the system which subsequently handle the data. It argues that "originated information" is the electronic mail message generated by an "originating processor." RIM argues that its constructions are supported by dictionary definitions of the term "originating" and "originate" which impose an "initiating" requirement on the claims. RIM argues that the '960 patent specification supports this construction, because it describes an "originating processor" as a processor at which an electronic mail message is composed by a person or inputted by a machine.

NTP responds that this dispute centers on whether an "originating processor" can include gateway switches. Before the district court, NTP urged that "originating processor" be construed to include not only "that processor upon which the sender types the message," but also "all of the constituent processors in an electronic mail system that run electronic mail programming to format and initiate transmission of electronic mail messages." NTP's Claim Construction Mem. at 37. NTP argues that RIM's proposed construction is erroneous because it ignores language in the written description specifying that a gateway switch can originate information, and thus would exclude embodiments in the written description. NTP argues that a construction which limited "originating processor" to only processors upon which senders actually type the electronic mail message is not required by RIM's dictionary definitions.

As we shall explain, we conclude that the district court erred in its claim construction of the term "originating processor." The term "originating processor" is properly construed as "a processor in an electronic mail system that initiates the transmission of a message into the system." We do not hold that the "originating processor" is always the processor on which text of the email message was created. As a practical matter this will probably be the case. However, there could be a situation where someone composes an email message on one processor, then perhaps transfers the message from the creating processor to the "originating processor" that initiates the message into the electronic mail system; e.g., by copying onto a disk.
Further, we conclude that the district court did not err in construing "originated information" as "the message text of an electronic mail message." RIM focuses its argument on the term "originating processor." Indeed, RIM presents no independent argument that "originated information" means anything other than the text of an electronic mail message to be transmitted in the electronic mail system. We see no reason to disturb the district court's claim construction of the term "originating information."

We begin with the language of the claims. See PSC Computer Prods., Inc. v. Foxconn Int'l, 355 F.3d 1353, 1359 (Fed. Cir. 2004). Claim 1 of the '960 patent recites:

1. A system for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising: ...

    at least one gateway switch in the electronic mail system ...

    at least one interface switch ...

'960 patent, col. 49, ll. 2-19 (emphases added). Construing "originating processor" to mean the processor that is the origin of the email message text comports with the goal of the system--to move "originated information" from the processor where the email message text originated to the processor(s) where it is intended to be received. Moreover, that construction is consistent with the overall context of the claim language. Claim 1 of the '960 patent contains a number of limitations relating to devices that process data, including, inter alia: "a plurality of originating processors," "at least one gateway switch," and "at least one interface switch." See '960 patent, col. 49, ll. 2-25. Nothing in the claim suggests that "a plurality of originating processors" defines a genus which includes the claimed "gateway switch" or "interface switch" as a species. Instead, these limitations are used as three separate, independent limitations to describe the various constituent components in an electronic mail system that prepares and transmits electronic mail messages. There is no antecedent basis in the claim language to signify that "at least one gateway switch" conceptually is contained within "a plurality of originating processors." See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1119 (Fed. Cir. 2004) ("While not an absolute rule, all claim terms are presumed to have meaning in a claim.").

In addition, as claim 1 above recites, the "originated information" originates from the "originating processor." '960 patent, col. 49, ll. 2-3. Thus, the plain language of the claims indicates that "originating processor" is not referring to every component that initiates data. Rather the "originating processor" is, more precisely, the processor that is the source of the "originated information"--the text of the electronic mail message.

Also, the claim language shows how a gateway switch is not included within the larger term "originating processor," but is rather a separate component from an "originating processor." That is because the "originated information" is transmitted from an "originating processor" to a gateway switch. Indeed, the "originating processor" and the gateway switch initiate different types of data. "Originated information"--the electronic mail message--originates with the "originating processor." By contrast, the gateway switch is never described as being the origin of the "originated information." Rather, it merely "receives" the "originated information" from the "originating processor." See, e.g., id. at col. 49, ll. 8-9; '611 patent, col. 19, ll. 60-63, col. 47, ll. 52-54. A gateway switch may sometimes add or initiate address information such as an address of an interface switch to the "originated information" that it receives from the "originating processor." See, e.g., '960 patent, col. 49, ll. 26-37. However, a gateway switch is not the origin of the "originated information" itself. According to the language of the claims, gateway switches are components that receive "originated information" from an "originating processor" and then sometimes append additional data to the information received from an "originating processor."

The written description is consistent with this interpretation and reveals that two different types of information are "originated" and transmitted within the claimed invention. First, there is "originated information." As the district court correctly held, "originated information" refers to the text of the electronic mail message being transmitted. One could analogize this to the contents of a physical letter one mails to a recipient via the postal system. Second, in the claimed invention there is also what one might call address information or destination information. This refers to an identifier of the intermediate components and/or the destination processor(s) to which the electronic message text should be delivered. See, e.g., '960 patent, col. 24, ll. 31-46 (discussing "address of the interface switch" and "identification number of the RF receiver"). Address information originated from a gateway switch or interface switch is never described as itself the
"originated information" or the "other originated information." Rather, it is described as separate information which is added to the "originated information" which came from an originating processor. See, e.g., id. at col. 21, ll. 54-56 (text notes that the address of the interface switch can be added "to the information originating from the originating processor"); id. at col. 22, ll. 24-26 (text notes that the destination address can be "added to the information from the originating processor"); id. at col. 26, ll. 39-41 (text notes adding information to the "information from the originating processor"); id. at col. 49, ll. 27-29 (claims describe adding "address information to originated information"); id. at col. 50, ll. 7-10 (text describes movement of both "originated information" and identification number in the RF transmission network); id. at col. 54, ll. 49-51 (text notes identification number added to the originated information"). This address information can be analogized to the address contained on the outside of an envelope that one mails with the post office, as well as information added by the post office, such as a barcode, which may direct the envelope through the myriad routes in the postal system. Thus, just as one physically mails a letter with two types of information--the text of the actual letter itself within the envelope and the address information on the outside of the envelope--the claimed invention "originates" two types of information.

From the written description, one skilled in the art would understand an "originating processor" to refer to a processor where "originated information"--the electronic mail message text--is introduced into the electronic mail system. In some cases, this "originating processor" is the point at which some or all of the second type of information, the address information, is added. In other cases, after the "originating processor" sends the "originated information" to a gateway switch, the gateway switch then "originates" and appends additional address information onto the "originated information." A user typing at the originating processor does need to provide at least some address destination information--for example, that the email message is intended for "John Doe." See, e.g., id. at col. 24, ll. 29-30. However, the user need not know precisely through which switches the email message needs to travel within the system to get to John Doe (or even whether John Doe's destination processor is a wireless or wireline processor). In the "most user friendly form" of the invention, the user need only indicate the intended recipient, and the proper address information can be added to the text of the electronic mail message either by the originating processor itself or by later components in the electronic mail system, such as gateway switches and/or interface switches. See, e.g., id. at col. 24, ll. 25-30. This is analogous to how, in the postal system, one need only indicate a destination address, and the postal system sometimes adds barcode information to envelopes which help indicate through which routes within the postal network the letter needs to travel to get to the proper destination.

The term "originating processor" does not encompass every constituent processor that initiates data into the system. "Originating processor" refers more precisely to the processor that initiates the electronic message text into the system. It is correct to conclude that other components besides an "originating processor" "originate" information. For example, components such as the gateway switches originate some of the address information to get the electronic message from the "originating processor" to the proper destination processor(s). However, there is nothing in the written description to suggest that one skilled in the art would blur the distinction between a component such as a gateway switch that sometimes "originates" address information, and an "originating processor," which is a separately labeled and separately claimed component than a gateway switch or an interface switch.

Referring specifically to the written description, Figure 1 of the '960 patent discloses a prior art electronic mail system in which the "originating processor" is depicted as the processor which originates the email message, which is separate and distinct from other constituent components such as gateway switches:

[SEE PRIOR ART IN ORIGINAL]

The specification states that Figure 1 shows that "communications between an originating processor A-N, which may be any of the processors within the groups of associated processors # 1-# 3 or processor # N and a destination processor A-N are completed through the public switch telephone network 12 to one or more gateway switches ...14." '960 patent, col. 2, ll. 23-28 (emphases added). This passage explains that the electronic mail message originates from the "originating processor" and then moves "to" an associated gateway switch. Thus, the "originating processor" is not a generic term referring to all data-generating constituent processors in a system, but more precisely refers to a processor that is separate from the gateway switches. Moreover, the written description repeatedly refers to the "originating processor" where the electronic mail message text is generated. See, e.g., id. at col. 3, ll. 12-21 ("Finally, the message or message text must be entered which is the information that is inputted by the person or machine which is originating the message at the originating processor A-N.

Upon completion of the message text, the user ...enters a series of commands or keystrokes on the originating processor to transmit the message to the gateway switch ..." (emphasis added); id. at col. 19, ll. 29-30 (explaining how, in the claimed invention, the "originating processor" might be associated with "an icon driven display" and a computer "mouse" for the
Components other than an "originating processor" can initiate data. The written description describes how, for example, "the identification of the RF receiver 119 and the address of the interface switch may be implemented by the originating processor A-N of one of the computing systems # 1-# N, a gateway switch 14 or an interface switch 304 ...." Id. at col. 24, ll. 42-46. This shows that three different components can initiate address information: (1) an "originating processor" A-N; (2) a gateway switch 14; or (3) an interface switch 304. However, simply because the "originating processor" is but one of three separate, differently named and labeled components that can serve as the initiator of address information, does not mean that the term "originating processor" covers all of these different components. If "originating processor" referred to all three components, then the specification would simply read "the identification of the RF receiver 119 may be implemented by an originating processor."

The specification makes clear that it may take several processors in Campana's claimed invention to successfully initiate an electronic mail message. As Campana teaches in his written description, to initiate an electronic mail message, the message text must be entered, then the addresses of various interface switches and the receiving destination processor must be entered and appended to the message. See id. at col. 19, ll. 26-39. The written description also teaches that entering the addresses of the interface switches, RF receivers, and destination processors may be accomplished by various components, including the originating processor or a gateway switch. See id. at col. 21, ll. 54-56, 65-66 (noting that the address of the receiving interface switch may be added by the originating processor or a gateway switch); id. at col. 22, ll. 10-15, 24-26 (noting that the address of the destination processor may be added by "the originating processor by an operator or a machine using the originating processor" or the gateway switch). However, the mere fact that a constituent component may tack on destination address information to the "originated information" coming from the "originating processor" does not turn that constituent processor into an "originating processor." Gateway switches are separate components from the "originating processor" that can also add address information after receiving the message text from the "originating processor." This is why Campana asserts that the invention is "user friendly" because only a "minimum amount of information ...must be provided to initiate the transmission of electronic mail from an originating processor to at least one destination processor." Id. at col. 19, ll. 20-25.

The written description further describes how either the "originating processor," "gateway switch," or "interface switch" can be used to add information needed to transmit the electronic mail message, such as addressing data. See id. at col. 22, ll. 24-26 ("The address of the destination processor may also be added to the information originated by the originating processor by the gateway switch."). Figure 11 of the '960 patent visually demonstrates various steps by which the "originating processor," "gateway switch 14," and "interface switch 304" could operate together to add address information to the text of the electronic mail message, i.e., the "originated information":

* * *

See '960 patent, col. 28, ll. 10-13 ("Figure 11 summarizes electronic mail message entry methods for messages (information) originating from originating processors within an electronic mail system." (emphasis added)). The arrows show the flow of the "originated information" from the "originating processor," the first processor in the system where the information is originated, to a gateway switch 14, and then to an interface switch 304. Campana describes the flow of data in the various entry methods. For example, in "entry method 1" the "originating processor" itself adds the appropriate destination address data. Id. at col. 28, ll. 13-17. When the "originated information" then reaches a gateway switch 14, the gateway switch takes no action, because all of the address data necessary at that point has already been added by the "originating processor." By contrast, in "entry method 3," a gateway switch, after receiving the "originated information" from the "originating processor," adds the wireless destination address. Id. at col. 28, ll. 24-29. Although under the various methods enumerated in Figure 11 either the "originating processor," "gateway switch," or "interface switch" may add address information to the electronic mail message, the gateway and interface switches do not initiate the message text of an electronic mail message and, thus, are not "originating processors."

This shows how the "originating processor" merely refers to the first (initiating) processor of the "originated information." A gateway switch is not an "originating processor." While the gateway switch serves as an initiator of address information, as in entry methods 3, 4, and 5, a gateway switch only does this after it gets the "originated information" from the "originating processor." "Originating processor" is not an umbrella term referring to all of the processors that add data into the system,
but rather would be understood to one skilled in the art to be the first processor, or the initial source of the "originated information" or email message text. All three different components in Figure 11, an "originating processor," a "gateway switch," and an "interface switch," are initiating address information. "Originating processor" refers to one of these components—the first processor, and not all three. Thus, the "originating processor" is the sole processor that initiates the transmission of the electronic mail message text into the electronic mail system and is separate from the gateway or interface switches.

3002

Originating switch

The Court adopts Ciena’s proposed construction and construes the term as “the first packet switch to forward a packet destined for the destination switch.” Nortel argues that the term should be construed as “the first path-oriented packet switch along the preferred path that serves to forward a packet destined for the destination switch.” For the same reasons discussed above, the Court rejects Nortel’s use of the term “path-oriented packet switch.” Accordingly, the Court construes the term without including “path-oriented.”

3003

I. "originating telephone number assigned to the caller"

Stanacard argues that the term should be given its plain and ordinary meaning or, in the alternative, be construed to mean "telephone number given to a caller from which the caller initiates a call." Rebtel seeks to define this term to mean "telephone number preprogrammed by the caller to correlate to the caller."

By the words of the claim term itself, the originating telephone number is one assigned "to the caller," meaning that it is a number assigned by someone else to the caller. The specification also explains that the "originating telephone number" is the phone number from which the caller initiated or placed the call. See '156 Patent, col. 3:54-56, 5:22-24, 6:43-48. The originating telephone number is thus the caller's own telephone number which was provided by the caller's telephone company. This is properly reflected in Stanacard's proposed alternate definition, "telephone number given to a caller from which the caller initiates a call."

Rebtel's definition attempts to introduce the requirement that the originating number is one that must be "preprogrammed by the caller" to be associated with his or her account in the system. As discussed supra in Sections IV.B & D, the introduction of the "preprogrammed" language into the claim definition would improperly limit the scope of the claim. Nor does the lack of disclosure of how, when, and by whom the number is assigned require the adoption of Rebtel's proposed definition.

The claim limitation "originating telephone number assigned to the caller" is therefore defined to mean “telephone number given to a caller from which the caller initiates a call.”

3004

A. "originator"

Rejecting the parties' proposed definitions of "originator," the magistrate judge recommended that "originator" be construed as: "A party who originates the transaction for exchanging information documents or for initiating payment via an electronic check or a payment transaction for goods and services from a recipient." First Report at 3, 11. No objections have been filed with respect to the magistrate judge's proposed construction. After careful review of the magistrate judge's findings and conclusions, record, legal briefing, and applicable law, the court determines that the magistrate judge's proposed construction of "originator" in patent '878 is correct, and it is hereby accepted as the court's construction of "originator."
A. Oscillator

In construing the claims in question, the Court first looks at the term "oscillator" found in the claims of Trilithic's '428 patent, specifically in claims 1, 8, 15, and 22. Those claims contain the element "an oscillator for generating at an oscillator output a signal having a frequency within the AGC bandwidth." '428 patent, col.9, ln. 29-31; col. 10, ln. 8-10, 59-61; col. 12, ln. 1-2. Most of the remaining claims of the '428 patent contain the word "oscillator." See generally '428 patent. Both parties appear to agree that the term "oscillator" is given no special meaning in the claims, the specification or the prosecution history. Tr. at 91. Def.'s Post-Hearing Br. at 12. Therefore, the term should be given its ordinary meaning in the context of the '428 patent. Renishaw, 158 F.3d at 1249. Accordingly, it must be determined what a person of ordinary skill in the art would have understood that term to mean as it applies to the patent.

Conflicting testimony has been presented to the Court concerning the ordinary meaning of the term "oscillator." After testifying early on in the hearing that an oscillator is an instrument that produces oscillations, Silva presented a definition of oscillator from the McGraw-Hill Dictionary of Scientific and Technical Terms ("McGraw-Hill Dictionary") as being an accurate, commonly understood definition of oscillator from a respected source. Tr. at 46, 88; Pltf.'s Ex. 9 at 1414 (McGraw-Hill Dictionary of Scientific and Technical Terms 1414 (5th ed. 1994)). That dictionary defines "oscillator" as "an electronic circuit that converts energy from a direct-current source to a periodically varying electronic output." Pltf.'s Ex. 9 at 1414. Silva explained that such a definition was consistent with how an oscillator would be used with a heterodyning circuit or with a modulator. Tr. at 90. He stated that the definition was an accurate description of how a person of ordinary skill in the art would understand the term "oscillator." Id. at 91-93.

Wavetek suggests that Trilithic's definition from the McGraw-Hill Dictionary is too broad and is not the ordinary meaning that a person of ordinary skill in the art, reading the claims in the context of the '428 patent, would give the term. At the hearing, Large explained that a person of ordinary skill in the art would understand "oscillator" within the context of the '428 patent to describe "essentially one family of circuits which has some kind of a gain control or amplifier and has some kind of frequency sensitive feedback such that a portion of the output of the amplifier is fed back in phase to the input of at least one frequency." Id. at 214. Large submitted a definition of oscillator that defines oscillator as "a circuit that consists primarily of an amplifier in which some portion of the output is applied, in phase, to the input to produce a periodically-varying output." Id. at 243; Def.'s Dem. Ex. 18. This definition was derived from a description given in the Encyclopedia of Electronics ("Encyclopedia"), which reads:

an oscillator is a circuit designed specifically to produce electric oscillation. All oscillators use the feedback principle. Although there are many different types of oscillator circuits, they all consist basically of an amplifier in which some of the output is applied, in phase to the input. . . . Specialized devices, such as the Gunn diode and the klystrom tube produce oscillation because of negative-resistance effects.

Def.'s Ex. 9 at 606 (Encyclopedia of Electronics 606 (2nd ed.)).

Large explained that the definition from the Encyclopedia came closest to how he believed a person of ordinary skill in the art would define oscillator. Tr. at 214-15. He modified the definition because there are oscillators that do not have a discreet amplifier or discreet feedback, though Large quickly noted that such oscillators would not be suitable for the '428 patent. Id. at 215. In response to Silva's remark that there is no evidence in the specification that the output of the low frequency oscillator depicted in Figure 1 is tied back into the input, Large commented that he would not expect to see internal parts of the oscillator, such as a feedback loop, depicted in a block diagram. Id. at 91, 219-20. Commenting on the awkwardness of such a definition, Silva did acknowledge that he would agree with the Encyclopedia's definition if it read to the effect that an oscillator is either an amplifier with a positive feedback or a multi-vibrator, a negative resistance device, or an atomic standard oscillator which provides a periodically varying output. Id. at 153-54. Large acknowledged that his definition, which did not contain the word "all," could not be found in the patent claims, specification, file history, or in any dictionary or article. Id. at 243. According to his testimony, Large issued his opinion based on his understanding of the technology and how he believed the term would be interpreted by people of ordinary skill in the art. Id. at 259.

Finding additional fault with Large's proposed definition, Silva pointed out that specifically, frequency synthesizers, a type of oscillator, do not have feedback. Id. at 168. In response to that criticism, Large explained that while a frequency
synthesizer may contain an oscillator output, the instrument in its entirety is not an oscillator. Id. at 221-22. Furthermore, he posited that an average equipment designer in 1993 or 1994 would not have considered using a frequency synthesizer for the low frequency oscillator in the context of the '428 patent. Id. Large also stated that direct digital synthesizers would not be considered an oscillator by a person of ordinary skill in the art. In an attempt to show that Large's understanding of oscillators was deficient, Trilithic directed Large's attention to an excerpt from a book and a product information sheet from Stanford Telecom. Id. at 257-59; Pltf.'s Exs. 90 & 91. Both documents referenced a direct digital synthesizer as a type of oscillator. Id. Large answered that although he had not researched such items when forming his definition, such evidence did not alter his opinion on the definition of an oscillator. Id.

Wavetek has attempted to make the issue of the "oscillator" claims one of whether the definition should include wording to the effect that oscillators generally have some portion of the output applied to the input. Both experts would likely agree that a person of ordinary skill in the art has a general idea of what an oscillator is. Trilithic has offered a more all-encompassing definition of an oscillator than has Wavetek. Trilithic's definition, though not stating that some oscillators work on the feedback principle, does not rule out such a conclusion. The Court does not accept the argument that a person of ordinary skill in the art would be so puzzled as to what an oscillator is or as to what type of oscillator to use in the context of the '428 patent that the term must be defined as operating on a feedback principle before a person of ordinary skill in the art would understand it. Accepting Silva's testimony as accurate, the Court interprets oscillator as "an electronic circuit that converts energy from a direct-current source to a periodically varying electronic output," thereby giving the term its plain and ordinary meaning. Such a reading is not disingenuous to the context of the oscillator's use in the '428 patent. The Court finds this definition from the McGraw-Hill Dictionary to be a reliable source for determining how a person of ordinary skill in the art would define the term "oscillator."

The Court notes that both experts agreed that the description of "oscillator" in the Encyclopedia was not exactly accurate. At Large's own admittance, his definition was not found in any patent, dictionary or article, and accordingly, is not as good of a source for an ordinary and plain definition of the term as is the definition from the McGraw-Hill Dictionary. Even assuming that Large is correct in his statement that a person of ordinary skill in the art would know that in many oscillators some portion of the input is applied in phase to the output, the person or ordinary skill can apply that knowledge in choosing an oscillator in the context of the '428 patent. There is no intrinsic evidence that suggests the term oscillator should not be given a broader definition.

The '428 patent is not concerned with the development of a specific type of oscillator. The testimony of both experts indicates that people of ordinary skill in the art know generally how an oscillator works, know that some run on the feedback principle, and know what types of oscillators could properly be used in the '428 patent. How an oscillator works is not the pertinent inquiry in reading this patent. The emphasis instead is on what an oscillator accomplishes. Therefore, the definition does not have to include a description of how an oscillator works. A person of ordinary skill in the art will know that and know how a particular oscillator will operate within the context of the '428 patent. Accordingly, it is enough in the context of this patent that the oscillator be given its plain and ordinary meaning, one that a person of ordinary skill in the art would give the term. The McGraw-Hill Dictionary definition, as given by Silva, meets that requirement.

The plaintiffs contend that no construction is necessary, but if a construction is required, they propose "the oscillator generates the signal(s) used for timing the operation of the CPU." The defendants propose "an oscillator that is itself determining the frequency of the signal(s) used for timing."

The Court agrees that the term requires construction. The Court construes the term to mean "an oscillator that generates the signal(s) used for timing the operation of the CPU."
9. "out of band signal"

Dependent claim 9 provides that "K2 is selected so that the out of band signal is less than a given level." Subsequent to the parties' briefing and argument on this term, the parties have agreed by letter to the Court, dated April 7, 2010, that the term "out of band signal" means "power outside the frequency band." However, Defendants still argue that claim 9 is invalid for failing to meet 35 U.S.C. § 112. The Defendants do not argue that "out of band signal" is indefinite, but that the subsequent phrase "less than a given level" is indefinite. It appears that Defendants did not contend that "less than a given level" needed to be construed, or that the specific phrase was indefinite, until the Defendants' responsive claim construction brief. Thus, Wi-LAN did not provide any proposed construction for the term and instead argued that the term "out of band signal" was not indefinite and had a particular meaning.

The Court finds that the phrase "less than a given level" is not indefinite. A claim is indefinite only if the "claim is insubordinately ambiguous, and no narrowing construction can properly be adopted." Exxon, 265 F.3d at 1375; Honeywell, 341 F.3d at 1338-39. This term is not "insubordinately ambiguous" so as to prevent construction. See Young, 492 F.3d at 1346 (claims are considered indefinite when they are "not amenable to construction or are insubordinately ambiguous"). The specification contains examples from which one of ordinary skill in the art could determine the scope of the claim. For example, the "two tail slots act as guard bands to ensure that the out-of-band signal is below a certain power level" and "to ensure that the out-of-band signal is ydB or less relative to the in-band signal…" 222 patent, 5:36-44; 6:46-48. The specification then provides an explicit example of what, in a particular instance, the "less than a given level" should be: "[t]he two tail slots of 195.3 KHz each (i.e. 8 points each) ensure that the signal outside the entire band of 100.39 MHz is below -50 dB." 222 patent, 7:57-60. In addition, the specification teaches that "to allow use of the radio frequency spectrum…[th]e system must satisfy federal regulations…[th]at impose limits on the power and the frequency spread of the signals exchanged…." 222 patent, 1:50-54. The Court finds that there is sufficient guidance in the specification as to the meaning of "less than a given level" to one of ordinary skill in the art. See Exxon, 265 F.3d at 1375 ("If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds."). The Court rejects Defendants' argument that because the "level" in the claim is unspecified, no meaningful bound is placed on the patent claim. Consistent with the parties' agreement, the Court construes the term "out of band signal" to mean "power outside the frequency band." The Court finds that the term "less than a given level" is not indefinite. The Court construes the term "less than a given level" to mean "less than a given power level to satisfy federal regulations."

C. "In-Band Telecommunications Signaling" and "Out-Of-Band Telecommunications Signaling"

Claim 38 of the '572 patent recites the term "in-band telecommunications signaling." Sprint contends that this is a term of art that should be construed to mean signaling that is sent on the same channel as that used for voice or data, whereas Vonage contends that it should be construed to mean signaling transmitted on the actual communications path. This claim also recites the term "out-of-band telecommunications signaling." Again, Sprint contends that this is a term of art which should be construed to mean signaling that is sent on a distinct channel from that used for voice or data, whereas Vonage contends that it should be construed to mean signaling message that is not transmitted on the actual communications path.

The crux of the parties' dispute is whether characterization of signaling as in-band or out-of-band is determined by whether that signaling is transmitted on the same or separate channels (Sprint) or by whether it is transmitted on the same or separate communication paths (Vonage).

Vonage relies on language included in the specification which addresses the nature of in-band and out-of-band signaling, as follows:

As is known in the art, in-band signaling is typically used in many user to network connections, such as the local loop. This is because only one connection or link is typically provided to the user premises and thus, the signaling must be placed on the actual communications path. The initial network switch typically removes the signaling from the communications path and transfers it to an out-of-band signaling system. The current invention is fully operational in this context. Although the switch may receive the signaling initially, it will only route the signaling to the CCP for processing. Even if in-band signaling is used within the network, the switches could remove signaling from the communications path and route it to the
'572 Patent at 7:50-63. Sprint, on the other hand, relies on Vonage's experts' understanding of the terms "in-band" and "out-of-band." Frank Koperda, Vonage's invalidity expert, stated in his expert report that "in-band" signaling is the exchange of signaling information . . . within the same channel that the telephone call itself is using and that out-of-band signaling is telecommunication signaling that is done on a channel that is dedicated for the purpose and separate from the channels used for the telephone call." Also, Joel M. Halpern, Vonage's noninfringement expert, testified in his deposition that out-of-band signaling "has to be in a separate band, a separate recognizable channel."

The evidence from Vonage's experts clearly views the teens "in-band" and "out-of-band" as being distinguished with respect to a channel, which leads the court to believe that these might be terms of art, as Sprint contends. In an attempt to understand the distinction between a "channel" and a "communications path," the court has consulted a technical dictionary to determine the meanings of the relevant terms as they would have been understood by a person of ordinary skill in the art at the time of the invention. "In-band signaling" means "[s]ignaling made up of tones which pass within the voice frequency band and are carried along the same circuit as the talk path that is being established by the signals." Harry Newton, Newton's Telecom Dictionary 537 (7th ed. 1994). "Path" means "[t]he route a telecommunications signal follows." Id. at 773. "Out-of-band signaling" means "[s]ignaling that is separated from the channel carrying the information -- the voice, data, video, etc." Id. at 756. "Channel" means "a voice-grade transmission facility with defined frequency response, gain, and bandwidth. Also a path of communication, either electrical or electromagnetic, between two or more points." Id. at 217.

The common and ordinary meanings of these words can be harmonized with the excerpt from the specification. In discussing "in-band signaling," the specification explains that only one connection or link is typically provided to the user premises and therefore the signaling "must be placed on the actual communications path." '572 Patent at 7:52-53. The initial network switch typically "removes the signaling from the communications path." Id. at 7:55-56. The specification further explains that even if in-band signaling is used within the network, the switches "could remove signaling from the communications path." Id. at 7:60-61. The technical definition of in-band signaling refers to the "talk path," and the term "path" means the route a telecommunications signal follows. With respect to the claim term "in-band," then, the intrinsic record establishes that its meaning is defined with respect to the communications path. There is no suggestion in the intrinsic record that it should be defined in terms of a channel. Consequently, the court must discount the expert opinions that are at odds with this intrinsic evidence. Accordingly, the court construes the claim term "in-band telecommunications signal" to mean signaling that is sent on the same communications path as that used for voice and/or data.

The specification does not, however, indicate that the claim term "out-of-band telecommunications signaling" must necessarily be construed as the counterpart to in-band telecommunications signaling. The specification sheds light on the meaning of the claim term "out-of-band telecommunication system," in that the network switch removes the "signaling from the communications path and transfers it to an out-of-band system." Certainly, this indicates that out-of-band means removing the signaling from the communications path. This is not inconsistent with what appears from the record to be the generally accepted meaning of the term within the telecommunications industry, which is that out-of-band signaling is signaling that is separated from the channel carrying the voice and/or data. And, defining out-of-band signaling in terms of a separate channel is also consistent with Vonage's experts' apparent understanding of this term. Thus, the court is persuaded that "out-of-band" signaling is indeed a term of art defined in terms of the channel, as suggested by Sprint. Accordingly, the court construes the claim term "out-of-band telecommunications signaling" to mean signaling that is sent on a separate channel from that used for voice and/or data. 1

1 The court recognizes the seeming incongruity in construing "in-band signaling" in terms of the communications path while construing "out-of-band signaling" in terms of a separate channel. But, this actually comports with the commonly understood meanings of those terms, as illustrated by the dictionary definitions set forth above. Moreover, the distinction is attributable to the "communications path" language included in the specification with respect to "in-band" signaling. In the absence of that language in the specification, the court would be inclined to construe both of the terms in light of the "channel" distinction.
I conclude that the term "purchase card outlet" as used in claim 1 of the '181 patent means a retail establishment, regardless of type, where purchase cards are offered for sale. I have adopted a modified version of defendant's proposed construction that resolves plaintiff's concern that defendant's proposed construction would create ambiguity. Plaintiff agrees that a "purchase card outlet" is a place where purchase cards are offered for sale. Plt.'s Resp. Br., dkt. 44, at 14. Its problem with the construction is that "retail establishment" could be understood to include only "bricks and mortar" retailers, that is, a physical retail building where a person can walk in and make a purchase, as opposed to including internet retailers. However, leaving "outlet" to its plain and ordinary meaning does not resolve this ambiguity. See, e.g., New Oxford American Dictionary 1208 (2d ed. 2005) ("outlet" -- "a place from which goods are sold or distributed: a fast food outlet. . a retail store that sells the goods of a specific manufacturer or brand: [as adj.] an outlet store.") Addition of the phrase "regardless of type" removes the ambiguity. Further, defendant agrees that the term should not be limited to a specific type of retail establishment. Def.'s Resp. Br., dkt. 45, at 12. Therefore, adding "regardless of type" is proper.

Additionally, I note that the specification's consistent use of "retail establishment" to define where a consumer can obtain a purchase card supports defining "outlet" as a "retail establishment." The specification does not use the term "purchase card outlet" to refer to the location where purchase cards are sold; instead, it refers to "retailers" or "retail establishments." See, e.g., '181 Pat., col. 3, lns. 4-6 ("a currency conversion must take place via an intermediary web site or the Internet or in a 'bricks and mortar' retailer"); lns. 7-8 ("a pre-paid purchasing card is to be offered by the retailer"); lns. 9-10 ("The consumer would visit the retail establishment 32 . . . to buy 31 one or more purchasing cards."); lns. 43-45 ("the retailer may also receive a fee from the purchasing intermediary for each purchasing card which was purchased at their retail establishment"); and lns. 46-47 ("The consumer then buys the purchasing card 40 at the retailer establishment 32"). "[W]hen a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term 'by implication.'" Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001) (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)). Accordingly, "outlet" as used in claim 1 of the '181 patent means "retail establishment," regardless of type.

9. Claim 6: Step (d)

Text:

(d) outlining the outer surface of the lesion in at least one of said ultrasound images; and

'026 Patent, col. 12, ll. 52-53.

NOMOS's Proposed Construction:

Step (d) should be interpreted as identifying the surface of the lesion in the ultrasound image and creating an outline of the surface of the lesion. This outlining may, for example, be accomplished using a conventional software program. Several methods were available at the time of the '026 patent to accomplish this. One embodiment of "outlining" would require a physician to trace a line on an image of the lesion, which was projected on a workstation display. Another embodiment would require the physician to adjust the contrast of the image so that the surface of the lesion was well defined. Another embodiment would use image processing algorithms that automatically identify the surface of the lesion.

NOMOS Opening Brief at 15 (citations omitted).

ZMED's Proposed Construction:
This step requires taking the two dimensional ultrasound image created by the probe and using the computer to draw a line along the surface of the lesion in that image.

ZMED Opening Brief at 27.

Construction:

Step (d) means "using computer software either to draw a line around the image of the surface of the lesion manually or through image processing algorithms that automatically identify the surface of the lesion, in at least one of said ultrasound images."

Commentary:

The term "outlining" is clarified by reference to intrinsic evidence (the specification and prosecution history). The specification states:

the outer surface of the lesion in each ultrasound image is outlined, such outlining being performed by a conventional software program, such as in the radiation treatment planning system previously described, which permits a physician to outline the outer surfaces of each ultrasound image, in a similar manner in which the outer surface of lesion was outlined on the diagnostic images, or slices . . . .

'026 Patent, col. 7., ll. 32-40 (figure numbers omitted). The "radiation treatment planning system previously described," is of no help.

I conclude that a person skilled in the art would interpret the word "outline" to mean using computer software either to draw a line around the image of the surface of the lesion manually or through image processing algorithms that automatically identify the surface of the lesion, in at least one of said ultrasound images. See Electro Med. Sys., S.A., v. Cooper Life Scis., Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994) ("Claims speak to those skilled in the art."). It does not include adjusting the contrast to see the surface of the lesion better.

3011

2. "Output buffer having a p-channel transistor and an n-channel transistor" (Claim 1)

Agere argues that the Court should find that this term is clear on its face and not in need of construction, while Broadcom argues that it should be construed as a device "known as a push-pull output buffer." Agere's expert, Dr. Blalock, testified that a person of ordinary skill in the art would understand this term to be self-explanatory. (See Blalock Rep. P 21.) Broadcom's expert, Dr. Fair, disagrees with this assessment, arguing instead that a person of ordinary skill in the art would understand the claim to describe only a push-pull output buffer because that is the only type of output buffer described in the specifications. (Fair '802 Rep. P 39.) Under Federal Circuit law, however, a claim term cannot be limited to its preferred embodiments absent evidence of a "clear disclaimer." See In re Am. Acad. of Sci. Tech Cent., 367 F.3d 1359, 1369 (Fed. Cir. 2004). Broadcom points to no evidence showing such a disclaimer. By contrast, Agere correctly notes, and Broadcom's expert agrees, that the patent does not contain language limiting the claim either to the specified embodiments or to push-pull buffers. (R. at 144 (May 7, 2004) ("It's a fact that [a structure drafted pursuant to the claim text] doesn't need to be a push-pull buffer . . . .") (Fair).) Thus, the Court declines to adopt Dr. Fair's limitation. Furthermore, in the absence of any other evidence contrary to Dr. Blalock's testimony that a skilled artisan would understand the term at issue without further construction, the Court finds that the term's customary meaning is self-explanatory.

Given that the term has a customary meaning to one of skill in the art, Broadcom can only prevail on its construction by showing that the patentee "manifestly" defined the term differently than the customary meaning. Teleflex, 299 F.3d at 1325. In support of this argument, Broadcom provides two rationales. First, Broadcom repeats its argument that all of the embodiments of the patent described in the specifications show push-pull buffers. (See R. at 141-42 (May 7, 2004) (introducing expert testimony that push-pull buffers are "preferred and only embodiments" of claim in specifications).) As stated above, however, there is no basis for limiting this claim term to its specified embodiments. Second, Broadcom argues
that the device simply would not work on any type of output buffer other than a push-pull buffer. Agere's expert, Dr. Blalock, disputes this claim as a technical matter, testifying that a person of skill in the art could design a non-push-pull buffer that would function properly with the patent. (Blalock Rep. P 21.) Broadcom's expert does not entirely dispute Dr. Blalock's testimony, noting instead that while it would be theoretically possible to use the patent with a non-push-pull buffer, there is "no guarantee" that such an implementation would function properly, and "substantial experimentation" would be needed to determine whether it would suffice. (R. at 144-45 (May 7, 2004).) The Court does not find Dr. Blalock's testimony sufficient to require limiting an otherwise clear and broad claim term, for it is not the patentee's burden to demonstrate every conceivable embodiment of the patent in order to avoid judicial narrowing of the claim. See Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001) (noting that specifications "need not present every embodiment or permutation of the invention"). Stated differently, the mere fact that there is "no guarantee" that the device would work with other types of buffers is not a "manifest exclusion" that would limit a broad claim term to a single embodiment thereof. Accordingly, the Court rejects Broadcom's proposed construction and agrees with Agere that this term is not in need of construction.

3012

ii) "output current set point data"

Power-One proposes this term means "data used to specify an output current level," while Artesyn proposes this term means "data provided to a POL regulator specifying the desired output current level for the POL regulator." Much of the analysis above applies here. Claim 4 of the '798 patent provides for the "power control system of claim 1, wherein said initial configuration data includes at least output current set point data corresponding to a desired maximum current level of said output." The '798 specification equates "output-current-set point data" with the "highest desired output current." See '798 patent, col. 2:13-14. Accordingly, the Court adopts Artesyn's proposed construction and construes "output current set point data" as "data provided to a POL regulator specifying the desired output current level for the POL regulator." GO BACK

3013

12. "output data"

Power-One proposes "data reflecting information affecting the provision of power to the load," while Artesyn proposes "real-time generated data reflecting information affecting the provision of power to a load." The dispute with respect to this term is whether the '999 patent's prosecution history shows that the data must be "real-time generated." A prosecution history disclaimer must be clear and unambiguous. See Sorensen v. International Trade Com'n, 427 F.3d 1375, 1378 (Fed. Cir. 2005) ("in order to disavow claim scope, a patent applicant must clearly and unambiguously express surrender of subject matter during prosecution."). Artesyn contends that during prosecution of the application that originally issued as the '999 patent, the claims were rejected over a prior art reference that disclosed a system including a "power-supply regulator 211" and a "look-up table 213" described by the patent examiner as "storage device 213." See Office Action, Mailed Jun. 3, 2004, for U.S. Patent Application No. 10/388,831. Artesyn argues that the applicant distinguished the claimed subject matter from the prior art on grounds that the "output data" in the "storage device" recited in the claim must be "real-time" data (as opposed to the type of data stored in the prior art device):

Since it is clear that the power supply controller 211 does not transmit output data, as discussed above, it further follows that there is no "storage device adapted to store said output data." The look-up table 213 cannot perform this function because, inter alia, it is not in communication with any device providing a "power supply controller." Further, a look up table generally contains an index of predetermined data and is not used to store real-time generated output data.

Id. Power-One contends that nothing in this passage concerning look-up tables can be fairly interpreted as a disclaimer of all but "real-time" output data in all the claims. The Court agrees. In the cited passage from the prosecution history, the applicant distinguished the prior art reference because it "does not transmit output data" and because it does not include a "storage device" that is in communication with any device providing a power supply controller. While the applicant further argued that a "look up table generally" is not used to store "real-time generated output data," the Court cannot conclude that
this passage constitutes a clear and unambiguous disclaimer of all but "real-time generated data." Thus, the Court construes "output data" as "data reflecting information affecting the provision of power to the load."

MASTER'S CONSTRUCTION

The term "output device" (# 1) appearing in this construction has been previously construed by the Master and that construction is incorporated by reference into this construction.

REASONS

INTRINSIC EVIDENCE

Patent claim 14 states that the output device is for using images obtained by the input device to enable image data to be communicated to a user of the system. Examples may include but are not limited to: cathode ray tube displays; television monitors; LCD panels and screens; EMM memory and dish memory; digital film recorders; post script color printers, raster driven film recorders and fast-driven printers.

The ordinary meaning of the term "output device" as used in the context of the Patent in the Specification and claims has been applied. This is what a person of ordinary skill in this art would understand the term to mean. The construction is consistent with the file history. Applicant refers to "output devices that enable image data to be communicated to medical practitioners" [Applicant's Response (Bates LUM 0000191) to Examiner's Office Action of April 18, 1994 under "REMARKS" p. 4, 2ND P, Ls. 6-7; (Bates LUM 0000194)].

EXTRINSIC EVIDENCE

Testimony given by Branson in the Markman Hearing is consistent with the above intrinsic evidence in the Patent (Markman Hearing, Branson Tr. 41:10-16).

LUMA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Luma's construction is set forth in (Luma May 4, 2005, p. 1).

Luma's construction requires "storing". While "storing" is not excluded, it is not required by the output device if the output device otherwise functions within the Master's construction. The phrase "enable image data" needs to be part of the construction and is not found in Luma's proposed construction.

STRYKER'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Stryker's position is set forth in (Stryker May 23, 2005, p. 2).

Stryker argues that "output device" does not need to be construed. Luma has requested that it be construed and Luma is entitled to construction of the term.
Stryker argues that Luma is proposing construction for selective claims terms and by doing this is inappropriately offering piecemeal construction for the term "output device" that is devoid of the context of the claim. Stryker argues that Luma's proposed construction is contradicted by the language of the Claims and Specification of the Patent.

In response to this point, the Master believes that the "output device" however construed will be limited by any other term language in the entire claim. The correct analysis for Stryker would be to insert the Master's Construction for "output device" and then Stryker can assert all the remaining language in the claim that Stryker believes limits the Master's Construction of "output device" when determining the meaning of the entire claim.

Stryker argues for "images" and "image data". The Master has included "images" and "image data" in the Master's Construction.

KSEA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

KSEA's position is set forth in (KSEA, May 23, 2005, Sheet 3).

KSEA's position is that the plain meaning of the term should be applied. This is what the Master has done consistent with the evidence.

Output Device for Outputting a Rhythmic Piece

This phrase is found in claims 11, 18, 27, and 46. The parties agree that "output device" is "an apparatus for signaling an output," and that "rhythmic piece" is "a work that includes a sound pattern or beat." Defendant MadCatz, however, proposes that the entire phrase should be construed to mean "loud speaker" because the only device that can output "a sound pattern or beat" is a loud speaker. However, the Court sees no reason to construe this language because an appropriate understanding of the phrase may be reached from the ordinary meaning of the claim language in conjunction with the agreed constructions of "output device" and "rhythmic piece." Further, if Court were to construe the phrase it would not adopt MadCatz construction because it seeks to improperly import limitations into the claims from the specification.

"We begin our claim construction analysis, as always, with the words of the claim." Teleflex, 299 F.3d at 1324. The ordinary meaning of this claim language embraces the purpose of the output device, indicating that its function is to output a "rhythmic piece." Thus, the claim language does not specify the type of "output device" contemplated, rather, it simply requires that the claimed "output device" be capable of "outputting a rhythmic piece." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) ("The terms used in the claims bear a presumption that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art."). In light of the assistance provided by the agreed constructions of "output device" and "rhythmic piece," a juror could arrive at a proper understanding of this phrase without need to resort to MadCatz's construction. Further, even assuming the plain and ordinary meaning of this claim language were insufficient to understand what is claimed, the Court would nonetheless decline to adopt MadCatz's construction because it improperly limits the meaning of this phrase.

MadCatz contends that a "rhythmic piece," is necessarily an auditory piece, in turn necessitating that the "output device" be a "loud speaker." In support, MadCatz points to specification excerpts referring specifically to "speakers," as well as Figure 2, which depicts speakers as a part of the claimed apparatus. 3:18-19; 3:32; 4:9-11; 7:27, 55; 9:54; 12:54. However, all of these excerpts appear in the preferred embodiment and cannot overcome the presumption that the claims' more general meaning should control. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d at 1366. Konami also points out that the parties agreed to construe "rhythmic piece" to mean "a work that includes a sound pattern or beat" and they go on to argue that a "beat," can include tactile or light signals, which do not require a "loud speaker" for output. n3 The Court agrees with Konami that "rhythmic piece" should not be so narrowly construed. Accordingly, the Court will not construe "output device for outputting a rhythmic piece," and additionally finds MadCatz proposed construction to be inappropriate.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
n3 Tactile or light signals would accommodate a hearing impaired player.

--- End Footnotes ---
Fiori claims that the output amplifier (65) generates a destination signal and a corresponding destination reference signal which is described in the specification as a return reference potential which is substantially equal to the output reference ground connected to cable 58 such that this destination signal is the result of the intermediate signal minus the received reference signal plus the destination reference. Accordingly, the destination signal is the output of the operational amplifier 65 and is the resultant end of the intermediate signal which is the output of 63 minus the ground reference potential signal at 18 plus the output reference ground connected to cable (58). The output portion has an output connection for transmission of the destination signal, shown as the connection to cable 58. The '148 Patent, column 4-5.

n23 This is described in the specification as being essential for the system to work. See '148 Patent, column 6, lines 22-29.

n24 Rockford argues that the function for the output portion specifies a gain factor of one (1), also called a "unity gain," because the claims call for a circuit to add and subtract signals without multiplication. (Def.'s Markman Br. at 19.) Defendant also asserts that the corresponding structures of the "means" include transformers of the power supply transformer because isolation is required to perform the function, and the transformer provides the isolation. Id.

n25 Rockford concludes that in contrast, "input portion" includes the word proportional and therefore allows for multiplication. Rockford alleges that neither the specification nor the prosecution history provides a special meaning for "plus," "minus," "proportional," or "resultant." (Def.'s Markman Br. at 22.) Rockford argues that the ordinary meaning of the words defining "destination signal" specify a gain factor of one (1). According to Rockford, the phrase "said intermediate electrical signal" refers to the identical signal defined in the limitation for the input portion. "Minus" is the operation of subtraction. "Plus" is the addition of two quantities. The claimed function is like 1+1=2. It adds and subtracts terms without any multiplication. The absence of multiplication is a gain factor of one (1).
Commonly the claims are drafted by the inventor's patent solicitor and they may even be drafted by the patent examiner in an examiner's amendment (subject to the approval of the inventor's solicitor). While presumably the inventor has approved any changes to the claim scope that have occurred via amendment during the prosecution process, it is not unusual for there to be a significant difference between what an inventor thinks his patented invention is and what the ultimate scope of the claims are after allowance by the PTO.

Markman, 52 F.3d at 985.

As a matter of law, the Federal Circuit's position is clear that Fiori's testimony is irrelevant to the matters which presently face this Court. Thus, Rockford's proposed construction, which relies on Fiori's testimony, is erroneous and unsupported. The output stage of claims 1 and 17 are defined in the specification as a second op-amp. The output portion (e.g. 65), described as being separate and independent from the input op-amp (e.g. 63), is demonstrated in Figure 1 of the '148 Patent. The output portion is a physical structure clearly defined as element 65 in columns 4 and 5 of the specification and the prosecution history of the '148 Patent.

6. "Output Section," "extracts said video and audio components from said storage device," and "assembles said video and audio components into an MPEG stream"

TiVo argues no construction of these terms is needed, or, if construed, should mean "hardware and/or code that takes program data from memory and brings it together as an MPEG stream for playback." See TiVo's Op. Br. at 15-16; '389 patent at cols. 4:23-33, 4:45-54, 5:33-6:15, 7:12-16; TiVo's Markman Slides at 122-31.

EchoStar argues "Output Section" is specially defined by the '389 patent as "a separate module that decodes an MPEG stream and produces TV output signals." See '389 patent at cols. 3:65-4:6 & Figs. 1 & 13; EchoStar's Opening Br. at 19-20; EchoStar's Slide Presentation at 99-104.

EchoStar further argues "said Output Section extracts said video and audio components from said storage device" means "the Output Section must obtain the separate video stream and audio stream from the storage device." See EchoStar's Opening Br. at 14; EchoStar's Slide Presentation at 76-98.

EchoStar further argues "said Output Section assembles said video and audio components into an MPEG stream" means "the Output Section must multiplex the separate video stream and audio stream into one MPEG Systems stream." See EchoStar's Opening Br. at 14; EchoStar's Slide Presentation at 82, 98.

The Court finds it need look no further than the claims themselves to define these terms, as the specification does not explicitly define them, and the claims are presumed to represent the understanding of those of ordinary skill in the art. See '389 patent at cols. 12:53-55, 15:35-37; TiVo's Op. Br. at Gibson Decl. P 38 (corollary of definition of "Input Section" for "Output Section" is the portion of a device that receives outputs). The plain and ordinary meaning of an "Output Section" to one of ordinary skill in the art is "the portion of a device that decodes data from memory and produces output signals." This definition is consistent with the use of the term in claims 1 and 32 and the context of the specification.

The Court finds it unnecessary to construe "extracts said video and audio components from said storage device" or "assembles said video and audio components into an MPEG stream." Further, the Court disagrees with EchoStar's argument that "extracts" should be construed as "obtains." In claims 31 and 61, both the terms "extract" and "obtain" are used. Each of these terms is presumed to have a separate meaning, and each term is presumed to have the same meaning throughout the patent claims. See Innova, 381 F.3d at 1119; see also Phillips, 415 F.3d 1303, 2005 WL 1620331 at *7. Although the term "obtain" is not used in claims 1 and 32, both terms are found in claims 31 and 61. Thus, in order to construe "extract" consistently in each of the four claims, "extract" cannot mean "obtain" or the construction would violate the presumption that each term has its own meaning and that the use of different terms reflects a differentiation in meaning. There is no
evidence rebutting these presumptions. Thus, "extracts" cannot be construed as "obtains."

GO BACK

3020

i) "[output] voltage set point data"

Power-One proposes "data used to specify the commanded output voltage level of the POL regulator," while Artesyn proposes "data provided to a POL regulator specifying the desired output voltage level for the POL regulator." Beginning with the claim language, claims 2 and 26 of the '999 patent refer to "voltage set point data providing a desired output voltage of the corresponding POL regulator." Claim 3 of the '798 patent provides for the "power control system of claim 1, wherein said initial configuration data includes at least output voltage set point data corresponding to a desired voltage level of said output." Thus, the claims appear to equate the voltage set point data with a "desired output voltage." The '798 specification calls for the following:

. . . the controller is adapted to provide initial-configuration data to each POL regulator. The initial configuration data, which may include output-voltage-set-point-data (i.e., a desired output voltage), output-current-set point data (i.e., the highest desired output current), low-voltage-limit data (i.e., the lowest desired output voltage), high-voltage-limit data (i.e., the highest desired output voltage), output-voltage-slew-rate data (i.e., the desired output slew rate) . . .

'798 patent, col. 2:10-17. The '999 specification further provides:

For example, a POL regulator might generate a one volt output five milliseconds after receiving activation data if it received voltage set-point data and sequencing data corresponding to one volt and five milliseconds, respectively. Alternatively, a POL regulator might generate a one volt output one millisecond after receiving activation data if it received voltage set point data, slew-rate data and turn-on data corresponding to two volts, one volt per millisecond and three milliseconds, respectively.

'999 patent, col. 4: 33-41. These excerpts show that the POL regulator receives specified types or categories of "data." More specifically, the examples in the latter excerpt show that the "voltage-set-point data" has a specified numerical value, i.e. one or two volts.

In support of its argument, Power-One argues, for example, that data telling a POL regulator to cap or limit its output voltage can also be "voltage set point data." The '798 specification, however, is clear that such data is categorized as "high-voltage-limit data," not "output-voltage-set-point-data." '798 patent, col. 2:10-17 Power-One offers an example of a situation where, a POL regulator receives voltage set point data of seven volts, but the POL has an upper voltage limit of five volts. Thus, because the upper limit is five, the actual output voltage would be five. Power-One contends that the upper voltage limit data should be considered as part of the data determining the voltage set point. While the upper voltage limit data may affect the actual voltage level at the output, that does not change the fact that the "output voltage set point data" specifies the "desired" output voltage and that the intrinsic record shows that the voltage set point data is a distinct category of data, rather than a collection of data from which a set point is derived. See Applied Med. Res. Corp. v. U.S. Surgical Corp., 448 F.3d 1324, 1333 n.3 (Fed. Cir. 2006) ("in the absence of any evidence to the contrary, we must presume that the use of . . . different terms in the claims connotes different meanings"). Accordingly, the Court adopts Artesyn's proposed construction and construes "[output] voltage set point data" as "data provided to a POL regulator specifying the desired output voltage level for the POL regulator."

GO BACK

3021

iii) "[output voltage] slew rate data"

Power-One proposes a construction of "data concerning the rate of change of the output of the device," while Artesyn proposes "data provided to a POL regulator specifying the desired slew rate (i.e., rate of change of output voltage) for the POL regulator." Claims 2 and 26 of the '999 patent describe "output data" transmitted by the controller comprising:
at least one of turn-on data providing a command to turn-on the corresponding POL regulator, voltage set-point data providing a desired output voltage of the corresponding POL regulator, slew-rate data providing a rate of change of output voltage of the corresponding POL regulator, and sequencing data providing a delay period between either a turn-on or turn-off command and actual generation of a corresponding output.

This claim language demonstrates that "slew-rate data" is distinct from the other "data" referenced in the claim and specifies a particular type of information. See Applied, 448 F.3d at 1333 n.3. Dependent Claim 7 of the '798 patent specifies that the initial configuration data includes "slew rate data corresponding to a desired slew rate of said output" again showing the distinctness of this category of data and what information it represents. The '798 specification also provides for distinct categories of data, including "output-voltage-slew-rate data," and states what each category represents. See '798 patent, col. 2:10-21. Similarly, the '999 specification provides for the POL receiving activation data including "voltage set point data, slew-rate data and turn-on data corresponding to two volts, one volt per millisecond, and three milliseconds, respectively." See '999 patent, col. 4:33-41. The specifications show that the slew rate data provided to the POL regulator is distinct from other categories of data and specifies a desired slew rate.

Plaintiff argues that the output of the POL need not be specified by the received data, but only in accordance with that data, citing, for example, column 5, lines 29-38 of the '999 patent and claim 11 of the '999 patent. First, Plaintiff's position would blur the distinctions between the different categories of data provided to the POL, whereas the patent specifications and claims clearly distinguish between them. Moreover, the fact that the POL produces an output "in accordance with" the provided data does not mean that the "slew rate data" need not specify a slew rate. Thus, the Court construes "[output voltage] slew rate data" as "data provided to a POL regulator specifying the desired slew rate (i.e., rate of change of output voltage) for the POL regulator."
11 In pertinent part, the specification reads:

The method of the present invention presumes a number of document authors distributed throughout a communication network. Such authors may be individuals, companies, company departments, etc., each representing a distinct and identifiable, e.g., by ID number or the like, member of the universe. In one embodiment of the invention, this universe may constitute the clientele of the time-stamping agency (TSA), while in another embodiment the distributed authors may serve as agents individually performing the time-stamping service for other members of the universe.

U.S. Pat. No. 34,954, col. 2, ll. 55-64.

This point also finds expression in claims 8-12 of the '954 patent, which describe the pseudorandom witnessing method of time-stamping. In this method, the outside agency is selected at random from among a predetermined universe of possible agencies, including "for example, the multiplicity of authors utilizing the time-stamping process," 12 which as the specification notes "may be individuals, companies, company departments." From this it is apparent that one company department may serve as the outside agency for another department of the same company. Thus, the claims, read in light of the specification make clear that an "outside agency," within the meaning of claim 1, need not be an entity or computer in a company or organization separate from or external to the originator's organization. Put another way, the "outside agency" could be a computer in the same department or company as that of the originator of the digital document to be time-stamped.

12 U.S. Pat. No. 34,954, col. 4, ll. 41-42.

For its contrary view, defendant relies on the '954 patent's general goal of providing reliable evidence that a digital document existed in a particular form at a particular time. This position is flawed legally and factually. It is settled law that where, as here, "a specification does not require a limitation, that limitation should not be read from the specification into the claims." Intel Corp. v. ITC, 946 F.2d 821, 836 (Fed. Cir. 1991) (emphasis in the original) (goal stated in the specification was not a limitation found in the claims and therefore could not be imported into the claims). Here, defendant derives from the specification that the invention's goal is to achieve time-stamping of digital documents in a fashion that is immune from interference or tampering by the document's originator, for only in this way is reliable time-stamping achieved. The goal defendant points to in the specification is a limitation that is not required by the patent and hence may not be imported into the claims.

Quite apart from this legal obstacle to defendant's argument, it is also apparent that defendant's proposed restrictive definition of "outside agency" would not necessarily achieve the patent's goal of providing reliable evidence that a particular document existed in a particular form at a particular time. Defendant argues unpersuasively that unless the outside agency is separate from and external to the originator's company or organization, there is a risk that the originator will collude with the outside agent to alter the time-stamp or document. Yet, there is no reason to believe that an agent in the same company or organization as the originator is necessarily more susceptible to corruption or tampering by the originator than an agent outside of the originator's company or organization. Indeed, the risk of collusion may well be greater if the outside agent, although in a separate or distinct company, is a relative of the document's originator or somehow indebted to her. If so, then, logically, defendant's proposed restrictive definition of outside agency should be amended to exclude even separate companies that employ the originator's relatives or persons indebted to the originator. This illustrates the fallacy of defendant's reliance on the patent's goal to construe "outside agency." In sum, interpreting "outside agency" to include persons or entities in the same company as the originator of the document is not inconsistent with the patent's goal of providing a reliable evidence that a document existed in a particular form at a particular time.

13
13 In fact, it appears that the inventors realized that in some circumstances, using an outside agency, by itself, as taught in claims 2, 3 and 4 may not be dependable. Thus, the patent also discloses the "pseudorandom witnessing" method, in which the time-stamping agencies are randomly chosen from among a predetermined universe, so that the originator cannot know beforehand who the time-stamping agencies will be and thus cannot collude with them.

The district court interpreted the terms "overlay" and "overlaid video signals" to "require the ability to place two separate images (or video signals) on top of one another such that they would both be at the same spot on the screen at the same time." (emphasis added). As support for this interpretation, the district court relied on the prosecution history of the '842 patent, the parent of the first patent in the priority chain of the patents. Specifically, the district court relied upon the preamble of a claim in the Second Preliminary Amendment in the '193 application on January 14, 1997, which recited a "circuit for producing video signals over video signals that are produced by a remote computer." The district court held "without question, this indicates that Plaintiff understood that 'overlay' means having the ability to physically place one signal over another."

Turning first to the claim language, the plain language of the limitations do not require display of two separate images at the same time. Instead, the language requires circuitry for producing "overlay" or "overlaid" signals. Again, claims are to be interpreted in light of the written description and with the knowledge and understanding of those of ordinary skill in the art. Vitronics, 90 F.3d at 1582, 39 USPQ2d at 1576-77. The Microsoft Computer Dictionary cites the definition of the term "overlay" as:

1. In computer graphics, to superimpose one graphic image over another. 2. In video, to superimpose a graphic image generated on a computer over video signals, either live or recorded.

This definition does not require simultaneous display of two separate video images, as the district court required.

The written description supports the ordinary meaning by providing numerous methods for displaying "overlaid" images in accordance with the present invention. '176 patent, col. 12, l. 39 - col. 13, l. 12. The prosecution history, contrary to the district court's decision, does not limit the ordinary meaning of the terms "overlay" and "overlaid." The district court looked to the prosecution history and determined that language in the preamble of a preliminary amendment of a grandparent application required a narrowed construction of the terms "overlay" and "overlaid." This single instance of "evidence" does not overcome the presumption that claim language takes on its ordinary meaning.

In short, nothing appears within the written description or the prosecution history that limits the ordinary meaning of the terms "overlay" or "overlaid" as the district court held. The terms "overlay" and "overlaid" have their ordinary meanings, to superimpose one graphic image over another. They do not require the two images to be present on the same spot on the monitor at the same time. Therefore, we reverse the district court's claim construction of the term "serial data packet."

Claims 1, 2, 12, and 17 of the '919 Patent describe either "patient-engaging conductive gel layer" or "conductive adhesive gel layer" "overlaying the base layer." The parties dispute the meaning of the term "overlaying the base layer." Cardiac Science asserts that "overlaying" means "spread over." Philips renews its disclaimer argument set forth in Section II.D.1,
above, and contends that "overlaying the base layer" should be defined as "spread directly on the surface of the base layer (i.e., without any conductive contact layer, such as a homogeneous, thinly deposited metallic layer, a conductive ink material, or a flexible metal mesh, between the gel layer and the base layer)."

The main dispute among the parties is whether the term "overlaying" requires the gel layer to be spread directly on the base layer, or whether there may be another structure in between. The specification offers no support for this term's construction other than Figures 13 and 14, which demonstrate that the gel layer is spread directly on the base layer. The dictionary defines "overlay" as "to lay or spread over or across." Merriam-Webster's Collegiate Dictionary supra, at 885. The inventors did not specify that the gel layer "directly" overlays the base layer. Thus, the Court finds that in the context of the '919 Patent, the term "overlaying" is construed consistent with its common meaning, as "laid or spread over."

3026

C. "override criteria"

Claim 9 of the '404 patent contains the term "override criteria": "establishing override criteria from a group consisting of billing, taxing, CP (communications process) rating, service requested by a user of a mobile unit and CMR (cellular mobile radio) system." Claim 9 expresses this term in the form of a Markush group. Manual of Patent Examining Procedure § 2173.05(h). The term "override criteria" is not found in the specification. The plaintiffs contend that this term means "a preemptive rule for deciding, updating or adjusting something." Centennial asserts the following construction: "two or more rules that alter the operation of the system based on the exact location of the mobile unit."

First, the defendant argues that the override criteria must be based on the exact location of the mobile unit. In claim 9, step (a) establishes the exact geographic location, step (b) establishes override criteria, and step (c) directs the communication process based on the override criteria. But neither step (b) nor (c) explicitly refer to or use step (a)'s exact geographic location. Thus, according to Centennial, the override criteria must be based upon the exact geographic location determined in step (a), or step (a) would be superfluous. EMSAT and LBS do not contest Centennial's argument. Thus, the court holds that the override criteria must be based upon the "exact geographic location."

Second, Centennial argues that two or more members of the Markush group must be selected because the claim uses the word "criteria," which is the plural form of "criterion." In response, the plaintiffs contend that "criteria" is commonly used in singular form. Merriam-Webster Online Dictionary, http://http://www.merriam-webster.com/dictionary/criteria ("The plural criteria has been used as a singular for over half a century."). But Centennial quotes other dictionary definitions that state that criteria is always plural. E.g., Webster's II New Riverside University Dictionary 328 (1994) ("Criteria is a plural form and should not be substituted for the singular form criterion."). EMSAT and LBS also cite the prosecution history, in which the examiner referred to "an override criteria"; according to the plaintiffs, this statement indicates that the PTO considered "criteria" to be singular. Finally, the plaintiffs assert that the specification uses "criteria" in its singular form. (’404 patent, Fig. 8, Step 114A ("Has update criteria expired?")). Centennial notes, however, that the specification also uses "criteria" in its plural form. (’404 patent, Fig. 8, Step 114B ("Update on interval criteria (time, distance)"), 7:16-17 ("when the criteria are met").

Although the prosecution history and specification are ambiguous, the claim language is drafted to require plural "criteria." The disputed claim language contains no words, such as "at least one," "one or more," or even an indefinite article like "a" or "an," that suggest the possibility of a single criterion. Therefore, the court construes "override criteria" to mean "two or more preemptive rules that alter the operation of the system based on the 'exact geographic location' of the mobile unit."

Oxidation Graded:

The difference between the two competing interpretations of the term "oxidation graded" is whether the oxidation should be considered as "progressively more or less oxidized through its thickness" (AFG) or as "having a change in the relative oxygen content in a region such that one portion contains more oxygen than another" (Guardian).

The patents' specifications and claims state that the oxidation grade runs through the thickness of the layer, so that it touches one layer say an IR reflecting layer with one certain degree of oxidation and touches upon another layer with another layer with either less or more oxidation. For example in '349 Patent, Col. 25, lines 38-40 claims state:

wherein at least said second contact layer is oxidation graded and becomes progressively more oxidized through its thickness proceedings further from said infrared reflecting layer; and

The '050 patent specifications similarly states:

wherein at least said second layer comprising NiCroOx is oxidation graded so that a first portion of said second layer close to said infrared layer is less oxidized than a second portion of said second layer that is further from said infrared (IR) reflecting layer;

The phrase "the two contact layers on either side of the Ag layer are progressively less oxidized through their respective thickness as they near the Ag layer" can be found in both the '349 and '050 patents. '349, Col. 10, lines 16-17; '050, Col. 10, 35-37; '. The '349 patent also defines oxidation graded as "the degree of oxidation in the contact layer is graded or changes through the thickness of the layer." Col. 2, lines 7-9. The figures submitted in the patents further support this definition.

What is most convincing to this court that the definition should include the word "progressively" is the common sense understanding of the word "graded." AFG's proposed interpretation would mean that the oxidation levels in one end of the thickness are the highest, and the farther you go from that end the less oxidized the material becomes, until you reach the other end of the thickness which has the least amount of oxidation. This court may give meaning to disputed claim terms as understood by a person skilled in the art merely from the claim language itself by applying the widely accepted meaning of commonly understood words. Phillips. 415 F.3d at 1313. The court adopts as its interpretation for the claim term oxidation graded, "a layer that is progressively more or less oxidized through its thickness."

GO BACK
The Court construes the term "package" as "at least one electronic component or die covered by encapsulating material." Although the parties generally agree on the Court's proposed construction, the Court rejects both parties' proposed constructions because they include unwarranted limitations. First, ST's proposed construction 25 requires "external terminals to provide access to the components found inside." Although the Court would imagine that such terminals would exist on any such semiconductor device, the Court finds no language in the claims that requires such terminals and finds no clear disavowal of claim scope in the specification. Moreover, Motorola's proposed construction 26 improperly incorporates the requirement of an "interconnect substrate" into the claims. Although the term "interconnect substrate" is mentioned in the description of one preferred embodiment, the specification does not exhibit a clear disavowal of claim scope or definition of the term such that the term "interconnect substrate" should be read into the claim. '798 Patent, 1:48-50.

25 ST's proposed construction is: "a protective container or housing for an electronic component or die, with external terminals to provide access to the components inside."

26 Motorola's proposed construction is: "an interconnect substrate holding at least one electronic component covered by encapsulating material."

Both parties agree that a "packet" is a "block of data used for transmitting information." The parties dispute whether a packet must also include a header and a payload. The specification explains that, "Data packets can be typically divided into two parts, the header and the payload parts." '175 patent, 4:41-42.

- 3359 -
Widevine argues that a packet, according to its plain meaning in the art, must include a header and a payload. Widevine points out that the specification identifies six types of packets, each of which include a header and a payload.

Verimatrix argues that nothing in the intrinsic record requires that a packet have a header and a payload. Verimatrix identifies a number of telecommunications packets that do not require a payload. Verimatrix also points out that including the word "header" in the definition of a packet will make some terms superfluous in certain unasserted claims. For example, claim 3 of the '175 patent teaches that "the non-payload portion of the packet data includes at least one of a header, control data and routing data." According to Verimatrix, defining "packet" to necessarily include a header would make '175 patent, claim 3 meaningless.

Widevine further argues that, in the context of the claims, a packet must both have a header and a payload. Each of the claims recites performing some action on the "payload portion" of a packet. For example, the '831 patent, Claims 1, 9, and 16 recite "examining a payload portion of the packet." Limitations in the '175 patent, Claims 1, 19, and 37 recite parsing a packet into payload and non-payload portions of a packet. A limitation in the '175 patent, Claim 50 recites, "examining the data of each received packet to identify a plurality of portions that include at least a payload portion and a non-payload portion."

There is not an ordinary meaning for "packet" at the level of detail requested by Widevine in its proposal. The protocol or communications platform determines the composition of a packet. Additionally, some TCP/IP packets (included as an example in the specification in the '175 patent, 2:43-58) are intentionally empty, even though a TCP/IP packet is defined with space for a payload. While most packets include a header and a payload, the specification and the claims do not expressly preclude packets without headers or payloads. Even though each claim recites parsing into a payload and non-payload portion, the claims do not preclude non-payload-bearing TCP/IP packets, for example. The invention is capable of ignoring non-payload-bearing packets. Some claims expressly specify that a parsed packet includes both payload and non-payload portions. '175 patent, Claim 19, 37, 50, 58, 64, 74, 81, and 92. Some claims implicitly require multiple portions in a packet, one of which is a payload. See '831 patent, claim 1 ("receiving a packet; examining a payload portion of the packet"). Claim 3 of the '175 patent expressly recites that the non-payload portion "includes at least one of a header, control data, and routing data." Construing "packet" to always include a header makes the term "header" in Claim 3 superfluous. Each packet does, however, have a payload portion and non-payload portion. The court construes "packet" to mean "a block of data used for transmitting information that may include payload and non-payload portions."

Both parties agree that "payload" is "data of interest." They dispute whether the definition should require that payload be "contained inside of the packet. Verimatrix draws its proposed construction from the specification, which states, "The payload is the portion of the data packet that is just the data of interest, in exemplary case: multimedia content." '175 patent, 4:44-46. It is the Court's view that the patentee was acting as its own lexicographer when he described a payload as, "the portion of the data packet that is just the data of interest." See Sinorgchem, Co., v. Int'l Trade Comm'n, 511 F.3d 1132, 1138 (Fed. Cir. 2007) ("We have frequently found that a definition set forth in the specification governs the meaning of the claims."). Therefore, the Court's construction of "payload" is "the portion of the data packet that is just the data of interest."

The dispute over "non-payload" is whether it is appropriate to include "header fields" and "control fields" in the construction. Verimatrix argues that Widevine is attempting to import unnecessary terms from the specification. Widevine, on the other hand, argues that Verimatrix's definition is "coextensive" with a header, which inappropriately limits "non-payload" to header data exclusively. The Court agrees that "header fields" and "control fields" do not belong in the definition. The Court is not persuaded, however, that Verimatrix's proposal is so narrow as to exclude any data within a payload that is not in the header. Both "such as" and "including" are permissive words that do not indicate any restriction against the presence of other data in the non-payload portion. Nonetheless, the Court will modify Verimatrix's proposed construction to incorporate Widevine's word choice: "the packet data that is not payload data, such as routing or configuration information."

GO BACK

3031

(1) packet, packet form
All the parties agree as to the general construction of "packet." N-Data disagrees, however, with two additional limitations asserted by Dell and National. Dell and National both assert that "packet" refers to "information that is bursty in nature." They also assert that such information "is transmitted as a whole from one node of a network to another." Regarding the first issue, Dell and National point to the '261 patent for support, and N-Data points to the '820 patent for support. The '261 patent states, "[o]ne type of non-isochronous data transfer is a packet-type transfer. . . . As seen in FIG. 1A, because the fields provided for data 14a, 14b are not substantially continuous, the packetized scheme of FIG. 1A is not isochronous but is 'bursty' in nature." '261 Patent, col. 1, ll. 37-53. Thus, according to the '261 patent, "packet" is described as being bursty in nature. In light of the agreement by the parties to define certain terms uniform across each patent, the court must also examine the '820 patent. The '820 patent states, "[s]ome types of information, such as the information in a typical telephone conversation, do not lend themselves to being accumulated over time and then being transmitted as a single large packet. . . . Frequent transmissions of small packets of information over the network is required. Ethernet is not well suited to this 'nonbursty' type of information transfer." '820 Patent, col. 1, ll. 29-49. Here, it is clear that the '820 patent describes a "packet" as being "non-bursty." As such, the court will not limit a "packet" to being "bursty in nature."

Regarding the second issue, the agreed-to definition sufficiently defines "packet;" there is no reason to limit the term by providing a method of transmission premised solely on an extrinsic source. 2

--- Footnotes ---

2 Dell and National rely on a technical dictionary definition of "packet" published seven years after the '261 patent was filed. See MICROSOFT COMPUTER DICTIONARY FOURTH EDITION 327 (Christey Bahn, ed., Microsoft Press 1999).

--- End Footnotes ---

The court thus defines "packet" as follows: "a collection of information, including a data field which may be preceded and/or followed by non-data information, such as preamble information, housekeeping information and data destination information."

The court gives "packet form" its plain and ordinary meaning in light of the above construction.

--- 3032 ---

b. "Packet": A group of data bytes which represents a specific information unit with a known beginning and end.

--- 3033 ---

- "packet" is construed to mean "a group of bits, including data and control limitations, which is switched and transmitted as a unit; the data is arranged in a specific format." (See D.I. 387, App. 24 (Modern Dictionary of Electronics 705 (6th ed. 1984)).)

Lucent contends that this term means "a group of bits including data and control limitations which is switched and transmitted as a unit." (D.I 396 at 18.)

Extreme contends that this term means "the message unit that leaves the source user to network interface module (UIM) and travels all the way to the destination UIM without alteration." (D.I. 395 at 26.)

Foundry contends that this term means "the message unit that leaves the source user input module and travels all the way to the destination user input module." (D.I. 385 at 22.)

The patent application for the '486 patent was filed on March 31, 1988. The Court finds that Lucent, in support of its contention, cites a dictionary published contemporaneously with the patent application. However, Lucent omits the part of the definition of "packet" where the dictionary specifies that "the data is arranged in a specified format." (D.I. 397, App. 24.)
Further, the Court finds that Defendants impermissibly try to restrict the claim to the particular type of message unit used in the preferred embodiment. Accordingly, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

2. "packet data" and "synchronous data"

The plaintiff proposes that "packet data" means "variable bit rate data" and "synchronous data" means "constant bit rate data." The defendants propose that "packet data" means "data that is transmitted in packets" and "synchronous data" means "constant bit rate data that is not transmitted in packets." Both parties appear to agree that "synchronous data" refers to constant bit rate data. The dispute is whether "packet data" can also include constant bit rate data.

The specification defines these terms:

The present invention relates to data communications, and more particularly to communications systems that have channelized network access, and may transport both synchronous data and variable-bit-rate data such as frame relay data (hereafter referred to as packet data), in a time-division multiplexed format.

'858 patent, 1:8-11.

Contrary to the defendants' arguments, the patent defines "variable bit rate data" as "packet data," and the court adopts this construction. Moreover, the court defines "synchronous data" as "constant bit rate data."

− "data packet header" is construed consistently with its plain meaning as a "data packet header." The Court declines to further interpret the term "data packet header."

Lucent contends that this term means "control information in a data packet that instructs network components how and where to send the packet." (D.I. 396 at 19.)

Extreme contends that the term "header" means "the portion of a packet consisting of a virtual circuit number, source and destination address, group ID, group and other fields shown in Figure 20 of the '486 patent." (D.I. 395 at 26.)

Foundry contends that the phrase "data packet header" means "two distinct and separate sets of control bits preceding the data where the first set of bits contains an identification of the source destination port and where the second set of bits contains at least the packet's source address and destination address, which are flat MAN addresses, and a group identifier and name of the group to which the source user belongs." (D.I. 385 at 21.)

The Court finds that Lucent cites dictionaries that were published in 1999 and 2001 for its proposed construction. The patent application for the '486 patent was filed on March 31, 1988. Because Lucent has not cited to a dictionary published contemporaneously with the patent application, the Court rejects Lucent's proposed construction. Further, the Court finds that Defendants impermissibly try to restrict the claim to the particular type of data packet header used in the preferred embodiment. Accordingly, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

Packet switch
The Court adopts Ciena’s proposed construction and construes the term as “a routing device that forwards packets.” Nortel argues that the term should be construed as “a path-oriented routing device that forwards packets.” For the same reasons discussed above, the Court rejects Nortel’s use of the term “path-oriented.” Accordingly, the Court construes the term without including “path-oriented.”

1. a data packet transferring computer network

A "data packet transferring computer network" is a computer system by which a block of computer information is broken into smaller information units called "packets." These packets are sent over a computer network over a variety of paths. The packets are automatically reassembled into their proper order at the receiving end.

3. packets having a fixed length (claims 8 and 9)

Plaintiff's construction: "packets each containing the same number of user data blocks" Defendants' construction: "a CD-RW data structures having a fixed number of user data blocks and a fixed number of linking blocks"

The difference between the parties' constructions with respect to this claim is much clearer. Defendants' proposal inserts a number of concepts that are not found in the claim, which immediately raises red flags. In particular, defendants seek to limit the packets to "CD-RW data structures" that have a fixed number of "linking blocks." In support of its CD-RW limitation, defendants cite a line in the specification that states, "[a] minimum unit for recording information on an optical disc such as a CD-R or a CD-RW is defined as a packet." '955 patent, col. 1, Ins. 21-22. (Because the patent encompasses rewritable disks only, '955 patent, col. 1, Ins. 10-14, defendants excluded CD-R disks from their proposed construction.) However, as plaintiff points out, it is clear from the use of the phrase "such as" that the reference is illustrative, not restrictive. JVW Enterprises, Inc. v. Interact Accessories, Inc., 424 F.3d 1324, 1335 (Fed. Cir. 2005) (examples are not limitations). Defendants point to nothing else in the claims or in the specification that would prohibit claims 8 and 9 from including rewritable DVDs.

Defendants also fail to show that "packets having a fixed length" means that the packets included a fixed number of "linking blocks," a term not used in the patent. The specification does refer to "link blocks," though exactly what they are is not disclosed. "Link blocks" are included in the packet. E.g., '955 Patent, col. 1, Ins. 22-24 ("Each packet comprises at least one user data block, five link blocks . . ."). But the specification does not define a "packet having a fixed length" as a packet having a fixed number of link blocks. Rather, the specification states that "[t]he number of user data blocks within a packet is referred to as a packet length or packet size" and that "[i]n the fixed packet write method [which is the method described in claims 8 and 9], a number of user data blocks within a track is set to a fixed number." '955 patent, Col. 1, Ins. 58-61 (emphasis added). Thus, although a packet includes link blocks, link blocks are not used to determine the packet's length. Because the length is determined using the data blocks only, a packet having a fixed length must have a fixed number of data blocks, but the number of link blocks is not so restricted.

Court's construction: "packets each containing the same number of user data blocks"

E. Construction of "Corner Pad"

LPL contends that the term "corner pad" does not require construction, but that the proper construction, if one is necessary is "a reference mark for cutting" (D.I. 135 at 24.) CPT contends that the Court should construe "corner pad" as "a pad of metal or other conductive materials that is located at the corner of an outer guard ring, and electrically connected with the outer
ring" (D.I. 137 at 15.) CPT argues, (Id.), and LPL does not dispute, that "corner pad" has no inherent meaning to one of
ordinary skill in the art and thus can be understood only within the context of the '002 patent's claims and specification. LPL
does concede that "[o]ne of ordinary skill in the art would understand the term 'pad' to be a conductive area." (D.I. 135 at
15; D.I. 143 at 15.)

The term "corner pad" appears in only one embodiment in the specification. (See '002 patent, col. 8, ll. 1-48.) That
embodiment describes three features of a "corner pad." First, it is connected to each other corner pad by conductive lines of
the outer guard ring. (Id., col. 8, ll. 8-11.) Second, it can be grounded. (Id., col. 8, ll. 11-12.) Third, it provides alignment for
the scribe lines. (Id., col. 8, ll. 12-15.) The second feature is explicitly optional, so it need not be included in the Court's
construction. The third feature is specifically claimed, so it too need not be included in the Court's construction. (See, e.g.,
Id., col. 9, ll. 29-33 ("7. The method as defined in claim 1 including forming a corner pad on at least one corner of the
display and aligning scribe lines with said corner pad for removing said outer guard ring and row and column
intersections.")) Therefore, the Court concludes that LPL's proposed construction of "a reference mark for cutting" is
unnecessary and would be redundant. The location of the corner pad is also specifically claimed as being "on at least one
corner of the display." (See, e.g., Id., col. 9, l. 30.) Thus CPT's inclusion of "located at the corner of an outer guard ring" in
its proposed construction is both unnecessary and inaccurate.

The remaining issue is whether the "corner pad" must be electrically connected to the outer guard ring. CPT bases its
contention that the "corner pad" must be "electrically connected with the outer ring" on a single sentence from the
specification: "A corner pad 208 is connected to each other corner pad (not illustrated) by respective outer conductive lines
210 and 212 of the guard ring 200." (Id., col. 8, ll. 8-11.) The Court concludes that it would be improper to import this
limitation from the specification into the claims. Therefore, to the extent that "corner pad" requires construction, the Court
will construe it as "an area of conductive material."

F. Construction of "Pickup Pad"

LPL's proposed construction of "pickup pad" is "a conductive area used to electrically connect the back plane to the front
plane" (D.I. 135 at 14.) CPT's proposed construction is "a pad located at the corner region of a backplane for aligning the
frontplane and backplane" (D.I. 137 at 13.) CPT contends, and LPL does not dispute, that the term "pickup pad" has no
inherent meaning to one of ordinary skill in the art, and thus, can be understood only within the context of the intrinsic
evidence. (D.I. 137 at 13.) The parties agree, however, that "pad" would be understood by one of ordinary skill in the art to
mean a conductive area. (D.I. 135 at 15; D.I. 143 at 15; D.I. 160 at 3.) The Court concludes that neither proposed
construction is appropriate and will decline to construe "pickup pad."

LPL's contention that the "pickup pad" is used to electrically connect the back plane to the front plane has no support in the
intrinsic evidence. Neither the specification nor the claims of the '002 patent mentions any electrical connection between the
front plane and the back plane via the "pickup pad." Both teach only the electrical connection of the "pickup pad" with other
elements on the back plane. Thus, LPL's proposed construction cannot be correct.

CPT's proposed construction would violate the doctrine of claim differentiation. In this context, claim differentiation "refers
to the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim."
Arm Holdings, PLC., 403 F.3d 1364, 1370 (Fed. Cir. 2005)). In the '002 patent, claim 5 depends from claim 3. n4 Claim 3
claims "[t]he method as defined in claim 2 including forming at least one pickup pad coupled to said resistance via a shunt
switching element." (002 patent, col. 9, ll. 16-18.) Claim 5 claims "[t]he method as defined in claim 3 including forming a
corner on the said pad to align the front plane and back plane of the display." (Id., col. 9, ll. 23-25.) To construe "pickup
pad" as CPT proposes, as "a pad . . . for aligning the frontplane and backplane," would be to read the limitation from claim 5
into claim 3, rendering claim 5 superfluous and violating the doctrine of claim differentiation.

--- Footnotes ---

n4 The discussion that follows applies identically to claims 16 and 14, 23 and 21, and 34 and 32.

- 3364 -
All of the significant attributes of the "pickup pad" mentioned in the specification are also specifically claimed. (Compare, '002 patent, col. 8, ll. 18-39, with id. col. 9, ll. 16-28.) Therefore, the Court concludes that no further construction of the term "pickup pad" is necessary.

I. "page" in the 351/ '696 patent

Lexar's proposed construction:
the unit of data, consisting of 256 bytes, programmed to and read from the memory at the same time

Toshiba's proposed construction:
the unit of data, consisting of a plurality of bytes, written to and read from the same time

Claims 4 and 5 of the 351 recite writing pages into memory and claim 2 of the 696 recites programming pages into memory. The parties' dispute over the proper construction of the term is twofold: first, the parties disagree about whether a page, in the 351/ '696 is limited to 256 bytes; and second, the parties disagree about whether a page is "written to" or "programmed to." The Court addresses each of these disputes in turn.

Lexar contends that a page, by definition, consists of 256 bytes. According to Lexar, the 351 and 696 specifications require such a limitation even though the claim language itself says nothing about page size. Indeed, both portions of the 351 specification cited by Lexar (column 24, lines 56-57 and column 32, lines 46-49), which describe preferred embodiments, teach 256 bytes per page. Column 24, lines 56-57 describes the preferred embodiment as exemplified by Figure 57 in which the EEPROM has "a structure of 256 bytes per one page." Similarly, column 32, lines 46-49 suggests that in the preferred embodiment described, a page consists of 256 bytes. The same holds true for the portions of the 696 specification cited by Lexar. The language describing preferred embodiments in column 35, lines 43-46 and in column 36, lines 52-53 of the 696, describing a page as 256 bytes.

Toshiba argues that nothing in the 351/ '696 claim language or the specifications limits a page to 256 bytes. Generally, a limitation from a preferred embodiment cannot be imported into the construction of a claim term. Markman, 52 F.3d at 980. However, Lexar contends that the consistent use of a 256-byte page in the specification means that under Alloc, Inc. v. ITC, 342 F.3d 1361, 1368 (Fed. Cir. 2003), the claim itself is so limited. The Court finds, however, that this argument is unavailing here. Here, the patent specifications' references to a 256-byte page (two references per specification) do not rise to the level described in Alloc of "mak[ing] clear . . . that the claimed invention is narrower than the claim language might imply." Id. at 1370. In Alloc, everything in the specification led to the unavoidable conclusion that "the invention as a whole, not merely a preferred embodiment, provides for play in the positioning of floor panels." Id. at 1368-69. The Court in Alloc also noted that the patent specification specifically criticized prior art floor systems without "play," strongly suggesting that the invention required it. Here, on the other hand, the Summary of the Invention sections of the 351 and the 696 patents say nothing about the size of a page, nor do the Abstracts. Moreover, there are only four references to 256-byte pages in the two patents. Additionally, the patents do not criticize prior art for using pages of other sizes. The Court finds that the references to 256-byte pages in the 351 and 696 patent specifications do not rise to the level of consistent usage dictating a limitation in the construction of the term. Therefore, because the claim language does not limit a page to 256 bytes and because the specification does not clearly and consistently narrow a page to 256 bytes, the Court rejects this portion of Lexar's proposed construction.
With regard to the parties' dispute over whether a page is written to or programmed to, Lexar contends that Toshiba's proposed construction is too broad because "writing" encompasses both programming and erasing. Lexar argues that limiting a page to that which is "programmed to" is more precise. "Program" is defined as "the operation of injecting electrons onto the floating gate of the memory cell." (IEEE FGA Standard Definitions at 23.) Lexar acknowledges the IEEE's definition of a page as "a section of an array that may be written to simultaneously." Lexar goes on to argue, however, that based on the specification and prosecution history, "page" must be further limited to that which is "programmed to" rather than "written to." Toshiba, for its part, only spends a few sentences in its Opening Brief (and no effort in its Reply) on the programming/writing dispute. Toshiba contends that the language of the 933's specification supports its construction but the Court declines to look to a wholly unrelated patent to construe a common claim term.

For these reasons, "page" in the 351/’696 is construed as the unit of data, consisting of a plurality of bytes, programmed to and read from the memory at the same time.

II. "page" in the 933 patent

Lexar's proposed construction: Toshiba's proposed construction:
the unit of data, consisting of 256 bytes, the unit of data, consisting of
programmed to and read from the memory a plurality of
the memory at the same time bytes, written to and read from
at the same time

The dispute here is the same. The parties propose the same respective constructions of "page" in the 933 patent that they propose for the 351/’696 patent and again, their dispute is focused on the size of a page and on whether a page is "programmed to" or "written to" the memory. At oral argument, Lexar and Toshiba reported that they agree that "page" in the 933 should be construed consistently with its construction in the 351/’696. However, the parties' agreement in that regard does not bind the Court. Because the 933 patent is wholly unrelated to the 351 and the 696 patents, the Court engages in a separate analysis of the disputed claim term here.

Here, unlike in the 351/’696 discussion supra, the parties' references to the 933 specification are relevant. Claims 1, 4, 31, and 34 of the 933 recite writing pages into memory. Lexar again urges the Court to find that a "page" is limited to 256 bytes. Nothing in the claims themselves restricts a page to 256 bytes. Therefore, Lexar relies on the specification language describing a preferred embodiment to support its proposed construction. Generally, as discussed supra, limitations from a preferred embodiment cannot be imported into the claims. Markman, 52 F.3d at 980. However, Lexar contends that the consistent reference to a 256-byte page in the 933 patent specification means that under Alloc, 342 F.3d at 1368, the claim term itself is so limited.

Lexar's Alloc argument is somewhat more compelling in the context of the 933 patent. In the 933, the specification frequently refers to a page of 256 bytes. (See, e.g., 933 patent 9:43-46.) However, the specification also frequently refers to memory cell pages without any reference to their size. (See, e.g., 933 patent 3:20-24, 3:38-40, 3:56-58.) This is at odds with Alloc where a narrower construction was only deemed appropriate where the limitation was made clearly and consistently throughout the patent. 342 F.3d at 1368. Moreover, the Summary of the Invention section also describes a page of 1024 bytes and "pages of different sizes." (’933 patent 10:42, 10:63, 11:48.) Lexar explains that these references correspond to the selection of multiple pages of 256 bytes each, not to single pages containing more than 256 bytes. However, the Court finds that the references to pages of different sizes preclude a finding that the specification's references to 256-byte pages rise to the level of "mak[ing it] clear . . . that the claimed invention is narrower than the claim language might imply, as described in Alloc. Therefore, the Court declines to limit the construction of "page" to 256 bytes.

With regard to the programming/writing dispute, Toshiba argues that the intrinsic evidence of the 933 describes only writing, rendering its proposed construction more consistent with the intrinsic evidence. Here, the Court agrees with Toshiba. The claim language of the independent claims (1 and 31) in the 933 teaches a semiconductor memory device containing a page in which "a read or write operation is performed." (’933 patent 15:24; 933 patent 18:51-52.) Toshiba's citation to a portion of the specification, column 2, lines 4-5 and 12-13, in which the reading and writing of pages is described, does not further the inquiry, however, because that language appears in the background of the invention section and does not describe the invention itself. But the language cited by Toshiba at column 10, lines 9-29, is instructive because it appears in the preferred embodiment section. The language there describes the write and read operations performed to a
Because it would be improper to construe a claim term to exclude a preferred embodiment of the invention and because, as Lexar itself points out, programming is, at least in some respects, a narrower process than writing, the Court cannot limit a "page" to be "programmed to" when a preferred embodiment teaches a page that is written to. Lexar argues that here that "writing" in the 933 patent really means "programming," but the Court is unconvinced.

The Court construes "page" in the 933 as the unit of data, consisting of a plurality of bytes, written to and read from the memory at the same time.

A. "page file" (Claims 1, 4, 5)

Plaintiff: A data element constituting at least a portion of a Web page and/or instructions for displaying content on a computer.

Defendant: A Web page file, such as an HTML file.

The Court adopts Defendant's construction. The claims of the '577 patent all refer to forming customized "web pages." Claim 1, for example, claims a method for forming customized "web pages" through forming page files. '577 Patent at 9:47-49. The only "page files" described in the Patent are web page files. For example, the Abstract states that "the ICP stores web page files designed for itself and its participating web sites." Id. at Abstract. The Abstract continues with: "Upon receiving a service request from a participating web site, the ISP dynamically forms customized web pages for the participating web site by combining the page files designed for itself and the page files designed for the participating web site." Id. The specification goes on to state:

Typically, a website stores information in a set of web page files, such as HTML, SHTML, DHTML, or CGI files. . . . A web page file may contain one or more page links containing the path information to other web page files in the same web site. Thus, using a web browser, a user can access a home page file (the page file at the root level) of a web site. From the home page, the user can browse subsequent web page files by selecting links contained in the home page file. The subsequent web page files may further contain one or more page links, which can be further selected to browse web page files at the next level. At any level, a browser can browse back to the previous web page file and re-select page links from the previous web page file. A web page may contain page links (foreign page links) containing path information to the web pages of the other web sites. Upon selecting a foreign page link contained in a web page file, a service request is sent to the web site indicated by the path information in the foreign page link, to retrieve the web page in the foreign web site.

In addition, a web page file may contain links to other types of files, such as AVI, GIF, JPEG, and PNG files . . . A web page file may also contain applets. Upon receiving a web page file, a web browser can display it as a web page on a user computer.

Id. at 5:14-43. Again, the only "page files" mentioned are "web page files."

Plaintiff complains that by adopting Microsoft's position, the Court is reading in an example from the patent's specification into the claim. See RF Del., 326 F.3d at 1264. The Federal Circuit has recognized "that the distinction between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim can be a difficult one to apply in practice." Phillips, 415 F.3d at 1323. "However, the line between construing terms and importing limitations can be discerned with reasonable certainty and predictability if the court's focus remains on understanding how a person of ordinary skill in the art would understand the claim terms." Id. Upon reading a specification, "it will become clear whether the patentee is setting out specific examples of the invention to accomplish those goals, or whether the patentee instead intends for the claims and the embodiments in the specification to be strictly coextensive." Id.

Here, Plaintiff emphasizes the portion of the specification that expressly distinguishes a "web page file" from "other types of files, such as AVI, GIF, JPEG, and other PNG files." Id. at 5:35-37. Yet this passage does not describe another type of page file, it merely describes other types of files. The only kind of "page file" described in the specification is a "web page file." Accordingly, by construing "page file" as a "web page file," the Court is not importing a limitation from the specification --
it is looking to the only type of page file referenced in the specification. It is clear from the specification that there was nothing in the context to indicate that the patentee contemplated any alternative embodiment to the one presented by Defendant. See Phillips, 415 F.3d at 1323; see also Decisioning.com, Inc. v. Federated Dept Stores, Inc., 527 F.3d 1300, 1308 (Fed. Cir. 2008) (construing broad term narrowly in light of the more limited language of the specification).

Plaintiff further argues that "claim 1 clearly indicates that more than one page file may make up the ultimate Web page," see Pl. Br. at 12, but that assertion is not in dispute. Microsoft agrees that multiple web page files may be combined to create a single customized web page. What is in dispute, rather, is what constitutes a "page file" as claimed in the '577 Patent. Reading the patent in its entirety supports a construction that "page file" would mean "web page file" to an ordinary person skilled in the art. See Netcraft, 549 F.3d at 1397 ("In order to properly determine the ordinary meaning of the entire phrase at issue in this case, we must consider the claim in light of the entire patent.").

Finally, Plaintiff complains that the Court should not adopt Defendant's construction because it uses the term to be construed, "page file," within the construction, "a web page file." The Court's task at claim construction is to determine the specific meaning of a term or phrase used within the Patent. When a party uses a broad or ambiguous term, part of the Court's function is to see whether there is a more specific definition that should apply. The term "page file" could, theoretically, encompass far more than what is contemplated by the claim. Accordingly, it is entirely proper for the Court to refine the term so that its construction comports with the intrinsic evidence.

The Court further notes that Plaintiff's proposed construction is unsatisfactory. Plaintiff fails to cite intrinsic evidence supporting its construction. Neither "data element" nor "instructions for displaying content" appears anywhere in the '577 Patent. Plaintiff has not provided other evidence suggesting that a person of ordinary skill in the art would assign its definition to the phrase "page file." Moreover, Plaintiff's construction adds ambiguity rather than clarity to the claim. It includes new, undefined terms which could require further construction by the Court.

In reading the Patent in its entirety, the Court concludes the term "page file" shall be construed as a Web page file, such as an HTML file.

---

9. Page Mode Type of Memory Access

The term "page mode type of memory access" refers to a type of memory access where blocks of memory cells in the same row are accessed by the assertion of the row address strobe signal followed by multiple assertions and deassertions of the column address strobe signal while the row address strobe signal remains asserted.

---

3. “Page Server”

“Page server” is utilized in asserted claims 1, 4, 7, and 9-11 of the ‘554 Patent and 1, 2, 5, 8, 15-16, 19, 22 and 29 of the ‘335 Patent. The Plaintiff asserts that the proper construction of “page server” is “a processing system operable to receive a request and dynamically generate content in response to the request.” The Defendants assert that the term should be construed as “page generating software that generates a dynamic Web page on a machine separate from the Web server machine.” In the claim construction Oral Argument, the Plaintiff agreed to the use of “page generating software” in place of the term “a processing system” as previously proposed by the Plaintiff. The differences between the parties with regard to the use of “content” verse “Web page” are rooted in the basic dispute over the meaning of Web page as discussed above. Both parties include the concept of dynamic generation in their proposed constructions.

In the post oral hearing briefing, the parties each acknowledged that the primary dispute regarding the construction of “page server” is whether the Page server has to be on a machine separate from the Web server. As discussed below, the Court agrees with the Plaintiff with regard
to this point of dispute.
Each party points to the specification to support their asserted position. The Plaintiff asserts
that the specification includes statements that indicate that the Page server could operate on the same
machine as the Web server. In particular, the Plaintiff has pointed to passages which state:
FIG. 1 illustrates a typical computer system 100 in which the present invention
The preferred embodiment of the present invention is implemented as a software
module, which may be executed on a computer system such as computer system 100
in a conventional manner. Col. 3:55-58.
Figure 1 illustrates a computer system having a processor, bus, memory and mass storage. Further,
it is stated that “the preferred embodiment of the present invention” may be implemented on a
personal computer or alternatively a workstation. Col. 2:67-Col. 3:5. The Plaintiff asserts that this
language is consistent with the specification as a whole by asserting that the specification describes
a partitioned software architecture in which in some embodiments the software modules may all
reside on the same machine and in other embodiments the software modules may reside on different
computers.
The Plaintiff also points to a passage that describes an embodiment that does not have the
advantage of “off-loading the processing of Web requests from the Web server machine” to a
separate machine. Col. 5:26-36. However, the Court notes that this passage makes specific
reference to the division between a Web server and a Dispatcher, and it is not clear in this passage
alone that the Page server is also included in this use of a single machine.
The Defendants argue that the specification describes a distinction over the prior art that
amounts to an explicit characterization of the invention that disclaims the prior art. See SciMed Life
Sys. V. Advanced Cardiovascular Sys., 242 F.2d 1337, 1343 (Fed. Cir. 2001). In particular, the
Defendants point to a passage of the specification that describes the multi-threading techniques of
prior art Web servers. Col. 4:32-53. This passage concludes with “[t]he claimed invention addresses
this need by utilizing a partitioned architecture to facilitate the creation and management of custom
Web sites and servers.” The Defendants assert that this clearly demonstrates that the purpose of the
invention was to partition the various modules on separate machines. As to the passages cited by
the Plaintiff, the Defendants assert those passages do not describe the entirety of the claimed
invention. The Plaintiff asserts that the passage cited by the Defendants is directed toward the Web
site management “need” recited in the passage, and this need is addressed by a partitioned
architecture.
The parties have thus each pointed to somewhat conflicting passages of the specification to
support their positions. The passages cited by the Plaintiff establish that there is not a clear
disavowal within the specification of the use of a partitioned software architecture on a single
machine. The Defendants do correctly point to cases which stand for the proposition that when the
specification makes clear that the invention does not include a particular feature than that feature is
deemed to be outside of the reach of the claims of the patent. Defendants’ Joint Sur-Reply, p. 8.
However, in the specification before this Court, the specification does not make clear that the
invention must only be operated on separate machines.
The Court construes “page server” to be “page-generating software that generates a
dynamic Web page.”

The Court is of the opinion that the findings and conclusions of the Magistrate
Judge are correct. Therefore, the Court hereby adopts the Report of the United States
Magistrate Judge as the findings and conclusions of this Court.
2. "Pages of data"

The court construes the term "pages of data" to mean "fixed size blocks of data." The court rejects the plaintiff's proposed construction because it includes an additional requirement of "fixed alignment." The court is persuaded that one of ordinary skill in the art would understand the term to connote the meaning ascribed to the term by the court.

4. "pair of pointers"

NICE's Construction
Digital information used to read data from and write data to a storage component.

Witness's Construction
Two pointers facilitating the simultaneous retrieval of data from the random access storage device and the writing of data thereto.

The parties dispute the meaning of pair of pointers," as used in claim 8 of the '371 patent. A "pointer" is digital information that refers, or "points," to an address, memory location, function, etc. Witness contends that NICE's proposed construction ignores the word "pair" and the clear meaning of the specification. Nice contends that, while the reading and writing pointers could operate simultaneously, there is no requirement that they do so. Nice contends that the specification makes clear that data is continuously being written to the RAS device, (col. 1:65-67), but is only retrieved when desired and "[u]pon input of the time and date of the data to be retrieved," (col. 4:3-4).

The Court construes the disputed language to mean "digital information used to read data from and write data to a storage component." The specification clearly discloses that the reading and writing of data to the RAS does not have to be simultaneous, even if, in some circumstances, it will be.

3. Paperless Facsimile Terminal Machine/Paperless Facsimile Device

6 The parties agree that these terms are used synonymously in the patents.

In the asserted claims, "paperless facsimile terminal machine" appears only in the '302 patent, claim 24, and "paperless facsimile device" appears only in the '034 patent, claim 1. As the claim language makes clear, this term describes the modem and specific software that allow a paperless fax terminal device to emulate fax terminals by using fax protocol. The '302 patent, claim 6 recites a "paperless facsimile terminal machine," and the balance of the claim requires a "signal modem" that can be programmed to operate in "facsimile communications mode so that facsimile messages stored in the subscriber's mailbox can be directly displayed on said display means of the paperless facsimile terminal machine." Similarly, the summary of the invention states the "so-called 'paperless' fax terminals" are "small portable computers equipped with modems and software programs which enable them to emulate fax terminals." ('034 patent, claim 4.) The summary also states that "[i]n recent years, paperless fax techniques allow a computer or a micro-processor equipped with
specific software and modem to directly transmit and receive facsimile messages." This confirms that the specific software and modem allow the "paperless fax device" to emulate a fax machine by sending or receiving messages over the switched telephone network using facsimile protocol.

Moreover, all embodiments in the '034 and '302 patent specifications require a modem to enable the paperless fax device to emulate a fax terminal. "Although patent claims need not be limited to the preferred embodiment when the invention is more broadly described, neither do the claims enlarge what is patented beyond what the inventor has described as the invention." Inpro II Licensing, 450 F.3d 1350 (Fed. Cir. 2006) (citation omitted). For these reasons, the Court construes this term as follows:

CONSTRUCTION: A machine that emulates facsimile terminals by using facsimile protocol

3051

B. "parsing"

<table>
<thead>
<tr>
<th>Term</th>
<th>Widevine Construction</th>
<th>Verimatrix Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parsing</td>
<td>Analyzing data to differentiate</td>
<td>parse = separate; parsing = separating</td>
</tr>
<tr>
<td></td>
<td>between different portions of data.</td>
<td></td>
</tr>
</tbody>
</table>

The parties agree that a "parser" is "software on a computing device that analyzes input data to differentiate between different portions of data." Widevine proposes a construction that is based upon this agreed definition for "parser." Verimatrix proposes "separating," arguing that the claims and specification show that parsing means separating. The specification explains the benefits of the invention over the prior art:

Without accurately parsing the data into payload and non-payload parts, the user specific data is readily damaged or scrambled during the encryption process, making it impossible for the firewall, proxy server or NAT to deliver the data to the requesting user. In contrast, the present invention accurately separates the payload and non-payload parts, encrypting only the payload part so that the data appears unchanged to the firewall, proxy server or NAT that requires only the non-payload part to affect delivery to the user requesting the data stream.

'175 patent, 8:58-9:3.

Widevine finds fault with Verimatrix's proposal because it implies a physical separation of data that the claims do not require. Verimatrix, on the other hand, argues that substituting Widevine's construction for "parsing", Verimatrix argues, yields a nonsensical result: "[analyzing data to differentiate between different portions of data] the received packet data into portions." See '175 patent, Claim 19. The Court agrees with both parties; neither proposal is appropriate. The parties have already agreed to what a parser does. The Court adopts a construction that captures the parties' agreement, as well as substitutes into the claims cleanly. "Parsing" means "differentiating."

3052

5. "Participant level:" 5 "Structured set of information about a person relevant to a claim." The parties agree with this construction, which also finds its basis in col. 84:37-63 of the specification.
"to partition said memory [means]"

Claim 1 of the '057 patent and claim 10 of the '362 patent contain the term "to partition said memory [means]." Typhoon suggests that the term needs no construction and simply means "to divide a memory." Defendants advocate that the definition is "to divide a memory into multiple locations recognized by the operating system as separate sections of memory for storing data." The fundamental dispute between the parties is whether "partition" should be given its technical definition. Since Phillips, claim terms are generally given their technical definition in lieu of a general dictionary definition. See Amgen Inc. v. Hoechst Marion Roussel, Inc., 469 F.3d 1039, 1041 (Fed. Cir. 2006) (citing Phillips, 415 F.3d at 1303); Mangosoft v. Oracle Corp., 525 F.3d 1327, 1333 (Fed. Cir. 2008) (construing a claim term consistently with its technical definition). Within the field of computer science, "partition" has a particular and well recognized definition meaning: "a section of a hard disk physically divided from other sections during the formatting operation and treated by the operating system as if it were a separate disk." See Defendants' Brief, Ex. 16, Docket No. 355-19 (referencing Que's Computer User's Dictionary 344-345 (1990)).

Further, the specification explains that "the host system 202 stores an application and associating libraries in memory locations partitioned by the application generator." Accordingly, this reference explains that the "data" (applications and libraries) are stored in memory locations (as opposed to physical locations) and that such memory locations were created by the application generator (the "operating system"). Therefore, besides the patented subject matter generally falling under the field of computer systems, the intrinsic evidence further supports use of the technical definition. Typhoon provides no evidence, either intrinsic or extrinsic, that supports the use of a broader definition outside the context of computer science. Accordingly, "to partition said memory [means]" means "to divide a memory into multiple locations recognized by the operating system as separate sections of memory for storing data."

3. Partitioning the cells into a plurality of partitions

<table>
<thead>
<tr>
<th>Disputed Claim Language</th>
<th>Synopsys's Proposed Construction</th>
<th>Magma's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partitioning the cells into a plurality of partitions</td>
<td>subdividing or distributing the cells into more than one partition groups of cells</td>
<td>subdividing cells in one region into multiple</td>
</tr>
</tbody>
</table>

The phrase "partitioning the cells into a plurality of partitions" appears in claims 1, 6, and 11 of the '114 patent. The parties dispute as to the construction of this term relates to whether "partitioning" is limited to subdividing a group of cells from a single region, or whether it also encompasses distributing cells to different partitions without moving the partition boundaries. In other words, if one analogizes a group of cells to a cherry pie, the dispute is whether the pie is "partitioned" only by cutting it into slices, or whether it also may be "partitioned" by moving individual cherries from one location in the pie to a different location in the pie.

The "Summary of the Invention" section of the '114 patent sets forth no requirement that the cells be partitioned in any particular manner, providing only that "[a] partitioning algorithm is then applied to group the cells into a plurality of partitions." (See '114 Patent at 2:23-25.) The specification of the '114 patent, however, expressly defines "partitioning" as "the process of subdividing the cells in order to better 'spread' them apart." (See id. at 3:48-49.) The specification nevertheless does go on to note that "[t]here are a number of different partitioning approaches that can be implemented with the present invention," citing two articles by name. (See id. at 5:38-56.) The patent also provides that "[o]ther approaches to
the partitioning process include min-cut, force-directed, simulated annealing, and spectral approaches." (See id. at 5:56-58.)

Magma argues that "partitioning," in the context of the '114 patent, requires "subdividing" the cells, i.e., dividing a group of cells into smaller parts, rather than distributing cells to different locations. As Magma notes, in a description of the preferred embodiment, "partitioning" is conducted as follows: "A cell (e.g., in the shape of a rectangle) is broken into two roughly equal sizes by drawing either a horizontal or vertical line through the approximate midpoint." 14 (See id. at 3:49-52.) In the preferred embodiment,

\[\text{[t]he first step of partitioning divides the n cells into two sets of n/2 cells. The number of cells in each side is approximately the same. The area of each half is proportional to the area of the cells included in it. The next step of partitioning is to divide each of these groups in two, this time on the other axis. This process continues until there are only a few cells in each group (e.g., twenty or less).}\]

(See id. at 4:43-50.) The above-cited language essentially describes partitioning contiguous groups of cells in the same manner as one might cut a pie into slices.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

14 It appears, based on the context of this statement, that partitioning applies to a group of cells, rather than to a single cell.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Synopsys argues that Magma's construction ignores an embodiment described in the '114 Patent in which, according to Dr. Harris, "it is not necessary to draw additional horizontal and vertical lines for subdividing the cells." (See Harris Decl. P 143 (citing '114 Patent at 4:28-36).) The '114 patent recognizes that during the various iterations of the rough placement process, additional cells might be added to the netlist, (see id. at 3:20-26), and that despite "efficient partitioning," "there might come a point where there is not enough room to add an additional cell." (See id. at 4:21-24.) According to the specification: "The present invention overcomes this limitation whereby, the total area is allowed to expand in order to accommodate additional nets and/or cells." (See id. at 4:24-26.) The embodiment cited by Dr. Harris is described in Figure 2 of the '114 Patent:

\[\text{An example of an expanded area is shown as 213. Expanding the total area affects the partitioning. For example, the location of vertical cutline 214 corresponding to the original area size is now moved to location 215 in order to account for the increase in size as the width of the original boundary 216 is increased by shifting the right boundary to location 217. A change in the partitioning might lead to different placements. For example, prior to enlarging the area, cell 218 belonged to the rightmost partition. After the enlargement, cell 218 now belongs to the leftmost partition.}\]

(See id. at 4:26-36 and Fig. 2.) Dr. Harris attests that "[t]his is a technique of subdividing the cells, where, as a result of shifting the partition boundary, the cells in two different regions are redistributed among each other to form two new partitions," and said technique "does not involve the drawing [of] either horizontal or vertical lines in one region." (See Harris Decl. P 143.)

The process described by Dr. Harris, however, is not part of the partitioning process itself, but rather, as Magma argues, a process that occurs during the step of "spacing" the cells in response to changes made to the netlist. 15 (See '114 Patent at 3:20-47, 5:33-35; see also Dr. Sarrafzadeh Decl. P 54.) Further, in such process, although cells may be reassigned from one partition to another, such reassignment again is accomplished by moving partition boundaries, not by moving the cells themselves. 16 In sum, the process cited by Dr. Harris not only does not result in "distributing" cells from one area to another, it is not part of partitioning at all.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

15 The Court notes that each of the claims that contains the step of "partitioning the cells into a plurality of partitions" also includes the step of "modifying the spacings of the cells responsive to changes made to the netlist." (See '114 Patent at 6:66-67, 7:24-25, 8:18-19.)

16 By expanding the area in order to modify the space between cells, the preexisting partition boundaries necessarily move

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -
to ensure that the partitions remain of equal size. (See id. at 4:22-36, 4:45-47.)

Moreover, although the specification expressly notes that "[t]here are a number of different partitioning approaches that can be implemented with the present invention," and although the patent expressly identifies a number of different approaches, (see id. at 5:38-40), Synopsys presents no evidence that any of these methods involves distributing rather than subdividing groups of cells. Magma, by contrast, presents evidence that one of the articles cited in the '114 patent, "A Procedure for Placement of Standard-Cell VLSI Circuits," (see '114 Patent at 5:49-50), discusses partitioning cells by "divid[ing]" cells, rather than distributing them. 17 (See Sarrafzadeh Decl. P 50 and Ex. 33.) Dr. Sarrafzadeh also cites his own textbook, "An Introduction to VLSI Physical Design," in which he states that "[p]artitioning is the task of dividing a circuit into smaller part," and includes a diagram that depicts a group of cells being subdivided. (See id. P 51 and Ex. 34.) Dr. Sarrafzadeh further attests that it would be "completely unusual" to use the term "partitioning" to describe "merely moving cells around between two partition[s]," and that "the specification of the '114 Patent is consistent with the ordinary use of the term partitioning to mean subdividing." (See id. P 53.)

17 Dr. Sarrafzadeh does not discuss the other methods of partitioning set forth in the '114 patent.

In his reply declaration, Dr. Harris points to two articles which, he contends, show that "one may 'partition' by redistributing cells between existing regions." (See Harris Reply Decl. P 61 and Exs.C and D.) Neither article is cited in the '114 Patent, however, and Dr. Harris has not opined that any of the methods of partitioning that are cited in the '114 Patent involve redistributing cells, rather than subdividing groups of cells.

Accordingly, as the patent specifically defines "partitioning" as "the process of subdividing the cells in order to better 'spread' them apart," (see '114 Patent at 3:48-49), and as there is no evidence that any of the particular methods of partitioning cited in the patent involve distributing cells, rather than subdividing groups of cells, the Court will adopt Magma's construction and construe the phrase "partitioning the cells into a plurality of partitions" as "subdividing cells in one region into multiple groups of cells."

As an initial matter, the Court concludes that the terms "use mode" and "fully enabled mode/full version run" mean the same thing. At the Markman hearing, Microsoft readily agreed that these terms are synonymous. Uniloc, however, was hesitant to agree to synonymous treatment on the spot. But importantly, when pressed by the Court, Uniloc was once again unable to offer an example of a situation when "fully enabled mode" would mean anything other than "use mode." So, although Uniloc has not explicitly agreed that these terms are synonymous, Uniloc has been unable to make an argument, compelling or otherwise, that the terms deserve different treatment. Moreover, the Court observes that Uniloc's proposed constructions for these terms do not vary materially. While Uniloc has included the word "unrestricted" in its construction of the term "fully enabled mode," there is nothing to indicate that "use mode" is restricted in any way other than the scope of the license. Indeed, Uniloc's own expert, David Klausner, stated that use mode is an unrestricted mode:

One of ordinary skill in the art recognizes the patent relates to the use of software or digital data in a restricted or unrestricted mode (use mode/non-use mode). The terms "fully-enabled mode" and "full version run" are used similar to "use mode" to mean allowing unrestricted use in accordance with the license.

Klausner Decl. at P 18. Moreover, the specification discusses these terms in a similar context by explaining that they are the converse of the term "partly enabled or demonstration mode." Compare '216 Patent, col. 2, ll. 44-48 ("The use mode is to be distinguished from what might generally be termed unlicensed modes of operation (which is not to say unauthorized modes of operation) as typified by the demonstration modes later described in this specification"), with id. at col. 15, ll. 1-5 (explaining that the mode switching means switches software between a fully enabled mode on the one hand, and a partly
Turning then to the parties’ proposed constructions, the main point of disagreement is whether the difference between the full and demonstration modes involves only functional limitations (such as limitations on the ability to save or print a document), or whether the claim terms should be construed broadly enough to encompass temporal limitations as well (such as only being able to use the software for two days). In support of its argument that the demonstration mode only involves functions being disabled, Microsoft cites portions of embodiments 1 and 5. See id. at col. 6, ll. 47-48 (explaining that "a demonstration of the software (which typically has features such as save and/or print disabled)"); id. at col. 11, ll. 14-17 (stating that the "[t]he registration code portion 38 can include a preview or demonstration related to a subset of the balance of the digital data on the CD 54 which can be executed by the platform without license"). But while these embodiments discuss characteristics which a demonstration mode can have, or typically has, the Court declines to read these examples from two embodiments to mandate that in all instances, the demonstration mode only can involve functional limitations. See generally Phillips, 415 F.3d at 1323 (the general rule is that "persons of ordinary skill in the art rarely would confine their definitions of terms to the exact representations depicted in the embodiments."). For these reasons, the words "functionality" and "functions are disabled" will not be part of the Court's construction of these terms.

Instead, the Court determines that the use and fully enabled modes are best described as allowing "full use" of software "in accordance with the license." This language is consistent with the specification's explanation of the term "use mode," see '216 Patent, col. 2, ll. 40-48 (explaining that use mode refers to use of the digital data or software so as to fulfill the licensor's obligations), as well as the specification's general guidance that once the registration routine is complete, "full access to the software is allowed." Id. at col. 8, l. 28.

Accordingly, the terms "use mode" and "fully enabled mode/full version run" shall be construed as: A mode that allows full use of the digital data or software in accordance with the license. n12

n12 Although Microsoft agreed that the terms "use mode" and "fully enabled mode/full version run" should be treated the same, it did not specify which of its proposed constructions was preferable in that event. Nonetheless, to the extent Microsoft may have intended to press its proposed construction of "use mode," this writer notes that the Court's construction incorporates the limitation expressed therein: that use mode means using the data in accordance with the obligations imposed by the license.

For the same reasons, because the term "partly enabled or demonstration mode" is the flip side of use mode/fully enabled mode, it shall be construed as: A mode that allows partial use of the digital data or software.

--- Footnotes ---

n12 Although Microsoft agreed that the terms "use mode" and "fully enabled mode/full version run" should be treated the same, it did not specify which of its proposed constructions was preferable in that event. Nonetheless, to the extent Microsoft may have intended to press its proposed construction of "use mode," this writer notes that the Court's construction incorporates the limitation expressed therein: that use mode means using the data in accordance with the obligations imposed by the license.

--- End Footnotes ---

For the same reasons, because the term "partly enabled or demonstration mode" is the flip side of use mode/fully enabled mode, it shall be construed as: A mode that allows partial use of the digital data or software.
It was undisputed at trial that Lightning Source prints on rolls or webs of paper rather than on pre-cut sheets. The district court ruled that "printing the text of said selected one of said books on paper pages" of clause [7] does not mean that the book must be printed on previously separated pages; that is, the printing can be on long webs or continuous rolls and then cut into pages. This resulted in the following jury instruction:

This clause requires the printing of one or more books. The term "paper pages" does not require the text to be printed on sheets of paper, as opposed to being printed on continuous rolls or any other of a variety of forms of paper, although the book which is produced by the process must be comprised of pages as opposed to rolls.

The defendants argue that this interpretation and instruction are incorrect, and that the claim requirement that the book be printed "on paper pages" means that the paper is in the form of pages when printed, rather than being cut into pages after printing. The defendants stress that the Ross patent is for an immediate-production automatic printing process, and not one that requires commercial-scale equipment for paper-cutting after printing.

The specification states that the patented invention is the printing of individual copies of books at the customer site rather than in a "factory setting," col. 1, lines 13-19, and illustrates a "page printer 26," which prints a "stack of paper text pages," col. 8, lines 22-40, showing page-size paper. The specification describes the Ross invention only as printing on individual pages, as distinguished from a "factory setting" and the production of multiple copies. The Ross invention, and the claims, are directed to the on-site printing and binding of a single copy, for which printing on large webs and the requirement of cutting to page size would require equipment and procedures inimical to the substance of the Ross invention.

We conclude that the district court erred in construction of this clause. When this clause is correctly construed, no reasonable jury could find that it reads on a process of printing on large sheets or webs of paper that require the further processing step of cutting into pages after printing.

C. Parallel Interface

1. Proposed Constructions

The parties agree that the construction of "parallel interface" must contain a "plurality of parallel data lines." Reply at 13. The parties, however, appear to have two main disputes regarding the construction of "parallel interface": (1) whether there can only be a single set of parallel data lines, and (2) whether serial and ATAPI data lines are excluded. Plaintiffs propose that "parallel interface" be construed as a plurality of parallel data lines that act as the interface for transferring corrected data to the MPEG decoder. Plaintiffs' '736 Br. at 22. Plaintiffs also assert that the claimed "parallel interface" excludes serial and ATAPI interfaces. Defendants appear to dispute this construction. Defendants construe "parallel interface" to mean a single parallel interface that 1) receives both the first or CD format and the second or DVD format corrected data on a parallel bus, 2) comprises a plurality of parallel data lines, and 3) transfers both the first or CD format and the second or DVD format corrected data to the MPEG decoder. Defendants' '736 Br. at 23-24; see '736 patent at 4:2-6, 4:24-30, 9:12-16, Schwartz Decl., Ex. B at ZC000221, 000246, 000338.

2. Claim Language

Claims 1 and 7 include a "parallel interface" limitation in the respective contexts of "a parallel interface that receives the corrected data on a parallel bus interface . . ." and "a parallel interface coupled to the MPEG FIFO interface. . . ." '736 patent at 11:11-12, 13:26.

Plaintiffs assert that the claims require the parallel interface to transmit two formats (first format and second format for claim 1; CD and DVD data for claim 7) of information to the MPEG decoder but that the claim language does not require that only a single parallel interface be present. Plaintiffs' '736 Br. at 22. Defendants, however, construe the parallel interface to be a single parallel interface over which all communications to the MPEG decoder pass. In response, plaintiffs reason that Phillips prevents defendants from importing the limitation of a single parallel interface since the term "single" is absent
from the claims. Id.

Plaintiffs further contend that although the claims contain no other specific limitations on the precise nature of the parallel interface, the ATAPI and serial data interfaces are disclaimed or outside the scope of the claims in light of particular statements in the specification and file history. Id.

3. Specification

In support of their assertion that ATAPI and serial data interfaces are outside the scope of the claims, plaintiffs note that columns 1 though 3 of the specification, which discuss the prior art, state that CD data in a conventional playback system was transferred to the MPEG decoder over the single data line of a serial interface. Id.; '736 patent, col. 2:27-30, col. 3:24-35. In the prior art, a conventional DVD player transferred data to the MPEG decoder over a parallel interface. Plaintiffs' '736 Br. at 22; '736 patent at 3:36-38. The specification then states:

Therefore, in conventional DVD/CD playback systems, the MPEG decoder normally has to support an 8-bit parallel interface for DVD and a serial interface for CD. The 8-bit parallel to serial conversion at CD controller and the serial to parallel conversion at MPEG decoder not only pose an unnecessary overhead in hardware for the playback system, but also requires an 8-times higher transfer rate for the serial interface [in order to keep pace with the parallel interface]. Thus, a new transfer protocol which eliminates the serial interface associated with traditional CD-DSP controllers is desired.

Plaintiffs' '736 Br. at 22-23; '736 patent 3:38-45. Based on this specification language, plaintiffs assert that the parallel interface of the claimed invention must exclude the conventional serial CD interface of the prior art since the patent specifically solves the problem of providing a single type of interface -- parallel only versus both serial and parallel.

To further demonstrate that the ATAPI and serial data interfaces are disclaimed, plaintiffs point out that the "Summary of the Invention" section of the '736 patent states that "[a]ccording to one aspect of the present invention, the DVD/CD controller includes a unique MPEG interface which facilitates transfer of CD data and DVD data from the DVD/CD controller to a MPEG decoder using a parallel interface," and that "[t]he parallel MPEG interface eliminates parallel-to-serial and serial-to-parallel conversion overhead problems associated with conventional DVD/CD playback systems. The parallel interface also obviates the need to transfer information at higher rates as in conventional DVD/CD playback systems." Plaintiffs' '736 Br. at 23; '736 patent 4:2-6, 24-30. Given this language in the '736 patent, plaintiffs conclude that the parallel interface must also avoid the need to convert CD data from parallel to serial for purposes of sending it to the MPEG decoder. Plaintiffs' '736 Br. at 23.

Plaintiffs also assert that defendants err in arguing that the claimed parallel interface does not exclude an ATAPI interface. Id. Plaintiffs allege that the specification repeatedly and at length discusses the disadvantages of the ATAPI interface and distinguishes the invention over ATAPI. Id.; '736 patent, 2:41-63, 4:16-19, 8:41-56. According to plaintiffs, the elimination of ATAPI is one of the stated goals of the invention. Reply at 14; '736 patent at 4:16-19. Lastly, plaintiffs cite to Scimed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc. 242 F.3d 1337, 1342-43 (Fed. Cir. 2001) and Phillips, 415 F.3d at 1325, in support of their argument that by discussing the advantages of prior art and distinguishing the claimed invention over the prior art, a patentee excludes that prior art from the scope of the claims. Reply at 14. Plaintiffs contend that such exclusion occurred here. Id.

To rebut plaintiffs' interpretation that the parallel interface excludes an ATAPI interface, defendants contend that, although the specification notes that the invention eliminates the need for an ATAPI interface, nothing in the claims or specification disclaims an ATAPI interface. Defendants' '736 Br. at 24. The court finds defendants' argument to be unpersuasive. The specification clearly disclaims serial and ATAPI interfaces. Indeed, as plaintiffs correctly point out, one purpose of the invention was to eliminate the need for such interfaces, such that two different formats of data could be transmitted over a single type of parallel interface.

In support of their proposed construction that there can only be a single parallel interface that transfers corrected data to the MPEG decoder, defendants note that the specification provides that "MPEG interface 104 reads CD or DVD data directly from memory subsystem 102 on to a single parallel bus and forwards the data via the parallel bus to MPEG decoder 40 using proper handshaking. In a specific embodiment, MPEG interface 104 provides a 8-bit parallel interface to MPEG decoder 40." Defendants' '736 Br. at 23; '736 patent at 9:11-16.
4. Prosecution History

To demonstrate that a parallel interface is a single parallel interface, defendants note that applicants repeatedly argued during the prosecution that a critical advantage that distinguished the patent over the prior art was that the prior art required two interfaces to transfer data to the MPEG decoder, while the invention required a single interface. Defendant's '736 Br. at 23; see ZC000221, ZC000247, ZC000338.

Rebutting defendants' use of the prosecution history, plaintiffs contend that during the prosecution, the applicants distinguished the claimed parallel interface over prior art. Reply at 13. According to plaintiffs, applicants stated that all of the prior art taught that two types of interfaces needed to be used -- a serial interface for CD data and a parallel interface for DVD data. Id.; see Schwartz Decl., Ex. B at ZC000339, 000230.

The court finds that the plain meaning of a parallel interface is an interface which transfers data over multiple channels simultaneously. This is in contrast to a serial interface, which uses a single data channel to transfer data. The plain meaning does not require a specific number of data channels, only that there are more than one. The parties agree that the construction includes a "plurality of data lines." With regard to their contentions that involve differing proposed additional limitations, the court finds that defendants' argument that there must be a single parallel interface over which all communications pass is not supported by the claim language, as there is no limiting language requiring only one instance of the parallel interface. Plaintiffs' argument that the specification disclaims ATAPI and serial data interfaces for transferring corrected data to the MPEG decoder as part of the parallel interface is persuasive, as the invention of a parallel interface to provide an alternative to the serial and ATAPI data interfaces is a key innovation in the '736 patent. This constitutes a sufficiently clear disclaimer of claim scope by the inventor. Phillips, 415 F.3d at 1316 ("the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor"). Thus, the court construes "parallel interface" to mean "a plurality of data lines that transmit both formats of information to the MPEG decoder." ATAPI and serial data interfaces are not within the scope of "parallel interface."

3059

Both patents use the term "parameter" in the claim language. For example, claim 1 of the '304 patent claims "in response to a selection of a particular location of the order entry region by a single action of a user input device, setting a plurality of parameters for a trade order. . . ." Claim 1 of the '132 patent claims "setting a preset parameter for the trade order" and "selecting a particular area in the order entry region through single action of the user input device with a pointer of the user input device positioned over the particular area to set a plurality of additional parameters for the trade order. . . ." Although the preset parameters and the additional parameters may be different, in all cases the term "parameter" means "an element of a trade order, including, but not limited to, quantity, price, type of order and the identity of the commodity." Defendants encourage us to limit our construction to the listed parameters. The specifications, however, state: "Similarly, every exchange requires that certain information be included in each order. For example, traders must supply information like the name of the commodity, quantity, restrictions, price and multiple other variables." As defendants' constructions do not account for restrictions or "multiple other variables," they Cannot he correct.

GO BACK

3060

7. "Credit Parameter" and "Account Parameter"

Walker proposes that the court construe these claim terms to mean ":[a] term of a credit account, such as the interest rate, credit limit and monthly minimum payment." Capital One proposes that the court construe these claim terms to mean "[a] term (provision) of a credit account." The parties agree that these terms refer to a term of a credit account and agree that both of these claim terms should have the same construction. Walker asserts, however, that the parties disagree on whether there is a need to expand on the word "term" within their proposed constructions. Walker proposes that the construction include examples of some terms of credit accounts, taken directly from the specification, so as to prevent either party from confusing the jury by arguing that an unspecified feature is a "term" within the meaning of the construction. Capital One
argues that the phrase "term of a credit account" is clear to a layperson and requires no further elaboration. Capital One also argues that Walker's construction, would likely confuse jurors by suggesting that only the three listed terms are parameters, or would cause them to question whether there is something special about the terms Walker recites.

The court is in agreement with Walker that the jury may be confused by the simple definition proposed by Capital One. The danger in a simple definition such as the one proposed by Capital One is that it may lead the jury to believe it understands what a "term" is when, in fact, it does not. The court believes that it is important to provide the jury with an example of a "term" to help it understand those provisions of a credit account that are "terms." However, the court also understands Capital One's concern that providing the jury with these three listed "terms" may cause the jury to place special emphasis on those "terms." The court believes it would better guide the jury to provide it with a single example of a term and explicitly state it may be one of several parameters. In that way, the jury may compare other proffered "terms" to that example to help them discern between those features of a credit account that are "terms" and those that are not, without placing special emphasis on a given set of "terms." For these reasons, the court construes the terms "credit parameter" and "account parameter" to mean "a term or provision of a credit account. For example, the interest rate may be one of several parameters of a credit account."

The parties dispute the definition of the terms "parameter values" and "procedure routines specifications" in claim 1. At its core, the parties' argument turns on whether the terms are numbers or software code. Roche contends that both terms refer to numbers or data values of different types. Defendants contend that "parameter values" are numbers, while "procedure routine specifications" are code. The Court agrees with Roche.

Although the parties dispute the proper construction for the term "parameter values," their definitions for the term are very similar. Roche contends that the term means "data values used in the algorithm," while Apex/HDI argue that the term means "constants and variables that are critical to the operation of the meter," and Biosite avers that the term means "constant values that are assigned to variables for a specified application." The Court finds the term "parameter values" has its ordinary meaning of "constants that are assigned to variables."

The ordinary meaning for the term "parameter" is a constant or value associated with a particular value or variable. See, e.g., WEBSTER'S THIRD NEW INT'L DICTIONARY at 1638; IEEE Std. Glossary of Software Eng'g Term., IEEE Std. 610.12-1990, at 55; Biosite Exh. 5, Louder Rep. P 15; Roche Exh. 5, Dunsmore Dep. at 55. The other claims of the 609 patent confirm that the ordinary meaning of the term should apply in this instance. Claim 4 is perhaps the most revealing claim with respect to the varied types of constants or data intended to be included as a "parameter:"

. . . pluggable memory key means including a plurality of stored parameter values for controlling operations of said meter; and

processor means . . . wherein the processor means is responsive to parameter values accessed from said pluggable memory key means, to cause said excitation supply means to apply a plurality of voltages to said first electrode, each said voltage having a potential and being applied for a duration that is determined by said processor means from parameter values accessed from said pluggable memory key means, and to further control said sense amplifier means to provide a plurality of signal outputs over a set duration and to further calculate from said signal outputs a value equivalent to a concentration of an analyte in said analyte-containing fluid in said sample well, all in conformance with parameter values accessed from said memory key means.

'609 Patent, col. 9, ll. 48-68. Likewise, claim 5 also designates that control values, or parameters, are accessed on the pluggable memory key means, including "values of said first and second excitation potentials and the number of signal outputs from said sense amplifier means controlled by parameter values accessed from said memory key means." Id. col. 10, ll. 31-35.

The specification also indicates that the plain meaning of "parameter values" should apply to the term in the context of the
609 patent. The summary of the invention teaches that "[a] microprocessor is responsive to a procedure routine and parameter values accessed from the pluggable memory key to cause the excitation supply to apply a plurality of potentials for preset durations, both the values of the potentials and the time duration of their application determined from parameter values derived from the memory key." Id. col. 3, ll. 49-55. Similarly, the 609 patent reads: "the sense amplifier [is] operated under control of specific parameter values derived from the pluggable memory key." Id. col. 3, ll. 57-60. From these passages alone, it is clear that a "parameter value" is a constant or data that is assigned to a variable in the programs that are run by the microprocessor. This is also consistent with the language used to describe the interaction between the microprocessor and the ROM key: "When ROM key 30 is inserted into meter 10, a plurality of flexible contacts . . . enable a microprocessor within meter 10 to access data stored in ROM chip 32." Id. col. 4, ll. 52-56.

The most compelling support for the ordinary meaning of "parameter value" in the 609 patent specification, however, is found in the more detailed descriptions of the contents of the ROM key. The 609 patent reads, in pertinent parts:

A microprocessor 59 . . . provides overall control of the operation of biosensing meter 10 in combination with data read from ROM key 30. ROM key 30 is pluggable into biosensing meter 10 and contains non-volatile memory that includes constants and other data required to carry out analyte-determination procedures. In general, a ROM key 30 will accompany each batch of disposable sample strips 18 and will contain constants and procedure code that enable meter 10 to adjust its measurement parameters to match the specific batch characteristics of disposable sample strips 18. Further, ROM key 30 will also contain a large number of additional variable values that control the operation of microprocessor 59 in performing the actual analyte determination tests.

***

As above indicated, the operation of a biosensing meter 10 is substantially controlled by data contained in ROM key 30. ROM key 30 will contain a variety of data values that are critical to the proper operation of meter 10. Those values encompass measurement delay times, an incubation time, the number of measurements to be taken during a measurement period, various thresholds against which voltage levels are to be compared, values of excitation voltage levels to be applied to sample strip 18 during a test procedure, glucose value conversion factors, and a variety of failsafe test threshold values.

Id. col. 5, ll. 3-18; id. col. 5, ll. 66-68, to col. 6, ll. 1-8. These passages indicate that "parameter values" must be "constants or data" because the same language is used to describe how those "constants or data" are used to control the microprocessor of the meter that is used in claim 1 to describe what the "parameter values" do to control the processor means. Compare id. col. 5, ll. 3-18 and id. col. 5, ll. 66-68 to col. 6, ll. 1-8 (the passages listed here), with col. 9, ll. 4-11 (describing the interaction between the processor means and the parameter values and procedure routine specifications on the memory key).

Roche contends that there are two types of constants, "parameter values" and "procedure routine specifications," where "parameter values" are constants used in the algorithm, but "procedure routine specifications" are data values or numbers used to control execution of the algorithm. Roche asserts that the first passage above teaches "constants and other data" and "additional variable data," which is two different types of data. Roche argues that the former type of data is "parameter values" and that the latter type of data is "procedure routine specifications." Furthermore, Roche argues that because dependent claim 2 specifically requires that the pluggable memory key means contain "procedure routines," which Roche agrees with Defendants must be code, the only way to differentiate claim 2 from claim 1 is if "procedure routine specifications" is not code, but numbers or data. In addition, Roche asserts that in the prosecution history, the inventors clearly intended to include two types of data: parameters and specifications. Roche Br. at 45-46. Defendants do not really address this reference in the prosecution history.

Although the Court does not agree with Roche's argument in its entirety, the three sources of intrinsic evidence indicate that "procedure routine specifications" are data rather than code. The Court looks to the claims first. Claim 1 uses the term "procedure routine specifications" three times:

... said pluggable memory key means including a plurality of stored parameter values and procedure routine specifications that are employed in controlling execution of an algorithm performed by said meter that enables determination of an analyte concentration value, said procedure routine specifications including stored values from which time values can be determined for controlling said sense means during execution of said algorithm; and

- 3380 -
processor means . . . responsive to parameter values and procedure routine specifications accessed from said pluggable memory key means, for controlling operation of said sense means in accordance with said algorithm and for calculating from signal outputs from said sense means a concentration value of an analyte in said analyte-containing fluid is said sample well.

Id. col. 8, ll. 62-68, to col. 9, ll. 1-11 (emphasis added). It is clear from the second usage of the term that "procedure routine specifications" must include "stored values from which time values can be determined for controlling said sense means during execution of said algorithm," therefore, to that extent, "procedure routine specifications" include values, or numbers. No other claims of the 609 patent uses the term "procedure routine specifications." Instead, the remainder of the claims use the term "parameter value" to describe all types of data values, including ones that Roche asserts are "procedure routine specifications."

Roche contends that two different types of data are referred to in the specification: "measurement parameters" and "additional variable values." Id. col. 5, ll. 12-15. The former, Roche argues, are "parameters" and the latter are "procedure routine specifications." However, several of the "additional variable values," described in more detail later in the specification, are identified by other claims as "parameter values." Compare, e.g., id. col. 5, ll. 3-18 and id. col. 5, ll. 66-68 to col. 6, ll. 1-8 (describing particularly the "additional variable values"), with col. 9, ll. 55-68 (describing the interaction between the processor means and the parameter values in claim 4). This evidence points away from a definition of "procedure routine specifications" that would limit the type of values that could serve as "parameter values," and suggests that an argument for an arbitrary distinction between the two types of data is flawed.

Roche also argues that the doctrine of claim differentiation supports its argument that "procedure routine specifications" are data. Apex/HDI contend that this is unworkable given the strong evidence that "procedure routine" is code and that the 609 patent specifically identifies that the pluggable memory key means has both procedure and code. See id. col. 5, ll. 9-11. To varying degrees, Roche and Biosure urge the Court to look to the plain meaning of the term "specification" to resolve the parties' dispute. The Court agrees that this approach helps illuminate the difference between "procedure routine specifications" and a "procedure routine" as those terms are used in the 609 patent. The plain meaning for specification is to make something more specific, or to identify something in greater detail. See WEBSTER'S NEW INT'L DICTIONARY at 2187; WEBSTER'S COLLEGIATE DICTIONARY(10th Ed.). Claim 1 already teaches that "procedure routine specifications" include "stored values from which time values can be determined for controlling said sense means during execution of said algorithm," 609 Patent, col. 9, ll. 1-3, therefore, it is not a stretch to combine the plain meaning of "specification" with "procedure routine" to decide that a "procedure routine specification" is something that identifies a procedure routine, or an identifier for something within the procedure routine. But, how is type of data distinguishable from a parameter value?

A definition for "procedure routine specification" that is data is consistent with the 609 patent specification's apparent reference to at least two different inventions, one in which there are two types of data on the pluggable memory key means, see id. col. 5, ll. 5-9 ("ROM key 30 is pluggable into meter 10 and contains non-volatile memory that includes constants and other data required to carry out analyte-determination procedures.") and one in which there are both "constants and procedure code." See id. col. 5, ll. 10-11 (stating "a ROM key 30 . . . will contain constants and procedure code"); id. col. 6, ll. 8-13 ("In addition, ROM key 30 may contain either a portion of or the entire code listing that controls the procedures of meter 10 so that, by substitution of a new ROM key, test procedures performed by meter 10 can be altered accordingly."). Moreover, it is the only definition that is consistent with the use of the term "specification" in the prosecution history. The prosecution history reads:

Claims 1-5, 15 and 16 were rejected under 35 USC [sic] 102(b) in view of Keiser et al. Prior to considering the rejection, it is worthwhile to briefly review Applicants' invention. Applicants biosensing meter resembles the meter of Keiser et al. in several respects, but departs therefrom in such a manner as to provide substantial functional improvements. Applicants' biosensing meter receives a pluggable memory key that contains a memory chip which stores (1) plural parameters, (2) specification values which are used to control the operation of an algorithm that analyzes a sample to determine the presence of analyte and (3) further contains in certain configurations, the actual procedure to be used by the meter. By inserting these parameters, values and procedures into the meter via a pluggable key, Applicants have enabled the meter to be reprogrammed at any time there is an improvement in the algorithm (e.g. an improvement which enables a faster or more accurate analysis procedure to be performed). Prior art biosensing meters were incapable of being modified to accept an improved algorithm for the performance of a test function. As a result, prior art biosensing meters had to be structurally

- 3381 -
altered so as to accommodate a revised algorithm, test procedure or other improvement.

***

Keiser et al. include no teaching that the pluggable memory chip contain parameters which define "procedure routine specifications that are employed in controlling execution of an algorithm performed by said meter . . . said procedure routine specifications including stored values from which are determinable time values used to control said sense means during execution of said algorithm" (see claim 1 [as then amended]). Claim 2 is dependent upon claim 1 and indicates that the pluggable key means includes "a procedure routine that when executed by said processor means, enables execution of said algorithm". [sic] Keiser et al. have no such data in their pluggable memory key.

Defs.' Exh. 2, at A71-A73 (emphasis added).

This section of the prosecution history teaches two things. First, that the inventors saw a distinction between "plural parameters" and "specification values." Id. at A71. Second, that in distinguishing their invention from that of the prior art, the inventors seemed to refer to the language of claim 1 regarding "procedure routine specifications" as a subset of "parameters" within the context of claim 1. Id. at A72 ("Keiser et al. include no teaching that the pluggable memory chip contains parameters which define procedure routine specifications that are employed in controlling execution of an algorithm performed by said meter . . ." (see claim 1)). It is this piece of information, in conjunction with the lack of evidence in the other claims or in the 609 patent's specification as to how to distinguish between data that comprises "parameter values" and data that comprises "procedure routine specifications," that convinces the Court that "procedure routine specifications" should be limited to the definition given it by claim 1 itself: "procedure routine specifications including stored values from which time values can be determined for controlling said sense means during execution of said algorithm." 609 Patent, col. 8, l. 68, to col. 9, ll. 1-3.

Roche's expert, Dr. H.E. Dunsmore ("Dr. Dunsmore"), an Associate Professor of Computer Science at Purdue University in West Lafayette, Indiana, opines that "procedure routine specifications" means "values that determine what the algorithm is," and distinguishes "procedure routine specifications" from "parameter values" by stating that the "parameter values" in claim 1 are narrower than the "parameter values" referenced in the remaining claims. Roche's Exh. 5, Dunsmore Rep. P 41. But, the Court sees no real way to distinguish between what is a "parameter value" and what is a "procedure routine specification" under this analysis. Yes, Dr. Dunsmore's report explains that a procedure routine specification could refer to numbers that change the formula for calculating a particular unknown, while parameter values are constants in the same formula, but there is nothing in the claims, the specification or the prosecution history that supports this distinction. Compare id. PP 15-22 with id. PP 23-41. In other words, this is an arbitrary differentiation between the two types of values that is only resolved by consultation with the description for "procedure routine specification" contained in claim 1.

The Court recognizes that limiting the definition of "procedure routine specification" to that found in the claim itself is extraordinary, however, the Court finds no better way to reconcile the clear meaning of the term "parameter value," the lack of evidence to support a more clear distinction between "parameter values" and "procedure routine specifications," and the evidence of two types of values in the prosecution history.

For the foregoing reasons, the Court finds that "parameter values" means: constants that are assigned to variables; and the term "procedure routine specifications" means: stored values from which time values can be determined for controlling a sense means during execution of an algorithm.

TiVo argues these terms should be construed to mean "analyzes video and audio data." See TiVo's Opening Br. at 9-11; TiVo's Op. Br. at 11-13; '389 patent at cols. 5:3-6, 5:33-36, 6:36-58, & Fig. 6; TiVo's Markman Slides at 135-39; see also id. at col. 12:48-50 (". . . parses said MPEG stream . . .").

EchoStar argues "parses" means "separates," and "parses video and audio data from said broadcast data" means "analyzes
the content of broadcast data and from it transmits two distinct components: one video component and one audio component." See '389 patent at Fig. 3 & col. 4:23-29; EchoStar's Opening Br. at 11-12; EchoStar's Response Br. at 7-10; EchoStar's Slide Presentation at 76-98, 123-24.

As was the Court's analysis of the term "parses" in the context of claims 1 and 32, the Court similarly finds that "parse" as it is used in claims 31 and 61 means "analyzes." These terms are recited clearly by claims 31 and 61 and understood by persons of ordinary skill in the art. See '389 patent at cols. 14:55-58, 18:5-8. This definition is consistent with the use of the term in claims 31 and 61 and the context of the specification. See, e.g., '389 patent at col. 4:23-33 & Fig. 3 (describing the analysis of interleaved video and audio streams from an incoming MPEG stream).

Therefore, the court defines "parses video and audio data from said broadcast data" as "analyzes video and audio data from the broadcast data."

3063
7. "particular user"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;particular user&quot;</td>
<td>one specific user</td>
<td>authenticated user</td>
</tr>
</tbody>
</table>

The dispute is whether a user needs to be authorized first to request access to metadata. The defendants contend that the '231 patent relates to controlling users' access to data, and Fotomedia's adoption of the English dictionary meaning of "particular" fails to acknowledge this. Defendants argue that to determine a user's role(s) and privileges, the system must be able to ascertain the identity of a user and distinguish that user from others. Otherwise, the system would not be able to limit the access to metadata. Hence, the defendants contend there is a need for the user to have been authenticated.

The specification discloses that "[i]n a preferred embodiment, the request includes the user's ID and identifies the type of access desired. The user is then authenticated and assigned the appropriate role for the specific image requested based on the user ID in step 202." See '231 Patent, col. 4, l. 66 - col. 5 l. 3. Plaintiff argues that nothing in the claims requires that the authentication be done before a user's request is received. Fotomedia points to Figure 6 in the specification as showing that the "receive user's request to access the image file and its metadata" step is done before authenticating the user.

The claim language does not clearly describe the authentication step. The claim recites: "receiving a request for access . . ., wherein the user's role is determined from the request." Although an authentication step must occur at some point, it is improper to read in a requirement that only authenticated requests arrive.

A "particular user" is, therefore, "a user who may be authenticated."

3064
1. "Products Carrying Participation Numbers"

The plaintiffs contend that the term "products carrying participation numbers" is straightforward and its meaning may be taken from the ordinary meaning of the words themselves. The defendants argue that the words "product" and "carrying" indicate that the product on which the participation number is carried must have inherent value apart from the number; thus, the defendants argue, "products" cannot include prepaid calling cards.

The term "products" is not used in the Katz patents as a term of art, as the parties agree. Thus, the Court should give the term its plain, ordinary English meaning. The Court concludes that the plain meaning of "products," which denotes an item produced for use in a commercial setting, does not support the construction given to it by the defendants. The plain meaning of the term "product" in the claim language does not connote something of inherent value apart from the number carried.
The specification does not contradict the plain meaning of "products." The only place in the specification that discusses products carrying participation numbers is Column 17, lines 13 through 17 of the '707 patent, which reads "[a] key to participation in the game show may involve the purchase of a particular product. For example, a person desiring to participate may purchase a product which carries a concealed key number. The number serves as a caller's key to participation in the game show." This passage in no way suggests that the product must have value independent of the participation number. The defendants also point to Column 9, lines 35 through 38 of the '707 patent, which discusses restricting callers to the purchasers of a medical apparatus. This discussion is given by way of example only and does not indicate that all "products" must have inherent value apart from the participation numbers.

The defendants rely on statements made by Katz during the prosecution of the '707 patent. In the August 31, 1995 Amendment, Katz distinguished the '275 patent to Kamil by stating that "Kamil discloses a telephone system enabling prepayment for telephone calls, wherein special code and credit information is stored in memory in special exchanges and debited as the call progresses" and that Kamil "does not disclose specific limitation recitations including consumable key operation, nor does it disclose providing a product bearing a participation number specifying a limit on use." (Ex. 51). The defendants argue that Katz clearly stated that his invention was distinct from Kamil because Kamil used prepaid tickets which do not have inherent value, and thus, are not "products."

The Court concludes that Katz did not unambiguously state that his invention required products with inherent value apart from the participation number; it is possible, for example, that Katz's distinction was based on the fact that Kamil's special code connected with the prepayment for telephone calls did not specify a limit on use. Katz did not mention Kamil's use of a prepaid ticket as a method of recording the prepayment in his statements so it is not clear that Katz was using the concept of a prepaid ticket as the basis for his distinction. In addition, these statements were made by Katz in a voluntary amendment, not in an effort to change the examiner's decision on a rejected claim. Thus, the Court concludes that Katz's statements do not indicate a clear disavowal of coverage so as to require that "products" have inherent value apart from the participation numbers. See York Products, 99 F.3d at 1575.

Based on the foregoing, the Court concludes that "products carrying participation numbers" means: a physical item sold or exchanged in a commercial setting which carries a number allowing participation in the Katz system.

10. "patient-specific rules"

Plaintiff proposes "a rule tailored to the medical condition of the patient." Defendants propose "a tailored rule designed for a particular patient based on that patient's personal medical condition." Defendants argue that the additional words "designed for a particular patient" are necessary because the specification talks about "patient-specific rules," as opposed to "disease-specific rules." The Court agrees with plaintiff's proposed construction for several reasons.

First, defendants agreed at the Markman hearing that its proposed term "customized" can be replaced with tailored. (Hr'g., Day 2, p. 7.) Thus, the remaining controversy pertains to whether the rules are tailored to the medical condition of a patient (plaintiff's version) or designed for a particular patient based on that patient's personal medical condition (defendants' version.)

Plaintiff argues that defendants take words from the specification out of context and seek to limit the ordinary meaning of "patient-specific rules" as understood by a person skilled in the art at the time of the invention. Based on an examination of the intrinsic evidence and viewed through the prism of a person skilled in the art, the Court finds plaintiff’s construction to be the most accurate and is not persuaded by defendants' argument to narrow the claim term. "Patient-specific rules" is construed as: "a rule tailored to the medical condition of the patient."
2. Partitioned (Claims 1, 10, 17, 23 & 35)

"Partitioned" refers to either logically dividing or physically dividing the memory into a plurality of sectors. When the patent refers to the memory array being "partitioned" into sectors it is not necessarily referring to the physical division of the memory into sectors such that each sector must be physically separated from the adjoining sectors.

6. Partitioning first and second registers into a plurality of floating point operands, said floating point operands having a defined bit width, wherein said defined bit width is dynamically variable

The court construes "partitioning first and second registers into a plurality of floating point operands, said floating point operands having a defined bit width, wherein said defined bit width is dynamically variable" to mean "dividing a first and a second register width-wise into a variable number of floating point operands based upon a variable width of the floating point element."

B

"[P]artitioning the memory cells within the individual sectors into at least a user data portion and an overhead portion" (claims 1 & 10)

The court previously interpreted the above term as meaning:

Construction: Each non-volatile memory sector contained within an array of non-volatile floating gate memory cells must include at least one user data portion and one overhead portion. Memory sectors are not limited to only one user data portion and one overhead portion.

Claim constr order (Doc # 318) at 16 (emphasis added).

The Federal Circuit held that this construction was erroneous. SanDisk Corp v Memorex Prods., 415 F3d 1292. Based on the plain language of the claim term, a strong presumption against excluding preferred embodiments of the invention and rejecting defendants' prosecution history estoppel argument, the Federal Circuit held that there may be memory sectors within a device that are not partitioned into at least one user portion and one data portion. Id at 1283-1290. The parties now all acknowledge "each" sector need not be partitioned into user data and overhead data.

But the dispute has shifted focus. SanDisk proposes: "The step of dividing (logically or physically) each individual sector used by the computer system in the practice of method claim 1 into at least one user data portion and at least one overhead portion." JCC (Doc # 371), Ex A at 11 (emphasis added). Quite similarly, Ritek proposes: "The memory cells within the individual sectors required to perform the steps of the claimed method are logically or physically divided (i.e., partitioned) into at least a user data portion and an overhead portion. Memory sectors are not limited to only one user data portion and one overhead portion." Id (emphasis added). Both SanDisk and Ritek agree that their constructions are largely the same. SanDisk Br (Doc # 373) at 10; Ritek Br (Doc # 390) at 16; SanDisk Reply Br (Doc # 396) at 6.

The only substantive differences are the terms "used by" and "required to perform." To the extent the parties' proposed constructions differ, Ritek argues that, while the "partitioning * * * into user and overhead data" step need not be performed on every sector in the memory system, the "partitioning" step must be performed on every sector in the memory array. According to Ritek, the significance of Ritek's proposed addition, "required to perform the steps of," is that it requires each
sector within an "array" to be partitioned. Ritek argues that this is merely what the Federal Circuit held in rejecting the court's first construction of "partitioning."

The court is not persuaded that the Federal Circuit stated as much. The Federal Circuit rejected the construction that "every Flash EEprom memory cell within an actual device [must] be grouped into a sector that is partitioned into user and overhead data portions." SanDisk Corp v Memorex Prods, Inc, 415 F3d at 1284. Ritek's additions do not necessarily follow from this rejection. The Federal Circuit did not address whether every sector within an "array" must be partitioned. Nor did the Federal Circuit address how an "array" is delimited from other arrays or other memory cells - nor did this court. By the plain language of the claims, the Federal Circuit stated that all that is required of the claimed memory system is "some memory cells, grouped into sectors, partitioned into user and overhead data portions," and "additional, unclaimed use" of memory cells is consistent with practicing the claimed invention so long as all of the limitations are met. Id; '987 patent.

There is a gap between what the Federal Circuit held (all that is required is "some memory cells, grouped into sectors, partitioned into user and overhead data portions") and what Ritek argues that the Federal Circuit held ("the Federal Circuit held that the 'array' practices the invention but that the 'memory system' may contain other, unclaimed, memory cells.") SanDisk Corp v Memorex Prods, Inc, 415 F3d at 1284; Doc # 400 at 6. The court does not need to visit this issue to arrive at a proper claim construction that is consistent with the language of the plain language and the intrinsic evidence.

Accordingly, the court declines to adopt Ritek's proposed construction of "partitioning." Similarly, the court declines to adopt SanDisk's proposed construction.

Instead, the court gives the following hybrid construction to conform with the Federal Circuit's rejection of the initial claim construction:

The non-volatile memory sectors contained within an array of non-volatile floating gate memory cells include at least one user data portion and one overhead portion. Memory sectors are not limited to only one user data portion and one overhead portion.

The changes in the court's construction being: (1) "Each" is now "The"; and (2) "must" is omitted. See claim constr order (Doc # 318) at 16. This construction is consistent with the Federal Circuit, the plain language and the intrinsic evidence.

3069

Parts

Defendants argue this term should be construed to mean "sub-components of equipment." Orion contends "parts" does not require construction, and the Court agrees. Defendants have not demonstrated that this term is used in a manner inconsistent with its ordinary lay meaning. Further, Defendants' construction overly complicates the term. "In the preferred embodiment, the types of parts under the cross-referencing/parts selection procedure include batteries, filters, remanufactured electric parts, lubrication and bearings." Col. 9:4-8. While a lay jury would likely consider batteries or lubrication to be "parts," it is less certain that they would consider them to be "sub-components of equipment."

GO BACK

3070

B. "First Party/Second Party"

Again, these are terms utilized throughout the patents-in-suit referring to the two entities which interact during the transfer of the digital signal, e.g., a "method for transmitting a desired digital audio signal stored on a first memory of a first party to a second memory of a second party . . . ." (Docket # 69, Exhibit J at 6). Plaintiff asserts that the term "party" should be construed as meaning "an entity and/or its agent." Defendants respond that the meaning, each time that the terms are used, should be "a single financially distinct entity at locations separate and distinct from each other."

Sightsound does not contest that, in the context of the claims at issue in this case, the "first party" and "second party" are
financially distinct from one another, or that various claims require that the transaction occur when certain items or entities are at distinct locations (Docket # 96 at 8). However, Sightsound takes the position that "financially distinct" and "at separate locations" are limitations imposed, where appropriate, in particular claims, and that there is no need to impose them on the definition of the terms "first party/second party" each and every time that those terms are used.

In claim 1 of the '573 patent, the reader is informed that during the transferring money step the "first party" is "at a location remote from the second memory," and that the "second party" is "financially distinct from the first party." (Docket # 70, Tab 51). This claim also contains the limitation that the second party is in the position of "controlling use and in possession of the second memory" (Id.). Later in this report, the "control and possession" question is addressed. It is enough to say, however, that the combination of the first party being at a location remote from the second memory, and the second party being in possession and control of the second memory, all but ensures that the first and second party will be at distinct locations. The remaining two claims in suit from the '573 patent, claims 2 and 3, are dependent claims which also have these limitations.

The '734 patent includes in each of the asserted claims the requirement that the memory of the first party and that of the second party be "remote" from one another (Docket # 71, Tab 35, '734 Patent Claims 1, 4, 11, 26) 9. Hence, the issue of whether the parties are at separate locations is not specifically addressed, although the use of memories at distinct locations would generally describe situations where the parties are with their respective memories. Further, as Sightsound suggests, the claims also include at least one step which requires that money or a fee be charged (Claims 1, 26), or that the digital audio signal is "sold" to the second party (Claim 4), or that there must be a means for "transferring money" between the first and second memories (Claim 11). None of these transactions makes sense unless they occur between parties which are "financially distinct."

9 Again, the remaining claims are dependent claims which incorporate these same limitations.

Finally, the '440 patent also contains language indicating distinct locations for the first and second party memories (Docket # 69, Exhibit K, Claims 2, 12, 22, 36, 41), as well as "charging a fee" or other indicia that the parties are, necessarily, financially distinct (Id., Claims 1, 12, 22, 36, 41).

Therefore, in virtually all of the claims asserted in this case, the "first party" and the second memory, or the first memory and second memory, must be remote from one another. 10 The context of those claims further requires that the parties be financially distinct in order for their actions to read on the patent. This distinction, however, is not a matter of construction of the terms "first party/second party," but of the language of each particular claim in which those terms are used. In other words, the location and financial distinctions arise, if at all, from other language in the claims, and not from the use of the terms "first party" or "second party." The terms will not be construed to include any location or financial distinctions apart from those imparted in the language of particular claims. 11

10 The two claims which do not contain such language are Claims 1 and 11 of the '440 patent, although each claim states that the connection between the first and second party memories is to be made through telecommunications lines. It may be possible, therefore, for these claims to apply to a situation where two financially distinct entities have their equipment at the same location, e.g., in the same room, even though the connection between them occurs over telecommunications lines. The court, however, again sees no basis for including within the term "party" the requirement that the parties be at distinct locations. Any further analysis of these claims must await issues which lie beyond claim construction.

11 The court's finding that "financially distinct" is a concept incorporated into each claim-in-suit by the use of the concept of a sale taking place makes it unnecessary for the court to address defendants' argument that the patentee bound himself to "financially distinct" parties through an amendment process before the PTO (See Docket # 75 at 7). Since the asserted limitation appears to be contained in each claim asserted by Sightsound, and since Sightsound does not contest that the first party and second party must be financially distinct from one another, there is no need to determine whether the claims must
be construed in light of subject matter allegedly abandoned during prosecution of the patents.

There is a further dispute, however, concerning the term "party," and it has to do with Sightsound's insistence that the term includes an entity or an entities' agent. Defendants assert that there is no indication in the patents or the specifications that an "agent" may act on behalf of either the first party or the second party. Defendants also argue that permitting the use of the term "agent" would create a situation where infringement may occur in one state, but not in another, because of differences in the laws of agency from state to state.

Sightsound responds that the term "agent," offered as part of the definition of "party," simply means "someone who stands in the shoes of the first party," and that there is no intent to imply any particular legal relationship (Docket # 96 at 9).

In the court's view, the use of the term "party" is clearly meant to include any legally distinct entity which performs the activities described. For example, a corporation could clearly be either the "first party" or the "second party" for purposes of the claims in suit. A corporation acts only through its employees or "agents". Likewise, a person may also act on behalf of another. The court agrees with plaintiff that there is no language in the claims which suggests that "first party" and "second party" must act for themselves in performing the tasks set forth in the claims. Likewise, nothing in the specification indicates that the patentee was restricting himself in such fashion.

On the other hand, defendants are correct that the term "agent" may add ambiguity to a term which is not ambiguous. There is no need to add such a term to make the meaning of the claims plain.

Reading the claims-in-suit, the court has no difficulty construing the term "party." A party is an entity, whether a corporation or real person, possessing and/or controlling the stated structure, or performing the necessary steps for the claims. One skilled in the art would understand that a party can act through another. Thus, although the term "agent" will not be added to the term party, the term will not be construed so as to require that a party act on its own behalf for purposes of the claims in suit, i.e., a party may, as in all other matters, act through others it authorizes to do so for purposes of the claims in suit.

3071

Element (a)(3) of claim 2 recites "a plurality of filters at the local color display including . . . (3) a third filter for filtering the red color band of the local source of light and passing a narrowband of the red color band." The Court of Federal Claims construed "local color display" and "color bands" to require perceptible red light. Claim Construction Order at 444; id. at 466 ("color bands' . . . 'include the range of wavelengths, within which the colors blue, red, and green are visible to the human eye" (emphasis added)). 2

2 The Court of Federal Claims further construed "red color band" to mean "[a] range of color from 620 nm to 780 nm" and "narrowband of the red color band" to mean "a narrow range of wavelengths within the red color band." Claim Construction Order at 471, 487.

Before the Court of Federal Claims, the parties' disputes regarding infringement and invalidity raised the issue of whether the claimed invention requires the passing of perceptible red light. With respect to claim 1, the court explained that this claim requires the "local color display" to emit perceptible light within the red color band. Infringement Order at 464 (concluding that the designated displays emit perceptible light within the red color band). During the phase of the litigation relating to the government's defenses, the Court of Federal Claims explained that this interpretation applies equally to claim 2. See Trial Tr. 17:25-18:15, Nov. 13, 2006.

On appeal, the obviousness dispute turns upon whether claim 2 requires perceptible red light. Claim construction is a question of law, which we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454-56 (Fed. Cir. 1998) (en
Claim 2—and specifically element (a)(3)—requires a local color display. The specification describes "[a] local color display which is . . . viewable by the crewmember, although the crewmember would tend to avoid looking through the [NVG] while viewing the color local display." '914 patent col.2 ll.40-44. The specification continues to explain that "[t]he cockpit has several local displays such as [the aforementioned] color display, which are illuminated so as to be clearly visible without the use of the [NVG]." Id. col.2 ll.57-59. In addition, figure 3 of the specification depicts a local color display with a local source of light that comprises red, green, and blue color bands. Id. col.4 ll.40-41. The district court's undisputed construction of color bands requires light that is "visible to the human eye."

We conclude that the proper construction of local color display is that it must emit perceptible red light. Furthermore, element (a)(3) is a filter that passes a narrow band of this red light. The claimed invention addressed the need for red warning lights in NVG-compatible cockpits, and it is inconceivable that an aircraft would use warning lights that are not perceptible to the crew. In other words, there would be no point, in the context of this invention, to pass a narrowband of red light that cannot be seen. The local color display emits perceptible red light, and element (a)(3) requires a narrow band of this perceptible red light to pass. We conclude, therefore, that element (a)(3) requires the passing of perceptible red light—i.e., red light which is visible to the human eye.

5. "telephone wiring network used for passing telephone signals in a telephone voice band between a plurality of telephone devices [or telephone devices at a residence] and a telephone exchange"; "circuitry for limiting transmission of signals in the high frequency band from the telephone wiring network to the telephone exchange and for passing signals in the telephone frequency between the telephone a telephone wiring network and the telephone exchange": the telephone wiring network (as defined above) is used for passing telephone signals in the telephone voice band (as defined above) to the telephone exchange.

Inline's proposed construction is adopted (as the court has defined the relevant claim terms recited in this phrase). Defendants' proposed construction, that the phrase "requires that telephone signals in the telephone voiceband (i.e., 0-4 kHz) be passed over the telephone wiring network extending between the telephone devices at one end and the telephone exchange at the other end" is rejected as the court has not construed "telephone wiring network" as extending to the telephone exchange." The court's construction of this phrase necessarily flows from the courts construction, above, of the terms contained therein.

(2) In Claim 25 of the '901 patent, "passing the video signal unchanged at other times" means "passing at least some portions of the video signal without changes or modifications. This step does not exclude replacing normal sync pulses with normal sync pulses."

Passive Attenuator Network/Circuit

PPC objects only to Magistrate Judge Peebles' proposed construction of the term "passive attenuator network/circuit" as meaning "a network/circuit of non-powered components that together have the effect of reducing or attenuating the level or strength of signals." PPC contends that the term should be construed to include the added requirement that the network/circuit be "resistive." Thus, PPC argues, the construction should read: "a resistive network/circuit of non-powered components that together have the effect of reducing or attenuating the level or strength of signals."

Upon de novo review, the Court agrees with Magistrate Judge Peebles' reasoning and his conclusion that the patent claims do not limit the passive attenuator network/circuit to a resistive network/circuit. The Court notes that PPC's argument finds no support in the claims themselves. Rather, application of the doctrine of claim differentiation supports the conclusion that
the independent Claim 12 does not include the "resistive" element; this limitation is added in the dependent Claim 15. See generally RF Del., Inc. v. Pac. Keystone Techs., Inc., 326 F.3d 1255, 1263-64 (Fed.Cir. 2003). Nor do the specification or prosecution history support the conclusion that the claimed invention is limited to one including a resistive element. PPC's arguments based on the specification lack merit for the reasons set forth by Magistrate Judge Peebles, and transgress the fundamental rule of construction that, although "the claims must be read in view of the specification, … limitations from the specification are not to be read into the claims." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1326 (Fed.Cir. 2002) (citations omitted). The Report and Recommendation is accepted and adopted in this respect, and the Court holds that the term "passive attenuator network/circuit" means "a network/circuit of non-powered components that together have the effect of reducing or attenuating the level or strength of signals."

GO BACK

3075

"password"

Various asserted claims of the '297 and '416 Patent3 contain the term "password." Though this term was originally disputed, during the claim construction hearing both sides agreed that the definition of the term is "a string of bits used for controlling access." This definition is consistent with the claim language, the specification, and the plain meaning of the term, and is adopted accordingly.

3076

11. Password Data Security System

The term "password data security system" appears in dependent Claims 2, 9, and 14 as a permissible structure for the "means for locking the storage means" identified in Claims 1, 8, and 13. The specification indicates that the term should not be construed in a limiting sense. Rather, it describes the term as a known security system which locks the network until it is unlocked by a password. See Col. 4, ll. 46-67. Reference is made to the system described in U.S. Patent No. 5,375,243 as an example of a password security system that may be used with the current invention. That limitation need not be read into the claim. Accordingly, the Court construes the term "password data security system" to mean a security system which locks the network until it is unlocked by a password.

GO BACK

3077

II. "AV path" / "data path" / "second path" / "path"

The parties request construction of three different types of "paths," as well as resolution of a global issue pertaining to all "paths" in the asserted claims. The three disputed uses of the term "path" appear in Claim 1 of the '654 patent:

1. A teleconferencing system for conducting a teleconference among a plurality of participants, comprising:

   (a) a plurality of workstations, each workstation having first and second monitors and in communication with audio and video (AV) capture capabilities;

   (b) a data path in communication with the plurality of workstations, over which data can be shared among the plurality
of participants; and

(c) an AV path in communication with the plurality of workstations, along which AV signals, representing video images and spoken audio of the participants, can be carried;

wherein, the system is configured to reproduce images, based on data signals shared along the data path, on at least two first monitors so as to permit participants associated with the workstations having the two first monitors to interactively share the reproduced images and reproduce participant video images, based on AV signals carried along the second path, on at least two second monitors.

'654 patent at 41:36-55.

A. "path"

Tandberg argues that each type of claimed path must be "defined" or specified before data or AV signals are transmitted. Tandberg argues that the claim language compels this finding. For example, claim 15 states that the data conferencing control establishes "communications with the central control manager to set up requested data paths along a second network over which the data conference can be conducted." '654 patent at 44:3-9. According to Tandberg, once the central control manager has "set up" the path (which occurs before transmission takes place), the path has been defined.

This argument depends on the meaning of "set up." For Tandberg's argument to be valid, "set up" must mean "define." The phrase "set up," however, encompasses other meanings, such as "establish" or "make ready." See, e.g., Webster's Third New International Dictionary of the English Language Unabridged 2079 (1993) ("to put (a machine) in readiness or adjustment"); Random House Unabridged Dictionary 1751 (2d ed. 1993) ("to be assembled or made ready for use") (emphasis added). Moreover, as discussed below, Tandberg's narrow construction would exclude all of the embodiments disclosed in the specification, which unquestionably make use of opportunistic routing and do not require predefined paths.

Tandberg next points to Figure 4 of the patent, which depicts different routes that an AV signal may take through the Wide Area Network ("WAN"). The portion of the Specification corresponding to Figure 4 states that "[t]he system also provides optimal routes for audio/video signals through the WAN. For example, in Figure 4, location A can take either a direct route to location D via path 47, or a two hop route through location C via paths 48 and 49." Spec. at 10:55-59. The fact that data can take one of two routes, however, says nothing about whether the choice of route is predetermined. Indeed, Tandberg observed at argument that in packet-switched networks such as those described in the Specification, the route through the WAN could change during the middle of a transmission, depending on network load and other factors. The routing of each packet through a packet-switched network is individually determined and can change to adapt to changing network conditions. See Spec. at 10:63-66 ("In a more complex network, several multi-hop routes are typically available, in which case the routing system handles the decision making, which for example can be based on network loading considerations.").

Tandberg's remaining arguments in support of its contention that all paths must be predefined relate to a different question—whether the AV and data paths must lie on physically separate wires. The court considers these arguments below. The fact that signals may travel on different wires, however, is not determinative of whether the path for each signal individually is pre-defined. The court will therefore not limit the claim terms as Tandberg requests, and construes "path" to mean "a route or course."

GO BACK

3078

Telecommunications path, communications path, and datapath

ConnecTel contends "telecommunications path," "communications path," and "data path" should be construed to mean "the physical and logical resources used to move the user data/traffic from one switch to another switch or one switch to or from a user, for example, a switch interface, its associated queues and a transport channel." Thus, ConnecTel argues the path includes more than just the transmission medium itself, but also includes the interface and associated queues.

As stated above, Cisco argues the determination of an optimal "telecommunications path" refers to a determination of a type
of network over which to transfer the data as opposed to determining the optimal path within a network for data transfer. Cisco proposes the Court construe the terms to mean "a transmission medium (a network type such as POTS, leased lines, mobile cellular networks, digital links, fiber optics, satellite links, and private and public packet switching networks such as the Internet)." n2

n2 POTS is "plain old telephone system." Col. 1:23-24.

The specification teaches a method and apparatus for determining the best medium or network for transmitting data. Each interface is "interconnected with an associated telecommunications path capable of transferring a data file." 307 patent, claim 1, 8:13-16; 3:1-3. Figure 1 is a block diagram illustrating the telecommunications switching system. Col. 3:54-55. "The switching system 10 is connected to various telecommunications media in accordance with the user's resources." Col. 3:58-60. Specifically, the system may be connected to a high-speed T1 interface, a wide area network (WAN), a local area network (LAN), a POTS, or a wireless communications network. Col. 3:60-66. These interfaces are exemplary; any number of the aforementioned interfaces may be used alone or in any combination as required by the user." Col. 3:66-4:4. For example, a user may be connected to common carriers such as MCI, SPRINT, or AT&T. Col. 4:4-8. A user may also configure a wireless interface for communication by various electromagnetic means, such as infrared, radio frequency, and the like. Col. 4:8-11. Thus, the preferred embodiment is not limited to the particular mediums listed. However, the specification is clearly directed towards the selection of a particular network as opposed to routing decisions within a network. This also conforms with the specification's description of the prior art's deficiencies in which choices between different networks were being made (not routing with a network). Col. 1:11-2:37. Further, "an object of the present invention is to overcome the shortcomings of the prior art systems as described above." Col. 2:38-40.

The specification does not disclose the selection of an optimal route within a given network. The specification specifically contemplates that the paths are networks, not paths within a network. Repeated references are made within the specification to "paths" in which the path is considered to be a network such as, the disclosed T1, LAN, WAN, POTS, and Wireless networks. For example the "path analysis block 24" makes an analysis of each of the different networks not an analysis within a network. Col. 4:12-23; Figure 1. Further, the routing optimization described within the specification is directed towards selecting one of the T1, LAN, WAN, POTS, and Wireless networks, and the specification describes this as a "path" selection "by employing the multi-protocol routing optimization of the present invention, the path chosen for transmission of a data file takes into account parameters which vary in real-time, thus not relying on a simple preprogrammed look-up table of low cost providers as in the prior art." Col. 5:3-8. Likewise the parameters of Table A and Table B of the specification are parameters of each network as whole as opposed to parameters of individual routes within a network and these parameters and the values derived from these parameters are repeatedly referred to as properties of the "paths." Col. 4:13-65; 5:12-6:9. Likewise the flowcharts of Figures 2 and 3 (which relate to choosing between the T1, LAN, WAN, POTS, and Wireless networks) are "flowcharts of the methodology employed by the present invention in arriving at the optimal choice for routing a data file amongst a plurality of available paths in accordance with the present invention." Col. 6:54-57. Also, a ping test can be used to test the latency for each path. Col. 6:1-9. "The ping routine sends a packet onto the network and obtains a value of the average delay encountered by that packet in reaching the destination and returning." Col. 6:4-7 (emphasis added).

Statements the Applicant made during prosecution of the 307 patent confirm this understanding of the medium is correct. The Applicant distinguished his system from a prior art system, Derby, that was concerned with "moving packets of information around a network faster":

Derby is interested in network packet switching, once the data file has in fact been formatted in packets and provided to the network. The applicant's invention is intended to select an appropriate transmission medium (i.e. wireless, WAN, POTS, etc.) in accordance with measured variables, predetermined parameters, associated with that medium, and properties of the
data file itself. Therefore, Derby is concerned with merely routing packets in a network, once that network (interface) has been selected.

ConnecTel argues this interpretation of the prosecution history is incorrect. ConnecTel contends the Applicant argued, without disavowing path selection within a network, that the combination of Derby and Kobayashi, other prior art, did not teach or suggest the claimed invention. ConnecTel is correct that the excerpt above is taken from an exchange with the Examiner in which the Applicant argued his invention was not obvious in light of Kobayashi and Derby. But ConnecTel misinterprets the exchange: "The Applicant clearly stated that Derby is only involved with the interhop transfers after the initial selection of services to be utilized, and that Derby performs such an interhop transfer analysis and determination in a different way from the Applicant's invention." See ConnecTel's Reply Brief, p. 5. Thus, ConnecTel contends the Applicant did not clearly disavow that the invention could be used within a network for routing packets.

The Applicant stated that "there is clearly no motivation to even combine the cited references. Even if one were to combine the references, the applicant's invention would not result." 370 patent application, Amendment 6/19/1998, p.8. The Applicant distinguished Kobayashi because Kobayashi used static parameters to determine route selection and did not look at the properties of the file to be transferred. Id. at 7. Derby looked at the available bandwidth and network loads for path selection and also did not examine the data file properties or static parameters. Id. at 8. It was in this context that the Applicant stated:

In fact, knowledge of properties of the data file being transferred is not even useful to Derby because Derby is interested in network packet switching, once the data file has in fact been formatted in packets and provided to the network. The applicant's invention is intended to select an appropriate transmission medium (i.e. wireless, WAN, POTS, etc.) in accordance with measured variables, predetermined parameters, associated with that medium, and properties of the data file itself. Therefore, Derby is concerned with merely routing packets in a network, once that network (interface) has been selected.

Id. In this exchange, the Applicant does not merely clearly disavow the scope of any claim but delineates the limits of the claimed invention. The Applicant clarifies that the "invention is intended to select and appropriate transmission medium (i.e. wireless, WAN, POTS, etc.)" rather than "routing packets in a network, once that network (interface) has been selected."

ConnecTel also argues that this view of the invention is incorrect since the specification teaches that all of the interfaces may be the same. See col. 4:2-4. As discussed above, this description in the specification is consistent with the Court's construction. The specification does teach that "any number of the aforementioned interfaces may be used alone or in any combination as required by the user." Col. 4:2-4. The specification then goes on to teach that the invention may be used to select from a number of common carriers such as MCI, AT&T, and SPRINT. Col. 4:4-8. A user may also use the invention to select the optimal wireless interface such as infrared, radio frequency, and the like. Col. 4:8-11. Thus, although the networks may all be of the same type, the invention is still used to select which of the networks is the optimal network.

The Court adopts Soverain's proposed construction and construes "path name in a uniform resource locator" to mean "a sequence of zero or more elements that follows the host address in a URL." The primary dispute between the parties is whether the path name includes the file name. Amazon proposes that the term means "the name of the directories leading to the file identified by the URL. Nothing after the file name is part of the path name."

The parties seem to agree that the ordinary and accustomed meaning to those skilled in the art would include the file name. Amazon argues that the patentee acted as his own lexicographer and defined the term to not include the file name. The parties focus on the following paragraph of the specification, which describes the URL naming system.

The URL naming system consists of three parts: the transfer format, the host name of the machine that holds the file, and
the path to the file. An example of a URL may be:

   http://www.college.univ.edu/Adir/Bdir/Cdir/page.html,

   where "http" represents the transfer protocol; a colon and two forward slashes (://) are used to separate the transfer format from the host name; "www.college.univ.edu" is the host name in which "www" denotes that the file being requested is a Web page; "/Adir/Bdir/Cdir" is a set of directory names in a tree structure, or a path, on the host machine; and "page.html" is the file name with an indication that the file is written in HTML.

Amazon contends that here the patentee expressly states that the file name ("page.html") is not a part of the path ("/Adir/Bdir/Cdir"). Soverain argues that this description expressly states there are only three parts to the URL naming system, and therefore the file name must be included in the path name. The Court agrees. While "page.html" may separately be referred to as the file name, it is included in the path name.

3080

"Path Setup Packet (SETUP)"

Alcatel's proposed construction for the term "path setup packet (SETUP)" is "a packet which contains the traffic load parameters for other packets in the corresponding data stream." Cisco's proposed construction is "initial control packet for an input stream which prepares a path through a network to be followed by other packets of the same communication as the path setup packet, and which contains the traffic load parameters for other packets in the communication."

While it is clear that the "path setup packet" contains the traffic load parameters for the packets in a corresponding communication, the parties' dispute centers on whether the "path setup packet" is required to be the first packet in that communication, which is then followed by the packets in that communication. Cisco argues that, when reading the claims together - claims 1 and 14 in particular - it is clear that the "path setup packet" was intended to be the first packet of a communication. See DePrycker, at 14:43-53, 16:43-54. On the other hand, Alcatel argues that the language of claim 9 does not require that the "path setup packet" be the initial packet in a communication, and that the language in claims 1 and 14 refer to a "first packet (SETUP)" instead of a "path set up packet," and thus the doctrine of claim differentiation mandates that the scope of the claims be construed differently. See, e.g., Comark Communications, 156 F.3d at 1187; but see Wenger Mfg., Inc. v. Coating Machinery Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001) ("[C]laim differentiation is not a 'hard and fast rule of construction,' and cannot be relied upon to 'broaden claims beyond their correct scope.'").

Nevertheless, as Alcatel itself argued to the Court in the context of the claim construction for other patents at issue in this case, claim differentiation only assumes that different claims have different meanings, not that every term in every claim has a different meaning. See Wenger Mfg., 239 F.3d at 1233 ("Under the doctrine of claim differentiation, each claim in a patent is presumptively different in scope,") (emphasis added). Therefore, since claims 1 and 14 differ in scope from claim 9 in many ways other than the use of the term "first packet (SETUP)" instead of "path setup packet (SETUP)," requiring the "path setup packet" to be the first packet in a communication would not run afoul of the doctrine of claim differentiation.

Additionally, the language in claim 14 states that "said first packet is said path set-up packet (SETUP)," and the specification identifies the first packet in a communication as the "call set up control packet." See DePrycker, at 4:23-24, 16:53-54. In light of the language in the claims and the specification, the Court agrees with Cisco that the "path setup packet" is the first packet in a communication. However, Cisco's argument that the term should also be construed to require that the other packets in the same communication necessarily follow the "path setup packet" does not find support in the claim language.

Therefore, the Court construes the term "path setup packet (SETUP)" as "the initial packet in a data stream which contains the traffic load parameters for other packets in that data stream."
"Patient" appears throughout the claims of the shock delivery patents. Even this most basic term gives the parties cause to argue. Philips contends that a patient is a person. Defibtech contends that a patient is any "recipient of a waveform." Philips queries whether, under Defibtech's construction, a "watermelon" could serve as a patient. Defibtech responds that a watermelon does not have a heart. The court wonders if it has accidentally wandered into a junior high school debate meet.

The patents uniformly discuss defibrillation of human patients. The court must construe the term "patient" accordingly, absent some indication that the inventors intended a broader scope. Prior art references that discuss defibrillation of other animals might bear on the validity of the patents-in-suit, but the inventions before the court are not intended for use on anyone but humans.

The parties' key dispute over the term "patient simulator" in Claims 1, 8, and 9 is whether the patient simulator is necessarily electrically connected to the defibrillator's electrode interface. Defibtech argues that this electrical connection is present in the preferred embodiment ('059 Patent at 3:15-65), and thus must be read into the claims.

The court cannot adopt Defibtech's proposed limitation. Defibtech seeks to import a limitation from the preferred embodiment into claims that do not require the limitation. The court declines to do so, for many of the same reasons it rejected Defibtech's construction of "through electrodes" and "indication of the condition of the defibrillator" in its first Markman order. October 25 order at 16-17, 23-25. The court construes "patient simulator" to mean "components or circuitry that simulate a patient."
1. "a pattern"

The parties agree that the word "pattern" has a well-established "ordinary meaning," Vitronics, 90 F.3d at 1582--specifically, "an arrangement of lines or shapes; a design according to which something is to be made"--and the parties appear to agree that the use of the indefinite article "a" connotes "one or more." See Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001); Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1216 (Fed. Cir. 1995). The parties do not agree, however, about how the ordinary meaning of "pattern" fits within the context of claim 1.

Plain language suggests that "pattern" denotes a design or series of marks in a semiconductor integrated circuit that is to be transferred to a photoresist layer of a substrate. In the relevant art, the term "pattern" signifies a series--often of a particular design or repetition--of circuit features in a semiconductor integrated circuit to be transferred to a photoresist layer of a substrate, and when it uses "pattern," the claim language depicts the exposure of a particular kind of pattern--viz., a circuitry pattern--onto a mask or circuitry chip. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1311 (Fed. Cir. 1999) (requiring each term [to] be read to correspond to the only plausible meaning in each context”). Specification language, in turn, references the "patterns" imposed on semiconductor memory devices and liquid crystal components through the process of photoresist-based photolithographic projection. See, e.g., '041 Patent at 1:19-24. As it is used in the relevant claim and specification language, then, "pattern" possesses specified meaning, not by virtue of improperly imported limitations, cf. N. Telecom Ltd. v. Samsung Elecs. Co., Ltd., 215 F.3d 1281, 1290 (Fed. Cir. 2000), but through claim and specification language itself. See Pall Corp., 66 F.3d at 1216. The term "pattern" is used to denote "a design or series of marks in a semiconductor integrated circuit that is to be transferred to a photoresist layer of a substrate." Neither party offers a more appropriate construction, and the court thus construes "pattern" accordingly.

13 Because neither party listed the term "pattern" in the lists of proposed terms and claim elements for construction, see Local Patent Rule 4-1, ASML objects to the late identification of this term for construction. The court notes ASML's objection, but the court will not refrain from construing the "pattern" term. ASML itself included "pattern" in its catalog of to-be-construed terms, and both parties attempted to define the term in their Local Patent Rule 4-2 preliminary proposed construction memoranda.

a. "pattern recognition system"

Plaintiff contends that the court should construe this phrase as "a system which classifies a pattern or patterns obtained from spatial and/or temporal data." (Chart at 28.) Defendant, however, contends that the court should construe this phrase as "as system that implements algorithms employing neural networks, sensor fusion, correlation technologies, or fuzzy logic to receive and compare signals to patterns that are characteristic of normal and abnormal vehicle performance." (Id.) Plaintiff asserts that Defendant's proposed construction is too limiting as to the type of technology used while Defendant asserts that Plaintiff attempts to insert a means-plus-function limitation in its proposed construction and that it is too broad.

The patent specification provides the following description:

Another method for controlling a part of the vehicle comprises the steps of mounting a plurality of sensor systems on the vehicle, measuring a state of the sensor system or a state of the respective mounting location of the sensor system, generating signals representative of the measurements of the sensor systems, inputting the signals into a pattern recognition
system to obtain a diagnosis of the state of the vehicle and controlling the part based at least in part on the diagnosis of the state of the vehicle.

'080 Patent col. 8 l.36-44. The specification also states: "The diagnostic module 170 compares the patterns of data received from each sensor individually, or in combination with data from other sensors, with patterns for which the diagnostic module has been trained to determine whether the component is functioning normally or abnormally." '080 Patent col. 14 l.24-30. Because the specification demonstrates that the pattern recognition system receives signals, and then compares the data from the signals to recognized patterns, the court will use Defendant's language of "receive and compare." Plaintiff, however, correctly identifies that Defendant's definition limits Plaintiff's claim to use of particular pattern recognition technologies. The court will include these in the construction but clarify that they constitute examples.

In addition, the court will include the phrase "normal or abnormal" because inclusion is supported by the specification which describes the learning process of the pattern recognition technologies: "In all cases, the pattern recognition technology learns from examples of data characteristic of normal and abnormal component operation." '080 Patent col. 16 l.14-16. Inputs from the sensors are thus compared to examples of both normal and abnormal operation.

Therefore, the court will construe "pattern recognition system" as "a system that receives and compares signals from vehicle sensors to patterns characteristic of normal or abnormal behavior through pattern recognition technology or technologies, such as, for example, neural networks, sensor fusion, or fuzzy logic, in order to diagnose the state of the vehicle."

3086

1. "patterning"

Agere argues that the term "patterning" should be construed as "performing the process of lithography (producing a pattern that covers portions of the substrate with resist) followed by etching (selective removal of material not covered by resist) or otherwise transferring the pattern into the substrate." Atmel argues that the term "patterning" should be construed as "the process steps of covering a semiconductor wafer with photoresist, selectively exposing portions of the photoresist to illumination through a mask, and then washing away the photoresist in selected areas." The essential difference between the parties' constructions is that Agere contends that patterning includes the step of etching, while Atmel contends that patterning does not include the step of etching. The Court concludes that Agere's proposed construction is the proper construction for the following reasons.

First, claim 1 expressly states that the patterning contemplated by the patentee will result in the formation of "holes" in the dielectric exposing the underlying material. Both parties agree that the step of etching is necessary to form holes, and Atmel does not appear to dispute that patterning, according to Atmel's own proposed construction (which excludes the step of etching), would not result in holes in the dielectric. Atmel contends, however, that to the extent that claim 1 does not make sense if Atmel's construction is adopted, the claim is poorly drafted and should not be redrafted by the Court. The Court finds that because claim 1 expressly indicates that patterning will result in the formation of holes in the dielectric, it is clear that a person of ordinary skill in the art would have understood the term patterning as used in claim 1 to include the step of etching.

In addition, the Court has referred to the "Comprehensive Dictionary of Electrical Engineering," which provides precisely the definition for patterning offered by Agere. See Comprehensive Dictionary of Electrical Engineering 475 (Phillip A. Laplante ed., 1999). Furthermore, Agere's expert witness testified that this definition would have been the definition used by a person of ordinary skill in the art at the time of the invention. See Transcript of Hearing on December 5, 2002 ("Tr. 12/5/02") at 33-34.

The Court has also examined the remaining intrinsic evidence (the specification and the prosecution history) to determine whether a deviation from this clear definition of patterning is expressed. See Interactive Gift, 256 F.3d at 1331. Atmel points to the specification which, in one instance, describe steps that "pattern" the dielectric and steps that "etch" the dielectric in such a way as to imply that they are distinct steps. See '335 Patent at col. 3:51-53. Also, Atmel points to one instance in which the specification appears to use the word "patterned" to refer to resist before etching has occurred. See '335 Patent at col. 5:10-13. However, an important, albeit subtle, distinction must be recognized here. Although the word "pattern" may be

- 3397 -
used in the specification in certain instances to refer to a step that does not include etching, and although the word "patterned" may be used in the specification in certain instances to refer to resist before it has been etched, all of the intrinsic evidence, including the claim language and the specification, shows that the word "patterning" (as opposed to "pattern" or "patterned") is consistently used in such a way as to include the step of etching. For example, the specification in one instance states that "the strong adhesion provided by thin glue layers is useful for patterning W interconnects," '335 Patent at col. 5:6-7, and, as explained by Agere's expert witness, the formation of "interconnects" requires the step of etching, see Tr. 12/05/02 at 38.

Thus, according to all of the intrinsic evidence, "patterning" as used in the claims of the '335 patent occurs when one first patterns the dielectric (producing a patterned resist) and then etches the dielectric. Accordingly, the Court construes "patterning" as "performing the process of lithography (producing a pattern that covers portions of the substrate with resist) followed by etching (selective removal of material not covered by resist) or otherwise transferring the pattern into the substrate."

3087

6. "patterning the continuous layer of transparent conductive material" (Claim Element 10) (Claims 22, 25, 26, and 29 of the '682 Patent)

ATI has proposed plain meaning for Claim Element 10. Dkt. No. 113, Ex. at 7-8. Sharp has proposed that Claim Element 10 is indefinite or, in the alternative, should mean: "patterning the continuous layer of transparent conductive material on the first substrate." Id. DNP has proposed that this term is indefinite or should mean:

After the second substrate and the first substrate are assembled so that the first and second substrates are spaced apart from each other and the layer of conductive material of the first substrate and the layer of conductive material of the second substrate face each other, the layer of transparent electrically conductive material is patterned to form a plurality of electrodes.

Id.

The Order construed this term to mean "patterning the continuous layer of transparent conductive material on the second substrate. This patterning step may be done before or after the substrates are arranged such that they face each other." Dkt. No. 117 at 49.

a. Sharp's Objections

Sharp argues that "ATI wants this [term] to mean that the second substrate can have a patterned layer of conductive material." Objections Tr. at 10:8-10. Sharp submits that the second substrate has a continuous layer and that "a conductive layer cannot be continuous and patterned at the same time." Id. at 9:4-6. Sharp also argues that the transition phrase "comprising" does not abrogate the limitation that the layer of conductive material on the second substrate is a continuous layer. Id. at 14:16-21.

ATI responds that use of the transition phrase "comprising" indicates that "before you take the two sides of the LCD and combine them together, you can treat that conductive layer on the second substrate," such as by patterning it. Id. at 17:7-9; see also Dkt. No. 131 at 12-13 (citing '711 Patent at 8:10-17 and Smith & Nephew, 276 F.3d at 1311). ATI argues that Sharp's proposal would conflict with the presumption that claim terms are used consistently throughout the claims. Dkt. No. 131 at 11 and 14.

In reply, Sharp reiterates that the antecedent for "the layer of transparent conductive material" is "a continuous layer of a transparent conductive material." Dkt. No. 138 at 4. As to consistent use throughout the claims, Sharp submits that Claim 22 of the '682 Patent is different from Claim 26 of the '711 Patent because Claim 22 also recites Claim Element 10, the step of "patterning the continuous layer of transparent conductive material."

b. DNP's Objections
DNP argues that the Order improperly splits Claim Element 9 (into a providing portion and an assembling portion), "thereby allowing another step (patterning) to intervene." Dkt. No. 126 at 16. DNP submits that "[t]he Order recognizes that patterning after the substrates are arranged would be inoperative . . . but nevertheless includes this inoperative embodiment within the scope of the claim by stating that the patterning may be done before or after the substrates are arranged to face each other." Id. at 18 (citing EMI Group N. Am., Inc. v. Cypress Semiconductor Corp., 268 F.3d 1342, 1349 (Fed. Cir. 2001)). DNP also argues that "disposed on one surface" means that the conductive material is placed in direct contact with the surface of the second substrate. Dkt. No. 126 at 18.

ATI responds that "the specification and the claims contemplate that the second substrate's continuous layer of conductive material may be further processed to provide a patterned layer." Dkt. No. 130 at 17. ATI cites a portion of the specification that discloses that "[t]he layer of transparent conductive material 42 may be either a continuous layer or may be a patterned layer . . . ." Id. (quoting '682 Patent at 8:14-16). ATI submits that "[o]ne of ordinary skill would not read the claims to require that patterning, such as by a photolithographic process, be applied to the conductive material only after the screen is assembled, because such a process would be nonsensical." Id.

DNP replies by citing authority that "courts should not rewrite claims to preserve validity." Dkt. No. 140 at 10 (quoting Nazomi Commc'ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364 (Fed. Cir. 2005)). DNP proposes that the Court "should either: (1) modify the construction order of claim 22 so that the claim steps must be performed in the order written; or (2) hold claim 22 invalid by recognizing that the current construction includes this inoperative embodiment because the Order states that the patterning may be done before or after the substrates are arranged to face each other." Dkt. No. 140 at 10.

c. Discussion

As the Order summarized, the parties dispute whether Claim Element 10 "relates to patterning the conductive layer on the first [substrate] or the second substrate, as each substrate includes a separate conductive layer." Dkt. No. 117 at 45. In "patterning the continuous layer of transparent conductive material," the constituent term "the continuous layer of transparent conductive material" includes the definite article "the," which generally refers back to a specific antecedent basis. See NTP, 418 F.3d at 1306; see also Baldwin Graphic Sys. Inc. v. Siebert, Inc., 512 F.3d 1338, 1342-43 (Fed. Cir. 2008). As noted in the Order, the only prior recitation of "continuous layer of transparent conductive material" in Claim 22 of the '682 Patent is to such a layer of the second substrate, recited in Claim Element 9. The Order's finding that "the patterning must be of the conductive layer on the second substrate, not of the conductive layer on the first substrate" should therefore be affirmed.

As to order of steps, the Order found that the "patterning step may be done before or after the substrates are arranged such that they face each other." Dkt. No. 117 at 49. Despite this conclusion, the Order also found that "after the two substrates are arranged so as to face each other, it would be unreasonable to then pattern the conductive layer." Dkt. No. 117 at 48.

Whether the order of the steps recited in a method claim must be performed in a particular order is properly a part of claim construction. See, e.g., Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1371-72 (Fed. Cir. 2003). Generally, steps may be performed in any order so long as "nothing in the intrinsic evidence" compels otherwise. Id. at 1370; see also Baldwin, 512 F.3d at 1345 (Fed. Cir. 2008) ("As a general rule the claim is not limited to performance of the steps in the order recited, unless the claim explicitly or implicitly requires a specific order.") (citing Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1342-43 (Fed. Cir. 2001)); Mantech Envtl. Corp. v. Hudson Envtl. Servs. Co., 152 F.3d 1368 (Fed. Cir. 1998).

ATI acknowledges that the "patterning" step must be performed before the substrates are "arranged": 2

One of ordinary skill would not read the claims to require that patterning, such as by a photolithographic process, be applied to the conductive material only after the screen is assembled, because such a process would be nonsensical. Because this reading is absurd, one of ordinary skill would not read such a limitation into the claims.

Dkt. No. 130 at 18 (emphasis added). In this quoted passage, ATI argues that the claim should not be interpreted to require that "patterning" occur after the "arrang[ing]" because such a process would be "nonsensical" and "absurd." Id.; '682 Patent at Claim 22, 11:33-41. Thus, ATI appears to acknowledge that "patterning" must occur before "arrang[ing]" in the context of
the '711 Patent and the '682 Patent. 3 DNP also agrees the order recited in the claim is technically impracticable. 4 However, DNP apparently acknowledges a required order based on the specification. Dkt. No. 84 at 8 ("The layer of conductive material may be left as a continuous layer or may be patterned by photolithography to form display electrodes. (Id. at Fig. 4, ref. No. 42; id. at 8:14-17). The two plates are then arranged so that the different layers of material disposed on the two substrates face each other. (Id. at Fig. 4; id. at 8:21-24)"). Also, the Order found that "even a rudimentary understanding of the technology behind the fabrication of a liquid crystal display would dictate against requiring such a construction [i.e., to require the patterning after the substrates are arranged]. Namely, after the two substrates are arranged so as to face each other, it would be unreasonable to then pattern the conductive layer." Dkt. No. 117 at 48.

2 The parties' briefing and arguments of counsel indicate that the term "arranged" in Claim 22 is being interpreted as "assembled," as evident from the following quoted text from ATI and from the following footnote regarding statements by DNP's counsel.

3 See also 1/22/2009 Claim Construction Hr'g Tr., Dkt. No. 116 at 143:11-14 ("In this case, based on the preferred embodiments and the specification in which photolithography is used to pattern this layer, logic dictates that you read the claim such that patterning occur before assembly.")

4 THE COURT: 
"[F]rom DNP's briefing it seemed to me that you seem to require or are wanting to require Claim 22 to be done in sequence. In other words you're - the way you interpret that is once the assemblies are put together, the subassemblies are put together, then if there is going to be any patterning on the second substrate, it has to happen then. Is that the way you're - is my reading of your position correct?

MR. CHALSEN: Yes, that's our argument, Your Honor. And actually this is another one of our indefinite - it's really an indefinite in that this claim really is inoperable or it's invalid. It can't be -- it's not practical --

THE COURT: And I take it --

MR. CHALSEN: -- to put in place and then do the patterning. So as it is written the claim is invalid.

THE COURT: So if that is correct, your interpretation is correct and Claim 22 has to be essentially performed or the product assembled in that sequence, any patterning of the second substrate would take place once it is put together.MR. CHALSEN: Yes.

THE COURT: And I take it from what everybody has said, these two panels, these two substrates are only a few fraction of an inch, a few millimeters perhaps, or less. I mean they're a very, very narrow space and there's no process to do that once they're together; is that accurate?

MR. CHALSEN: Well, I mean in the current manufacturing environment where practical devices are being made, yes. But theoretically the claim is not limited to micron --

THE COURT: As I understand it, the laser that's used, that's described here and the other processes that were described, these essentially are big - these are big machines. I mean they are physically large things. They are not microscopic in size is what I'm getting at.

MR. CHALSEN: Yes, that's true, Your Honor. I think our point is really that the claim says what it says, interpret it that way, in sequence that the steps should be performed at the point in the claim where it says it is performed.

THE COURT: All right.

MR. CHALSEN: And if it can't be, it's inoperable.

The Court applies a two-part test to determine whether a particular order of steps in a method claim is required: "First, we look to the claim language to determine if, as a matter of logic or grammar, they must be performed in the order written." Altiris, 318 F.3d at 1370. (citation omitted). "If not, we next look to the rest of the specification to determine whether it directly or implicitly requires such a narrow construction." Id. at 1371 (citation omitted).

The specification describes the steps of forming a continuous layer and then patterning the continuous layer associated with the first substrate. The same is done for the layers of the second substrate: forming a continuous layer, then patterning of the continuous layer associated with the second substrate. '682 Patent at 8:10-25. The disclosure then describes the step of arranging together the first substrates and the second substrates. Id. at 7:39-52. In particular, "[t]he layer of conductive material may be left as a continuous layer or may be patterned by photolithography to form display electrodes . . . . The two plates are arranged so that the different layers of material disposed on the two substrates face each other." Id. at 8:14-24.

Moreover, the drawings demonstrate the same sequence described in the disclosure: patterning the continuous conductive layer and then arranging the two substrates together. The procedure of patterning is depicted by the drawings, such as Figures 3B and 3C, which show that the first conductive material layer ("transparent conductive oxide material 30") may be continuous initially and then "patterned" by etching away parts of the material, leaving rectangular stubs ("electrodes 32a - 32f," Fig. 3C). Id. at 7:39-50. Patterning can thus be performed to provide electrodes. '682 Patent at 8:10-25. In addition, the specification describes that either or both continuous layers may be patterned to form electrodes due to the symmetry of the technology. Id. at 7:39-47 and 8:14-17. The specification refers to either of two "transparent conductive oxide material" layers (30 (Fig. 3B) and 42 (Fig. 4)) that are continuous initially and then may be subsequently patterned by a photolithographic process. Id. Finally, after patterning a continuous layer in Figure 3C, the two substrates with their associated layers are arranged together, as shown in Figure 4. The written description and the drawings are thus consistent with first requiring "patterning the continuous layer" and then the "second substrate being spacedly disposed from said first substrate and arranged . . . ."

Claim 22 does not explicitly recite the order described in the specification. Rather, Claim 22 recites the step of "patterning" after the step that includes arranging the substrates together. The term was apparently added to the limitations of claim 13 of the originally-granted patent, U.S. Pat. No. 5,576,070, during reissue prosecution to create Claim 22 of the '682 Patent. The term was presumably inserted after the second "providing" step so that "the continuous layer" in the "patterning" step would have proper antecedent basis. That is, by appearing in the claim after the initial recitation of "a continuous layer" in the second "providing" step of Claim 22, "the continuous layer" would have refer back to "a continuous layer" earlier in the claim. In adding the "patterning" step during reissue, the patentee did not disturb the wording of the second "providing" step, which appears immediately before the "patterning" step.

Although the recited order of these two particular steps in the claim is apparently impracticable, the intrinsic evidence demonstrates the necessary order, as discussed above. See Phillips, 415 F.3d at 1313. As the Baldwin court explained: "The specification informs the meaning of the claims. [Phillips] acknowledged the difficult distinction between 'using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim.' [Phillips] explained, however, that the distinction is manageable 'if the . . . focus remains on understanding how a person of ordinary skill in the art would understand the claim terms.' Baldwin, 512 F.3d at 1345. A person of ordinary skill at the time of filing the application would have understood, in light of the entire specification, that the step of "patterning" must be performed before "arrang[ing]" the substrates so as to be "spacedly disposed" from one another. '682 Patent at 11:33-43.

At the time of the patent application, a person of ordinary skill in the art would have known of photolithographic techniques applicable to the color liquid crystal display devices. See id. at 7:32-37 ("Thereafter, employing photolithographic techniques well know[n] in the art, the layer of transparent conductive material 30 is patterned to form a plurality of electrodes 32a-32f . . . ."). Moreover, the "Background of the Invention" of the '682 Patent cites to photolithographic articles. Id. at 1:62-2:21. An electrical engineering handbook published near the filing of the patent confirms the general knowledge of photolithography as described in the '682 Patent. See Richard Dorf, The Electrical Engineering Handbook 487-89, 1159-60, 1772-1775 (1993). Also, the "Background" section of the specification states that "color liquid crystal display devices are well known in the art, and one exemplary such device is set forth in United States Patent No. 4,632,514 to Ogawa, et al, entitled 'COLOR LIQUID CRYSTAL DISPLAY APPARATUS.'" Id. at 1:57-60. The Ogawa reference describes a distance of only five to eight microns in a gap region between two substrates when arranged together. Reading
the '682 Patent, a person with even rudimentary knowledge of photolithography at the time of filing of the patent application would have thus recognized the impracticability of patterning the continuous layer after the two substrates have been arranged together. See Dorf at 445, 487-89, 1159-60, 1772-1775 (noting that "[l]ithography is a patterning process in which a mask pattern is transferred by a radiation source to a radiation sensitive coating," and illustrating (in Figures 21.3, 53.3) the relative size of the necessary equipment, which appears too large to fit within gaps that are on the order of microns in width.).

The present case is distinguishable from Altiris, which found that "the district court ran afoul of our prohibition against importing a limitation from the specification into the claims -- here [the imported limitation being] the order of steps used by the sole, preferred embodiment." 318 F.3d at 1369. The district court under review in Altiris relied on the specification to construe an order of recited steps even though the claims did not recite a required order. Id. The Altiris court found that the specification did not state that the particular order described was important. Id. at 1371. Moreover, expert testimony considered by the Altiris court supported finding that a person of ordinary skill would have understood that any order was technologically feasible. Id. In the context of the layered-fabrication methodology before this Court, however, "patterning" after "arrang[ing]" would be technically impracticable, or "nonsensical," as discussed above. Further, the specification of the '682 Patent provides no apparent support for "patterning" after "arrang[ing]," so construing Claim 22 to allow such an order of steps is disfavored. See Modine Mfg. Co. v. I.T.C., 75 F.3d 1545, 1557 (Fed. Cir. 1996) ("When claims are amenable to more than one construction, they should when reasonably possible be interpreted so as to preserve their validity.") (citations omitted).

For at least the foregoing reasons, the Court construes the term "patterning the continuous layer of transparent conductive material" to mean "patterning the continuous layer of transparent conductive material on the second substrate, wherein the patterning is performed before the second substrate is spacedly disposed from said first substrate and arranged so that the layer of transparent conductive material of the second substrate faces the layer of transparent conductive material of the first substrate."

As to indefiniteness, the portion of the Order's construction holding that "[t]his patterning step may be done before or after the substrates are arranged such that they face each other" is modified by this order. DNP's indefiniteness argument is therefore moot.

As to DNP's objection based on the purported invalidity of Claim 22 under 35 U.S.C. § 101, whether a claim satisfies utility requirements is a question of fact. See, e.g., In re Fisher, 421 F.3d 1365, 1369 (Fed. Cir. 2005); Raytheon Co. v. Roper Corp., 724 F.2d 951, 956 (Fed. Cir. 1983). Any such issues should be presented in a motion for summary judgment or during trial rather than during claim construction. The Court accordingly declines to address utility at this time.

GO BACK

3088

 Pause state

 The Court construes "pause state" to mean "the camera delays taking a picture for a predetermined amount of time in response to one or more signals from a motion detector." Again, this construction is taken from the claim language and the specification. The claim states that when the camera is in the pause state, it "ignor[es] the signal from the motion detector until a predetermined amount of time has passed." Claim 17, col. 6:65-67. The specification teaches that, "[w]hen put into a pause state, the controller ignores any triggering events of motion detector 106 until a predetermined amount of time has elapsed." Col. 4:36-40.

Like with "burst state," Defendants seek to include a user-selection limitation. Specifically, Defendants urge the Court to construe "pause state" to mean "a user-selected mode of operation of the motion detector camera in which signals from the motion detector cause no pictures to be taken for a user-selected period of time." Defendants' construction also requires that the user determine the length of the delay in the pause state. While both of these limitations are features of preferred embodiments, neither is required by the claim language or the specification. Defendants argue that the user-selection limitation is required by the claim language "selectively placing the motion detector camera into. . . ." Defendants' construction excludes the possibility that a camera may be preprogrammed by the manufacturer with default states, shipped with a default state already selected, or that the length of the pause state may be set by the manufacturer. These possibilities
are not excluded by the claim language or disavowed in the specification or prosecution history. Accordingly, the Court will not limit the claim in this manner.

3. The parties agree that the term "the system," as used in Claims 1 and 13 of the 298 Patent and Claims 1 and 6 of the 456 Patent, refers to the "payee's agent's system," and that both terms should be construed to mean "a system of someone who acts for or in the place of a payee with authority." (Def. Resp. Br. at 4; Plf. Reply Br at 5). The dictionary defines "agent" as "one empowered to act for or represent another." THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE at 33. In ordinary usage, the "payee's agent's system" is a system belonging to someone authorized to act on behalf of the payee. The construction suggested by the parties is consistent with the ordinary and customary meaning of these terms and should be adopted by the court.

"Payment computer"

The Court defines "payment computer" to mean "a computer processing payment information." Although the parties agree that "payment computer" does not have an ordinary and customary meaning in the art, the term "payment" has an ordinary and customary meaning, and the Court has already construed the term "computer." Accordingly, the Court is able to infer the phrase's meaning from the ordinary meaning of payment and the construed meaning of computer without importing limitations from the specification. See Bancorp Servs, 359 F.3d at 1372 ("the components of the term have well-recognized meanings, which allow the reader to infer the meaning of the entire phrase with reasonable confidence"). Amazon's proposed construction, which cobbles together descriptions from the specification, requires the payment computer to "accept and verify payment by the buyer, and authorize purchase of products from the merchant." Such a construction impermissibly reads in limitations from the specification.

[b] payment-due data representing a seller's fulfillment of a sale-of-goods transaction between the seller and a buyer.

[b] electronically transmitted data representing that (a) a seller has satisfied its obligations under a sale-of-goods transaction or (b) that a buyer has otherwise accepted the seller's performance, and that a buyer's obligation to pay for the goods is due.

The next disputed term, "payment mechanism," first appears in claim 1 and occurs in several subsequent, dependent claims, including the disputed claim 49. Plaintiffs define "payment" as "paying money in some form," and "mechanism" as "machinery or process for achieving a result." (Pls.' Mem. On Claim Construction 13). Defendant interprets "payment mechanism" to mean "an arrangement of connected parts for payment that is part of the vending machine," as based on its understanding of the specification and the dictionary definition of mechanism. (Def.'s Rebuttal Claim Construction Br. 19). Defendant properly disputes plaintiffs' construction of mechanism as a process or method, since the Patents disclose an
apparatus, not a method or process. The specification language cited by plaintiffs in support of its proposed definition allows payment by currency or "in electronic form," referring to contemporaneous payment by an electronically-read or magnetically-read card (e.g., credit card, debit card, hotel key card) or other such device. ('400 Patent 2:50-56). The specification also suggests that payment may be "carried out through software that is present in the user's laptop or other device," and that "no physical method need be included in the vending machine." ('400 Patent 2:55-56, 3:23). Contrary to plaintiffs’ claim, this does not mean that the vending machine's payment mechanism is located external to the vending machine, especially in light of the specification and claim language that clearly defines a vending machine as comprised of, in part, a payment mechanism. Rather, instead of being made by a credit card, the payment may be made by electronic currency, e.g., "e-money," or an online service that issues credit to the user and separately bills the user. These are examples of forms of payment, and while these may be dictated by the type of payment mechanism located in the vending machine (for example, if the vending machine does not contain a mechanism for accepting currency but only for processing e-money), they do not dictate the location of the vending machine's payment mechanism.

Accordingly, I construe the disputed claim language as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Payment mechanism</td>
<td>An arrangement of connected parts for paying money in some form and that is part of the vending machine</td>
</tr>
</tbody>
</table>

B. Payment Mechanism

Claim 1(a) discloses "a payment mechanism for obtaining information from the customer to initiate a vending transaction." '400 patent col. 16, 11. 5-6. The parties' dispute concerns the meaning of the term "mechanism." T-Mobile argues that a mechanism is "an arrangement of connected parts," T-Mobile Br. at 19, while PowerOasis contends that "mechanism' means machinery or process for achieving a result." PowerOasis Br. at 13.

T-Mobile offers two unconvincing arguments to support its interpretation. First, T-Mobile notes that the dictionary definition of "mechanism" is "an arrangement of interconnected parts." T-Mobile Br. at 19 (citing American Heritage College Dictionary). In fact, "mechanism" has several dictionary definitions, including ones that comport with PowerOasis' proposed construction of "payment mechanism." See Compact Oxford English Dictionary of Current English (defining "mechanism" as "the way in which something works or is brought about"). Thus, dictionaries are unhelpful.

Second, T-Mobile argues that the patentees' earlier patents used "mechanism" in terms such as "cover mechanism," '643 patent col. 9, 1. 22, "steam supply mechanism," '169 patent col. 18, 11. 25-26, "hydrocarbon supply mechanism," id. col. 18, 11. 28-29, and "electric supply mechanism," id. col. 18, 1. 34, "to describe items that are made of connected parts." T-Mobile Br. at 19. These references do not support T-Mobile's argument because they use "mechanism" in the same way as it is used in the phrase "payment mechanism" without providing any additional guidance as to the term's intended meaning. n7

n7 In contrast to the other "mechanisms," the patentees explained that a "cover mechanism" is a protective enclosure for the customer's electronic device. '643 patent col. 9, 11. 17-23. While I agree with T-Mobile that a "cover mechanism" is a physical structure, my conclusion derives from the patentees' explication of how the "cover mechanism" functions as a cover for the customer's device rather than their use of the term "mechanism." Accordingly, "cover mechanism" sheds no light on the meaning of "mechanism" in "payment mechanism."

T-Mobile's argument also falters in light of the specification's statement that "no physical payment method is required [in which case] payment is carried out through software that is present in the user's laptop or other device." '400 patent col. 2, 11. 54-56; see also '400 patent col. 3, 11. 22-23. I agree with PowerOasis that this language refutes T-Mobile's contention that a "mechanism" must be "an arrangement of connected parts." As this statement demonstrates, the patentees clearly
envisioned an embodiment in which the "payment mechanism" consists of software on the customer's laptop rather than a coin acceptor, card reader, or other "arrangement of connected parts."

Although I agree with PowerOasis that "payment mechanism" includes software loaded on the customer's computer, I decline to adopt its proposed definition without qualification. As T-Mobile has correctly pointed out, the '658 and '400 patents are apparatus claims rather than method claims. PowerOasis' definition of "mechanism" as "a process for achieving a result" improperly attempts to convert disclosed structure into a method for achieving the result. In order to clarify that the term "payment mechanism" does not encompass all possible methods for obtaining payment from the customer, I construe "payment mechanism" to mean "a mechanical, electrical, or electronic (i.e., software) means for achieving payment."

Various claims in the 298 Patent and the 456 Patent refer to "payment number." The parties agree that this term should be given the same construction wherever it appears and that any construction adopted by the court should include both debit card numbers and credit card numbers. However, BMC maintains that "payment number" also includes debit payments in the form of an electronic check. (Plf. Op. Br. at 23). In support of this argument, BMC points out that Claim 3 of the 456 Patent, a dependent claim that incorporates Claim 1 of the same patent, expressly provides that "said payment number is a debit card number or debit payment in the form of an electronic check." (Plf. App., Exh. 3 at 42) (emphasis added). Independent claims should be construed to be at least as broad as the claims that depend from them. A. K. Steel Corp. v. Sollac and Ugine, 344 F.3d 1234, 1242 (Fed. Cir. 2003). Therefore, the court should construe "payment number" to mean "debit card numbers, credit card numbers, and debit payments in the form of an electronic check."

M. "payment transaction"

Visa objects to the magistrate judge's recommendation that the court apply the ordinary meaning of the term "payment transaction." See First Report at 10. Visa asks the court to adopt the following definition, taken from the patent claims and specification: "A transaction performed in paying bills, sending refunds on return merchandise, sending awards, etc." Def. Obj. to First Report at 17. In support of its argument that the magistrate judge should have construed the claim term, Visa points out that the specification expressly defines "purchase transactions" and "payment transactions" as two distinct types of economic commerce. Having reviewed the specification, and in light of the teaching of Phillips, the court sustains Visa's objection and rejects the magistrate judge's recommendation that the term "payment transaction" be given its ordinary meaning. See generally Phillips, 415 F.3d at 1316 ("[O]ur cases recognize that the specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs."). Accordingly, the court construes payment transaction as: "A transaction performed in paying bills, sending refunds on return merchandise, sending awards, etc."

Flashmark suggests that no construction is necessary. In the alternative, Flashmark proposes "a material that responds distinctively to an intensity of light in a range of wavelengths, or of heat, which is not normally encountered in ordinary use in amounts sufficient to cause said material to discolor." GTECH has suggested:

"Material, peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor." Used in Claim 1.

Flashmark suggests that no construction is necessary. In the alternative, Flashmark proposes "a material that responds distinctively to an intensity of light in a range of wavelengths, or of heat, which is not normally encountered in ordinary use in amounts sufficient to cause said material to discolor." GTECH has suggested:

"Material, peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor." Used in Claim 1.
Infrared wavelengths, in comparison to dry silver materials. 5

A construction of this term requires a definition of "radiant energy," which is addressed above. The court must also construe the "ambient light" in which the "radiant energy" is not normally present.

5 In the responsive brief, GTECH suggested: "a material including an infra-red absorbing dye, formulated to dramatically enhance sensitivity to radiant energy and to reduce the amount of time and energy required to cause the material to become visible in response to wavelengths of radiant energy outside the visible spectrum in the range of about 750-950 nm, and at intensity levels not normally encountered in ordinary use, namely about 50 ergs per square centimeter."

a. Use of Term in Claims and Specification

Claim 1 describes the material as being responsive to radiant energy that is "not normally present in ambient light in amounts sufficient to cause said material to discolor." '153 patent, col. 7, 11. 22-23. It does not place any further restrictions on the type of material that can make up the article.

The specification states that the "material" is normally invisible, which means that the "material is only slightly visible or visible as background, and does not interfere with the genuinely visible markings on the coupon." '153 patent, col. 3, 11. 25-30. "The material 13 may be responsive to radiant energy such as heat or light. Upon being exposed to heat or light energy not normally encountered in ordinary use, the material 13 will become visible." '153 patent, col. 3, 11. 33-37.

In a preferred embodiment, the specification states that the "presently preferred material 13 is a photosensitive material formed by a mixture of a dry silver material and an infrared absorbing dye." '153 patent, col. 3, 11. 42-44. "The preferred materials exhibit high absorption of light wavelengths in the approximate range of about 750 nanometers to 950 nanometers." '153 patent, col. 3, 11. 61-63.

This preferred embodiment is seen in Claims 5 and 6, which are dependent on Claim 1. Claim 5 states: "The article of claim 4 wherein said range of light wavelengths covers about 750 nanometers to about 950 nanometers." Claim 6 states: "The article of claim 5 wherein said material comprises a mixture of dry silver and infra-red absorbing dye."

GTECH's proposal, therefore, is based upon limitations in a preferred embodiment and the dependent claims. In general, an independent claim is presumed to be broader in scope and to encompass the dependent claim. See Phillips, 415 F.3d at 1315 ("[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.")

Flashmark argues that in defining this term, the words "ambient light" be changed to "ordinary use," relying upon a single appearance of that phrase in the specification at Col. 3, 1. 36. If "ambient light" could just be changed to "ordinary use" then "radiant energy" would be more likely to refer to "heat" in forms other than electromagnetic wavelengths. The patentee could have picked any words he wanted for the claims, but he chose to add "ambient light," not "ordinary use," to Claim 1 to overcome the Examiner's initial rejection. Amendment, 6/25/1991 p. 2, FLASH 0000078 in GTECH's Ex. E [Doc. # 107, Attach. # 11, p. 18 of 76]. And, in distinguishing prior art while trying to overcome that rejection, the patentee stressed that prior inventions discolored in ambient light. Amendment, 6/25/1991, pp. 4-5, FLASH 0000080-81 in GTECH's Ex. E [Doc. # 107, Attach. # 11, p. 20-21].

A further indication of what the patentee intended by the use of "ambient light" is found in the same amendment: "As stated in the description, color formation is caused in DYLUX by UV found in daylight or artificial light which contains UV. To prevent discoloration in ambient light the DYLUX paper must be deactivated . . . ." Amendment 6/25/1991, p. 8, FLASH 0000084 in GTECH's Ex. E [Doc. # 107, Attach. 11, p. 24] (emphasis added). The court need not consider at this point whether the "ordinary use" term is a disclosure of an invention in the specification which was not claimed, and so is donated to the public. Johnson & Johnston Assoc. V. R.E. Serv. Co., 285 F.3d 1046, 1054 (Fed. Cir. 2002) ("[W]hen a patent drafter discloses but declines to claim subject matter, . . . this action dedicats that unclaimed subject matter to the public.").
At the hearing the court discussed a proposed definition, together with numerous changes suggested by the parties. In the end, Flashmark would not agree to a construction that defined "ambient light" as anything but "ordinary use." For the reasons noted above there is no basis to adopt "ordinary use," especially when the patentee chose not to use the phrase in amending the claim.

Flashmark's expert stated that while "direct" light would be "focused," ambient light would include "normal lighting" in a room and direct sunlight outdoors, or "conditions of the environment without that presence of the directed light." This is a more expansive definition of ambient light than that suggested by the court, and agreed to by GTECH. However, it is not outside the ambit of the use of the term in the specification and in the prosecution history references set out above, and it comports with its use in some dictionaries.

The court was concerned about imposing a limitation requiring that the "material" of the invention not discolor even in direct sunlight, as will a newspaper and many other papers. However, Flashmark insisted that "ambient light" included direct sunlight, perhaps because their idea of "ordinary use" includes using the articles in direct sunlight. The court is not adverse to adopting this concept as it is reasonable and narrows, rather than expands, the scope of the claim. This term will be construed as follows:

### Material peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor

**Means** "a substance which darkens or changes color when exposed to radiant energy (as previously defined by the court) of a type or intensity (or both) that is not ordinarily present in sunlight or normal indoor lighting."

10. "Pending message list" (*771, Claims 1, 2)

This dispute concerns whether the "pending message list" is a notification to the roaming terminal that it needs to request transmission of its pending messages, as Broadcom argues, or also contains the text of those messages, as Agere argues. Agere claims that the dictionary definition of "list" is "an item-by-item series," and therefore a "pending message list," as understood by a person of ordinary skill in the art, is an "item-by-item series of pending messages." The Court notes, however, that the word "list" has other dictionary definitions, many of which do not support Agere's construction. For example, Webster's dictionary defines a list as "(a) a simple series of words or numerals . . . (b) [synonymous with] index, catalog, checklist . . . (c) the total number to be considered or included." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 1320 (1993). All of these definitions would tend to limit the pending message list to an "index" of pending messages, rather than the messages themselves. Thus, at best, there is ambiguity among dictionaries as to which party's construction is accurate. As discussed previously, Courts faced with such ambiguity consult the specifications and prosecution history to determine which definition is most consistent with the patent's use of the term.

Agere cites three pieces of evidence in support of its construction. First, one specification states that "pending messages for
roaming] terminals are stored in lists in the parent node." (771 patent, col. 34, ll. 35-38.) As Dr. Goodman conceded, however, this specification refers to messages stored on the parent node, not to the "pending message list" transmitted to the roaming terminal. (R. at 74-75 (May 6, 2004).) As there is no indication or evidence that these two lists are the same, the cited language has no apparent bearing on the term at issue. Second, Agere cites a specification that refers to "unsolicited messages" being sent to the roaming terminals ("771 patent, col. 39, ll. 44-49), 43 and argues that if the messages are sent unsolicited, they must be sent in the first transmission to the roaming terminal upon its awakening, i.e., in the pending message list. This interpretation, however, is contradicted by the same specification, which notes that the roaming terminal "must request a saved message by examining the pending message list." Thus, the text of the pending messages cannot be included in the pending message list, for if it were, there would be no subsequent "request" from the terminal.

Finally, Agere cites the prosecution history. This history shows that the Examiner rejected the application because the original phrasing of this term, "indications of pending messages," was too indefinite. (Agere Resp. Ex. 34 at 4 (Letter rejecting application 08/545,108, July 23, 1997).) 44 Consequently, the applicant changed this language to "pending message list." Agere argues that the change from the indefinite "indication" to the more concrete "list" means that a list cannot merely be an indication of pending messages, and must therefore include some message content. The Court disagrees with Agere's conclusion. The word "indication" is extremely broad--it could refer to literally anything (e.g., a single bit, a buzzer, a flashing light) that informed the roaming terminal that it had a message pending. The term "list" is considerably narrower, specifying that the terminal is not simply being notified that messages are pending but also being given some information (e.g., the quantity, length, or location of the messages). There is no basis, however, for Agere's argument that this information must include message content. In other words, the applicant's amendment, while slightly narrowing the body of transmissions that could qualify as a "pending message list," does not narrow it so greatly as to require that the list actually contain a message. Accordingly, the Court finds that Agere's proposed limitation is unsupported by the specifications and the prosecution history discussed above.

The term "appears to the user to be the same tool," "perceptible as the same tool/display object," & "not including a display object that is perceptible as the same tool"

The term "appears to the user to be the same tool" appears in claims 9 and 10 of the '412 patent. The term "perceptible as the same display object" appears in independent claim 8 of the '412 patent, and the term "perceptible as the same tool" appears in claims 1, 24, 38, 44, 49-52, 56, and 59 of the '412 patent, claims 1 and 8 of the '521 patent, and claims 1, 3, and 12 of the '183 patent. 1 Claim 19 of the '412 patent contains the related term "not including a display object that is perceptible as the same tool." The parties agree that the term needs no further construction beyond defining "perceptible as the same tool." The parties have agreed on the definitions for "tool" and "display object." Therefore, the true terms in contention are "perceptible as" and "appears to the user to be the same." IPI argues that these terms as a whole should be defined as "requiring the phenomenon of object constancy, under which two successively displayed objects are perceived as the same tool/display object, even if the objects have some different positions, sizes, and contexts. Object constancy can result from
many cues including similarities of position, size, context, contents, labels, text, and/or history." Defendants respond that the terms mean "generated to achieve object constancy such that changes made to shared features of a tool appearing in one workspace, e.g. content, data, etc. are reflected in features of tools in other workspaces."

For ease of reference these terms will collectively be referred to as the "appearing" terms.

IPI's construction is taken directly from the specification describing Figures 1a and 1b. Those Figures show two different windows containing different objects, and the specification explains that the Figures "illustrate the phenomenon of object constancy." '412 Patent at 10:31-31. Some of the objects in the two figures "appear to be the same object despite having different characteristics." Id. at 10:35-36. As IPI's proffered definition suggests, the specification gives examples of various characteristics that may be different while maintaining object constancy. Id. at 10:36-37 ("positions, sizes, and contexts").

As an additional example, the specification explains that "[o]ther shared features which can result in object constancy include sharing of an application, such as an editor; sharing of data; sharing of the state of the application as applied to the data; sharing of a history of continuous operation without interruption." Id. at 10:43-47.

However, while "object constancy" serves as a guide for defining these terms, the claim terms themselves are phrased as a matter of "perception" by "the user." Because of this phrasing, Defendants' proposed construction must be rejected. Defendants attempt to define how a computer might achieve object constancy rather than in terms of what perceptible features result in object constancy. Their inclusion of the word "generated" is unsupported by the specification. Though Defendants opine that a "display system object" may "generate" the same tool in multiple workspaces, this portion of the specification has nothing to do with what is perceived by a user. See id. at 8:22-45. Thus, these claim terms do not require, as Defendants argue, that a tool/display object be generated or stored in a certain way. Adding such a limitation to the definition of the "appearing" terms would improperly limit the claims. Further, while the specification describes that object constancy is achieved through "shared features," Defendants' construction seems to suggest that features must share a data structure to meet the limitation. Nothing in the specification's description of object constancy requires tools/objects to share a data structure. The claim terms only speak to the "appearance" of objects in two workspaces and not how the data structures comprising tools/display objects are organized.

One skilled in the art would understand that the "appearing" terms refer to object constancy as described by IPI. However, as "object constancy" itself is a specialized term, to include it in the definition of the disputed terms would not assist the jury. But, as described above, the essential characteristic of object constancy is recognition, by the user, of a tool/display object despite some different characteristics. Accordingly, the "appearing" terms mean "recognized as the same tool [display object], even if the objects have some different display characteristics, including different positions, sizes, and contexts."

Thus, the term "not including a display object that is perceptible as the same tool" means "not including a display object that is recognized as the same display object, even if the objects have some different display characteristics, including different positions, sizes, and contexts."

13. "performance monitoring information"

Power-One proposes no construction or, in the alternative, "information concerning one or more performance characteristics of the device." Artesyn proposes "information obtained through systematic measurements that tracks one or more performance characteristics of a device." Artesyn advocates a dictionary definition of "monitoring" to arrive at its proposal of "systematic measurements." However, it is unclear what "systematic measurements" means and, therefore, the phrase would not appear to provide any additional clarity to the term at issue. Moreover, the patent specification does not support "systematic measurements" as being a requirement of "performance monitoring information." The Court finds that Power-One's proposal would assist the jury and, thus, construes this term as "information concerning one or more performance characteristics of the device."
VI. "performance of the buyer" 13

13 The term "performance of the buyer" is in claims 1 and 18.

Plaintiff's Proposed Construction

<table>
<thead>
<tr>
<th>the buyer's actions or deeds in the Price-Determining Activity</th>
</tr>
</thead>
</table>

Defendants' Proposed Construction

| the buyer's level of success (at the Price-Determining-Activity) |

Plaintiff argues that the buyer's performance at the PDA is separate and distinct from the buyer's "level of success," as proposed by Defendants. OPENING at 27. Defendants argue that the buyer's performance at the PDA is an assessment of how well the buyer performed. RESPONSE at 12.

Claim 1 of the '253 patent discloses that the price for a product or service is determined based on the performance of the buyer while participating in a PDA. '253 patent at 9:30-46 (claim 1); see also id. at 10:34-47 (claim 18), 11:13-23, 12:1-7 (claim 30). The specification adds that in the auction or reverse auction model, "the buyer may be entitled to a further discount of the auction or reverse auction price, which discount may be greater if the buyer performs well at the PDA, and not so great if the buyer performs poorly." '253 patent at 4:39-43. A preferred embodiment discloses a PDA that is a trivia quiz of ten questions. Id. at 5:49-67, 6:1-18. If the buyer gets nine questions correct on the quiz, this performance locks in the price according to the predetermined algorithm as presented to him at the start of the game. Id. Thus, in this embodiment, the "performance of the buyer" which determines the price is the buyer's performance of answering nine questions correctly.

As previously noted, the specification consistently indicates that if a buyer performs poorly at the activity, the price will be higher, whereas if the buyer does well, the price will be lower. See '253 patent at 2:26-28, 2:52-56, 3:64-67, 4:1; see also 5:39-67; 7:40-52; 8:14-23, 8:46-58. The prosecution history includes similar statements. See RESPONSE, SISTOS DEC., EXH. 2 at 118 ("[t]ypically, the better the buyer performs during the PDA, the lower the price will be of the product being purchased"); see also id. at 149. The intrinsic record indicates that a buyer's score or performance level is directly connected to the price of the product and a better performance results in a lower price. Thus, the intrinsic record unambiguously indicates that it is not the buyer's actions or deeds that determine the price, but the buyer's achievements, accomplishments, or level of success that determine the price to be paid. Therefore, the Court finds that the proper construction for "performance of the buyer" is "the buyer's level of success at the Price Determining Activity ("PDA")."

D. The '376 Patent

The first step in resolving the parties' dispute regarding the '376 patent is to construe the term "performance report." Before doing so, it is helpful to discuss briefly the function of the system and methods claimed in the '376 patent. The '376 patent discloses a "System, Method, and Computer Program Product for Near-Real Time Load Balancing Across Multiple Rendering Pipelines." The patent describes a "system, method, and computer program" that produces computer graphics through the use of "multiple graphics rendering pipelines." Each "graphics rendering pipeline" is assigned some portion of the desired image, which it produces. When each "graphics rendering pipeline" completes its assigned portion of the image, it produces a "performance report." These "performance reports" are compared to determine whether there is a disparity in the workloads of the "graphics rendering pipelines." If the disparity in the workloads exceeds a "threshold," work is reallocated among the "graphics rendering pipelines."
Defendants argue that the "performance report" must contain "the amount of time that the rendering pipe required to render a [portion of the assigned image]," or, in other words, "numerical time values." Plaintiff asserts that a performance report need not be numeric in nature or measure time required for rendering. To evaluate the parties' arguments, I turn first to the claims of the patent. Phillips, 415 F.3d at 1314. By their own terms, claims 1, 7 and 8 require the performance report to be compared to a threshold, and if the threshold is surpassed, work to be reallocated accordingly. Claims 7 and 8 direct reallocation of work when the difference between the performance reports is above a threshold. A simple report regarding which pipeline completed its work first would not provide information that could be compared to a threshold. Moreover, it would be odd to compare a report of non-numeric values of any sort to a "threshold" and seemingly impossible to calculate the "difference" between two non-numeric reports.

Next, the patent specification states that "the performance report states the amount of time that was required to render a [portion of the assigned image]." This provides additional support for the proposition that the "performance reports" reflect not only numeric values, but specifically, numeric time values. Abbott Laboratories v. Andrx Pharmaceuticals, Inc., 452 F.3d 1331, 1336 (Fed. Cir. 2006) ("Where claim terms are ambiguous or disputed, then we turn to the specification as the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term."). Further, during the prosecution of the '376 patent, the examiner rejected all original claims, and plaintiff amended claims 1, 7 and 8 to include the word "threshold." This is additional evidence that the requirement for comparison to some fixed value is an important aspect of the claims.

Thus, I am inclined to agree with defendants that the claims require the performance report generated by the graphics rendering pipelines to include information about the length of time required for processing. However, even if I adopted plaintiff's construction of the term "performance report," defendants would still be entitled to summary judgment with respect to plaintiff's claims of infringement of the '376 patent because plaintiff has adduced no evidence that any of the accused products produce "performance reports" of any variety.

The term "performing procedures" is found in claim 1 of the 366 Patent, which claims the following:

   Apparatus for use with a data network and a mass storage device, comprising of the combination of first and second processing units, said first unit being coupled to said network and performing procedures for satisfying . . . a pre-defined non-NFS class of requests,

   . . .

   and said second processing unit being coupled to said network and to said mass storage device and decoding NFS requests from said network, performing procedures for satisfying said NFS requests, and encoding NFS reply message for transmission on said network . . .

366 Patent, 51:35-47. In addition, claim 5 of the 366 Patent and claims 1 and 4 of the 918 Patent recite "a means for performing procedures for satisfying . . . NFS requests," id. at 52:48-48, or "for satisfying file system requests," 918 Patent, 127:27-28. Plaintiff contends that the phrase "performing procedures" is unambiguous and therefore need not be construed by the court. See, e.g., Liquid Dynamics Corp. v. Vaughan Co., 355 F.3d 1361, 1368-69 (Fed. Cir. 2004). While also claiming that the disputed term has a well-established ordinary meaning, defendant argues that this meaning is "executing software instructions."

The crux of the parties' dispute is whether the procedures at issue include procedures performed by hardware, or whether the claim term is limited to procedures performed in response to software instructions. Defendant urges the court to rely on the definition of "procedures" found in the Academic Press Dictionary of Science and Technology (1992) (hereinafter "AP Dictionary"), which defines "procedure" in the field of computer technology as "a sequence of program components that collectively accomplish some task . . . generally used in reference to higher-level languages." Id. at 1729. Admittedly, the

- 3411 -
cited definition limits the scope of the term "procedure" to "a sequence of program components" -- i.e., software. However, other dictionary definitions -- including technical references apposite to the art of file server architecture -- define "procedure" far more broadly. For example, The Authoritative Dictionary of IEEE Standards Terms (2000) (hereinafter "IEEE Dictionary"), defines "procedure" as, inter alia, "[t]he course of action taken for solution of a problem" (computers), or alternatively, as "a course of action to be taken to perform a given task" (software). Id. at 870. Thus, contrary to defendant's assertion, there is no single, well-established meaning for the term "performing procedures."

Where a disputed claim term has more than one possible meaning, "[t]he objective and contemporaneous record provided by the intrinsic evidence is the most reliable guide to help the court determine which of the possible meanings was intended by the inventor." Texas Digital, 308 F.3d at 1203 (citing Renishaw PLC v. Marposs Societa per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998)). "The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Id. at 1203-04. In the instant case, taking claim 1 of the 366 Patent as an example, the procedures at issue are performed by the first and second processing unit and are undertaken for the purpose of satisfying NFS or non-NFS requests from a data network. 366 Patent, 51:35-48. The 918 Patent replaces "NFS requests" with the somewhat broader term "file system requests," 918 Patent, 127:7-8, but in substance the procedures performed by the two inventions are closely related.

The claim language of the patents in suit makes clear that the term "performing procedures" is intended to be given an extraordinarily broad meaning. Taking claim 1 of 366 Patent as an example, the term "performing procedures" is used to describe any operation performed by the claimed processing units except for decoding NFS requests and encoding NFS reply messages. See 366 Patent, 51:35-48. While these procedures may include executing software instructions, the specification discloses that the processing units perform a broader range of tasks. For example, in order to perform the procedures necessary to satisfy an NFS request, the network controller may need to request a system memory location from the file server. The specification discloses that this request is carried out by the network controller, which accesses the file server via VME bus. See, e.g., id. at 19:25-27, 19:50-58. This procedure is best described as "accessing another processor" rather than "executing software instructions." Likewise, claim 5 of 366 Patent, which recites a "means for performing procedures for satisfying . . . NFS requests," identifies one such procedure as "accessing [a] mass storage device" -- a process involving both software and hardware. Id. at 52:48-49. The court therefore rejects defendant's attempt to limit the scope of the term "performing procedures" to "executing software instructions."

While a narrowing construction of a claim limitation may sometimes preserve the validity of a claim, "[n]othing in precedent permits judicial redrafting of claims." Becton Dickinson & Co. v. C.R. Bard, Inc., 922 F.2d 792, 799 n.6 (Fed. Cir. 1990). Given the broad scope of the meaning of the performing procedures term in the context of the claims at issue, the court sees no principled basis for narrowing the meaning of the term based on a single, identifiable technical definition. Accordingly, the court finds the term unambiguous and declines to construe the term.
Moreover, figure 1 describes the “peripheral management station” as a “JukeBox Management PC,” and it depicts the station as a desktop personal computer. A construction of “peripheral management station” as a computer would not, as plaintiffs argue, import limitations from the specification into the claim. The claim language itself indicates that, at the very least, the “peripheral management station” includes a computer. And because “peripheral management station” apparently does not have any particular meaning to a person with ordinary skill in the field, the Court must construe the term in light of the specification. The specification reflects that the “central management station” includes a computer. The parties also dispute whether the “central management station” is “used to” service the jukeboxes, or whether it “allows” the servicing of the jukeboxes. It is difficult to see the difference between these proposed constructions, and the parties’ references to language in the specification do not provide much clarity. On the whole, however, the specification indicates that the purpose of the invention is to provide a means for multiple computer jukeboxes to be serviced from decentralized locations. Id., Ex. 7 at 1:55-58. This can be accomplished only if the central management station does the servicing. The Court therefore adopts defendants’ proposed construction.

4. Period of Time

The construction of the phrase "period of time" is in dispute. It appears in the following contexts: "directing a recirculating spray of concentrated detergent solution having a concentration level in the range of 0.5 to 12 % detergent by weight onto said fabric for a first period of time"; "after said first period of time, diluting said concentrated detergent solution to a lesser detergent concentration level, no less than 0.28 % by weight, and spinning said wash chamber to effect less than a one gravity centrifugal force on said fabric that said fabric will again tumble"; "after said first period of time"; "directing a recirculating spray of said lesser concentrated detergent onto said fabric for a second period of time"; "for a third period of time." ('370 patent, claims 1, 8, 15, 17; '718 patent, claim 1.)

Whirlpool seeks the following construction: "The first period of time may vary and is not limited to any predetermined or specified length of time. The end of the first time period is marked by a termination of the recirculating spray and the tumbling of the fabric." "The second period of time may vary and is not limited to any predetermined or specified length of time." "The third period of time comes after the first and second periods of time. Nothing in this term requires the third time period to be of a particular or specified length of time." Whirlpool would construe the term to encompass both fixed or predetermined lengths of time, as well as varying or unspecified lengths of time.

LG argues for the following construction: "for a first predetermined period of time (i.e., predetermined concentrated wash period)"; "after the first predetermined period of time (i.e., predetermined concentrated wash period)"; "for a second predetermined period of time (i.e., predetermined diluted wash period)"; and "for a third predetermined period of time."

The dispute centers on whether "period of time" means only a predetermined length of time, as LG argues, or can
encompass both predetermined and variable lengths of time, as Whirlpool argues. Dictionary definitions of the word "period" support Whirlpool's position that the term is open ended. See NEW SHORTER OXFORD ENGLISH DICTIONARY ("period" is "a course or extent of time"); AMERICAN HERITAGE DICTIONARY ("period" is "an interval of time characterized by the occurrence of a certain condition or event"). These definitions contain no requirement for a predetermined or fixed length of time. Furthermore, the Court discerns nothing in the phrases "first period of time," "second period of time," and "third period of time" that requires the periods to be of particular or specified lengths. The words "first," "second," and "third" appear to serve no function beyond distinguishing one step from the other. See 3M Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1371 (Fed. Cir. 2003) ("In the context of claim 1, the use of the terms 'first…pattern' and 'second…pattern' is equivalent to a reference to 'pattern A' and 'pattern B,' and should not in and of itself impose a serial or temporal limitation onto claim 1.").

The '370 patent specification, LG argues, requires construing "period" to mean a predetermined time. In LG's view, the specification unambiguously discloses an automatic control system that chronologically cycles through preset or preselected steps whereby the recirculating spray of concentrated detergent solution is directed onto the fabric. The specification describes "a machine having a presettable sequential control means for operating a washer through a preselected program of automatic washing, rinsing, and extracting operations" (370 patent, col. 2, lines 58-61) (emphasis added); the patent explains that the washing steps occur as "a predetermined period" or "designated time" (370 patent, col. 6, lines 52-57, 67-68; col. 8, lines 26-30). Also, the specification speaks of "some predetermined period of time specified by the cycle type." (370 patent, col. 6, lines 52-53.) In the diluted wash step, "the type and length of tumbling action varies with the cycle desired"; for example, "maximum time may be selected for maximum soil removal, while lesser times offer less fluid flow and fabric flexing for delicates, silks, wools, sweaters, and other fine washables." (370 patent, col. 8, lines 27-30.) Thus, LG maintains, the specification indicates that the first, second, and third periods of time are predetermined periods dictated by the user's needs. LG also argues that during the patent prosecution, the examiner's discussion of the Johnston patent revealed the examiner's understanding of "period of time" to mean a predetermined period of time. (Australian Patent 209,436 at 6, LG Br. Ex. 106 (discussing a "first period of time" and a "second period of time" and explaining that "the agitation and scrubbing of the fabrics in the low level, highly concentrated solution is carried out for about five minutes or until the segment 59 engages the contact finger 72."))

The Court agrees with LG that the specification indicates that the time periods' lengths depend upon the user's choices. For example, if the user selects maximum soil removal, then the period will be one preset length; if the user selects delicates, then the period will be preset for a shorter length. It is true, as Whirlpool notes, that the period of time varies with the cycle type, but once the cycle type is selected, the time is fixed. The preferred embodiment, however, is only one example of the claimed invention. As the Court has stressed elsewhere in this Opinion, the claims are not to be limited to the preferred embodiment in the absence of "words or expressions of manifest exclusion or restriction" representing a clear intent to disavow the claim's scope, none of which appear in the intrinsic evidence of this patent. Liebel-Flarsheim Co. v. Medrad. Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). Just because Whirlpool's preferred embodiment appears to feature preset time periods does not mean that the claims are necessarily so limited. In addition, the word "predetermined" appears in the claims themselves only in claims 1 and 6 of the '718 patent, which both describe "repeating steps (d) and (e) a predetermined number of times." This language pertains to the number of times the recirculation process is repeated, not the length of any "period," and thus has no bearing on the construction of the term "period."

Accordingly, the Court adopts Whirlpool's construction of the phrase "period of time" to include both fixed, predetermined lengths and open, unspecified lengths.

2. "Periodic" and "periodically." Discontinuously. (144 patent, col. 2, ll. 22-23)
The first disputed term is "periodic." This term is used within '401, '856, '825 and '764. Counsel agree that this term has the same meaning in each of these patents. See Dec. 1, 2004 Tr. at 39. Claim 1 of '401 states:

...said record carrier comprising:

...a substrate provided with substantially parallel elongated tracks each having a periodic undulation in a direction transverse thereto at said predetermined frequency, so that during scanning of any portion of a track by said scanned beam to record and/or reproduce information thereon a beam of radiation is produced therefrom which is periodically modulated at said predetermined frequency...

The parties dispute whether "periodic," as used within the patents, means "identical." Philips argues that a periodic event is one that occurs at regular, but not necessarily identical, intervals. See Dec. 1, 2004 Tr. at 20 ("Everyone agrees that the '401 patent clock signal is a periodic signal. What the defendants argue is that once that clock signal...is changed by being frequency modulated...they say it is not periodic."); at 21 ("This ['825] makes clear that what is being called a periodic signal is also a frequency modulated signal....And it ends with a piece of the specification that specifically says that the deviation of the frequency from the clock-signal frequency is plus or minus one kilohertz. So that's what the specification says is a periodic frequency."). Defendants argue that "periodic" means "identically occurring. See id. at 37 ("Periodic means 'repeating itself identically at regular intervals.'"); at 38 ("The only modulations that are disclosed in the '825 patent are, again, identical modulations. ...Nowhere in any of the Philips patents is there any disclosure of a modulation that is anything but periodic or identical.").

The Defendants argue that periodic must mean identical, because '401 is designed to generate a clock signal. In order to function correctly in correcting tracking errors, a clock signal must be an identically repeating event. See id. at 41 ("A clock signal can't be generated by random periods because you would have a clock that - you would have a start and stop, or you would have a. ...let's put it this way. You would have a velocity for this disc that would change constantly because the clock would be going back and forth; it wouldn't be constant.").

Philips asserts that the patentee is permitted to define "periodic" in the manner in which it chooses, and extrinsic dictionary definitions are not controlling upon intrinsic evidence. See id. at 21 ("The Federal Circuit. ...is very clear that the patentee's entitled to be his own lexicographer. He can explicitly or implicitly tell the reader what he means by a term that's used in the claim, and when he does that, you can't go to a dictionary."). Notwithstanding, the dictionary is a good place to begin.

Periodic

1. Of, pertaining, or proper to the revolution of a heavenly body in its orbit, as periodic motion, time.

2. Characterized by periods; recurring at regular intervals; spec. in Path. having regularly recurring symptoms, as periodic fever. Often loosely, Recurring or reappearing at intervals; intermittent.

3. Of or pertaining to a rhetorical or grammatical period; characterized by or expressed in periods.

4. = PERIODICAL a, 5. rare.

5. Relating to a period or space of time. rare.

6. as n. pl. = PERIODICAL n. 3.

See also Websters' Third New International Dictionary, unabridged

1a. characterized by periods: occurring at regular intervals &t; phases of the moon&t; &t;&t; municipal elections&t;;

b. occurring repeatedly from time to time: RECURRENT, INTERMITTENT &t; epidemics&t; &t; drinking sprees&t;: FREQUENT &t;&t; one of Bermuda's power failures - &t;ITALICS&t; Time &t;:
2. consisting of a series of stages or processes that is regularly repeated: CYCLIC &t; vibration;&t;

3. of or relating to a period &t;&t;house was pleasant and comfortable, they were too sophisticated to be - &t;ITALICS&t;&t;Scribner's;&t;;

4a. of or relating to a form of construction found in some Greek odes in which the second and third in a group of four strophes are alike in structure and the first and fourth differ from these and from each other;

b. expressed in or characterized by periodic sentences &t; style;&t;.

Regardless of any dictionary definitions of periodic which seem to suggest, or even require identical elapsed time between events, or occurrences, in order for something to be described as "periodic" (and as noted above, they do not), the common speech of the people supports Plaintiff's position. The language belongs to the people and not to the lexicographers. For example, the rise and fall of the tides in an harbor are called periodic, yet the times elapsed between them are not identical. Neurotics are described as having "periodic mood swings", clearly not identical. Wars, famines, volcanic eruptions, hurricanes, tsunamis and other naturally recurring phenomena are recognized in the English language as periodic. Fortunately, they do not recur after identical time lapse; similarly we speak of the weather: "a period of sunshine followed by rain": a time in history: "the interwar period" an evolutionary or developmental unit: "Picasso's blue period": a time regularly set aside for a purpose: "rest period", "lunch period." All such periods are properly described by the adjective "periodic." The words "intermittent" and "recurrent" are both recognized synonyms for "periodic." 3

3 See Roget's II, the New Thesaurus, New York 1988, listing "intermittent" and "recurrent" as synonyms for "periodic."

The various patents' specifications demonstrate that the "periodic undulations" that are referenced are regularly occurring intermittent events, but these events are not identically occurring. '825 17: 65-68:

Moreover, it is to be noted that on account of the d.c. component of the position-information signal the average frequency of the FM-modulated signal is exactly equal to 22.05 kHz. . .

The FM-modulated signal has an "average" frequency of 22.05 kHz. Claim 1 of '856 is clear as to why the signal is measured by its average, instead of its identically repeating value. See '856 6: 68- 7: 5:

characterized in that each of said tracks has a periodic modulation of its position in a direction transverse thereto and which, without occupying any portion of the track, generates a periodic clock signal in the radiation therefrom having a substantially constant frequency corresponding to the velocity of scanning of said track, the frequency of said clock signal only varying in accordance with variations in said scanning signal. . . .

The "periodic" clock signal varies based upon variations in the scanning signal. Because of these variations, the clock signal is frequency modulated, with an average frequency of 22.05 kHz. This average is based upon fluctuations between a high frequency of 23.05 kHz and a low frequency of 21.05 kHz. The reference to an average indicates that the undulations are not identical. If it were otherwise, the frequency would not be an average, but rather a simple measurement of identically repeating frequencies. Defendants' argument that the clock signal must be identical to function appropriately is belied by the language of the patents themselves. The clock signal itself has a "substantially constant frequency" which varies in accordance with "variations in [the] scanning signal." A signal with a "substantially constant frequency" which varies is not the same as an identically repetitive signal. Defendants' argument does not find support in the patent, which teaches a periodic clock signal that is not identical, but varies. Because the language of the patents' claims and specifications teach a modulated clock signal, the Court should not contradict the language usage chosen by the patentee, especially where, as here, periodic has the accepted secondary dictionary definition of "intermittent." Accordingly, the Court interprets "periodic" to mean "regularly but not necessarily identically repeating."
3. "periodic"

The parties dispute the meaning of the term "periodic" in the phrase "selectively connecting the subscriber location to a remote location over non-dedicated phone lines on a periodic basis unrelated to the receiving of the scrambled program signal" of claim 9, which relates to the transmission of billing data from the subscriber location to the remote location. Echostar argues that "periodic" means at a regular interval, whereas IPPV contends that "periodic" means at a regular interval or intermittently.

In support of its proposed construction, Echostar directs the court to a portion of the specification which refers to "the placement of a call on a monthly basis" as an example of when the subscriber location would contact the remote location. Based on this example, it contends that "periodic" means at a regular interval.

IPPV, on the other hand, argues that "periodic" is defined in other portions of the specification to include contact on an intermittent basis. In describing when money is to be collected in certain prior art devices, the specification states that "the billing entity (the system operator) must collect the money from the coin boxes on a periodic basis." IPPV contends that the specification is suggesting that the physical collection of the money may be accomplished on an intermittent basis.

The specification also states that "it will be appreciated that the invention provides a relatively simple manner of subscriber billing that allows for the identification of programs actually viewed and the rapid gathering of this information on a periodic basis long after a program has been viewed." IPPV argues that nothing in this passage suggests that "periodic" should be limited to regular predetermined time intervals only.

After reviewing the parties' arguments and the specification, the court concludes that "periodic" is not limited to regular intervals. The "monthly basis" example referenced by Echostar precedes the following statement: "Similarly, when the signal storage device is full and can store no more program codes, the access unit [located at the subscriber location] may place a call to the data gathering unit [located at the remote location] to transfer billing information thereto." When read in conjunction with the "monthly basis" example, this passage indicates that even if the subscriber location normally contacts the remote location to transmit billing information on a set interval, the subscriber location may also contact the remote location when it is full of billing information. If the subscriber location contacts the remote location on a set interval and intermittently, "periodic," which describes the contacts, cannot be limited to set intervals. Thus, the court concludes that "periodic" may include intermittent contacts.

1. Periodic

Claim 1 lists nine actions that the program performs, e.g., receiving messages from employees, reallocating resources, and issuing reminders and status reports, and indicates that the program "repeat[s] steps (a) through (h) on a periodic basis, as desired by said organization work-group team members." Def. Ex. A at col.9, lines 12-14 (emphasis added). Based on this language, defendant argues that Claim 1 is limited to a program that issues reports and performs the other described functions at fixed, regular intervals, as opposed to intermittently, or on request.

The patent language supports this limitation. For example, a specification for the Reporting function of the program distinguishes between reports which are generated "periodically" and special reports generated "on request." See Def. Ex. A at fig.10 ("Reports Flowchart"). Similarly, the patent's specifications provide that the Reminder function was intended "to track pending tasks and remind task owners on a pre-determined frequency on when to start/finish their tasks." Def. Ex. A at fig.6. Other specification language explains that the Program "is a software process that runs at fixed intervals (example: at the end of the day)," and "responds to the messages and is thus 'event driven,' though the response does not occur immediately but rather batched together for the end of day processing." Def. Ex. B at 11, 15. Finally, the Academic Press Dictionary of Science and Technology defines "periodic" as "occurring at regular intervals."
Accordingly, we construe the Patent to reach only project management programs which perform their functions at fixed intervals, rather than intermittently or on request. However, the Patent could still encompass programs which allow for both fixed-interval and on-demand reports, because Claim 1 states that the Program performs its functions "on a periodic basis, as desired by said organization work-group team members." Thus, the Patent teaches that team members can reset the periods when the Program issues status reports and other reminders. Although the claim should be limited to a program performing the above functions at fixed intervals, individual team members may modify these fixed intervals for their own purposes in any construction of Claim 1.

12. "Periodically."

The court shall apply the ordinary definition of the word "periodically." Thus, the term "periodically" shall be construed to mean "taking place now and then; intermittent." 2

This case is before the court for ruling on the Motion for Clarification on Proposed Jury Instruction 2.2.3 (# 160) filed by Horizon Hobby, Inc. (Horizon). This court has carefully reviewed the arguments of the parties set out in Horizon's Second Motion for Summary Judgment of Noninfringement (# 101), the Response filed by Ripmax Inc., under seal (# 122) and Horizon's Reply (# 130). Following this careful and thorough consideration, this court concludes that the phrase "periodically repeated time frame," included in claim 1 of the '128 patent is properly construed as meaning "control data is transmitted continuously in repeated frames without interruption."

This court concludes that this is the proper construction based upon the language included in the claim, the specification, and the prosecution history of the '128 patent. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (the claims, specification, and prosecution history of a patent make up the "intrinsic evidence" to which a court should look first when construing claims); see also Phillips v. AWH Corp., 415 F.3d 1303, 1317 (Fed. Cir. 2005) (the prosecution history provides evidence of how the PTO and the inventor understood the patent). This court specifically notes that, as part of the prosecution history of the '128 patent, Ripmax argued before the U.S. Patent Examiner that, in the model-application claimed, "the transmitter is switched on and continuously transmits control data in repeated frames" and that "signals on the same channel, being continuous, must be avoided." This court further notes that this court's construction is entirely consistent with the opinion of Ripmax's expert, Dr. Kourosh Parsa, who stated that "the receiver identifying code and control data is sent at regular intervals on a continuous basis without interruption." This construction is also consistent with Ripmax's argument, included in its Memorandum in Opposition to Horizon's First Motion for Summary Judgment (# 68), wherein Ripmax argued that the "claim term 'periodically repeated time frame' as used in the patent means that the receiver identifying code and control data is sent at regular intervals on a continuous basis without interruption" and also argued that the "control data must be continuously sent to and received by the on-board receiver so that the airplane's control devices can be continuously updated."

This court's construction will be included in Jury Instruction 2.2.3.

IT IS THEREFORE ORDERED THAT:

(1) Horizon's Motion for Clarification on Proposed Jury Instruction 2.2.3 (# 160) is GRANTED.
(2) This court construes the phrase "periodically repeated time frame," included in claim 1 of the '128 patent, to mean "control data is transmitted continuously in repeated frames without interruption."

(3) This court's construction will be included in Jury Instruction 2.2.3.

3112

F. "Periodic Fee."

The term "periodic fee" was used only in claim 34 of the '381 patent. It recited in pertinent part (col. 15:34-38):

34. A computer-implemented method for renting movies to customers, the method comprising:

  establishing over the Internet a rental agreement with a customer that provides for charging the customer a periodic fee.

  providing electronic digital information that causes one or more attributes of movies to be displayed;

  establishing, in electronic digital form, from electronic digital information received over the Internet, a movie rental
  queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer;

  causing to be delivered to the customer up to a specified number of movies based upon the order of the list;

  in response to one or more delivery criteria being satisfied, if the customer is current on the periodic fee, selecting another
  movie based upon the order of the list and causing the selected movie to be delivered to the customer;

The parties disagree over whether the fee must be associated with the items rented. Blockbuster proposes that "periodic fee" should mean "an amount incurred, paid, or charged at regular intervals for a service -- for example, and without limitation, an hourly, daily, monthly, or annual fee." Netflix contends that the term should mean "fee to be paid per subscription period for the right to rent." Blockbuster contends that the fee could be for any period of time, while Netflix contends that the fee must be associated with the subscription period.

As with all other terms construed in this order, both of these terms are commonly-understood English words. Any juror would understand a "fee" to be an amount charged. "Periodic" means "occurring or recurring at regular intervals." Merriam-Webster, Ninth New Collegiate Dictionary, 1984.

Netflix argues that the term should be narrowed to indicate that the periodic fee is a subscription fee and that it is paid for the right to rent. The latter requirement is more or less already found in claim 34 as recited above. The paragraph of the claim in which the term "periodic fee" appeared recited "establishing over the Internet a rental agreement." It is clear from the claim language that the fee is paid for the right to rent items.

As to the subscription requirement, plaintiff cites several places in the specification of the '381 patent that refer to a "subscription period," but none of these passages defined the term "periodic fee," or specifically required that the fee cannot be separated from the concept of a subscription (col. 6:1-2, 9-10, 32-34, 36-37). The subscription model is an attribute of a preferred embodiment that the plaintiff attempts to read into the claims as an additional limitation.

In any event, plaintiff's proposed definition would add little to the claim. The claim at issue indicated that the periodic fee was not charged per item as in traditional a la carte rental programs. Specifically, claim 34 recited that the customer will only be sent an additional item if they are current on their periodic fee. That claim separated the concept of the fee, which is based on time, from sending another item. This order will not go so far as to adopt Netflix's overly-narrow definition, but it will make clear that the "periodic fee" at issue is not charged per item rented but for a specific time period.

Accordingly, this order holds that the term "periodic fee" will have its ordinary meaning, a fee charged or collected at regular intervals, based on time, and not calculated per item rented.
E. Periodic Interrupts ('950 patent, Claims 8, 11)

PCTEL contends that the term means "a signal that recurs or repeats, at time intervals that are not necessarily precise or the same that attempts to get the host processors attention." Agere asserts the proper construction of the term is "an identical signal repeated at regular intervals to the host processor to suspend other tasks on the host processor while the processor addresses the device, which signal is not asserted in conjunction with Direct Memory Access transfers."

This term does not require the Court to engage in any new analysis. For the reasons previously set forth, the Court disagrees with Agere that "periodic" should be construed as "regular intervals." The Court also rejects Agere's use of the phrase "which signal is not asserted in conjunction with Direct Memory Access transfers" for the reasons stated in Sec. II(C). However, the Court agrees with Agere regarding the ordinary meaning of the term "interrupt." Accordingly, the Court construes "periodic interrupts" as a signal that recurs or repeats, at time intervals that are not necessarily precise or the same, that suspends other tasks on the host processor while the processor addresses the device.

GO BACK

(3) Periodic Save Code

Square D contends that "periodic save code" should be construed to mean "code that is operative to periodically transfer at least a portion of the working data from volatile memory to non-volatile memory." EI argues that it means "repeatedly executed firmware for copying data into data flash memory, ensuring erased flash memory blocks, and asserting a flag to prevent a second data save operation."

According to EI, both sides agree that "periodic save code" is explicitly defined in the specification. It did not appear to the Court that Square D accepted this proposition; indeed, counsel for Square D seemed to say exactly the opposite at the Markman hearing ("[t]here is no such explicit definition anywhere in the patent as they're representing." Transcript of Proceedings of December 3, 2009, p. 47).

The specification states that "[t]he periodic save task is responsible for saving the device data to the flash memory and ensuring that there is always sufficient amount of erased flash memory blocks ready to accept data during power down event." U.S Patent No. 6,745,138 B2, col. 24, lines 54-57. And that "[d]uring normal operation (i.e., with stable power) . . . the periodic save task is responsible for copying of the relevant data to the data flash memory 1960 and erasing the flash memory blocks." Id., col. 25, lines 24-28. Although EI cites some additional language to suggest that the periodic save code must also assert flags, that language can reasonably be read to be required only under certain circumstances (i.e., when the periodic save task is saving a data unit other than the power down data unit). See id., col. 25, lines 32-40. And this language relates to the preferred embodiment being discussed in this section, not necessarily to every embodiment of the invention. Accordingly, the Court will not read this limitation into the claim.

At bottom, the language of the claim defines the task of the periodic save code: the code operates "to periodically transfer at least a portion of said working data code from said volatile memory to said non-volatile memory." Thus, the Court adopts Square D's proposed construction.

GO BACK

C. Periodically Asserts a First Signal While Operating in the First Mode ('950 patent, Claims 1, 13; '780 patent, Claims 1, 7)

PCTEL contends that the disputed term is defined as "the assertion of a first signal that recurs or repeats, at time intervals that are not necessarily precise or the same, which must occur, at least, some time during the first mode." Agere contends
that the term is limited to "produces and repeats an identical non-DMA related signal at regular intervals while operating in a first mode (the normal mode of operation).

PCTEL states that its proposed construction is consistent with intrinsic evidence, which discloses embodiments wherein the interrupt signal does not recur at regular intervals. See '950 patent, col. 4:12-15; '780 patent col. 4:4-7. PCTEL also relies upon U.S. Patent No. 5,721,830 ("the '830 patent"), which is incorporated by reference into the '950 and '780 patents, to argue that not all interrupts occur at regular intervals. PCTEL also asserts that the prosecution history does not clearly indicate that the patentee disclaimed DMA related signals from being interrupts.

Agere contends that its construction of "periodically" as occurring a regular intervals is consistent with the ordinary meaning of that term. (Mills-Robertson Decl., Ex. 16, McGraw-Hill's Dictionary of Scientific and Technical Terms (1994) (defining "periodic" as "[r]epeating itself identically at regular intervals"). Agere also asserts that its proposed construction is consistent with the specification, and the single disclosed embodiment that generates "periodic" interrupts every 3.3 milliseconds. See '950 patent, col. 4:4-12; '780 patent 3:63-4:4. Agere also notes that its construction excludes "DMA-related signals" to account for the alleged disclaimer that PCTEL made to the PTO.

As an initial matter, the Court must determine the ordinary and customary meaning of "periodically." Following the Federal Circuit's teaching in Phillips, the Court begins by reviewing the specification. n8 Phillips, 415 F.3d 1303, 2005 WL 1620331, at 13. In support of PCTEL's argument that the inventor intended to give special meaning to "periodically," it cites the following specification language: "More generally, the number of samples read or written per interrupt is about equal to the product of the period of the interrupts and a sampling frequency used by converters 34." '950 patent, col. 4:12-15; '780 patent, col. 4:4-7 (emphasis added). Based on this language, PCTEL asserts that since the sampling frequency used by the converters 134 is fixed, a change in time between interrupts results in a change in the number of samples read or written to the buffer so that the near equality (i.e., about equal) is maintained. n9

n8 The Court agrees with Agere that, based on the only technical dictionary definition provided by the parties, the ordinary meaning of "periodically" is "repeating itself identically at regular intervals." To the extent that PCTEL relies upon general-usage dictionaries to support its argument that periodically means "from time to time," such reliance is misplaced. See Vanderlande Indus. Nederland BV v. ITC, 366 F.3d 1311, 1321 (Fed. Cir. 2004) (stating that general-usage dictionary definitions are irrelevant where an artisan would attach a special meaning to the term).

n9 To the extent that Agere seeks to limit the patents' claims to preferred embodiment that generates interrupts every 3.3 milliseconds, the Court rejects this argument. See Eckchian v. Home Depot, Inc., 104 F.3d 1299, 1303 (Fed. Cir. 1997) (holding that courts should not "limit[] the claimed invention to preferred embodiments or specific examples in the specification.").

During the ITC investigation, an ALJ considered whether the term "periodic" and "periodically" in the claims of the '950 and '780 patents required that interrupts occur at regular intervals and concluded that:

Therefore, the foregoing "about equal" relationship means that the relationship between the number of samples read or written per interrupt varies inexacty with the periodicity of the interrupts. In other words, the longer or shorter the interval between interrupts, the more or fewer samples will be read or written, but not by an exact ratio. One likely reason for this inexactitude is because the interval between interrupts itself varies, even though those interrupts are considered in the art and the patent itself to be "periodic."

(O'Grady Decl., Ex. 7 at P0007715-P0007716). While the ITC decision is not binding, see Texas Instr. Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558, 1569 (Fed. Cir. 1996), the Court concludes that the ALJ's conclusion was well reasoned and persuasive. It appears that the only requirement for the time between interrupts is to keep the computer's power management system from switching the device from the first ("normal") to the second ("wait") mode. In this respect, it does not appear that the specification requires the time between such interrupts to be exact. n10
n10 The ITC concluded, and the Court agrees, that the specification of the '830 patent also supports this conclusion.

Regarding the issue of "DMA-related signals," the prosecution history reveals that, in an attempt to overcome the examiner's original rejection, PCTEL distinguished the Gross patent as follows:

Gross does not suggest providing an interrupt signal to a host computer. Typically, conventional modems such as Gross discloses, transfer data to a host computer using DMA transfers to avoid disturbing the host processor. Accordingly, Gross fails to suggest a device that 'periodically asserts a first signal while operating in the first mode. . . .

(Mills-Robertson Decl., Ex. 7 at AL 14994-95).

Based on this disclaimer, Agere contends that PCTEL expressly distinguished DMA transferring modems from its invention. PCTEL disagrees, and asserts that it is the transfer of data, not the use of "DMA transfers," that avoids having to disturb the host computer. PCTEL notes that since what is being transferred from the hardware modem (as in Gross) to the host computer is data, the host computer need not run any software to convert the material it receives from the modem into data. To the contrary, when digital samples are transferred from the HSP modem to the host computer (as in the '950 patent), the host computer must be interrupted and its processor must run HSP software that converts digital samples into data.

The Court finds that PCTEL's interpretation of the prosecution history is reasonable. Without further disclaimer language, the Court cannot conclusively determine that the patentee distinguished Gross based on the use of "DMA transfers" as opposed to the "transfer of data." See Omega Eng'g, Inc. v. Raytek, Corp., 334 F.3d 1314, 1326 (Fed. Cir. 2003) (stating that for prosecution disclaimer to attach, the alleged disavowing actions or statements made during prosecution be both clear and unmistakable). Given that the patentee's disclaimer of "DMA transfers" was not "clear and unmistakable," prosecution disclaimer does not attach.

Given these considerations, the Court construes "periodically asserts a first signal while operating in the first mode" as the assertion of a first signal that recurs or repeats at regular intervals while operating in the first mode.
1. Reconsideration of construction of Claim 14

Claim 14 was addressed in the Court's First Markman Order. That construction did not address all of the elements of the Claim. This Order reconsiders the construction of Claim 14 and supersedes the First Markman Order with respect to Claim 14.

Claim 14 discloses a method for controlling the movement of a cursor of a video display. The method comprises four steps, which may be summarized as follows: (1) providing a hand-holdable device which has a two-dimensional array of photosensors; (2) tracking movement of the device in the environment; (3) forming a cursor-control signal which corresponds to the movement which is tracked in step (2); and (4) transmitting the cursor-control signal to the video display.

2. Step (1): The "providing a hand-holdable device step," imposes a structural limitation on each element of Claim 14

Step (1) of the method recites a particular structure for performing the method, namely, "a hand-holdable device having a two-dimensional array of photosensors." When a method claim includes as one of its elements a particular structure, unless the language of the claim provides otherwise, the structure is a limitation on the claim. See Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261 (Fed Cir. 1986). Based on the language of Claim 14, the Court finds that the method is limited to a particular apparatus: "a hand-holdable device having a two-dimensional array of photosensors."

3. Step (2): The Tracking Step

Step (2) of the method provides: tracking movement of said device relative to a region of an environment in which said device resides. The "tracking movement" step includes three substeps. Substep (a) is: "periodically forming largely overlapping images of a field of view of said array." The parties dispute the construction of this substep. To arrive at a construction, the Court begins by giving separate consideration to the words and phrases of the substep.

a. "said array"

Substep (a) claims as part of the "tracking movement" step, periodically forming largely overlapping images of a field of view of "said array." When an element uses the word "said," it is referring back to a device already disclosed. See Nautilus Group, Inc. v. Icon Health and Fitness, Inc., 308 F. Supp. 2d 1198 (citing Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1356 (Fed. Cir. 1999), cert. denied, 529 U.S. 1037, 120 S. Ct. 1531, 146 L. Ed. 2d 346 (2000)). The phrase "said array" refers to the "two-dimensional array of photosensors" of the device disclosed in step (1).

b. "field of view"

In the section of the written description entitled "Best Mode for Carrying Out the Invention," the inventor describes an embodiment of the array of photosensors of the invention as follows:

"With reference to FIG. 1, a hand-holdable controller device 10 is shown as including an integrated circuit package 12 for acquiring and processing image data. On the surface of the package is an optoelectric integrated circuit chip 14 having a two-dimensional array 16 of photosensors and having processing circuitry 18. The array and processing circuitry are used to acquire successive frames of image data, permitting the attitude of the device to be tracked."

('804 Patent, Col. 5:3-11.)

A person of ordinary skill in the art would understand that the inventor of the '804 Patent is using the phrase "said array" to mean the two-dimensional array of photosensors and associated circuitry of the hand-held device. Although the written description discusses a 32 X 32 array 2, the device is not limited to an array of a particular size.
the patent documents to determine if the inventors used the phrase in any specialized way. In the written description, the inventor uses the phrase "field of view" to describe the environment which is detectable by the full photosensor array.

The sensor array and the processing circuitry 18 are mounted on the front of the controller device 10 with the array facing outwardly. A lens 26 is shown in FIG. 1 as being partially cutaway in order to expose the array and circuitry. The lens may be an inexpensive plastic lens that is molded to the integrated circuit package 12. The focus of the lens is set nominally at infinity. The lens provides an image of a region of the surrounding environment to the sensor array 16.

('804 Patent, Col. 5:23-30.)

The width of the field of view for imaging the environment is a matter of balancing the desire of capturing as much visible detail as possible with the requirement of avoiding excessive distortion. A 64 [degrees] field of view provides a reasonable compromise between the two concerns. The dashed lines 28 in FIG. 1 represent the field of view for the sensor array 16. The arrangement of the optics and the sensor array may be selected to reduce any adverse effects of curvilinear distortion of the attitude-tracking approach of the invention.

('804 Patent, Col. 5:38-47.)

The inventor also uses the phrase "field of view" when discussing the environment which is detectable by each individual photosensor:

As previously noted, the field of view 28 is contemplated to be approximately 64 [degrees]. In a sensor array of 32X32 photosensors, a single pixel will have an approximately 2 [degrees] field of view (64 [degrees] /32 pixels).

('804 Patent, Col. 6:34-37)

In both instances the inventor is using the phrase with its customary and ordinary meaning. A person of ordinary skill in the art would understand that the inventor used the phrase "field of view" to mean the region of the environment optoelectrically detectable by the array of photosensors.

c. "periodically . . . forming largely overlapping images"

Substep (a) discloses "periodically forming largely overlapping images of a field of view of said array." The '804 Patent includes drawings and written descriptions in which the inventor discusses what is meant by "periodically" forming largely overlapping images:

Referring now to FIGS. 1 and 2, a control clock 36 determines the timing of operations for the controller device 10. The image-capture rate is at least partially determined by the features that are to be imaged. Where the field of view 28 is a living room of a person engaged in operation of an ITV system, the image capture rate must be sufficiently great to ensure that the image data is sufficiently intelligible to permit correlation between successive images. The circuitry of FIG. 2 includes an exposure control 38 which shows a minimum exposure of 5 [mu] s and a maximum exposure of 5 ms. Electronically, the "exposure time" is the interval during which charge generated by the individual photosensors is allowed to integrate during the 5 ms period between successive image captures.

('804 Patent, Col. 6:14-33.)

A person of ordinary skill in the art would understand that the word "periodically . . . forming largely overlapping images" refers to a process in which a device takes multiple separate optoelectric readings of the environment and at such frequency that the areas being read overlap one another.

d. "forming . . . images"

Substep (a) discloses "forming images" in execution of the substep. Although the word "forming" is not used in the written description, the inventor discusses embodiments of the invention which "capture" and "process" "image data."
The word "images" is a general term with many meanings, which depend on how the images are created. Therefore, with respect to the '804 Patent, the word "images" must be defined in a manner which recognizes that the "images" are formed using a photosensor array and associated circuitry.

One of ordinary skill in the art would know that each photosensor in an array responds to gradations of environmental light and the array's associated circuitry converts the light from each photosensor into an electrical voltage. The Court examines the written description to determine what the inventor meant by the phrase "forming images" from voltages from a photosensor array.

FIG. 3 is disclosed as a diagram of the array of photosensors and transfer amplifiers labeled "SENSOR ARRAY" in the FIG. 2 block diagram:

As previously noted, the embodiment of FIGS. 1 and 2 includes a sensor array having thirty-two columns and thirty-two rows of photosensors. Referring now to FIG. 3, five columns and six of the thirty-two rows are shown. Each column is operatively associated with a separate transfer amplifier. A photosensor in a column is connected to the operatively associated transfer amplifier for closing a read switch. In the operation of the circuitry of FIG. 3, no two photosensors are connected to the same transfer amplifier simultaneously.

Each transfer amplifier includes an input that is connected to a source of a fixed voltage. A second input is capacitively connected to the output by a transfer capacitor. In the operation of the circuit of FIG. 3, the read switches of the first row may be closed, so that each transfer capacitor receives a charge corresponding to the light energy at the associated photosensor in the first row. The received charge is transferred to subsequent processing circuitry via the output lines. Following the readout of the first row, the read switches of the first row are opened and the transfer amplifiers are reset. The read switches of the second row are then closed in order to transfer the signals from the photosensors of the second row. The process is repeated until each row of photosensors is read. By the operation of the transfer amplifiers, photosensor signals are transferred in a row-by-row fashion to subsequent circuitry.

Substep (b) discloses "storing" a "first image" as a "reference frame." This is helpful because the inventor states that the
circuitry of substep (a) "forms" "images," and the circuitry of substep (b) stores one of the images as a "reference frame."

The Court presumes that the images which are stored as a "reference frame" have identical characteristics to the images which are formed. The written description discloses that the inventor uses the word "frame" to mean a collection of "pixel values" from a particular optical acquisition:

The sensor array 16 is used to acquire a frame of 32 X32 pixel values. The first captured frame is referred to as a reference frame.

('804 Patent, Col. 6:51-52.)

The phrase "pixel value" is a phrase coined by the inventor. If the disputed word or phrase is coined by the inventor, the definition must be clearly stated in the patent documents. Vitronics Corp., 90 F.3d at 1582. In the written description, the inventor defines "pixel value" as a voltage which is created from processing the input from a photosensor or group of photosensors 5 in an array and which is stored in the circuitry associated of that particular photosensor or group of photosensors. Thus, "pixel value" is a phrase which indicates size, intensity and location. The Court will discuss how it arrives at that construction.

5 In describing FIG. 6, the written description uses conditional language: "If there is a one-to-one correspondence of computation cells and photosensors, the embodiment of FIGS. 1-3 will have 1,024 computation cells." This suggests that the circuitry could have a many-to-one relationship between photosensors and a computation cell. This is significant because if there is not a one-to-one relationship, conceivably, a pixel value may represent the output of more than one photosensor.

The word "pixel" is a commonly used term in computer graphics which means one picture element in a rectilinear grid of multiple such elements which can be manipulated by a computer to display characters or graphics. See Microsoft Computer Dictionary, 406 (5th ed. 2002). The inventor coined the phrase "pixel value" to signify that tracking the movement of the "device" is done computationally on a sensor-by-sensor basis, similarly to how movement is displayed on a computer monitor on a pixel-by-pixel basis:

[E]ach pixel value is indicative of light energy received at a particular photosensor at a specific time.

('804 Patent, Col. 3:49-59) 6

6 The Court relies on Claim 9 as further support that the inventor used the word "image" to mean a periodically acquired set of pixel values. In Claim 9, the inventor discloses ". . . storage means connected to said array for storing a reference frame of pixel values in which each pixel values is indicative of light energy received at a particular photosensor at a specified time. . . ."

Just as pixels in computer graphics are elements on an X -Y axis, the inventor coined the phrase "pixel value" to signify that computationally, each "pixel value" has a known location on an X - Y axis of the array. The content of each cell 7 of the array is a voltage generated by the circuitry:

Loading a reference frame of pixel values is required before any image correlations can be calculated. To load the reference frame, all of the voltages at the CDATA nodes 104 in the computational array must be transferred to the REFH nodes 134.

('804 Patent, Col. 11:47-51.)
The inventor used the phrase "pixel cell" to describe the place where the voltages are stored. (See '804 Patent, Col. 10:14.) The Court noted earlier that a "cell" is described as capable of holding the voltages of more than one photosensor, depending on the layout of the circuit.

After the voltages are stored, the correlation process involves computational comparisons between the electrical values stored in the reference frame with the values generated by photosensor captures of overlapping areas and stored in sample frames:

The correlation processing generates an attitudinal signal indicative of any changes in angular orientation of the controller device 10. In FIG. 2, the correlator 42 is shown as generating a signal in which change along the X axis is +0.75 pixels, while the change along the Y axis is -0.31 pixels. In FIG. 1, positive movement along the X axis may be indicated as a result of angular displacement of the device 10 such that the field of view 28 is moved in the direction of arrow 44, while a negative movement along the X axis is one in which a component of displacement of the field of view 28 is in the direction indicated by arrow 46. Regarding the Y axis, a positive value at the attitudinal signal indicates manipulation of the device 10 to rotate the field of view as shown by arrow 48, while a negative value of .DELTA.Y indicates displacement in the direction shown by arrow 50.

The preferred approach for operation of the correlator 42 is one in which nearest-neighbor pixel shifts are executed in order to track changes in attitude of the controller device. This approach will be detailed when referring to FIGS. 4, 5 and 6. However, the attitude tracking alternatively may be carried out using correlations requiring shifts of greater than a single pixel. For either approach, interpolations are computationally performed to identify fractional pixel values. Such image correlating interpolating is well understood by persons skilled in the art.

('804 Patent, Col. 7:6-30.)

Therefore, the Court construes the phrase "periodically forming largely overlapping images of a field of view of said array" to mean: Acquiring optoelectric signals from an array of photosensors and, using circuitry, converting the signals to values which represent the field of view to which the array is being exposed at discrete points in time. The substep of forming an image is not otherwise limited to any particular process. This substep includes processing of the signals from acquisition up to but not including storing as a frame.

Periodically forwarding

Plaintiff advances a construction for "periodically forwarding" of "forwarding at intervals defined by time or predetermined amount." Plaintiff points to two specific situations described in the illustrated embodiments in the '281 specification:

In another embodiment, the merchant processor may periodically forward at least a portion of the payment to the lender or designee. For example, the merchant processor may forward payment amounts every month, or based on an amount such as after each one thousand dollars ($ 1000) worth of transactions. Col. 2, lines 20-25.

Also, as another example, the merchant processor 300 can periodically forward payment to the lender 60, such as upon every other payment received from the card issuer 50. Col. 5, lines 45-48.

Plaintiff interprets these two statements to require that "periodically forwarding" occurs either: (1) after a period of time has elapsed (e.g., every month), or (2) after an event has occurred (e.g., after an amount has been reached or after a certain number of payments have been received). According to Plaintiff, the proper construction of the term "periodically forwarding" must therefore encompass both of these scenarios.

Defendants, however, argue that "periodically forwarding" should be construed as "forwarding at an interval other than upon every payment," according to its ordinary and customary meaning. Defendants argue that Plaintiff's proposed
construction violates the principle of claim differentiation in that dependant Claims 8 and 17 refer to accumulation to a predetermined amount, but under Plaintiff's construction, Claims 9 and 18 will improperly include the scope of Claims and 17. Further, Defendants argue that Plaintiff's construction is premised on an incomplete excerpt from the '281 specification. The Court fords that Plaintiff improperly seeks to limit the claim language to only those situations described in the above-mentioned illustrated embodiments. The claim language is broader in scope. The independent claims are specific that forwarding is conducted contemporaneously with each payment. The dependent claims' use of the "periodically" limitation only distinguishes that forwarding is not done contemporaneously with each payment. Thus, the Court finds Defendants' construction to be correct and construes the term "periodically forwarding" as "forwarding at an interval other than upon every payment."

3118

3. "peripheral device"

The parties agree that a "peripheral device" is an add-on device, but dispute whether the add-on device must be on a bus, and if so, the type of bus. OPTi argues that the "peripheral devices" of the LPC patents must be peripheral devices on an I/O bus. Defendants contend that OPTi's construction impermissibly reads details from the specification into the claims.

OPTi points to language in the background and abstract of the specification where the patent is directed to an I/O interface, compatible with industry standards, for interfacing a host to a peripheral device. 9 Defendants argue that nothing in the claims requires a particular type of bus. Defendants contend that the Summary of the Invention does not use the phrase "I/O bus" and even though the phrase may have been used in other parts of the specification, the claims do not specifically refer to an "I/O bus." '807, 3:21-4:3; '141, 3:24-4:7.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
9 "The present invention, roughly described, is directed to an interface to be used between a host device and one or more peripheral devices." '141 Patent, 3:24-27.
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The claims of the '807 patent only claim "a bus" and refer back to "said bus." Additionally, when the patent claim requires a particular kind of bus it so provides. 10 For example, claim 1 of the '141 patent specifically states in part: "a plurality of signal lines coupling the host platform to said peripheral device, said plurality of signal lines comprising: an address-data bus to carry in a multiplexed manner address information for a first cycle..." The core of the invention requires that the peripheral devices are connected to some type of bus. '807, 3:33-44; '141, 3:38-47. The term "peripheral bus" entails the specific bus types contemplated by the specification and suggested by OPTi. Consistent with the construction of "host platform," peripheral buses connect the host platform to the peripheral devices. Similarly here, the term "peripheral device" is construed to mean "an add-on device on a peripheral bus."

3119

2. "peripheral logic-circuit"

Claim 1 of the 229 patent includes the term "peripheral logic-circuit." UniRAM propounds a construction similar to its
proposed construction for "logic circuit," and argues that "a peripheral logic-circuit is a type of logic circuit (namely a peripheral one)." UniRAM Br (Doc # 91) at 17. In particular, UniRAM explains that "a peripheral logic-circuit is simply a logic circuit located outside of, but on the same substrate as, a memory circuit thereby forming an embedded memory device." Id at 30. MoSys construes peripheral logic-circuit as "a circuit outside of the memory array that performs some processing or controlling function." TSMC adopts the same construction but omits the word "some" and changes "function" to "functions." Jt Cl Const, Ex B at 13. Under UniRAM's construction, the 229 patent covers only embedded DRAM; under MoSys's and TSMC's constructions, the patent covers both embedded and stand-alone DRAMs.

The court agrees with UniRAM that the 229 patent pertains to embedded, and not stand-alone, memory technology, and therefore, MoSys's and TSMC's proposed constructions for "peripheral logic-circuit" are incorrect. The specification never discusses stand-alone DRAM, but discusses embedded technologies at length. 229 patent at 2:16-24 (discussing the difficulty in prior art embedded DRAM manufacturing and the novel approach employed in the invention), 20:16-24 (discussing the advantages obtained according to this invention as "[c]omparing with current art embedded memory technologies, the present invention simplifies the manufacture technology by more than 30%"), 22:2-19 (discussing the transistor properties of prior art embedded technology), 24:31-52 (discussing novel design methods to reduce effect of higher leakage current for transistors in embedded technology). The patent title, field of invention and various invention objectives all refer to embedded memory. Id at cover (Title: "High Performance Embedded Semiconductor Memory Device * * * "), 1:15-19 (Field of invention: "The present invention relates * * * particularly to embedded memory devices * * * "), 3:36-44 (Invention objectives: "to manufacture [embedded device] without using complex manufacture technology * * * to make embedded DRAM to have the same performance as high-speed logic circuits * * * to improve yield and reliability of embedded memory products"). Moreover, the theme of manufacturing the DRAM memory cell using standard logic technology appears throughout the specification. A memory cell manufactured in this way would likely be part of an embedded, not stand-alone, DRAM. Id at 5:11-12 ("process step to manufacture a DRAM memory cell by adding one masking step to standard logic technology"), 17:48-52, 19:48-65, 20:18-20 ("the procedures used to build the DRAM cell are existing procedures of standard logic technology, except one masking step and one plasma-etching step"), 20:29-32. The specification also discusses the simultaneous manufacturing of memory cells and logic circuits. A memory cell manufactured in this way would be a part of an embedded, not stand-alone, DRAM. Id at 21:41-44 ("The word line transistor (1402) in the memory cell of the present invention has the same properties and it is manufactured in the same time as the transistors used for peripheral circuits and logic circuits.").

Nonetheless, MoSys and TSMC argue that this court cannot import limitations from the specification based on the patent title, invention objectives, field of invention and disclosed embodiments. But this argument overlooks the court's duty to interpret claims in light of the specification. The Federal Circuit has described the balance between these competing interests:

[The] balance turns on how the specification characterizes the claimed invention. In this respect, this court looks to whether the specification refers to a limitation only as a part of less than all possible embodiments or whether the specification read as a whole suggests that the very character of the invention requires the limitation be a part of every embodiment. For example, it is impermissible to read the one and only disclosed embodiment into a claim without other indicia that the patentee so intended to limit the invention. On the other hand, where the specification makes clear at various points that the claimed invention is narrower than the claim language might imply, it is entirely permissible and proper to limit the claims.

Alloc, Inc v ITC, 342 F3d 1361, 1370 (Fed Cir 2003) (internal citations omitted) (emphasis added). Here, the whole character of the invention is geared toward embedded technology. The patent title, field of invention, invention objectives and disclosed embodiments all relate to embedded, not stand-alone, DRAM. Accordingly, the court concludes that the claims in the 229 patent were directed only at embedded DRAM.

Nonetheless, UniRAM's proposed construction is problematic because, as with its proposed construction for "logic circuit," UniRAM defines peripheral logic-circuit at a level of detail that is unsupported by the specification. UniRAM once again imports limitations that the patent never discusses, such as the use of a microprocessor or ASIC.

Moreover, contrary to UniRAM's proposed construction, the specification teaches that "peripheral logic-circuit" encompasses both embedded logic circuits and peripheral circuits. When discussing threshold voltages and gate thicknesses, the specification states:

- 3429 -
The word line transistor (1402) in the memory cell of the present invention has the same properties and it is manufactured in the same time as the transistors used for peripheral circuits and logic circuits.

'229 patent at 21:41-44. Claim 1 of the 229 patent states in relevant part:

1. A DRAM (dynamic random access memory) cell array supported on a substrate comprising * * *
said select-transistor-gate and said logic-circuit-gate having substantially a same thickness;

said select-transistor for each of said memory cells having a select-transistor threshold voltage and each of said logic-transistors of said peripheral logic-circuit having a logic-transistor threshold voltage wherein said select-transistor threshold voltage is substantially the same as said logic-transistor threshold voltage.

Id at 25:29-26:11. The comparison in the specification between the properties of a word line transistor and the properties of a transistor used for peripheral and logic circuits finds a parallel in the comparison in claim 1 between the threshold voltage/gate thickness of a select-transistor and the threshold voltage/gate thickness of a logic-transistor in a peripheral logic-circuit. This parallelism is reinforced by the specification that alternatively refers to the "word line transistor (1402)" as "select transistor 1402." Id at 17:53-57. The parallel use of "peripheral logic-circuit" and "peripheral circuits and logic circuits," demonstrates that the former term encompasses peripheral circuits. Because courts should not construe patent terms to exclude disclosed embodiments, C R Bard, Inc, 388 F3d at 865, the court concludes that "peripheral logic-circuit" includes both embedded logic circuits and peripheral circuits.

Having determined that the patents-at-issue only relate to embedded technology, and that "peripheral logic-circuit" includes both peripheral circuits and logic circuits, the court construes "peripheral logic-circuit" to mean "a peripheral circuit and/or embedded logic circuit."

Peripheral region of the semiconductor chip

The Court agrees with the MEI and construes the term as the "region outside the area of the semiconductor chip in which the internal circuit is formed." Samsung's proposed construction--"the outermost region of the semiconductor chip"--merely substitutes "outermost" for "peripheral." The claim language recites "a surge protection apparatus for protecting an internal circuit." '588 Patent col. 9:3-8 (emphasis added). The surge protection apparatus is formed outside of the internal circuit. "Peripheral" in this context connotes an area outside of the internal circuit. Furthermore, there is no basis to require this surge protection apparatus be built on the "outermost" area of a chip.

A permission

Digital Reg first contends that only "a permission" in "a permission that is locked uniquely to the client" requires construction, and "a permission" should be construed as "information which grants access." Defendants contend that the entire phrase, "a permission that is locked uniquely to the client" requires construction.

To support its construction, Digital Reg relies on claim 4, which states "wherein the permission comprises a unique coded key corresponding to the digital content." Digital Reg also cites to claims 21 and 26, which include a "permission key," as consistent with its proposed construction. Finally, Digital Reg cites to the specification, which states, "[e]very unique object has a unique coded key which acts as a key for accessing the object." Col. 8:58-61. This unique coded key acts as a key for accessing the object. Digital Reg contends this explanation of a unique coded key supports its construction of "a permission" as "information which grants access."
Defendants contend that "a permission" should not be construed outside the broader phrase of "a permission that is locked uniquely to the client." Defendants do however state that "permission" is synonymous with "unique coded key." Responsive Brief (Docket No. 238) at 23 ("the inventor used the term 'permission' as a synonym for the 'unique coded key'"). Defendants contend Digital Reg's proposed construction is unsupported by the specification or prosecution history and that Digital Reg does not explain how claim 4 supports its construction. Finally, Defendants argue that "a permission" is used in different ways in claim 1, which raises issues of indefiniteness and written description that Digital Reg seeks to avoid by only construing "a permission" as it is used in the phrase "a permission that is locked uniquely to the client." Sony moves for summary judgment based on indefiniteness and lack of written description on these grounds. See Docket No. 237.

A claim is invalid under 35 U.S.C. § 112, P 2 if it fails to particularly point out and distinctly claim the subject matter that the applicant regards as the invention. The party seeking to invalidate a claim under 35 U.S.C. § 112, P 2 as indefinite must show by clear and convincing evidence that one skilled in the art would not understand the scope of the claim when read in light of the specification. Intellectual Prop. Dev., Inc. v. UA-Columbia Cablevision of Westchester, Inc., 336 F.3d 1308, 1319 (Fed. Cir. 2003).

"The definiteness requirement of § 112, P 2 'focuses on whether the claims, as interpreted in view of the written description, adequately perform their function of notifying the public of the [scope of the] patentee's right to exclude.'" Honeywell Intl', Inc. v. Int'l Trade Comm'n, 341 F.3d 1332, 1338 (Fed. Cir. 2003) (quoting S3 Inc. v. nVidia Corp., 259 F.3d 1364, 1371-72 (Fed. Cir. 2001)). "It requires that the claims be amenable to construction, however difficult that task may be. Because a claim is presumed valid, a claim is indefinite only if the claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Id. at 1338-39 (citations omitted).

"[T]he purpose of the written description requirement is to 'ensure that the scope of the right to exclude, as set forth in the claims, does not overreach the scope of the inventor's contribution to the field of art as described in the patent specification.'" ICU Med., Inc. v. Alaris Med. Sys., Inc., 558 F.3d 1368, 1376 (Fed. Cir. 2009) (quoting Univ. Rochester v. G.D. Searle & Co., 358 F.3d 916, 920 (Fed. Cir. 2004)). The written description requirement protects the quid pro quo between inventors and the public, where the public receives meaningful disclosure of the invention in exchange for being prohibited from practicing the invention for a limited time period. Id. at 1377. To comply with 35 U.S.C. § 112's written description requirement, the applicant must "convey with reasonable clarity to those skilled in the art that, as of the filing date sought, he or she was in possession of the invention," which is whatever is now claimed. Id. (quoting Vas-Cath Inc. v. Mahurkar, 935 F.2d 1555, 1563-64 (Fed. Cir. 1991)). The description does not need to "recite the claimed invention in haec verba but must do more than merely disclose that which would render the claimed invention obvious." Id.

"A permission" satisfies § 112's written description requirement. Defendants admit that the term "permission" is generic to the disclosed species of a "unique coded key." Claims commonly use a generic term when only a species is disclosed. One example is a disclosure of a novel dwelling of frame construction wherein the illustrated embodiment only describes that nails are used to connect the framing materials together. A nail is one species of fastener and a screw is another. A claim to the dwelling structure permissibly recites a "fastener," which is a generic term to both a nail and a screw. Similarly, the generic term "permission" is properly used in view of the disclosure of only a single species, a "unique coded key." See Ethicon Endo-Surgery, Inc. v. U.S. Surgical Corp., 93 F.3d 1572, 1582 n.7 (Fed. Cir. 1996) (citing In re Vickers, 141 F.2d 522, 525, 31 C.C.P.A. 985, 1944 Dec. Comm'r Pat. 324 (C.C.P.A. 1944) ("an applicant . . . is generally allowed claims, when the art permits, which cover more than the specific embodiment shown"); In re Rasmussen, 650 F.2d 1212, 1214 (C.C.P.A. 1981) (disclosure of a single method of adheringly applying one layer to another was sufficient to support a generic claim to "adheringly applying" because one skilled in the art reading the specification would understand that it is unimportant how the layers are adhered, so long as they are adhered).

Additionally, the term "permission" when read in the context of its usage is clear. "A permission," as used throughout the claim language, is not indefinite or insolubly ambiguous. When the same term appears in different portions of the claims, courts presume that it should be given the same meaning "unless it is clear from the specification and the prosecution history that the terms have different meanings at different portions of the claims." Fin Control Sys. Pty, Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001). Step 1 uses the phrase "whether the client holds a pre-existing permission." Step 2 claims "requesting permission," and step 4 claims "an installation process that generates at the client a permission." Both sides agree that "a permission" is used differently in steps 1 and 4 than in step 2. This is clear from the claim language itself and does not render the term insolubly ambiguous. The same term may be interpreted differently at different portions of the
A permission that is locked uniquely to the client

Digital Reg contends that this phrase does not require construction or alternatively should be construed as "information which grants access, said access specific to the client." Defendants contend that "a permission that is locked uniquely to the client" should be construed as "a unique coded key that is stored at the client along with a machine identification code of the client. The permission is separate and distinct from the token."

Digital Reg contends Defendants' construction is improper because it imports limitations from the specification and dependent claims. Specifically, Digital Reg contends that Defendants' attempt to limit the claims to the preferred embodiment and subject of claim 4 of "a unique coded key" is improper. Relying on a preferred embodiment described at column 10, lines 62 to column 11, line 3, Digital Reg also contends that incorporating the machine identification code of the client within the permission is improper because these are two different bits of information. Finally, Digital Reg contends that Defendants' limitation that the permission is "separate and distinct" from the token is incorrect because the token and permission work in tandem--when the token is received, an installation process is executed, and a permission is generated. Whether the permission is attached to the object, token, or nothing is irrelevant to claim 1's method.

Defendants support their limitation of "a unique coded key" by arguing that support for the step of "executing an access checking process to determine whether the client holds a pre-existing permission" is found in Figure 5, which the patent refers to as "a flow chart illustrating a check coded key, or 'access check,' function." See col. 6:61-62. Defendants also contend the claimed permission is "locked" to the client and whenever the specification discusses "locking" something to a client, it refers to storing a unique coded key along with a machine ID of the client. As previously stated, Defendants contend "permission" is used in the specification and prosecution history synonymously with a "unique coded key." See Ex. B at 138; col. 8:58-61. Defendants contend that the claims require the permission is separate and distinct from the token because the claims separately recite a "token" and "permission" and a dependency between them (that the permission is generated based on the token). See claim 1 ("based on the received token, executing an installation process that generates at the client a permission that is locked uniquely to the client . . . "); see also col. 10:59-11:9.

For the reasons discussed above, "permission" is not limited to a "unique coded key." Defendants' construction limits the term to the details of the disclosed embodiment and narrows the term to include the machine ID, which is not part of the information that grants access to the digital content. Accordingly, the Court does not adopt Defendants' construction.

Digital Reg's construction is correct as to "information which grants access" but "said access specific to the client" does not properly take into account the portion of the claim that states "that is locked uniquely to the client." The specification indicates that the permission (e.g., the coded key) is locked to the client in the sense that key cannot be moved to another machine along with the object. See col. 11:2-7. Thus, when the key is locked to the client, it is confined from moving to another machine. It is described that the key is confined by associating the client machine ID with the key. Accordingly, the Court construes "a permission that is locked uniquely to the client" as "information which grants access, said access being confined to the client."

"Wherein a voice recognition system further permits the surgeon to select commands or operating modes from menus." The voice recognition system of the robotic surgical system permits the surgeon to select commands or operating modes from displayed menus.
J. Permit[ing] access

Defendants have urged the Court to construe "permit[ing] access" as meaning "authorizing the use of," which they contend reflects the term's ordinary meaning in light of the specification. However, Defendants have not presented sufficient evidence to warrant departing from the claim language in favor of a synonym. Accordingly, the court will construe "permit[ing] access" to mean "permitting the subscriber client computer to access said selected computer resources."

12. Persistent connection

Seven contends that this term means "a full-time connection." Visto argues that the term means "a connection that continues for the entire time an application is in use." Viewed in the context of the specification, Visto's construction is closer to correct. The court construes the term to mean "a connection that exists the entire time the application is used." 542 patent, col. 7, lls. 25-28 (describing non-persistent connection and stating that "[t]his is very different from a persistent connection based client/server model where the connection exists the entire time an application is used, and data is only retrieved when the user request it.").

11. Non-persistent connection

Seven argues that the term means "a connection that is not full time." Visto argues that the term means "an occasional and intentionally short task oriented session defined by a connection to a remote host, the performance of a specific task or set of tasks, and then a disconnection. This is very different from a persistent connection where the intent is for the connection to persist while an application is being used." The court rejects both parties' definitions. As used in the patents, a non-persistent connection means "an occasional connection that does not exist for the entire time an application is used." 542 patent, col. 1, lls. 24-25; col. 7, lls. 20-25.

<table>
<thead>
<tr>
<th>Term</th>
<th>Plaintiff's Proposed Construction</th>
<th>Defendant's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>persistently unique sequence numbers</td>
<td>Plaintiff contends that this term does not require construction. In the alternative only, Plaintiff contends that this term should be accorded the meaning that would have been understood by one of ordinary skill in the art at the time of the invention, which is:</td>
<td>&quot;unique sequence numbers used to ensure that all objects (i.e., whether newly created or already persisted in the database) will have different identification numbers&quot;</td>
</tr>
</tbody>
</table>
"Unique sequence numbers used to ensure that all objects using the particular named sequence generator (e.g., whether newly created or persisted in a database) will have different identification numbers."

Plaintiff argues the construction of "persistently unique sequence numbers" must allow for multiple named sequence generators. PL.'S BR. at 14-15. Defendant argues the word "unique" and portions of the specification support a conclusion that the sequence numbers are universally unique. DEF.'S RESP. at 29-31. Essentially, Plaintiff's construction would only require that every sequence number generated by a given sequence generator is unique amongst the numbers generated by that sequence generator, whereas Defendant's construction would require every sequence number to be unique amongst all numbers generated by all sequence generators.

The specification describes the behavior of named sequence generators. '776 Patent 9:9-65. "Named Sequence Generators 226 are routines or modules that generate persistently unique sequence numbers." Id. at 9:10-12. "These sequence numbers . . . can be used to assign unique ids to different objects." Id. at 9:26-27. The specification describes sequence numbers as unique only within a particular domain. Id. at 9:34-39 (describing "the way sequences are named by the Named Sequence Generators 226 is done in a manner convenient for application programmers because it uses meaningful names (e.g., imageIdSequences) for the sequence generators, and allows the creation of multiple sequence number domains (e.g., partIdSequences, customerIdSequences, etc.).") Although portions of the specification describe reserving blocks of numbers for use with a particular application, see id. at 9:55-65, this utility operates within a given domain and does not require universal uniqueness. See id. at 20:9-19 (describing a reserved block of numbers as "a unique set of numbers with respect to the given sequenceName"). Thus, Defendant's proposal is unsupported by the specification and improperly excludes a preferred embodiment. See Vitronics Corp., 90 F.3d at 1583 (noting an interpretation that excludes a preferred embodiment is "rarely, if ever, correct").

Accordingly, the Court finds the proper construction of this term is "unique sequence numbers used to ensure that all objects using the particular named sequence generator (i.e., whether newly created or already persisted in a database) will have different identification numbers."

A. "personal communication device" ("PCD")

The Defendants argue that this term should be construed as part of a means-plus-function limitation because "personal communication device" does not connote sufficient structure for performing the claimed functions, i.e., "generating at least one reservation request," "transmitting the reservation request," and "receiving a proposed reservation time." Pursuant to 35 U.S.C. § 112, P 6, patentees may draft claims as means-plus-function or step-plus-function limitations. In such a format, a patentee may "recite a function to be performed as a claim limitation rather than reciting structure or materials for performing that function." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1322 (Fed. Cir. 2003). The claim, however, will cover only the corresponding step or structure disclosed in the specification and its equivalents. 35 U.S.C. § 112, P 6; CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002). The construction of a means-plus-function limitation follows a two-step approach. First, the claimed function is identified based on the claim language and the limitations expressed in the claims. Next, the court ascertains the corresponding structure in the written description that performs the identified function. Omega Eng'g, Inc., 334 F.3d at 1321. "A disclosed structure is corresponding only if the specification or the prosecution history clearly links or associates that structure to the function recited in the claim." Id. (internal punctuation and citation omitted). Only those structures that are "necessary to perform the claimed function" may be incorporated from the written description. Micro Chem., Inc. v. Great Plains Chem. Co., Inc., 194 F.3d 1250, 1258 (Fed. Cir. 1999); see Golight, Inc. v. Wal-Mart Stores, Inc., 355 F.3d 1327, 1334-35 (Fed. Cir. 2004) (structures are superfluous if "they are not required for performing the claimed function").
Before engaging in a means-plus-function construction, however, the court must determine if § 112, P 6 is applicable to the particular claim. The use of the term "means" is "central to the analysis because the term 'means,' particularly as used in the phrase 'means for,' is part of the classic template for functional claim elements." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (internal punctuation and citations omitted). Accordingly, "[a] claim limitation that actually uses the word 'means' invokes a rebuttable presumption that § 112, P 6 applies." CCS Fitness, Inc., 288 F.3d at 1369. In those instances, the "means" term is "essentially a generic reference for the corresponding structure disclosed in the specification." Chiuminatta Concrete Concepts, Inc. v. Cardinal Indus., Inc., 145 F.3d 1303, 1308 (Fed. Cir. 1998). Conversely, if a claim term does not use "means," there is a rebuttable presumption that § 112, P 6 does not apply. CCS Fitness, Inc., 288 F.3d at 1369.

In this case, the claims at issue do not contain the term "means." Therefore, there is a rebuttable presumption that § 112, P 6 does not apply. This presumption is "a strong one that is not readily overcome." Lighting World, Inc., 382 F.3d at 1358. Nevertheless, the presumption may be rebutted if the "claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Id. (internal punctuation and citation omitted). In order to recite sufficient structure, a claim term need not denote a specific structure. Id. at 1359. Rather, "it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function." Id. at 1359-60; see also CCS Fitness, Inc., 288 F.3d at 1369 ("To help determine whether a claim term recites sufficient structure, we examine whether it has an understood meaning in the art.").

The Defendants, as the parties advocating construction under § 112, P 6, bear the burden of establishing that the claims fail to recite sufficient structure. See Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1319 (Fed. Cir. 2004). This burden must be met by a preponderance of the evidence. Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1372 (Fed. Cir. 2003). The Defendants have offered no evidence to overcome the presumption and support their assertion that "personal communication device" does not connote sufficient structure. To the contrary, the Plaintiff's expert, a professor in the electrical engineering and communications field, testified that a person of ordinary skill in the art would understand "personal communication device" to have an ordinary meaning and denote a portable device capable of transmitting and receiving information. (Frost Decl. P 4.) The fact that the term does not specifically evoke a particular structure does not prevent the term from connoting structure. See Apex Inc., 325 F.3d at 1372 ("[A] claim term need not call to mind a single well-defined structure to fall within the ambit of § 112, P 6.") (internal punctuation and citation omitted). Nevertheless, the Defendants argue that "device" is a generic structural term and, therefore, does not connote sufficient structure. See Personalized Media Communns., L.L.C. v. ITC, 161 F.3d 696, 704 (Fed. Cir. 1998). However, they ignore the fact that the term "device" is modified by "personal communications." Such an adjectival qualification, or identifier, serves to narrow the scope of the structure and makes the term more definite. Personalized Media Communns., LLC, 161 F.3d at 704; see also Apex Inc., 325 F.3d at 1373-74 (although term "circuit" does not always connote sufficient structure, adding identifiers such as "interface," "programming," and "logic," identifies some structural meaning). Because the Defendants have failed to rebut the presumption that § 112, P 6 does not apply, the Court finds that the term "personal communication device" is not a means-plus-function limitation. Therefore, the Court must determine the correct construction of the structural term "personal communication device."

The Plaintiff proposes that "personal communication device" means "portable hand-held device capable of communicating information." This construction is supported by the specification. For instance, the specification states that "[t]he present invention relates to scheduling patron reservations in facilities offering numerous attractions, and more particularly, to systems, methods, and apparatuses for assigning and managing reservations using wireless personal communication devices." (col. 1, ll. 8-12.) In an effort to remove the inconvenience of time spent waiting in lines, one purpose of the invention is to allow patrons to schedule reservations remotely while engaging in other activities. (See col. 2, ll. 36-42.) The "personal communication device" is the device through which the patron may schedule reservations.

Accordingly, a "personal communication device" must be portable and, thus, hand-held. In addition, in order for the present invention to function effectively, the PCDs must be able to transmit and receive information with the other components of the system responsible for establishing reservations via a wireless communication network. (See col. 2, ll. 53-55; col. 3, ll. 3-7; col. 6, ll. 7-10.)

Although they agree that "personal communication device" is a portable hand-held device, the Defendants' proposed
construction includes a number of additional elements. According to the Defendants, the specification clearly defines "personal communication device" as:

A portable computing device that includes: a CPU or microprocessor, a data storage device, a display screen, input device (such as a pen-based input), auxiliary output device, wireless communication hardware and software, a user interface designed to accept input from the user, patron information storage, and storage containing a list of attractions.

In support, the Defendants cite to Figure 1A, which illustrates the "hardware architecture of a personal communication device according to the present invention," col. 4, ll. 9-11, as well as various parts of the specification that discuss the structure of the PCD. Figure 1A indicates that a personal communication device includes: (1) an input device; (2) random access memory ("RAM"); (3) wireless transmitter/receiver; (4) a CPU; (5) a screen; (6) other output; and (7) a disk drive. Consistent with Figure 1A, in the section devoted to "System Architecture," the specification states that PCDs are small, hand-held portable computers that include a microprocessor or CPU, display screen, auxiliary output device, input device, RAM, and a storage device. n3 (col. 5, l. 62 to col. 6, l. 1.) The inclusion of the display screen and input device requirements is further supported by a portion of the specification that states that "[e]ach PCD includes a screen display for displaying text and graphic information as well as an input device for receiving input from the patron using the device." (col. 2, ll. 59-62.) As noted above, to function consistent with the present invention, PCDs must also include "wireless communication hardware 112 for transmission and reception of data to other components of system 100 over wireless communications network." (col. 6, ll. 7-10; see also col. 3, ll. 3-4.)

- - - - - - - - - - - - -Footnotes- - - - - - - - - - - - -
n3 Although these elements are described as part of a preferred embodiment, the inclusion of each structural element is consistent with the overall purpose and function of the present invention in general.

- - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - -

Although the specification supports the inclusion of a number of the Defendants' proposed limitations, namely a CPU or microprocessor, data storage device, display screen, input device and output devices, wireless communication hardware and software, the same cannot be said for the following limitations: (1) a user interface designed to accept input from the user; (2) patron information storage; and (3) storage containing a list of attractions. As noted above, claim construction starts with the language of the claims themselves. Semitool, Inc. v. Dynamic Micro Sys. Semiconductor Equip. GMBH, 444 F.3d 1337, 1346 (Fed. Cir. 2006) (quoting Phillips, 415 F.3d at 1314) ("Quite apart from the written description and the prosecution history, the claims themselves provide substantial guidance as to the meaning of particular claim terms."). The Federal Circuit has also explained that:

Other claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term. Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims.

Phillips, 415 F.3d at 1314 (internal citations omitted). "Personal communication device" appears in numerous claims other than claims 5, 17, and 19. Although not directly at issue in the present construction, the language of these claims is useful in discerning which structural elements may not be an inherent part of the ordinary meaning of "personal communication device." For instance, claim 1 includes language indicating that the "PCD comprises . . . a user interface for receiving the reservation request from the patron and for providing output to the patron; . . . [and] patron information storage coupled to the user interface and to the request generation module, for storing information describing the patron. . . ." (col. 25, ll. 47-50, 58-60) (emphases added). Similarly, claim 14 states, in pertinent part: "a personal communication device associated with at least one patron, comprising . . . a user interface for receiving from the patron a reservation request for a selected attraction; . . . [and] patron information storage coupled to the user interface for storing information describing the patron. . . ." (col. 30, ll. 22-23) (emphases added). See also col. 26, ll. 30-33 (claim 3); col. 27, ll. 4-7 (claim 4); col. 28, ll. 29-36 (claim 10); col. 29, ll. 30-33 (claim 12), ll. 50-53 (claim 13). The fact that other claims describe specific elements that are part of a PCD, namely the user interface and patron information storage, indicates that the patentee did not contemplate that "personal communication device" inherently includes those limitations. See Phillips, 415 F.3d at 1325 (inclusion in other claims of particular functions served by "baffles" "makes it likely that the patentee did not contemplate that the term 'baffles' already contained that limitation"). Thus, the Court will not read the "user interface designed to accept
input from the user" and the "patron information storage" limitations into the construction of "personal communication device."

Moreover, the doctrine of claim differentiation provides support for excluding "patron information storage" from the ordinary meaning of "personal communication device." As discussed above, "patron information storage" appears in a number of claims as a PCD limitation. However, the phrase is not found in all claims describing the PCD. For instance, claims 3 and 4 set forth what the PCD comprises but "patron information storage" is not included as a limitation. Under the doctrine of claim differentiation, "the presence of a specific limitation in one claim gives special significance to the absence of that specific limitation in another claim, in that it shows that when the limitation was intended it was expressed." Acacia Media Techs. Corp. v. New Destiny Internet Group, 405 F. Supp. 2d 1127, 1137 (N.D. Cal. 2005) (citing Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 950 (Fed. Cir. 1993)). As such, the fact that "patron information storage" is present in some claims but not others indicates that the limitation is not an inherent requirement of a PCD.

Finally, the Defendants contend that in order to allow patrons to select an attraction, "personal communication device" must include "storage containing a list of attractions." In support of this limitation, the Defendants rely on a portion of the specification that describes attraction description records. However, in the paragraph immediately preceding the identified portion, the specification states that the PCD "optionally contains descriptions of the various attractions in the park, stored in attraction description storage." (col. 7, ll. 52-54) (emphasis added). Additionally, in describing the "PCD Operation," the specification indicates that "[a]ttraction description information may be provided to PCD 102 for local storage in attraction descriptions 205." (col. 13, ll. 49-50) (emphasis added). Although it may be preferable or advantageous to include attraction information in the PCD, it is clear from the specification that "storage containing a list of attractions" is not required. Therefore, the Court will not read this limitation into the ordinary meaning of "personal communication device." Rather, consistent with the claims and specification, the Court construes "personal communication device" as "a portable hand-held device capable of receiving and transmitting information -- that includes a CPU or microprocessor, a data storage device, a display screen, input device, output device, and wireless communication hardware and software."

3129

"Personal Computer"

"Personal computer" or "PC" appears in Claims 1 and 17 of the 709 Patent (709 Patent: 1, 17). The plaintiff contends that "personal computer" means "a computer system" (Doc. 60 at 18). Emphasizing the word "personal" in "personal computer," the defendants argue that "personal computer" means "a computer designed for use by one person at a time and designed to be independent of a mainframe or other computer. Personal computers have their own operating systems, software, and peripherals so that they can be set up and operated without additional equipment" (Doc. 62 at 19-20). Presumably, the plaintiff's urged construction includes any computer system, mainframe, or server. The defendants contend that the plaintiff's urged construction ignores "personal" while impermissibly inserting the "system" to include a server, mainframe, or "computer means."

The patentee's use of "personal computer" in the claims distinguishes a "personal computer" from a server or mainframe. The specification describes a "personal computer" as a general purpose computer that utilizes input devices such as a keyboard, mouse, or touchpad (709 Patent 15:44-55; 15:64-16:8). The specification further provides: "Many varied computing means pervade today's society. PCs, web browsers, e-mail clients, e-mail servers, network file servers, network messaging servers, mainframes . . . ." (536 Patent at 5:51-59; 709 Patent at 5:52-59). This specification reveals that "PC" or "personal computer" denotes one species of "computer means" but not all "computer means."

The patentee also distinguishes between a "stand-alone PC" and a "server" in the 709 Patent's specification: "Finally, the PC system 700 according to the present invention may simply comprise a stand-alone PC, a server, a PC or workstation coupled to a server" (709 Patent at 42:61-63). This specification reveals that a "personal computer" cannot encompass a server. In addition, one of ordinary skill in the art distinguishes a "personal computer" from a mainframe or server (Doc. 62 at 17). The plaintiff's construction of "personal computer" as "a computer system" (which "system" apparently could encompass the entire "world wide web") is unsupported by the intrinsic evidence. Accordingly, "personal computer" or "PC" means "a computer capable of operation without additional equipment, independent of a mainframe or other computer, and designed for use by one person."
1. "computer" and Related Terms

* * *

The issues regarding these terms are (1) whether the court should include a limitation, as the defendants suggest, indicating that a computer cannot be a microprocessor or microcontroller, and (2) whether all four terms should have the same general construction.

Regarding the defendants' limitation, the defendants argue that the patentee expressly disclaimed embedded microprocessors and microcontrollers. In support, they cite portions of the prosecution history in which the patentee attempts to distinguish the present invention from U.S. Patent No. 5,841,865 ("the Sudia patent"). See Ex. 16-17 of Defs.' Claim Construction Brief. The Sudia patent discusses RNGs that are interfaced to microcontrollers. See the Sudia Patent, col. 13, ll. 35-65. In response to the examiner's discussion of the Sudia patent, the patentee declared, "[a]n embedded microprocessor, or microcontroller, taught in Sudia '865, is designed for a specific task to control a particular system. The embedded microcontroller of Sudia '865 is supposed to conduct specifically programmed functions related to encryption and decryption and is not operable to conduct other functions." See Ex. 17 of Defs.' Claim Construction Brief.

Claim 1 of the '242 patent contemplates a RNG interfacing with a general-purpose computer. See '242 Patent, cl. 1. As indicated by the prosecution history, the present invention does not contemplate a scenario in which the RNG directly interfaces only with a microprocessor that performs only one function and is divorced from a general purpose computer. Indeed, both parties concede that a stand-alone microprocessor is not a computer. The operative fact of the disclaimer contained within the prosecution history is the scope of the capabilities of the microprocessor, not the fact that it is embedded, stand-alone, or otherwise. The disclaimer does not preclude an interface with a microprocessor capable of performing multiple tasks or one that is part of a general-purpose computer.

The court will not typically define a term in the negative, but in light of the parties' stipulation and the discussions contained within the prosecution history, the court will do so in this instance. See Hutchins v. Zoll Med. Corp., 492 F.3d 1377, 1381 (Fed. Cir. 2007). Such construction falls squarely in line with the court's duty to define the scope of a term, as well as its meaning, when both are contested. See O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351 (Fed. Cir. 2008).

The second issue is whether all of the "computer" terms have the same meaning. Quantum relies on a claim differentiation argument, while the defendants, again, cite to portions of the prosecution history. See Ex. 17-19 of Defs.' Claim Construction Brief. The court concludes that "computer" and "general purpose computer" mean the same thing. In addition, "personal computer" and "general purpose personal computer" should be construed consistently.

Accordingly, the court defines "computer" and "general purpose computer" as follows: "a programmable machine that is operable to conduct a wide variety of tasks using a variety of applications programs that can be accessed and operated. The term does not include a microprocessor or microcontroller that is operable to conduct only a single, specific task."

The court defines "personal computer" and "general purpose personal computer" as follows: "a computer designed for use by one person at a time, such as a desktop PC or a laptop."

A. For use in a personal computer (claim 1) and personal computer (claim 2)

1. Parties' positions on preamble limitation

The disputed term, "personal computer," is recited in the preambles of both claim 1 and claim 2. The initial dispute
concerning this term is whether or not it is to be construed as a claim limitation. Dell contends that neither "for use in a
personal computer" (claim 1) nor "personal computer" (claim 2) should be construed as claim limitations because the
preambles of each claim, which contain that term, merely state the intended use or purpose of the claimed invention. Dell
urges the court to apply the general rule that a preamble which only states the intended use or purpose of the claimed
invention is not part of the claim and does not limit the scope of that claim. 31

31 See Apple Computer, Inc. v. Articulate Sys., Inc., 234 F.3d 14, 22 (Fed. Cir. 2000) (stating that "language in a claim
preamble … acts as a claim limitation only when such language serves to 'give meaning to a claim and properly define the
invention,' not when the preamble merely states a purpose or intended use of the invention." (citing In re Paulsen, 30 F.3d
1475, 1479 (Fed. Cir. 1994) (quoting DeGeorge v. Bernier, 768 F.2d 1318, 1322 n.3 (Fed. Cir. 1985))).

Tulip argues that the term "personal computer" should be construed as a claim limitation thereby restricting claims 1 and 2
to covering desktop or deskside computers, as distinguished from notebook computers. Tulip notes that language in the '621
patent specification distinguishes the claimed invention from prior art covering a notebook computer. The specification
recites that "this [prior art, the Lam patent] concerns a notebook computer and not a desktop computer as with the present
invention." 32 Tulip asserts that this language explicitly acknowledges that a notebook computer is beyond the scope of the
invention claimed by the '621 patent. Tulip also references the prosecution history of the '621 patent where the inventor
distinguished the prior art notebook computer by arguing to the patent examiner that the physical environment of a notebook
computer could not accommodate the invention claimed in the '621 patent application and that the asserted benefits of its
invention could not be achieved in such physical environment.

32 '621 at 2:54-56.

2. Court's finding on preamble limitation

A court's determination of whether a preamble serves as a limitation upon a claim is "resolved only on review of the entirety
of the patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim." 33
Generally, a preamble is not limiting if it "offers no distinct definition of any of the claimed invention's limitations, but
rather merely states, … the purpose or intended use of the invention." 34 A preamble may be limiting, however, when there
is "clear reliance on the preamble during prosecution to distinguish the claimed invention from the prior art." 35 That
reliance "transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in
part, the claimed invention." 36

Ben Venue Labs, Inc., 246 F.3d 1368, 1375 (Fed. Cir. 2001)).
36 Id.
for use in a personal computer," '621 at 5:62-63 (claim 1)) or a statement for the intended environment for the claimed combination ("[a] personal computer having," '621 at 6:36 (claim 2)). Because the bodies of claims 1 and 2 never refer back to any term in the preamble, and therefore the preambles do not provide antecedents for ensuing claim terms, Dell contends that this court should find that "personal computer" is not a limitation on the claims. 37

37 See C.R. Bard, Inc. v. M3 Sys., Inc., 157 F.3d 1340, 1350 (Fed. Cir. 1998) (stating that a preamble that "simply states the intended use or purpose of the invention … usually does not limit the scope of the claim unless the preamble provides antecedents for ensuing claim terms and limits the claim accordingly" (citation omitted)).

Tulip does not argue that the bodies of claims 1 and 2 refer back to the "personal computer" described in the preambles to those claims. Tulip contends, however, that the preambles of the claims in issue are one of the "rare instances" described by the Federal Circuit where statements of intended use in the preamble do limit the claims because, here, "the applicant clearly and unmistakably relied on those uses or benefits to distinguish prior art." 38 Tulip maintains that the specification and prosecution history of the '621 patent each demonstrate an acknowledgment by the patentee that the "personal computer" claimed is not a notebook computer.

38 Catalina Marketing, 289 F.3d at 809.

The specification of the '621 patent distinguishes prior U.S. Patent No. 5,121,295 (the "Lam patent") as "concerning a notebook computer and not a desktop computer as with the present invention." 39 The same distinction with respect to the Lam patent was made during the prosecution of the '621 patent application. In response to the examiner's initial rejection of claims 1 and 2 as originally filed as obvious, Tulip emphasized the differences between the notebook computer claimed by the Lam patent and the personal computer claimed in the '621 patent application. Tulip pointed out that, unlike its invention which teaches a riser card capable of accommodating a plurality of expansion boards, the Lam patent teaches a riser card that can accommodate a single expansion board in a notebook computer. 40 Furthermore, Tulip explained to the examiner that the physical environment of contemporary notebook computers was incapable of housing a riser card with a plurality of expansion connectors located thereon. 41 Finally, Tulip noted that because a notebook computer does not contain a cooling fan, "the problem of impeding directed air flow simply does not exist there." 42

39 '621 at 2:53-55.

41 Id.42 Id.
conclude the term "personal computer" recited in the preambles of claims 1 and 2 limits the scope of those claims to the extent that a notebook computer is excluded from the meaning of that term. 43

3. Parties' positions on claim construction

Each of the parties assert that their construction of the term "personal computer" gives that term its ordinary and accustomed meaning. Tulip proposes the term be construed as meaning a personal computer of the AT type, and specifically desktop and deskside computers. Dell argues that, even if the court determines that the preambles of claims 1 and 2 are found to be relevant claim limitations, Tulip's proposed construction is not consistent with the ordinary and accustomed meaning of "personal computer." Dell states that, at the time of Tulip's '621 patent application, the ordinary and accustomed meaning of "personal computer" meant a computer for individual or home use. 44 During the same time period, Dell notes that a portable computer was defined as a "personal computer that is designed and configured to permit transportation as a piece of handled luggage." 45 Based on these definitions, Dell argues, the ordinary and accustomed meaning of "personal computer" at the time of Tulip's '621 application included a portable, or notebook, computer.

43 See e.g., SciMed Life Sys., Inc. v. Adv. Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) ("Where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question."); Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973 (Fed. Cir. 1999) (concluding that argument distinguishing prior art during prosecution resulted in the disavowal of a potential claim interpretation encompassing the distinguished characteristic of that prior art); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution.").

44 D.I. 323 at 13 (citing MCGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNICAL TERMS 1840 (5th ed. 1994)).

45 Id. at 13 (citing NEW IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONIC TERMS 975 (5TH ED. 1993)).
Dell contends that there is nothing in the specification or prosecution history that clearly indicates an intention to define "personal computer" in a manner contrary to the ordinary and accustomed meaning of that term. The specification describes the invention as "[a] (personal) computer of the AT type or a computer which is compatible therewith." Dell maintains that by including the term "compatible," Tulip signaled its assertion that the '621 patent covered later-developed generations of the personal computers described in the specification and, therefore, was not altering the definition of the term "personal computer" from its ordinary meaning.

Dell asserts that Tulip's construction improperly limits the scope of the invention claimed by the '621 patent. The patent's written description states that:

although the motherboard according to the invention is applicable in various type [sic] of housings for personal computers of the AT type, in which there is a need for a riser card with at least two but preferably more positions for expansion cards, the motherboard has the most advantages when used in a computer of the desktop type. 47

Dell contends that this language recites a preferred embodiment of the claimed invention and not that the scope of the invention was limited to only desktop computers. Dell suggests that its proposed construction is the most appropriate as it does not improperly limit the scope of the claims to the preferred embodiment of a desktop computer. 48

Dell states that other claims of the '621 patent support its contention that the ordinary and accustomed meaning of the "personal computer" of claims 1 and 2 included a portable, or notebook, computer when the '621 patent was filed. Dell notes that claim 3 of the patent, from which claim 2 depends, claims "the personal computer of claim 2 wherein the computer is a desktop computer." According to Dell, claim 3 is directed at a subset (e.g., desktop computers) of the general set of personal computers covered by claims 1 and 2. Any other interpretation, Dell contends would render the words "desktop type" in claim 3 redundant.

Dell points to the prosecution history of the '621 patent as further support for this argument. Dell notes that the language of claims 1 and 2, as originally filed, contained the phrase "a computer of the AT type" and that original claim 3 depended from original claim 2 and limited original claim 3 to "[a] computer according to claim 2, characterized in that the computer is of the desktop type." Dell argues that this is additional evidence indicating that Tulip intended to claim all personal computers, in original claims 1 and 2, and a subset of all personal computers, a desktop computer, in original claim 3.
50 D.I. 324, Ex. 2 at TLP2 117060-61.

Tulip responds that, in view of its unequivocal disavowal of a notebook computer, the claim 3 reference to a "desktop type" computer having a housing as described in that claim distinguishes the invention of claim 3 from a mini tower computer, not a notebook computer, particularly in light of the stated applicability of the claimed invention "in various type[s] of housings for personal computers of the AT type." Tulip also notes that claim 3 includes additional limitations, like a box housing, than differentiate it from claim 2, thereby making it unnecessary that the phrase "desktop type" differentiate the claims.

4. Court's construction

The court accepts as the ordinary and accustomed meaning of "personal computer," cited by Dell, as a computer for individual or home use. That definition, however, must be limited by the acknowledgment, evident from the '621 patent specification and its prosecution history, that the computer for individual or home use claimed does not include a portable, or notebook, computer. Such a construction does not apply a meaning contrary to the ordinary and accustomed meaning of "personal computer," as that term was understood by one of ordinary skill in the art at the time Tulip applied for its '621 patent. That construction accepts the ordinary and accustomed meaning of the term as limited by the intrinsic evidence read as a whole.

At oral argument, Dell contended that the citations to the specification and prosecution history relied upon by Tulip pertained to an obviousness argument about the combinability of prior art references, not a definition of personal computer. The representations Tulip made with regard to the obviousness of its invention, however, resulted in a clear disclaimer of notebook computers from the scope of its claimed invention. The scope of the claims being thus narrowed, cannot be re-broadened by this court's construction of the term "personal computer" to include the very type of computer disclaimed.

Construing "personal computer" to mean a computer for individual or home use, but not including a notebook computer, is also consistent with the language of the specification cited by Dell describing "[a] (personal) computer of the AT type or a
computer which is compatible therewith" 55 as it protects what Dell characterized as Tulip's assertion that the '621 patent covers later-developed generations of personal computers described by the claims. The court's construction also avoids Dell's concern over the improper importation of a preferred embodiment limitation from the specification. As Dell correctly notes, the language of the written description stating that "the motherboard has the most advantages when used in a computer of the desktop type" 56 does not limit the scope of the invention to only desktop computers. Despite that fact, the language of the written description immediately preceding the just-quoted language, describing a personal computer "in which there is a need for a riser card with at least two but preferably more positions for expansion cards," 57 and the language of claims 1 and 2, calling for a "riser card [in which] … a plurality of expansion boards can be simultaneously mated," 58 does preclude the invention from covering a notebook computer. As explained above, at the time of Tulip's '621 patent application, notebook computers could not accommodate a riser card with more than one expansion board. 59 The court's construction, therefore, avoids both limiting the claims to a preferred embodiment and broadening the scope of those claims to cover a notebook computer.

The court disagrees with Dell's assertion that the language of claim 3, claiming "the personal computer of claim 2 wherein the computer is a desktop type," 60 would be rendered redundant if notebook computers are determined to be outside of the scope of the term "personal computer." The "desktop type" computer of claim 3 may properly be directed to a subset of the "various types of housings for personal computers" 61 to which the specification states the invention is applicable. Moreover, the limitation of dependent claim 3 is directed not only to a desktop type computer but also to the housing for the computer described in that claim. These additional areas of claim coverage are consistent with Dell's assertion that claim 3 contains a definition of personal computer that claims a subspecies of the personal computer of claim 2, notwithstanding the court's determination that it is clear, as demonstrated above, that notebook computers are excluded from the term "personal computer." Therefore, the court finds that the disputed term "personal computer" means a computer for individual or home use, but not including a notebook computer.

The parties agree that this preamble is a claim limitation. See Lewis Decl. Ex. 12 Tab A at 1; Id. Ex. 13 Tab A at 2. The
"multifunction communication system" includes the communication module hardware, as well as its control software, for use with a personal computer. '289, Abstract; '289, claim 1.a; '289, col. 1:37-40 ("The subject of the present multiple inventions is a personal communications system which includes components of software and hardware operating in conjunction with a personal computer."). The hardware components include "telephone communication equipment, digital signal processors, and hardware to enable both fax and data communication with a hardware components [sic] at a remote site connected through a standard telephone line. The functions of the hardware components are controlled by control software operating within the hardware component and from the software components operating within the personal computer." Id. at col. 1: 46-54. The claim language and the specification establish this element requires the multifunction communication system to be separate from the personal computer. '289, col. 8: 3-11; id. at col. 36: 66-68. The disclosure describes a "complex computer assisted communications system" consisting of multiple component parts. '289, col. 1: 35-37. The term "personal computer" means a stand-alone computer (not sharing the processing or disk resources of another computer) designed for use by one person at a time, and excludes mainframe computers or mini-computers. Multi-Tech Br. App. I Ex. 19 (Microsoft Computer Dictionary 4th Ed. 339 (1999)). The personal computer must have a processor, memory and peripheral data store.

10. Personal digital assistant

Dependent claim 8 reads: "The device of claim 7, wherein the portable electronic navigational aid device includes a personal digital assistant (PDA)." The parties dispute the construction of "personal digital assistant," but neither party has proposed an adequate construction of the term. Plaintiff's definition, "handheld computing device," is too broad. Defendant's definition ("a hand-held computer with a keyboard, display, and personal organizer functionality including data indicative of calendar, address book, scheduler, etc."), is too narrow and deviates from the specification because it focuses on conceivable features of personal digital assistants that are not critical to the '873 patent. The specification recites the following regarding the personal digital assistant:

The navigational device 310 shown in FIGS. 3A-3C includes a personal digital assistant (PDA) with integrated GPS receiver and cellular transceiver according to the teachings of the present invention. The GPS integrated PDA operates with an operating system (OS) such as, for example, the well-known Palm or Pocket PC operating systems, or the lesser-used Linux OS. As shown in the top view of FIG. 3A, the GPS integrated PDA 310 includes an internal integrated GPS patch antenna 314 and a cellular transceiver 316 contained in a housing 318. . . . It should be understood that the structure of GPS integrated PDA 310 is shown as illustrative of one type of integrated PDA navigation device. Other physical structures, such as a cellular telephone and a vehicle-mounted unit are contemplated within the scope of this invention.

'873 pat., col. 4, Ins. 59-67; col. 5, Ins. 1-2, 22-26. In the context of the '873 patent, the essence of a personal digital computer is that it must be capable of interacting with a GPS information system. The personal digital assistant can come in many forms, including cellular telephones and vehicle mounted units. Accordingly, I construe "personal digital assistant" to mean "a hand-held computing device with an integrated GPS receiver."

Personal Identification Number

Fenner maintains that a PIN is "a number corresponding to individual system users," while Defendants advocate, "a number, separate from a billing code, identifying an individual mobile user that permits someone to call the user using that number." At the hearing, the parties agreed to the following language, "a number, separate from a billing code, identifying an individual system user," but Defendants persist that the construction should conclude with their additional language "that permits someone to call the user using that number."

Defendants argue Fenner disclaimed claim scope by distinguishing a prior art code that, "does not permit someone to call the mobile user using the code." Amendment, 11/30/95 at 6. However, this portion of the prosecution history does not
amount to an express or unequivocal disclaimer as Defendants suggest. Middleton, Inc. v. Minn. Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed.Cir. 2002). The quote is the last line in a paragraph where Fenner principally described a prior art code, which identified, "a description of the services stored in a national database" that the user could, "temporarily program . . . into a local public telephone exchange, for use with a particular telephone number." Id. Fenner distinguished its PIN, which identifies a system user, from a code used to retrieve a set of personalized services. Fenner's statement that the prior art does not permit the user to be called is a permissive and relatively generalized statement, especially in view of the specificity with which the prior art was described. Without further discussion clarifying how the PIN participates in permitting the user to be called, this portion of the prosecution history cannot be characterized as an unequivocal disclaimer. Middleton, 311 F.3d at 1388.

Accordingly, the Court construes personal identification number to mean, "a number, separate from a billing code (as construed herein), identifying an individual system user."

3135

The '073 patent describes a system and method for providing an end user with a personalized page containing a list of links to the user's accounts. The links allow the user instant access to each account through login credentials stored with the personalized page. The '766 patent contains similar claims to the '073 patent, with the addition of the concept of "user-defined functions," which allow the user to, for example, set the system to update information on the user's personalized page on a periodic basis.

"Personalized page" and "stored personal pages" appear in both the '073 and '766 patents. n1 Yodlee believes that both terms are straightforward and require no construction. CashEdge disagrees, arguing that both terms should be limited to pages that "provide actual user access to Internet sites without being required to enter additional passwords or codes or other user input." In other words, CashEdge argues that a "personalized page" or "stored personal page" must take the user to a secured site when the user clicks on the corresponding hyperlink.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n1 "Personalized page" appears in independent claims 1, 18, and 36 of the '073 patent and independent claims 1 and 21 of the '766 patent. "Stored personal page" appears in independent claims 18 and 28 of the '073 patent, and independent claim 11 of the '766 patent.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

CashEdge's proposed limitation has some support in the specification, which provides "[i]n step 58 a user will, minimally, select a URL from his or her bookmarked destinations [in the personalized page], and as is known by hyperlink technology, the transparent URL will be invoked, and the user will navigate to that destination for the purpose of normal user interaction." '073 patent at col. 9, lines 31-35 (emphasis added); '766 patent, col. 9, lines 38-42 (emphasis added). In addition, the specification also provides that "after transparent log-on to an invoked destination [from a personalized page], the page at the destination is conveyed to and displayed for the user." '073 patent, col. 2, lines 60-62; '766 patent, col. 2, lines 64-66.

Both of these excerpts, however, are descriptions of embodiments of the invention. Because the claim terms themselves are not so limited, it would be inappropriate to "import[] limitations from the specification into the claims." Phillips, 415 F.3d at 1323. Accordingly, the Court agrees with Yodlee that these terms need not be construed.
With the disputed terms in bold, claim 2 states:

2. Apparatus according to claim 1, wherein there are at least two data signaling pairs connected between the data node and the access device to supply phantom power from the secondary source to the access device, and wherein said access device includes a pair of data transformers having center taps connected for locally powering the access device.

**Phantom Power**

The Court modifies Network-1’s proposed construction and construes the term as "operating power transmitted over the data signaling pairs." Network-1 omitted the word "operating" from its proposed construction. Phantom power is the power that is delivered to an access device over the data signaling pair as opposed to power delivered from a wall outlet. See Col. 3:44-45. The type of power delivered is operating power for the device, thus the Court includes the word "operating" in its construction.

Network-1 also used the phrase "over a data signaling pair" as opposed to D-Link's proposed construction, "over ... data signaling pairs." The term "phantom power" appears in Claim 2, which states "apparatus according to claim 1, wherein there are at least two data signaling pairs ...." Therefore, the Court construes the term as having "data signaling pairs," plural.

**3137**

Phantom power

Claim 2 of the '930 Patent contains the term "phantom power." Network-1 contends that the term means "operating power transmitted over the data signaling pairs that does not affect the simultaneous transfer of data," while Defendants contend that it means "operating power transmitted over the data signaling pairs." The parties disagree whether or not the term "phantom power" relates to the effect of power on data.

Network-1 asserts that the term signifies the transparency of the power to the data. Defendants counter that the term only signifies that power and data are both transmitted over the same signaling pairs.

Network-1’s proposed construction imposes an absolute condition on the phantom power, but the specification does not indicate that there is no effect on the data. Instead, the specification indicates that power on the signaling pairs does not prevent data transmission, and some effect on the data by the power does not prevent suitable data transmission operation over the network. See '930 Patent, col. 1:54-56. Accordingly, the Court adopts its construction in the D-Link case and Defendants' construction and construes the term "phantom power" to mean "operating power transmitted over the data signaling pairs."

**3138**

3. Phase shifted burst mode signals/phased burst signals/phased burst mode signals.

The court defines these terms to mean "a burst mode signal that is shifted in phase with respect to another burst mode signal." The court incorporates by reference its definition of burst mode signal.

**3139**

VI. Motion for Summary Judgment of Invalidity of Claim 6 n12
The Defendants' motion seeks summary judgment on Claims 6 and 7 of the '088 patent on the grounds of invalidity. Lectrolarm has not asserted that the Defendants infringed Claim 7 of the '088 patent, and there is no need for the court to consider whether Claim 7 is invalid.

Patent claims must "particularly point out and distinctly claim the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2. This requirement is known as definiteness. Determination of claim indefiniteness is a legal conclusion that is the responsibility of the court. Exxon Research and Engineering Co., v. United States, 265 F.3d 1371, 1376 (Fed. Cir. 2001). The test for definiteness is whether "one skilled in the art would understand the bounds of the claim when read in light of the specification." Id. at 1375. "Because a claim is presumed valid, a claim is indefinite only if the claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Honeywell Intern., Inc. v. International Trade Com'n, 341 F.3d 1332, 1338-39 (Fed. Cir. 2003) (emphasis added) (internal quotes and citations omitted).

The parties' dispute centers on the definition of the term "photocoupler." Lectrolarm argues that a photocoupler consists of a light-emitting and a light-receiving diode that are not necessarily located in the same discrete device. The Defendants contend that a photocoupler must be a discrete package containing both a light-emitting and a light-receiving diode.

Paragraphs 3 and 4 of Claim 6 involve the photocoupler:

- a photocoupler including a light-emitting element that transforms said electrical signal from said control box to a light signal, said light-emitting element being provided in said control box,

- said photocoupler further including a light-receiving element that transforms the light signal from said light-emitting element to an electrical signal and outputs the electrical signal to said rotating camera base, said light-receiving element being provided in said rotating camera base...

The specification discloses a definition of "photocoupler" consistent with that in the claims. The specification refers to light-emitting and light-receiving element pairs in discrete packages as photocouplers. The specification also describes light-receiving and light-emitting element pairs where the two elements are at different locations. Although the specification does not refer to this second configuration explicitly as a "photocoupler," it is obvious from the context of the patent that this is the "photocoupler" referred to in Claim 6.

The word photocoupler was added to the claim during the amendment process. The Defendants argue that to give "photocoupler" any meaning other than its ordinary meaning would impermissibly "read out of the claim the only element that preserved the issued Claim 6 from a finding of invalidity by the patent office." (Def.'s Post-Hearing Mem. Concerning Claim Interpretation Issues at 15.) To the contrary, the patent examiner rejected Claim 6 because communication between the two sides of the device using a light-emitting and receiving element pair and optical cable is a "well known technique" for communication and would have been "obvious to one of ordinary skill in the art." (Examiner's Action at 3 (January 18, 1990).) The attorney prosecuting the patent responded by adding the word "photocoupler" to paragraphs 3 and 4 of Claim 6. The attorney explained that the addition of the word "photocoupler" clarified that the optical link was not only a means of communication, but also a way to reduce noise. (Patent Attny.'s Resp. to Patent Rejection at 5-7.) This amendment, with its accompanying explanation, was accepted. Because the amendment purpose of noise reduction as well as communication the amendment did not limit the scope of the '088 patent.

The term "photocoupler" in Claim 6 is not insolubly ambiguous. Irrespective of the ordinary meaning of the term "photocoupler," a person of skill in the art reading the claims and specification of the '088 patent would understand that the patent uses the term "photocoupler" in a manner that encompasses light-emitting and light-receiving element pairs where the elements are at different locations and not in a discrete packet. Claim 6 of the '088 patent is not indefinite.
Physical Interface Connection Elements

In their briefing, the parties nearly agreed on the construction of this term: "Elements such as electrical pins and socket connections that link two discrete electronic external devices, allowing the devices to transfer information." Digi's proposed construction contained the additional italicized words. Digi argued the patent specification supports its inclusion of "such as electrical pins and socket connections":

"Generally the present invention comprises a connector having a housing which contains at least two physical interface connection elements such as electrical pins and socket connections, through the walls thereof, for connection to at least two external devices."

'470 patent, 1: 41-45. Lantronix did not dispute the inclusion of "such as electrical pins and socket connections." Lantronix did however argue that Digi's inclusion of "discrete electronic external" fundamentally misrepresents how the structures fit together. According to Lantronix, the "physical interface connection element" is the part of the connector at which each external device connects to the connector. Therefore, the connector as a whole links two discrete external devices, but a single physical interface connection element does not. A single physical interface connection element links the connector with one of the external devices.

During the hearing, the parties reached a compromise construction: "elements such as electrical pins and socket connections that link the connector to a discrete external electronic device." In light of the claim language and specification, this is an appropriate construction.

1. "Physical Layer" and "Physical Layer Modulation"

The court concludes that the term "physical layer" means "the lowest layer of the Open Systems Interconnect (OSI) seven layer model, concerned with establishing the mechanical, electrical, functional, and procedural connection between two modems." Similarly, "physical layer modulation" means "a protocol that is concerned with establishing the mechanical, electrical, functional, and procedural connection between two modems."

Physical Media Path

In an effort to come to an agreement on this term, both sides have changed their original positions and offered compromise constructions. Fenner proposes physical media path should be construed as, "any path or route which allows
the transfer of data packets to or from the node," and Defendants propose, "a path or route including a physical link which allows the transfer of data packets to and from the node." The Court construes "physical media path" to mean "a physical route or path which allows the transfer of data packets to and from the node."

--- Footnotes ---

n6 Fenner's original construction: a path or route corresponding to a physical layer link, such as ETHERNET, TOKEN RING, TOKEN BUS, FDDI and the like. Defendants original construction: a path or route including a physical link leading into and out of the communications node.

--- End Footnotes ---

Fenner's construction provides that the physical media path, "allows the transfer of data packets to or from the node" whereas Defendants' construction provides for "the transfer of data packets to and from the node." Although Fenner does not maintain the physical media path is a one-way path, the word "or" creates the possibility that the path either allows transfer to the node or from the node, but not both. Defendants' use of "and" will avoid that potential misunderstanding and properly describe the physical media path as facilitating transfer of data packets to the node as well as from the node.

The Court construes "physical media path" to mean "a physical route or path which allows the transfer of data packets to and from the node."

--- Footnotes ---

n7 The parties agreed to construe "data packet" as "a bit string of specifically arranged fields including address fields and a message data field."

--- End Footnotes ---

The next dispute involves references in Claim 1 of the '070 Patent to the "central picture element" and "surrounding picture elements." The entire phrase reads as follows: "a comparison circuit means responsive to said input video signal to compare a central picture element of said video signal to at least one of the surrounding picture elements of said video signal to determine the difference thereof to further compare said difference to a threshold . . . ." A related dispute centers on the term "neighboring pixels" in Claim 25 of the '070 Patent, which includes the phrase "comparing two neighboring pixels to determine the difference thereof."

Each of these claims concerns the aspect of the technology by which a given pixel is compared to the pixels around it, both spatially and temporally, in order to sharpen the pixel that is being compared. Defendant submits that the "central picture element" is "the pixel under consideration at a given time in the process," and that "surrounding picture elements" are "one or more picture elements which surround a central picture element in either time or space." Plaintiff wishes the Court to construe "central picture element" as "a sample of picture information being noise reduced." In addition, plaintiff objects to defendant's proposed construction of "surrounding picture elements" because the definition employs the word "surround," which plaintiff believes to be "entirely unhelpful in illuminating the proper meaning of the term." Pl.'s Reply at 19. Instead, plaintiff proposes that the Court construe "surrounding" to mean "nearby, proximate to, or within the environs/vicinity of."

Significantly, the parties have agreed that the terms "surrounding picture elements" and "neighboring pixels" should be construed in identical fashion. See Pl.'s Proposed Claim Constr. Order at 10. As such, the Court must construe the former term in a manner that is not inconsistent with the construction it would give to the latter.

The parties are not far apart on the meaning of "central picture element." Both parties understand the term to refer to a particular pixel that is undergoing the noise-reduction process taught by the '070 Patent. Plaintiff objects to defendant's
proposed construction because "various picture elements may be 'under consideration' at any point in time." This objection is well-taken. The Court will construe "central picture element" in the manner proposed by plaintiff.

The dispute over "surrounding" and "neighboring" pixels presents the issue of how far away from the central pixel the invention can go in its search for other pixels to compare to and/or combine with the central pixel. While discussion of this topic at the claim construction hearing revealed that the outer boundary is not well-defined, the parties agree that comparison is not limited to the pixels immediately adjacent to the central pixel. In light of this agreement, and in keeping with the precept that words in a claim "are generally given their ordinary and customary meaning," Vitronics, 90 F.3d at 1582, the Court will construe "surrounding picture element"--and, by extension, "neighboring pixels"--to mean one or more pixels sufficiently near the central pixel in time or space to be useful for the purpose of noise-reducing the central pixel. 6

In light of this construction of "neighboring pixels," the Court rejects plaintiff's proposed construction of the phrase "said elements which are normally combined" in Claim 43 of the '070 Patent. The "said elements" in that claim are "a first element and two neighboring elements." '070 Patent, Col. 16:36-37. The Court's construction of "neighboring" renders plaintiff's proposed construction of Claim 43, which seeks to specify that the combined elements are those that "potentially have noise reduction information about each other," superfluous.

The Court construes the term "pins" as "external connection points of a device." The Court finds that this construction comports with the relevant dictionary definitions submitted by the parties and most accurately reflects the meaning as understood by one of ordinary skill in the art.

Intergraph contends this term is defined in the claims as an identifier indicative of a processing pipeline for executing an associated individual instruction. Intel argues, however, that the specification and prosecution history of the '028 patents limit "pipeline identifier" to a "compiler-generated tag embedded within each instruction that identifies the explicit processing pipeline that will execute the instruction." While the prosecution history cited by Intel does support a requirement that instructions be "embedded," the history relates only to specific claims that included the term "embedded." This history in no way imposes an "embedded" requirement on every claim using the term "pipeline identifier." Further, Intel's citations fail to support its requirement that the identifier necessarily identify the explicit processing pipeline.

The Court construes "pipeline identifier" as a designation indicative of a processing pipeline. '028 patent 3:9-17; 5:15-17.

A. "Pipeline Identifier"

Intel first takes issue with the district court's construction of the claim term "pipeline identifier" found in both the '028 patent and the '003 patent. Pointing to the claim language, the specification, and the prosecution history, Intel argues that a "pipeline identifier" must identify the specific pipeline to which an instruction will be routed. Intel asserts that, under its proposed construction, the accused devices do not have "pipeline identifiers" because their templates do not identify specific
pipelines. Even under the district court's claim construction, however, Intel challenges as clearly erroneous the court's finding that the templates in the accused devices are "pipeline identifiers," arguing that the templates are not "unique" identifiers embedded within each syllable.

Intergraph responds that the district court correctly interpreted the term "pipeline identifier" to require only identification of the type of pipeline through which an instruction will be processed. Intergraph maintains that the claim language and the specification compel such an interpretation and that the specification's disclosure of a "specific" pipeline relates only to a preferred embodiment. According to Intergraph, the one prosecution history remark regarding a "specific" pipeline should not negate the contrary meaning found in the patent itself. With respect to infringement, Intergraph contends that the district court correctly found that the template bits associated with each instruction in the accused devices satisfy the "pipeline identifier" limitations.

We agree with Intel that the district court erred in its construction of the claim term "pipeline identifier." We commence our analysis, as we must, with the claim language. To begin with, some claim language can be read to suggest that a "pipeline identifier" identifies a particular pipeline. For example, claim 20 of the '028 patent recites "a unique pipeline identifier indicative of the processing pipeline which will execute that individual instruction." (emphases added). And claims 1 and 22 of the '003 patent refer to using "pipeline identifiers" to supply each individual instruction to "the appropriate instruction pipeline." (emphasis added). At the same time, however, other claim language can be read to suggest that a "pipeline identifier" need not identify a specific pipeline. For instance, claim 20 also recites "using the unique pipeline identifiers . . . [to control switches and] thereby supply each individual instruction in the at least one group to be executed in parallel to an appropriate processing pipeline." (emphasis added). Claim 6 of the '003 patent similarly refers to using "pipeline identifiers" to supply each instruction to "an appropriate instruction pipeline." (emphasis added). Still, that language does not clarify the degree of specificity required by the term "pipeline identifier," for both the specific pipeline that will execute an instruction and the type of pipeline that will execute an instruction are "appropriate" pipelines. We therefore read the claim language as being susceptible to both parties' proposed definitions.

4 Both parties argue, and we agree, that the term "pipeline identifier" should be interpreted consistently throughout the claims in each patent. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001).

5 Intergraph argues that Figures 12 and 13 of the '028 patent illustrate "pipeline identifiers" that identify pipelines by type. Those figures, however, illustrate an instruction frame and a group of instructions. They, along with their accompanying text, depict instruction types and group tags but, importantly, do not show "pipeline identifiers." See '028 patent, col. 10, ll. 44-67. We therefore find Figures 12 and 13 to be unhelpful to our interpretation of the term "pipeline identifier."

On the other hand, the specifications also contain statements suggesting that a "pipeline identifier" need identify only the type of pipeline to which an instruction will be routed. For example, both specifications explain that, in some embodiments,
the compiler's determination of "the appropriate pipeline for execution of an individual instruction . . . . is essentially a
determination of the type of instruction provided." '028 patent, col. 6, ll. 56-59 (emphasis added); '003 patent, col. 3, ll. 64-
67 (emphasis added). That statement is qualified, however, by the following sentence, which provides examples of pipeline
types and states that "load instructions will be sent to the load pipeline [and] store instructions to the store pipeline." '028
patent, col. 6, ll. 59-61 (emphases added); '003 patent, col. 3, l. 67 to col. 4, l. 2 (emphases added). Similarly, the statement
that "preferably, the pipeline tag will correspond to the type of functional unit required for execution of [an] instruction" is
qualified by its ensuing example, which identifies a particular execution unit--namely, "floating point unit 1." '028 patent,
col. 3, ll. 15-17 (emphasis added). Thus, the two examples that refer to identifying pipelines by type actually identify
specific pipelines. We therefore find them to be of little assistance to our claim construction analysis. 6

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 Elsewhere, the specifications, like the claim language, ambivalently disclose that a "pipeline identifier" determines "an
appropriate pipeline." E.g., '028 patent, col. 3, ll. 13, 28-29; see also '028 patent, col. 5, ll. 31-32 (stating that each
instruction in a group is routed to "its appropriate pipeline, as determined by the pipeline tag of the instruction").

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Finally, we arrive at the prosecution history, which, unfortunately for Intergraph, resolves any ambivalence. A patentee may,
of course, act as his own lexicographer and define a claim term in either the specification or the prosecution history.
Mycogen Plant Sci., Inc. v. Monsanto Co., 243 F.3d 1316, 1327 (Fed. Cir. 2001). We conclude that Intergraph did just that
during prosecution of the '028 patent. In the first office action, the examiner rejected claims 1-23 as indefinite under 35
U.S.C. § 112, stating, among other reasons, that it was "unclear what constitutes a pipeline identifier" in claims 20 and 21.
In response, Intergraph amended claim 20 and explained that a "pipeline identifier" is a "tag . . . indicative of the specific
processing pipeline to which [an] instruction will be dispatched." (emphasis added). With that statement, Intergraph clearly
and unambiguously defined the term "pipeline identifier" as referring to the particular pipeline to which an instruction will
be routed, and Intergraph cannot now obtain a broader interpretation of that term. See Honeywell Inc. v. Victor Co. of Japan,
298 F.3d 1317, 1323-24 (Fed. Cir. 2003).

Nevertheless, Intergraph argues that that prosecution history statement referred only to a preferred embodiment and
therefore should not be applied to limit the scope of the claims. We disagree. The examiner's question regarding the meaning
of the term "pipeline identifier" was raised in the context of rejecting claim 20, so Intergraph's response is at least relevant to
that claim's use of the term. Moreover, just before defining the term "pipeline identifier," Intergraph stated in its response to
the examiner that the "pipeline identifiers are described throughout the specification, for example, beginning on page 8 at
line 15." Although the text at page 8, line 15 does indeed appear to refer to the embodiment depicted in Figure 1, Intergraph
explicitly identified its discussion of pipeline identifiers as occurring "throughout the specification," with the page 8, line 15
reference being only one example of its use of the term. We therefore read Intergraph's prosecution history statement as not
being limited in scope to a preferred embodiment, but rather as indicating the meaning that Intergraph ascribed to the term
"pipeline identifier" throughout the '028 patent.

Intergraph's statement made during prosecution of the '028 patent is also relevant to our interpretation of the '003 patent.
Because the claim language and the specification of the '003 patent have not resolved the ambiguity surrounding the term
"pipeline identifier," we find the prosecution history of the '028 patent to be highly relevant to our construction of the term
"pipeline identifier" in the '003 patent. The '003 patent incorporates by reference copending U.S. Patent Application
08/147,800, which led to the '028 patent, and more particularly cites that application for a description of the overall system
within which the '003 patent's "associative crossbar switch" is implemented. '003 patent, col. 2, ll. 52-58. Because the
overall system disclosed in the '800 application plainly includes "pipeline identifiers" and because the two patents in suit
contain overlapping (and at times identical) claim language and disclosures regarding "pipeline identifiers," we consider that
Intergraph intended that term to have the same meaning in both patents. We therefore apply Intergraph's definition of the
term "pipeline identifier" made during prosecution of the '028 patent to the '003 patent as well.

In sum, we conclude that Intergraph expressly defined the term "pipeline identifier" during prosecution of the '028 patent. In
light of that prosecution history, as well as the claim language and the specifications, we hold that, for both the '028 patent
and the '003 patent, a "pipeline identifier" must identify the specific processing pipeline to which an instruction will be
dispatched.

- 3453 -
Having revised the district court's construction of the claim term "pipeline identifier," we turn next to the question of infringement. Unfortunately, we are unable to determine from the record whether the templates in the accused devices identify the specific pipelines to which instructions will be routed, and the district court made no findings of fact regarding that aspect of the accused devices. We therefore vacate the district court's finding of infringement and remand for the court to determine in the first instance whether the accused devices have "pipeline identifiers" under our construction of that term.

A. "Pit"

Plaintiff's construction: an area which creates a difference in reflected light to represent information

Defendants' construction: depression in the surrounding land area, where the depth is the principal factor creating a difference in reflected light intensity for encoding information

The parties' dispute boils down to whether the "pits" referenced in claim 1 and dependent claim 2 of the '651 patent should be limited to actual physical depressions in the disc. Defendants argue in favor of this limitation, contending that the language of the patent is directed at pre-recorded optical discs that have stamped or embossed pits. Defendants rely heavily on the '651 patent specification and preferred embodiment. Plaintiff disagrees that the patent claim or specification requires the term "pit" to be so limited and provides examples of intrinsic and extrinsic evidence in support of its theory that the ordinary meaning of "pit" at the time the patent application was filed included non-stamped "pits" formed on recordable and rewritable discs by color change, laser ablation or phase-change technology.

The "ordinary and customary" meaning of "pits" is not apparent from the claim language itself. Thus, I turn to the patent specification for guidance in construing the term. The abstract, written summary of the invention and description of the figures in the patent support defendants' proposed construction of the term because only pits that are physical depressions comport with the descriptions provided in the patent. The patent teaches that the shape and depth of embossed pits in the substrate of the disc affects a disc player's ability accurately to read pits. '651 patent, 5:58-65. The specification depicts examples of pits having a depth "hm." Id., Fig. 4 (showing range of depths from 2/32 to 8/32); Fig. 6 (depth = 0.2 [mu] m); Fig. 7 (depth = 0.2 [mu] m); Fig. 8 (depth = 0.2 [mu] m); Fig. 9 (depth = 0.2 [mu] m); Fig. 16 (depicting perspective view of pits and lands, showing depths of pits).

In the abstract and in numerous places throughout the specification, the inventors describe "the present invention" as a disc on which information is recorded as "trapezoidally shaped" pits whose upper width, lower width and angle of inner walls fall within a certain range of values. Id., Abstract, 2:40-44, 55-59; 3:1-4. Specifically, the patent teaches that the "ideal" pits should be trapezoidally shaped, with a wide top, inclining walls and a narrower bottom. Id., Fig. 13. When describing the basic concept of the invention, the inventors state that:

According to the present invention, there is provided an optical disk which enables the track pitch to be made much smaller in order to achieve a much higher density and greater capacity . . . by optimizing the pit shape . . . . Hereinafter, the pit shape in the present invention will be described in detail.

Id., 5:58-65. The inventors go on to describe the shape of the pit in detail by referring to Figure 1 in the patent:

FIG. 1 is an explanatory diagram of the shape of a pit in an optical disk according to the present invention. As shown in the figure, the shape of a pit 10 is approximated by a shape with a trapezoidal cross section. The inner wall 11 of the pit 10 is inclined downward and its bottom portion 12 is almost flat. Numerical 13 indicates the cross section of the pit 10 along the radius of the optical disk (the track width direction); Wm the size of the top of the pit 10 across the track width (hereinafter the upper width); Wi the size of the bottom of the pit 10 across the track width (hereinafter the lower width); hm the depth of the pit 10, Zm the length of the pit 10 along the track; and [THETA] represents the angle of the inner wall of the pit 10 (the angle that the inner wall forms with respect to the surface of the optical disc).

As the inventors explain in the written description of the invention, "[b]y setting various parameters of the pit shape at the above-described values, the amount of crosstalk between adjacent tracks is suppressed . . . " Id., 3:21-24. Later in the patent, the inventors explain Figure 4, stating that "[t]o minimize a decrease in the push-pull signal level and obtain the maximum playback signal level, it is desirable from FIG. 4 that the pit depth should be approximately \[\text{l}/5, preferably in the range of \[\text{l}/5.2 to \[\text{l}/5.2\] ." Id., 6:55-59. When explaining Figure 6, the inventors state that "it can be seen that crosstalk changes greatly with the pit shape." Finally, in explaining Figure 16B, the inventors state that in an "optical disk according to the present invention . . . one surface of each transparent substrates . . . is embossed with pits . . . ." Id., 8:48-51 (emphasis added).

These myriad references to embossed, trapezoidal-shaped pits, pit depth and angled pit-walls support defendants' argument that a person of ordinary skill in the art of optical discs, considering the context of the claim language and patent specification, would understand "pit" as used in the patent to mean a pit that is three-dimensional and depressed into the substrate of the disc. Only a pit that is a physical depression could have trapezoidal shape, depth, a wide top, a narrower bottom and angled walls. Further, only a pit that has a depth can create the best combination of push-pull signal and minimal cross-talk to increase the capacity of the disc.

Plaintiff raises several arguments in opposition to defendants' proposed construction, but none is persuasive. First, plaintiff contends that the language of claim 1 shows that the inventors deliberately claimed a broad set of "pits" so as to not limit the scope of the invention to stamped or embossed pits that have depth in prerecorded discs. In particular, plaintiff contends that although claim 1 includes an equation with values or variables for track pitch, light beam wavelength, lens numerical aperture, radial tilt and substrate thickness, claim 1 does not include a variable for pit dimensions.

Plaintiff points to related patents to support their argument: U.S. Patent No. 5,592,464 (the '464 patent) and U.S. Patent No. 5,459,712 (the '712 patent). The '464 patent is the "parent" of the '651 patent and claims pits of certain depths and dimensions. Marshall Decl., Ex. A, dkt. 73, '464 patent, claim 1. Similarly, the "grandparent" of the '651 patent, the '712 patent, claims a trapezoidal-shaped pit having specific upper and lower widths and inner walls of a specific angle. Id., Ex. B, '712 patent, claims 1 and 2. Plaintiff contends that the fact that the inventors claimed specific pit dimensions in the parent and grandparent patents but did not do so in the '651 patent indicates that the inventors wanted the '651 patent to have a broader scope than the previous patents. In other words, the patentees knew how to write claims so that they would cover a specific type of pit, and although the inventors discuss pit depth and size in the '651 specification, they intentionally declined to include such values in the claim so as to broaden the scope of the invention to include pits formed by laser ablation, color change or phase change. This argument is unpersuasive.

Plaintiff's argument ignores the fact that all three patents refer to a pit as a trapezoidally-shaped depression in the substrate. Given that the pits in the '464, '712 and '651 patents are all similar, it stands to reason that the '651 pits should be given a meaning that would make sense for all three patents. That meaning is that pits that are physical depressions. As plaintiff notes, the parent and grandparent patents claim specific pit dimensions (e.g., '464 patent, claim 1, dkt. 73, at 11:1-5), while the '651 patent does not; because of this, I agree with plaintiffs up to this point: in drafting the '651 patent, the patentees were claiming a broader set of pits than in the previous patents. But it is an illogical and off-target to infer that this difference expands the '651 patent to include pits without depths. Rather, this choice expands the patent to cover embossed pits with depths other than those specifically claimed in the parent and grandparent patents.

Plaintiff's second argument is based on the doctrine of "claim differentiation." Claims 1 and 2 state only that there are a "plurality of pit trains" including a "plurality of pits." Claim 6, which is part of an apparatus claim in the patent and not asserted in this lawsuit, claims:

An optical disk apparatus according to claim 5, wherein said sensing means produces a push-pull signal and a playback signal, said push-pull signal representing a difference between signals sense in at least two areas along a track of said optical disk, and wherein each of said pits has a depth to enable both said push-pull signal and said playback signal to have large levels.
'651 patent, 12:3-9 (emphasis added).

Plaintiff contends that because claim 6 requires pits to have a depth, the pits in claim 1 and 2 encompass pits without depth because they have no such limiting language. Plaintiff cites Intamin Ltd. v. Magnetar Technologies, Corp., 483 F.3d 1328, 1335 (Fed. Cir. 2007), in which the court of appeals concluded that the claim term "intermediary" was not limited to "nonmagnetic" intermediaries, in part because a dependant claim specifically claimed an embodiment in which the intermediary was non-magnetic. Id. The court explained that the "dependant claim show[ed] both that the claim drafter perceived a distinction between magnetic and non-magnetic intermediaries and that independent claim 1 impliedly embraced magnetic intermediaries." Id.

However, claim differentiation does not apply in this case. Claim 6 of the '651 patent does not differentiate pits with depth from pits without depth. Instead, it claims pits with a depth sufficient "to enable both said push-pull signal and said playback signal to have large levels." '651 patent, 12:8-9. Thus, the pits in claim 6 are differentiated from pits that do not have sufficient depth for this particular playback purpose.

Plaintiff's third argument is that restricting "pit" to only embossed or stamped pits would import a limitation from one embodiment into the claims. Plaintiff points to language in the specification stating that "the invention in its broader aspects is not limited to the specific details, and representative devices shown and described herein." Id., 10:46-48. Similarly, the Court of Appeals for the Federal Circuit has warned repeatedly against confining claims to specific embodiments of the invention. E.g., Phillips, 415 F.3d at 1323. This warning applies even where, as here, there is only one embodiment described in a specification. Id.

Duly noted. But that is not what this court is doing. Many of the cited passages from the specification arose in the context of explaining "the present invention," not merely an embodiment. The specification makes clear that embossed and stamped pits have been tested to optimize disc capacity and work with the invention. Therefore, it is appropriate to apply this limitation to the invention as a whole. Verizon Services Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1308 (Fed. Cir. 2007) ("When a patent thus describes the features of the 'present invention' as a whole, this description limits the scope of the invention."); Honeywell International, Inc., v. ITT Industries, Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006) (written description discussing "this invention" and "the present invention" may limit claim scope); C.R. Bard, Inc. v. United States Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) ("Statements that describe the invention as a whole, rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term.").

Further, although the patentees refer to other types of embodiments, this does not mean that the claim can be applied to embodiments without embossed pits, it means that the claim could be applied to discs with embossed pits whose dimensions are different from those illustrated in the patent.

Fourth, plaintiff contends that prior art cited in the patent indicates that "pit" covers multiple types of physical changes. In the '651 patent, the inventors identify as prior art U.S. Patent No. 4,587,648 (the '648 patent), which was issued on May 6, 1986. In the discussion of its invention, an "Optical Disk," the '648 patent identifies multiple ways to form pits, including pits formed by high intensity laser beams. Hesselink Decl., Ex. F, dkt. 78, 1:16-21, 65-66. The '651 patent also cites as prior art U.S. Patent No. 5,274,623 (the '623 patent), which was issued on December 28, 1993. Hesselink Resp. Decl., Ex. G, dkt. 85. The '623 patent's specification discusses recordable and rewritable media and how "pits" are formed through chemical or physical changes on that media. Id., Abstract.

It's true that if a patent applicant cites to prior art, then the use of a term in the prior art is intrinsic evidence that "can have particular value as a guide to the proper construction of the term, because it may indicate not only the meaning of the term to persons skilled in the art, but also that the patentee intended to adopt that meaning." Arthur A. Collins, Inc. v. Northern Telecom Ltd., 216 F.3d 1042, 1045 (Fed. Cir. 2000). However, it "is rare that references that were submitted with a disclosure document, but not even cited by the examiner, are probative of an intent to depart from the plain technical meaning of terms used in the specification and claims." Osram GmbH v. International Trade Commission, 505 F.3d 1351, 1358 (Fed. Cir. 2007). In this case, there is no evidence that the patentee or patent examiner discussed or cited the '648 or '623 patents.

As discussed above, the '651 patent specification provides a clear and consistent meaning for the term "pit" by referring repeatedly to pits as having depth and shape, consistent with the pits in pre-recorded optical discs. It would be improper to use the '623 and '648 patents to construe the meaning of the term pit in a manner contrary to the teachings of the patent.
Vitronics, 90 F.3d at 1584-85 ("Once again, however, reliance on such [prior art] evidence is unnecessary, and indeed, improper, when the disputed terms can be understood from a careful reading of the public record. Nor may it be used to vary claim terms from how they are defined, even implicitly, in the specification or file history.") (internal citations omitted).

Finally, plaintiff cites several examples of extrinsic references that existed at the time the '651 application was filed, including patents, patent applications and a computer science doctoral dissertation, in which the authors use the term "pit" in discussing multiple types of physical changes to record information on optical discs. Plf.'s Resp. Br., dkt. 84, at 13-16. Plaintiff also points to the testimony of its expert, Professor Hesselink, to explain the knowledge of a person of ordinary skill in the art at the time of the invention. There is no dispute that at the time, the term "pit" could have had a broader meaning than that endorsed by this court, but in the '651 patent it didn't, as is clear from the unequivocal language throughout the patent specification. Thus, it is unnecessary to evaluate extrinsic references and expert testimony to discern a meaning. Vitronics, 90 F.3d at 1584-85. Plaintiff simply cannot overcome the evidence in the patent itself regarding the term pit.

Defendants' proposed construction of the term "pit" captures the meaning of pits as used in the patent and applied by the inventors. See Kinetic Concepts, Inc. v. Blue Sky Medical Group, Inc., 554 F.3d 1010, 1019 (Fed. Cir. 2009) (rejecting broad construction of "wound" because "[a]ll of the examples described in the specification involve skin wounds" and a broader construction would "expand the scope of the claims far beyond anything described in the specification"); Decisioning.com, Inc. v. Federated Department Stores, Inc., 527 F.3d 1300, 1311 (Fed. Cir. 2008) (construing the term "remote interface" to exclude personal computers in part because the features of the remote interface, as set forth in the specification, "do no evoke the use of consumer-owned personal computers."); Phillips, 415 F.3d at 1316 ("Ultimately, the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventors actually invented and intended to envelop with the claim.").

As detailed above, the patent specification repeatedly illustrates and describes the "pit" as a three-dimensional depression that is embossed in the substrate of the disc. This depth creates a difference in reflected light that allows the player to read information from the disc. Thus, the phrase "depression in the surrounding land area" in defendants' construction captures the physical characteristics of the pits, without limiting the construction with details regarding the specific size or shape of the pits. The phrase "where the depth is the principal factor creating a difference in reflected light intensity for encoding information" captures the function of the pits because the depth of the pits creates a difference in the intensity of light reflected between the pits and the lands. This difference in light intensity enables the sensor in a disc player to determine if a pit or land is being read and then reproduce the encoded information. In sum, I agree with defendants that "pits" as used in the '651 patent means pits that are actual physical depressions on the substrate of the disc where the depth is the principal factor creating a difference in reflected light intensity for encoding information.

**Court's construction:** depression in the surrounding land area, where the depth is the principal factor creating a difference in reflected light intensity for encoding information

3149

A. "Pit"

Plaintiff's construction: an area which creates a difference in reflected light to represent information

Defendants' construction: depression in the surrounding land area, where the depth is the principal factor creating a difference in reflected light intensity for encoding information

The parties' dispute regarding "pits" is the same dispute they had with respect to the '651 patent. That is, the parties dispute whether "pits" referenced in claim 1 of the '751 patent should be limited to actual physical depressions in the disc. Defendants contend that it should be so limited, and plaintiff disagrees. Both parties contend that the term "pit" should be construed the same for both the '651 and '751 patents, each side championing its own definition. While this could be the appropriate outcome, it is not ineluctable, and neither party has convinced the court that it is correct on this point.

Plaintiff contends only that it is "clear that both patents cover a broader array of discs" and thus should be construed the
same. Transcript, dkt. 92, at 10. But as noted in the previous section, the '651 patent defines "pit" much more narrowly than plaintiff advocates.

Defendants contend that "there is no indication in the '751 patent that Toshiba meant something different than what it meant in the '651 patent." Defs.' Br., dkt. 71, at 34. "Toshiba," however, was not the inventor of the '651 or '751 patented inventions. In fact, although both patents are assigned to plaintiff, the patents have different inventors. When queried at the claims construction hearing, defendants suggested that the term "pit" should be construed the same for both patents because the patent applications were filed in 1994 and 1995 by the same law firm, the applications were examined by the same patent examiner and the inventors were colleagues. Hrg. Tran., dkt. 92, at 61-63. These are not persuasive reasons to construe terms in separate patents in the same way; indeed they border on non sequiturs. It's not surprising that inventors in the same field would be colleagues and would retain the same law firm for patent applications; this tells us nothing about their actual inventions. As always, the best way to determine the meaning of the term "pit" as used in the '751 patent is to consider the claim language, patent specification and other evidence.

The meaning of "pit" is not readily apparent from claim 1 itself, which sheds little light on what type of pits can form the test pattern. Therefore, I turn to the patent specification to determine the meaning of the term as it is used in the '751 patent. Unlike the '651 patent specification, the '751 patent specification does not describe the figures or descriptions contained with as depicting "the present invention." Instead, the specification states that the examples are "embodiments" of the invention. '751 patent, 9:8-9. The section entitled "Detailed Description of the Preferred Embodiments" states:

As is know[n], the optical disk 10 can have various structures. This optical disk 10 may be a read only disk on which data is recorded at a high density as shown in Figure 3.

* * *

[In] the data recording area . . . reproduction information, video data, sub-picture data and audio data are recorded as pits (i.e. physical changes) . . . . For the read only optical disk 10, rows of pits are previously formed on the transparent substrate 14 by a stamper, a reflection layer is vapor-deposited on the pits-formed transparent substrate 14, and this reflection layer is formed as the recording layer 16. In the read only optical disk 10, normally, grooves as tracks are not provided but pit rows formed on the transparent substrate 14 are specified as tracks.

This excerpt from the specification provides useful insight into the inventor's concept of "pits."

Defendants are correct that the process described for forming pits on a substrate is used only for pre-recorded discs and creates pits that are actual physical depressions. Thus, it is clear that the inventors chose to use a pre-recorded optical disc as an example to explain their test pattern invention. However, the statement also indicates that the inventors knew that optical discs come in other forms, including discs that are not pre-recorded, read-only discs. The specification states that the disc "may be" a read only disc, not that it "is" or that it "must be." Also, the inventors reference discs that have "grooves as tracks," explaining that normally, read only discs do not have grooves. Recordable discs do have grooves. Immink Decl., dkt. 79, at 13. Further, the specification states that data is recorded as "pits (i.e. physical changes)," and then says that in read only discs, these pits are formed by a stamper. Notwithstanding the grammatical awkwardness noted above, courts still presume when construing claims that inventors choose their words carefully. Phillips, 415 F.3d at 1313-14. Here, the inventors could have said "pits (i.e. depressions)" or "pits (i.e. stamped data points)." Instead, they used the broad phrase "physical changes," indicating that there is more than one possible type of physical change that could create a pit, especially in discs that are not read only discs.

Later in the specification, the inventors describe the process for creating the "read only disk 10." In particular, the specification states that

[A] description will now be given of a method of recording evaluation data together with picture data and management data for reproducing the picture data on the optical disk, and a recording system to which this recording method is adapted.

'751 patent, 18:6-9 (emphasis added).
The inventors then describe the process for creating a read-only disc 10. Id., 18; 19. The inventors describe how the test pattern invention can be used to evaluate the disc that "was manufactured by the above-described method." Id., 20:47-49. The test pattern can determine whether the pits were formed correctly and whether there is enough of a difference between the pits and surrounding land that a player can distinguish between the two and reproduce the recorded information. Id., 20:64-65.

At the claims construction hearing, defendants contended that this discussion in the patent specification regarding the creation and evaluation of a read-only disc makes it clear that the test pattern invention was directed solely at evaluating pits in prerecorded --ROM discs. Transcript, dkt. 92, at 80-87. However, as I noted above, the specification does not describe this process as the invention. The specification says this recording process is "a method" of recording evaluation data, and the resulting disc is an "embodiment." '751 patent, 18:7, 20:36. There is no evidence that the test pattern claimed in the patent would not evaluate data that was recorded on discs through other methods or embodiments. Presumably, it is important for data areas ("pits" or "marks") on recordable and rewritable discs to be distinguishable from the land area so that a player may read and reproduce the information.

A description of one preferred embodiment cannot be read into the claim unless the specification makes it clear that the description relates to the invention as a whole rather than to one example. Phillips, 415 F.3d at 1323. Defendants have not shown this for the '751 patent. These inventors did not use the phrase "the present invention" when describing pits, nor did they otherwise state that depressed pits are "required" or necessary. Rather, the '751 specification refers to the optical disk 10 in Figures 3 and 4 as one "embodiment." This makes sense because unlike the '651 patented invention, the invention in the '751 patent is not related to or affected by pit depth or dimensions.

Further, defendants point to nothing in the specification suggesting that the inventors used Figures 3 and 4 as anything more than a simplified form of what an optical disc may look like for purposes of demonstration. Because the '751 patent is not related to pit shape and size, it makes sense that the inventors would not find it necessary to describe every type of possible pit, disc structure or method of manufacturing optical discs. The inventors describe only one type of disc in order to explain the test pattern invention.

As already noted above in construing "pit" for the '651 patent, the Court of Appeals for the Federal Circuit has "repeatedly warned" against limiting the scope of a claim on the basis of a preferred embodiment. Phillips, 415 F.3d at 1323. An embodiment may serve to limit a claim only if it is clear that the patentee intends the claims and embodiments to be strictly coextensive, id., or the examples used make it clear that a limitation was intended. On Demand Machine Corp. v. Ingram Industries, Inc., 442 F.3d 1331, 1339-40 (Fed. Cir. 2006) (limitation warranted because specification used the term "customer" repeatedly in specialized context); Nystrom v. TREX Co., Inc., 424 F.3d 1136, 1144-45 (Fed. Cir. 2005) (limitation warranted because written description and prosecution history consistently used the term "board" to refer to wood decking materials cut from a log). Nowhere else in the '751 patent is there any indication that this embodiment represents the only type of pits used in the invention as a whole.

Although I conclude that the '751 specification does not limit the term "pit" to physical depressions, nothing in the claim terms or the specification of the '751 patent provides an adequate definition for the term. Therefore, I must turn to other evidence to determine whether plaintiff's or defendants' proposed construction is accurate. The parties rely on a number of extrinsic reference documents and dueling expert opinions to support their arguments. As for the latter, this case presents a clear example of why expert evidence may be of limited value in claim construction. Plaintiff's expert states that "a person of ordinary skill in the art would consider 'pit' as referenced in the '651 and '751 patents to be any area which creates a difference in reflected light to represent information." Hesselink Decl., dkt. 78, at 10. Defendants' expert takes the opposite position, asserting that at the time the '751 patent was filed "a person of ordinary skill in the field of optical data storage, having read these patents, would have understood the term 'pit' to refer to a depression in the land area of the disc substrate . . . ." Mansuripur Decl., dkt. 71, at 14; Immink Decl., dkt. 79, at 20.

More useful are the extrinsic documents. Plaintiff points to a number of extrinsic documents indicating that the meaning of "pit" covers multiple types of physical changes. For example, U.S. Patent No. 4,190,843 issued in 1980, entitled "Recording Methods for a Multilayer Optical Record," states that when a recording laser is focused on an optical disc, "the peak intensity of the focused light sufficient to cause ablation of the absorbative layer, an information track is formed as a succession of spaced pits in which the reflecting layer is effectively exposed." Hesselink Decl., Ex. B, dkt. 78, at 2
Similarly, in a computer science doctoral dissertation published by the University of California at Berkeley in 1995, the author discusses the process of data storage on recordable discs, stating that

During writing, in response to an electrical input signal, a highly-charged focused laser beam can melt a small region of the metal layer, opening a hole or 'pit.' Later, during reading, a lower-intensity, unmodulated laser beam is reflected off the surface of the disk. A photodetector interprets information stored on the disk by detecting differences in reflectivity between pits and the surface of the thin metal layer, called the 'land.' Data are encoded and stored as alternating regions of pits and land.

Plaintiff points to several other extrinsic references that refer to "pits" as being created by various methods, all of which amount to a data area that creates a difference in reflected light to represent information. E.g., U.S. Patent No. 4,551,413, id. at P 21; U.S. Patent No. 5,084,370, id., Ex. E; Japanese patent application number S60-79227, id., Ex. G; U.S. Patent No. 6,156,482, Hesselink Resp. Decl., Ex. A, dkt. 85; U.S. Patent No. 5,325,351, id., Ex. B; and U.S. Patent No. 5,495,466, id., Ex. C.

Defendants attempt to rebut this evidence with examples of patents that use the term "pit" to describe pits with depth. Mansuripur Decl., dkt. 82, at 8-11. However, the fact that another patent that covers pre-recorded discs describes a pit as having depth does not mean that a person of ordinary skill in the art would conclude that pits in the '751 patent must have depth. Defendants do not dispute that technology, such as color change, laser ablation and phase change, existed in 1994 and was used for encoding data on other products. It is clear from the extrinsic evidence provided by plaintiff that people in the optical disc field were using "pit" to describe information recorded by various methods. The recorded information creates a difference in reflected light that can be read by a player to reproduce information. Thus, I conclude that plaintiff's definition of "pit" is appropriate for the '751 patent.

Court's construction: an area which creates a difference in reflected light to represent information

3150

c. "Pixel" and "Image Element"

The next two terms we must consider, "pixel" and "image element," are undeniably related, but the issue we need to decide is the extent of their similarity. IP differentiates between these two concepts; Lexmark and Dell ask that they be considered synonymous. n6 According to IP, "pixel" refers to the smallest complete element of an image, and it can be formed of subpixels that contribute to the formation of a complete element but that are not complete in themselves. IP urges a broader construction for "image element" as any element found within an image, including complete pixels, portions of pixels, and other elements of images that are not pixel-related. n7 Lexmark and Dell insist that "pixel" and "image element" are interchangeable. In their opinion, both terms refer to the smallest electronically coded part of an electronically coded input image. When the terms are used in the context of discussing a display device, Lexmark and Dell argue that they must mean the smallest addressable element of the display device.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n6 In the joint claim construction chart, the parties also indicate that the meaning of the term "plurality" is disputed, but they offer no development of that issue. In light of the absence of a crystallized dispute, we offer no construction of that term.

n7 Examples could include the RGB components of a video signal or the yellow, cyan, and magenta components of a single pixel used in color laser printing.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

An examination of the intrinsic evidence reveals that IP has the better argument. For example, the specification of the 780 patent states that "voids in the image may be filled with all or a portion of a pixel," which is consistent with IP's position.
that pixels can be formed of subpixels. U.S. Patent No. 5,424,780, col. 4, Ins. 50-51; see also col. 5, Ins. 48-50 ("New pixels or pixels used for filling, substitution or replacement may be comprised of all or a portion of a pixel."). Examples could include the RGB components of a video signal or the yellow, cyan, and magenta components of a single pixel used in laser printing.

Although in many circumstances the patents use the terms interchangeably, that is not inconsistent with IP's proposed definitions, wherein all pixels are image elements, but not all image elements are pixels. Though the intrinsic evidence from the 780 patent does not provide a great deal of illumination on these issues, the language of the 637 patent directly supports IP's position. The parties agree, and we concur, that the terms "image element" and "pixel" should be construed consistently as to both patents, so the guidance provided by the 637 patent clarifies the meaning of these terms in the 780 patent as well. Dependent claims 34, 51, 140, and 161 all have one limitation that states: "image elements are pixels." Here again, the doctrine of claim differentiation provides helpful guidance. See Comark, 156 F.3d at 1187. When applied to these four claims, the doctrine supports the conclusion that the image elements referenced in the independent claim are not always pixels, which indicates that they should not be treated as synonyms.

Furthermore, though the intrinsic evidence gives no indication that Cooper intended these terms to carry an idiosyncratic meaning, Lexmark and Dell's proposed definition adds in requirements that pixels and image elements must be an addressable element contained in electronically coded input image. They have not provided convincing support that these aspects are included in the ordinary and customary meaning of these terms, nor have they shown that Cooper intended to use these terms in an idiosyncratic way. See Phillips, 415 F.3d at 1312.

Therefore, we construe "pixel" to mean the smallest complete element of an image and "image element" to mean any element of an image, whether complete or not and whether pixel-related or not.

---

3151

i. Pixel

The term "pixel" is used throughout the '780 family of patents, including contested claims 15, 110, and 146 of the '780 patent, claims 1 and 107 of the '637 patent, and claims 4 and 10 of the '964 patent. Claim 15 serves as an example of how the term "pixel" is used within the patents. Both parties agree that the term should be construed consistently throughout the three patents-in-suit, and thus the meaning the Court adopts with respect to the '780 patent will apply to the '637 and '964 patents as well.

IPI contends that the term "pixel" is an acronym for "picture element" and is defined as the smallest complete element of an image. According to IPI, pixels can be formed of sub pixels, which themselves are not considered complete pixels as defined above. Sony argues that IPI's proffered definition is incomplete, as it does not take into account that the meaning of pixel is dependent on whether it is being used in the context of an electronically coded image or in an electronic display device. Instead, Sony asserts that the better definition is the following one set forth in the McGraw-Hill technical dictionary: "the smallest part of an electronically coded picture image" or "the smallest addressable element in an electronic display; a short form for picture element..." n1 McGraw-Hill Dictionary of Scientific and Technical Terms 1436 (4th ed. 1989).

n1 Sony first defines pixel to mean "the smallest part of an electronically coded picture image, and the smallest addressable element in an electronic display." Def's Brief at 4 (emphasis added). It later inserts an "or" in place of the "and." Because the Court has not adopted Sony's definition, it is unnecessary to address the discrepancy.

---

When defining terms, courts are directed to give words their broadest reasonable construction that is consistent with the use of the term in the patent. See In re Am. Acad. of Sci. Tech Ctr., 367 F.3d 1359, 1364 (Fed. Cir. 2004). In this instance, as defendant avers, the definition of pixel is highly context dependent. See Def's Brief at 4. IPI's definition more fully encompasses the range of meanings for pixel, as it is not obvious from the patent that the term is used only in the context of
III. Pixel and Image Element

Plaintiffs propose to construe the term "pixel" (‘964 Patent, claim 1; ‘929 Patent, claims 1, 16, 32, 48) broadly, as the smallest complete element of an image and propose to construe the term "image element" (‘964 Patent, claim 1) as encompassing pixels and pels as well as sub pixels and sub pels, noting that an element of an image may be something other than a pixel. Defendants propose to construe both terms more narrowly, defining "pixel" as the smallest independently addressable location capable of being displayed on a display device and "image element" as one or more pixels.

Defendants point out, and Defendants agree, that in Sony and Lexmark Plaintiffs' proposed claim construction prevailed. 2005 U.S. Dist. LEXIS 17962, 2005 WL 2035578, at *3-*4; 424 F.Supp.2d at 1087-88. Defendants contend, however, that these prior constructions addressed the '780 and '637 Patents and that, in Sony, the court's constructions extended to the '964 Patent only to the extent that both parties agreed that the term should be construed consistently among the three patents involved in that case. Defendants contend that the parties have not agreed to such a construction in this case. However, as discussed above, the claim constructions in Sony and Lexmark are applicable to the instant claim construction, and in accordance with Miken, the prior constructions are part of the prosecution history in this case. Thus, it is unnecessary for the parties to have a prior agreement for adopting constructions since the prior constructions in this case are part of the intrinsic record.

Defendants also argue that although the terms "pixel" and "image element" appear in both prior patents and the current ones, we should disregard the claim constructions in Sony and Lexmark since the '780 Patent contains a different specification, and the language of the claims in the '637 Patent is not identical to the language in the claims in this case. In regard to differences in specification and claim language, both the Sony and Lexmark courts construed the '637 Patent consistently even though it was a continuation-in-part of the '780 Patent, meaning that it necessarily added material not disclosed in the '780 Patent, its parent patent. The '964 and '929 Patents, as divisional patents, disclose and claim the same subject matter as their parent, the '637 Patent. If the Sony and Lexmark courts construed a continuation-in-part, with new material consistently, then it necessarily follows that a court also construe divisional patents, with no new material, consistently.

Defendants also argue that the '780 and '637 Patents "are not at issue here and were held unenforceable." (D CL C 10). Defendants indicate early in the main body of their opening claim construction brief, that a prior judge "ruled unenforceable the '780 and '637 patents because of inventor Carl Cooper's inequitable conduct in prosecuting those patents." (D CL C 1). In addition, Defendants present arguments later in their opening claim construction brief concerning the unenforceability of the patents. (D CL C 10, 15). Plaintiffs contend that Defendants' statements and arguments are misleading, since the judge who made the unenforceability ruling subsequently vacated that ruling. Despite the fact that Defendants present various arguments regarding unenforceability premised on the prior ruling, Defendants in fact concede in a footnote on page 1 of their opening brief that the ruling was vacated. New Medium LLC v. Barco N.V., 2009 U.S. Dist. LEXIS 38767, 2009 WL 2385890 (N.D. Ill. 2009)(vacating a prior order, 582 F.Supp.2d 991 (N.D. Ill. 2008), which had declared the '780 and '637 Patents unenforceable). Therefore, we construe the terms "pixel" (‘964 Patent, claim 1; ‘929 Patent, claims 1, 16, 32, 48) and "image element" (‘964 Patent, claim 1) in a manner consistent with Plaintiffs' proposed construction.

f. "A pixel interpolator for generating values representing pixels interstitial to pixel values represented by said processed video signal;"
The parties dispute the meaning of the phrase "a pixel interpolator for generating values representing pixels interstitial to pixel values represented by said processed video signal." As stated above in section II.B.2.d., the court finds that this claim element is not a means-plus-function element. The term "pixel interpolator" means a device that calculates spatially interpolated pixel values, from the pixel values of a previous image, which approximate the values of fractionally offset pixels between pixels. See col. 22:64-23:13; col. 25:36-41. As noted above, the term "interstitial" is defined as relating to or situated within the space between things closely set. See Webster's Third New Int'l Dictionary 1183 (Unabridged ed. 1986); see also Fig. 9A (illustrating interstitial pixels).

1. Literal Infringement

A literal infringement analysis requires two separate steps. First, the claims asserted to be infringed must be construed to determine their meaning and scope. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 U.S.P.Q.2D (BNA) 1321, 1326 (Fed. Cir. 1995) (in banc). Second, the claims as construed are compared to the allegedly infringing device. Id. To infringe, the accused device must contain every limitation of the asserted claim. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1535, 19 U.S.P.Q.2D (BNA) 1367, -1369 (Fed. Cir. 1991).

On appeal, Gussin argues that summary judgment was inappropriate because genuine issues of material fact exist regarding the construction of the asserted claims. In particular, Gussin asserts that the declarations of his experts, the admissions of Nintendo's experts during depositions, and the prosecution history of the '335 patent create genuine issues of material fact precluding summary judgment.

This court recently rejected similar arguments concerning claim construction in Markman v. Westview Instruments, Inc., 52 F.3d 967, 34 U.S.P.Q.2D (BNA) 1321 (Fed. Cir. 1995) (in banc), in which we held that claim construction is a question of law amenable to summary judgment. The alleged conflicting opinions of both parties' experts do not create genuine issues of fact precluding summary judgment as to the meaning of the claims at issue. See Markman, 52 F.3d at 983, 34 U.S.P.Q.2D (BNA) at 1333 ("When 'legal' experts offer their conflicting views of how the patent should be construed, . . . such conflict does not create a question of fact . . . ."). Therefore, we reject Gussin's argument that summary judgment was inappropriate.

Gussin further argues that the court improperly construed the "pixel memory" limitation of claims 1 and 2. We disagree. The court properly construed the claims, based on the specification and prosecution history, to require a pixel memory that stores actual color data, instead of one that stores "pointers" to a memory separate from the pixel memory.

Both claims 1 and 2 state that the "color data" to be stored in the pixel memory should be the "color of the cursor." Specifically, claim 1 requires a "pixel memory comprising a random access memory (RAM)" into which "the color and position of the cursor on the video monitor are written." Col. 9, 11. 49-58. Claim 2, as amended after reexamination, requires "a pixel memory comprising a random access memory, and means operative in said first mode to store the commanded color of the cursor in said pixel memory." Reexamination Certificate B1 4,782,355, col. 2, 11. 23-25. Thus, both claims require storage of the color of the cursor in the pixel memory rather than permitting the pixel memory to store pointers to color data stored in a separate color memory.

The specification and the prosecution history further make clear that the claims, as properly construed, only read on devices that store actual color data in the pixel memory. The patent specification describes the "color data" of the present invention as consisting of "a single six bit data word in which two bits represent the intensity of the color red, two bits represent the intensity of the color blue and two bits represent the intensity of the color green." Col. 5, 11. 64-68, and col. 6, 11. 1-3. As
Figure 2 of the patent illustrates, Gussin discloses the use of two memories for storing the color data: a color ROM and a pixel memory. The specification describes the interaction of these two memories:

Information as to a picture to be displayed on video monitor 20 is represented electronically by data words stored in the pixel memory 46 at addresses corresponding to the address of the pixels of the video monitor 20. . . . The position of the joystick 24 determines a six bit color data word from the color ROM 44 which is enabled onto data lines coupled into the pixel memory 46 . . . . The six bit color data word from the color ROM 44 is recorded at the address [in the pixel memory] corresponding to the coordinates of the pixel on the video monitor 20 at which the cursor 18 is located.

Col. 6, 11. 16-36. The specification consistently refers to the data that are transferred from the color ROM and stored in the pixel memory as consisting of actual "color data," not a pointer to a separate memory containing the actual color data.

The prosecution history further supports a claim construction requiring the storage of actual color data in the pixel memory. During reexamination of the patent, Gussin distinguished his claimed invention from the '867 patent issued to Hill. The '867 patent discloses a home entertainment system that, like the invention disclosed in Gussin's '335 patent, allows a user to draw and paint color images on a conventional television monitor. In its "Office Action in Reexamination," the PTO rejected claim 2 under 35 U.S.C. § 102(b) as being anticipated by the '867 patent. The PTO further rejected claim 1 under 35 U.S.C. § 103 as being unpatentable over the '867 patent in view of other prior art.

Gussin filed a "Response to Office Action in Reexamination," in which he distinguished his claims from the '867 patent. Gussin argued:

The PTO also fails to understand important differences between the function of the pixel memory in claim 1 of the '335 patent and the pixel memory in Mr. Hill's color palette systems. In Gussin's claim 1, the pixel memory receives and stores digital signals representing the actual color of the cursor. In Mr. Hill's color palette systems, the pixel memory does not receive or store a signal representing the actual color of the cursor. Instead, Mr. Hill's pixel memory receives, and stores a color pointer, namely a signal representing the address of a color in the separate color memory of Hill's color palette systems [emphasis added].

In support, Gussin filed the declaration of Hill, the named inventor of the '867 patent, which stated:

The devices described in the '335 patent, claims 1 and 2, directly store in a pixel memory the digital value corresponding to the color that the operator has commanded to produce on the screen of a color TV receiver or monitor. The devices described in my '867 patent require an additional color memory to store the digital representation of the color values that the operator creates by mixing together various proportions of the primary colors or by adjusting the hue, saturation and brightness of the signals [emphasis added].

Gussin also submitted a declaration in which he argued that claims 1 and 2 were patentable over the '867 patent because "the products described in my '335 patent do not include color memory or color mixing means as described in the '867 patent . . . ."

Gussin asserts that these arguments were limited to distinguishing Gussin's claims from the '867 patent based on the use of a separate memory that stores "user-mixed" colors. Gussin therefore argues that the pixel memory limitation should be broadly construed to cover any pixel memory system that stores "pre-mixed" colors. We disagree that Gussin's arguments during reexamination were so limited.

While it is true that Gussin distinguished the claimed invention from Hill during prosecution based on the storage of "user-mixed" colors instead of "pre-mixed" colors, Gussin also distinguished the claims from the '867 patent based on the way the pixel memory operates. He consistently argued before the PTO that his invention was distinguishable from the '867 patent because he did not claim a pixel memory that stores a color pointer instead of actual color data. In fact, the examiner specifically noted this distinction when he allowed claim 1: 3

None of the references . . . teach a "random access memory" wherein the "color and position of the cursor on the video monitor are written into said pixel memory", lines 16 and 24-25 of claim 1. Hill does not store color data into the pixel memory, rather he uses the pixel memory to address a second memory which acts as a color palette [emphasis in original].
Gussin argues that the examiner's statement in the March 10, 1993 "Office Action in Reexamination" that the "'335 patent is actually a two-memory system" is inconsistent with our claim construction. To the contrary, the examiner's complete statement adds support to our claim construction:

The '335 patent is actually a two-memory system. Figure 2 of the '335 patent shows a color memory 44 ("COLOR ROM") and a "PIXEL MEMORY" 46. Memory 46 of the '335 patent is similar to memory 164 of the '867 patent and memory 44 of the '335 patent is similar to memory 166 of the '867 patent, i.e. one is a pixel memory and the other is a color memory. How these two memories interact is different. In the '867 patent the pixel memory reads data out to the address port of the color memory. The '335 patent reads color data into the pixel memory to be stored. Therefore the '867 patent does not store color cursor data in it's [sic] pixel memory [emphasis in original].

The examiner, accepting Gussin's argument in his "Response to Office Action in Reexamination," merely emphasized the difference between how the pixel memory in each system interacts with the rest of its respective system - the key distinction being that "the '867 patent does not store color cursor data in it's [sic] pixel memory." Based on the foregoing, we conclude that claims 1 and 2, as properly construed, require that the pixel memory store actual color data, not merely pointers to color data stored in a separate memory.

Finally, Gussin argues that even if the claims require that the pixel memory store actual color data, genuine issues of material fact exist as to whether Nintendo's SNES device meets this limitation. In support, Gussin claims that Nintendo's expert witnesses admitted in their declarations and during depositions that the SNES stores actual color data. However, the declarations indicate instead that the pixel memory in the SNES device stores pointers rather than actual color data, and the deposition testimony relied upon by Gussin is not inconsistent with these declarations. Thus, Gussin has failed to establish the existence of any genuine issue of material fact regarding the operation of the pixel memory of the SNES device.

We need not address Gussin's other asserted errors in the district court's claim construction and infringement analysis. Our determination that Nintendo's SNES device does not meet the pixel memory limitation as properly construed is sufficient to cause us to affirm the trial court's grant of summary judgment that Nintendo's device does not literally infringe. See Lantech, Inc. v. Keip Mach. Co., 32 F.3d 542, 547, 31 U.S.P.Q.2D (BNA) 1666, 1671 (Fed. Cir. 1994) ("For literal infringement, each limitation of the claim must be met by the accused device exactly, any deviation from the claim precluding a finding of infringement.").
"The pixels of the ballot image are stored in a TIFF, BMP or other bitmapped or pixelated format, for each mark space are tested to determine whether it is a 'light' (e.g., not marked) pixel or a 'dark' (e.g., marked) pixel." (Col. 21, ll. 1-7) "If a sufficient portion of the tested pixels in a given marked space are 'dark' pixels, then that mark space is considered to be marked, . . ." (Col. 21, ll. 11-13) The specification teaches that the ballot image is captured by a ballot reader, and the ballot must be read to determine which mark space has been marked significantly to count as a voting selection. (Col. 22, ll. 60-64) "The ballot reader produces an image . . . that is preferably in a pixelated or bitmapped format, e.g., a TIFF or a BMP image, or other bitmapped format." (Col. 22, l. 65 to Col. 23, l. 2.)

Figures 10A, 10B, and 10C illustrate the desired markings on pixels, and the specification teaches the process. "The maximum number of pixels that a mark could darken . . . is determined by subtracting the number of pixels of the outline of mark space from the total number of pixels in reading region." (Col. 23, ll. 37-42) There is a predetermined threshold of dark marked pixels that is established to determine whether a mark space has been "marked (voted)." (Col. 23, ll. 44-50.) The pixel intensity or brightness is tested, and each pixel is determined to be either "light" or "dark." (Col. 25, ll. 58-61.)

Nothing in the specification teaches that the pixelated or bitmapped format must be "a viewable electronic reproduction of an actual document." The ballot image is captured by a ballot reader to determine the mark spaces or pixels. The ballot reader produces an image in a pixelated or bitmapped format. The pixelated or bitmapped format is a collection of data that represents the location, density, and darkness of the number of individual pixels. There is a considerable amount of support in the specification that provides for the darkness of a pixel as the determinating factor on whether a mark space has been marked to indicate a voting selection.

For the foregoing reasons, the Court construes the terms "pixelated or bitmapped format" as follows:

A collection of data elements representing the individual pixels of the ballot image such that the darkness of each pixel may be determined. The images are typically stored in formats such as .BMP, or .TIFF, or other bitmapped format.

E. Ref. No. 86 "Pixels."

This term is recited in or referred to in Claims 47 and 48.

The sole dispute on the construction of this term is that Defendants include the word "distinct" in defining pixels and Plaintiff does not. Defendants cite no authority for the use of the term "distinct." The Court will rely on those specification references cited in the discussion on Ref. No. 79, supra. Column 7, lines 36-49 teaches that "each mark space is in a predetermined position relative to indicia or fiducial marks," and "[w]here ballots are imaged, the positions of each indicia or fiducial mark is defined in the same coordinate system as are the pixels of the ballot image . . . ." Id. Further explanation of pixels is contained in Column 25, lines 29-57 and Figures 10A, 10B, and 10C. Figure 10C clearly shows the pixels in a distinct location on the ballot. Regardless, in Defendants' construction, the term "distinct" defines "data." There is no support for this construction in the specification.

For the foregoing reasons, the Court construes "pixels" as: Ballot image data elements.

"placing"

The parties agree on the plain meaning of the word "placing," but JVL takes issue with what it sees as Merit's collapse of the terms "options" and "choices" into the single term "item". JVL's proposed construction of "placing" is "putting the selectable game menu option into a particular desired location in the display of the chosen game menu choice." Def.'s '717 Presentation at 31. Merit's is "putting the selectable game menu options item into a particular desired location in the display of the chosen game menu choice item." Thus, the constructions are identical, except Merit inserts "item" after "options" and
There is no question that "game menu options" and "game menu choices" are different things. It does not appear that Merit presumes otherwise. However, Merit does not offer adequate justification for inclusion of "item" in its construction, stating simply that "[w]hat is displayed or shown on the video screen are symbols, or items, representing the actual video games." Pl.'s Opening Markman Br. at 18. There is no rationale offered for equating "symbols" and "items." Nor has Merit offered any explanation, based on the specification or otherwise, of why the word "item" is necessary. It is understood that the symbols or icons displayed on the screen represent video games. "Item" does not clarify this point. Thus, it is not imported into the meaning of the term. No construction of "placing" is required.

B. "a step of placing an amount of liquid crystal on plural locations on the first substrate"

Plaintiff argues that "a step of placing an amount of liquid crystal on plural locations on the first substrate" should be construed to mean "depositing an amount of a liquid crystal material in multiple locations on a substrate." Defendants argue that the phrase should be construed to mean "depositing an amount of liquid crystal material in multiple locations on a substrate." The parties' constructions differ in only one respect: whether the invention is limited to displays filled with "a" liquid crystal material-a single type.

The parties have reversed roles for this claim term, plaintiff arguing for a limitation based on the description of the invention in the specification, and defendants arguing that the claim language is broader than what is expressly described. Plaintiff notes that the specification describes only one type of liquid crystal material-"octyl-oxy-benzyli-dene-amino-methylebuthyl-benzoate." Id. at 2:66-67. The specification introduces this example by stating that "[o]n the oriented surface is placed an amount of liquid crystal 2 such as S8 (octyl-oxy-benzyli-dene-amino-methylebuthyl-benzoate)." As with other patent terms construed in this order and in this patent (such as "substrate," supra), the language in the specification is deliberately open-ended, allowing the claims to encompass other liquid crystal materials. The court will not limit the scope of the claims to the embodiments in the specification unless there is some reason to do so.

Plaintiff argues that the claims should be read only to include other single liquid crystal materials. As defendants note, however, the claims do not require placing an amount of "a" liquid crystal material; rather, they require placing "an amount of liquid crystal material."

Plaintiff also argues that the prior art, in which an already-sealed LCD is filled with liquid crystal material through capillary action, can only accommodate a single liquid crystal material. If so, then the claimed invention has a further advantage over the prior art: the ability to accommodate multiple different materials.

Finally, plaintiff argues that using the claimed invention with multiple liquid crystal materials would eliminate the "efficiencies" of the claimed invention, such as the ability to fill the LCD more quickly. Plaintiff provides no basis, either in the intrinsic record or through extrinsic testimony, for reaching that conclusion.

The court therefore adopts defendants' proposed construction, "depositing an amount of liquid crystal material in multiple locations on a substrate".

VII. "placing the FCC unit under control of a computerized control device and thereby . . ." '236 patent, col. 16, ll. 11-12.

Plaintiff defines this phrase as "controlling the FCC unit and/or equipment normally associated with the FCC unit by virtue of addition or withholding of catalyst additive such as by a valve regulated by a computerized control device." 71

Defendants contend that no construction is necessary. 72
The Court finds that the specification confirms Plaintiff's view that the FCC unit is controlled by adding or withholding catalyst additive by a valve regulated by a computer. The specification teaches that "control over an FCC unit operating according to the general teachings of this patent disclosure will be achieved through only addition of (or withholding of) a particular catalyst additive to solve a particular problem. ..." '236 patent, col. 7, ll. 51-55 (emphasis added). It also teaches, by reference to Figure 1, that "the entrainment of the catalyst 14 into the stream of plant air 34 is preferably controlled by valve 58 which is, in turn, most preferably regulated and monitored by a computer memory and control device 70." Id., col. 15, ll. 23-26. "The objective and contemporaneous record provided by the intrinsic evidence is the most reliable guide to help the court determine which of the possible meanings of the terms in question was intended by the inventor to particularly point out and distinctly claim the invention." Texas Digital, 308 F.3d at 1203 (citation omitted). Accordingly, the Court concludes that the phrase "placing the FCC unit under control of a computerized control device and thereby . . ." means "placing the FCC unit under control through the addition or withholding of catalyst additive by a valve regulated by a computerized control device and thereby. . .".

3160

3. Claim 10: "planar filters" "Planar filters" is construed to mean "two or more non-cavity resonator, essentially flat surface, film devices for separating, according to radio frequency, signals received on the communication pathways, each communication pathway having a pre-assigned radio frequency."

3161

1. Second Planarizing Pattern (Claims 22 and 23)

Matsushita argues "second planarizing pattern" should be construed as "a pattern for making flatter in shape." Mediatek argues 'second planarizing pattern" should be construed as "a pattern formed of at least one indiscrete figure formed in the (first) wiring layer and in an area other than the vicinity of any wiring pattern." 1

The Court finds, for the reasons stated by Matsushita, "second planarizing pattern" is properly construed as "a second pattern for making flatter in shape."
or whether it involves a Z coordinate as well. The parties do not dispute that the calculation occurs prior to the inspection, or run-time. Scanner asserts that the term is defined as a calculation of a representation of a calibration plane in two dimensions where a three dimensional model is formed by views from two different cameras. (Scanner Post-Hr. Br. at 14). ICOS asserts that the term includes the calculation of the Z=0 world plane during the calibration process. (ICOS Post-Hr. Br. at 22).

Figure 2B is "a flow chart illustrating the steps within the pre[-]calculated calibration process." (Tr. at 144, ll. 1-3). The final step of Figure 2B, step 114, states "define X and Y world coordinates." Step 114 does not include any reference to determining the Z=0 world plane. (See Fig. 2B). According to the written specification describing step 114, however, the process includes determining the Z=0 world plane as well. (See Col. 7, ll. 6-8 ("In step 114 the processor defines the X and Y world coordinate and the Z=0 plane.").) Because the description of Figure 2B expressly states that the processor defines the Z=0 world plane, the term "pre-calculated calibration plane" is construed to define the X and Y world coordinate and the Z=0 world plane.

D. Construction of "Plasma"

1.

The district court did not explicitly construe the now-disputed claim limitation of "plasma." However, the district court's opinion did provide the following working definition of the term "plasma" in its discussion of the technology of the '223 patent:

Plasma is a charged collection of particles. It has no shape or form. Although the density of the plasma can vary in different locations, the plasma reaction occurs throughout the chamber. During the ionization process, charged particles are created that strike all of the surfaces on the interior of the chamber.

Opinion, slip op. at 2-3 (citations to the record omitted).

TEA asserts that the district court improperly relied on extrinsic evidence in "construing" the term plasma and that the intrinsic evidence, particularly the prosecution history, "unambiguously defines 'plasma' to mean a 'glow discharge.'" TEA maintains that a glow discharge is a particular type of plasma characterized by having a current within a specific range, and argues that Tegal relied on this distinction in the prosecution history of the '223 patent to obtain allowance.

Tegal responds that the district court never construed the term "plasma" because TEA failed to identify it as a disputed term, and that TEA has therefore waived any argument concerning the meaning of this term. Tegal states that TEA failed to identify "plasma" as a disputed term in its Markman brief, its Rule 26 Expert's report, its expert's deposition, any pre-trial filing or trial brief, or its opening statement at trial. Tegal alleges that TEA first raised the issue during trial and then again in post-trial briefing. Tegal also responds that the intrinsic evidence supports a broad construction of "plasma" and that TEA improperly resorts to extrinsic evidence for its narrower definition of glow discharge.

2.

Although it is unclear why the parties did not identify the term "plasma" as a disputed claim limitation before trial, it is not disputed that they did so at trial. If Tegal thinks that TEA waited too late, Tegal should have prevailed upon the district court to exclude TEA's evidence of what "plasma" meant. The term having been brought into dispute at trial, and the district court having addressed the term in its opinion, albeit informally, we do not consider the issue to have been waived. Cf. Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1426, 44 U.S.P.Q.2d (BNA) 1103, 1108 (Fed. Cir. 1997) ("With a few notable exceptions, . . . appellate courts do not consider a party's new theories, lodged first on appeal. If a litigant seeks to show error in a trial court's overlooking an argument, it must first present that argument to the trial court.").

As with "electrode" above, we need not address each of the parties' claim construction arguments directly, but proceed to construe the term "plasma" according to the normal rules of claim construction. Looking to the claims, we note that the term
"plasma" occurs only in claim preambles. '223 Reexam. Cert., col. 1, l. 28 (claim 1), col. 1, l. 43 (claim 2), col. 2, l. 8 (claim 6), col. 2, l. 19 (claim 7). Preambles are not necessarily limiting. Kropa v. Robie, 38 C.C.P.A. 858, 187 F.2d 150, 152, 88 U.S.P.Q. (BNA) 478, 481 (CCPA 1951) (stating that a preamble is limiting when it is "necessary to give life, meaning and vitality to the claims or counts"). However, the parties do not dispute that "plasma" is a limiting term in the claims at issue and, at least for the reason that we have construed "electrode" in terms of "plasma," we agree. The term "plasma" is not limited to any narrow definition by its use in the claims. It is also clear that "plasma" is a term of art susceptible to various meanings, so we go to the specification, as indeed the parties direct us, to determine the scope of this term.

The specification also supports a broad construction of "plasma," in which the "plasma" need only contain ions and be generated by electric fields. As explained earlier, the specification states that the plasma is "generated by the high and/or low frequency electric fields established between the electrodes." '223 patent, col. 1, ll. 55-57. The specification also emphasizes the need to control both the density and the energy of the ions in the plasma, thus focusing on the fact that the plasma must contain ions. Id. at col. 1, l. 39, col. 2, ll. 15-24, col. 3, ll. 37-42. Beyond the obvious requirement that there be ions in the plasma, to perform the ion bombardment, the specification does not impose further requirements and uses the term "plasma" in a broad sense. The various examples illustrate that the plasma can be created from a variety of gases and used at a variety of operational settings (power, duration of exposure, frequencies, pressures). Id. at cols. 4-5. Further, there is no indication in the specification that the claimed invention is to be restricted even to these illustrated ranges.

The prosecution history primarily reinforces the specification's broad use of the term "plasma." TEA first argues that Tegal equated "plasma" with a "glow discharge." We agree. Tegal used the terms "discharge" and "plasma" interchangeably, or even together as in "plasma discharge," in referring to the prior art references and the claimed invention. For example, Tegal refers to: (1) the claimed invention's plasma as a discharge; (2) the Cotton reference as disclosing either a discharge or a plasma; and (3) the Chapman reference as disclosing either a discharge or a plasma. Tegal also equated the claimed "plasma" with a "glow discharge," stating that a "plasma in accordance with the present invention is a glow discharge," and that the claimed "invention relates to apparatus for processing semiconductor wafers in a plasma glow discharge."

TEA's second argument, however, is that Tegal's use of the term "glow discharge" is limiting and is defined by its current. We disagree. TEA relies on a figure from a physics book, published approximately ten years after the '223 patent issued. The figure shows that a "glow discharge" is differentiated from other discharges by the amount of current flowing through the discharge. In order of ascending current flow, ranging from approximately 10-10 amps to 10 amps, the figure depicts a Townsend discharge, a glow discharge, an "abnormal glow discharge," and an arc discharge. TEA's reliance on this figure is misplaced. Neither the claims, the specification, nor the prosecution history even suggest that the claimed plasma is limited to the particular range of current TEA proposes, and TEA's use of extrinsic evidence to establish such a contrary proposition is improper. Interactive Gift Express, 231 F.3d at 866, 56 U.S.P.Q.2D (BNA) at 1652-53.

Although Tegal did not restrict the claimed "plasma" to the current range proffered by TEA, Tegal did distinguish the claimed "plasma" from the discharge of the Cotton reference. Tegal's statement, quoted above, that "[a] plasma in accordance with the present invention is a glow discharge," was followed by the statement that "Cotton, on the other hand, is concerned primarily with an arc discharge." Tegal also characterized the Cotton discharge as a spike discharge, emanating from a spiked electrode at frequencies up to 300 GHz. Accordingly, "plasma" must be construed so as not to cover a spike or arc discharge emanating from a spiked electrode.

In sum, we construe "plasma" as a charged collection of particles, generated by the high and/or low frequency electric fields established between the electrodes, excluding arc or spike discharges such as would emanate from a spiked electrode.

In the TEA litigation, the district court construed the term "plasma" to mean "a charged collection of particles." On appeal in that case, we modified that interpretation: "we construe 'plasma' as a charged collection of particles, generated by the high and/or low frequency electric fields established between the electrodes, excluding arc or spike discharges such as would emanate from a spiked electrode." Tegal, 257 F.3d at 1345, 59 U.S.P.Q.2D (BNA) at 1396.

In the present case, the district court adopted the construction of "plasma" suggested by Tegal:
The terms "plasma" and "glow discharge" are used interchangeably in the '223 specification and claim language and have the same meaning. "Plasma" means excited species created by the application of one or more rf frequencies to reactant gases within a reaction volume. The levels of dissociation within the plasma and the levels of ion energy across the plasma sheath will vary at different locations within the reaction volume. Ion bombardment takes place where the plasma couples to electrode surfaces, causing etching and sputtering at those surfaces. An arc discharge is not a plasma within the meaning of the '223.

The district court's construction of "plasma" is based on statements in the specification to the effect that a plasma is an excited species of the reactants and can be generated at a wide range of pressures. TEL argues that plasma should be interpreted to mean a "glow discharge" (see claim 7) having specific numerical ranges of plasma density and electron temperature. TEL argues that the intrinsic evidence fails to define "glow discharge," and that it provided the only extrinsic evidence on the topic, which shows that the term is limited to its proposed specific ranges.

As we noted in our July 16, 2001 opinion, the prosecution history supports equating the term "plasma" with "glow discharge" in the '223 patent. Tegal, 257 F.3d at 1345, 59 U.S.P.Q.2D (BNA) at 1395. In remarks distinguishing the Cotton reference during reexamination, the patentee stated, "[a] plasma in accordance with the present invention is a glow discharge. Cotton, on the other hand, is concerned primarily with an arc discharge." Id. However, we noted that use of the term "glow discharge" is not necessarily limiting at all, much less restrictive in a quantitative manner. Id.

Like the district court, we find no support in the record to support TEL's arguments for a quantitative definition of "plasma." Claim 7 was amended during reexamination to recite "glow discharge," but no other claims were so amended. The evidence does not show that "glow discharge" means what TEL proposes, and there is no evidence that a person having ordinary skill in the art would interpret "glow discharge" any differently from the construction we adopted in the TEA litigation. We see no reason to deviate from the construction we applied on appeal in the TEA litigation, and therefore we adopt the construction of "plasma" set forth in that opinion. See id. 59 U.S.P.Q.2D (BNA) at 1396.

A. "Plasma Etching"

Samsung argues that "plasma etching" as used in the Ingrey patent has a narrow meaning. Samsung contends plasma etching means: a strictly chemical process where the wafer being etched sits in a plasma, there is no bias potential (electrical charge) intentionally applied and the pressure is so high that there is negligible ion bombardment, for purposes of etching the wafer by direct involvement of the plasma, and which results in isotropic etching. Samsung identifies a number of differences between the process it practices -- reactive-ion etching -- and its definition of plasma etching as used in the Ingrey patent.

Northern Telecom, on the other hand, argues that plasma etching as envisioned by the Ingrey patent encompasses etching conducted in a broad range of reactors and under different process conditions, so long as the initial step involves a gaseous trihalide, comprising at least in part a boron trihalide, which is broken up in a radio frequency plasma into chemically active radicals that react with aluminum and aluminum oxide to form a volatile compound that can easily be removed from the etching chamber. This definition includes reactive ion etching as practiced by Samsung. Put another way, Northern Telecom contends the Ingrey patent does not exclude processes in which mechanisms in addition to the chemical reactions in a plasma -- e.g., ion bombardment of the work surface -- contribute to the etching.

Although plasma etching is not defined in the Ingrey patent's claims themselves, it is described in the specifications as follows:

In plasma etching, etchant gas molecules are broken up in an RF plasma into chemically active radicals that react with the workpiece, etching occurs and, if the reaction products are volatile, the reaction will continue until one or other of the reactants is completely removed.

Hess Decl., Ex. A (Ingrey patent), col. 1, 1.37-42. Northern Telecom argues the court need only look to this definition to determine the meaning of plasma etching in the claims, while Samsung argues that the meaning of plasma etching must also
be interpreted in light of the prosecution history, the remainder of the patent specifications, and relevant extrinsic evidence.

While it is axiomatic that neither the prosecution history nor the specifications can be used to enlarge, diminish or vary the limitations of the claims, nothing in this rule implies the court should not consider both the specifications and the prosecution history in interpreting what the claims mean. See Markman, 52 F.3d at 980. Indeed, the Federal Circuit has clearly held that courts should interpret the meaning of claim language with reference to such evidence. Id. Accordingly, the court will consider the specifications and the prosecution history in determining the meaning of the terms used in the claims.

1. Prosecution History/File Wrapper Estoppel

The centerpiece of Samsung's claim construction argument are statements made by Northern Telecom to the Patent Examiner in the "Remarks" section of its January 7, 1997 Response to the Examiner's initial rejection. See MacPherson Decl., Ex. J (Response). Northern Telecom contends that the Remarks are irrelevant because the Examiner had already determined that claims in the amended form would be allowable, see Londen Decl., Ex. I (PTO Office Action), and thus the Examiner did not rely on the Remarks.

A patentee who construes the claims in a patent application narrowly before the Patent Office is estopped from later construing them broadly before the courts. Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 399 (Ct. Cl. 1967), cert. denied, 434 U.S. 1051, 54 L. Ed. 2d 804, 98 S. Ct. 903 (1978). Assertions made by a patent applicant to the Patent and Trademark Office in support of patentability are part of the file wrapper or prosecution history and may be used to interpret the claims and define their terms. Id. at 398-99. 12

Footnotes

End Footnotes

Here, it is not at all clear that the Examiner did not rely on the Remarks. While the Examiner had indicated that with the suggested amendments the claims would be allowable, the Examiner did not actually issue the Notice of Allowance until February 4, 1977, after receiving the Response which contained both the amendments and the Remarks. See Supp. MacPherson Decl., Ex. B (communication from Examiner closing prosecution on merits in view of January 17, 1977 response). Thus, it is reasonable to assume that the Examiner at least read the Remarks prior to issuing the Notice. However, whether or not the Examiner relied on the Remarks, the Federal Circuit has clearly stated that such representations, whether or not made to secure patentability, may estop the patentee from subsequently advancing a contrary interpretation and are relevant to ascertaining what the applicant meant by terms used in the claims. See E.I. Du Pont De Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1438 (Fed. Cir.), cert. denied, 488 U.S. 986, 102 L. Ed. 2d 572, 109 S. Ct. 542 (1988). Accordingly, Northern Telecom's assertion that the Remarks are irrelevant to claim construction is incorrect.

In its January 17, 1977 Response to the Examiner's initial rejection of the Ingrey application, Northern Telecom amended the claims in conformity with the Examiner's suggestions and also made the following Remarks:

It is not agreed that the references cited in any way disclose the present invention as defined by the claims originally filed or as now filed, nor do the references foreshadow the present invention.

The references A, B and C, U.S. patents 3,975,252; [sic] 3,985,597 and 3,436,327 are concerned with a totally different process. In sputter etching the plasma is entirely incidental to the ion bombardment, which bombardment is the etching mechanism. The effect can as readily be affected by using a non-plasma condition by bombarding the surface with ions from an ion gun. Further, a plasma is defined as neutral environment, that is one that has equal members of positive and negative ions. In ion etching (as compared to plasma etching) the target does not sit in the plasma but in a positive space charge.

In the references the plasma plays no part in the etching, being incidental. In the present invention the plasma is part of
the etching process in that the etching process uses neutrals, (uncharged particles) in the reaction, these being from the plasma.

MacPherson Decl., Ex. J.

The court must determine whether these Remarks distinguish the Ingrey invention from sputter etching or from reactive ion etching. Unfortunately, while the question is straightforward, the answer is not, due to mistakes and poor draftsmanship which render the Remarks fundamentally ambiguous.

The parties agree that references A (Fraser) and B (Zielinski) disclose reactive ion etching processes, i.e. etch mechanisms that include both ion bombardment and chemical reactions involving plasmas, and that reference C (Shockley) discloses a sputter etching process, i.e. one that is purely mechanical.

Paragraph 2 of the Remarks begins with the statement: "the references A, B, and C . . . are concerned with a totally different process." This suggests that the Remarks define plasma etching as a purely chemical process and distinguish it from processes which include the physical component of ion bombardment. 13 Read in isolation from the surrounding sentences, this sentence appears to distinguish the Ingrey invention from prior art references disclosing reactive ion etching. The next sentence, however, refers to sputter etching ("in sputter etching the plasma is entirely incidental to the ion bombardment, which bombardment is the etching mechanism"), indicating that Northern Telecom's patent agent Sidney Jelly may have misunderstood or overlooked what references A and B disclosed.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

13 Northern Telecom attempts to construe this statement as a reference to the fact that the Ingrey patent discloses the use of a boron trihalide and the three references do not; this attempt fails completely. In context, it is clear that the Remarks are concerned with the etch mechanism, not the etch gas.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Samsung suggests a different interpretation. Samsung argues that the second and third sentences (beginning "In sputter etching . . ") refer to reference C, which discloses a sputter etching process, while the fourth and fifth sentences refer to references A and B, which disclose reactive ion etching. Under this interpretation, Jelly used the term "ion etching" to mean reactive ion etching. This interpretation is attractive because it allows paragraph 2 to be read as internally consistent.

Samsung's interpretation of the terms "sputter etching", "ion etching", and "plasma etching" in paragraph 2 is the most sensible one presented to the court. However, Samsung's proposed interpretation of paragraph 2 is not consistent with any reasonable interpretation of paragraph 3. Paragraph 3 appears to contrast the three references as a group to the use of chemical reactions in a plasma. The parties agree that the statement in paragraph 3 that "in the references the plasma plays no part in the etching, being incidental" does not as a simple matter of fact correctly describe the processes in references A and B. In fact, references A and B disclose reactive ion etching processes, a process in which the plasma does play an active role in etching the work surface. Thus, paragraph 3 suggests that Jelly did not know that references A and B disclosed processes which were in part chemical. This is evidence that he used the terms "sputter etching" and "ion etching" interchangeably to refer to an exclusively mechanical process.

Samsung is correct that Northern Telecom must be held to the representations it made to the Examiner, whether factually correct or not. However, Northern Telecom is correct that the factually erroneous remark in paragraph 3, which perhaps pervades the Remarks as a whole, cannot be interpreted to hold the meaning Samsung wishes to give it -- that the Ingrey patent claims only an exclusively chemical etch mechanism. When the first sentence of paragraph 3 is placed in context with the second, which states: "in the present invention the plasma is part of the etching process . . ." (emphasis added), it is obvious that Samsung's preferred interpretation of the Remarks as a whole is not a reasonable one. If a person skilled in the art was familiar enough with references A and B to be aware of the factual error in the first sentence, that person would have to disregard that sentence as nonsensical. In that case, the first sentence would shed no light on the meaning of the second sentence, which is crucial here. If, on the other hand, a person skilled in the art was not familiar enough with references A and B to be aware of the factual error, that person would interpret paragraph 3 to mean Ingrey was claiming a process where plasma was a part of the etch mechanism. Neither situation lends itself to an interpretation that Ingrey was claiming a
process in which plasma was the exclusive etch mechanism. Read as a whole, the third paragraph clearly does not indicate that the claimed invention is exclusively chemical, but only that it is at least partly so.

In light of the ambiguities and errors which pervade the Remarks, the court concludes that it cannot be known with certainty precisely what Jelly meant by "sputter etching," "ion etching," and "plasma etching." The Remarks are so muddled as to shed little light on the claim construction question before the court. Thus, while the court finds that Northern Telecom's interpretation is the more reasonable, the court places little weight on the Remarks in construing the disputed claims.

2. The Specifications

It is axiomatic that limitations that do not appear in the claims cannot be imported from the specification. See Markman, 52 F.3d at 979-80. "One cannot avoid infringement merely by adding elements if each element recited in the claims is found in the accused device." Stiftung v. Renishaw PLC, 945 F.2d 1173, 1178 (Fed. Cir. 1991) (quoting A.B. Dick Co. v. Burroughs Corp., 713 F.2d 700, 703, cert. denied, 464 U.S. 1042, 79 L. Ed. 2d 171, 104 S. Ct. 707 (1984)). Thus, the court examines the specifications solely for the light they shed on the meaning of plasma etching as used in the claims. See Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561 (Fed. Cir. 1991). The specifications are the "single best guide to the meaning of a disputed term". Vitronics, 90 F.3d at 1582. In this case, the court must determine whether the specifications establish that plasma etching as used in Claim 1 precludes the use of a process that also involves ion bombardment.

The Ingrey specifications describe plasma etching as follows:

In plasma etching, etchant gas molecules are broken up in an RF plasma into chemically active radicals that react with the workpiece, etching occurs and, if the reaction products are volatile, the reaction will continue until one or other of the reactants is completely removed.

Hess Decl., Ex. A (Ingrey patent), col. 1, 1.37-42. This sentence does not appear on its face to describe an exclusive process.

Samsung points to two other portions of the specifications to support its theory that reactive ion etching is outside the scope of the patent. First, the specifications describe parameters for the etching equipment: "Further constraints on the plasma parameters are that the RF power should be sufficiently low as not to damage the photoresist through ion bombardment . . . " Id. at col. 2, 1. 53-56. Second, the specifications indicate that high pressure should be used, which suppresses ion bombardment. (In reactive ion etching as practiced by Samsung, low pressure is used in order to promote ion bombardment.) Samsung interprets this language to mean that in the claimed process ion bombardment should not occur. Northern Telecom interprets the same language as evidence that ion bombardment does in fact occur in the plasma etching process described in the specifications.

The Ingrey patent is a process patent, not a patent on a particular apparatus. In a process patent, apparatus distinctions that are not specifically claimed are not controlling in determining the scope of the claims. See Polaroid Corp. v. Eastman Kodak Co., 789 F.2d 1556, 1562 (Fed Cir.), cert. denied, 479 U.S. 850, 93 L. Ed. 2d 114, 107 S. Ct. 178 (1986), and Amstar Corp. v. Envirotech Corp., 730 F.2d 1476, 1482 (Fed. Cir.), cert. denied, 469 U.S. 924, 83 L. Ed. 2d 240, 105 S. Ct. 306 (1984). The specifications show that the Ingrey inventors considered ion bombardment, or at least some excessive level of ion bombardment, to be deleterious. In so showing, the cited lines also indicate that a certain amount of ion bombardment does occur in the embodiment described in the specifications. Thus, the specifications demonstrate, and all the other evidence in the record agrees, that ion bombardment will take place even in the embodiment described in the specifications.

While the embodiment set forth in the specifications minimizes ion bombardment, the claims themselves concern only the chemical reactions taking place in a plasma. They do not speak to whether the ion bombardment which will take place is minimized, as in the Ingrey embodiment, or enhanced, as in reactive ion etching as practiced by Samsung. The court discerns no language in the specifications indicating that the claims are limited to a process of chemical reaction in which ion bombardment is limited or reduced below some specified level.

3. Extrinsic Evidence

The parties agree that terminology in the field of semiconductor manufacturing was not used consistently or without ambiguity in the late 1970s. Samsung nevertheless contends that those skilled in the art in the late 1970s would understand the term "plasma etching" to exclude the process called reactive ion etching, and submits substantial evidence to support
this position. See Supplemental Cecchi Decl. Northern Telecom submits a volume of contrary evidence. See Hess Decl. PP 24-25. There is ample evidence that each of the terms in question were used in the industry in the late 1970s in a variety of ways and without much consistency. However, in light of Vitronics, it is clear that the court should not weigh the opinions of competing experts in order to define the terms because that would likely vary or contradict the claim language. The court finds that it should and can interpret the claims based on the specifications and prosecution history. Based upon those, the court concludes that the term "plasma etching" refers to a chemical process without excluding the non-chemical process of ion bombardment. While the evidence is far from clear, and the prosecution history in particular presents serious problems of interpretation, the court finds that Claim 1, read together with the specifications and prosecution history, contains no indication that ion bombardment or reactive ion etching is specifically excluded from the claimed process.

3166

B

Samsung also argues that the district court erred when it construed "plasma etching" to allow reactive ion etching. According to Samsung, "plasma etching," as used in claim 1, specifically excludes all forms of "ion bombardment" etching. Because the accused process uses reactive ion etching -- a combination of both plasma etching and ion bombardment -- Samsung asserts that no infringement can lie. Samsung asserts that both the specification and prosecution history of the '967 patent support its view of "plasma etching". We disagree.

Some background is in order. There is no dispute between the parties that plasma etching, as that term is commonly used in the field, is a "chemical" process. In plasma etching, electrical power is applied to a gas, creating a plasma of chemically-active radicals, which react with the workpiece, causing etching. There is also no dispute between the parties that ion bombardment is a "mechanical" process, whereby an electrical field creates a plasma that emits charged particles, which physically strike the workpiece, causing etching. Reactive ion etching, used in the Samsung process, is a combination of the chemical and mechanical processes. In reactive ion etching, the plasma created by the electrical field creates both chemically-active and charged particles, allowing etching to proceed both by chemical reaction and by physical bombardment.

Claim 1 of the '967 patent requires "an initial step of plasma etching." The claim does not mention ion bombardment or reactive ion etching. Thus, there is no dispute between the parties that the '967 patent does not claim ion bombardment as an etching mechanism. But this in itself does not allow the Samsung process to escape infringement: the reactive ion etching of the Samsung process, as we noted above, uses "plasma etching" (the chemical process) as part of the etching mechanism. The use of ion bombardment as another part of the etching mechanism, an additional element of the accused process, will not ordinarily prevent a finding of infringement. See, e.g., A.B. Dick, 713 F.2d at 703, 218 U.S.P.Q. (BNA) at 967. Samsung, recognizing this tenet of the law, argues instead that the limitation "plasma etching" in claim 1, read in light of the intrinsic and extrinsic evidence, specifically requires the exclusion of ion bombardment as any part of the etching mechanism.

Samsung does not argue that the ordinary meaning of "plasma etching" itself excludes ion bombardment. See Johnson Worldwide, 175 F.3d at 989, 50 U.S.P.Q.2D (BNA) at 1610 ("The general rule is, of course, that terms in the claim are to be given their ordinary and accustomed meaning."); Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576 ("Words in a claim are generally given their ordinary and customary meaning."). Instead, Samsung argues that the intrinsic and extrinsic evidence of record compels the conclusion that "plasma etching" in claim 1 must be limited to circumstances where chemical processes are the only etching mechanism. See Johnson Worldwide, 175 F.3d at 989-90, 50 U.S.P.Q.2D (BNA) at 1610 (describing circumstances under which a term's ordinary meaning may be set aside). Thus, the issue is not whether the '967 patent contemplates the presence of ion bombardment, but whether it contemplates it and specifically excludes it.

We begin with the specification. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577 ("It is always necessary to review the specification to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning."). Samsung is correct in noting that the written description broadly describes "plasma etching" in terms of a chemical reaction. See '967 patent, col. 1., II. 37-42. Indeed, the only mention of "ion bombardment" is the statement that
"the RF power should be sufficiently low as not to damage the photoresist through ion bombardment." See id. at col. 2, ll. 54-56. Samsung seizes upon this statement as evidence that the claimed "plasma etching" must completely exclude ion bombardment. We disagree. By suggesting -- in connection with a description of the preferred parameters for the claimed "plasma etching" process -- that steps "should" be taken to reduce or avoid ion bombardment, the patentees fall far short of excluding ion bombardment altogether. Cf. Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1463, 46 U.S.P.Q.2d (BNA) 1609, 1614-15 (Fed. Cir. 1998) (adhering to clear assertions in written description that the invention "requires" a narrow construction of a claim term). See also Johnson Worldwide, 175 F.3d at 991, 50 U.S.P.Q.2d (BNA) at 1611 (discussing Laitram). Indeed, wholly contrary to Samsung's view, that sentence clearly contemplates that ion bombardment may be present in the claimed process, but states that the patentees prefer that it be reduced or eliminated. In other words, the low level of ion bombardment in conjunction with the claimed plasma etching is plainly a preferred embodiment of the '967 patent. This court consistently declines to construe claim terms according to the preferred embodiment. See, e.g., Johnson Worldwide, 175 F.3d at 990-92, 50 U.S.P.Q.2d (BNA) at 1610-12; Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2d (BNA) at 1120-22; Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571, 7 U.S.P.Q.2d (BNA) 1057, 1064 (Fed. Cir. 1989). We see no reason to abandon that practice in this case.

Samsung's reliance on Figure 2 of the '967 patent is no more persuasive. Figure 2 shows the wafer (i.e., the "workpiece") located in a plasma region, rather than in a DC electric field as would be the case if ion bombardment was to be the primary or only etching technique. While we can agree that Figure 2 makes clear that the patentees preferred gas plasma etching over ion bombardment, that fact, of course, cannot lead to the conclusion that ion bombardment was specifically excluded from the scope of the claims. As we note above, the entire specification plainly expresses a preference for gas plasma etching over ion bombardment. But preferred embodiments, without more, do not limit claim terms. See, e.g., Johnson Worldwide, 175 F.3d at 990-92, 50 U.S.P.Q.2d (BNA) at 1610-12; Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2d (BNA) at 1120-22; Advanced Micro-Devices, 848 F.2d at 1571, 7 U.S.P.Q.2d (BNA) at 1064.

2

Samsung next points to passages in the prosecution history, where, it asserts, the patentees unambiguously disclaimed the existence of any ion bombardment in the claimed process. During prosecution of the '967 patent, the Examiner rejected several claims as obvious over Shockley, in view of Zielinski and Fraser. Shockley discloses a sputter etching process. Fraser and Zielinski disclose methods of reactive ion etching aluminum and aluminum oxide, respectively. None of the references discloses etching in the presence of boron trihalide. In response to the Examiner's rejection, the applicants amended claim 1 and remarked:

[1] It is not agreed that the references cited in any way disclose the present invention as defined by the claims originally filed or as now filed, nor do the references foreshadow the present invention.

[2] The references . . . are concerned with a totally different process. In sputter etching, the plasma is entirely incidental to the ion bombardment, which bombardment is the etching mechanism. The effect can as readily be affected by using a non-plasma condition by bombarding the surface with ions from an ion gun. Further, a plasma is defined as neutral environment, that is one that has equal members of positive and negative ions. In ion etching (as compared to plasma etching), the target does not sit in the plasma but in a positive space charge.

[3] In the references the plasma plays no part in the etching, being incidental. In the present invention the plasma is part of the etching process in that the etching process uses neutrals, (uncharged particles) in the reaction, these being from the plasma.

Response to Office Action dated January 7, 1977, pp. 1-2 (paragraph numbers supplied). Samsung argues that the above remarks clearly portray "plasma etching" as a process that must exclude ion bombardment because the inventors remarked that the asserted references (which disclosed ion bombardment and reactive ion etching) are "concerned with a totally different process," in paragraph 2.

We find the passage does not support Samsung's argument. In the main, paragraphs 1 and 2 above are descriptions of the asserted references, as opposed to a description of the "plasma etching" process of claim 1. By contrast, it is paragraph 3 which describes the invention, and the specific way that the claimed process differs from the asserted references. Paragraph 3 describes the plasma as "part" of the etching process, and states that the "etching process uses neutrals" in the reaction.
These statements, while describing features of plasma etching, do not exclude the possibility of ion bombardment. Indeed, describing the plasma as "part" of the etching mechanism rather than as "the" (or, perhaps, "the only") etching mechanism, the language instead supports the inference that other mechanisms may also be "part" of the etching process. Again, much like the specification, this language evinces the inventors' clear focus on plasma etching. It does not explicitly call for ion bombardment; but neither does it specifically state its exclusion as part of the invention. See, e.g., Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1458, 46 U.S.P.Q.2d (BNA) 1169, 1175-76 (en banc) (refusing to limit scope of claim language where prosecution history did not clearly call for a narrower definition).

The description of the asserted references as "concerned with a totally different process" in paragraph 2 is far too slender a reed to support the judicial narrowing of a clear claim term. The inventors do not specify (except in paragraph 3, of course) how the references are "totally different." Perhaps the inventors considered the references as "totally different" due to their failure to disclose plasma etching in the presence of a boron trihalide, or because of the relative importance of gas plasma etching in the ‘967 invention. Or, as Samsung suggests, perhaps the inventors considered the presence of ion bombardment as creating a "totally different process." Or it could be any number of other unstated reasons. Like the district court, we simply cannot tell.

In sum, we find that the prosecution history fails to prove Samsung's assertion that "plasma etching" in claim 1 of the '967 patent requires the exclusion of ion bombardment. That is, under these circumstances, we cannot conclude that Samsung has demonstrated that the patentees -- with reasonable clarity and deliberateness, see In re Paulsen, 30 F.3d 1475, 1480, 31 U.S.P.Q.2d (BNA) 1671, 1674 (Fed. Cir. 1994) -- defined "plasma etching" as excluding ion bombardment. See Johnson Worldwide, 175 F.3d at 989, 50 U.S.P.Q.2d (BNA) at 1610 (noting the "heavy presumption in favor of the ordinary meaning of claim language").

3

Samsung next argues that ambiguity in the prosecution history places this case within the ambit of our holding in Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 37 U.S.P.Q.2d (BNA) 1365 (Fed. Cir. 1996). Samsung suggests that Athletic Alternatives established a rule that when the prosecution history presents an unclear choice between a broader and narrower meaning of a claim term, then the narrower meaning controls. Accordingly, Samsung asserts that the confusing language from the prosecution history noted above requires that a narrower meaning of "plasma etching" -- that which specifically excludes ion bombardment -- applies. This is a misreading of Athletic Alternatives.

In Athletic Alternatives, our review of the prosecution history led to "two strong and contradictory interpretive strands . . . . Each strand, considered alone, leads to a coherent and distinct meaning of the disputed claim." 73 F.3d at 1580, 37 U.S.P.Q.2d (BNA) at 1371. That is, Athletic Alternatives did not turn on ambiguity -- it turned on clarity. The inventors in Athletic Alternatives had provided, in the prosecution history, two "coherent and distinct" definitions of the relevant claim limitation. When presented with the situation where two clear yet contradictory definitions are provided by the patentee, we stated that this court would choose the narrower of the two, as such a practice would "best serve[]" the notice function of the claim. Id. at 1581, 37 U.S.P.Q.2d (BNA) at 1372. Samsung appears to read Athletic Alternatives as requiring that courts choose a narrow definition of a claim limitation whenever there is a dispute over meaning and ambiguity in the intrinsic evidence. This is incorrect. The plain and ordinary meaning of claim language controls, unless that meaning renders the claim unclear or is overcome by a special definition that appears in the intrinsic record with reasonable clarity and precision. See, e.g., Johnson Worldwide, 175 F.3d at 990-91, 50 U.S.P.Q.2d (BNA) at 1610. Vagueness and inference cannot overcome an ordinary meaning of a claim term; nor can it serve to invoke the rule of Athletic Alternatives. Under Samsung's reading, Athletic Alternatives would substitute for reasoned analysis. To the contrary, Athletic Alternatives considers the case where reasoned analysis leads to two clear and distinct definitions of claim language. It does not apply here, where confusing statements in the prosecution history simply fail to overcome the ordinary meaning of the "plasma etching" limitation.

4

Samsung's final argument is that extrinsic evidence supports a construction of "plasma etching" that requires the exclusion of any ion bombardment. In particular, Samsung points to an article published in August 1976, written by Gordon Poulsen, a named inventor of the '967 patent. In that article, Mr. Poulsen described "plasma etching" as "unlike reactive ion etching," being "a strictly chemical process." Poulsen, Plasma etching in integrated circuit manufacture -- A review, J. Vac. Sci.
Technol., Jan./Feb. 1977, at 266-274. Samsung argues that this contemporaneous record -- the Poulsen article appeared two weeks after the '967 patent's application was filed -- demonstrates that the term "plasma etching" was intended by the inventors to exclude any ion bombardment.

We first note, of course, that extrinsic evidence is rarely, if ever, probative of a special and particular definition of a limitation found in a claim. This is because extrinsic evidence "may not be used to vary or contradict the claim language" as discerned from the intrinsic record. Vitronics, 90 F.3d at 1584, 39 U.S.P.Q.2D (BNA) at 1577. That is, claims are assumed to take on their ordinary meaning. See Johnson Worldwide, 175 F.3d at 990-91, 50 U.S.P.Q.2D (BNA) at 1610; Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576. That ordinary meaning may in some cases be overridden by clear definitional statements in the intrinsic record, but it may not, of course, be altered by reference to extrinsic evidence -- for that would allow the public record of the patent to be changed for purposes of litigation, thus abrogating the notice function of the patent documents. See Vitronics, 90 F.3d at 1583, 39 U.S.P.Q.2D (BNA) at 1577 (warning against the loss of the public's right to ascertain the patent's scope from public documents); Southwall Techs., Inc., v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) (same).

In any event, we find Samsung's reliance on extrinsic evidence in this case to be unpersuasive. Poulsen's statement that plasma etching was "unlike" reactive ion etching merely states technologic fact: plasma etching, a chemical process, is different from reactive ion etching, which uses both mechanical and chemical techniques to etch. His statement in no way, however, makes the claim that plasma etching must exclude any ion bombardment. Indeed, the Poulsen article is much like the intrinsic evidence proffered by Samsung -- it supports the argument that plasma etching is different from ion bombardment, but it does not support the view that "plasma etching", as claimed, must preclude the presence of any ion bombardment.

Samsung also points to statements made by the inventors in the course of prosecuting a related Japanese application. There, the inventors again distinguished plasma etching from processes using ion bombardment as an etching mechanism, arguing that references disclosing sputter etching (i.e., ion bombardment) or reactive sputter etching (i.e., reactive ion etching) were not "identical" according to Japanese patent law. To the extent that statements construing terms in different claims in a different application, made to distinguish different references according to different legal standards, are relevant, we again find that they demonstrate little more than the inventors' view that plasma etching and ion bombardment are different (i.e., not "identical") etching mechanisms. But, as we noted before, such evidence cannot convince us that the inventors of the '967 patent accorded "plasma etching" a meaning in claim 1 that required the exclusion of any ion bombardment.

Even if we were to find persuasive the extrinsic evidence proffered by Samsung, we would, of course, have to balance that against the strong evidence submitted by Northern Telecom. In particular, we note that Northern Telecom's expert, Dr. Hess, explained that those of skill in the art would unquestionably recognize that ion bombardment would result from the etching process described in the '967 specification, that the depiction of Figure 2 of the '967 patent "makes clear that ions will bombard the surface" of the workpiece, and that the results reported in the written description indicate the presence of ion bombardment -- thus supporting Northern Telecom's argument that the specification specifically contemplates the presence of ion bombardment. Further, Dr. Hess testified that experts in the field used the term "plasma etching" to apply to both a purely chemical process, as well as the chemical portion of the combination chemical-mechanical reactive ion etching technique.

In sum, we find that Samsung's argument in favor of a narrow meaning of "plasma etching" -- one that requires the exclusion of any ion bombardment -- falls short. While we agree that the record makes clear that the patentees considered plasma etching to be different from ion bombardment, we cannot agree that this mandates a finding of noninfringement. That is, if a patent requires A, and the accused device or process uses A and B, infringement will be avoided only if the patent's definition of A excludes the possibility of B. See, e.g., Northern Telecom, Inc. v. Datapoint Corp., 908 F.2d 931, 945, 15 U.S.P.Q.2D (BNA) 1321, 1332 (Fed. Cir. 1990) ("The addition of features does not avoid infringement, if all the elements of the patent claims have been adopted."); Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044, 1057, 5 U.S.P.Q.2D (BNA) 1434, 1444 (Fed. Cir. 1988) ("Adding features to an accused device will not result in noninfringement if all the limitations in the claims, or equivalents thereof, are present in the accused device."); A.B. Dick, 713 F.2d at 703, 218 U.S.P.Q. (BNA) at 967. Statements simply noting a distinction between A and B are thus unhelpful: what matters is not that the patent describes A and B as different, but whether, according to the patent, A and B must be mutually exclusive. While Samsung's "plasma etching" argument has demonstrated that plasma etching and ion bombardment are indeed different techniques, it has failed to show that the '967 patent requires, as a part of claim 1, that no ion bombardment be present.
Accordingly, we hold that the district court's claim construction of "aluminum and aluminum oxide" as well as "plasma etching" was correct, and affirm the partial summary judgment based thereon.

3167

2. play list

This term appears in claims 1, 3, 6, 7, 9, 22, 34, 46, 74, 84, and 112 of the '725 patent and claims 1, 19, 31, 32, and 57 of the '345 patent. The plaintiff's proposed construction is "a list of works, selected from an inventory of works, that can be stored, retrieved and sequentially played." The defendant proposes a construction of "a list of works to be played."

The court's review of the intrinsic record reveals that the plaintiff's proposed definition is derived from several non-limiting excerpts from the specification and prosecution history of the '725 patent. Apple correctly attacks the propriety of Premier's definition by arguing that the limitations proposed by the plaintiff are separately recited in several of the claims. For example, claim 26 of the '345 patent recites "instructions for creating and storing a plurality of different play lists." '345 patent, cl. 26. As such, Apple argues that the plaintiff's limitations are improper.

At oral argument, the plaintiff divorced itself from its own construction, arguing that the essence of the term "play list" simply requires the court to define the term as something distinct or independent from a media inventory list, while at the same time requiring the play list to be derived from an inventory. But the intrinsic record counsels otherwise. Claim 74 of the '725 patent specifically refers to "building a plurality of play lists having entries selected from an inventory." '725 patent, cl. 74. As such, the court agrees with the defendant that the plaintiff's "selected from an inventory" limitation is improper insofar as the construction of "play list" is concerned.

A review of the patents reveals that the term "play list" is uniformly used in the context of a list of works that can be presented sequentially. See '725 patent, col. 1, 11. 41-43 ("A system and method of arranging media elements for later replay make it possible to create new sequential presentations of the elements."); '725 patent, col. 1,11.56-57 ("[t]he collection can be played back or performed sequentially as specified on a list."). Given the repeated description of a play list as a list of works that can be played sequentially, the court construes the term "play list" to mean "a list of works that can be played sequentially."

3168

11. "playing back the stored copy of the information using the receiving system"

Claim 19 provides in pertinent parts:

A distribution method responsive to requests from a user identifying items in a transmission system containing information to be sent from the transmission system to receiving systems at remote locations, the method comprising the steps of:

* * *

sending a request, by the user to the transmission system, for at least a part of the stored information ... 

sending at least a portion of the stored information from the transmission system to the receiving system at the selected remote location;

receiving the sent information by the receiving system at the selected remote location;

storing a complete copy of the received information in the receiving system at the selected remote location; and
playing back the stored copy of the information using the receiving system at the selected remote location at a time requested by the user.

This step in the method uses the phrase "playing back," which is commonly understood to mean to reproduce stored audio and video information in real time. In this step playing back is accomplished by "using the receiving system." The specification does not disclose any embodiments of the "receiving system" that includes speakers or video displays which would facilitate "playback." Instead, the specification discloses that the "receiving system" outputs to "receiving devices" of the user for "playback:"

The separated audio and video information are respectively decompressed by audio decompressor 209 and video decompressor 208. The decompressed video data is then sent simultaneously to converter 206 including digital video output converter 211 and analog video output converter 213. The decompressed audio data is sent simultaneously to digital audio output converter 212 and analog audio output converter 214. The outputs from converters 211-214 are produced in real time. The real time output signals are output to a playback system such as a TV or audio amplifier.

The real time output signals are output to a playback system such as a TV or audio amplifier. They may also be sent to an audio/video recorder of the user. By using the reception system 200 of the present invention, the user may utilize the stop, pause, and multiple viewing functions of the receiving device. Moreover, in a preferred embodiment of the present invention, the output format converters may be connected to a recorder which enables the user to record the requested item for future multiple playbacks.

('992 Patent, Col. 18:27-45.)

The specification discloses embodiments of the "receiving system" which have playback controls, though there are no disclosures of speaker or video displays:

The reception system 200 has playback controls similar to the controls available on a standard audio/video recorder. These include: play, fast forward, rewind, stop, pause, and play slow.

('992 Patent, Col. 17:35-38.)

The specification discloses two configurations of a reception system, "direct connection" n9 and "non-direct connection." However, the specification discloses no structure which would allow a user to communicate directly with the reception system in a non-direct connection configuration. The Court interprets the embodiment of the reception system with playback controls as referring to a direct connection configuration. Accordingly, the "playback" step under consideration is defined to include both embodiments.

The Court construes the term "playing back ... using the receiving system," as follows:

In a distribution method as disclosed in Claim 19 of the '992 Patent, in which a transmission system sends information to receiving systems at remote locations in response to a user's request, "playing back the stored copy of the information using the receiving system" means "using the receiving system to output the stored copy of the information in real time."

n9 In direct connection configurations, such as reception system 200 shown in Figures. 1e and 1f, the user preferably select the reception system 200 to which the requested material is sent, and optionally selects the time playback of the requested material as desired. Accordingly, the user may remotely access the transmission system 100 from a location different than the location of receptions system 200 where the material will be sent and/or played back. Thus, for example, a user may preferably call transmission system 100 from work and have a movie sent to their house to be played back after dinner or at any later time of their choosing." ('992 Patent, Col. 5:10-21.)
4) "playlist" (claims 1, 15, 16)

STV Asia asserts that "playlist" means "program selection." In its Reply, it proposes in the alternative, "a list of selected audiovisual clips" or "selected audiovisual clips." Defendants assert the term should be construed as follows: "a list of video clips that are to be displayed at a retail store or stores. The playlist is created by a user who is located in a distribution center." The parties agree that a "playlist" at least includes the ordering or sequencing of audiovisual material. They disagree, however, as to whether a "playlist" also includes the sequenced audiovisual material itself. STV Asia asserts that it does, while Defendants argue it does not.

Defendants assert that the term "playlist" is defined in the specification and that that definition should be adopted by the Court in construing the term. In particular, the specification states that "[p]laylists are lists of video clips that are to be displayed at each of the retail stores." '069 patent, col. 9, ll. 44-45, and that "a playlist is a particular program sequence requested by a user who is located in the distribution center." '069 patent, col. 2, l. 67 - col. 3, 1. 2.

STV Asia, however, points to the latter statement as evidence that the playlist includes not only the sequencing of audiovisual materials but also the actual audiovisual materials themselves. It also points to the following statements in the specification that it asserts support such a dual meaning of the term:

.. "The Playlist Database has . . . a contents table for each playlist that gives information on the clips (e.g. clip sequence number) included in each playlist." '069 patent, col. 11, ll. 16-24.

.. "When playlists or [sic] created or updated, the program determines which additional video clips are needed at the stores and sets a pending flag." '069 patent, col. 12, ll. 17-20.

.. "After the clips have been received and stored in the receiving sites, the system's software scheme performs the on-line program formation automatically in order to form the playlists. In the preferred embodiment, users enter the desired playlists for each receiving site into the system from the technical operation center. The user may enter one set of playlists for many stores, etc. For each individual receiving site, the software assembles the desired playlist with the clips stored in that receiving sites, and then forwards the clips to monitors for display." '069 patent, col. 5, ll. 5-15.

STV Asia also points to the usage of the word "playlist" in the claims. In particular, STV Asia asserts that while claim 16 appears to use the term "playlist" to refer only to include the sequencing of the audiovisual material, claims 1 and 15 use the term in a manner that suggests it may include the sequencing or the content.

A number of the citations to the specification offered by STV Asia in support of its proposed construction are not persuasive. It is unclear, for example, why the statement "The Playlist Database has . . . a contents table for each playlist that gives information on the clips (e.g. clip sequence number) included in each playlist" shows that the "playlist" includes the content of the playlist. See '069 patent, col. 11, ll. 16-24. Similarly, the statement "When playlists or [sic] created or updated, the program determines which additional video clips are needed at the stores and sets a pending flag" does not provide strong support for STV Asia's position. '069 patent, col. 12, ll. 17-20.

Nonetheless, the Court finds support for STV Asia's proposed construction in at least one statement in the specification, found in col. 5, ll. 5-15 (quoted above), and in claim 1. In both places, the inventor appears to have used the word "playlist" as a shorthand to refer to the assembled audiovisual clips on the playlist. Claim 1 refers to a "network management system forming playlists" and "display units for displaying the playlists." While the first usage of "playlist" appears to refer to the list of audiovisual clips, it seems fairly clear that the second use of the term "playlist" refers not to the sequencing of the clips but rather, to the assembled audiovisual clips themselves. Similarly, when the specification states that the software "assembles" the "playlist with the clips stored in that receiving site," '069 patent, col. 5, ll. 13-14, the common-sense reading of that statement is that the "playlist" is the audiovisual clips themselves.

In reaching this conclusion, the Court is mindful of the general presumption that "the same terms appearing in different portions of the claims should be given the same meaning unless it is clear from the specification and the prosecution history
that the terms have different meanings at different portions of the claim." Fin Control Sys. PTY, Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001). Here, however, the Court concludes, based on the description of the invention in the specification, that the inventors used the term "playlist" both to refer to the sequencing of audiovisual material and as a shorthand for the sequenced material itself. In particular, when the inventors used the phrase "displaying the playlists" in claim 1, they were referring to the audiovisual clips themselves. All other references to "playlists" in the disputed claims are to the sequencing of the audiovisual clips.

The Court construes the claim term "playlist" as follows: "a particular program sequence requested by a user who is located in the distribution center." The Court construes the phrase "displaying the playlists" as "displaying the audiovisual content listed in the playlists."

"a game playable in the non-tournament mode"

The next term that requires construction appears in dependent claim 4:

(4) A system according to claim 1 further comprising a non-tournament mode, at least some of the plurality of tournament games being playable in the non-tournament mode.

Claim 4 describes a non-tournament mode. JVL's proposed construction of a "game playable in the non-tournament mode" is "a standard game which, unlike a tournament game, is not extended." Def.'s '887 Presentation at 26. Merit construes the last phrase of this claim as "[a]t least some of the more than one tournament game are playable in the non-tournament mode." Pl.'s '887 Presentation, Ex. 3 at 9.

JVL points out that the patent distinguishes between games played in and out of the tournament mode: "each of the video games may be played in either a regular, non-tournament mode, or in a tournament mode." '887 patent at 4:50-51. (emphasis added) On the other hand, Merit points out that the claim language itself allows for tournament games to be played in a non-tournament mode. '887 patent, claim 4.

JVL's construction introduces unnecessary confusion into the claim interpretation process.

The plain and ordinary meaning of "game playable in the non-tournament mode" is clear and no construction is required.

Plug electrode

The Court combines the parties' proposals and construes the term as "a metal conductor formed in a contact hole, which connects two layers." Samsung's proposed construction--"a conductor formed in a contact hole"--is consistent with the specification, the claims, and the agreed-upon construction of "contact hole"--"a vertical hole that allows electrical contact." See '195 Patent col. 5:63-67. However, the Court agrees with MEI that the specification discloses only a metal plug. See '195 Patent col. 14:49; col. 15:6; col. 19:29-34, 49; col. 20:6, 9, 23; and all figures referenced therein. MEI's proposed construction--"a metal which connects two metal layers"--is too narrow because it improperly includes what the electrode is connected to. MEI's definition is also too broad because it encompasses all metal regardless of conductivity.

Plug electrodes are connected respectively to both sides which are positioned across a part of said fuse portion where cutting off is to be performed

The Court agrees with MEI and construes the term as "at least one plug electrode connected to the fuse portion on each side"
Samsung argues that the phrase cannot be understood or construed because this phrase appears in a claim 2, which depends from claim 1, and claim 1 is ambiguous because a plug electrode cannot be "formed in a plural number." Samsung's argument that "connected respectively to both sides" cannot be understood fails in light of the intrinsic evidence, which describes plug electrodes connected across either side of a fuse portion. See ’195 Patent Figs. 9g, 11e; col. 19:15-35.

1. Pluggable Memory Key Means

Roche contends that the term "pluggable memory key means" connotes sufficient structure such that § 112, P 6 should not apply. Roche would construe the term as: a module containing memory that is "pluggable" (i.e., capable of repeatedly establishing and breaking electrical contact by insertion and removal). Roche Br. at 36. Apex/HDI contend that the term is written in means-plus-function language and should be construed using § 112, P 6. Apex/HDI assert that the term's functions are 1) mating with an electrical receptacle in the meter and 2) storing parameter values and procedure routine specifications. Apex/HDI argue that the structure that corresponds to this function is: a ROM that is received by a meter that includes a programmable Read Only Memory chip containing stored parameter values and procedure routine specifications. Apex/HDI point to evidence that Roche intended for the PTO to interpret the term as a means-plus-function term in claim 5 to bolster their argument that Roche has failed to rebut the presumption that the language used for the term makes it a term subject to § 112, P 6.

To determine whether or not a term that uses the word "means" should be construed pursuant to § 112, P 6, "the focus is on whether the claim term recites no function corresponding to the means or recites sufficient structure or material for performing that function." Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1372 (Fed. Cir. 2003) (citing Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999)). The Court finds that the term "pluggable memory key means" has sufficient structure to fall outside the ambit of § 112, P 6. There is no dispute between the parties that the term "pluggable" allows the memory key to be alternatively inserted and removed from the meter. Furthermore, there is no dispute between the parties that the "memory key" is a chip or module that contains data.

Apex/HDI contend that the prosecution history makes clear that the "pluggable memory key means" is a means plus function term. However, as pointed out by Roche in its reply brief, the references cited by Apex/HDI all refer to claim 5. The prosecution history reads:

Claim 5 specifically recites the operation of the processor means performing certain functions in relation to a CRC value read from the pluggable key means. . . . Applicants are unable to comprehend the basis for the inclusion of claims 5 and 16 in the rejection under 35 USC 112 [sic], fourth paragraph. Applicants respectfully submit that claims 5 and 16 are clearly proper dependent claims and fall well within the bounds of paragraph 6 of 35 USC 112 [sic]. Applicants further submit that the Examiner's statement at the bottom of page 6 of the official Office Action is in clear error when considering the recitations contained in the presently pending claims. For the record, the Examiner indicated as follows:

"The dependent limitations with respect to how the processor or pluggable memory key means is to be sued have not been given any patentable weight with respect to the apparatus limitations. Patentability of apparatus claims are dependent upon features not on how the particular feature is to be used. The claimed feature only need to be capable of performing the function". [sic]

35 USC 112 [sic], sixth paragraph provides a statutory basis for means plus function claims. Function recitations is [sic] means plus function claims limit how the "means" are to be used. Thus, by definition, the functional recitations contained in the pending claims are entitled to be given "patentable weight" and to be considered as defining Applicants [sic] invention in full conformance with 35 USC [sic]. Applicants respectfully submit the Examiner was in error in taking the above-noted position. Withdrawal of the rejection of claims 5 and 6 under 35 USC 112 [sic], fourth paragraph is respectfully requested.

***

. . . Claim 5 recites that the pluggable key means stores a cyclic redundancy check value (CRC). Claim 5 further recites a
function performed by the processor means in combination with the CRC values. No such teaching is present in Keiser et al.

Apex Defs.' Exh. 2, at A70-A73. In summary the patentees stated:

In view of the above, Applicants respectfully submit that claims 1, 2, 5, 15, and 16 clearly differentiate over any teaching of Keiser et al. or any teaching which one skilled in the art might derive from Keiser et al. Applicants respectfully submit that the functional statements contained in the rejected claim must be considered in determining the patentability thereof in conformance with 35 USC 112 [sic], sixth paragraph. Reconsideration and withdrawal of the rejection of claims 1, 2, 5, 15 and 16 under 35 USC 102(b) [sic] is respectfully requested.

Id. at A73. These sections indicate that the patentees argued for evaluation of at least original claims 5 and 16 pursuant to § 112, P 6, however, there is no connection between these arguments and claim 1.

Even if there were such a connection, there is no distinguishable difference between the structure identified by a plain-meaning interpretation of the term "pluggable memory key means" and a means-plus-function interpretation of the term. The clear meaning and/or structure for the term "pluggable memory key means" in the 609 patent is: a removable and/or reinsertable read-only-memory ("ROM") chip and/or module. The parties apparently agree that the 609 patent specification repeatedly refers to interchangeably a "removably, pluggable memory module" or a "pluggable read only memory(ies)" or a "pluggable memory key" or "pluggable ROM key" or simply a "ROM key." See, e.g., 609 Patent, col. 1, ll. 9-10; id. col. 3, ll. 13-33; id. col. 3, ll. 46-64; id. col. 4, ll. 40-56; id. col. 5, ll. 5-17. It is the reinsertable, ROM or memory key/module that is inserted into an electrical receptacle of the meter, and stores parameter values and procedure routine specifications (or procedure routines), throughout the 609 patent's specification.

For the foregoing reasons, the Court finds that the "pluggable memory key means" is: a removable and/or reinsertable read-only-memory ("ROM") chip and/or module.

3174

10. "one or more plugs for external drives and devices, and ports for switches"

This term appears in the '408 patent claim 9. Rackable contends that "one or more plugs for external drives and devices, and ports for switches" means "one or more plugs for drives and peripheral computer subsystems (such as disks, keyboards, monitors, mice, printers, scanners, tape drives, microphones, speakers, or cameras) that are external to the computer chassis, and one or more ports for switches." Supermicro asserts that "one or more plugs for external drives and devices, and ports for switches" means "one or more connectors for drives or elements that are external to the computer, and openings that provide access to switches."

Again, it is helpful to provide the full language of claim 9 of the '408 patent, which recites:

A computer comprising:

- a main board having I/O connectors including one or more data transmission ports mounted thereon; and
- a chassis comprising a front panel providing access to the I/O connectors including the one or more data transmission ports and access to each component provided for the computer selected from the group consisting of removable power supplies, removable drives, removable media drives, one or more plugs for external drives and devices, and ports for switches.

The essence of this dispute is really how "device" should be defined. It is clear to the court from the parties' arguments in their papers and at the hearing that there really is no dispute regarding the definition of "plug" or "drive;" that the drives and devices are "external" to the computer; and that "ports for switches" are openings. Accordingly, the court declines to define those terms, which are undisputed.

As for the definition of "device," Supermicro advocates a broad definition of the term, contending that "device" is
synonymous with "element," and should be construed as a generic term referring to any item that is hooked up to a 
computer. Rackable, on the other hand, argues for a narrower definition, one that limits a "device" to a "peripheral computer 
subsystem" and provides examples of "peripheral computer subsystem[s]."

Rackable argues that Supermicro improperly attempts to broaden the definition of the term "device." Rackable cites to the 
'366 patent specification, including figure 1, in support of its argument that "referred-to 'devices'" include "peripheral 
computer devices, such as keyboards, monitors, mice, printers, scanners, tape drives, microphones, speakers or cameras." 
See '366 patent at 6:11-18. Rackable also cites to a dictionary definition for "device." See Ostrapuk Decl., Exh. DD.

Supermicro counters that Rackable's narrow definition of the word "device," limiting it to a "peripheral computer 
subsystem" is contrary to the specification. It asserts that the patent application intentionally chose to use the generic term 
"device," as opposed to the more specific "computer subsystem" or "peripheral device." Supermicro also cites to a technical 
dictionary definition for the term "device."

It is not necessary for the court to resort to extrinsic evidence to construe the term "device" because the specification 
provides meaning for the term. The related '366 patent abstract clarifies that Supermicro's broader construction of "device" 
is more appropriate. That abstract explains that "by placement of access space to all elements which require periodic 
attention at the front of each computer, the need for significant space at the rear of a computer is eliminated." '366 patent 
abstract. Later in the specification's "summary of invention," the specification utilizes a similar broad term for "devices" -- 
"attachments." '408 patent at 4:8. The specification also provides examples of such "devices," but the list is not exhaustive. 
In the detailed description of the embodiments, the specification provides that "a number of devices may be optionally used 
in this port" and then continues with a discussion of the possible types of "drives" (not to be confused with "devices"). '408 
patent at 6:7-13. The specification then suggests that devices may include "USB/external SCSI or parallel port devices or 
other auxiliary data drives configured for plug-in use." Id. at 6:13-19. However, nowhere does the specification define 
"devices" as narrowly as Rackable would have the court construe it.

Because the court finds that the specification supports a broader construction of "device," and also finds that "attachment" is 
clearer than "element," as advocated by Supermicro, the court construes "one or more plugs for external drives and devices, 
and ports for switches" as one or more plugs for external drives and attachments, and ports for switches.

**3175**

**Plural protective transistors**

The Court modifies MEI's proposal and construes the term as "multiple transistors which provide a discharge path for 
current to flow between the first power supply wire and the second power supply wire when activated." MEI's argument that 
"plural" in this claim has a special meaning--i.e., "three or more"--is unsupported. Also, "plural" is used in a means-plus-
function term in claim 2. MEI agreed to a construction of that term that does not include a special "three or more" 
construction of "plural." See Third Amended Joint Supp. Claim Const. Chart at 55 (Docket No. 141); Fin Control Sys. Pty, 
Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001)("[T]he same terms appearing in different portions of the claims 
should be given the same meaning unless it is clear from the specification and prosecution history that the terms have 
different meanings at different portions of the claims.").

---

B. "A plurality of active MOS regions within a semiconductor substrate" (715 patent, claim 1)

The parties agree that this language should be construed to mean "At least two active MOS regions (construed elsewhere) 
within a common semiconductor substrate;" defendant argues that this court should understand this language to also require 
that the active regions be "separate." At the outset, it is not entirely clear what APT means by the word "separate." At some 
points, APT appears to argue that the "plurality" of regions must be "distinct" or "distinguishable" from one another. APT 
Opp. Br., at 5. On the other hand, Ixys suggests (with a greater degree of clarity than APT itself) that APT is instead
advancing a limiting construction that the regions must not be "connected." Ixys Reply Br., at 3.

Of these two options, the former limitation is part and parcel of the phrase "at least two." A substrate cannot be said to contain "at least two" active regions if those regions cannot be distinguished from one another, namely if it is impossible to identify a point at which one region exists, and the other does not. The latter option is foreclosed by the specification, which states that "The embodiments shown may comprise, for example, cells which are all connected in parallel." '715 patent, 7:53-56. A claim construction that would not cover a preferred embodiment in the specification "is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583. The language of the second half of this claim--"each of said active MOS regions having a source region, channel region, and drain region"--is not to the contrary, and does not provide near the evidentiary support necessary to overcome the Vitronics presumption. '715 patent, 7:63-65. Regardless of whether this means that each active region must have its own source, channel, and drain regions, or whether regions may share a source or drain, 2 the active regions may nevertheless be connected in some manner, such as through a bus.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 
2 Indeed, most power MOSFETs are designed such that all of the transistors placed on a substrate share a common drain.
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - 

The court has not been asked to construe the phrase "each of said active MOS regions having a source region, channel region, and drain region," and so it will not pass upon the question described above regarding whether multiple active regions may share a source, drain, or channel. It is worth noting only that "multiple" active regions cannot share a source, channel, and drain, since the active regions would cease to be in any way distinct or distinguishable, and thus no longer constitute "more than one" region. Since the language of the claim and specifications are sufficiently clear on these points, the court need not reference any extrinsic evidence.

The court construes this claim language to mean: "At least two distinguishable, active MOS regions within a semiconductor substrate."

3177

The contested phrase "a plurality of beams of light" appears in claims 1 and 3 of the '272 patent. They read

1. A method for producing on a photoreceptor an image of generated shapes made up of spots, comprising: directing a plurality of beams of light toward a photoreceptor, each beam of light generating a spot on the photoreceptor and controlling a parameter of the light beams to produce spots of different sizes whereby the appearance of smooth edges are given to the generated shapes.

3. Apparatus for producing on a photoreceptor an image of generated shapes made up of spots, comprising: means for directing a plurality of beams of light toward a photoreceptor to generating a plurality of spots on the photoreceptor and means for generating spots of different sizes whereby the appearance of smooth edges are given to the generated shapes. (emphasis added)

It is undisputed that the accused HP printers use the same prior art light scanning system as that shown in Figure 1 of the '272 patent. The HP printers employ light from a single laser source which is reflected off a polygonal mirror to a photoreceptor mounted on a drum. Instead of adjusting either the beam's intensity or diameter, as is described in the '272 patent, the accused printers solve the "jaggies" problem by modifying the duration of time the laser beam is on.

In 1990, PB notified HP that several of HP's marketed laser printers infringed the claims of the '272 patent. This action followed.

STANDARD

Summary judgment is appropriately granted when the evidentiary record reveals that there are no genuine issues of material fact and the moving party is entitled to judgment as a matter of law. Fed. R. Civ. P. 56(c). In determining whether the record
presents genuine issues for trial, the court must view all inferences and ambiguities in a light most favorable to the non-moving party. See Bryant v. Maffucci, 923 F.2d 979, 982 (2d Cir.), cert. denied, 502 U.S. 849, 112 S. Ct. 152, 116 L. Ed. 2d 117 (1991). A plaintiff raises a genuine issue of material fact if "the jury could reasonably find for the plaintiff." Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 252, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). Rule 56(c) "provides that the mere existence of some alleged factual dispute between the parties will not defeat an otherwise properly supported motion for summary judgment; the requirement is that there be no genuine issue of material fact." Liberty Lobby, supra, at 247-48. The Supreme Court noted that:

Rule 56 must be construed with due regard not only for the rights of persons asserting claims and defenses that are adequately based in fact to have those claims and defenses tried to a jury, but also for the rights of persons opposing such claims and defenses to demonstrate in the manner provided by the Rule, prior to trial, that the claims and defenses have no factual basis.

Celotex v. Catrett, 477 U.S. 317, 327, 91 L. Ed. 2d 265, 106 S. Ct. 2548 (1986). "One of the principal purposes of the summary judgment rule is to isolate and dispose of factually unsupported claims... [and] it should be interpreted in a way that allows it to accomplish this purpose." Celotex, supra, at 323-24. In a case of patent infringement, summary judgment is appropriate when comparison of the accused device and the claim reveals that there is an absence of disputed material fact. Chemical Eng'g Corp. v. Essef Indus. Inc., 795 F.2d 1565 (Fed. Cir. 1986).

DISCUSSION

I

Claim Construction

"The construction of a patent, including the terms of art within its claim, is exclusively within the province of the court." Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1386, 134 L. Ed. 2d 577 (1996). In determining the meaning of a claim, the court first examines the intrinsic evidence of the record, including the claims, specification, and the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Intrinsic evidence is "the most significant source of the legally operative meaning of the disputed claim language." Id. at 1582. If the intrinsic evidence does not sufficiently resolve ambiguities, then the court may consider extrinsic evidence, including expert and inventor testimony, in order to arrive at a "proper understanding of the claims." Id. at 1583.

1. Intrinsic Evidence

a. Language of the Claims

HP first argues that the term "a plurality of beams" plainly means that a device must direct "two or more beams of light originating from two or more separate light sources" toward a photoreceptor. Alternatively, they contend the "plurality of beams" limitation requires that a single light beam must be "split or divided into multiple beams." Since it is undisputed that the accused devices employ neither multiple light sources nor beam splitters, HP argues that they do not infringe the '272 patent.

PB responds that the plain meaning of a "plurality of beams" does not require a device to use either multiple light sources or beam splitters. They argue that there are no limitations in the claim which require that "each beam of light originate from a different power source or be divided into multiple beams." Rather, given the nature of the described invention, they propose that it is possible to generate a plurality of beams from a single laser source.

Interpreting the claim language is of primary importance. The "language of the claims frames and ultimately resolves all issues of claim interpretation." Abtox, Inc. v. Exitron Corp, 122 F.3d 1019, 1023 (Fed. Cir. 1997). Claim terms are to be given their ordinary and customary meaning, unless it is apparent that the inventor expressly intended a different meaning. Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578 (Fed. Cir.), cert denied, 519 U.S. 911, 117 S. Ct. 275, 136 L. Ed. 2d 198 (1996). When reviewing claim language, a court must apply "normal rules of syntax" and consider the context of the claim. Eastman Kodak Co. v. The Goodyear Tire and Rubber Co., 114 F.3d 1547, 1553 (Fed. Cir. 1997).

Applying these principles to the instant case, the court concludes that the phrase "a plurality of beams of light" when used in
the '272 patent means multiple beams of light generated sequentially from one or more light sources. The plain language of the '272 claims indicates that PB's invention operates by "directing a plurality of beams of light toward a photoreceptor, each beam of light generating a spot on the photoreceptor." The relevant dictionary definition for the word plurality is a "state or condition of being plural or numerous," with the word plural being defined as "containing, consisting of, or designating more than one." See Funk and Wagnall, Standard College Dictionary, (1963). 2 Multiple beams of light can be generated sequentially over time by one laser source. The ordinary meaning of the word "plurality" contains no requirement that "a plurality of beams" be created simultaneously, as suggested by HP.

Applying the "normal rules of syntax" to the claims provides further support for the conclusion that "a plurality of beams" can be generated sequentially. See Eastman Kodak Co. v. The Goodyear Tire and Rubber Co., 114 F.3d 1547, 1553 (Fed. Cir. 1997). Claim 1 describes a method which operates by "directing a plurality of beams of light toward a photoreceptor, each beam of light generating a spot on the photoreceptor." The use of the phrase "each beam of light generating a spot" modifies the term "plurality of beams." The use of the term "each beam" implies that multiple beams can individually strike the photoreceptor in turn to create multiple spots. The preferred embodiment of the '272 patent describes a system in which beams of light are reflected off a rotating polygon mirror towards a photoreceptor. Sequential production of multiple light beams by one or more laser source produces a plurality of beams, which are individually directed toward the photoreceptor by the rotating mirror.

Further, if this court were to adopt HP's suggestion that multiple laser sources are required to produce a plurality of beams of light, the preferred embodiment of the '272 patent would fall outside of the claims. Figure 1 of the '272 patent depicts a device which employs a single laser source and does not discuss the use of beam splitters. To hold that a plurality of beams can only be generated either by the simultaneous operation of multiple laser sources or by the use of beam splitters would exclude coverage of the preferred embodiment from the claims of the '272 patent. "Such an interpretation is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). Since such evidence is lacking in the instant case, it is logical to conclude that the preferred embodiment is covered by the patent claims.

b. The Specification

HP next argues that the specification of the '272 patent describes the apparatus in Figure 1 as a device which "directs a single beam of light toward a photoreceptor." They contend that the only instance where the specification refers to multiple beams of light is in the discussion of the two laser embodiment. "The use of the term 'beams' exclusively in connection with the embodiment of the alleged invention which employs two light sources . . . is in stark contrast to the description of the first embodiment." They contend that "a plurality of beams" can only be produced by the multiple laser version of the '272 patent, not the single laser embodiments depicted in Figure 1.

PB replies that the specification reveals that Figure 1 is "the one and only preferred embodiment" of the '272 patent. "The teaching in the specification confirms that the invention applies to printers with one or two laser power sources." PB contends that either embodiment generates the required "plurality of beams."
After reviewing the claim language, the court must review other parts of the patent document, including diagrams or figures, which are collectively referred to as the specification. Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1387-88, 134 L. Ed. 2d 577 (1996); see also Al-Site Corp. v. Bonneau Co., 22 F.3d 1107 (Fed. Cir. 1994). "The specification contains a written description of the invention that must enable one of ordinary skill in the art to make and use the invention. For claim construction purposes, the description may act as sort of a dictionary, which explains the invention and may define terms used in the claims." Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (internal citations omitted). A court reviews the patent specification to determine whether the patentee "used any terms in a manner inconsistent with their ordinary meaning." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). However, although a review of the specification may add context to the claim language, it may not be used to read limitations into the claims. Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571 (Fed. Cir.), cert. denied, 488 U.S. 892, 102 L. Ed. 2d 218, 109 S. Ct. 228 (1988).

In the instant case, the specification of the '272 patent provides, 4 inter alia,

The light source, such as the laser 10, which may be a three mw helium-neon laser, generates a collimated beam 12 of monochromatic light which is direct through a neutral density filter 14 to control the light intensity. The beam 12 then passes through a modulator 16, such as an acousto-optical modulator. The beam 12 is next directed through a first lens 20 and intercepted by a knife edge 22 placed at the focal point of the first lens 20. […] It is desirable to use the first order beam to produce a spot because the position of the spot can be displaced in accordance with the frequency modulation applied to the modulator which will selectively deflect the beam 12 in a desired direction such as indicated by the arrows a, b. The first order beam 12 is then directed towards a second lens 24 which directs the converging beam onto a reflecting face of facet of a rotating polygonal mirror, herein referred to as polygon 28. The polygon 28 is continuously driven by a motor drive 30 and preferably is maintained at a constant velocity. . . . The beam 12 is thus reflected successively from each of the facets off the rotating polygon 28 and onto a photoreceptor 32.

--- Footnotes ---

4 Numbered references refer to Figure 1 of the '272 patent, which is contained in Exhibit 1 of this decision.

--- End Footnotes ---

The specification supports the conclusion that the phrase "a plurality of beams" when used in the '272 patent means multiple beams of light generated sequentially from one or more light sources. It indicates that reflecting each beam of light "off the rotating polygon and onto a photoreceptor" creates a small discharged area on the photoreceptor. Each symbol or picture produced by this process is composed of hundreds or thousands of these small discharged areas. Since each discharged area is created by one beam of light, it takes many beams, or a plurality of beams of light, to create one image. The specification of the '272 patent teaches that these beams can be produced sequentially by one or two laser sources. The meaning of the phrase a "plurality of beams of light" derived from the specification is consistent with the plain meaning of the claim language.

c. The Prosecution History

HP further argues that the prosecution history of the '272 patent supports the assertion that a "plurality of beams of light" requires more than one laser source. Specifically, they direct this court's attention to the PTO office action of September 23, 1981, which rejected claims 15 and 16 of the '532 application. These claims, which eventually became claims 1 and 2 of the '272 patent, were initially rejected since the examiner believed the specification did not clearly describe how "one photoreceptor would distinguish between the plural beams and how one or both beams would be controlled." HP contends that this rejection is evidence that the preferred embodiment of the '272 patent requires multiple laser sources to create a plurality of beams.

PB responds that the examiner's initial rejection was in reference to the two laser source embodiment of the application, not the "plurality of beams" language found in claim 1 and 3 of the '272 patent.
The undisputed public record of the proceedings in the PTO is of primary importance in understanding the claims. Markman v. Westview Instruments, Inc., 52 F.3d 967, 980-81 (Fed. Cir. 1995). The file history can function to limit claim construction so as to exclude any interpretation which was disclaimed during prosecution. Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1570 (Fed. Cir.), cert. denied, 516 U.S. 987, 116 S. Ct. 515, 133 L. Ed. 2d 424 (1995). The prosecution history must be read "in its full context, not on the basis of snippets lifted out of context." J.T. Eaton & Co. v. Atlantic Paste and Glue Co., 106 F.3d 1563, 1576 (Fed. Cir. 1997).

In the instant case, there is nothing in the prosecution history which indicates that multiple laser sources are required to create a plurality of beams. The text of the examiner's initial rejection of the '532 application indicates that he was referring to the two laser embodiment of the invention. For example, his concern that the initial application did not teach how "one or both beams" indicates that he was discussing the two laser embodiment. Interpreting this single comment to require that the PB patent covers only multiple laser source applications would improperly "diminish or vary the limitations of the claims." Goodyear Dental Vulcanite Co. v. Davis, 102 U.S. 222, 227, 26 L. Ed. 149 (1880); see also Constant v. Advanced Micro-Devices Inc., 848 F.2d 1560, 1571 (Fed. Cir.), cert. denied, 488 U.S. 892, 102 L. Ed. 2d 218, 109 S. Ct. 228 (1988)(holding that it is improper to read limitations from the specifications into the claims).

2. Extrinsic Evidence

The court concludes that the use of extrinsic evidence is unnecessary in this case. Extrinsic evidence may be evaluated "in order to aid the court in coming to a correct conclusion as to the true meaning of the language employed in the patent." Markman v. Westview Instruments, Inc., 52 F.3d 967, 981 (Fed. Cir. 1995)(internal citations omitted). However, "reliance on such evidence is unnecessary, and indeed improper, when the disputed terms can be understood from a careful reading of the public record." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 (Fed. Cir. 1996).

In this case, the meaning of the phrase "a plurality of beams of light" can be understood from a careful reading of the claims, the specification, and the prosecution history. Accordingly, consideration of extrinsic evidence is unnecessary and improper.

5. "a plurality of calibration images including a calibration marker" (claims 6-9); "a plurality of alignment images including an alignment marker" (claims 11-13); "a plurality of calibration marks" (claims 14-16)

PolyVision's proposed construction
More than one individual mark or target serving as touch points for the calibration process.

Smart's proposed construction
Indicia serving to indicate the positions to be used in calibrating the large-screen display surface, at least one of said indicia being a visible marker.

PolyVision argues that the term plurality should be given its ordinary meaning, as "more than one," as set forth in its proposed construction. Smart contends its construction will avoid limiting the claim to the specific embodiments set forth in the specification. However, as set forth above, the Court believes that resort to the specification is permissible and necessary in order to properly construe the claim language. In addition, as PolyVision correctly notes, Smart's proposed construction, which includes the phrase "at least one of said indicia being a visible marker," is at odds with the requirement of "a plurality." The Court will thus accept PolyVision's construction.

1. Plurality of coordinates being included in a plurality of respective distinct blocks

The focus of the parties' dispute over the construction of Claim 3 concerns whether there is necessarily a one-to-one
correspondence between one set of coordinates (out of the several sets provided) and a particular block in the set of data blocks. Google proposes a construction of "each one of the plural sets of coordinates being included in a separate distinct one of a plurality of data blocks describing three-dimensional terrain," while Skyline proposes "more than one set of coordinates being described by the data contained in more than one data block."

Comparing Claim 3 to Claim 1, it is clear that Claim 1 is not limited to situations where a single point is provided to the renderer. Rather, the renderer may receive "one or more coordinates," indicating that several coordinates, defining particular points, could be provided to the renderer simultaneously. The question then necessarily arises how Claim 3, which calls for several sets of coordinates to be passed to the renderer, differs from Claim 1. The difference is illuminated in the detailed description of Fig. 7, which describes two different ways the renderer might specify which blocks are necessary.

Preferably, renderer determines the exact blocks needed and calls for them using their (x, y) coordinates and their resolution level. Alternatively or additionally, renderer specifies, for each resolution level, the coordinates of the boundaries of the necessary areas, and cache manager determines the identities of the required blocks.

The method described in Claim 1 seems to correspond to the first method in the Fig. 7 description (providing specific required points), while the Claim 3 method appears to follow the second description (using several points to define the boundaries of an area). Although Fig. 7 is not itself part of a claim, of course, it does shed light on the meaning of Claim 3, particularly given the somewhat Delphic phrase at issue.

As Skyline notes (Plaintiff's Claim Construction Slides, p. 22), "respective distinct" modifies blocks, not the plurality of coordinates. However, Skyline's proposed construction reads "respective distinct" out of the claim entirely. I read the disputed language in Claim 3 as largely descriptive -- the several sets of coordinates at issue are, by definition, contained within available data blocks, which are themselves distinct from one another. In this reading, several sets of coordinates may be contained within one distinct block, but the blocks do not overlap. In this way, the blocks are "distinct," and coordinates are found in their "respective" blocks. Because I do not find anything in the claim language or elsewhere requiring a strict one-to-one correspondence between coordinates and blocks (so that each point describes only one data block, and the same number of points and blocks are contained in each plurality), I construe this language more broadly, allowing a one-to-many relationship between the blocks and the coordinates, n12 while still emphasizing the distinctiveness of each block.

n12 The concept is that one block may contain many coordinates and each set of coordinates may be contained within only one block. This one-to-many concept is in contrast to Google's one-to-one and Skyline's many-to-many.

Construction: (plurality of coordinates being included in a plurality of respective distinct blocks) Several coordinates, where each set of coordinates is contained within one block in a set composed of data blocks that are distinct from one another.

A

The method of claim 1 includes the steps of "receiving a plurality of demands" and "receiving a plurality of settlement offers." 551 patent, col. 19, ll. 33, 35. Although Cybersettle's brief is unclear on the point, Cybersettle agreed at oral argument that the claim term "plurality" refers to two or more of something. That definition is consistent with the well understood meaning of the term "plurality" both in general and in patent parlance. Nonetheless, Cybersettle argues that the method of claim 1 does not require the receipt of multiple offers and demands, but instead is satisfied if the executing computer has the capacity to receive multiple offers and demands, even if only one demand and one offer are received before settling the dispute. The district court agreed with that claim construction, holding that claim 1 "contemplates a dispute resolution method that is capable of, but does not require, multiple rounds."
We do not agree with that aspect of the district court's claim construction. A patented method is a series of steps, each of which must be performed for infringement to occur. It is not enough that a claimed step be "capable" of being performed. See Ormco Corp. v. Align Tech., Inc., 463 F.3d 1299, 1311 (Fed. Cir. 2006) (rejecting an argument that a claim requiring the replacement of appliances can be performed if the appliances are merely "capable of" being replaced); NTP v. Research in Motion, Ltd., 418 F.3d 1282, 1318 (Fed. Cir. 2005) ("[T]he use of a [claimed] process necessarily involves doing or performing each of the steps cited."). A party that does not perform a claimed step does not infringe a method claim merely because it is capable of doing so.

It is of course true that method steps may be contingent. If the condition for performing a contingent step is not satisfied, the performance recited by the step need not be carried out in order for the claimed method to be performed. But Cybersettle does not argue that the two "receiving" steps are contingent on some unspecified condition, and the "receiving" steps of claim 1 contain no conditional language.

To interpret claim 1 as Cybersettle suggests, we would have to interpret the phrases "receiving a plurality of demands" and "receiving a plurality of settlement offers" not to require receipt of pluralities of demands and offers. Instead, we would have to interpret the "receiving" steps as if they read "receiving one and, if necessary, a plurality" of demands and offers. There is no textual basis for such a dramatic alteration of the claim language, a serious shortcoming of Cybersettle's argument. See Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 950 (Fed. Cir. 1993) ("It is improper for a court to [add limitations] ... wholly apart from any need to interpret what the patentee meant by particular words or phrases in the claim." (quotation marks omitted)); see also Amgen, Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed. Cir. 2003) ("The danger of improperly importing a limitation is even greater when the purported limitation is based upon a term not appearing in the claim."). Such a construction would amount to rewriting the claim.

Cybersettle argues that it would be illogical to interpret claim 1 restrictively, to require the submission of at least two bids and at least two offers, because it would "require[] actions (submission of multiple bids and running a second round) which are completely unnecessary if there is a settlement in the first round." That restrictive construction of claim 1 is not illogical. Although that construction would cover the impractical embodiment to which Cybersettle refers, it would also cover the ordinary process of receiving a first pair of bids, determining that it fails the settlement condition, receiving a second pair of bids, and determining that the second pair of bids produces a settlement. Nor is the restrictive construction illogical on the ground that it excludes an embodiment that would be natural to include in a dispute resolution method--settlement and termination of the process after receipt of only a single pair of bids. Patents frequently contain claims to devices or methods whose scope includes fewer than all the embodiments that would routinely be used in practice.

Cybersettle also argues that interpreting claim 1 to require the receipt of multiple demands and offers would exclude a preferred embodiment of the invention and would therefore be an incorrect construction of that claim. It is true that the specification describes methods in which a dispute settles without the receipt of two offers and two demands. In one embodiment, even if the sponsor has submitted several settlement offers, the claim may settle when the claimant submits the first demand. '551 patent, col. 7, ll. 29-30; col. 8, ll. 41-42 (providing for the receipt of multiple offers and providing that a demand is "instantly compare[d]" to the offer for the given round). Further, figure 2 indicates that settlement may occur after just one offer and one demand have been received. Step 23 of that figure indicates that the depicted interaction applies to the claimant's first demand, stating that the system will recite the claimant's previous demand "if a previous demand has been made." Step 24 of that figure recites comparing the demand and the stored offer for that round and, if they match, announcing a settlement. Figure 2 thus does not require either party to enter multiple bids before a dispute may settle.

Although Cybersettle's characterization of the specification is accurate, its argument based on the specification is flawed. That is because our interpretation of claim 1 does not exclude the discussed embodiments from the scope of the claimed invention, but only excludes those embodiments from the scope of that claim. Although claim 1 does not capture the discussed embodiments, other claims do. Claim 133, for example, covers a system that includes a "means for introducing to the processor ... a series of demands ... and a series of offers." '551 patent, col. 30, ll. 57-61. Because the system is claimed using "means for introducing" language, claim 133 merely requires that the system be capable of receiving two or more demands and offers, not that the system actually receive two or more demands and offers. Method claim 59 is similar in that regard. Claim 59 requires executing a program "for receive[ing] values" representing a series of bids and "for sequentially comparing" the bids, but it does not require actual receipt of the bids after execution of the programs that can receive them. Id., col. 24, ll. 32-47. Thus, claim 59 also allows for the interaction depicted in figure 2. Accordingly, we
reject Cybersettle's argument that construing claim 1 to require multiple offers and demands would impermissibly exclude preferred embodiments from the scope of the invention.

With respect to claim 27, we agree with NAF that the reference to testing bids "in one of at least two rounds" requires at least two rounds and therefore the receipt of two pairs of bids. According to the specification, a round is an opportunity to settle a claim by comparing a settlement offer and a demand. '551 patent, col. 7, ll. 28-32; col. 7, ll. 65-67. Hence, performing two rounds requires receiving two demands and two settlement offers. Cybersettle takes the position that claim 27 does not require two rounds because the claim requires testing a pair of bids "in one of" at least two rounds. That reading, however, would render the "of at least two rounds" clause superfluous. If the "of at least two rounds" clause is to have any meaning, it must require that the entity executing the method perform a second round of settlement testing.

Importantly, the patentees added and relied on the "of at least two rounds" clause to overcome the examiner's initial rejection of claim 27 over a prior art reference. The cited reference disclosed the method of testing a demand and a settlement offer in one round and calculating a settlement value if a settlement test is satisfied. In response to the rejection, the patentees added the "of at least two rounds" qualifier, after which the examiner allowed the claim because he found no motivation to combine the prior art reference with "multiple rounds of negotiation." By adding that unconditional limitation, the patentees added a required step to the method claim, not merely a permitted step.

We reject Cybersettle's argument that our construction makes the "in one of" clause superfluous. That clause serves the purpose of specifying in how many rounds any one pair of values must be tested. Without that clause in the claim, the claim would direct the testing of a single pair of bids in two or more rounds, contravening the patentees' definition of each round as involving a distinct pair of bids.

In sum, independent claims 1 and 27 both require the receipt of at least two demands and at least two settlement offers. Although that modification of the district court's claim construction may have little effect on the ultimate outcome of this case, that is a matter for the district court to determine on remand. In the course of their operation, the accused ANS 3 and ANS 1x systems would infringe (assuming all the other claim limitations were satisfied) only when they received multiple demands and multiple offers; proof that those systems were capable of receiving multiple demands and multiple offers is not proof that they ever performed the claimed methods.

3181

A. "Plurality of Different Modes"

Covad argues that the Court should construe claim 1's transceiver that operates in a "plurality of different modes" and claim 21's "ADSL/AVR" transceiver to be:

- a transceiver that operates by dividing available bandwidth between two channels in at least two of the following ways, (1) where the first channel is smaller than the second ("conventional ADSL" mode); (2) where the two channels are of "roughly" equal size ("bi-directional" mode); and (3) where the first channel is larger than the second ("reversible" mode).

Bell Atlantic asserts that neither claim 1 nor claim 21 makes a reference to "bandwidth" and argues that the Court should construe the term "mode" as used in claim 1 as "the operational state of the claimed transmission system (when transmitting) as defined by the upstream and downstream transmission rates."

Covad relies exclusively on intrinsic evidence in support of its position. The patent explains that the microprocessor assigned to each unit selects "the transmission bandwidth and mode of the ADSL/AVR transceiver." Col. 11, ll. 61-62. In this context, it discusses using filters to ensure that data transmission occurs over the appropriate bandwidths. See col. 11, ll. 62-67. The patent discusses three "different modes," which are the only ones discussed anywhere in the patent, namely, the "conventional ADSL" mode, the "bi-directional" mode, and the "reversible" mode. The conventional ADSL mode allocates more capacity to the downstream channel than to the upstream channel, as shown in Figure 4 of the patent. See col. 12, ll. 3-10; fig. 4 (attached). The bi-directional mode is one in which the transmission capacity is shifted from one channel to the other to provide "roughly equivalent" upstream and downstream channels, as shown in Figure 10 of the patent. See col. 12, ll. 11-21; fig. 10 (attached). The reversible mode allocates less capacity to the downstream channel than to the upstream...
channel, such that the bandwidth allocation is the reverse of the conventional ADSL mode. See col. 12, ll. 22-30.

The patent specification explains that the bandwidth may be allocated between the upstream and downstream channels without making changes to the transceivers:

The encoder/decoder in the digital circuit may controllably transmit and receive over, in effect, the entire range, and use the range in different ways. Conventional ADSL has three different predefined spectrums as described previously. The firmware in the microprocessor/controller can enable the ADSL/A VR transceiver to transmit and receive anywhere in the spectrum … The range of the spectrum can be set so that it is possible to get more bandwidth going upstream and less bandwidth going downstream.

* * *

The structure of the chips in the chip set does not need to be changed to vary the mode of the transceiver or the transmission rates. Instead, the transceiver may be given another set of program guides telling it how to reallocate the spectrum.

Col. 13, ll. 12-23, 39-43.

The specification clearly states that this ability to manipulate the bandwidth is one of the useful innovations of the '786 patent: "This capability to manipulate the bandwidth range opens up possibilities to obtain transmission rates greater than the … rate typically used in ADSL systems." Col. 13, ll. 24-26.

Throughout the patent specification, the inventors describe only three "different modes": conventional ADSL, bi-directional, and reversible ADSL. See, e.g., col. 12, ll. 3-30; col. 13, ll. 6-12, 47-62; col. 14, ll. 7-21. As the patent defines different modes as the shifting of bandwidth back and forth between two channels, then there are only three logical possibilities for the different modes: where the downstream has greater capacity than the upstream, where the two channels have equal capacity, and where the downstream has smaller capacity than the upstream.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

8 Despite Bell Atlantic's assertion that downstream and upstream flows of information may also be separated by time or through the use of echo cancellation, the '786 patent only refers to the use of frequency separation (manipulation of the available bandwidth) as a means to separate flows of information. No reference is made to either time separation or echo cancellation within the language of the patent itself.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The patent abstract further clarifies that an "ADSL/A VR transceiver" must operate in multiple modes, and the abstract only discusses the same three modes:

Asymmetrical digital subscriber line interface units operating at variable rates and in variable modes (ADSL/AVRs) over a local loop offer one-way video-on-demand and other services and carry the necessary signaling between the subscribers and information providers. In an asymmetric mode, the interface units frequency multiplex digital information with voice information to the subscriber and support transmission of a reverse control channel from the subscriber to the central office for transmission back to the information provider. Other modes are supported which permit selective bi-directional and reversible communications as well.

Abstract.

The patent repeatedly refers to the "ADSL/A VR" transceiver as including multiple modes, and the only three modes discussed are the conventional ADSL mode, the bi-directional mode, and the reversible ADSL mode. See, e.g., col. 4, ll. 20-23; col. 4, ll. 29-32; col. 10, ll. 59-67; col. 11, l. 61-col. 12, l. 2; col. 13, l. 63-col. 14, l. 5; col. 15, ll. 29-35.

The prosecution history also supports Covad's position with regard to the definition of "plurality of different modes" and the
"ADSL/AVR" transceiver. The PTO initially rejected the '786 patent claims as obvious over a prior ADSL patent to Arnon. See U.S. Patent No. 5,408,260. In Arnon, the bandwidth of the ADSL channels does not change once communications are established. Bell Atlantic then amended the claims and argued that the Arnon prior art did not bar the '786 patent claims because Arnon did not shift bandwidth from one channel to another as it changed modes. See July Amendment, at 14. Bell Atlantic described the Arnon prior art reference as having a single conventional fixed bandwidth distribution: "However, with the ADSL unit of Arnon's subscriber loops appear to be [a] conventional ADSL unit having a bandwidth distribution of the type illustrated in Applicant's Fig. 4." Id. Bell Atlantic then distinguished this single bandwidth distribution structure from the scope of the '786 patent's claims:

This is completely different from the present invention in which the ADSL terminal selectively changes the bandwidth for both control [upstream] and data [downstream] channels in the subscriber loop. … Even though Arnon teaches a fault induced substitution mode in col. 7, lines 26-44, the bandwidth or transmission rates in the ADSL loops during the fault mode or during the normal modes remain unchanged.

Id. at 15 (emphasis in original).

Bell Atlantic therefore represented that a conventional bandwidth system is "completely different" from the '786 patent system, which "selectively changes the bandwidth" of the DSL channels. See id.

Bell Atlantic has further stated to the PTO that the '786 claims require that bandwidth be reallocated between channels:

The ADSL/AVR's of the present invention are a modification of, and an improvement over, conventional ADSL units such as those shown in Figs. 3 and 6 of the disclosure. Conventional ADSL units multiplex voice and signaling information and other information on the subscriber loop using frequency multiplexing to divide the available loop bandwidth into three channels, such as channels 302, 304, and 306 of Fig. 4. … In the present invention, the transmission bandwidth of channels 302, 304, and 306 are controlled for various modes using a microprocessor/controller in the ADSL/AVR unit. The exemplary ADSL/AVR embodiment shown in Fig. 7 operates in one of three modes. The first mode is a conventional ADSL mode, as shown in Fig. 4 … The second mode is a bi-directional transmission mode … The third mode is a reversible mode … Hence, an ADSL/AVR unit effectively functions as a variable rate/variable mode modem …

Id. at 11-12.

Bell Atlantic added that the "ADSL/AVR" functions "as a variable rate/variable mode modem" operating at the "optimum mode." See id. at 13. The prosecution history, as with the language in the patent itself, only refers to three modes, and the only means discussed to change modes is through the reallocation of bandwidth.

Bell Atlantic asserts that the term "mode" as used in claim 1 should be construed by the Court as "the operational state of the claimed transmission system (when transmitting) as defined by the upstream and downstream transmission rates." Bell Atlantic relies first on extrinsic evidence in support of this construction. Bell Atlantic cites to two dictionary definitions of the term "mode." The first is "the operational state of a computer or program." Microsoft Press Computer and Internet Dictionary. The second is "[a] particular functioning arrangement or condition: STATUS <<a spacecraft in reentry> <<a computer operating in parallel>>." Merriam Webster's Collegiate Dictionary.

Bell Atlantic challenges Covad's argument that "modes" must differ in "bandwidth" and states that the dictionary definitions make sense in the context of the patent. Bell Atlantic argues that Covad is attempting to read language into the claims that was not intended, and Bell Atlantic refers to the initial description of the object of the invention, which states:

It is the broad object of the invention to controllably operate in one of a plurality of different modes and at any one of a plurality of different bit rates so as to provide a single transmission platform which may support a plurality of different services …

Col. 2, ll. 48-52.

Bell Atlantic states that while the preferred embodiment addresses the notion of modes and how one changes them, there is no limitation to changing transmission rates by one particular method such as changing bandwidths. Bell Atlantic asserts that
Figures 4 and 10 of the patent support Bell Atlantic's construction as these figures serve as mere illustrations of two examples of implementing modes. With regard to the nature of preferred embodiments, the patent states:

Although the present invention has been described and illustrated in detail, it is clearly understood that the same is by way of illustration an example and is not to be taken by way of limitation, the spirit and scope of the present invention being limited only by terms of the appended claims.

Col. 16, l. 66-col. 17, l. 3.

Bell Atlantic argues that additional limitations cannot be imported into a claim from the written description or preferred embodiment. The Court may, however, construe a specifically claimed limitation in light of the specification, which is all the Court does here. See Phonometrics, 133 F.3d at 1466. Further, taking guidance from the Court of Appeals for the Federal Circuit in Wang, the discussion of the three modes in the preferred embodiment and the means of changing modes by altering bandwidth are the only references to "modes" in the patent. The Court will not broaden claims 1 and 21 beyond their support in the specification, as the three modes discussed in the patent specification literally occupy the field of possibilities contemplated by the '786 patent. If the Court broadened the claims beyond technology even referred to in the patent itself, the purpose of the patent to inform the public of the scope of the claim would be defeated entirely. 9 It is the opinion of this Court that Bell Atlantic's arguments are an attempt to abuse the privileges of the patent by extending the "right to exclude" beyond the scope of the patent itself. During the prosecution history, Bell Atlantic was careful to define the scope of the patent claims narrowly in order to distinguish it from prior patents such as Arnon. Once the '786 patent had been awarded, however, Bell Atlantic may not later alter its claim definitions in an effort to define the patent as broadly as possible in order to establish a better litigation position.

9 A patent is a fully integrated written instrument. By statute, a patent must provide a written description of the invention "in such full, clear, concise, and exact terms" that will enable one of ordinary skill in the art to make and use it. See 35 U.S.C. § 112. The applicant for a patent is also required to conclude the specification with claims "particularly pointing out and distinctively claiming the subject matter which the applicant regards as his invention." Id. Further, the Court of Appeals for the Federal Circuit in Markman emphasized the need to determine the scope of patent: "it is only fair (and statutorily required) that competitors be able to ascertain to a reasonable degree the scope of the patentee's right to exclude." Markman, 52 F.3d at 978; see also Merrill v. Yeomans, 94 U.S. 568, 573-74, 24 L. Ed. 235 (1877) ("It seems to us that nothing can be more just and fair, both to the patentee and to the public, than that the former should understand, and correctly describe, just what he has invented, and for what he claims a patent.").

The Court further recognizes that the Court of Appeals for the Federal Circuit has described intrinsic evidence as "the most significant source of the legally operative meaning of claim language." Vitronics, 90 F.3d at 1582. The Court will not, as Bell Atlantic requests, rely on extrinsic evidence in the form of dictionary definitions and expert testimony referring to time separation and echo cancellation, as an analysis of intrinsic evidence alone will resolve any ambiguities in the disputed claim terms. Thus, the Court finds that claim 1's transceiver that operates in a "plurality of different modes" and claim 21's "ADSL/AVR" transceiver mean:

- a transceiver that operates by dividing available bandwidth between two channels in at least two of the following ways, (1) where the first channel is smaller than the second ("conventional ADSL" mode); (2) where the two channels are of "roughly" equal size ("bi-directional" mode); and (3) where the first channel is larger than the second ("reversible" mode).
argues that the phrase "plurality of different modes" simply requires "multiple operational states providing different transmission services, as distinguished by their upstream and downstream transmission rates, whether the differences are achieved by altering bandwidth or by the other familiar methods of altering transmission rates." Bell Atlantic argues that the universe of "modes" contemplated by the '786 patent is not limited to the three modes discussed by the district court (conventional, bi-directional, and reversible). Bell Atlantic reasons that these three modes are simply "three broad categories" that may encompass other operational "modes." Specifically, Bell Atlantic contends that the rate of data transfer (as opposed to the bandwidth) within each of the three broad categories can be changed to create additional modes.

For example, Bell Atlantic posits that a bi-directional service "offering 192 Kbps [kilobits per second] in each direction is quite different from one offering 1.1 Mbps [megabits per second]." Under the district court's construction, both services would operate in the same "mode" (bi-directional) because both services allocate the same amount of bandwidth to both the upstream and downstream directions. However, Bell Atlantic argues that the 192 Kbps bi-directional service would operate in a different "mode" than the 1.1 Mbps bi-directional service because the rate of data transmission varies between the two services. Bell Atlantic also suggests that a transmission system may be changed from a conventional ADSL mode to a bi-directional mode by increasing the coding to allow "more bits per baud" or by "bit stuffing" without altering the relative bandwidth distribution of the upstream and downstream channels. In short, Bell Atlantic argues that "a plurality of different modes" also encompasses different methods of altering the transmission rates within the three broad categories.

It may be true that the ordinary meaning of the word "mode" supports a broader meaning than the construction ascertained by the district court. However, we must look at the intrinsic evidence to determine whether the patentee has given the term an unconventional meaning. Hockerson, 222 F.3d at 955, 55 U.S.P.Q.2D (BNA) at 1490; Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576. We are mindful that the patentee may act as his own lexicographer by using the specification to define terms either expressly or "by implication." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. Moreover, the ordinary meaning of the non-technical term "mode" is sufficiently broad and amorphous that the scope of the claim language can be reconciled only with recourse to the written description. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998).

a. The '786 Patent Specification

At the outset, we note that the '786 patent is entitled "Variable Rate and Variable Mode Transmission System." Consistent with the title of the patent, the patentees, throughout the specification, use the terms "rate" and "mode" to refer to separate and distinct concepts. In the summary of the invention, the specification states that it is an object of the invention to operate in:

a plurality of different modes and at any one of a plurality of different bit rates . . . . Still another object of the invention is to simply and easily vary the bit rates of the upstream and downstream channels, or the modes of the transceivers . . . . Another object is to either automatically control bit rate or mode by the CO or selectively control bit rate or mode by the subscriber.

'786 patent, col. 2, ll. 49-64 (emphasis added). Later, the Summary of the Invention notes that the present invention "has the advantages of conventional ADSLs, while allowing the data rate of the reverse control signaling channel to be controllably increased so as to have a higher rate transmission than ADSL in a bi-directional mode." Id. at col. 3, ll. 15-19 (emphasis added). The specification continues:

This variable rate / variable mode ADSL service will accommodate access to a wide variety of information providers . . . . In addition to variable bit rates for the control channel, the invention enables at least two modes for the ADSL transceivers, one providing bi-directional communications and the other providing asymmetrical communications.

Id. at col. 3, ll. 36-46 (emphasis added). Thus, before we even reach the Detailed Description of the Preferred Embodiments, it is clear that the '786 patent specification (in the Summary of the Invention) refers to the terms "rate" and "mode" as two separate and distinct concepts. The term "rate" describes the data rate within a given channel, while the term "mode" differentiates between asymmetrical and bi-directional communications.

The written description of the preferred embodiments also guides our interpretation of the claim language, as claims must be read in light of the specification. Scimed, 242 F.3d at 1340-41, 58 U.S.P.Q.2D (BNA) at 1062. We are mindful of the fact
that limitations from the specification may not be read into the claims. Comark, 156 F.3d at 1186, 48 U.S.P.Q.2D (BNA) at 1005. Indeed, Bell Atlantic argues that by limiting the construction of the term "mode" to the three broad categories described in the specification, the district court improperly imported the limitations of one embodiment into the claim term. We disagree.

We recognize that there is sometimes "a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification." Comark, 156 F.3d at 1186, 48 U.S.P.Q.2D (BNA) at 1005. For example, relying on Johnson Worldwide, Bell Atlantic argues that it is impermissible to rely on the written description of a preferred embodiment to limit the claim language. In Johnson Worldwide, we held that the meaning of a claim term was not limited by its specific usage in the written description of a preferred embodiment. 175 F.3d at 991, 50 U.S.P.Q.2D (BNA) at 1611. We reasoned that the "varied use of a disputed term in the written description demonstrates the breadth of the term rather than providing a limited definition." Id.; see also Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1310, 51 U.S.P.Q.2D (BNA) 1161, 1170 (Fed. Cir. 1999) (holding that the written description of the preferred embodiments can set forth more than one definition of a claim term).

However, Bell Atlantic's reading of Johnson Worldwide and characterization of the role of the written description is too narrow. We held in Scimed, 242 F.3d at 1344, 58 U.S.P.Q.2D (BNA) at 1065, that the written description "can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format." Id. (emphasis added). Thus, when a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term "by implication." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577; see also Hockerson, 222 F.3d at 955, 55 U.S.P.Q.2D (BNA) at 1490.

In this case, in addition to the Summary of the Invention, the Detailed Description of the Preferred Embodiments continues to use the terms "mode" and "rate" to refer to two separate and distinct concepts. The specification notes that the arrows used in figure seven "illustrate the reversible mode feature of the system and no fixed data rate is given due to the capability of the system to transmit at any one of a number of different transmission rates." '786 patent, col. 10, ll. 64-67 (emphasis added). This passage uses the term "rate" to refer to the speed of data transmission, and uses the term "mode" to refer to the reversible mode feature. When describing the microprocessor that controls the transceivers, the specification states that "the variable transmission rates are controlled by a first [program] and the mode of the transceiver is controlled by a second [program]." '786 patent, col. 11, ll. 35-39 (emphasis added). Thus, the "mode" and "rate" of the transceiver are controlled by separate programs.

Further, the specification states that the system "operates in one of three selectable modes." '786 patent, col. 12, ll. 3-4 (emphasis added). The specification describes the modes:

   The first mode is conventional ADSL, which is appropriate for applications in which a subscriber wishes to view video data (using the fixed rate interface) or download a large amount of information in a predetermined downstream direction (utilizing the ethernet interface).

   The second mode is a bi-directional transmission mode which improves upon conventional ADSL by increasing the transmission rate of the upstream channel while decreasing the transmission rate of the downstream channel. This mode is preferable for certain interactive real-time applications such as video games and distance learning, in which a 8 Kbps or 16 Kbps upstream channel is insufficient for the flow of data in the upstream direction. An example of the channelization in the bi-directional mode in which the downstream and upstream channels are roughly equivalent is illustrated in FIG. 10 by channels 302', 304' and 306'.

   The third mode is a reversible mode in which the asymmetrical transmission of data and other information is carried out in the same manner as conventional ADSL shown in FIG. 4, but the direction of flow is selectively reversed so that the upstream direction becomes the downstream direction and vice versa. This mode is especially useful for applications in which there are non-simultaneous, non-real-time, exchanges of large amounts of information in both directions.

'786 patent, col. 12, ll. 3-29 (emphasis added).

These passages refer to Figure 10 of the '786 patent, which illustrates the described distribution of channel bandwidth.
Channel 306' is the downstream channel, while channel 304' is the upstream channel:

[SEE ORIGINAL FIGURE 10 IN ORIGINAL]

Although these passages offer the clearest description of the meaning of the term "mode" in the specification, the remainder of the written description also refers to the terms "mode" and "rate" as separate and distinct concepts:

The structure of the chips . . . does not need to be changed to vary the mode of the transceiver or the transmission rates . . . [The] microprocessor/controller enables the rate or mode of the ADSL/AVR to be selected in any one of a number of ways . . . . A menu [may query for] the desired mode and/or data rate . . . . The changes in mode and rate for the channel can be accomplished by the ADSL/AVR interface . . . . Once the mode and rate has been set . . . . The ADSL/AVR thus effectively functions as a variable rate/variable mode modem.

Another passage refers to an "asymmetrical mode." '786 patent, col. 13, ll. 6-7 (emphasis added). Other passages discuss the "reversible ADSL mode." '786 patent, col. 13, ll. 51-52. Still others explain how the system may change from "bi-directional mode to ADSL mode." '786 patent, col. 14, ll. 7-8, 44-58.

In short, there is no question that the '786 patent specification uses the terms "mode" and "rate" to refer to two different and distinct concepts. The "rate" of data flow is characterized as the transmission rate within a given channel. The "mode" is characterized by whether the relative bandwidth between the upstream and downstream channels is symmetrical or asymmetrical. Moreover, because the two terms are used separately and distinctly, different "modes" cannot be created by varying the data rate within one of the three broad categories. In other words, although a bi-directional service "offering 192 Kbps in each direction is quite different from one offering 1.1 Mbps," nevertheless, the two services do not constitute different "modes." Thus, given the single meaning of the term "mode" contemplated by the '786 patent specification, there are only three possible permutations by which the relative bandwidth may be characterized: (1) where the first channel is smaller than the second (conventional mode); (2) where the two channels are of roughly equal size (bi-directional mode); and (3) where the first channel is larger than the second (reversible mode).

We acknowledge that it is generally impermissible to limit claim terms by a preferred embodiment or inferences drawn from the description of a preferred embodiment. Johnson Worldwide, 175 F.3d at 992, 50 U.S.P.Q.2D (BNA) at 1612. However, that is not the case here. We note that "the usage 'preferred' does not of itself broaden the claims beyond their support in the specification." Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1383, 53 U.S.P.Q.2D (BNA) 1161, 1165 (Fed. Cir. 1999). Moreover, unlike Johnson Worldwide, this case does not involve the "varied use of a disputed term." Id. at 991, 50 U.S.P.Q.2D (BNA) at 1611. Instead, the patentees defined the term "mode" by implication, through the term's consistent use throughout the '786 patent specification. Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. Given this definition, the three modes described in the Detailed Description of the Preferred Embodiments describe the three possible modes of the invention, and the claims are not entitled to any broader scope. Wang, 197 F.3d at 1383, 53 U.S.P.Q.2D (BNA) at 1165.

b. Prosecution History

The prosecution history also supports limiting the transceiver to the three possible modes. During the prosecution of the '786 patent, the examiner rejected the relevant claims as obvious over U.S. Patent No. 5,408,260 ("Arnon"). Arnon describes an ADSL transmission system and transceiver that combines ADSL data with television signals, and transmits the data at varying frequencies over coaxial cable wires. Arnon, col. 2, ll. 9-50. Arnon describes a system that combines the ADSL data signals with the cable television signal at ADSL "terminal units" within a residential building. Arnon, col. 3, ll. 23-57. The examiner initially rejected the relevant claims of the '786 patent because:

Arnon did not expressly detail that the controller selected the mode of operation for the transceivers. Arnon however taught that the receivers and transmitters could be automatically retuned to a different frequency when a terminal unit was faulty . . . . Therefore, it would have been obvious to one of ordinary skill in the [data processing] art at the time of the claimed invention that the Arnon system comprised control means which retuned the receivers and transmitters when a terminal unit was faulty so that it could communicate via another terminal unit. Also clearly it would have been obvious that this operation would have comprised selecting the new mode of operation for transmission of data. Further since the Arnon system operated on different channels at different rates it would have been obvious to a routine that even in normal operation the Arnon system would have used a control means to change modes of transfer and speeds of transfer.
Although the statements of an examiner will not necessarily limit a claim, we observe that the examiner understood that the "mode of transfer" was a separate and distinct concept than the "speed of transfer."

Moreover, in an attempt to distinguish his invention from Arnon, the patentees responded with various statements. Importantly, the patentee argued:

In the present invention, the transmission bandwidth of channels 302, 304, and 306 are controlled for various modes using a microprocessor/controller in the ADSL/A VR unit.

(Emphasis added.) It is clear from this statement that the "mode" of the present invention varies solely by changing the amount of bandwidth allocated between the upstream and downstream channels. In subsequent statements, the patentees described the "exemplary ADSL/A VR embodiment" that operates "in one of three" modes: conventional, bi-directional, and reversible. The patentees observed that the invention allows one to perform various functions "in the optimum mode and at the optimum transmission rate for that function." (emphasis added). The patentees further distinguished Arnon because:

The ADSL unit of Arnon's subscriber loops appear to be conventional ADSL unit having a bandwidth distribution of the type illustrated in Applicants' Fig. 4 . . . Arnon's ADSL terminal comprises transmitters and receivers for communicating bi-directional data and control signals via the coaxial cable between the ADSL units and the subscriber, in each case modulated at a frequency which is not used for television signals. This is completely different from the present invention in which the ADSL terminal selectively changes the bandwidth for both control and data channels in the subscriber loop."

(emphasis in original). Bell Atlantic now contends that this statement merely distinguishes the fact that Arnon's terminal units operated within a residential unit, while the transceivers described by the '786 patent operate outside the building, or "in the subscriber loop." It is true that the emphasized language supports this distinction. However, the statement also states that, "the present invention . . . selectively changes the bandwidth." Thus, not only did the patentees distinguish that the invention operated in the subscriber loop, but they also emphasized that a conventional bandwidth distribution is "completely different" from the invention's system of "selectively changing the bandwidth."

That the transceivers must operate in one of the three described modes is further supported by the language of dependent claims 9 through 12:

9. The transmission system of claim 1, wherein said plurality of different modes includes a conventional ADSL mode and a bi-directional mode.

10. The transmission system of claim 1, wherein said plurality of different modes includes a conventional ADSL mode and a reversible mode.

11. The transmission system of claim 1, wherein said plurality of different modes includes a bi-directional mode and a reversible mode.

12. The transmission system of claim 1, wherein said plurality of different modes includes a conventional ADSL mode, a bi-directional mode, and a reversible mode.

'786 patent, col. 17, l. 59 to col. 18, l. 3. These four dependent claims contemplate the only four possible permutations of a "plurality of different modes." It is true that limitations stated in dependent claims are normally not to be read into the independent claim from which they depend. Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 972, 50 U.S.P.Q.2D (BNA) 1465, 1468 (Fed. Cir. 1999). However, our acknowledgement of dependent claims 9-12 simply further demonstrates that the '786 patent defined the term "mode" by implication to mean the relative allocation of bandwidth between the first and second channel. Such a meaning leaves only three possible modes: conventional, bi-directional, and reversible.

Bell Atlantic observes that independent claim 21 does not contain the "plurality of different modes" language contained in claim 1. Nevertheless, the district court held that the "ADSL/AVR transceiver" described in claim 21 must also operate by dividing available bandwidth between the two channels in conventional, bi-directional, and reversible modes. We agree with the district court. The second sentence of the '786 patent abstract refers to ADSL transceivers "operating at variable rates
and in variable modes (ADSL/AVR)." (emphasis added). In the Summary of the Invention, the '786 patent specification defines the invention as "an ADSL having adjustable variable rate functionality (ADSL/AVR)." '786 patent, col. 3, l. 10-11. The '786 patent uses the terms "transceiver," "ADSL/AVR," and "ADSL/AVR transceiver" interchangeably throughout the written description and the prosecution history. Therefore, one of ordinary skill in the art would understand that the transceiver described in claim 1 is the same transceiver described in claim 21. Thus, at the same time the patentees defined the term "mode" by implication, they also defined the ADSL/AVR transceivers as those that operate in conventional, bi-directional, and reversible modes by allocating bandwidth between the first and second channels. For these reasons, the transceivers described in claims 1 and 21 are construed synonymously with the definition of "mode" set forth above.

3183

b. "Plurality of electronic switches" and "means for selectively connecting the energy source to the electrodes in a first polarity and a second polarity"

The "plurality of electronic switches" of Claim 8 and the "means for selectively connecting the energy source to the electrodes in a first polarity and a second polarity" of Claim 1 refer to the same element of the defibrillator. This element is generally described as a "connecting mechanism" or "connector" that connects the defibrillator's energy source to the electrodes for shock delivery. 212 Patent at 6:44-50 & Fig. 10, element no. 34. Subsequently, the patent describes the connector in substantially greater detail as a specific five-switch configuration. 212 Patent at 6:61-7:52 & Fig. 11. The dispute over these terms is whether, as Defibtech contends, Claims 1 and 8 require this five-switch configuration. Philips contends that any of numerous configurations of two or more switches known to persons of skill in the art would satisfy Claims 1 and 8.

The means-plus-function term in Claim 1 presents the easier interpretation issue. Philips points to the general disclosure of a "connecting mechanism" as sufficient disclosure of the structure corresponding to the claimed function. The court disagrees. The patent's discussion of a "connecting mechanism" discloses no structure at all. As Defibtech noted in oral argument, the "connecting mechanism" corresponds to no more than a two-dimensional box in Figure 10 of the 212 Patent. This is insufficient, as a matter of law, to fulfill the inventors' duty to pinpoint a structure that corresponds to the function cited in a means-plus-function term. See Med. Instrumentation & Diagnostics Corp. v. Elekta AB, 344 F.3d 1205, 1211 (Fed. Cir. 2003). n1 The court cannot designate the "connector" in Figure 10 and the written description of a "connecting mechanism" as corresponding structure, because they serve merely as an introduction to the five-switch configuration in Figure 11 and the accompanying disclosure of actual structure. See Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1212 (Fed. Cir. 2003). Moreover, Philips cannot cure the lack of structure other than the five-switch configuration by noting that "[o]ther switches and switch configurations may be used, of course, without departing from the scope of the invention." 212 Patent at 7:48-49. An inventor cannot meet his obligation to disclose structure corresponding to a means-plus-function term merely by stating that the structure will be obvious to those of skill in the art. Med. Instrumentation, 344 F.3d at 1212 ("It is important to determine whether one of skill in the art would understand the specification itself to disclose the structure, not simply whether that person would be capable of implementing that structure."). Claim 1 sends the public on a search for structure corresponding to a "means for selectively connecting." It would be incongruous to conclude that the inventors satisfied their obligation to reward that search by disclosing nothing more than a "connecting mechanism." The only disclosure of structure corresponding to the "means for selectively connecting . . ." is the five-switch configuration noted above, and the court interprets the means-plus-function claim accordingly. n2

n1 Med. Instrumentation and other Federal Circuit precedent focus on an inventor's duty to "clearly link[]" structure in the specification to a means-plus-function term. 344 F.3d at 1211. Philips did not fail to "clearly link" the "connecting mechanism" to its means-plus-function term; it failed instead to pinpoint any structure for the connecting mechanism other than the five-switch configuration.

n2 The court notes that Claim 7, which depends from Claim 1, discloses the five-switch configuration. Claim differentiation compels the presumption that the terms have different scope. In this case, however, because the "means for selectively connecting" has no corresponding structure other than the five-switch configuration, Defibtech has overcome the presumption. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) ("A means-plus-function limitation is
not made open-ended by the presence of another claim specifically claiming the disclosed structure which underlies the means clause or an equivalent of that structure.")

The "plurality of electronic switches" in Claim 8 presents a closer question. Freed from the strictures of means-plus-function format, the inventors arguably signaled their intent to permit other switch configurations by noting that such configurations would be apparent to those of skill in the art. 212 Patent at 7:48-49. In addition, because Claim 11 depends from Claim 8 and discloses the five-switch configuration explicitly, claim differentiation requires the court to presume that Claim 8 encompasses other configurations.

Defibtech insists that Philips disavowed all but the five-switch configuration as a "plurality of switches" in the prosecution of the patent. Defibtech points to an office action in which the examiner rejected Claims 1 and 8 as obvious in light of the Swanson Patent, which also disclosed a five-switch configuration in an internal defibrillator, although not the same configuration as in the 212 Patent. J.A. 02692. Defibtech correctly notes that the inventors disavowed Swanson's five-switch configuration. J.A. 02692, 02697. The inventors did not, however, expressly limit the invention to the five-switch configuration that they disclosed in their patent application. The inventors explained that it would take undue experimentation to implement Swanson's five-switch configuration in an external defibrillator because the configuration would not work with high voltage. J.A. 02692. In an affidavit accompanying the response to the office action, inventor Daniel Powers stated that Swanson's five-switch configuration would not work in an external defibrillator, and that "[d]eveloping a circuit design that protects the [external defibrillator] circuit from load faults is a major design challenge." J.A. 02701.

The interpretation of the "plurality of switches" term, for which the intrinsic evidence does not provide an unambiguous definition, requires the court to consider extrinsic evidence for the first time. In a rebuttal report, Philips expert Dr. Leslie Geddes reviewed a different prior art reference and noted that it did not disclose "what types of switches" should be used, and that one skilled in the art would have "extensive difficulty" designing an external defibrillator switching circuit based on that reference. Snyder Decl. Ex. 12 (Geddes Rebuttal Report at 23). Unlike Dr. Powers, Dr. Geddes does not even mention the configuration of the switches. The court cannot draw conclusions regarding his views on the ease of configuring an appropriate switch array. The court concludes that Dr. Geddes' testimony lends some support to the notion that designing an appropriate switch array was no simple task for one skilled in the art.

n3 In its prior order, the court stated that the only extrinsic evidence before it was a set of dictionary definitions. October 25 order at 5. That was true for the first round of asserted terms, but the parties have introduced inventor and expert testimony in support of some of the remaining terms. The court is mindful of the Federal Circuit's cautious approach to extrinsic testimony, id., and has considered the evidence accordingly.

The court has also considered Mr. Powers' deposition, in which he testified that he knew of no functional switch configurations other than the five-switch configuration when the inventors first filed a shock delivery patent application. Powers Dep. at 85 (DM 034). Defibtech has not provided enough of the deposition transcript to provide full context for his testimony. The court determines that, like Dr. Geddes' testimony, Mr. Powers' testimony slightly strengthens the evidence in favor of a limited construction of "plurality of switches," because it shows that they, as persons of skill in the art, had no actual alternative configuration to back up their statement in the 212 Patent that other switch configurations would be apparent to those of skill in the art.

Based on all of the evidence before it, the court concludes that the "plurality of switches" is limited to the five-switch configuration disclosed in the specification. Philips cannot deny that it disavowed the Swanson five-switch configuration. Thus, the construction of "plurality of switches" is not as broad as the claim language would suggest. At best, the court could construe the term to mean "a plurality of switches, but not the plurality of switches disclosed in Swanson." Even this interpretation, however, would be unreasonable in light of the inventors' statements during prosecution. Mr. Powers admitted in prosecuting the patent that designing an appropriate switch configuration was difficult. In light of that
admission, the statement in the specification that "other switches and switch configurations may be used" rings hollow, at least as a statement of what one of skill in the art could accomplish without undue experimentation. Although the inventors' five-switch configuration might be equivalent to other configurations, the term "plurality of switches" must be limited to the disclosed five-switch configuration and those equivalents. The court therefore construes the "plurality of switches" in Claim 8 in the same manner it construed the "means for selectively connecting" in Claim 1. n4 The term requires the five-switch configuration from the 212 Patent or its equivalent.

--- Footnotes ---

n4 Philips suggests, without explanation, that the presence of the "plurality of switches" term in Claim 17 of the 454 Patent (which neither party has offered for construction) should affect the court's construction. Phillips Opp'n at 29. As the court previously noted, the 454 Patent incorporates the specification of the 212 Patent (October 25 order at 6), and the court finds no new disclosure in the 454 specification that would alter its construction of "plurality of switches."

--- End Footnotes ---

3184

"Plurality of optical communication channels" means "two or more optical communication channels; each optical communication channel providing an optical signal path separated in frequency from other optical signal paths."

3185

B. The '780 Patent - Claim 4

Claim 4 provides:

A hand held pointing device for a computer system, the pointing device comprising:

- a housing having a bottom surface that moves against a work surface; the housing also having a top surface shaped to receive the human hand;

- the housing also having a skirt connecting a perimeter of the bottom surface with the top surface;

- the housing also having a first axis extending generally in the direction from where the heel of the hand rests on the top surface to where the middle finger rests on the top surface, and a second axis perpendicular to the first, both axes parallel to the bottom surface;

- an aperture in the bottom surface;

- a source of illumination mounted within the interior of the housing, proximate the aperture, that illuminates a portion of the work surface opposite the aperture and having surface height irregularities forming a micro texture with feature sizes in the range of about five to five hundred microns, the illumination producing a pattern of highlights upon surface height irregularities that extend out of the desktop surface and that intercept the illumination and of shadows upon surface height irregularities that extend into the desktop surface and whose illumination is blocked by adjacent surface height irregularities that are illuminated;

- an optical motion detection circuit mounted within the interior of the housing and optically coupled to the pattern of highlights and shadows from the surface height irregularities of the illuminated portion of the work surface, the optical motion detection circuit producing motion signals indicative of motion in the directions along the first and second axes and relative to the surface height irregularities of the illuminated portion of the work surface;
wherein the optical motion detection circuit comprises a plurality of photo detectors each having an output, a memory containing a reference frame of digitized photo detector output values and a sample frame of digitized photo detector output values obtained subsequent to the reference frame, and further wherein a plurality of comparison frames, each being a shifted version of one of the reference frame or the sample frame, is correlated with the other of the reference frame or the sample frame to produce a corresponding plurality of correlation values and ascertain motion in the directions along the first and second axes;

and an arithmetic comparison mechanism coupled to the plurality of correlation values, and wherein the motion signals are not output to the computer system whenever a correlation surface described by the plurality of correlation values fails to exhibit a selected curvature.

The parties dispute the construction of the phrase: "a plurality of photo detectors each having an output, a memory containing a reference frame of digitized photo detector output values." To determine a construction, the Court considers the constituents of the phrase.

1. "a plurality of photo detectors"

The '780 Patent claims as an invention a "Seeing Eye Mouse for a Computer System." In the "Summary of the Invention" the inventors disclose that the invention is an "optical" mouse, which "detects motion by directly imaging as an array of pixels the various particular spatial features of a work surface below the mouse." (Col. 3:1-3.) In the written description, an embodiment of the "photo detectors" is described as follows:

The photo detectors may comprise a square array of say, 12 to 24 detectors on a side, each detector being a photo transistor whose photo sensitive region is 45 by 45 microns and of 60 microns center to center spacing.

('780 Patent, Col. 8:48-52.)

Although, the size and layout of the embodiment are not limitations on the Claim, one of ordinary skill in the relevant art would understand from reading the patent documents that by "plurality of photo detectors" the inventors meant a semiconductor device which generates an electrical signal in response to light.

2. "each having an output"

The plain meaning of the phrase, "each having an output," to one of ordinary skill in the relevant art is that there is a one-to-one connection between each photodetector and an input to something else.

3. "a memory"

The plain meaning of the phrase, "a memory," to one of ordinary skill in the relevant art is that the circuitry of the mouse contains a device where information can be stored and retrieved.

4. "containing a . . . frame of . . . output values"

The phrase "containing a . . . frame of . . . output values" is a limitation on the memory component. There are two aspects of how the phrase is worded which require attention. First, one of ordinary skill in the relevant art would understand that "a . . . frame of . . . output values" is a phrase coined by the inventors to describe a collection of data. The optical mouse of the invention detects movement and direction of movement of the mouse on a surface by comparing successive optical images of the surface. In the Summary, the inventors disclose:

The responses of the individual photo detectors are digitized to a suitable resolution (say, six or eight bits) and stored as a frame into corresponding locations within a array of memory.

('780 Patent, Col.3:30-34.) One of ordinary skill in the relevant art would understand that the word "array," in the computer data processing context means: a list of data values, all of the same type, any element of which can be referenced by an expression consisting of the array name followed by an indexing expression. See Microsoft Computer Dictionary, 35 (5th
The inventors are using the word "frame" to refer to storage, as an array in memory, of individual values which represent the response of each photo detector to a surface at a given point in time.

A second aspect of the phrase is the inventors' use of the stative verb 8 "containing" in combination with a description of data generated from using the device as a limitation on the device, itself Claim 4 is a patent on the device as opposed to a patent drawn to the functionality of a device. Nevertheless, in the element under consideration, the inventors describe the device as already containing data, namely, "a reference frame of digitized . . . output values," "a sample frame of . . . output values," and "a plurality of comparison frames."

8 Verbs in English are classified into two categories: dynamic and stative. Dynamic verbs (commonly referred to as "action verbs") usually describe actions that happen. Stative verbs usually refer to a state or condition which is not changing or likely to change. Stative verbs can refer to the relationship between two things. The word "contain" is a stative verb when used in the sentence "the box contains 12 cans of soda." The ending "ing" when added to a dynamic verb usually describes an on-going action (e.g., swimming, passing, heating). When "ing" is added to a stative verb, it usually describes an on-going state of being (having, owing, containing).

Ordinarily, in a claim, a description of the structure of a device is a limitation on the device. If a stative verb is used to describe the structure, the condition being described is an inherent, unchanging part of the structure. Thus, for example, a patent claim element which states "a circuit containing three transistors," limits the element to a circuit having three transistors. In the element of Claim 4 under consideration, the inventors disclose a circuit which comprises "a memory containing a reference frame of digitized photo detector output values." The literal language requires the reference frame to be an existing part of the "memory." The written description discloses that the values are not an inherent part of the memory. The "output values" only become a part of the memory if the device is used. For the time being, subject to further consideration, the Court will treat the stative word "containing" to mean "having the capability of containing." The Court invites the parties to address this issue in subsequent proceedings.

The final component of the phrase under consideration is "digitized photo detector output values." The Summary states:

The responses of the individual photo detectors are digitized to a suitable resolution (say, six or eight bits) and stored as a frame into corresponding locations within a array of memory.

("780 Patent, Col.3:30-34.")

The emphasized phrases clarify that the "responses" (i.e., outputs) of each photo detector is "digitized." A person of ordinary skill in the art would understand that by the word "digitized" the inventors meant that the output voltage 9 of each photo detector is converted to a binary number. 10 By their use of the word "corresponding," one of ordinary skill in the art would understand that the inventors intended that what was to be stored in each cell of the frame was a binary number representing the voltage output by each photo detector.

9 The written description discloses that each photo detector outputs a voltage which is digitized: "The photo transistors charge capacitors whose voltages are subsequently digitized and stored in memory." ("780 Patent, Col.8:53-55.)

10 A "digit" is any whole unit in a numbering system. See Microsoft Computer Dictionary, 157 (5th ed. 2002). Since the patent discloses that the output values are stored in computer "memory," one of ordinary skill in the art would understand that the digitized value would be expressed in binary digits, a form storable in computer memory. The description of a preferred embodiment expresses the digitized value in bits. ("780 Patent, Col.3:30-34.)

Therefore, the Court construes the phrase "a plurality of photo detectors each having an output, a memory containing a
a device in which the voltage from each photo detector is converted to a binary number, which number is stored in memory in an array.

Claim 17 recites of Patent '894 recites, in part:

a microcontroller for determining operating values including the difference between the speeds of said primary drive line and said secondary drive line and the identity of one of said drive lines overrunning the other of said drive line, comparing said operating values with a plurality of predetermined values and engaging said clutch in increments when said predetermined values are exceeded by said operating values and disengaging said clutch in increments when said predetermined values exceed said operating values.

Claim 11 recites a microcontroller that performs substantially the same operations.

BorgWarner:

"Plurality of predetermined values" is a predetermined difference between the speeds of the output shafts and a determination of which shaft is overrunning (i.e., rotating the fastest), and the microcontroller causes the clutch to engage when the slip is greater than the amount of the predetermined difference. (Plaintiff's Markman Brief, at 20).

NVG:

A microcontroller having circuitry and predetermined information (i.e., determined beforehand) to (1) determine operating values, (2) perform a comparison between at least two operating values with at least two pre-set values and based on this comparison, (3) engage the clutch assembly when both pre-set values are judged to exceed both operating values; and (4) disengage the clutch assembly when both operating values exceed both pre-set values. (Markman Brief of NVG, at 29).

The parties had some difficulty, on paper and at the hearing, with this particular dispute, to the extent that it is unclear exactly what the dispute is about. Certainly, even in a patent claim, that meaning of the phrase "plurality of predetermined values" is self-evident. In ordinary language, at least, it would refer to at least two values that are set prior to comparison with operating values. Once the parties begin arguing over the interpretation, however, the problems begins.

BorgWarner's interpretation of the disputed claim term starts with the "operating values," which BorgWarner says are determined by the microcontroller, and include (1) the speed difference between the output shafts and (2) a determination of which shaft is overrunning. (Plaintiff's Markman Brief, at 29 (citing Patent '894, col. 30, ls. 33-42)). BorgWarner then explains that these operating values are compared with a "plurality" of "predetermined values," meaning, not surprisingly, "two or more predetermined values." (Plaintiff's Markman Brief, at 29-30). NVG argues that "a person of ordinary skill in the art would understand from the plain wording of the claim language that at least two 'operating values' must be compared with at least two 'predetermined values.'" (Markman Brief of NVG, at 29-30). After the initial round of briefing, it was difficult to grasp exactly what was in dispute.

The Markman hearing was of little help in this regard, as the parties went back and forth in a similar manner:

BorgWarner: We believe that the predetermined values, your Honor, are the different speed differences that are calculated -- or, I'm sorry, the different allowed speed differences that are determined based on the different operating conditions.

Court: Yes.

BorgWarner: And I'm not sure what NVG believes what the predetermined values are. They haven't identified what they believe the predetermined values to be.
As [NVG] said, as the vehicle is moving, the operating conditions are changing. The predetermined values will change.

Court: Predetermined values is going to change predicated on the operating conditions which include utilization of the brakes, steering angle compensation; there are some others.

BorgWarner: Identity of the shaft that is overrunning.

Court: [NVG], where is the difference here? I don't see it. I'm just having trouble understanding where the dispute lies with respect to understanding this term.

NVG: What BorgWarner is saying is that it says, "...operating values including the difference between the speeds of the said primary drive line and said secondary drive line ... ,"

And those are all the values he's talking about. That's one operating value.

Court: Well, BorgWarner, you disagree with that?

BorgWarner: I'm not sure I understood. I think what it has to do, your Honor, it has to determine the predetermined values, whatever they may be, based on the operating conditions --

Court: And it's a plurality of them.

BorgWarner: Right. It could be many.

Court: It's a predetermined value. As I understand the "predetermined value," the predetermined value of allowable slippage, and there is a plurality of those because you're computing more than one factor. You're computing a number of different factors that have changing values within themselves that give different, and this computer takes into account and comes up with the answer, what the single predetermined value is of the plurality. Am I missing something?

NVG: Well, the way we understand their argument, and it's based on their claim interpretation, is that there is one single difference. And we say there has to be two single differences.

BorgWarner: Well, the microprocessor constantly computes different predetermined values.

Court: Yes, a plurality of them.

BorgWarner: Right.

Court: And takes them into account a bunch of different operating values.

BorgWarner: Yes.
Court: So where are we, then, on this thing?

* * *

NVG: ... We see their interpretation as requiring only one comparison, ours talks about plural comparisons. And if they don't have a problem with ours, we ask that you adopt ours and we'll move on.

Borg Warner: Theirs doesn't identify what the predetermined values are, your Honor. That's the problem. With predetermined values --

Court: The predetermined value is constantly changing.

Borg Warner: That's right.

Court: That's why you have a plurality of predetermined values.

Borg Warner: Exactly.

* * *

Court: First of all, the term "plurality of predetermined values," again, to me, the microprocessor I guess, maybe has to be included, but to me it means a computation of a number of predetermined values from a number of operating values. That's all it means to me, with or without a microprocessor.

NVG: And that there has to be this comparison of more than one.

* * *

Borg Warner: I think we're almost on the same page here, your Honor. I think that what it is is that there is a plurality of predetermined values of speed differences based on different operating conditions.

Court: Yes.

Borg Warner: And that is as the system is functioning --

Court: All right, [NVG] suggests that your definition is in the singular, that the microprocessor reviews one operating value only and comes out with a plurality of predetermined values. He says that's not correct, a plurality of predetermined values is something that emanates from the analysis of more than one, several different operating values.

Borg Warner: Right, there are several operating values and you come up with different predetermined values.

Court: I don't think you guys have a dispute.

NVG: Then I ask that you accept ours and adopt ours.

Court: . . . I want you two fellows to meet because I don't get the problem here.

NVG: I guess I'm the only one who sees it as a difference between plural and singular.

Court: . . . whatever it is, certainly the plurality of predetermined values comes from more than one, and indeed several, operating factors. Can that be the definition?

NVG: That is the definition.
BorgWarner: Your honor, I would agree that the plurality of predetermined values, those values are the plurality as
determined based on different operating conditions.

(Markman Hearing Transcript, at 345-53). Nevertheless, the parties could not agree on a definition, or on exactly what was
in dispute. (Id. at 357-58; Plaintiff's Post Markman Hearing Brief, at 17; Post Markman Hearing Brief of NVG, at 14-15).

A review of the parties' somewhat jejune presentation on this claim dispute leaves the court where it was to begin with.
"Plurality of predetermined values" means more than one pre-set value. To the extent that the dispute is over the phrase
"operating values," that, too is plural. As is stated in the claim, "includes the difference between the speeds of said primary
drive line and said secondary drive line and the identity of one of said drive lines overrunning the other of said drive line." That
"operating values" is said to "include" these two conditions, we would think, means that operating values is not limited
to these two conditions. That is as far as the court can go on this record. A "plurality of pre-determined values" means that
the "said operating values" must be compared with at least two values that are set prior to that comparison.

GO BACK

3187

B. Plurality of Pulse Amplitude and Location Coded Signals

The phrase "plurality of pulse amplitude and location coded signals" appears in claims 40 and 42. Claim 40 states in
relevant part:

Apparatus for producing a speech message comprising: means for receiving a sequence of speech message signals for the
successive time intervals of the speech message, each time interval speech message signal including a set of coded spectral
representative signals for the time interval portion of said speech message and a plurality of pulse amplitude and location
coded signals representative of the differences between the time interval portion of the speech message and the time interval
proportion of the speech message formed from said spectral representative signals.

(emphasis added.) Claim 42 states in relevant part:

A method for producing a speech message comprising the steps of: receiving a sequence of speech message signals for
the successive time interval portions of the speech message, each time interval speech message signal including a set of
coded spectral representative signals for the time interval portion of said speech message and a plurality of pulse amplitude
and location coded signals representative of the differences between the time interval portion of the speech message and the time interval
portion of the speech message formed from said spectral representative signals.

(emphasis added.)

Microsoft’s proposed definition for this disputed claim term is "two or more pairs of amplitude and location values having a
prescribed format (b(i), m(i)), where b(i) is the amplitude and m(i) is a location of that amplitude." (Joint Letter, Ex. B.)
AT&T counters with the definition "two or more pulse amplitude values having a formatted representation and two or more
pulse location values having a formatted representation. " (Joint Letter, Ex. B.) The parties agree that the plain meaning of
the word "signal" is "a sequence of values" (JCCS at 34-36), and that the plain meaning of the word "coded" is "a formatted
representation of." (Tr. at 87.) Additionally, both parties agree that the word "plurality" means two or more. (Microsoft Post
Hearing Brief ("PHIB") at 9; AT&T Post Hearing Reply Brief ("PHRB") at 4.) Thus, the main issue is whether the coded
signals are restricted to the particular prescribed format Bi followed by Mi.

1. Plain Meaning of "Pulse"

Microsoft contends that "pulse" means "an amplitude and location pair [Bi, Mi]," while AT&T argues that pulses are not
always defined by amplitude and location, and may be reflected by a number of different formats. The McGraw-Hill
Dictionary of Scientific and Technical Terms, 1293 (3d ed. 1984), defines "pulse" as "a variation in a quantity which is
normally constant; has a finite duration and is usually brief compared to the time scale of interest." Microsoft cites to a
treatise which describes the concept of "pulse" to support its assertion that the term at issue mandates a prescribed format
(Bi, Mi). See Clare D. McGillem & George R. Cooper, Continuous and Discrete Signal and System Analysis, 275-76 (Holt,
Rinehart and Winston, Inc. 1974) (“McGillem Text”). The McGillem Text, however, notes that pulses can be represented mathematically or visually, and does not state that such representations must follow any particular format such as Bi, Mi. See McGillem Text at 275-76. For example, the pulses illustrated in the McGillem Text are in an evenly spaced series and could be described as a series of amplitudes (B1, B2, B3). In contrast, unequally spaced pulses may be reflected either by Microsoft’s proposed (Bi, Mi) format or by alternative formats such as sending the amplitudes first (B1, B2, B3), sending the locations second (M1, M2, M3), and reinterpreting the codes to build multiple pulses. Accordingly, the dictionary and treatise definitions support AT&T’s position that one skilled in the art would know from the plain meaning of the claim that a "pulse" is not restricted to a prescribed, paired format (Bi, Mi), but rather may be reflected by several different formats.

2. Prosecution History

Microsoft argues that the patentees clearly disavowed AT&T’s broader definition during prosecution and that the ’580 patent specification defines "pulse" in terms of Bi, Mi. (See Microsoft PHB at 12; Microsoft PHRB at 9-10 discussing Pros. Hist. at 116.) In examining the prosecution history, one of the passages distinguishes the patentees’ invention from United States Patent No. 4,130,729 (the ”’729 patent”) on the grounds that the ’729 patent does not claim the “formation of a coded excitation signal,” and “requires high bit rate transmission.” (Pros. Hist. at 116). The prosecution history further distinguishes the ’729 patent by noting that the patentees’ invention provides “a prescribed format coded signal (B, M) that can be transmitted at a substantially lower bit rate . . .” (Pros. Hist. at 116.) However, that passage addresses the patentees’ proposed claims 1-39 in the underlying ’832 patent, which do not contain the phrase “plurality of pulse amplitude and location coded signals.” As the term at issue here only appears in re-issue claims 40 and 42, the cited prosecution history is not applicable to that term. See Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1460 (Fed. Cir. 1998) (declining to rely on statements made during prosecution that are relevant to claim language different from, albeit related to, the term at issue).

Additionally, the prosecution history does not include a manifest disavowal of the plain meaning of the phrase, as contemplated in Teleflex. A manifest disavowal cannot derive from statements made to the examining attorney concerning other claims. Teleflex, 299 F.3d at 1328. The prosecution history cited by Microsoft does not contain an expression of manifest exclusion. Accordingly, those portions of the prosecution history on which Microsoft relies do not support its narrow, limiting interpretation of the claim term. See Teleflex, 299 F.3d at 1328; Laitram, 143 F.3d at 1460.

3. Specification

AT&T asserts that Microsoft’s use of the words "prescribed format b(i), m(i)" to describe a "pulse" improperly imports a limitation into the claim from the preferred embodiment shown in the specification. (Tr. at 87-91.) Microsoft counters that the phrase is defined by implication because every time the word "pulse" appears in the specification’s preferred embodiment, it is listed as an amplitude and location pair; and that "when a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term by implication."

(Microsoft PHRB at 7-8 citing Bell Atlantic Network Serv., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001)). However, the Federal Circuit has instructed that a preferred embodiment should not be read into a claim as a limitation, even if there is only one embodiment in the specification. See Teleflex, 299 F.3d at 1328.

In support of its more limited construction, Microsoft also cites to the specification's "Summary of Invention," which "sets forth in clear and concise terms an embodiment of the invention." (Pros. Hist. at 106.) However, that Summary merely describes how a problem "may be solved," does not refer to the proposed Bi, Mi format, and makes no overarching statements to limit the invention. (’580 patent, Col. 1:63-2:7.) Although several references to the pulse signals in the specification’s description of the preferred embodiment describe a prescribed format of Bi, Mi, there are no statements in the prosecution history or in the claims themselves to the effect that all the contemplated embodiments must use pulse codes formatted in the Bi, Mi order. Because those limitations are absent in the claims themselves and the descriptions leave open the possibility of other embodiments, they do not negate the claim term's plain meaning. See Teleflex, 299 F.3d at 1327.

Microsoft’s citation to Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999), to support its proposition that the Bi, Mi format depicted by one embodiment limits the claim itself, is misplaced. The Federal Circuit specifically rejected Microsoft’s position in Teleflex, and stated that "the number of embodiments disclosed in the specification is not determinative of the meaning of the disputed claim terms." 299 F.3d at 1327. Claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate by redefining the claim term or
used "words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, 299 F.3d at 1327; accord Altiris, 318 F.3d at 1370-71 ("Nor are claims ordinarily limited in scope to the preferred embodiment."). Even where the specification describes only one embodiment of the structure, courts are still "constrained to follow the language of the claims, rather than that of the written description." Teleflex, 299 F.3d at 1328. "An accused infringer cannot overcome the 'heavy presumption' that a claim term takes on its ordinary meaning simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history." Teleflex, 299 F.3d at 1327; accord Texas Digital Sys., 308 F.3d at 1204-05.

Accordingly, this Court will not read those limitations into the plain meaning of the claim itself. See Teleflex, 299 F.3d at 1326-27 (finding claim terms not limited to depiction of one embodiment in specification); SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985) (en banc) (same).

In conclusion, this Court construes the phrase "plurality of pulse amplitude and location coded signals" to mean "two or more pulse amplitude values having a formatted representation and two or more pulse location values having a formatted representation." This definition is based on the plain meaning of the phrase as would be understood by one skilled in the art.

A. "Information"

Claim 1 from the '961 patent is written in a means-plus-function format. By statute, in order to construe it, the function within the element must be identified and matched to a corresponding structure from the specification, which is then read into the claim. See 35 U.S.C. § 112, P 6; Braun, 124 F.3d at 1424. The element primarily in dispute is that which contains the function of "processing said information to generate a screen identification ("ID") from said first image." '961 Pat. at col. 8, ll. 22-23. The specification reveals only one structure tied to this function: "an algorithm which recognizes the screen by the layout and fields therein, not based solely upon the particular screen ID number." Id., col. 3, ll. 22-24. Consistent with the language of the function described in the claim, the specification states that after "an image recognition algorithm is utilized to recognize and display the information stored" in a buffer, the information is read from the buffer "and processed by an algorithm which generates a unique ID number." Id., col. 3, ll. 25-29 (emphasis added).

In its description of the preferred, embodiments, which provides only one embodiment of the invention, the specification more fully explains the structure by describing "a particular algorithm" which derives the following parameters in order to generate a unique screen ID:

a) the number of fields on the screen
b) type of each field
c) coordinates of the fields (row, column)
d) length of the field

When a screen is received in the buffer, the above parameters are determined in order to generate a unique screen ID. Id., col. 5, ll. 42-45.

One dispute that has arisen between the parties concerns whether the algorithm discussed in the specification evaluates attributes of all of the fields of an incoming screen of data, or simply attributes of some of the fields in order to uniquely identify the incoming screen. ResQNet, focusing on the claim language "image on a screen," urges the Court to adopt the latter approach. Specifically, ResQNet states that the element in dispute does not call for the identification of the screen itself, but rather for the identification of some smaller portion of the screen that represents an image to be displayed on the screen. However, there is no mention in the description just cited, nor in any other part of the specification or prosecution history of the '961 patent, of the algorithm being based upon a subset of the incoming screen.
Both the specification and the prosecution history clarify that the purpose of the invention is to uniquely identify a screen in order to overcome the problems of the prior art. For example, the specification states that one of these problems is identifying a screen as new "if the location of fields on the screen being received from the remote host has changed." Id. at col. 2, ll. 64-66 (emphasis added). The specification then states that "the above and other problems of the prior art are overcome in accordance with the present invention which relates to a display routine which is based upon an algorithm which recognizes the screen by the layout and fields therein, not based solely upon the particular screen ID number." Id. at col. 3, ll. 20-24 (emphasis added). If the information evaluated were construed as involving less than all of the fields of a screen, the prior art problem would not be overcome, as changes to the screen may or may not be identified.

This interpretation is confirmed in the prosecution history. On May 19, 1995, the USPTO issued an Office Action rejecting all 13 pending claims from the application that ripened into the 961 Patent. Almost all of these claims were rejected as being unpatentable over the U.S. Patent NO. 5,179,700 to Aihara et al. (1993) (the "Aihara patent"). In their first Response to the Office Action, the applicants argued that:

rather than rely on a remotely generated screen ID which is, as in Aihara, simply "a unique name assigned to each source panel," Applicants' invention generates the screen ID, at the personal computer, based upon the values and positions of the fields in the screen of information received from the mainframe computer. Accordingly, if the layout of a screen is changed at the applications program, on the mainframe, even if the screen ID at the mainframe remains the same, the personal computer will generate a new screen ID, because the information upon which the ID is generated (e.g., location and length of fields) will change. Accordingly, Applicant's unique invention overcomes these numerous drawbacks.

(Def. Cl. Constr. Mem., App. A., Ex. 9 at 8). This argument over the prior art reveals that the information received is the "layout" of the entire screen and that the applicant disclaimed the invention evaluating less than the entire screen, for to do so would not uniquely identify the screen.

Nevertheless, it cannot be said, as Lansa proposes, that the "information" processed encompasses "at least the number, location, type, and length of every field in the green screen." (Def. Reply Mem. at 3). This broad limitation, which includes the "type" attribute, is found nowhere in the claim language itself. And although the specification excerpt quoted above from Patent '961, column 5, lines 42-45, contemplates a screen recognition algorithm which makes use of all four of the field characteristics just mentioned (number, location, type, and length), the language of that portion of the specification expressly designates the algorithm as being exemplary, not mandatory. Column 5, lines 34-39 states:

The particular algorithm used to recognize the screen and generate the screen ID may vary from system to system, but a particular such algorithm will now be described. The screen recognition algorithm is based on a combination of information available to the program from the display buffer sent by the remote computer, plus information entered by the user.

Given this language, the limitation Lansa proposes cannot be read into the claim.

Lansa, citing Toro Co. v. White Consolidated Industries, Inc., 199 F.3d 1295 (Fed. Cir. 1999), argues that despite the broader language in the claim element, which facially mentions only three of the four parameters from the specification (number, location, and length), the construction must be based upon the more limited structure set forth in the only embodiment described by the specification. However, this very argument was rejected recently by the Federal Circuit in Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 2002 U.S. App. LEXIS 12361, 2002 WL 1358720 (Fed. Cir. 2002), where the court stated:

The number of embodiments disclosed in the specification is not determinative of the meaning of disputed claim terms…. An accused infringer cannot overcome the heavy presumption that a claim term takes on its ordinary meaning simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history. We hold that claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope.

Id. at *10.
The prosecution history also supports this interpretation. In the applicant's Response to the May 19, 1995 Office Action, cited by Lansa and quoted above, it was stated that "if the layout of a screen is changed . . . the personal computer will generate a new screen ID, because the information upon which the ID is generated (e.g., location and length of fields) will change." (Def. Cl. Constr. Mem., App. A., Ex. 9 at 8). Thus, while the Response indicates that an entire screen of information is received, it contemplates a situation wherein only location and length of fields is used to generate an ID.

Moreover, it must be recognized that the application that eventually matured into the '961 patent was originally filed on April 21, 1994. That application included a relatively broad claim 1 which did not specify how the screen was identified, but simply claimed a "means for processing said information to generate a screen ID from said image, said ID uniquely identifying said screen." (Pl. Cl. Const. Mem., App. D at 15). After several rejections and responses, the examiner refused to allow the broader claims but specifically indicated that the narrower claims, which specified that the identification of the screen is derived from the number of fields, field location, and field lengths, were patentable over the prior art. The examiner did not in any way indicate that a fourth limitation, namely the field "type" as recited in claim 1 of the '608 patent, was also necessary to render the invention in the '961 patent patentable. No amendment or original claim ever called for such a limitation, no office action addressed this additional limitation, and it is therefore improper to read this limitation into the claim.

Lansa has also argued that this same limitation -- ascertaining the number, location, type and length of every field of the "green screen" -- should also be read into claim 1 of the '608 patent. Like claim 1 of the '961 patent, this claim is also written in a means-plus function format. The function in the disputed claim element is "identifying based upon a position, length and type of each of a plurality of fields, a particular screen to be displayed to said user." 1 The language of this claim element is not identical to that of the disputed claim element in the '961 patent, but it is clear from the specification that the corresponding structure is in essence the same as that provided in the '961 patent. The specification states:

Upon a screen of information being downloaded to a personal computer . . . the personal computer analyzes the screen with respect to the location of particular fields, and other attributes thereof, in order to recognize the particular screen downloaded. A technique for performing such analyses is described fully in copending application Ser. No. 08/231,373 [the '961 patent], which is commonly assigned with the present application and which is incorporated herein by reference.

'608 Pat. at col. 2, ll. 51-58. However, the language of the claim itself makes clear that, unlike the '961 patent, the algorithm is dependent on three parameters for identifying a screen: position, length, and type. Id. at col. 4, ll. 42-43. There is therefore no evidence in the claim language, nor in the specification, that the limitation Lansa has proposed should be read into the claim.

--- Footnotes ---

1 Claim 1 of the '608 Patent states in full that what is claimed is:

Apparatus for implementing a computer terminal to be connected to a remote computer, said apparatus comprising:

means for identifying a particular user logged on to said remote computer through said computer terminal;

means for identifying, based upon a position, length and type of each of a plurality of fields, a particular screen to be displayed to said user; and

a plurality of special function keys, each key performing a specified function, the specified function performed by each key being determined by the particular user logged on and the particular screen identified to be displayed.

Pat. '608, col. 4, ll. 37-49.

--- End Footnotes ---

The term "information" is again specifically used in the '075 patent. The '075 patent relates to a similar system as previously described, but the screen recognition software is obtained from a server that is separate and apart from the computer that displays the screens. Although claim 1 from the '075 patent is not in a means-plus function format, it is still necessary to
resort to the specification to construe it. 2 ResQNet states that the step in the claim stating, "If said received screen matches one of the plurality of specific screen identifying information, displaying a customized GUI screen," requires only that the screen be compared to some other identifying information to determine if a match exists. However, the element language is not facially clear, and those skilled in the art of screen recognition techniques would not know what was meant by such language. Therefore, the phrase "plurality of specific screen identifying information" must be construed based upon the specification. See NeoMagic Corp. v. Trident Microsystems, Inc., 287 F.3d 1062, 1071. That specification describes an algorithm that identifies a screen of data in order to match it to a GUI. The specification incorporates by reference the '961 patent. Thus, the "information" which was defined by reference should be consistent with the use of that term in the '961 patent, insofar as all fields on the screen are utilized. To interpret the language otherwise would include identifying a screen in ways taught by the prior art.

2 Claim 1 of the '075 patent states that what is claimed is:

The method of communicating between a host computer and remote terminal over a data network comprising steps of:

establishing a first communication session between said terminal and a communications server via a first communications channel;

downloading, from said server to said terminal, communications software for communicating between said terminal and said host and a plurality of specific screen identifying information;

utilizing said communications software to implement a second communications session between said terminal and said host via a second communications channel independent of said server;

receiving a screen from said host to said terminal;

if said received screen matches one of the plurality of specific screen identifying information, displaying a customized GUI screen; and

if said received screen does not match one of the plurality of specific screen identifying information, displaying a default GUI screen.

'075 Pat. at col. 4, l. 65 - col. 5, l. 19.

Claim 1 of the '075 Patent

Even though the '961, '608, and '075 patents claim similar (but not the same) subject matter, the '075 patent does not share the genealogy of the other two patents. The disputed language in claim 1 of the '075 patent, furthermore, does not appear in either the '961 or the '608 patent. Quite simply, this court detects no reason to construe the '075 claims as identical to similar claim terms in the other two patents.

Unlike the '961 and '608 claims, claim 1 of the '075 patent does not invoke section 112, sixth paragraph, in any of its limitations. Rather, claim 1 is a pure method claim. The disputed language reads "downloading, from said server to said terminal . . . a plurality of specific screen identifying information." '075 patent, col. 5, ll. 6-7 (emphasis added). As previously noted, "plurality" ordinarily means "at least two"; thus, "a plurality of specific screen identifying information" means "at least two pieces of specific screen identifying information." Moreover, the presence of "specific" connotes selected or particular. This phrase does not equate to "all."
In relevant part, the specification discloses: "The particular screen recognition algorithm used is not critical to the present invention but may be of the type described in the '961 patent." '075 patent, col. 4, ll. 8-10 (emphases added). The presence of "not critical" and "may" indicates a preference, not a requirement. See also id. at col. 3, ll. 40-43 ("These green screens, as they are called, are processed through screen recognition algorithms such as that described in the previously incorporated '961 patent and '383 application." (emphasis added)). Thus, the '075 patent lacks "expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, 299 F.3d at 1325. Accordingly, the written description of the '075 patent does not restrict the scope of the claim language with regard to this limitation. Similarly, the prosecution history of the '075 patent, to the extent it is in the record on appeal, does not clearly and unmistakably restrict the meaning of this claim term. See Omega Eng'g, 334 F.3d at 1326. Because the district court improperly construed claim 1 of the '075 patent, this court reverses.

3190
"point of interest motion"

Claim 52 of the '785 Patent contains the term "point of interest motion." IPI contends the term means "a sequence of images that are perceptible as views of a three-dimensional workspace including a moving or displaced point of interest." Google contends the term means "a change in location of the point of interest as indicated by a user."

As an initial matter, IPI's reference to "displaced" point of interest is improper for the same reasons explained in the Court's construction of "viewpoint motion." Further, IPI's entire proposed construction suffers from the same fatal flaw as its proposed construction for "viewpoint motion." That is, its proposed construction sets forth "when" and "how" "point of interest motion" occurs, rather than identify what "point of interest motion" is. Although Google's proposed construction for "point of interest motion" does not carry forward with the same flawed approach, it unnecessarily includes reference to a user. Google contends that in order for a point to be "of interest," it must be "of interest" to the user. Claim 52 already recites that the request for "point of interest motion" comes from the "user input means." '785 Patent, col. 26:38-47. Thus, there is no need to state "as indicated by a user," as Google proposes. Lastly, Google's use of "change in location" suffers from the same flaw as IPI's inclusion of "displacement." "Change in location" is narrower than the claim term "motion" and it would be improper to narrow "point of interest motion" to simply "a change in location of the point of interest."

Claim 52 uses "point of interest motion" in the same manner as "viewpoint motion" is used in other claims of the '785 Patent. Thus, the Court's construction of the term "point of interest motion" should mirror that of "viewpoint motion."

Accordingly, the Court construes the term "point of interest motion" to mean "perceived movement of a point of interest on an image presentation on a display."

3191
1. "POL regulator"

The first term at issue is "POL regulator," which is found in every asserted claim of each of the four patents-in-suit. Power-One argues that this term should be construed as a "dc/dc switching voltage regulator designed to receive power from a voltage bus on a printed circuit board and adapted to power a portion of the devices on the board and to be placed near the one or more devices being powered as part of a distributed board-level power system." Artesyn contends that this term is indefinite and cannot be properly construed.

Power-One asserts that "POL regulator" had an ordinary meaning in the art at the time of the invention and cites, among other things, Artesyn's own literature in support of this contention. Artesyn argues that "POL regulator" is not defined in the specification and that the intrinsic evidence provides no objective criteria to determine a proper definition of the term. Further, Artesyn contends that the extrinsic evidence cited by Power-One fails to convey an ordinary meaning. More specifically, Artesyn contends that Power-One's use of the term "near" in its proposed construction is problematic and unhelpful because it fails to convey any objective standard by which one would determine "nearness" in the context of "POL regulator."
In Datamize v. Plumtree Software, LLC, 417 F.3d 1342 (Fed. Cir. 2005), the Federal Circuit set forth the following principles pertaining to indefiniteness.

According to the Supreme Court, "[t]he statutory requirement [35 U.S.C. § 112, P2] of particularity and distinctness in claims is met only when [the claims] clearly distinguish what is claimed from what went before in the art and clearly circumscribe what is foreclosed from future enterprise." The definiteness requirement, however, does not compel absolute clarity. Only claims "not amenable to construction" or "insolubly ambiguous" are indefinite. Thus, the definiteness of claim terms depends on whether those terms can be given any reasonable meaning. Furthermore, a difficult issue of claim construction does not ipso facto result in a holding of indefiniteness. "If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." In this regard it is important to note that an issued patent is entitled to a statutory presumption of validity. "By finding claims indefinite only if reasonable efforts at claim construction prove futile, we accord respect to the statutory presumption of validity and we protect the inventive contribution of patentees, even when the drafting of their patents has been less than ideal." In this way we also follow the requirement that clear and convincing evidence be shown to invalidate a patent.

Id. at 1347 (citations omitted). Turning first to the specification of the '999 patent, it is important that the POL regulator is discussed in terms showing its familiarity to those skilled in the art. See '999 Patent, col. 1:12-14 (Point-of-load ("POL") regulators, which are also referred to as voltage regulators or DC/DC converters, are commonly used in conjunction with electronic circuits.); 34-35 ("Traditionally, POL regulators operate in conjunction with at least one power supply controller."); Col. 2:12-14 ("POL regulators are traditionally adapted to receive . . ."). The specification of the '125 patent identifies problems facing complex electronic systems and how POL regulators help alleviate these problems.

With the increasing complexity of electronic systems, it is common for an electronic system to require power provided at several different discrete voltage and current levels. . . It is undesirable to deliver relatively high current at low voltages over a relatively long distance through an electronic device for number of reasons. First, the relatively long physical run of low voltage, high current lines consumes significant circuit board area and congests the routing of signal lines on the circuit board. Second, the impedance of the lines carrying the high current tends to dissipate a lot of power and complicate load regulation. Third, it is difficult to tailor the voltage/current characteristics to accommodate changes in load requirements.

In order to satisfy these power requirements, it is known to distribute an intermediate bus voltage throughout the electronic system, and include an individual point-of-load ("POL") regulator, i.e., DC/DC converter, at the point of power consumption within the electronic system. . . Ideally, the POL regulator would be physically located adjacent to the corresponding electronic circuit so as to minimize the length of the low voltage, high current lines through the electronic system. The intermediate bus voltage can be delivered to the multiple POL regulators using low current lines that minimize loss.

Col. 1: 13-15, 19-35, 42-47. Further, Figure 1 of the '125 patent shows a prior art power system where POLs 22, 24 and 26 are at the point of power consumption. The '125 specification also describes the functions and uses of POLs: "Each circuit has an associated point-of-load ("POL") regulator located closely thereby, such as POLs 22, 24, and 26. Each POL regulator converts the intermediate bus voltage to a low voltage, high current level demanded by the electronic circuit, such as 1.8 volts, 2.5 volts, and 3.3 volts provided by POLs 22, 24 and 26." Col. 3:22-27. "By locating the POLs 22, 24, and 26 close to their corresponding electronic circuits, the length of the low voltage, high current lines on the printed circuit board are minimized." Col. 3:32-35. The '798 specification again describes POL regulators in terms of the problems the POL is designed to address:

Similarly, some electronic devices include circuits that require low voltage (e.g. 1 v), high current (e.g., 100 A) power supplies. This is problematic in that it is impractical to deliver high current at low voltage levels over a relatively long distance and still meet desired regulation performances. A common solution is to use a high voltage, low current power supply and design a POL regulator near the internal circuit. This allows low current to travel throughout the device, and provides a low voltage, high current power supply (i.e., using the POL regulator) near the internal circuit.

See col. 1:25-35.
One problem with Artesyn's approach is that it ignores the intrinsic record's repeated acknowledgment of a known prior art POL device. The term "POL" is not a coined term in the patents-in-suit; rather, a "POL" was a known device in the art. Artesyn also ignores numerous statements in the intrinsic record concerning the function and purpose of a POL regulator. The specification of the '999 patent explains that "POL regulators" are also referred to as "voltage regulators" or "DC/DC converters." It describes a prior art system that utilized POL regulators. See '999 patent, col. 1:12-14; col. 3:4-11; Figure 1. The specification goes on to say that "the voltage/current requirements of electronic circuits typically differ from the voltage that is readily available or the current that can practically be delivered. For example, some electronic devices only include a single voltage input (e.g., 12v), but require different voltages for circuits contained within (e.g., 3v, 5v, 9v, etc.). A common solution is to design multiple POL regulators within the device for converting the single input voltage into multiple voltage levels." See '999 patent, col. 1:14-22. The intrinsic record also explains that prior art POL regulators were placed "near" the load to be serviced by the POL so high currents would not be delivered over "relatively long distance[s]." Locating the POL regulator near the load to be serviced "allows low current to travel throughout the device, and provides a low voltage, high power supply (i.e., using the POL regulator) near the internal circuit." See '999 patent, col. 1:25-33. Therefore, the intrinsic record makes clear that one skilled in the art would know that a POL regulator should be placed in such a way to accomplish certain objectives.

Q. And how close to the load does a regulator have to be a point-load-regulator?

A. It has to be close enough to fulfill the need to manage transients and regulate the voltage in a tight fashion such that there is no disturbance to the load as a result of changes in load, changes in line, changes in the environmental conditions which it is. So those requirements define the requirement for the nearness.

The Court sees nothing problematic in describing the POL regulator as being "near" the load. This is simply a way of saying that the POL regulator should be located so as to alleviate the problems associated with complex power systems that require "several different discrete voltage and current levels." n3 See '125 patent, col. 1:15. The intrinsic record shows that there is no "one size fits all" approach to electronic systems and therefore, the term "near" is as precise as this particular subject matter permits. See, e.g., BJ Services, Co. v. Halliburton Energy Services, Inc. 338 F.3d 1368, 1373 (Fed. Cir. 2003) (upholding jury's verdict rejecting indefiniteness defense because those skilled in the art would understand a "C* value of about 0.06"); Exxon Research Engineering Co. v. United States, 265 F.3d 1371, 1379-81 (Fed. Cir. 2001) (finding "for a period sufficient" definite because the limitation was expressed in terms that are reasonably precise in light of the subject matter); Orthokinetik Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986) (construing "so dimensioned" as definite and stating that the term "is as accurate as the subject matter permits, automobiles being of various sizes"); Seattle Box Co., Inc. v. Industrial Crating and Packing, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984) (rejecting claim that "substantially equal to" was indefinite and noting that the fact "some claim language may be imprecise . . . does not automatically render a claim invalid").

n3 There are additional reasons why the Court rejects Artesyn's indefiniteness argument. First, Artesyn initially proposed a construction of "POL regulator" indicating that the meaning of this term can be discerned. See Joint Claim Construction Statement. Not only did Artesyn propose a construction, but it did so describing a POL as being "placed near the one or more devices being powered." Second, Artesyn's own literature uses the term "point of load" and describes "POLs" as being near the load, See Ex. B to Power-One's Reply Brief, showing, at the very least, that the term has meaning to those skilled in the art. Third, when asked about "POLs," Trey Burns, Artesyn's 30(b)(6) witness on claim construction, did not testify that he was unaware of or unable to understand the term. Rather, Burns testified that, with a couple of caveats, Power-One's proposed definition of a "POL" is "a reasonable statement." See Ex. I to Power-One's Claim Construction Brief, p. 100, lines 3-11. Burns also discussed "point-of-load converters" as being part of a "distributed power architecture where we

- 3517 -
move the regulation function closer to the load" to "eliminate the effects of distribution resistances and distribution inductances." Id. at p. 26, line 11 - p. 27, line 3. Finally, nothing in the prosecution history shows that the patent examiner had any trouble understanding the term. This evidence plainly suggests that POLs were well known devices whose locations and functions relative to other components was understood by those of ordinary skill in the art.

Artesyn relies on Halliburton Energy Services, Inc. v. MI, LLC, 456 F.Supp.2d 811 (E.D. Tex. 2006) (Davis, J.) to support its indefiniteness contention. In that case, however, the patentees relied upon the term "fragile gel" to distinguish their invention from the prior art tending to show that the characteristics of "fragile gel" were novel and a basis for patentability. Id. at 816. Having presented "fragile gel" in that fashion, the Court found that the patentees had failed to provide an objective standard for its definition. Id. at 817. Here, on the other hand, the specifications and prosecution history treat POL regulators as a known device in the art. See, e.g., '999 Patent, col. 1:12-14. And, while the specifications may describe new features for POL regulators, the specifications use the term "POL regulator" in its "traditional" sense (see '999 patent, col. 1:34-35) to refer to a device in a system for supplying power to components in an electronic system. Accordingly, the Court adopts Plaintiff's construction and construes "POL regulator" to mean "a dc/dc switching voltage regulator designed to receive power from a voltage bus on a printed circuit board and adapted to power a portion of the devices on the board and to be placed near the one or more devices being powered as part of a distributed board-level power system."

3192

A. Claim Construction and Indefiniteness

1. Adequacy of the District Court's Claim Construction

We review claim construction de novo. See Ball Aerosol & Specialty Container, Inc. v. Ltd Brands, Inc., 555 F.3d 984, 989 (Fed. Cir. 2009); Young v. Lumenis, Inc., 492 F.3d 1336, 1344 (Fed. Cir. 2007). When construing claims, the intrinsic evidence is the primary resource. See Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). Claim terms are "generally given their ordinary and customary meaning," the meaning that the term would have to "a person of ordinary skill in the art . . . at the time of the invention." Id. at 1312-13 (internal citations omitted). The terms, as construed by the court, must "ensure that the jury fully understands the court's claim construction rulings and what the patentee covered by the claims." Sulzer Textil A.G. v. Picanol N.V., 358 F.3d 1356, 1366 (Fed. Cir. 2004).

Artesyn first contends that the district court's construction of the claim term POL regulator is flawed because it fails to articulate the scope of the asserted claims of the '125 patent in any meaningfully precise manner. Specifically, it argues that the court's construction of the terms "adapted to" and "near" are facially vague and subjective, such that the construction left the jury free to make its own determination as to the claims' scope in violation of Markman.

Here, the district court construed the claim term "POL regulator" in a meaningfully precise manner. The court construed "POL regulator" to mean:

[A] dc/dc switching voltage regulator designed to receive power from a voltage bus on a printed circuit board and adapted to power a portion of the devices on the board and to be placed near the one or more devices being powered as part of a distributed board-level power system.

The intrinsic record supports the district court's construction, and despite Artesyn's contention, the terms "adapted to" and "near" are not facially vague or subjective. Claims using relative terms such as "near" or "adapted to" are insolubly ambiguous only if they provide no guidance to those skilled in the art as to the scope of that requirement. See Datamize, 417 F.3d at 1347 (the definiteness of a claim's terms depends on whether those terms can be given a reasonable meaning by a person of ordinary skill in the art); see, e.g., Young, 492 F.3d at 1346 ("near" not indefinite); Central Admixture Pharm. Servs., Inc. v. Advanced Cardiac Solutions, 482 F.3d 1347, 1356 (Fed. Cir. 2006) ("adapted to" not indefinite); Verve, LLC v. Crane Cams, Inc., 311 F.3d 1116, 1120 (Fed. Cir. 2002) (same). Here, a person of ordinary skill in the field would understand the meaning of "near" and "adapted to" because the environment dictates the necessary preciseness of the terms.
The phrase "[t]o be placed near the one or more devices being powered as part of a distributed board-level power system," as recited in the court's construction, implies that the dc/dc switching voltage regulator is to be placed on the printed circuit board--somewhere close to or at the load--the device being powered as part of the distributed board--level power system. Moreover, reference to the '125 patent's specification demonstrates that the term "near" means close to or at the load. As the specification of the '125 patent states:

[I]t is known to distribute an intermediate bus voltage throughout the electronic system, and include an individual point-of-load ("POL") regulator, i.e. DC/DC converter, at the point of power consumption within the electronic system.

This language indicates that the POL regulator is to be located just upstream from the load being powered. Likewise, Figure 1 of the '125 patent illustrates a prior art power system where the POL regulator is located at the point of power consumption, providing a standard for measuring the term "near." The specification further provides guidance on where it is to be located in relation to the load. The specification recites:

Ideally, the POL regulator would be physically located adjacent to the corresponding electronic circuit so as to minimize the length of the low voltage, high current lines through the electronic system. The intermediate bus voltage can be delivered to the multiple POL regulators using low current lines that minimize loss.

This language unambiguously states that the regulator is to be placed adjacent to the corresponding load that it is powering so that low voltage/high currents will not be delivered over relatively long distances. The patent's functionality requirement restricts the boundaries of where the regulator can be located in relation to the load it is powering. A skilled artisan in distributed power systems would know where to place the regulator to accomplish that stated objective.

Similarly, the phrase "adapted to power a portion of the devices on the board," when read in conjunction with the intrinsic record, makes clear that a POL regulator is one that is capable of delivering power, at the appropriate intensity, to one or more loads on the circuit board. The specification of the '125 patent states:

[A] POL regulator would be included with each respective electronic circuit to convert the intermediate bus voltage to the level required by the electronic circuit.

This language unambiguously indicates to a skilled artisan that the output power of a POL regulator would be at the level required by, and thus "adapted to," the electronic circuit receiving power from the POL regulator.

The fact that the claim is not defined using a precise numerical measurement does not render it incapable of providing meaningful guidance to the jury because the claim language, when taken in context of the entire patent, provides a sufficiently reasonable meaning to one skilled in the art of distributed power systems. Therefore, we find that the district court's claim construction of the term POL regulator was adequate to fully describe the scope of the claims.

2. Definiteness of the term "POL regulator"

Artesyn asserts, as an alternative basis for reversing the district court's judgment, that the district court committed error in finding the term "POL regulator" not indefinite. A determination of indefiniteness is reviewed de novo. See Young, 492 F.3d at 1344. Pursuant to § 112 of the Patent Act, to be sufficiently definite, a patent specification must "conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2. To comport with § 112's definiteness requirement, the boundaries of the claim, as construed by the court, must be discernible to a skilled artisan based on the language of the claim, the specification, and the prosecution history, as well as her knowledge of the relevant field of art. See Halliburton Energy Servs., Inc. v. M-1 LLC, 514 F.3d 1244, 1249-51 (Fed. Cir. 2008). When a claim is "not amenable to construction or [is] insolubly ambiguous" it is indefinite. Datamize LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005). However, a claim is not indefinite merely because it poses a difficult issue of claim construction. Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). Rather, "if the meaning of the claim is discernible, even though the task may be formidable and the conclusions may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." Id. at 1373.

Here, the term "POL regulator" is not indefinite. The intrinsic evidence of the '125 patent supports that POL regulators are
well known devices whose locations and functions relative to other components in the power system are understood by those of ordinary skill in the art. See, e.g., Verve, 311 F.3d at 1119-20 (recognizing that guidance as to measurement of a term of degree can come from the intrinsic record or from the knowledge of a person of ordinary skill in the art); Exxon, 265 F.3d at 1379-81 (finding "for a period sufficient" definite because the limitation was expressed in terms that were reasonably precise in light of the subject matter). Because a person having ordinary skill in the art would know where to place the POL regulator and how to use it, we find that the claim term "POL regulator" is not indefinite and does not render the claims of the '125 patent indefinite.

I. Point of Sale Location

The district court made several findings with regard to the construction of the expression "point of sale location." We address these findings below, agreeing with some and disagreeing with others.

1.

In response to the district court's request for binding definitions of the disputed terms, described earlier, IGE identified the passage at column 5, lines 47-50 as defining a point of sale location. That passage states that a point of sale location is "a location where a consumer goes to purchase material objects embodying predetermined or preselected information." Freeny patent, col. 5, ll. 47-50. The district court held this definition to be correct, and we agree. Clear support is provided for this definition in the Freeny patent specification at column 5, lines 47-50.

2.

The district court further held that, although point of sale locations are not restricted to retail locations, a home is not a point of sale location. See Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810 & n.9. IGE contends that the district court was wrong. IGE urges that a point of sale location is simply the location at which the consumer makes or effects a purchase. IGE argues that the concept of a home being a point of sale location is not new, citing home shopping networks, pay-per-view cable television, and home Internet shopping. IGE further argues that the specification defines a home as a point of sale location and discloses at least two embodiments in which the home is a point of sale location. IGE also argues that the prosecution history lists several transmission systems that could be adapted for use in the home. The appellees respond that IGE's asserted definition before the district court precludes a home from being a point of sale location, and that any references in the specification to homes as point of sale locations cannot overcome this definition. The appellees further respond that the rest of the intrinsic evidence, as well as the extrinsic evidence of standard dictionaries and references, supports the district court's construction.

We agree with IGE's position that a home is not precluded from being a point of sale location. Looking first, as we must, to the claim language itself, we find nothing precluding a home from being a point of sale location. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576. Except for requiring that an IMM be present, the independent claims are silent regarding the possible venues of a point of sale location.

Looking next to the specification, see id. at 1582, 39 U.S.P.Q.2D (BNA) at 1577, we acknowledge the great likelihood that a point of sale location will not be a home, given that: (1) IGE's asserted definition, with which we agree, requires that a consumer go to a point of sale location "to purchase material objects," Freeny patent, col. 5, ll. 48-49; and (2) the specification requires, and IGE does not dispute, that the IMM be located at the point of sale location, see, e.g., Freeny patent, col. 5, ll. 32-33, col. 12, ll. 66-67. However, IGE's asserted definition, premised on the specification at column 5, lines 48 and 49, does not preclude a home from serving as a point of sale location, and the specification further describes a vending machine embodiment that could be utilized in a home. See Freeny patent, cols. 26-27. This intrinsic evidence unambiguously allows a home to serve as a point of sale location. Therefore, it is unnecessary to address IGE's arguments alleging that the prosecution history additionally supports our conclusion.

Given the lack of ambiguity in the intrinsic evidence, it would be improper to address any of the parties' arguments relating to extrinsic evidence, such as other examples of point of sale locations and standard references. See Vitronics, 90 F.3d at
1583, 39 U.S.P.Q.2d (BNA) at 1577 ("In those cases where the public record unambiguously describes the scope of the patented invention, reliance on any extrinsic evidence is improper.").

3.

The district court also held that a point of sale location "must have . . . at least two blank material objects." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810. IGE argues that this limitation is not recited in the claims or required by the specification and has improperly been read into the claims from a particular embodiment. The appellees respond that the specification supports the requirement that there be two or more blank material objects. We agree with IGE that a point of sale location need not have two blank material objects.

We begin, as we must, with the language of the claims. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576 (stating that construction begins with the claim language). The claim language specifically recites "reproducing in a material object." Freeny patent, col. 28, l. 44 (claim 1; emphasis added); id. at col. 36, l. 63 (claim 37; emphasis added). Although the single element of claim 37 initially mentions material objects in the plural, it is later modified by a singular reference and does not require more than one material object. Compare id. at col. 36, l. 49 with id. at l. 63. The preambles of the independent claims similarly recite plural "material objects," but they do so in the context of multiple IMMs and/or multiple point of sale locations. See, e.g., id. at col. 28, ll. 22-24 (claim 1); id. at col. 36, ll. 45-46 (claim 37). The preambles do not require multiple material objects at each point of sale location. Given the preambles' generality, we need not consider whether they are more than statements of intended use.

We look next to the specification. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. We note that the district court based the requirement of two blank material objects on a passage in the specification stating that "each point of sale location has . . . a plurality of blank material objects." See Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1805 (citing to the Freeny patent, col. 12, ll. 66-68). From the passage itself, it is unclear whether this isolated statement in the specification is intended to be a general statement or to be limited to a particular embodiment. However, there is nothing in the rest of the specification supporting the position that a point of sale location is defined as having at least two blank material objects. To the contrary, it is clear that the IMM requires only a single material object to fully process a consumer's request. See, e.g., Freeny patent, col. 5, ll. 21-31 ("Each [IMM] 14 is constructed to . . . provide . . . information . . . to a reproduction unit 24 which is adapted to reproduce received information in a material object.") (underlining added). Further, the opening sentence of the background section of the Freeny patent states that "the present invention relates generally to a system for reproducing information in a material object." Freeny patent, col. 1, ll. 7-8 (emphasis added).

Accordingly, we hold that the entirety of the specification dictates that the reference to a plurality be understood to refer to a "supply" of blank material objects, and that the supply can consist of one material object. See Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1345, 47 U.S.P.Q.2D (BNA) 1418, 1425 (Fed. Cir. 1998) (basing the claim construction on the entire written description, despite an isolated passage in apparent conflict).

4.

The district court also held that a point of sale location must have blank material objects "available for sale to consumers." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810. IGE argues that this limitation is not recited in the claim or required by the specification and has improperly been read into the claim from a particular embodiment. Notably, the appellees do not argue in defense of this limitation. We agree with IGE that a point of sale location need not have any blank material objects separately for sale.

Looking again to the claims, nothing in the claim language itself requires that blanks be for sale. The claims require only that information be reproduced in a material object. See, e.g., Freeny patent, col. 28, ll. 22-23 (preamble to claim 1) and 44-45 (step four of claim 1); id. at col. 36, ll. 45-46 (preamble to claim 37) and ll. 62-63 (single element of claim 37). Looking next to the specification, we note that nothing in IGE's asserted definition, derived from the Freeny patent at column 5, lines 47-50, requires that blanks be for sale. That definition refers exclusively to the purchase of non-blank material objects, that is, to "material objects embodying . . . information." Id.

The district court based its conclusion that blanks must be for sale on the passage at column 13, lines 25-44. See Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1805. However, that passage does not state that the blanks are sold to the customers.
as blanks, but only that the retailer is reimbursed for the cost of blanks on which information is reproduced. See Freeny patent, col. 13, ll. 25-44. The district court, therefore, misconstrued the specific embodiment in that passage. Further, there is no support in the rest of the specification for this requirement; all of the embodiments are directed at providing material objects with information on them and not at selling blank material objects. See, e.g., id. at col. 13, ll. 1-13 (reproducing information on an 8-track or cassette tape); id. at col. 22, l. 62 - col. 23, l. 6 (describing various material objects in which information can be reproduced); id. at cols. 26-27 (describing the reproduction of information in the vending machine embodiment). Indeed, the opening sentence of the background section of the Freeny patent states that "the present invention relates generally to a system for reproducing information in a material object." Freeny patent, col. 1, ll. 7-8 (emphasis added).

Accordingly, we construe a point of sale location to be a location where a consumer goes to purchase material objects embodying predetermined or preselected information. This construction permits a home to be a point of sale location. A point of sale location need not have more than one blank material object and it need not have any material objects separately for sale as blanks.

The plaintiff argues that these terms do not need any construction. In the alternative, the plaintiff proposes that "point-of-sale" means "any place where a consumer enters a transaction with a merchant," "point-of-sale transaction" means "transactions between a consumer and a merchant," and "point-of-sale terminal" means "an electronic device that is used to enter information in connection with a transaction." The defendant proposes that "point-of-sale" means "the place in a store at which goods are paid for," "point-of-sale transaction" means "transactions that take place in a store at which goods are paid for," and "point-of-sale terminal" means "an electronic device that is located in a store and is used to enter information in connection with a transaction."

The principal dispute is whether the constructions should be limited to a store or can involve transactions occurring over the internet, telephone, or mail. The defendant cites to an extrinsic dictionary definition in support of its construction.

After considering the parties' arguments, the court construes "point-of-sale" to mean "the physical location where a consumer enters a sales transaction with a merchant" and "point-of-sale transaction" to mean "the sales transaction occurring at the point of sale." "Point-of-sale terminal" means "an electronic device at the point-of-sale for entering a point of sale transaction."

The relevant language in claim 7 of the '222 patent is as follows: "the frequency band is formed from a first set of K1 points and a pair of tail slots each having K2 points, each of the points being separated by a frequency range of [DELTA] f." Claim 7 also states that "the frequency band" is that upon which information is multiplexed. The specification expressly defines that the entire available bandwidth B is divided into a number of points K, where adjacent points are separated by a frequency band, [DELTA] f. See '222 patent, 5:26-31; 17:17-22. The available bandwidth B is the product of a number of points K multiplied by a frequency band [DELTA] f, that is B=K [DELTA] f. Id. The K points are grouped into a frame of K1 points and two tail slots of K2 points each, so that K = K1 + K2. Id. Thus, based upon Figure 2 and the corresponding
specification, it is clear that the points are located within the bandwidth, that there can be K1 points or K2 points, and that K1 points are located in the frame and K2 points are located outside the frame but still in the available bandwidth. See id. and FIG. 2. The Court finds that "points" does not equate to merely "frequencies" as Wi-LAN suggests. However, the Court finds that points can exist in the frame and outside the frame in the tail slots, and thus disagrees with Defendants' proposed construction that points means "divisions within a frame." The specification also expressly states that "each point in the frame corresponds to one information symbol." '222 patent, 5:35-36. However, because the Court finds that the "tail slots" of K2 points are outside of the frame of information, then those K2 points would not necessarily correspond to "an information symbol" based upon the specification. Thus, Defendants' proposed construction including "corresponding to one information symbol each" is incorrect. The Court construes the term "points" to mean "divisions within the frequency band."

3196

4. **Pointer memory** (claim 2)

Plaintiff's Construction: This term is indefinite. In the alternative, it is a memory used to store pointers until the processor can perform a read bus transaction to read the full message from the central memory.

Defendant's Construction: A memory for storing pointers, i.e., a variable that indicates the memory location (e.g., address) of some data, rather than the data itself.

Although plaintiff argued half-heartedly in its opening brief that this term was indefinite, it abandoned that argument in its response brief and at the claim construction hearing. (In fact, plaintiff failed to meaningfully develop any of its arguments that various terms are indefinite. Accordingly, I consider such arguments waived.) At the hearing, the parties agreed that a pointer is a variable that contains the address of a message or other data. Plaintiff continued to object to defendant's construction, but it provided no reasoned basis for doing so. Its own alternative construction comes from a description in an embodiment of "ring memories," which are only one kind of pointer memory. Accordingly, I will adopt defendant's construction with a slight modification: "a memory for storing variables that indicate the memory location of some data, such as by an address."

3197

D. **"policy information"**

Finally, the parties dispute the district court's construction of "policy information indicating a permitted neighboring node/network from which a packet transfer by the label switching is to be permitted." This claim term only appears in the '127 patent. The district court construed the term as requiring the policy information to relate to an upstream node/network. Toshiba argues on appeal that the claims read on systems storing information related to downstream nodes, as embodied in Juniper's routers. Again, Toshiba points to nothing in the patent supporting its proffered construction.

We agree with the district court's construction. The claim language "from which" modifies the "neighboring node/network," not the "policy information." If the patentee desired the latter construction, it would have used commas to set off the phrase "indicating a permitted neighboring node/network." Lacking grammatical signals to the contrary, we hold the claim more logically supports a construction requiring a transfer from a neighboring node or network. As such, that node or network must sit upstream relative to the claimed router device. **We therefore affirm the district court's construction and the judgment of noninfringement of the '127 patent.**

3198

3. "Policy level:" 3 "Structured set of information about an insurance policy." The court finds that "an insurance policy" clarifies any ambiguity inherent in plaintiffs' proposed construction of "any insurance policy." This construction accords
3199

11. The ordinary meaning of "polygon" is "a closed plane figure bounded by straight lines." Webster's Ninth New Collegiate Dictionary, p. 912. Although the preferred embodiment shown in the specification employs equilateral hexagons, Claim 3 (unlike Claim 1) is not limited "hexagonal base regions" but to "polygonal base regions". The specification also expressly notes that, in addition to hexagons, "other shapes such as squares" are also possible. ('725 Col. 2, lines 54-59.) Further, the prosecution history makes clear that other shapes such as rectangles having sides of unequal length are nevertheless also "polygonal." 3

3 For example, the examiner relied for an obviousness rejection (later overcome by IR) on the rectangular base in Fig. 3 of Takakuwa to construct a hypothetical device having an array of rectangular bases. (Reexam. Control No. 90/003,495, Paper No. 6, pp. 3, 5.)

12. Moreover, the patent specification explains that, because of the way the bases are made, they are only "generally polygonal in configuration": "By using suitable masks, a plurality of P type base regions such as regions 22 and 23 in FIGS. 3 and 4 are formed in one surface of the semiconductor wafer region 21, where these regions are generally polygonal in configuration . . . ." ('725 Col. 2, line 65- Col. 3, line 2.) A person of ordinary skill in the art would have understood that regions defined, as described in the specification, by a finite number of straight line segments at the top semiconductor surface ('725 Col. 3, lines 34-46) would deform slightly during diffusion or other processing steps giving those regions depth into the wafer. 4

4 Declaration of John D. Shott, Ph.D. in Support of IR's Motion for Sum. Adj. of Infringement of U.S. Patent Nos. 5,008,725 and 5,130,767, filed October 16, 2001 ("Shott Decl."). P6.)

13. For example, although IXYS argues that "polygons" must have "corners" (Defendant IXYS Corporation's Opposition To Motion For Summary Adjudication That Accused IXYS Products Infringe The '725 and '767 Patents, p. 6), it would have been understood by those of skill in the art -- as it was clearly understood by the Patent Office examiner 5 -- that these "corners" would take the form of spherical (i.e., round) junctions after processing, and would not take the form of straight lines intersecting at a point to form a well defined angle. Accordingly, the resulting regions would be generally, but not perfectly, polygonal in shape when viewed from the first semiconductor surface. Thus, within the meaning of the claim, a "polygon" would have been understood to be a region defined by a finite number of straight line segments at the first semiconductor surface, which lines could deform slightly during diffusion or other processing steps resulting in a region only generally polygonal in configuration when viewed from the device surface. To hold otherwise would exclude even the patent's preferred embodiment from the scope of the claim. A claim construction that excludes the preferred embodiment is "rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). 6
3200

J. Limitation 9: At least one base a polygon

37. The final element of Claim 1 is as follows: "at least said first base region being a cellular polygonal region; said cellular polygonal region being surrounded by said common conduction region; said first source region having the shape of an annular ring disposed within said cellular polygonal first base region." The example of this structure in the specification is central square base 94 in Figure 8, which has an annular source region disposed within it and is surrounded by a common conduction region.

38. As defined in the dictionary, a polygon is a closed plane figure bounded by straight lines. The specification describes Figures 7 and 8 as "a planar configuration which is a simple rectangular arrangement." ('699 patent, 6:22-23.) Although called a "rectangular arrangement," the metalization patterns shown in Figure 8 are generally square shapes with rounded corners. Likewise, the underlying base regions within the silicon formed by diffusion through the windows would not be perfectly polygonal, as both experts agree that it is inherent that the polygonal shape used to define the base shape is distorted during the manufacturing process.

39. For these reasons, this limitation is properly construed to require the base shape, at the surface, to be generally but not perfectly polygonal -- i.e., the surface expression of the base will be a closed figure with generally (not necessarily perfectly) straight sides.

3201

1. "Polygonal"

The word "polygonal" is used to describe a semiconductor base region in forty-four of the forty-eight claims asserted against IXYS--namely all of the asserted claims of the '725 and '767 patents, and all of the asserted claims of the '699 patent except claims 19, 22, 24, and 27. The district court construed this limitation to require that the shape of the region "be generally but not perfectly polygonal--i.e., the surface expression of the base will be a closed figure with generally (not necessarily perfectly) straight sides." Int'l Rectifier Corp. v. IXYS Corp., 2001 U.S. Dist. LEXIS 25711, No. CV-00-6756-R (C.D. Cal. July 25, 2001) ("Infringement Order '699 Patent"), at para. 39. The district court further modified its construction by noting that "the 'corners' of the polygonal regions may take the form of spherical junctions (i.e., round) after processing, and are not necessarily formed by straight lines intersecting at a point to form a well defined angle." Int'l Rectifier Corp. v. IXYS Corp., 2002 U.S. Dist. LEXIS 27247, No. CV-00-6756-R (C.D. Cal. Mar. 5, 2002) ("Construction Order '725 and '767 Patents"), at para 3. Both IR and IXYS agree that the ordinary and customary meaning of the term "polygon" is "a closed plane figure bounded by straight lines." The parties, dispute, however, the propriety of the district court's relaxation of the requirement for straight lines and well-defined angles. In particular, IXYS argues that the district court's claim construction did not give the word "polygonal" its ordinary and customary meaning and that there is no basis in the written description for giving the term "polygonal" anything other than its ordinary and customary meaning. IR, on the other hand, argues that the district court's construction and reasoning in support should be affirmed.

In searching for the ordinary and customary meaning of the expression "polygonal region," we begin with an examination of possible dictionary definitions of the word "polygon." The district court, citing Webster's Ninth New Collegiate Dictionary,
stated that: "As defined in the dictionary, a polygon is a closed plane figure bounded by straight lines." This is consistent with dictionary definitions contemporaneous with the patents at issue. See Webster's Third New International Dictionary 1758 (1966) ("Webster's") (defining "polygon" as "a closed figure consisting of straight lines joined end to end"); Webster's Third New International Dictionary 1758 (1993) (same). The parties do not advance any other dictionary definition, nor do the alternative definitions in the dictionary pertain even superficially to the issue at hand. By necessity, the boundary of a closed plane figure will also include multiple included angles, formed at the intersection of the straight lines. The dictionary definitions and the context of the claims themselves do not further illuminate the analysis; "polygonal" is not surrounded in the claims by any context that limits or helps to define its meaning.

We look next to the written description for context and guidance as to the meanings attributed by those of ordinary skill in the art to the term "polygonal" and to see whether the patentee acted as his own lexicographer, or otherwise disavowed or disclaimed the full scope of the ordinary and customary meaning of the term in question. The square base regions depicted in Figure 7 of the '699 patent and the hexagonal base regions depicted in Figure 3 of the '725 and '767 patents are recognizably "closed plane figures bounded by straight lines." The depictions and descriptions of the patents are consistent with the ordinary dictionary definition of the word "polygon" cited by the district court. IR points to no disavowal or disclaimer of this scope and does not contend that the patentee acted as his own lexicographer. Moreover, neither party argues that anything in the prosecution history affects the scope of any of the disputed claim terms.

Because the polygonal base regions are formed by the diffusion of dopants into the silicon substrate, a process which necessarily blurs the outline of the regions, IR argues that those skilled in the art and informed by the written description would understand "polygonal" to encompass shapes with curved corners. Moreover, IR asserts that the square base region depicted in Figure 7 of the '699 patent has slightly rounded corners, and "a claim interpretation that excludes the preferred embodiment is rarely, if ever, correct." Gentry Gallery, Inc. v. Berkline Corp., 134 F.3d 1473, 1477 (Fed. Cir. 1998) (internal quotation marks omitted). While IR is correct that the meaning of claim terms must be considered from the perspective of one of ordinary skill in the art, that does not mean that the inventor's choice of words may be ignored. Hoganas AB v. Dresser Indus., 9 F.3d 948, 951 (Fed. Cir. 1993) ("As we have repeatedly said, the words of a claim 'will be given their ordinary meaning, unless it appears the inventor used them differently.'" (citations omitted)); see also Brookhill-Wilk, 334 F.3d at 1298; Voice Techs. Group Inc. v. VMC Sys., Inc., 164 F.3d 605, 615 (Fed. Cir. 1999). In the present case, one of ordinary skill in the art would understand from the written description that the diffusion resulting from the doping process will naturally cause some blurring of the corners and sides of the polygonal regions. There is nothing, however, to suggest that the recognition of these diffusion effects by those skilled in the art warrants the re-definition of the term polygon to mean anything other than "a closed plane figure bounded by straight lines." The district court's construction, relaxing the requirements so much as to allow round corners and not straight edges, is erroneous. The correct construction of the term "polygonal," consistent with the written description, is simply "a closed plane figure bounded by straight lines." The patentee, being fully aware of the effects of the doping process, could have claimed the regions more broadly but chose to use the word "polygonal" without modification or qualification. The district court was not free to attribute new meaning to the term or to excuse the patentee from the consequences of its own word choice.

Plaintiff's Construction: This term is indefinite. In the alternative, a collection of pointers located at a discrete location within the memory.

Defendant's Construction: More than one pointer

At the claim construction hearing, plaintiff more or less adopted defendant's alternative construction with the only caveat being that the location of the pool of pointers is not fixed. But saying that the pool is at a "discrete" location does not necessarily mean that the location cannot change. Nevertheless, plaintiff does not offer any specific support for its inclusion of the word "discrete"; it simply seeks a construction that prohibits the pool from being at two places at once, an idea that defendant does not dispute. Accordingly, I will adopt plaintiff's proposed construction with a slight modification: "a collection of pointers in a particular location at any given time."
9. **popularity**

The term "popularity" appears in claim 112 of the '725 patent and claims 12, 20, 31, 38, 63, 87, and 93 of the '345 patent. The plaintiff's proposed construction is "a ranking based on the number of times a particular work has been downloaded or played back, indicating how popular the particular work is." The defendant proposes "how much an item is liked or admired by a group of people."

The intrinsic record reflects that claim 89 of the '725 patent states "the remote source includes instructions for establishing popularity information indicative of plays of works during predetermined time intervals." '725 patent, claim 89 (emphasis added). Claim 113 of the '725 patent states "including executable instructions for establishing popularity information indicative of plays of works during predetermined time intervals." '725 patent, cl. 113 (emphasis added). Additionally, the specification of the '725 patent states

If desired, processor 12a in system 10-1 can keep track of the number of plays and total play time and transmit that information to processor 20a, for billing purposes. Reports producible by the processor 20a include total plays and play time along with invoices for end users. Documentation for royalty payments to the appropriate recipients can also be created. Finally, the reports can list those works by demand or popularity by day, week or month.

'725 patent at col. 7, 11. 3-10 (emphasis added).

The intrinsic record supports the plaintiff's proposed construction. **The court construes this term to mean "information indicative of the number of times a particular work has been downloaded or played back, indicating how popular the particular work is."**

**GO BACK**

### A. Claims 6 And 26 Of The '622 Patent

Claim I of the '622 patent states:

1. System for remotely determining the position of a selected category of items of interest in selected geographic vicinity from a database, the system comprising:

   (A) a database for storing information about a plurality of items of interest, the information including, for each of the items of interest, a geographical position and at least one associated category,

   (B) a communications link for communicating between a user of the system and the database,

   (C) an information controller for transmitting a portion of the information in the database to the user via the link upon receipt of a request signal representative of a selected category and geographic vicinity, the transmitted portion of the information including identification of geographic position for at least one of the items of interest within the selected category and geographic vicinity, and

   (D) a port for remotely accessing the portion of information via the link, the port generating the request signal in response to inputs by the user which are representative of the selected category and geographic vicinity, the port having a user interface for accepting the inputs and for indicating to the user the position at least one of the items of interest in the selected category and geographic vicinity.

(DSUF P 6.) Claims 6 and 26 depend from Claim 1 and therefore include each of the limitations of Claim 1. 35 U.S.C. § 112, P 4 ("A claim in dependent form shall be construed to incorporate by reference all the limitations of the claim to which
Expedia first argues that it does not infringe Claims 6 and 26 because it does not use the claimed port or communications link. The Court has construed the term "port" to mean a "terminal, e.g., a personal computer with a modem, from which a user of the invention can access the database storing the information about the items of interest." The Court has also ruled that "user" refers to a "human being." In opposing summary judgment, Civix argues that Expedia does use the claimed system by controlling its customers' use of the ports. 11

11 Civix also argues that Expedia is a co-infringer along with its customers and suppliers and is therefore jointly liable for infringement. Civix argues that Expedia induces the infringement of claims 6 and 26. Because the Court finds that genuine issues of fact exist whether Expedia, itself, uses the claimed system, the Court does not reach Civix's other arguments.

During claims construction, the court construed the terms "port," "switching/transferring," and "session." The parties agreed on the construction of "PPP state," "PPP session" and "dormant/dormant PPP session," and the court adopted the agreed-upon construction of those terms.

The court construed "port" as "a defined physical or logical connection where data enters or leaves a network device."

The court construed "switching" and "transferring" as "shifting or reassociating PPP state to another session associated with the new call set-up message."

The court construed "session" to be "a PPP session."

The parties' agreed upon construction of "PPP Session" is "the time during which a communications device and a network access server are maintaining a negotiated PPP state."

The parties' agreed upon construction of "PPP State" is "a set of parameters negotiated pursuant to PPP sufficient for a PPP session."

Based on the parties' agreement at the claims construction hearing, the court construed "dormant" as "no active data transfer for a predetermined period of time allowing reallocation of resources, but from which active data transfer can resume more efficiently than it could from an inactive state."

Based on the parties' agreement at the claims construction hearing, the court construed "dormant PPP Session" as "a PPP
The term "port" appears in numerous claims of the '670 patent (claims 1-7, 9-11, 18-19, 21-23, 30-34, 36-37, 40-42, 46, 51). Informatica asserts that the plain meaning of the term is understood by those in art and proposes the term be construed to mean "An abstraction for describing the inputs and/or outputs of sources, targets or transformation objects." BODI offers the construction:

A port is analogous to a column of a table and provides the primary means of parameterized dataflow between various objects in a mapping. A port must have a name, data type it holds, and its data flow type (i.e., in, out, or in/out). A port must always be defined within the definition of a source, target, or transformation object; thus it would be meaningless to have a stand-alone definition of a port. Ports provide the means for transferring data between sources, targets, and transformation objects.

A port has the following specification:

```xml
<port_def>::=<port_name><data_type_def><port_type>
<port_name>::=<string>
<port_type>::=|IN|OUT|INOUT|
<data_type_def>::=<data_type>[<precision>[,<scale>]]
<precision>::=<integer>
<scale>::=<integer>
```

BODI asserts that the term port has no generally accepted meaning within the industry; accordingly, it refers the Court to the patent specification and pulls its proposed construction from this source. Informatica responds that BODI's proposed construction impermissibly imports a limitation from the specification into the claims. Moreover, Informatica asserts that the patent as a whole claims an apparatus and method for performing data transformations in data warehousing; the functional specification for a transformation description language ("TDL") -- the basis for BODI's construction -- is merely a preferred embodiment disclosed in the specification.

Claim construction requires courts to walk the fine line between interpreting the claims in light of the specification, Markman, 52 F.3d at 979, and impermissibly reading a limitation into the claim from the specification, Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186-87 (Fed. Cir. 1998). The balance maybe found by determining how the specification characterizes the claimed invention. In other words, does the specification discuss a limitation only as part of some of the possible embodiments or does the specification read as a whole imply that "the very character of the invention requires the limitation be a part of every embodiment." Alloc, Inc. v. Int'l Trade Comm'n, 342 F.3d 1361, 1371 (Fed. Cir. 2003), cert. denied, 541 U.S. 1063, 158 L. Ed. 2d 963 (2004); see also Nazomi Communications, Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1369 (Fed. Cir. 2005) (discussing that claims may embrace "different subject matter than is illustrated in the specific embodiments in the specification").

The written description of the '670 patent focuses almost exclusively on the TDL process, thereby lending support to BODI's argument. Nevertheless, the specification does not state that TDL is the actual invention, rather it recites that TDL, in the context of the preferred embodiment, is the process created for describing the data definitions, manipulations, and other types of transformations in the data warehousing domain. The Federal Circuit has instructed that even in cases where the specification describes only one embodiment, that embodiment only rarely limits the scope of the claim term. See, e.g., Innova/Pure Water, Inc., 381 F.3d at 1117 (stating that "even where a patent describes only a single embodiment, claims will
not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction" (internal quotation omitted); SRI Int'l v. Matsushita Elec. Corp of Am., 775 F.2d 1107, 1121 n. 14 (Fed. Cir. 1985) ("That a specification describes only one embodiment does not require that each claim be limited to that one embodiment."). It is the claims that measure the invention, not the specification. Interactive Gift Express, Inc. v. CompuServe, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001) ("In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to particularly point out and distinctly claim the subject matter which the patentee regards as his invention." (internal quotation omitted). The specification here does not contain any statements of limitation or disclaimers that limit the definition of port to something other than the plain meaning.

The doctrine of claim differentiation also undermines BODI's proposed construction. The Federal Circuit has recognized that, while not a hard and fast rule of construction, the doctrine of claim differentiation creates a presumption that each claim in a patent has a different scope. Comark Communications, 156 F.3d at 1187. This presumption "is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the dependent claim should be read into the independent claim. Sunrace Roots Enter. Co. v. SRAM Corp., 336 F.3d 1298, 1303 (Fed. Cir. 2003). Normally, "limitations stated in dependent claims are not to be read into the independent claims from which they depend." Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 972 (Fed. Cir. 1999).

A review of all the claims at issue, supports the conclusion that BODI's proposed construction is untenable. Dependent claim 19 adds to independent claim 18 only the clause: "wherein the ports are comprised of a name, a data file, and a flow type." Similarly, dependent claim 36 adds to independent claim 30 only the clause: "wherein the ports are comprised of a name, a data file, and a flow type." The juxtaposition of the independent claims lacking any reference to name, data file, and flow type with the dependent claims that add this limitation provides strong support for Informatica's argument that the independent claims were not intended to require the presence of the details contained in BODI's construction. Adopting BODI's proposed construction would import the nuances of the dependent claims into the independent claims; the dependent claims thereby would be rendered entirely redundant. BODI has not coarsely forward with a persuasive argument to rebut the presumption that the independent claims should not be so limited as to render the dependent claims superfluous.

The Court adopts Informatica's proposed construction and construes the term "port" to mean: An abstraction for describing the inputs and/or outputs of sources, targets or transformation objects.

3208

"Portable"

The term "portable" appears in claims 1-2, 6-12, and 14 of the '057 patent and claims 1-8, 10 and 12 of the '362 patent. Typhoon suggests that the term means "easily carried around during use and not unwieldy." Defendants urge that the term means "designed to be carried by an individual." Thus, the parties agree that term requires that a device have the ability to be carried by an individual. However, the parties disagree over whether "portable" requires that a device be capable of operation while moving.

Both patents begin by describing "portable" devices in the prior art as "includ[ing] hand-held units and lap-top computers." '362 Patent at 1:22-25; '057 Patent at 1:20-24. The patents also acknowledge that lap-top computers are generally not operated while being carried. See '057 patent at 1:51-52 ("the lap-top is intended for use while supported on the user's lap, as the name imports"); '362 Patent at 1:51-52 (same). Typhoon's proposed construction equates ambulatory use with portability. However, as the above-quoted passages suggest, the specification clearly distinguishes between a "portable" device and one which is capable of ambulatory use. Furthermore, the description of the invention describes "portability" in terms of "compact design" and describes an "optional" carrying case that "is specifically adapted for ambulatory use of the portable computer." See '362 Patent at 4:42; '057 Patent 17:28-29, 45-56 & Fig. 14. Thus, there is clearly a distinction between ambulatory use and portability. The Court rejects Typhoon's suggestion that portability requires ambulatory use.

However, Defendants' suggestion that portability be by "design" introduces an element of subjectivity into the term that is not warranted by the claim language or specification. See Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1350
(Fed. Cir. 2005) ("The scope of claim language cannot depend solely on the unrestrained subjective opinion of a particular individual purportedly practicing the invention."). The essence of portability, as reflected in the specification, is not the fact that a device has the ability to move, but rather the ease with which it can be moved. See '057 Patent at 1:54-58 (describing lap-top as portable but having "unsymmetrical dimensions, bulkiness, [burdensome] weight, and [an] off-set center of gravity"). Accordingly, "portable" is defined as "physically configured to be easily carried by an individual."

**3209**

5. Portable

The term "portable electronic navigational aid device" appears in claims 9, 10 and 11. The dispute is over the term "portable." The parties advance the same arguments they made in the context of the '873 patent. For the reasons discussed in section C.9, I construe "portable" as "easily transportable."

**3210**

1. Laptop exclusion

Defendants contend that the '645 patent should be construed not to cover laptop computers, which they define as computers that contain a built-in keyboard and display. (At the claims construction hearing, defendants explained that a keyboard or display is "built-in" when it cannot be detached from the computer.) According to defendants, Ergo Computing, Inc., which is listed as the assignee of the '645 patent, developed a line of "brick-style" computers and compatible docking stations in the late 1980s. "Ergo's brick-style computer was distinct from laptop computers in that it did not have a built-in keyboard or display monitor, although it had several ports to which a user could connect a monitor, a keyboard, and other peripheral devices, such as a printer." Dfts.' Opening Br., dkt. # 86, at 1-2. Defendants argue that the court should construe the phrase "portable computer," which appears in independent claims 17 and 28, and the phrase "portable computer microprocessing system," which appears in independent claim 20, to mean "a computer without a built-in display or keyboard that is capable of being carried or moved about." In addition, defendants argue that the phrase "a housing containing the microprocessor," which appears in claims 20 and 28, should be construed to mean "an enclosure, without a built-in display or keyboard, that contains a microprocessor" and the phrase "containing the microprocessor within the housing," which appears in claim 17, should be construed to mean "enclosing the microprocessor within an enclosure that does not have a built-in display or keyboard."

Defendants contend that their proposed constructions are supported by the '645 patent's specification and prosecution history and by several pieces of extrinsic evidence. With regard to the specification, they note that every "embodiment of the invention described in the specification is a computer without a built-in display or keyboard." Dfts.' Opening Br., dkt. # 86, at 5. Also, the inventors distinguished laptop computers from "microcomputers" in the specification, '645 pat., col. 1, Ins. 15-20, and repeatedly described their system as a microcomputer. Id. at col. 2, Ins. 64-66; col. 7, Ins. 23-24. Among the pieces of extrinsic evidence cited by defendants are (1) Ergo's 1990 product catalog; (2) a May 21, 1990 press release from Ergo in which it states that its brick computer "has desktop power and true portability without the limitations of laptop displays and keyboards"; and (3) a June 10, 1990 article from the Boston Globe that described Ergo's computer in the following terms: "you buy one Brick and haul just the brains of the computer around, keeping a full-sized monitor and keyboard at each site." Aff. of Vito Canuso, dkt. # 87, Exhs. B, G and H.

The crux of defendants' argument is that the applicants disclaimed coverage of laptop computers during prosecution of the '645 patent. In their briefs and at the claims construction hearing, defendants focused on a June 15, 1992 response written by the applicants to the Patent and Trademark Office after the patent examiner had rejected the '645 application. Defendants contend that the applicants distinguished their invention from laptop computers in this response to overcome the examiner's rejection of their claims in light of U.S. Patent 5,030,128, issued to Herron.

Plaintiff opposes defendants' proposed constructions. It argues that the word "portable," as used in the terms "portable computer" and "portable computer microprocessing system," has a commonly understood meaning that should be applied to
the claims. Therefore, the phrases require no further construction. Alternatively, if the court decides that the phrases need further construction, plaintiff suggests that the court construe them to mean "a computer that is capable of being easily carried or transported." Plt.'s Opening Br., dkt. # 84, at 3. Plaintiff argues that this construction is supported by the specification, in which the inventors use the terms "portable" and "portability" to "describe the ease with which something is carried or transported." Id. at 7. It makes the same argument with respect to the phrases "housing containing the microprocessor" and "containing the microprocessor within a housing," stating that these phrases require no construction beyond application of the plain and ordinary meanings of the words used. If the court determines that further construction is required, plaintiff proposes that the word "housing" be construed to mean "an enclosing structure." Accordingly, "housing containing the microprocessor" would mean "an enclosing structure containing the microprocessor" and "containing the microprocessor within a housing" would mean "containing the microprocessor within an enclosing structure." Id. at 9.

Plaintiff objects to a construction of the claims that excludes laptop computers on the ground that such a limitation is not found anywhere in the claims of the '645 patent. It argues that defendants are attempting to import a limitation into the claims that is inconsistent with their plain language. Playtex Products, Inc. v. Procter & Gamble Co., 400 F.3d 901, 906 (Fed. Cir. 2005)("The court must take care in its analysis, when locating in the written description the context for a disputed term, not to import a limitation from that written description."). Plaintiff contends further that defendants' proposed construction would exclude from the claims a preferred embodiment shown in figure 13 of the '645 patent. Vitronics, 90 F.3d at 1583 (claim construction that excludes preferred embodiment shown in figure 13 of the '645 patent. Vitronics, 90 F.3d at 1583 (claim construction that excludes preferred embodiment is "rarely, if ever, correct and would require highly persuasive evidentiary support"). Also, plaintiff contends that the extrinsic evidence concerning Ergo's brick-style computer is irrelevant to claim construction. Finally, plaintiff argues that the evidence of disclaimer in the prosecution history is insufficient to warrant application of that doctrine.

It is well established that "a patentee may limit the meaning of a claim term by making a clear and unmistakable disavowal of scope during prosecution." Purdue Pharma L.P. v. Endo Pharm., Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006). Examining prosecution history for instances of disclaimer insures that claims "are not construed one way in order to obtain their allowance and in a different way against accused infringers." Chimie v. PPG Industries, Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005). Holding an applicant to his representations during prosecution does not alter the scope of what the applicant has claimed as his invention. Rather, it protects the right of competitors to rely on those representations to guide their own conduct. Seachange International, Inc. v. C-COR, Inc., 413 F.3d 1361, 1372 (Fed. Cir. 2005).

Prosecution disclaimer is not to be employed "where the alleged disavowal of claim scope is ambiguous." Omega Engineering, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). For example, if statements in the prosecution history are susceptible to more than one reasonable interpretation, disclaimer will not lie. Northern Telecom Ltd. v. Samsung Electronics Co., Ltd., 215 F.3d 1281, 1294-95 (Fed. Cir. 2000). "But where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecutorial disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Omega Engineering, 334 F.3d at 1324.

SciMed Life Systems, 242 F.3d 1337, presents an example of the clarity needed before a patent holder will be held to have disclaimed subject matter. That case involved patents covering certain features of balloon dilatation catheters, which are used in angioplasty. The court of appeals concluded that the asserted claims were limited to catheters that used a coaxial lumen configuration, in which one lumen is contained inside the other, and did not cover catheters that featured a dual lumen configuration in which "the two lumens are positioned side-by-side." Id. at 1339. The court looked to the patents' common specification and determined that the applicants had made a clear disavowal of the side-by-side configuration. It noted that the applicants had described the lumen structure as coaxial in the abstract of each of the patents. Id. at 1342. Also, the applicants had highlighted the disadvantages of dual lumens in discussing the prior art and had described their "invention" as having a coaxial lumen. Id. at 1342-43. Finally, the court highlighted a statement in the specification in which the applicants indicated that the coaxial lumen structure was used in "all embodiments of the presented invention contemplated and disclosed therein." Id. at 1343.

The present case is distinguishable from SciMed Life Systems because the '645 patent's prosecution history and specification do not contain a simple, explicit statement that all embodiments of the claimed invention exclude laptop computers. Nonetheless, I am convinced that the specification and prosecution history support the conclusion that the applicants clearly and unmistakably disclaimed laptop computers. There is compelling evidence in both the prosecution history and the specification that the portable microprocessing system claimed in the '645 patent is distinguishable from a laptop computer and that the applicants emphasized differences between the two in order to overcome the patent examiner's
objections to their original application. Therefore, application of the prosecution disclaimer doctrine is appropriate.

As originally filed, the '645 application contained 26 claims. On December 13, 1991, the Patent and Trademark Office issued an office action rejecting all of the claims. Aff. of Vito Canuso, dkt. # 87, Exh. J. The patent examiner rejected claims 1, 3, 4, 6, 11, 13, 14, 20, 21, 23 and 24 as anticipated by the Herron patent, which claims a docking module that "facilitates conversions of a portable computer between a laptop mode of operation and a desk-top mode of operation" by connecting the computer to peripheral devices. Id. at Exh. K (‘128 pat.), Abstract. The examiner concluded that the claims were anticipated by Herron because the patent disclosed a "portable microprocessor system with a docking connection means" and taught "the steps of using the docking connection means including the ejector which pushes the docking connection means away from the housing when disconnecting the docking connection means from the housing." Id. at Exh. J, at 4.

The applicants wrote a response to the office action, dated June 15, 1992, in which they attempted to distinguish their invention from Herron. Aff. of Vito Canuso, dkt. # 87, Exh. F. The contents of this response indicate that the applicants did not contemplate laptop computers as part of their invention. They began by describing their "invention" as

a portable microprocessing system with a microcomputer contained within a housing. As is typical of such systems, the microprocessor interfaces with several peripheral devices including a keyboard, display, modem, serial and parallel port devices, a power source, etc. The Applicants' system provides all of the interfaces for these devices at a set of interface connectors on the rear bezel of the housing.

Id. at 13 (emphasis added). In this excerpt, the applicants distinguish their invention, a portable microprocessing system, from the peripheral devices with which it interacts. A keyboard and display are listed as peripheral devices. Moreover, the applicants indicate that the interfaces for the devices are located at the rear of the housing. This shows that the applicants were not contemplating a system that contained a built-in keyboard and display. After describing the single connector on the housing and the function of the docking connection means, the applicants highlighted the advantages of their invention and juxtaposed them against the limitations that laptops contained at the time:

The Applicants' system therefore provides an extremely powerful utility. A full-sized microprocessor with large memory capacity is made completely portable. The processing unit housing or "brick" can be easily removed from one system and transported in a briefcase to another system. Rather than requiring a portable display and keyboard, the present invention concentrates on portability of an exceptionally large memory capacity in hard disk drive. . . . For the same sized unit as a conventional laptop computer, the invention does require that peripherals be made available at each location, a requirement that would lead one away from the present invention. However, even that requirement can be an advantage over laptop computers in that higher quality peripherals will more likely be used since they need not be transported. Thus, laptop machines make concessions in memory, display and other areas in favor of portability. The Applicants' system, on the other hand, is a portable full service microprocessing system which concedes portability of peripherals.

Id. at 14-15. Here, the applicants narrow the focus of their invention to a "large memory capacity in hard disk drive" that is portable. It is the microprocessor that is portable, not the peripherals. Again, the applicants contrast their invention to keyboards and displays, which are categorized as peripheral devices. They state that their invention requires the user to provide peripherals wherever he uses the system. They state that their system "concedes portability of peripherals," which I construe as a disclaimer of portable peripherals. Perhaps most important, the applicants distinguish their system from laptop computers specifically, noting that their system captures the portability of laptop computers without making sacrifices in "memory, display and other areas."

Finally, the applicants make the following remarks to distinguish their invention from Herron:

The Herron reference discloses a docking module which is latched to the rear of a laptop computer. The computer and docking module rest on a desk top.

* * *

The Herron system does not allow a microprocessor having state-of-the-art memory capacity and other capabilities to
interface to a full-service processing system as does the Applicants' system. The Herron system allows a laptop computer with its own flat panel display and keyboard to interface to other peripheral devices. This laptop computer does not possess utilities and functionalities comparable to those of the Applicants' system.

* * *

Also, the computer in Herron is not oriented vertically as in the Applicants' system. It would make no sense to do so with the Herron laptop with its attached keyboard and display.

Id. at 16-17. The applicants distinguished their system from Herron because the laptop machine did not have the "state-of-the-art" memory capacity of their system and because a user would not be able to use a laptop machine that was held vertically in the docking station.

The specification of the '645 patent reinforces the distinction between the claimed invention and laptop machines. In setting out the background for their invention, the applicants divide computer systems into a four-tiered hierarchy according to their size and processing abilities: mainframe systems, "mini-computer systems," microcomputer systems, "often referred to as personal computers," and laptop computers. '645 pat., col. 1, Ins. 7-22. The applicants describe their invention as a portable microcomputer repeatedly throughout the specification. In the abstract, the applicants describe their invention as a "microcomputer system," which "includes a microprocessor and a housing for holding the microprocessor." This characterization is repeated in the section entitled "Summary of the Invention," where the applicants state that "present invention concerns a portable microprocessor system having a microprocessor for processing instructions and a main housing for housing the microprocessor." Id. at col. 1, Ins. 24-27.

Also, various figures in the patent are described as versions of the applicants' microcomputer system. Id. at col. 2, Ins. 39-40, 64-66; col. 3, Ins. 1-3. As in the June 15 response, the applicants distinguish their system from peripheral devices such as a keyboard and display by describing the devices as "options available with the system." Id. at col. 2, Ins. 8-10. Admittedly, the inventors do not explicitly disclaim laptop computers in the specification. But the distinctions drawn between laptop machines and their invention in the specification reinforce the disclaimer made in the June 15 response.

Plaintiff argues that the June 15 response does not contain a clear and unmistakable disavowal of laptop computers. Plaintiff acknowledges that the applicants highlighted differences between laptop computers and their system in the June 15 response. However, it notes that the applicants listed several novel features of their invention to distinguish it from Herron and other pieces of prior art and indicated that each of the amended independent claims incorporated "at least one of these novel features." Aff. of Vito Canuso, dkt. # 87, Exh. F, at 16. In other words, if there was a disclaimer of laptops, the applicants did not state that it applied to all of the independent claims.

This argument does not comport with the language of the independent claims. If, as plaintiff contends, not all of the independent claims exclude laptops, one would expect to find an explicit limitation excluding laptop computers somewhere in the language of the independent claims. This language would alert the reader to which independent claim or claims excluded laptops. However, none of the independent claims contain this exclusionary language. There is only one way to incorporate the laptop disclaimer into the patent. That is to infer that it is inherent in the terms "portable computer" and "portable computer microprocessing system." One of these terms appears in the preamble of each of the independent claims. Therefore, the laptop disclaimer applies to all of the claims of the '645 patent.

If these terms are not construed to exclude laptops, claims 1 and 14 would not make any sense because they both disclose a portable computer microprocessing system that includes "a support holding the housing in a vertical position." '645 pat., col. 8, In. 55; col. 9, In. 65. Laptop computers are not designed to be used while the housing is held vertically and it would be inappropriate to construe the term "portable computer microprocessing system" to exclude laptops as it appears in claims 1 and 14 but not as it appears in independent claim 20. Phillips, 415 F.3d at 1314 ("claim terms are normally used consistently throughout the patent").

Plaintiff argues next that language in the specification argues against a laptop exclusion. It notes that the applicants included a statement indicating that the claims were not to be interpreted narrowly to cover only the embodiments discussed in the patent:
While the invention has been particularly shown and described with reference to preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and detail may be made without departing from the spirit and scope of the invention as defined in the appended claims.

'645 pat., col. 8, Ins. 12-17. This vague statement is insufficient to overcome the more specific statements made in the June 15 response distinguishing the claimed invention from laptop computers. Moreover, the Court of Appeals for the Federal Circuit has found that statements of disclaimer in prosecution history can limit the scope of patent claims even where the disclaimer excludes a preferred embodiment from coverage or conflicts with statements in the specification. In Rheox, Inc. v. Entact, Inc., 276 F.3d 1319 (Fed. Cir. 2002), the court of appeals upheld a construction of a patent for a method of remediating lead from soil that excluded a chemical compound known as "monocalcium orthophosphate" or "triple superphosphate" even though that compound was listed in the patent's specification as a preferred embodiment. The court examined the prosecution history and noted that the applicants had included triple superphosphate in their original claims but had deleted references to the compound in subsequent amendments to distinguish their invention from the prior art. Id. at 1326-27. Although the court recognized that a claim construction that excludes a preferred embodiment is rarely appropriate, it considered the specific disclaimers made in the prosecution history paramount and persuasive enough to adopt the limiting construction. Id. at 1327. The present case is similar to Rheox in that the statements made by the applicants in the June 15 response emphasizing the advantages of their invention over laptop computers are controlling over the language in the specification indicating that "changes in form and detail may be made without departing from the spirit and scope of the invention." '645 pat., col. 8, Ins. 15-17.

Plaintiff contends further that claims 1, 9 and 10 prove that there was no disclaimer. Claim 1, an independent claim, contains the phrase "portable computer microprocessing system." Claims 9 and 10, which are dependent on claim 1, require connectors for a keyboard and visual display on the system's housing. '845 pat., col. 9, Ins. 13-19. According to the doctrine of claim differentiation, claim 1 does not contain the limitations disclosed in claims 9 and 10. Therefore, plaintiff argues, because the housing in claim 1 may not have connectors for a keyboard and display, those peripherals must be built into the system. Accordingly, claim 1 would encompass laptop systems as defendants have defined them.

The doctrine of claim differentiation is only a "presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006). This presumption cannot be used to broaden claims beyond their proper scope. Kraft Foods, Inc. v. International Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000)(quoting Multiform Desiccants Inc. v. Medzam, Ltd., 133 F.3d 1473, 1480 (Fed. Cir. 1998)). Moreover, it can be overcome by statements of disclaimer in the prosecution history. Fantasy Sports Properties, Inc. v. Sportslines.com, Inc., 287 F.3d 1108, 1115 (Fed. Cir. 2002); Kraft Foods, 203 F.3d at 1367-69. Such is the case here. The applicants disclaimed laptop computers in the course of prosecution. This disclaimer trumps the presumption that the "portable computer microprocessing system" in claim 1 does not have connectors for a keyboard and visual display.

Plaintiff argues that defendants' construction excludes from the claims the embodiment shown in figure 13 of the '645 patent. SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005)(quoting Vitronics, 90 F.3d at 1583) ("claim construction that excludes preferred embodiment is "rarely, if ever, correct.").

[SEE FIGURE 13 IN ORIGINAL]

Plaintiff contends that this figure shows an embodiment of the invention that includes a keyboard and display. Plaintiff is correct, but figure 13 does not depict a "laptop" computer as defendants have defined that term. The keyboard and display in figure 13 are detachable from the housing. Under defendants' proposed construction, laptops are defined as computers with built-in displays and keyboards. Defendants defined "built-in" to mean that the display and keyboard could not be detached from the computer. In contrast, the keyboard and display in figure 13 are described as being "coupled" to the microcomputer system. '645 pat., col. 7, Ins. 23-24. Figure 14 shows the connector and thumbscrews used to connect and disconnect the display from the housing. Both the keyboard and display in figure 13 are detachable from the housing. Accordingly, the embodiment in figure 13 is not excluded by defendants' proposed construction.

Finally, plaintiff argues that defendants' construction "ignores the fact that each of the claims is either a 'system comprising' certain steps . . . or a 'method . . . comprising [certain] steps." Plt.'s Opening Br., dkt. # 84, at 9-10 (emphasis in original). The word "comprising" "is inclusive or open-ended and does not exclude addition, unrecited elements or method steps." Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327 (Fed. Cir. 1999). Therefore, plaintiff argues, the
claims could cover a housing that contains a keyboard or monitor. This argument is not persuasive. As defendants note, use of the word "comprising" does not overcome the applicants' disclaimer of laptops during prosecution. Spectrum International, Inc. v. Sterilite Corp., 164 F.3d 1372, 1380 (Fed. Cir. 1998) ("'Comprising' is not a weasel word with which to abrogate claim limitations.").

In conclusion, I agree with defendants that the claims in the '645 patent asserted in this case should be construed not to cover laptop computers. Accordingly, I will adopt defendants' proposed construction of the terms "portable computer" and "portable computer microprocessing system." As used in the '645 patent, the terms will be construed to refer to "a computer without a built-in display or keyboard that is capable of being moved or carried about." In light of this conclusion, I agree with plaintiff that incorporating the "lack of built-in display or keyboard" limitation to the phrases "a housing containing the microprocessor" and "containing the microprocessor within the housing" would be needlessly duplicative. Therefore, I will not adopt this proposed construction.

2. "Another single connector on the housing, said single connector comprising a set of pins, said set further comprising a plurality of subsets of computer-peripheral-device-specific pins being in electrical communication with said microprocessor such that one of each of said subsets of computer-peripheral-device-specific pins provides the same computer-peripheral-device-specific data link as said each of said plurality of computer-peripheral-device-specific connectors, said single connector for making all connections from the microprocessor to said specific computer peripheral devices"

For ease of reference, I will adopt the parties' convention and refer to this phrase as the "long phrase." The long phrase appears in independent claims 17(c), 20(d) and 28(d) of the '645 patent. The parties raise four construction issues concerning it. I will start with the dispute that was resolved at the claims construction hearing.

At the hearing, the parties agreed that the claims of the '645 patent establish two paths through which the microprocessor may communicate with peripheral devices. First, the devices may be connected to the microprocessor through their corresponding individual connectors, which are mounted on the housing. Second, the devices may be connected to the microprocessor through a docking connector, which mates with a single connector found on the housing. At the hearing, plaintiff stated that it was under the impression that defendants' construction of the long phrase required the connections between the microprocessor and the peripheral devices to pass through the single connector, even when the peripheral devices were connected to the microprocessor through their individual connectors. Trans., dkt. # 101, at 53. As a result, when the peripheral devices are connected to the microprocessor through their individual connectors, the claims would be infringed only when the signals to each peripheral device passed from the microprocessor to the single connector and then from the single connector to the individual connectors. Defendants stated that this was not their position. Id.

The remaining three disputes concerning the long phrase are as follows. First, defendants contend that a portion of the long phrase is indefinite under 35 U.S.C. § 112. Second, defendants argue that another section of the long phrase, "said single connector for making all connections from the microprocessor to said computer peripheral devices," should be construed to require that "all individual peripheral devices connections on the housing that connect to the microprocessor also pass through the single connector." Dfts.' Opening Br., dkt. # 86, at 10. Third, defendants contend that this section should be construed to require that "the microprocessor directly drives all peripheral devices, either through the housing's individual connectors or through the single connector." Id.
within "portable computer means" in the '713 Patent. The parts include: a portable bar code reading means, a portable processing means, a portable memory means, and a portable display means. The recited functions include: storing the patient history file and the physician instruction file on that patient; identifying the patient and the medications, goods, services, or procedures proposed to be delivered to that patient by reading the bar codes on the patient's wrist identification band and on the medications, goods, services, or procedures; processing the bar codes read by the bar code reader to determine by comparing the patient history file and the physician instruction file to calculate whether the identified medications, goods, services, or procedures may be given to that patient at that time; and indicating the determination on a portable display. The defendants argue that there is no evidence that one of ordinary skill in the art in the 1980s would have understood the term "portable computer" to connote a structure capable of performing these functions, including the function of reading a bar code. (Id.).

The record contains no evidence that a person of ordinary skill in the art would have understood the term "portable computer" by itself to connote sufficiently definite structure to perform the specific functions that the claim recites. The case law does not support Brown's argument that in the '713 Patent, the term "portable computer means" is sufficient to overcome the means-plus-function presumption.

In Catch Curve, Inc. v. Venali, Inc., No. CV 05-4820, 2007 U.S. Dist. LEXIS 93667, 2007 WL 3308101, at *10 (C.D. Cal. May 11, 2007), for example, the court examined a patent for a fax communications system that was designed to improve security and save redial efforts by a "store and forward facility." If a receiving fax machine was busy or unavailable, the claimed facility would receive faxes transmitted by an originating machine, store them, and, if retransmit them to their intended destinations when the receiving machine became available. 2007 U.S. Dist. LEXIS 93667, [WL] at *4. A "computer means" was claimed as a means for controlling the store and forward facility. "The plaintiff argued that "computer means" should not be construed according to section 112, P 6, because the word "computer" meant a sufficiently definite structure to rebut the presumption. 2007 U.S. Dist. LEXIS 93667, [WL] at *10. The court rejected this argument because the word "computer" did not connote sufficient structure to perform the claimed function of operating the store and forward facility. The function of receiving facsimiles transmitted by an originating fax machine, storing them, and forwarding or retransmitting the facsimiles to their intended destinations once the receiving machine was available, was not common to all computers but instead would require special programming. The court observed that "[w]hile every computer may have a defined structure, it does not follow that every computer has structure sufficient to control the operation of a store and forward facility [for facsimiles]." 2007 U.S. Dist. LEXIS 93667, [WL] at *11. The court concluded that "computer means" was a means-plus-function phrase. Id.

The court reached a similar conclusion in Verizon California, Inc. v. Ronald A. Katz Tech. Licensing, L.P., 326 F. Supp. 2d 1060, 1101-02 (C.D. Cal. 2003). In that case, "computer means" performed the functions of connecting incoming customer calls to an operator terminal and visually displaying data about the customer. The court accepted the argument that "computer" connoted a structure but held that the structure was not "sufficient to perform the recited functions" in the claim. Id. at 1102 n. 13. The court concluded that "computer," as understood by one of ordinary skill in the art, would not connote sufficient structure to perform the function of connecting incoming calls to an operator terminal. The corresponding required structure -- a computerized transmission line between the computer and the interface terminal -- was not included in the word "computer." Id. at 1102. The claimed term "computer means" was subject to section 112, P 6.

T-Netix, Inc. v. Global Tel*Link Corp., 2:01-cv-189, 2003 U.S. Dist. LEXIS 27830, 2003 WL 25782759, at *9 (E.D. Tex. Aug. 15, 2003), provides another example. The "computer means" in the claim at issue performed the function of "enabl[ing] the use of an on-site telephone to make calls by another party at a location remote from the site, without the intervention of a human operator." Id. The court accepted the argument that "computer" had "sufficient structure by itself to describe the physical object" but concluded that the term did not connote sufficient structure to overcome the means-plus-function presumption. "[T]he word computer, by itself, does not tell us anything except that it is capable of computing something or controlling some process." Id. The function that "computer means" was required to perform in the patent at issue would require special programming or software, not common to all computers, which left "the entire clause up for construction." Id.

These cases support the conclusion that the term "portable computer means" in the '713 Patent is subject to means-plus-function analysis. As in Catch-Curve, Verizon, and T-Netix, a general-purpose computer is not a sufficient description of the structure necessary to perform the claimed functions. In the '713 Patent, the functions assigned to "portable computer means" would require special structure and special programming, including reading barcodes. Brown has presented no
The second step is to determine the corresponding structure disclosed in the specification and equivalents thereof. The "portable computer means" must also be specially programmed to perform the function of determining that the identified medications, goods, services, or procedures are the right ones to give to the particular patient at the particular time. Brown has presented no evidence that "computer means" would, by itself, connote sufficient structure to perform this function. "Computer means" as used in the '713 Patent does not overcome the means-plus-function presumption.

Brown cites the Federal Circuit's unpublished decision in Optimal Recreation Solutions, LLP v. Leading Edge Techs., Inc., 6 F. App'x 873, 878 (Fed. Cir. 2001), in arguing that the specification supports the conclusion that "computer means" is reasonably well understood in the art and overcomes the presumption that section 112, P 6 applies. In Optimal, the court concluded that the terms "global positioning receiver means," "memory means," and "display means" provided "sufficient structure for accomplishing the functions recited in the pertinent claim limitations," as evidenced by the fact that the specification repeatedly referred to these terms without defining them. Id. The court treated the specification as evidence that the disputed claim terms had "well understood meanings as the names for [the] structure." Id.

The Optimal case does not support Brown's argument that "computer means" in the '713 Patent connotes sufficient structure to overcome the means-plus-function presumption. The court in Optimal emphasized that "it is important to bear in mind the context of the invention and the relevant arts involved." Id. The invention claimed in that case involved a GPS receiver. The specification repeatedly referred to GPS receivers. The court concluded that the relevant arts were GPS receivers and computer programming and considered what a person with ordinary skill in those arts would understand by the terms "global positioning receiver," a "memory," and a "display" as the names for structure. The court concluded that those terms "have reasonably well understood meanings in those arts and are sufficient structure for accomplishing the functions recited in the pertinent claim limitations." Id. The specification did not "redefine" these terms. In the present case, by contrast, to one skilled in the relevant arts at the relevant time, "computer" in the context of the invention does not connote a sufficiently specific structure to perform the recited functions, including the function of reading barcodes. And in the present case, in contrast to Optimal, the specification in the '713 Patent does "redefine" the term "computer." The specification defines the term by describing it and giving specific examples:

The portable computer means should be small in size and equipped with a barcode reader. A hand held portable computer means such as Model PTC-701 manufactured by Texlon Corporation, or the Advanced Pocket Computer manufactured by Hand Held Products, is able to read the barcode on the patients' information band and a variety of other standard barcode formats.

(Docket Entry No. 132, Ex. A, col. 2 ll. 22-29). The definition in the specification confirms that the functions a "portable computer means" must perform require a structure beyond that which a person of ordinary skill in the art would understand by the term standing alone.

Brown also cites two pre-Phillips cases holding that terms such as "baffle" and "perforation" were sufficiently specific to overcome the means-plus-function limitation. In the first case, Envirco Corp. v. Clestra Cleanroom, 209 F.3d 1360, 1365 (Fed. Cir. 2000), the court used the dictionary definition of "baffle" -- "a surface which deflects air" -- to hold that the "second baffle means" element in the claim imparted sufficient structure to rebut the means-plus-function presumption. In the second case, Shelley K. Cole v. Kimberly-Clark Corp., 102 F.3d 524, 530-31 (Fed. Cir. 1996), the court looked to the dictionary definition of "perforation" as "for tearing," and held that the term "perforation means" recited sufficient structure to perform the recited function and overcome the presumption. In these cases, the terms "baffle" and "perforation" themselves supplied a general structure that could perform the claimed general functions. These cases do not support the argument that a person of ordinary skill in the art would have understood the words "portable computer" to supply a sufficiently specific structure to perform the functions claimed in the '713 Patent, including reading a bar code.

The means-plus-function presumption applies. The first step is to identify the functions of the "portable computer means." They are:

- housing components including a "portable bar code reading means," "portable memory means," "portable display means," and "portable processing means"; performing the functions enabled by these components; connecting to a "host computer means" by a "communication link means"

The second step is to determine the corresponding structure disclosed in the specification and equivalents thereof. The
structure disclosed in the specification that corresponds to these functions is:

a portable computer small in size and equipped with a barcode reader, such as Telxon Corporation Model PTC-701 or Advanced Pocket Computer by Hand Held Products or their equivalents.

(Docket Entry No. 132, Ex. A, FIG. 1; col. 2 ll. 22-29).

3. "Portable Memory Means" and "Portable Display Means"

The '713 Patent claim describes, as part of the "portable computer means," a "portable memory means for storing said patient history file and said physician instruction file." The "portable processing means" checks these files in determining if the medications, goods, services, or procedures proposed to be delivered are correct for that patient at that time. If the medication, good, service, or procedure is delivered, the "portable processing means" updates the patient history file in said "portable memory means" to show that the medication, good, service, or procedure was delivered to the particular patient at the particular time. The claim also describes a "portable display means for indicating the determination of said portable processing means."

Brown contends that the terms "memory" and "display" "impart structure sufficient to rebut the presumption that § 112, P 6 applies." (Docket Entry No. 132 at 15). Citing the Federal Circuit's opinion in Optimal, Brown contends that "[t]he term 'memory' has an accepted meaning to those skilled in the art and is defined as a 'storage capacity of a computer.'" (Id. (quoting Optimal, 6 F. App'x at 878)). Brown also argues that "'display' . . . has an accepted meaning to those skilled in the art and is defined as 'visually representing information.'" (Id. (quoting Optimal, 6 F. App'x at 878)). The defendants cite cases that have construed "memory means" and "display means" as means-plus-function terms and contend that Brown has failed to meet his burden of overcoming the means-plus-function presumption.

As with "computer means" and "processing means," the case law shows that whether the terms "memory means" and "display means" overcome the means-plus-function presumption turns on whether these terms connote sufficient structure to perform the claimed functions. If those functions go beyond those included within the generic structure connoted by these terms, the means-plus-function presumption is not rebutted.

In Data General Corp., 93 F. Supp. 2d at 95, for example, one of the disputed claims was for "memory means" for "storing and providing data items in response to memory commands, each said memory command including an address specifying a location in said memory means." Id. at 91. The claim did not make clear whether the term "address" referred to "logical address" or "physical address." The court rejected the plaintiff's contention that "memory means" overcame the means-plus-function presumption, explaining that "[a]lthough the memory of a general purpose computer system is a sufficiently described structure to perform the function of 'storing and providing data,'" the term "memory" did not connote sufficient structure to determine whether the memory was capable of "storing and providing data" in the form of "logical addresses." Id. at 95. To store and process "logical addresses," the memory would have to be "logical memory" or "physical memory [with] a mechanism to convert logical addresses into physical addresses." Id. The court concluded that the term "memory," without more, did not connote sufficient structure to perform the required function for storing and providing data in the form of logical addresses. The court concluded that reference to the specification was required and that "memory means" as used in the claim was a means-plus-function term.

The defendants also cite to several cases that conclude, without significant analysis, that "memory means" and "display means" are means-plus-function terms. See Genlyte Thomas Group LLP v. Lutron Elecs. Co., No. 3:02-cv-0602, 2004 U.S. Dist. LEXIS 5311, 2004 WL 690847, at *11 (N.D. Tex. Mar. 31, 2004) (concluding that section 112, P 6 applied to "memory means" because the claim itself did not include structural details but the specification provided a "detailed description of the structure used to carry out the function"); the court did not state the function that "memory means" was to perform); PCTEL, Inc. v. Agere Sys., Inc., No. C 03-2474, 2005 U.S. Dist. LEXIS 34288, 2005 WL 2206683, at *5 (N.D. Cal. Sept. 8, 2005) (citing Lutron and several cases in which the parties stipulated that "memory means" was a means-plus-function term and concluding that "memory means" was subject to section 112, P 6; the court did not state the function that "memory means" was to perform); Khyber Tech. Corp. v. Casio, Inc., No. Civ. A. 99-12468, 2004 U.S. Dist. LEXIS 15714,
2004 WL 1790173, at *8 (D. Mass. Aug. 11, 2004) (construing, without discussion, "display means" for "displaying written messages" as a means-plus-function term; there was no evidence that either party disputed the construction).

Other cases have concluded that "memory means" and "display means" connoted sufficient structure to overcome the means-plus-function presumption. For example, in Optimal Recreation Solutions, LLP v. Leading Edge Technologies, Inc., 6 F. App'x at 878, the Federal Circuit, analyzing a patent for a global positioning system for determining the distance to holes on golf courses, concluded that the terms "memory means" and "display means" overcame the means-plus-function presumption. The claim recited a "memory means for storing the position of the golf cup" and a "display means for displaying the distance [between the GPS receiver and the golf cup]." Id. at 875. The court concluded that "memory" and "display" had "reasonably well understood meanings in those arts and [were] sufficient structure for accomplishing the functions recited in the pertinent claim limitations." Id. at 878.

1 Several district courts have reached similar results. Western Union Co. v. Moneygram Int'l, Inc., No. 07-0372, 2008 U.S. Dist. LEXIS 108129, 2008 WL 5731946, at *12 (W.D. Tex. Nov. 6, 2008), involved patents for a system for performing money transfer transactions. One of the claims described "memory means in the cash register for storing the transaction data received from the money order dispenser." Id. The court noted a dictionary definition of "memory" as "a unit of a computer that preserves data for retrieval; capacity for storing information." Id. The court concluded that the claim recited sufficient structure to overcome the means-plus-function presumption. Id. Similarly, in St. Clair Intellectual Property Consultants, Inc. v. Canon Inc., No. Civ. A. 03-241, 2004 U.S. Dist. LEXIS 17489, 2004 WL 1941340, at *14 (D. Del. Aug. 31, 2004), the court considered a claim for "removably mounted memory means for storing digitized image data" as part of a patent for an electronic still camera. The court concluded that the claim recited sufficient structure to overcome the means-plus-function presumption: "As the surrounding claim language indicates, that 'memory means' is removably mounted in a camera body and must store digitized image data. In this context, 'memory means' . . . would be understood by one skilled in the art as a definite structure. This recited structure is capable of performing the described function, and therefore 'memory means' is not a means-plus-function term." 2004 U.S. Dist. LEXIS 17489, [WL] at *15.

In Nonin Medical, Inc. v. BCI, Inc., No. 02-0668, 2004 U.S. Dist. LEXIS 3824, 2004 WL 442894, at *6 (D. Minn. Mar. 8, 2004), the court construed the term "display means" in a patent for a device to measure blood oxygen levels. The claim at issue recited a "display means for displaying the sensed and determined blood oxygen saturation level." 2004 U.S. Dist. LEXIS 3824, [WL] at *2. The court concluded that the claim recited sufficient structure to overcome the means-plus-function presumption: "The terms "memory" and "display" do not describe devices; these terms simply describe functions. One of ordinary skill in the GPS field would not equate "display" [or "memory"] to any specific, definite structure. . . . [The means-plus-function presumption] is not rebutted by the claim language itself because these limitations do not recite sufficient structure to perform the "memory" and "display" functions. The majority's references to the use of the terms "memory" and "display" in the specification of the . . . patent is inappropriate.

Id. at 880 (Gajarsa, J., dissenting).

In the present case, referring to the specification does not help in construing the terms "memory means" or "display means." The specification does contain two references to "display" as a verb. Neither reference defines "display." The specification states: "If the interval is correct the portable computer means will display the message 'verified.' If an error occurs in this process, an appropriate error message will be displayed by the portable computer means." (Docket Entry No. 132, col. 3 ll. 32-36).

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
"Memory means" in the '713 Patent performs the function of storing the patient history file and the physician instruction file. "Display means" in the '713 Patent performs the function of indicating the determination of the portable processing means. Even assuming that these functions are within the "plain meaning" of these terms, see Optimal, 6 F. App'x at 878 ("storage capacity of a computer"), Western Union, 2008 U.S. Dist. LEXIS 108129, 2008 WL 5731946, at *12 ("a unit of a computer that preserves data for retrieval; capacity for storing information."); Nonin, 2004 U.S. Dist. LEXIS 3824, 2004 WL 442894, at *6 ("a visual presentation of data from a computer"), both are components of the "portable computer means," itself a means-plus- function term. The structure associated with "portable computer means" is "a portable computer small in size and equipped with a barcode reader, such as Telxon Corp. Model PTC-701 or Advanced Pocket Computer by Handheld Products or their equivalents." As component parts, the structure of "portable memory means" and "portable display means" must be compatible with the structure of the "portable computer means."

The facts of Khyber Technologies Corp. v. Casio, Inc., No. Civ. A 99-12468, 2003 U.S. Dist. LEXIS 12450, 2003 WL 21696354, at *4 (D. Mass. Mar. 31, 2003), are similar. The patent at issue involved a personal organizer and messaging device that could be carried "substantially within a shirt pocket." 2003 U.S. Dist. LEXIS 12450, [WL] at *3. The parties disputed the construction of "memory means" in the claim. Because "the memory means must be contained within the handheld housing of the device," the term was limited to certain formats, to the exclusion of others. 2003 U.S. Dist. LEXIS 12450, [WL] at *4. For example, "memory means" could not include "writable optical disks that are independent of the device" because this would not operate within the battery-powered device, would not operate reliably unless placed on a stable, flat surface, and would not have been available at the time the patent was developed and granted. Id. The means-plus-function analysis applied. A subsequent decision in the Khyber case determined that "display means" was also subject to the section 112, P 6 analysis because it was a component part of the handheld device. The court noted that the structure of the handheld device constrained the graphics display to be "relatively high resolution (so it can easily be read, especially considering the relatively small size (handheld, shirt-pocket size) of the device), and (2) low power consumption (so the device can be made small)." Khyber, 2004 U.S. Dist. LEXIS 15714, 2004 WL 1790173, at *8.

The '713 Patent specification does not disclose a specific structure for "portable memory means" and "portable display means" but does disclose a structure for the "portable computer means" of which these items are a part. This court has already construed that structure to be: "a portable computer small in size and equipped with a barcode reader, such as Telxon Corporation Model PTC-701 or the Advanced Pocket Computer by Hand Held Products or their equivalents." Because "portable memory means" and "portable display means" must be read to exclude types of memory and display that would not be compatible with the disclosed structure for the "portable computer means," the means-plus-function presumption applies.

The function of "portable memory means" is:

storing the patient history file and the physician instruction file

The structure in the specification disclosed for this function is:

a type of memory that is compatible with a portable computer small in size and equipped with a barcode reader, such as Telxon Corporation Model PTC-701 or the Advanced Pocket Computer by Hand Held Products or their equivalents

The function of "portable display means" is:

indicating the determination of the "portable processing means"

The structure in the specification disclosed for this function is:

a type of display that is compatible with a portable computer small in size and equipped with a barcode reader, such as Telxon Corporation Model PTC-701 or the Advanced Pocket Computer by Hand Held Products or their equivalents.
After considering the parties' proposed constructions, the Magistrate Judge recommended that the term "a portable point of sale terminal," as used in Claim 9 of the '821 patent, should be construed to mean "a portable computer terminal that is capable of handling a sales transaction." (D.I. 133 at 7-11.) For the reasons set forth in the Report and Recommendations, the Court will adopt this construction.

2. "Portable Processing Means"

The '713 Patent states that a "portable computer means comprises," in part:

portable processing means for processing the bar codes read by said portable bar code reading means so as to determine if said identified medications, goods, services or procedures are permitted to be delivered to said identified patient, according to said patient history file and said physician instruction file in said portable memory means, and for updating said patient history file in said portable memory means if said identified medications, goods, services, or procedures are permitted to be delivered to said identified patient,

wherein said determination requires that said identified medications, goods, services or procedures are related to said identified patient in said physician instruction file in the portable memory means and that said identified medications, goods, services or procedures would be delivered to said identified patient at an appropriate time according to when identified medications, goods, services or procedures were last delivered to the identified patient in the past as indicated in the patient history file in the portable memory means and according to the time interval in said physician instruction file in said portable memory means to grant permission to deliver said identified medications, goods, services or procedures, and portable display means for indicating the determination of said portable processing means,

(Docket Entry No. 132, Ex. A, col. 4 ll. 30-57). Brown argues that "portable processing means" overcomes the means-plus-function presumption because "[i]t is clear to one skilled in the art of computer programming that 'processing' takes place in a computer." (Id. at 16). The defendants counter that the case law supports their position that "the recitation of 'processing means' is insufficient to rebut the presumption that § 112(6) applies." (Docket Entry No. 138 at 17).

The case law shows that "portable processing means" as used in the '713 Patent is subject to means-plus-function analysis. In Centillion Data Systems, LLC v. Convergys Corp., 529 F. Supp. 2d 982, 984-85 (S.D. Ind. 2008), the court concluded that the term "data processing means" in a patent claiming the function of "generating and organizing" "summary reports" in a credit-card billing system did not overcome the means-plus-function presumption. The term "data processing means" merely "identify[d] a computer with corresponding operating system software. In other words, a general purpose computer." Id. at 997. The claim at issue "require[d] that the data processing means perform specific functions, which, according to the specification, require a computer to be programmed to carry out certain steps, or to perform a certain algorithm." Id. at 997-98. The court concluded that "data processing means" did not connote sufficient structure to describe the particular program required and that the means-plus-function presumption was not rebutted. Id. at 998.

The court reached a similar conclusion in Cummins-Allison Corp. v. Glory, Ltd., No. 02-cv-7008, 2005 U.S. Dist. LEXIS 6150, 2005 WL 711991, at *11 (N.D. Ill. Mar. 28, 2005). The patent in that case was directed to currency counting. One of the claim terms was a "signal processing means" to perform the functions of receiving signal samples and "(1) determining the denomination of each scanned bill by comparing said stored signal samples with said output signal samples produced by the scanning of each bill with said scanning head, (2) counting the number of scanned bills of each denomination, and (3) accumulating the cumulative value of the scanned bills of each denomination." 2005 U.S. Dist. LEXIS 6150, [WL] at *2. The court stated that "one skilled in the art would generally equate 'signal processing means' with a CPU," and that those skilled in the art would be aware of specific algorithms with which the "signal processing means" could be programmed to perform the denomination function. 2005 U.S. Dist. LEXIS 6150, [WL] at *11. The court emphasized that this was a separate inquiry from whether the term "signal processing means" connoted sufficient structure by itself to perform the denomination-determination function. The court concluded that "signal processing means" did not connote such structure and that section 112, P 6 applied. 2005 U.S. Dist. LEXIS 6150, [WL] at *12.
Similarly, in Roche Diagnostics Corp. v. Apex Biotechnology Corp., 455 F. Supp. 2d 840, 849-850 (S.D. Ind. 2005), the court examined the term "processor means" in a patent for a "biosensing meter with a pluggable memory module." The court concluded that the "processor" used in the claim was "not a generic one, but one that runs a particular algorithm" to perform the claimed function. Id. at 863. The court concluded that although "there [w]as no dispute that "'processor' has a well-known meaning in the art," that was not sufficient to rebut the presumption if the structure necessary to perform the disclosed function was not a "general purpose" processor but a special purpose processor programmed to perform the disclosed algorithm. Id. The court in Digital Technology Licensing, LLC v. Cingular Wireless, LLC, No. 2:06-cv-0156, 2007 U.S. Dist. LEXIS 57492, 2007 WL 2300792, at *8 (E.D. Tex. Aug. 7, 2007), reached a similar result, concluding that "[n]either the verb 'processing' nor the gerund 'processor' recite[d] sufficient structure, material, or acts" to encompass a function that involved "modify[ing] sequences of groups of digital bits." Id.

The Federal Circuit's opinion in WMS Gaming Inc. v. International Game Technology, 184 F.3d 1339, 1348 (Fed. Cir. 1999), is instructive. The plaintiff in that case agreed that section 112, ¶ 6 applied but contended that the general-purpose microprocessor disclosed in the specification provided sufficient structure for "means for assigning" numbers in the programming of an electronic slot machine to decrease the user's probability of winning. The Federal Circuit rejected the plaintiff's argument. The court stated that in a means-plus-function claim, "[a] general purpose computer, or microprocessor, programmed to carry out an algorithm creates a new machine, because a general purpose computer in effect becomes a special purpose computer once it is programmed to perform particular functions pursuant to instructions for program software." Id. (citations and quotation omitted). The necessary structure is therefore "not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm." Id. at 1349.

The court in Data General Corp. v. International Business Machines Corp., 93 F. Supp. 2d 89, 96 (D. Mass. 2000), found that the term "processor means" was not subject to means-plus-function analysis because the claimed function was generic and could be performed by a general-purpose "processor." The patent claimed a method for a computer to resolve unresolved "pointers," data items used in a computer system to "point" to a location in a computer's memory where information to be used is stored. One of the claims recited a "processor means connected to said memory means for providing said memory commands and providing and receiving said data items in response to sequences of instructions of said data items executed by said processor means." Id. The court found that the claimed functions, including "1) providing memory commands, 2) providing and receiving data items which are sequences of instructions and 3) executing those sequences of instructions," were all general-purpose functions. Id. at 97. The court concluded that one skilled in the art would understand a "processor" to encompass a general-purpose structure that could perform all of the general-purpose functions described in the claim. Id.

The "processing means" in the '713 Patent describes a "special purpose computer programmed to perform" more specialized functions than the general functions involved in Data General. The functions recited in the '713 Patent claim for "processing means" include processing barcodes on patient wristbands and on labels for medications, goods, services, or procedures; reading patient history and physician instruction files; determining, based on these files, whether medications, goods, services, or procedures identified by the barcodes are permitted to be delivered to the particular patient identified by the wristband barcode; and determining the time for delivery of medications, goods, services, or procedures to a particular patient according to the time of last delivery as listed in the patient history file and according to the time interval prescribed in the physician instruction file. Brown has presented no evidence that these functions may be accomplished by the general-purpose structure that "processing" or "processor" would connote to a person of ordinary skill in the art. "Portable processing means" is subject to means-plus-function analysis.

Applying the means-plus-function analysis first requires identifying the functions claimed for the disputed term. "Portable processing means" performs the functions of:

- processing the barcodes read by the "barcode reading means"; determining, by referencing the patient history file and the physician instruction file in the "portable memory means," whether the medications, goods, services or procedures identified by barcode are permitted to be delivered to the patient identified by barcode; reaching this determination by calculating the time elapsed since last delivery by referencing the patient history file and comparing this time to the prescribed time interval in the physician instruction file; displaying this determination through the "portable display means"; and updating the patient history file if the identified goods, services or procedures were delivered to the identified patient.

The defendants assert, and Brown does not dispute, that the specification does not identify a structure associated with
"portable processing means." The specification contains a description of the functions that the "portable computer means" is to perform but discloses no particular program or algorithm to perform these functions. The specification states:

The invention will permit a portable computer means to automatically record the time, date, patient identification code, and medications, goods, services or procedures delivered.

... [When a barcode is scanned,] [t]he portable computer means will check its internal file of physician's instructions to verify that the identified medication, goods, service or procedure has been prescribed for the identified patient. If the medication and dosage, goods, service or procedure is correct the portable computer means will check the transaction file to [sic] for the last recorded delivery of the medication, goods, service or procedure. The portable computer means will calculate the time interval since the last recorded delivery of the medication, goods, service or procedure with the time interval prescribed in the physician instruction file. If the interval is correct the portable computer means will display the message "verified." If an error occurs in this process, an appropriate error message will be displayed by the portable computer means.

(Docket Entry No. 132, col. 2 ll. 65-68, col. 3 ll. 13-36).

In Finisar Corp. v. DirecTV Group, Inc., 523 F.3d 1323, 1340-41 (Fed. Cir. 2008), cert. denied, ___ U.S. ___, 129 S. Ct. 754, 172 L. Ed. 2d 727 (2008), the Federal Circuit recently reaffirmed that language in the specification that describes the function for a program or algorithm recited in the claim does not disclose sufficient structure for that program or algorithm. The claim at issue involved "an information database" and "database editing means," coupled to said one or more computer memory devices, for generating a hierarchically arranged set of indices for referencing data in said information database, including distinct indices for referencing distinct portions thereof, and for embedding said indices in said information database." Id. at 1340. The patent specification described the "database editing means" as "software . . . (executed by CPU . . . ) [that] generates a hierarchical set of indices referencing all the data in the information database . . . and embeds those indices in the information database." Id. The specification also described an alternate embodiment in which "a block of packet ID values are assigned to an off-line information provider, which then organizes them into a database." Id. The Federal Circuit affirmed the district court's conclusion that these descriptions in the specification provided "nothing more than a restatement of the function, as recited in the claim" and did not provide an "algorithm or description of structure corresponding to the claimed function." Id. The Federal Circuit concluded that although a patentee may express an algorithm "in any understandable terms including as a mathematical formula, in prose, or as a flow chart, or in any other manner that provides sufficient structure," the descriptions in the specification did "not even meet the minimal disclosure necessary" to supply a structure for "database editing means." Id. (internal citation omitted).

Another recent Federal Circuit case, Aristocrat Technologies Australia PTY Ltd. v. International Game Technology, 521 F.3d 1328 (Fed. Cir. 2008), cert. denied, ___ U.S. ___, 129 S. Ct. 754, 172 L. Ed. 2d 727 (2008), reached a similar result. The claim in Aristocrat recited a "control means" for determining winning combinations in an electronic slot machine. The specification stated that the "control means" could be implemented "on any standard microprocessor base gaming machine by means of appropriate programming," provided an equation that expressed the mathematical result of performing the "control means" function, and presented figures and tables describing possible outcomes of the "control means" function. Id. at 1334-35. The Federal Circuit concluded that these examples "disclosed, at most, pictorial and mathematical ways of describing the claimed function of the game control means," which did not supply sufficient structure to rebut the presumption that a means-plus-function analysis applied. Id. at 1335. The court stressed that it was not sufficient for section 112, ¶6 purposes that the examples in the specification "might enable one of ordinary skill to make and use the invention." Id. at 1336. The relevant inquiry was "whether one of skill in the art would understand the specification itself to disclose a structure, not simply whether that person would be capable of implementing that structure." Id. at 1337; see also Med. Instr. & Diagnostics Corp. v. Elekta AB, 344 F.3d 1205, 1212 (Fed. Cir. 2003) ("The correct inquiry is to look at the disclosure of the patent and determine if one of skill in the art would have understood that disclosure to encompass software" with sufficient structure to perform the recited function, "not simply whether one of skill in the art would have been able to write such a software program.").

In the '713 Patent, the specification describes the same functions for "processing means" recited in the claim but does not disclose the structure of any specific program or algorithm that would perform these functions. Although a person of skill in
the art of "processing means" in possession of the specification might be able to write a program that would enable the "processing means" to perform the functions recited, this is not the relevant inquiry. The specification does not disclose the programming structure that would allow the "processing means" to perform the recited functions. "[A] person of ordinary skill in the art would not recognize the patent as disclosing any algorithm at all." Aristocrat, 521 F.3d at 1337-38. Brown has not argued that the specification provides such structure. The "713 Patent does not disclose a structure for "portable processing means."

1. "Portable terminal" (Claims 1, 2, 10, 11, 12)

The key issue is whether this term is unambiguous and needs no construction, as Broadcom contends, or whether it should be construed to require that the terminal is "designed to be carried by or on a person," as Agere proposes. The limitation that Agere propounds is derived from Webster's II New College Dictionary and certain embodiments in the specification. The Webster's definition cited by Agere, however, does not include any reference to how or by whom the terminal should be carried. WEBSTER'S II NEW COLLEGE DICTIONARY 860 (1999) (defining "portable" as "easily carried or moved"). Furthermore, Agere's own expert, Dr. Goodman, does not support its proposed limitation, testifying in his report that one of ordinary skill in the art would understand the term "portable terminal" to mean "a terminal that is easily carried or moved." (Goodman Rep. P 65.) In addition, although the specifications describe "hand-held" devices ("705 patent, col. 2, ll. 22-26, col. 7, ll. 31-36, Fig. 25), Agere's proposed limitation would violate the canon of claim construction that claim language is not limited to the embodiments described in the specification. See Teleflex, 299 F.3d at 1328; Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) (cautioning against limitation of claimed invention to preferred or specific embodiments or examples). The Court agrees with Broadcom's expert, Dr. Acampora, who testified that the term does not have a technical definition but does have a plain and ordinary meaning that is obvious to both persons skilled in the art and laypersons alike. (Acampora Rep. at 39.) As the Court finds no basis to limit this term's obvious, plain, and ordinary meaning, the Court holds that the term "portable terminal" does not require construction.

18 For discussion regarding the definition of "portable" in a similar context, see infra Part II.E.5.

B. "portal"

The term "portal appears in claim 7 of the '704 patent: "A media asset management system comprising: a portal comprising: a user account . . . a virtual media asset library . . . and a plurality of media player devices." The Abstract describes the portal as shown below:

A portal is provided comprising at least one server computer. The portal executes a media library database server application that manages access [to] a master library of media assets that can be accessed by users via one or more communication networks. A plurality of media player devices communicate with the portal to access media assets for use.

According to the patents' written description, "[t]he portal [] communicates with media player devices [] via communication network [] that may consist of the Internet and/or a combination of wireless communication networks, such as cellular networks, PCS networks, etc." ("704 patent, 3:48-51). The plaintiff's proposed definition is "a computer server or group of servers accessible over the Internet and allowing the storage, stream and download of media assets to a media player." Alternatively, Zapmedia contends that "portal" means "a main screen/page serving as an opening or gateway through which other screens/pages are accessed." Apple assets that the term should be construed as "a site serving as a guide or point of entry to the World Wide Web."
The plaintiff asserts that its proposed construction closely tracks the Abstract and written description, quoted above. The defendant responds that its construction is consistent with the ordinary meaning of the term "portal." E.g., Computer Dictionary Online, at "portal" ("a web site that aims to be an entry point for the World Wide Web"). Apple also contends that its construction is supported by Figure 4 of the '704 patent, which is "[a]n example of a web site home page through which a user interacts with the portal." ('704 patent, Fig. 4 & 3:61-63). Finally, Apple argues that the prosecution history precludes a broad definition of "portal." In distinguishing the Milsted reference to the PTO, the applicants argued, "The communicating, downloading, or distributing media assets as described in Milsted is the purchasing, downloading, and receiving of media assets from a media asset provider, . . . rather than from a portal, to a media player device for utilization by a user." (Dkt. No. 84, Ex. O, at 11).

The court is not persuaded that Apple's narrow construction of "portal" is correct. Dictionary definitions of a claim term are subordinate to the meaning provided by the patent's specification. Phillips, 415 F.3d at 1316. Furthermore, the specification does not limit the portal to communications solely over the World Wide Web. (See '704 patent, 3:29-32 ("The portal 300 may be accessible . . . through one or more web sites and may provide a customizable interface or view to each user, if desired.").) Even if the specification does mention the portal being accessed over the World Wide Web, there is no express reason to limit the scope to the preferred embodiment. See Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 907-08 (Fed. Cir. 2005) (stating that "[c]laims of a patent may only be limited to a preferred embodiment by the express declaration of the patentee"). Finally, the prosecution history distinguishes the Milsted and Reed references, not based upon distribution of media assets to media players, but on bi-directional synchronization:

One function of the present invention is to synchronize the media assets available on the server and the media player devices in a bi-directional manner. . . . Thus, in utilizing a one-way communication, Reed teaches away from the present invention. As amended, independent claims 1 and 25, on the other hand, describe a two-way synchronization between a portal and a media player device. . . . Thus, changes to any of the assets on any media player device are updated to the portal and changes to any of the assets on the portal are updated to all media player devices . . . . Therefore, Milsted alone, nor Milsted in view of Reed do not [anticipate] nor make obvious . . . synchronization between a client and a server application so that the database stores and updates information identifying media assets that a user has licensed user rights.

(Dkt. No. 84, Ex. O, at 11-12) (emphasis added). This functionality of the portal is also described in the specification: "The portal 300 allows for synchronization and replication of a user's licensed assets with each of the user's media player devices 200." ('704 patent, 3:22-24).

As to Zapmedia's proposal, nothing in the specification or the claims limits the communication medium to solely the Internet. (See '704 patent, 3:48-51 ("The portal [] communicates with media player devices [] via communication network [] that may consist of the Internet and/or a combination of wireless communication networks, such as cellular networks, PCS networks, etc.").) Also, as discussed above, the prosecution history explicitly disclaimed unidirectional synchronization. Therefore, the court construes the term "portal" to mean "a computer server or group of servers that stores media assets and transmits and receives media assets to and from media players over a communications network."

The parties have stipulated that this term means "some or all of an item." To the extent that this definition encompasses a whole item, it is inconsistent with the ordinary meaning of the word, and nothing in the patent itself suggests that the applicant meant to assign a meaning other than the customary meaning to the term. Cf. Victronics Corp., 90 F.3d at 1582 (court will respect applicant's use of a term in a manner inconsistent with customary meaning "as long as the special definition of the term is clearly stated in the patent specification or file history").

I construe the term to mean: "a part of any whole."
5. "the portion of the IP data session"

The parties dispute the meaning of "the portion of the IP data session," as used in claim 1. NICE reiterates its contention regarding "data packets" and non-IP communications made above, and also contends that the specification does not support the requirement that "all" IP data be recorded. Witness contends that NICE's "one or more" language is contradicted by the preamble to claim one, which explains that the claimed steps apply "for each IP data session." Further, Witness contends its construction preserves the limitations inherent in the structure of the claim by including, not an amorphous "part," but "the part of the IP data session being recording."

In light of the claim language and specification, the Court construes the disputed term to mean "all the data packets transmitted between the first and second participants during the part of the IP data session being recorded." The term "all," in this context, refers to all of the data packets transmitted during recorded parts of the sessions, not all of the data packets transmitted, whether recorded or not.

3. "portion of the [predefined] bandwidth"

The intrinsic evidence does not support a construction which departs from the ordinary meaning of "portion." As argued by the defendants, the purpose of the invention was to facilitate the transmission of both packet and synchronous data over the TDM bus. See '858 patent, 2:42-45 ("I have realized an alternative approach to the design of TDM-based equipment that supports both synchronous data and packet data and, in addition, provides an efficient substrate for packet handling." (emphasis added); Figs. 3, 5 (depicting the allocation of a part of the TDM bus to the multiple access packet channel). As used in the patent, "portion" means less than all. Accordingly, the court construes the term to mean "the part, but less than all, of the data transfer capacity of the bus that is allotted to packet data and to synchronous data."

10. "at least a part [portion] of the stored information"

Claim 19 provides in pertinent parts:

A distribution method responsive to requests from a user identifying items in a transmission system containing information to be sent from the transmission system to receiving systems at remote locations, the method comprising the steps of:

storing, in the transmission system, information from items in a compressed data form, the information including an identification code and being placed into ordered data blocks;
sending a request, by the user to the transmission system, for at least a part of the stored information to be transmitted to one of the receiving systems at one of the remote location selected by the user;

sending at least a portion of the stored information from the transmission system to the receiving system at the selected remote location.

The Court finds as follows:

The phrases "portion of the stored information" and "part of the stored information," as used in Claim 19 of the '992 are synonymous. n8

The Court does not find it necessary to further construe these phrases.

--- Footnotes ---
n8 The same terms appear in Claims 2 and 5 of the '275 Patent. Unless otherwise ordered, the Court's construction of these phrases as they appear in Claim 19 of the '992 Patent applies to these phrases as they appear in the '275 Patent.

--- End Footnotes ---

3221

1. "wherein a portion of the patterned second semiconductor film is exposed"

The patent provides relatively little guidance on the meaning of "exposed," which is used in the contested sense only in the claims.

Based on the available intrinsic evidence, however, the court finds that "exposed" means "made subject to etching." The claim language supports the preceding construction: the full clause of claim 3 that contains the disputed language requires "patterning the conductive layer to form source and drain electrodes by using a mask wherein a portion of the patterned second semiconductor film is exposed between said source and drain electrodes." 258 patent at 12:48-51. The following claim element requires "etching the exposed portion of the second semiconductor film." Id. at 12:52-53. The exposed portion is etched.

Moreover, as the parties do not dispute, the portion of the semiconductor film that will be etched depends on the type of etchant used. If a dry etchant is used to remove the semiconductor film, only the area not covered by the mask will be removed, regardless of whether the conductive layer was previously overetched using a wet etchant. If a wet etchant is used to remove the semiconductor film, part of the semiconductor film lying underneath the mask will also be removed, regardless of whether the conductive layer was previously etched using a dry etchant. As discussed in more detail below, the claims encompass the use of both wet and dry etchants in performing the patterning step, and also encompass the use of a dry etchant in performing the etching step. Defendants' proposed construction is therefore too narrow.

The specification, to the extent it discusses the patterning step, also supports the court's construction: "[the conductive] layer was patterned, using a third photomask P3. At this time, the . . . amorphous silicon layer was patterned by dry etching without peeling off resist 8." Id. at 7:12. The "resist," which the parties do not dispute is synonymous with the "mask," is present for both the patterning of the conductive material and the subsequent etching of the amorphous silicon. With the mask still present, as discussed above, the material that will be removed (the "exposed" material) in both the patterning and etching steps depends on the type of etchant used.

In sum, the court construes the first disputed phrase to mean "part of the second semiconductor film is made subject to etching."
5. Portions of the First Layer Beneath the Valleys of the Hemisphere Polysilicon Particle Layer

The term "portions of the first layer beneath the valleys of the hemisphere polysilicon particle layer" describes the portions of the first layer that are removed, i.e., the portions of the first layer between the raised, rounded polysilicon particles.

10. "position information" (Claims 1, 3, 6-9, 11)

This phrase appears in claims 1, 3, 6-9, and 11. See Tang Decl., Ex. A at 12:34-49; 12:53-63; 13:6-22; 14:4-14; Ex. D at 2 (amended Claims 1, 3). In each claim, the phrase appears differently, as 'position information,' 'positioning information,' or 'positioning data.' The Joint Claim Construction Statement states that the parties have agreed that these terms have the same meaning, and that the court's construction of 'position information' will dictate construction of the remaining two phrases. Trimble contends that the above phrases -- represented by the term "position information" -- should be construed to mean "data used in determining location." Defendants, by contrast, contend that the phrase should be construed to mean "geographic positions computed by a GPS receiver."

Plaintiff's arguments are largely based on the specification language in the patent that notes that the data used by the claimed system in pinpointing precise geographic location is not all GPS data. The specification states, for example, that correction information from "FM subcarrier broadcasts or from other sources" may be used to more precisely pinpoint geographic location, and furthermore states that the guidance system described in the '383 patent may be "supplemented with non-satellite based guidance systems and methodologies. See Tang Decl., Ex. A at 5:32-40; 4:6-11(noting that supplemental systems could include "inertial navigation systems, distance and gyro compass and/or other heading indicator systems, laser range finding and bearing indicator systems, etc."). According to plaintiff, this means that "position data" must be construed in a fashion that is not limited to "GPS" references.

Plaintiff is correct, to an extent. The specification does, indeed, contemplate that information aside from GPS satellite information may be used to determine the precise geographical location of the vehicle at any given time. See, e.g., id. For instance, as cited above, the specification notes that the data provided via the GPS antenna mounted in the vehicle may come "from one of a variety of sources," including non-GPS sources. See id. at 5:30-43.

However, the specification also goes on to state that all information -- both GPS satellite data, and the "differential GPS correction information" that comes from non-GPS sources via GPS antenna -- will be transmitted through the "GPS receiver." See id. at 40-43 ("GPS receiver 60 uses the GPS data provided through antenna 44 from the GPS satellites 46 and the differential GPS information received through antenna 48 to compute position information for sprayer rig 30") (emphasis added). Accordingly, defendants' construction, which states that position information means geographic positions computed by a "GPS receiver," is not only consistent with the specification, but it does not, as plaintiffs argue, limit position information to GPS sources only; it specifically takes "differential GPS correction information," which may be based on non-GPS sources, into account. Plaintiffs' proposed construction, by contrast, ignores the fact that all data will be transmitted through a GPS receiver specifically.
Moreover, plaintiff's argument that, pursuant to the specification's language, non-GPS "systems and methodologies" may also provide "position information" -- therefore prohibiting a construction that is tied to the GPS system -- is not plausible. Plaintiff relies on the specification's statement that "the form line following guidance system described herein may be supplemented with non-satellite based guidance systems and methodologies, such as inertial navigation systems, distance and gyro compass and/ or other heading indicator systems, etc." See Tang Decl., Ex. A at 4:6-11. However, the key word in this specification is that the guidance system actually described by the patent may be "supplemented" with non-satellite based guidance systems. This is not the same as saying that the guidance system described by the patent includes non-satellite based guidance systems. Indeed, following the very sentence that plaintiff relies on, the specification states that "the use of such systems to assist in terrestrial navigation is well known in the art and will not be described further so as not to unnecessarily obscure the present invention." See id. at 4:11-14. This statement belies plaintiff's argument here, since it expressly states that the other non-GPS systems that plaintiff points out are distinct, and different from, the present GPS-based system described by the patent's claims. As such, the term "position information" -- as used in the claims -- should not be construed to include non-GPS based systems entirely, even though it should be construed to include "differential GPS correction information" that stems in part from non-GPS satellite sources -- as long as those Sources are transmitted through a "GPS receiver."

In sum, and for all the above reasons, the court adopts defendants' proposed construction. As such, "position information" is construed as: "geographic positions computed by a GPS receiver."

3224

1. Claims 1, 17 & 26 -- "Positional Coordinates"

CIVIX contends that "positional coordinates" are a collection of values sufficient to identify a geographic vicinity. Defendants, on the other hand, argue that this term means "coordinates defining a single reference point within a corresponding geographic vicinity which also operate to determine the corresponding geographic vicinity." I agree with Defendants' definition.

From Defendants' definition of "positional coordinates," as a set of values defining a single location, Defendants argue that this single point or location determines the surrounding geographic vicinity. Defendants emphasize that the positional coordinates work to locate a single point of reference which in turn generates a geographical vicinity. They deny that multiple sets of coordinates work to locate multiple points of reference that in turn represent a vicinity.

The '525 patent's claims, specifications, and prosecution history, support Defendants' construction of "positional coordinates." Although a preferred embodiment cannot be read into a claim as a limitation, I may look to the embodiments and their written descriptions to assist in defining a term, such as "positional coordinates" already in a claim limitation. See Renishaw, 158 F.3d at 1248. A claim must be read in view of the specification of which it is a part. See id. Figure 4A of the patent:

[SEE FIG. 4A IN ORIGINAL]

This depicts a "hierarchical structure of geographical vicinities, according to the invention." (525 patent, Col. 4 lines 21-22). More specifically, Figure 4A shows the positional coordinates, labeled 77, for each geographical vicinity, labeled 75a and 76a. (525 patent, Col. 8 lines 37-38). In describing the embodiment, the patent states that "there are a plurality of discrete geographic vicinities (each set of positional coordinates corresponding to one discrete location within the geographical vicinity)." (525 patent, Col. 3 lines 3-5) (emphasis added). Figure 4A and the specification clearly show that the positional coordinates define a single reference point which operates to determine the corresponding geographic vicinity.

This definition of "positional coordinates" is supported throughout the patent and its prosecution history.

The positional coordinates . . . operate to locate the geographic vicinity. Briefly, the positional coordinates locate one location within the geographic vicinity -- such as the center of the vicinity -- so that items of interest can be determined relative to the positional coordinates and within the geographic vicinity.
Positional coordinates, made up of an undetermined number of values, are used in the '525 patent to produce a single location within a geographic vicinity. Therefore, although positional coordinates can be made up of any number of values, the resulting set of positional coordinates can work only to locate one single point of reference, around which a geographical vicinity is determined.

The prosecution history further shows that the inventors contemplated positional coordinates defining one discrete location within a geographic vicinity. The '525 patent was intended to provide a "virtual kiosk," similar to the actual user station in the '170 patent, but not fixed in location. A user can access a virtual kiosk, in a discrete location, and obtain information about items of interest surrounding this discrete location. A letter from William Semple to co-inventor William Bouve, dated April 1, 1994, describes this limitation:

In effect, instead of requiring the user to physically go to a kiosk to retrieve information for a defined geographic area of the kiosk . . ., you would create an opportunity for the kiosk to go the user . . .

To take this one step further (and this was your idea), you could derive geographically-defined information based on locators other than kiosks, such as street intersections or landmarks. (For example, you could provide data for businesses, events, etc. for an area with 500 yards walking distance of the Washington Monument, or some known location that a tourist might want to visit, but not know what else was in the immediate vicinity).

In order to keep the system consistent, directed, and understandable, it would be my suggestion that the software interface and information derived essentially mimic that available at the physical kiosks themselves. . . . It is important to maintain the essential characteristics of your primary systems so that competitors cannot duplicate or transfer parts of the "Walking Locator" technology without patent, trademark, or copyright infringement.

Whatever you do, the essential characteristics of my proposed computer tele-link would have to remain relevant to the patented functions provided by the kiosks themselves. That is, information would be geographically determined from a defined and identifiable point; information would be accessed by category; and at least some of the data would have to be printed to be read. . .

This letter shows that the inventors contemplated users accessing a single discrete, defined, and identifiable point, around which a geographic vicinity would be defined. Also in the prosecution history are documents proving that the inventors referred to these discrete locations as "virtual kiosks." (CIV 0000263).

CIVIX argues that software disclosed in the '525 patent application expressly discloses a system in which a collection of values with hierarchical layering "are used to identify a unique location and vicinity for each item of interest." (CIVIX brief, p. 34) (emphasis added). CIVIX argues that positional coordinates do not have to be made up of merely a pair of numbers or values. It cites to the declaration of Mr. Oxman for the proposition that, "these positional coordinates are a collection of values that identify a location or a vicinity. Since locations and areas are organized in a collection of related layers in the preferred embodiment, the number of positional coordinates varies depending on the number of layers that must be linked to produce the requested result. This is why there can be no numeric limit on the number of positional coordinate values that identify a location." (Oxman Declaration, P 5) (emphasis added).

CIVIX' contention that a number of values can make up one set of "positional coordinates" in identifying one location, has some support in the software disclosure. However, the software does not support CIVIX' further contention that positional coordinates can define more than one discrete location. Because the software disclosure, Exhibit A to the patent specification, is written in computer-speak (CIV 0000315-0000337), I turn to the declarations submitted by the parties. CIVIX submits the declaration of C. David Dickerson. With regard to the software disclosure, Mr. Dickerson states:

I have looked through the source code for some indication that the maps stored and called by the program are defined by a relationship to a single positional coordinate pair. I see no reference in the code to such a method.

(Dickerson Declaration, P 13). This declaration does not support CIVIX' contention that "positional coordinates" can define
more than a single discrete location. Further, the declarations submitted by Defendants, analyzing the source code, support their conclusion that "positional coordinates" define only one discrete location. (Mavis Declaration, P 11) ("Each area of interest is defined by reference to a single (x,y) coordinate pair representing the center point to which the boundary algorithm is applied which sets the boundaries of the area of interest."). Therefore, I conclude that "positional coordinates," as used in the '525 patent, means a set of coordinates defining a single reference point within a corresponding geographic vicinity which operates to determine the corresponding geographic vicinity.

3225

13. positive optical anisotropy ('412 patent)

CEA's proposed construction is "a characteristic of a birefringent material wherein the extraordinary index exceeds an ordinary index."

Samsung's proposed construction is "a characteristic of a birefringent material wherein the values of two of the three principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) is greater than the other two."

The specification supports Samsung's proposed construction 41 and is adopted by the court: "a characteristic of a birefringent material wherein the values of two of the three principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) is greater than the other two."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

41 See '412 patent, 4:61-64 ("This nematic liquid crystal layer is also a positive optical anisotropy uniaxial medium, the extraordinary index NeCi of said medium exceeding its ordinary index NoCl.").

3226

A Positive Supply Voltage

The Court adopts Motorola's construction and construes "a positive supply voltage" as "a voltage at an external source to the gate drive circuits that has a positive potential relative to a reference potential." Motorola's construction is consistent with the appropriate dictionary definition and is supported by the specification. Moreover, the Court finds that Motorola's construction more clearly defines the term's boundaries than ST's proposal.

3227

"Potential First Parties"

Defendants argue that the term "first parties" should be understood as referring to a caller or a person who is making a telephone call. (Doc. No. 240, p. 4). Defendants also assert that the term "potential," which allegedly modifies the term "first parties" in every claim, means the "first parties" are not actual callers, i.e., a person who has made or is making a call, but rather a person who may make a telephone call. (Id.). 800 Adept contends that "potential first parties" should be construed as "those parties who can be assigned latitude and longitude coordinates and can also be assigned to a destination according to the second parties' criteria." (Doc. No. 268, p. 9).

Each of the independent claims of these two patents provides the context in which to construe "first parties." The preambles of claims 1, 9, 17, 29 and 41 of the '111 Reissue all recite "a telephone call from a first party who has an originating
telephone number," and the preamble of claim 1 of the '689 Patent recites "a telephone call from a first party who dials one of an 800-type, 900-type or other special access code telephone number." This is not to say that the preambles act as a limitation of the claims, but such language places the claim term in a context that is absent from the rest of the claim. Thus, the claimed "first parties" are colloquially "callers" or "individuals who place telephone calls."

It is also clear from the specification that the term "first parties" must refer to callers. The written description describes "a system for automatic direct routing of telephone calls from customers" ('111 Reissue, col. 1, ll. 19-20) designed to reduce the amount of computer interaction by "causing the call to be direct-routed" (id. at col. 2, l. 7). It also states that a prior art patent "requires that the caller dial from a 'touch-tone' phone." (Id. at col 2, ll. 19-20). Under the heading "Summary of the Invention," the patent discloses that the "primary object of the present invention is to provide a reliable and cost-effective manner of directly connecting callers interested in an advertiser's product. . . ." (Id. at col. 3, ll. 10-12). The abstracts and specifications repeatedly and consistently refer to "calls" and "callers" but fail even once to use the term "first parties" except in the claims. (See id. passim). Put simply, the terms call and caller are used throughout both patent specifications, and "first parties" is not. (See id. at face page).

Defendants offer two definitions for "potential" from internet dictionaries which do not differ substantively from the definition found in the bound dictionaries available to the Court. (See Doc. No. 240, p. 4 n.6). Defendants' definitions are "existing in possibility" and "capable of development into actuality." (See id.). Plaintiffs do not offer any dictionary definition for the term. Webster's II New Riverside University Dictionary defines potential as "1. Capable of being but not yet in existence. 2. Denoting possibility, capability, or power." WEBSTER'S II NEW RIVERSIDE UNIVERSITY DICTIONARY 920 (1994). The Court of Appeals for the Federal Circuit permits the use of general purpose dictionaries in cases that involve commonly understood words having widely accepted meanings. Phillips, 415 F.3d at 1314. Such is the case here.

The ordinary meaning of "potential" is also consistent with the use of the term in the specification. The term "potential" is found only within the abstract and claims of each patent. The abstracts are identical:

A method and system for direct routing of telephone calls made by a caller originating from within specific calling areas to one of a plurality of locations of a second party according to certain criteria established by the second party. This routing is accomplished based on the assignment of latitude and longitude coordinates to a potential caller's location. Once these coordinates are assigned to each of the potential callers, the second party's criteria is applied to assign the potential caller to a second party. Such criteria could be existence within a previously-defined geographic area, a custom defined geographic area, or through calculations such as the shortest distance between coordinate points. Once all such assignments have been made, a database is assembled to be used by a long distance carrier for direct routing of telephone calls from callers to an assigned second party.

(Id. at face page, emphasis added). Such disclosure does not add much of substance other than indicating the term is used as one would expect, and that the written description of the patents does not "reveal a special definition . . . that differs from the meaning [that the term] would otherwise possess." Phillips, 415 F.3d at 1316.

Here, the adjective, "potential," modifies the meaning of the noun "parties" which has already been modified by the adjective "first." That is, the meaning of "potential first parties" is a specialized meaning of the broader term "first parties." As discussed above, the term "first parties" refers to a universe of callers or individuals who place telephone calls, and the adjective "potential" narrows that universe of individuals to those having the capability of placing a telephone call but who have not done so. Consequently, the Court construes the term "potential first parties" to mean "individuals who can place a telephone call but have not yet done so."

**3228**

B. The '366 Patent - "Power"

After considering the parties' proposed constructions, the Magistrate Judge recommended that the term "power," as used in Claim 7 of the '366 patent, should be construed to mean "voltage." (D.I. 133 at 13-15.) For the reasons set forth below, the Court will overrule the recommended construction and will adopt Defendant's proposed construction. Specifically, for
purposes of the Motion for Preliminary Injunction, the Court will construe the term "power" to mean "the rate at which energy is transferred, calculated by multiplying electric current times voltage."

Claim 7 of the '366 patent recites, in part:

7. A method for facilitating power shutdown protocol of a computing device, comprising the steps of:
   using a first cell as a primary portable power supply. . .
   using a secondary cell as a backup portable power supply. . . and
   using a boost circuit to increase the power of the secondary cell. . .

   wherein the secondary cell supplies power to the computing device upon a voltage of the first cell dropping below a predetermined value.

'366 patent at col. 11, ll. 42-53 (emphasis added).

With respect to Claim 7, the dispute between the parties primarily centers around whether "power" should be interpreted according to its ordinary, "textbook" definition or whether it should be interpreted according to a "colloquial" definition, proposed by Plaintiff. It is undisputed that, among those of ordinary skill in the art, the well-established, textbook definition of "power" is "voltage multiplied by current." (D.I. 133 at 14-15.) Plaintiff contends, however, that "power" also has a second, colloquial definition, which is simply "voltage." (D.I. 171 at 6.) This colloquial definition is contrary to the textbook definition, because it does not account for current. More precisely, the colloquial definition assumes that current is constant. Plaintiff contends that a person of ordinary skill in the art, upon reading the specification of the '366 patent, would understand that the patent embraces the colloquial definition of "power." Specifically, Plaintiff contends that: 1) the specification does not explicitly adopt the textbook definition of "power;" 2) the specification uses the terms "power" and "voltage" loosely and interchangeably when referring to the output of a battery; and 3) the preferred embodiment described in the specification describes boosting the power of a secondary battery only by boosting its voltage, thus implying that current is constant.

The Court also does not agree with Plaintiff's contention that the patent uses the terms "power" and "voltage" loosely and interchangeably. The specification consistently uses "power" in the context of a "power supply" or "output power." 3 Importantly, the patent does not quantify "power" according to volts, the scientific unit for voltage. Measurements in volts in the patent appear in the context of "voltage." 4 At one point, the specification describes "a 5 volt power supply circuit and a 3 volt power supply circuit," but the same paragraph then clarifies that these circuits provide "a steady 5 volt DC [(direct current)] power" and "a steady 3 volt DC power." 366 patent at col. 7, ll. 19-34 (emphasis added). Thus, even where the specification uses volts in connection with a "power supply circuit," it describes the circuit's power output as a combination of both voltage and current. Additionally, the specification provides an example of a circuit for boosting "power output." Id. at col. 7, ll. 41-55. This circuit "produces an electro-magnetic field current (EMF) at a desired voltage level." Id. (emphasis added). This again fits the textbook definition of "power," which includes both voltage and current. Thus, the usage of "power" and "voltage" throughout the patent supports the conclusion that the patentees intended these terms to have different, though related, meanings.

 Footnotes

3 See, e.g., '366 patent at col. 2, ll. 5-20, 29, 37, 39, 55, 59; col. 9, ll. 14, 38-41; col. 10, ll. 2, 30-31 ('"power supply," "power
Finally, the Court is not persuaded by Plaintiff's argument that the preferred embodiment, which describes increasing the power of a secondary cell only by increasing its voltage, should limit the interpretation of a circuit for increasing "power" in the claims. The preferred embodiment is an illustrative example, and "when claim language is broader than the preferred embodiment, it is well-settled that claims are not to be confined to that embodiment." DSW, Inc. v. Shoe Pavilion, Inc., 537 F.3d 1342, 1348 (Fed. Cir. 2008); see also Acumed LLC v. Stryker Corp., 483 F.3d 800, 807 (Fed. Cir. 2007) ("[In their claims, patentees] could have used the word 'perpendicular,' as they did in discussing their preferred embodiment. Instead, they chose a different term that implies a broader scope.") Moreover, the term "voltage" appears later in the same claim, indicating that the patentees intended the term "power" to have a meaning other than simply "voltage." See Helmsderfer, 527 F.3d at 1381-82 ("different claim terms are presumed to have different meanings").

Accordingly, the Court will overrule the recommended construction and will adopt Defendant's proposed construction.

Specifically, for purposes of the Motion for Preliminary Injunction, the Court will construe the term "power" to mean "the rate at which energy is transferred, calculated by multiplying electric current times voltage."

"Power Conditioning Circuit" in the '067 Patent's Claim 32

Claim 32 of the '067 Patent includes (emphasis added):

- a power conditioning circuit having (i) power input terminals connected with the AC terminals, and (ii) power output terminals connectable with the lamp terminals; the power conditioning being functional, as long as the lamp terminals are indeed connected with the power output terminals, to properly power the gas discharge lamp; the power conditioning circuit being further characterized by:
  
  (a) including a transistor having a pair of transistor output terminals across which exists a transistor output voltage whose magnitude varies in accordance with a periodic waveform...and

  (b) having a pair of DC terminals between which exists a DC voltage whose absolute magnitude is substantially constant and distinctly higher than the peak absolute magnitude of the AC power line voltage.

M. Mem. 20 asserts that this is framed as a purely functional claim--a "power conditioning circuit...being functional to...properly power the gas discharge lamp..." N. Mem. 14-15 responds by stating, and Motorola does not dispute (see M. Mem. 20-21 and M. Resp. 7-8), that the claim element's subparagraph (a) describes the inverter and its subparagraph (b) describes the rectifier, both of which are included in the circuit.

But the flaw in Nilssen's position is that those elements (well known as they are to persons skilled in the art) do not form the totality of the power conditioning circuit--as the claim element itself states, that circuit includes those elements but is not said to comprise only those elements. Not only is that the normal reading of the word "include" rather than "comprise," 25 as well as the obvious fact that the entire circuit must include more than those two elements, but the matter is made doubly clear by Nilssen's use of "comprises" in the corresponding specification when he says "the power supply also comprises a voltage doubler and rectifier..." (col. 3, lines 29-30).
25 Experience teaches that if there is one word in the English language that patent lawyers know how to use, it is "comprise"—in sharp contrast to the mine run person, who is far more likely to say incorrectly that "Illinois is comprised of 102 counties" than to employ the correct usage: "Illinois comprises 102 counties."

That being the case, it appears that the disclosed structural elements--the inverter and rectifier alone--do not suffice "to perform entirely the recited function" (Sage Prods., 126 F.3d at 1428). And to repeat, as counseled in such cases as Cole, 102 F.3d at 531, "merely because an element does not include the word 'means' does not automatically prevent that element from being construed as a means-plus-function element."

So this Court construes claim 32 of the '067 Patent to be in means-plus-function form, without the factors that might take the claim out of the purview of Paragraph 6. This Court therefore treats that claim in conjunction with the related specification.

GO BACK

VII. "Power conversion circuit"

Next, the Court addresses the term "power conversion circuit" in claim 1 of the '059 patent and claims 1 and 2 of the '925 patent.

A. The Parties' Proposed Constructions

Black & Decker argues that the term "power conversion circuit" means "a circuit that changes electrical energy." Bosch proposes construing the term "power conversion circuit" as: "A plurality of DC/DC converters that convert DC at one voltage to DC at a different voltage, either higher or lower. A converter is distinctly different from a voltage regulator that holds the output voltage to a constant value under varying line or input voltage conditions or output current conditions."

B. The Court's Construction

Bosch makes two general arguments related to its proposed claim construction. First, Bosch argues that the Court should limit the term "power conversion circuit" to "a plurality of DC/DC converters that convert DC at one voltage to DC at a different voltage, either higher or lower." Second, Bosch contends that the Court should expressly exclude a voltage regulator from the scope of the "power conversion circuit" claim term.

The plain language of the claim term, and its surrounding claim language, do not mention any DC/DC converters. Rather, than claiming a DC/DC converter, or a combination of multiple DC/DC converters, the patentee, in claim 1 of the '059 patent and claims 1 and 2 of the '925 patent chose to claim a type of a circuit. In the claims that depend from claim 1 of the '059 patent, however, the patentee further limited the "power conversion circuit." Claim 2 of the '059 patent requires that the "power conversion circuit" include a "first converter circuit for receiving the second DC output voltage from the removable DC power supply and generating a third DC output voltage having a magnitude sufficient to power the radio." Also, claim 3 depends from claim 2 and requires that the "power conversion circuit" further include a "second converter circuit for receiving the first DC output voltage from the AC powered DC power supply and generating a fourth DC output voltage that is suitable for charging the removable DC power supply." Further, claims 4 and 5 both depend from claim 3 and further limit whether each respective conversion circuit includes an "up-converter" or a "down-converter." Accordingly, the Court presumes that claim 1 is broader than its dependent claims and does not contain the dependent limitations. See RF Delaware, Inc. v. Pacific Keystone Techs., Inc., 326 F.3d 1255, 1263 (Fed. Cir. 2003).

Bosch relies on the preferred embodiment described in the specification for its proposed construction. Bosch, however, does not point to any specific language in the specification requiring that the "power conversion circuit" contain the limitations of the preferred embodiment. Nor does Bosch point to any express disclaimer or disavowal of "power conversion circuits" other than those taught in the preferred embodiment. The Court declines to incorporate limitations from the preferred embodiment into the plain claim language. See Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1370 (Fed. Cir. 2003)
The prosecution history of the '059 patent also discusses the "power conversion circuit" limitation. In overcoming the Examiner's rejection, Domes specifically explained the importance of "the provision of circuitry in the subject invention that allows the portable radio to operate off of various types of conventional, portable tool battery packs, regardless of output voltage." (R. 53-1; FH059086.) After explaining that claim 27 (in the application) provides for a "power conversion circuit," Domes proceeded to make clear that "in the preferred embodiment, the power conversion circuit is implemented by a pair of DC/DC converters, one which adjusts, up or down, the output voltage from the AC powered DC power supply to the removable DC power supply, and the second that adjusts, up or down, the voltage supplied from the DC removable power supply to the radio." (Id.) Accordingly, Domes made it clear in the public record that the pair of DC/DC converters was merely the preferred embodiment of the claimed "power conversion circuit."

Bosch contends that Domes acquiesced to a construction of the "power conversion circuit" limited to a pair of DC/DC converters during the application process. In his reasons for allowance, the Examiner stated that "no combination AC powered radio/battery charger that containing [sic] a removable DC power supply with DC to DC converters producing various higher and lower voltage outputs than the DC output produced by the fixed-in-enclosure AC powered DC output was neither found, suggested, nor made evident by the prior art." (R. 53-1; FH059093.) Bosch contends that this reason for allowance demonstrates that the Examiner limited the construction of the term "power conversion circuit" to a pair of DC/DC converters. According to Bosch, because Domes failed to object to this reason for allowance, he acquiesced to this construction. Bosch's argument fails. The Examiner's statement, followed by Domes' silence, does not reflect a clear disavowal of any "power conversion circuit" other than a pair of DC/DC converters sufficient to rebut the presumption that a "power conversion circuit" has its plain and ordinary meaning. Aquatex Indus., Inc. v. Techniche Solutions, 419 F.3d 1374, 1381 (Fed. Cir. 2005.) Earlier in the prosecution history, Domes plainly identified pair a DC/DC converters as merely the preferred embodiment, and not a limitation to the claimed "power conversion circuit." (Id. at FH059087.) In the Examiner's reasons for allowance, the examiner noted that the Chen reference did not disclose "converter circuits" without specifying that those "converter circuits" had to be a pair of DC/DC converters. (Id. at FH059093.) Therefore, the Examiner was looking in the prior art for structures other than DC/DC converters that constituted the claimed "power conversion circuit." Further, the Examiner did not identify any prior art reference as disclosing a "power conversion circuit" other than a pair of DC/DC converters, such that Domes' claims were only patentable because they required DC/DC converters. Accordingly, the Examiner's reasons for allowance did not specifically limit a "power conversion circuit" to a pair of DC/DC converters.

In light of the ambiguity in the Examiner's statement as well as Domes' previous prosecution history statement that the pair of DC/DC converters was merely a preferred embodiment, Domes' failure to respond to the Examiner's reasons for allowance does not amount to acquiescence to the narrower construction proposed by Bosch. Congress amended the patent rules, on September 8, 2000, deleting the sentence that previously stated: "Failure to file such a [statement in response to the Examiner's reasons for allowance] does not give rise to any implication that the applicant or patent owner agrees with or acquiesces in the reasoning of the examiner." 37 C.F.R. § 1.104; 65 Fed. Reg. 54671 (2000). Congress did not, however, include a requirement that an applicant must respond to an Examiner's reasons for allowance in order to avoid acquiescing to those reasons. Rather, the plain language of those rules does not address the issue of acquiescence to such reasons for allowance. Bosch relies on the legislative history of Congress's amendment to the rules, and the associated comments. The comments, however, provide that Congress's "revision of § 1.104(e) does not provide any new policy, but rather tracks the state of the case law established in the decisions of the Supreme Court and the Federal Circuit." 37 CFR § 1.104(e), comments; 65 Fed. Reg. 54633 (2000). Bosch does not point to any case law where the court found that an applicant acquiesced to a narrow limitation for a claim by failing to respond to an Examiner's reasons for allowance, when the reasons for allowance did not amount to a clear disclaimer of claim scope. Accordingly, while certain circumstances may require the Court to find that an applicant acquiesced to a narrow construction of a claim term set forth in the Examiner's reasons of allowance, the circumstances here, as discussed above, do not require or support such a finding. n8

n8 In particular, because claims depending from issued claim 1 contain limitations on the claimed "power conversion circuit," the Court presumes that those limitations are not incorporated into claim 1. Although a party may overcome that presumption by showing that the applicant disclaimed subject matter, Fantasy Sports Props., Inc. v. Sportstline. Com, Inc., 287 F.3d 1108, 1115 (Fed. Cir. 2002), Bosch has failed to show that Domes ever disclaimed "power conversion circuits" other than a pair of DC/DC converters. Also, as discussed, earlier in the prosecution history, Domes plainly set forth that the
The Court next addresses Bosch's proposal that a "voltage regulator" is not within the scope of the claimed "power conversion circuit." The language of the claims do not discuss a "voltage regulator," nor does Bosch point to any portion of the intrinsic record that addresses such a device. Bosch fails to prove that the applicant ever expressly disclaimed or disavowed a "voltage regulator" as being a "power conversion circuit." Accordingly, the Court does not have to address this issue in construing the claims as a matter of law. Rather, whether or not a "voltage regulator" falls within the scope of the claimed "power conversion circuit," as construed by the Court, is a question of fact for the jury to decide. Cybor, 138 F.3d at 1454 (the comparison of the construed claims to the accused device is a question of fact).

Accordingly, the Court construes the term "power conversion circuit" as a "circuit that changes electrical energy." This construction closely tracks the plain language of the claim and is supported by the intrinsic record, specifically the language of other claims, such as the dependent claims, and Domes' statements in the prosecution history identifying the importance of a "power conversion circuit" and identifying a pair of DC/DC converters as the preferred embodiment. n9

n9 Bosch attacks Black & Decker's proposed construction as having less detail than the claim term. The Court notes that the detail that Bosch contends is absent from this construction is provided by the language of the claims following the "power conversion circuit" term.
After a trial, the jury found that Bosch had infringed claims 1, 2, 6, 7, and 10 of the '059 patent and claim 1 of the '925 patent, and that those same claims were not invalid, but that claims 2 and 10 of the '925 patent were invalid as anticipated and obvious. Injunction Order; B&D JMOL. Based on the jury's finding that Bosch willfully infringed the patents, the district court enhanced damages by fifty percent. Black & Decker, No. 04-CV-7955, 2006 U.S. Dist. LEXIS 84969 (N.D. Ill. Nov. 20, 2006). The district court denied Bosch's inequitable conduct claim after a bench trial. Black & Decker, No. 04-CV-7955, 2006 U.S. Dist. LEXIS 78062 (N.D. Ill. Oct. 24, 2006) ("Inequitable Conduct").

The district court issued an injunction directed at the Bosch radios considered at trial, but specifically exempted a newer model radio that the court had excluded from trial by granting a motion in limine. Injunction Order. Considering post-trial motions, the district court denied Bosch's motions for JMOL and for a new trial that it did not infringe B&D's patents, willfully or otherwise. Black & Decker, No. 04-CV-7955, 2006 U.S. Dist. LEXIS 92882 (N.D. Ill. Dec. 22, 2006; 2007 U.S. Dist. LEXIS 2714, Jan. 12, 2007). Finally, the district court granted B&D's motion for JMOL that claims 2 and 10 of the '925 patent were not invalid as anticipated or obvious in light of the asserted prior art. B&D JMOL. This appeal and cross-appeal followed. We have jurisdiction pursuant to 28 U.S.C. 1295(a).

DISCUSSION

I

On appeal, Bosch challenges the district court's construction of "power conversion circuit," which the district court construed as a "circuit that changes electrical energy." Bosch contends that the proper construction should require a plurality of DC to DC ("DC/DC") converters, which can convert an input DC voltage to a different output DC voltage, either higher or lower. It also asserts error in the court's refusal to construe "regardless" as used in the claims.

B&D claims that, by failing to object to the claim construction jury instructions and failing to argue claim construction in its motion for JMOL, Bosch has waived the ability to challenge those constructions. It also disputes the correct construction for "power conversion circuit," asserting that the district court correctly construed the broad claim language by refusing to limit it to the preferred embodiment as captured by the dependent claims.

As an initial matter, we agree with Bosch that the Seventh Circuit futility exception controls the wavier issue here. Because Bosch proposed and argued for its construction at the Markman hearing, "[o]bjection under Rule 51 was not required to preserve the right to appeal the Markman ruling." Cardiac Pacemakers, Inc. v. St. Jude Medical, Inc., 381 F.3d 1371, 1381 (Fed. Cir. 2004) (considering the applicable rule under Seventh Circuit precedent).

The district court based its construction of "power conversion circuit" in large part on the principle of claim differentiation, because dependent claims require a power conversion circuit ("PCC") that produces a voltage different from the power supply or battery. Black & Decker, 389 F. Supp. 2d 1010, 1015-16 (N.D. Ill. 2005). That doctrine, however, cannot serve as a basis to give a patent scope beyond the invention it discloses. See Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000). Any presumption arising here from the dependent claims fails to override the proper construction of "power conversion circuit" provided by the claims, the specification, and the prosecution history. Accordingly, as discussed below, the district court erred by construing "power conversion circuit" without sufficient consideration of factors beyond those three words and the dependent claims.

A

The surrounding claim language provides an important consideration for construing a particular term within a claim. Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005). To provide for functionality with a variety of battery voltages, the patents claim a "power conversion circuit . . . to enable [the battery] to power [the] radio and be charged by [the power supply], regardless of the [battery voltage]." E.g., '059 patent, col.5 ll.38-45. Claim 1 of the '925 patent requires only that the PCC enables the battery to power the radio regardless of battery voltage. '925 patent, col.5 ll.46-50. In either case, the surrounding claim language requires that the PCC operates to enable certain functionality in the combination radio.

To understand this requirement, we must consider three possibilities: (1) the battery provides approximately the same voltage as the power supply, (2) the battery provides a higher voltage than the power supply, and (3) the battery provides a lower voltage than the power supply. The claims contemplate all of these three conditions. E.g., '059 patent, col.5 ll.32-37. Under all conditions, we assume that the power supply can power the radio directly. With a battery of the same voltage as
the power supply, either the battery or the power supply may power the radio; similarly, the power supply can charge the battery directly. With a battery of a higher voltage than the power supply, the PCC must increase the voltage from the power supply in order to charge the battery, and reduce the voltage from the battery in order to power the radio from the battery. Conversely, for a battery of a lower voltage than the power supply, the PCC must increase the voltage from the battery in order to power the radio, and reduce the voltage from the power supply in order to charge the battery appropriately.

Combining all of these possibilities, as the claims require, a PCC that enables the desired functionality must contain circuitry to both increase and reduce voltages. Accordingly, a proper construction for "power conversion circuit" must include the requirement that the circuit can both increase and reduce voltages.

B
Beyond the language of the claims, the specification also provides meaningful guidance when construing claim terms. Phillips, 415 F.3d at 1317. The claim, however, should contain a linguistic "hook," or some point to tie it to a concept from the specification. NTP, Inc. v. Research In Motion, Ltd., 418 F.3d 1282, 1310 (Fed. Cir. 2005) (quoting Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998)). Here, the claim does exactly that by using the term "conversion."

While the specification of the patents here does not use the exact phrase "power conversion circuit," it does touch on conversion a limited number of times. First, the Summary of the Invention states:

An optional variable voltage feature permits use of battery packs lower or higher than 12 volts to be used by the radio. The variable voltage feature includes a socket having a plurality of contacts mating with an adapter, matching predetermined requirements of a DC source battery pack, and a double pole single throw on/off switch controlling a DC/DC power source converter for supplying power to said radio.

'059 patent, col.2 ll.57-64 (emphasis added). Then, describing the preferred embodiment, it states:

In an alternate embodiment, additional circuitry is provided to permit the use of battery packs lower or higher than 12 volts to be used in radio 1. In this embodiment, socket 45 is replaced with socket 70 which now has six contacts mating with adapter 61, which match the requirements of a particular battery pack 60. The on/off switch is now upgraded to a double pole single throw variety for controlling output DC/DC converter 68 for battery operation of radio 1. This extra pair of contacts eliminate the "standby" losses of converter 68 when radio 1 is turned off.

Charging DC/DC converter 69 is selected via relay 70 when the charger is turned on. Although electromagnetic relay 70 is shown, a solid state relay can be used instead. If battery pack 60 has a voltage rating higher than 12 volts (e.g. 18 volts), the output converter 68 is a step down type reducing the battery voltage to a nominal 12 volts while charge converter 69 is a step up converting a nominal 12 volts from the charger to a nominal 18 volts at the battery. If the battery voltage were lower than 12 volts (e.g. 9.6 volts), the output converter 68 is a step up type while the charging converter 69 is a step down type. Diodes 56 and 67 are used for power steering while diodes 66 and 65 are used for DC/DC converter isolation.

Id. at col.4 l.55 to col.5 l.10 (emphases added). The specification does not elsewhere use a form of "convert" in the context of permitting various voltage batteries. Both portions of the specification cited above describe a circuit that adjusts voltage using a DC/DC converter. In the first example, from the Summary of the Invention, the patent describes a circuit that adjusts the power of the battery to allow it to power the radio. In the second example, from the Detailed Description, the patent describes a circuit that both raises and lowers voltage, to allow the battery to power the radio and to allow the power supply to charge the battery.

B&D argues that only the preferred embodiment contains a DC/DC converter and that we should not limit construction of the "power conversion circuit" to such a device. But we can find nothing in the patent that discloses a PCC other than the one shown in the preferred embodiment. Indeed, at oral argument, counsel for B&D admitted that Figure 6 of the patents, illustrating a more general embodiment, does not contain a power conversion circuit. Oral Arg. at 20:58-21:02, available at: http://www.cafc.uscourts.gov/oralarguments/mp3/2007-1243.mp3 ("[I]t's not present in [figure] six. There's no conversion circuit in six."). The specification consistently describes a circuit that has the ability to change voltages using a DC/DC converter. For that reason, we conclude that the specification requires that a "power conversion circuit" includes a DC/DC converter.
While the specification requires a "power conversion circuit" to include a DC/DC converter, it does not limit the PCC to only such a device. Both instances in the specification discussing conversion also describe a circuit containing other electrical components such as switches. Additionally, the specification does not consistently require multiple DC/DC converters in the PCC, as the appellant urges. The first use of "converter," in the Summary of the Invention, describes only a single converter. We therefore reject Bosch's suggestion that the proper construction requires two DC/DC converters.

The prosecution history further confirms the correct construction of "power conversion circuit." Remarking on an amendment submitted to the examiner after an interview, the applicant described the invention as including a "power conversion circuit that adjusts the voltage that is either supplied by the [power supply] to the [battery], or supplied by the [battery] to the radio. In the preferred embodiment, the power conversion circuit is implemented by a pair of DC/DC converters . . . ." '059 patent prosecution, Amendment of Apr. 26, 2001, at 7. This statement confirms that (1) the PCC must adjust voltage up and down and (2) the PCC in the preferred embodiment uses two DC/DC converters. As we have discussed, the surrounding claim language also requires the PCC both increase and reduce voltage. And the fact that the preferred embodiment uses two DC/DC converters comports with the specification's requirement that the PCC includes a DC/DC converter. In sum, the prosecution history confirms the proper construction of "power conversion circuit" provided by the claim language and the specification.

As mentioned, above, the district court's reliance on claim differentiation cannot survive the definition for "power conversion circuit" provided by the claim, the specification, and the prosecution history. Further, our construction—requiring circuitry to increase and reduce voltages and requiring a DC/DC converter—does not make redundant the requirement in dependent claim 2 of the '059 patent that the PCC generates a third voltage sufficient to power the radio. A PCC meeting the limitations of claim 1 may generate a voltage equal to that of the power supply, and thus would not satisfy the "third voltage" requirement of claim 2.

Therefore, because the dependent claims do add additional limitations, and because even if they did not, the presumption of scope applied to the independent claims under the doctrine of claim differentiation here does not overcome the definition from the intrinsic record, we reject the district court's reliance on that doctrine. Giving appropriate consideration to the surrounding claim language, the specification, and the prosecution history, we construe "power conversion circuit" as a circuit that can increase and reduce DC voltages and includes a DC/DC converter.

b. "power factor correction converter means"

Lumileds argues that 35 U.S.C. § 112, P 6 governs the construction of claim 1's "power factor correction converter means" and limits it in scope to the corresponding structure disclosed in the specification: a switchmode buck/boost converter and a commercially available power factor controller. Relume argues that 35 U.S.C. section 112, paragraph 6 does not apply because the language "power factor correction converter" implicitly recites sufficient structure to one of ordinary skill in the art of LED array power supplies.

Claim 1 describes the "power factor correction converter means" as

having an input connected to said output of said rectifier means (32) and an output, said power factor correction converter means (38) being responsive to said rectified d.c. power at said power factor correction converter means input for generating regulated voltage d.c. power at said power factor correction converter means output.

'645, 13:22-28. By associating the word "means" with two functions - power factor correction 8 and voltage regulation - claim 1 uses express means-plus-function language to describe the "power factor correction converter means" element. This creates a presumption that the "power factor correction converter means" is a means-plus-function element governed by 35
U.S.C. section 112, paragraph 6. See Al-Site Corp. v. VSI Int'l, Inc., 174 F.3d 1308, 1318 (Fed. Cir. 1999) ("if the word "means" appears in a claim element in combination with a function, it is presumed to be a means-plus-function element to which 35 U.S.C. § 112, P 6 applies").

8 The '645 patent explains that "power factor (p.f.) is well understood in the electrical engineering community as the ratio of real power to real power plus reactive power." '645,2:10-12. The closer a device's power factor ratio is to one, the better its efficiency. Poor power factor typically results when voltage and current are out of phase, but it can also result from harmonic distortion.

Relume contends that claim 1 overcomes this presumption by reciting sufficient structure. Relume specifically argues that a person of ordinary skill in the art would understand a "power factor correction converter" to be "a switching power supply that has some control feature to improve diode conduction time and increase power factor and reduce distortion." (Pl.'s Consolidated Opp. at 22.) Relume also notes that the claim language recites a location for the "power factor correction converter means" in the invention - between the rectifier and the LED array - and describes it as having an input and an output. (See id.)

The Federal Circuit has determined that a presumption of 35 U.S.C. section 112, paragraph 6 governance "can be rebutted if the evidence intrinsic to the patent and any relevant extrinsic evidence so warrant." Personalized Media v. Int'l Trade Comm'n, 161 F.3d 696, 704 (Fed. Cir. 1998). Throughout the rebuttal inquiry, "the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of 35 U.S.C. § 112, P 6." Id. A claim recites sufficient structure when it elaborates the structure, material, or acts necessary to perform entirely the recited function. See Sage Products, Inc. v. Devon Industries, Inc., 126 F.3d 1420, 1427-28 (Fed. Cir. 1997).

Close scrutiny of the term "power factor correction converter means" reveals that it implicitly elaborates sufficient structure to a person of ordinary skill in the art of power supplies. The structural device claimed is a "converter means," and its functions are "power factor correction" and "being responsive to said rectified d.c. power…for generating regulated voltage d.c. power." 9 Although perhaps unremarkable to the layperson, the word "converter" is a structurally meaningful term-of-art to those of ordinary skill in the art of power supply electronics. According to Marty Brown's Power Supply Cookbook (1994), it connotes the generic structure of a switching power supply: that is, a switch and its controller circuit. 10 See id. at 25-26. The Power Supply Cookbook also makes it clear that power factor correction and voltage regulation are typical functions for a switching power supply to perform. See id. Thus claim 1's association of "converter means" with its specified functions of power factor correction and voltage regulation would reinforce the structural connotations of "converter" to one of ordinary skill in this art.

9 Identification of the "power factor correction" function is less obvious than the voltage regulation function because the qualifier "power factor correction" is not phrased in the "means…for" format that usually specifies a function in claim language. The "means…for" formality, however, need not be present for me to interpret "power factor correction" as an additional functional constraint on the "converter means." See Personalized, 161 F.3d at 705 (finding that the adjective "digital" functionally constrained the word "detector" even without "means…for" language).

10 The Power Supply Cookbook is an authoritative instructional design text for engineers in the field of power supply electronics. The background section of the '645 patent cites it as relevant prior art. Thus I consider it to be evidence intrinsic to the '645 patent and properly considered in my Markman construction of the claim term "converter." See Markman, 52 F.3d at 979.

I conclude that the implicitly sufficient level of structural elaboration in the term "converter" removes the "power factor correction converter means" from its presumed statutory category as a means-plus-function element governed by 35 U.S.C.
section 112, paragraph 6. See Personalized, 161 F.3d at 705 (holding that the term "detector," even though it does not "specifically evoke a particular structure," nevertheless elaborates sufficient structure because it conveys "to one knowledgeable in the art a variety of structures known as 'detectors'"; see also Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531-32 (Fed. Cir. 1996) (affirming a district court's conclusion that the "perforation means" did not fall under 35 U.S.C. section 112, paragraph 6 because the ordinary meaning of the term "perforation" recites sufficient structure to one of ordinary skill in the relevant art). Accordingly, I hold that a person of ordinary skill in the art of LED array power supplies would understand claim 1's "power factor correction converter means" to require the structure of a switching power supply.

3233

Power lines

The Court agrees with Samsung and construes "power lines" in claims 1 and 3 of the '490 patent as "conducting paths that provide electric power." The parties agree that both power lines are conducting paths. See Claim Const. Hr'g Tr. at 62. MEI's proposed construction--"conducting paths, each independently providing electric power"--requires that each and every power line be independently coupled to each circuit. MEI's construction improperly imports limits from the preferred embodiment; while noise reduction is optimized by independent power lines, the patent does not require such independence for each power line.

3234

1. "Power mode setting for setting the emitter module in one of a plurality of different operating power modes"

ITW offers the following construction: "an operating mode that defines the type of waveform voltage signal that is used to cause an ion emission." Pl.'s Revised Proposed Order Regarding Claim Construction at 8. Ion proposes that this element of the claim means: "a setting that can adjust a pulse width of a signal that supplies power." Def.'s Proposed Order re Claim Construction for the '756 patent at 11. The parties' dispute centers around the form of the high voltage signal that, when applied to an emitter, creates ions. This signal has a waveform that determines the mode in which the ions are created. There are different types and widths of waveforms. The parties disagree about how the claim construction should recognize the various manifestations a waveform can take. Each accuses the other of unreasonably selecting a narrower interpretation. Pl's Reply Claim Construction Br. at 25; Def.'s Opp'n Br. re Claim Construction of the '756 patent at 36.

Helpfully, ITW provides an entry from a technical dictionary. The IEEE Standard Dictionary of Electrical and Electronics Terms defines "waveform" as: "[a] manifestation or representation or a visualization of a wave, pulse, or transition." IEEE Standard Dictionary of Electrical and Electronics Terms (6th 1996) (parentheticals omitted). This definition, under Texas Digital, presumably represents the meaning of waveform as understood by one of ordinary skill in the art. It is broad enough to encompass both the type and width of a waveform. Accordingly, the claim shall be construed as "a setting that defines the type or width of the high voltage signal that supplies power.

3235

8. Power regulating signal.

Samsung contends that "power regulating signal" means "a signal that adjusts power to a desired level based on feedback." The dispute here is whether the power must be regulated based on feedback. Samsung argues that "regulating," in the context of the patents, means control, and the specification describes a circuit that maintains control based on feedback. Samsung points to col. 8, 1. 54-col. 9, 1.9, which describes Figure 8 of the patent. O2 argues, however, that nothing in the specification mandates that the regulation be based exclusively on a feedback signal. The court agrees with O2 that Samsung is attempting to read in a feedback limitation from the preferred embodiment. The court construes this term to mean "a signal for controlling power to a load."
On appeal, Clearwater argues that the district court erred in its claim construction when it improperly imported unclaimed functions into the disputed claim limitations. We agree. The district court determined that the "power source" in the body of claim 21 referred to the same power source as in the preamble of the claim; i.e., the "powered by a source" limitation. Clearwater Sys., 596 F. Supp. 2d at 301. Based on the preamble language, the district court concluded that claim 21 required that the "power source" directly power the entire apparatus. Id. Clearwater argued that the "power source" could mean any type of power source anywhere in the apparatus—including a power source found within the apparatus that powers only a portion of the apparatus, such as the coils.

The district court rejected this claim interpretation and concluded that "said power source" must power the entire apparatus. Clearwater Sys., 596 F. Supp. 2d at 301. This ruling is erroneous because it imported an extraneous limitation into the claim.

While the district court was correct that the preamble is limiting because it is necessary to provide context to the claim, see Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999), it was incorrect in concluding that the "power source" must power the entire apparatus. There is no limiting language in the claims, written description, or prosecution history requiring that the "power source" power the entire apparatus. Accordingly, the district court improperly imported an extraneous limitation into the claim. E. I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1998); Comark Commun. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998).

Clearwater's expert, Dr. Horenstein, explained that the "apparatus" of the preamble can refer to either the high or low frequency circuits alone and that the "power source" may power either of these components:

I do not believe that the requisite antecedent power source described in Claim 21 must be derived from a wall socket. This opinion stems, in part, from the fact that the "apparatus" claimed can be understood to refer to the high-frequency circuit alone, or the low-frequency circuit alone, considered as separate entities. Nothing in the patent precludes this understanding. . . .

We agree. The term "apparatus" may be understood as the high frequency circuit, and there is evidence on the record creating a material issue of fact regarding its power source. The Pulse-Pure contains an integrated circuit, the L293B, which is the power source for the high frequency coils, which is in turn powered by a 60 Hz alternating current. This evidence creates a genuine issue of material fact regarding the "power source" limitation. Thus, the district court improperly granted summary judgment based on the "power source" limitation.

1. Power Source (claims 30, 46, 51, 54) 3

3 Although the disputed terms often occur in claims other than those identified by the parties, the Court will limit itself to identifying those claims in which the parties indicate the disputed terms occur. In so doing, the Court notes that it has nevertheless considered each term in the context of the entire patent, including the specification and the unasserted claims.

Plaintiff a combination of galvanic and electrolytic power sources
Defendant generates, rather than consumes, power

The parties agree that the term "power source" means, at a minimum, something that generates, or contributes power to the patch. Plaintiff argues that the term "power source" also includes parts of the patch, which, although they may not individually generate power, are used to regulate the provision of power to the patch. Defendant responds that the term "power source" cannot include portions of the patch that do not directly generate power to the patch.

The Court finds that defendant's proposed definition is the most appropriate construction of the term "power source." The ordinary and customary meaning of the term "power source," means something that is a source of, or generates, power.

Further, this construction of the term "power source" is supported by the claim specification. In particular, the description of Figure 10 in the '014 specification refers to a patch that contains both a battery as well as electrodes, but makes clear that the
pair of electrodes would provide power to the patch in addition to the battery:

Figure 10 represents a schematic diagram of another multiple-cell . . . embodiment of the power source . . . [with] an electrolytic battery or cell that produces one volt. To this is added . . . a galvanic cell [pair of electrodes] that also produces one volt . . . resulting in an overall total system that will theoretically produce a two-volt source . . . .

'014 Patent, col. 7, lines 24-59 (emphasis added). Expanding the meaning of "power source" to include portions of the patch that do not generate power, as plaintiff asserts, would be contrary to the ordinary and customary meaning, as understood by a person of ordinary skill in the art. Therefore, the Court construes the claim term "power source" to mean only parts of the patch that generate power, and parts of the patch that merely regulate the provision of power to the patch, but do not individually generate power, are not part of the "power source."

3238

XIV. "First power source including an electrical cord engageable with an electrical outlet"

The Court next turns to the term "first power source including an electrical cord engageable with an electrical outlet" from claims 9 and 10 of the '925 patent.

A. The Parties' Proposed Constructions

Black & Decker proposes construing the term "first power source including an electrical cord engageable with an electrical outlet" as "a power source having an electric cord." Bosch argues that the term means "an AC/DC power supply that receives an AC voltage through an electrical cord engageable with an electrical output and transforms that AC voltage into a DC output voltage powering said radio receiver means."

B. The Court's Construction

The Court agrees with Black & Decker and construes the term "first power source including an electrical cord engageable with an electrical outlet" as "a power source having an electric cord engageable with an electrical outlet." Bosch's only support for requiring that the first power source be an "AC/DC power supply that receives an AC voltage through an electrical cord" is from the discussion of the preferred embodiment in the specification. Bosch, however, does not point to any language in the specification requiring that the first power source be limited in such a way. The Court rejects Bosch's attempts to improperly limit this term to the embodiment disclosed in the specification. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) ("This court has expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment.") Accordingly, the Court construes this term according to Black & Decker's proposed construction.

3239

a. "power supply"

The term "power supply" appears in two of the asserted claims of the '806 patent. Claims 7 and 18 require a "second dopant-type well connected to a first power supply, and said substrate connected to a second power supply at a negative voltage
with respect to said first power supply . . . " NeoMagic argues that "power supply" means a source connection or line to the integrated circuit that is at a particular voltage. Trident counters that "power supply" requires a complete circuit (with a return path) and cannot consist of a single power supply line.

According to NeoMagic, each of the voltages supplied to the chip, V[DD], V[SS] and V[BB], is a "power supply." NeoMagic contends that the "first power supply" referred to in Claims 7 and 18 is the power supply line V[DD] and the "second power supply" is the power supply line V[BB]. The following illustration, which was submitted by Trident at the Markman trial, helps explain NeoMagic's proposed construction of "power supply." The illustration represents a horizontal cross section of a graphics controller chip with the graphics engine and video memory combined on the same silicon substrate. As before, the N+ and P+ logic gates on the left side of the substrate make up an inverter from a graphics engine. The N+ logic gate and the capacitor on the right side of the substrate are standard DRAM components. V[SS] and V[DD] represent source and drain terminals and the voltage applied to the substrate is referred to as V[BB].

[SEE illustration IN ORIGINAL]

On the other hand, Trident argues that V[DD], V[SS] and V[BB] are "power supply lines" rather than "power supplies." According to Trident's proposed construction of "power supply," the term refers to a source of electrical energy, such as a battery, that requires at least two power supply lines to deliver power in an electrical circuit. Thus, Trident contends that "first power supply" refers to the source that delivers electrical energy via the power supply lines V[DD] and V[SS], and "second power supply" refers to the source that delivers electrical energy via the power supply lines V[SS] and V[BB].

The following illustration, which was submitted by Trident at the Markman trial, helps explain Trident's proposed construction of "power supply." The illustration represents a horizontal cross section of a graphics controller chip with the graphics engine and video memory combined on the same silicon substrate. The N+ and P+ logic gates on the left side of the substrate make up an inverter from a graphics engine. The N+ logic gate and the capacitor on the right side of the substrate are standard DRAM components. V[SS] and V[DD] represent source and drain terminals and the voltage applied to the substrate is referred to as V[BB].

[SEE illustration IN ORIGINAL]

i. NeoMagic's Proposed Construction

According to NeoMagic, the claim language, the specification, the prosecution history and the extrinsic evidence support interpreting "power supply" to mean a source connection or line that may be at a particular voltage level.

NeoMagic looks first to the claim language to support its construction. Claims 7 and 18 of the '806 patent specify "a second power supply at a negative voltage with respect to said first power supply." According to NeoMagic, this claim language demonstrates that "power supply" is a source that is "at" a voltage. In addition, NeoMagic argues that Claims 22 and 23, which depend from Claim 18, support its interpretation of "power supply." Claim 22 states that the "second power supply is at approximately -1.5 volts" and Claim 23 states that the "first power supply is at approximately +3.3 volts."

Next, NeoMagic turns to the specification. Although the term "power supply" is not used in the common specification of the '955 and '806 patents, the term "supply voltage" is used in several instances. For example, the specification describes an integrated circuit process that "uses one of the external supply voltages V[DD] or V[SS] depending on the substrate type) as the voltage to bias the substrate." NeoMagic contends that the references to "supply voltage" in the specification "make it clear that . . . the supply lines V[DD], V[BB], and V[SS] (which indicate voltages supplied to the chip) are examples of 'power supplies' as that term is used in the claims."

NeoMagic also relies on the prosecution history to support its construction of the term "power supply." Specifically, NeoMagic points to several claims in the June 20, 1994 parent application that were later abandoned. For example, Claim 18 of the parent application provided that the "first power supply is at approximately +5 volts, said second power supply at approximately 0 volts and said third power supply at +6 volts." NeoMagic contends that this reference in the prosecution history demonstrates that the inventors used the term "power supply" to mean any one of the source lines or connections to the various source potentials, V[DD], V[SS] and V[BB].
Finally, NeoMagic argues that its construction of "power supply" is consistent with the extrinsic evidence. The McGraw-Hill Dictionary of Electronics and Computer Technology defines "power supply" to mean "a source of electrical energy, such as a battery or power line, employed to furnish the tubes and semiconductor devices of an electronic circuit with the proper electric voltages and currents for their operation." NeoMagic argues that this definition supports its position that a "power supply" is used to provide a voltage potential to the chip. NeoMagic also contends that two prior art patents in the semiconductor field, U.S. Patent Nos. 5,268,597 and 5,030,852, use "power supply" in a manner that is consistent with its construction of the term.

ii. Trident's Proposed Construction

Trident argues that "power supply" means a device which has two or more terminals and which is capable of providing power to a circuit. Trident contends that NeoMagic's proposed construction of "power supply" is contrary to the customary meaning of the term and unsupported by the specification. According to Trident, the use of the term "supply voltage" in the specification does not support NeoMagic's proposed construction of "power supply." Trident argues that all "power supplies" provide "supply voltages" via their power supply lines. Since two power supply lines are required in order for current to flow, Trident contends that one skilled in the art would not refer to a single line connected to a terminal of a power supply to be the power supply itself.

According to Trident, NeoMagic's own expert in electrical engineering, Joseph C. McAlexander, testified during a deposition that "power supply" commonly refers to a complete circuit and not a single power supply line. McAlexander testified that "when you switch something on, you are providing power and providing a source of current and voltage to that one light bulb. And you've got a complete direct circuit, completed circuit. So in that case, I would view that as a single power supply." Trident points to eight patents that use the term "power supply" according to its customary meaning.

Trident also contends that the definition of "power supply" from the McGraw-Hill Dictionary of Electronics and Computer Technology actually supports Trident's construction of the term. According to Trident, the dictionary defines "power supply" as a source of electrical energy, such as a battery or power line, used to furnish the "proper electric voltages and currents . . . ." Trident notes that the same dictionary defines "power line" as "two or more wires conducting electric power from one location to another." Thus, Trident argues that two power supply lines are required in order for current to flow from a power supply through an electric circuit.

While Trident acknowledges that a patentee can be his own lexicographer, in this case Trident contends that "power supply" has its plain meaning because NeoMagic did not clearly set forth an alternative definition in the specification. Trident argues that NeoMagic's construction of the term is inconsistent with other claims of the invention. According to Trident, the '955 and '806 patents specify that the voltage, V[BB], which reverse biases the substrate, is generated from an on-chip charge pump that is separate from the external power supply which provides the voltages V[DD] and V[SS]. Therefore, Trident contends that the invention requires two power supplies that share a common ground, V[SS].

Trident also argues that the prosecution history does not support NeoMagic's proposed construction of "power supply." Trident contends that the court should not rely on canceled claims from the parent application to inform its construction of the term. According to Trident, the canceled claim "exists as nothing more than an artifact of a path not taken, and does not come close to providing clear notice of a special definition contrary to common usage."

iii. Court's Construction of "power supply"

The words of a claim should generally be given their customary meaning to one of ordinary skill in the art at the time the patent application is filed. Markman, 52 F.3d at 986. The court agrees with Trident that a person of ordinary skill in the art would generally understand the term "power supply" to mean a device which has two or more terminals and which is capable of providing power to a circuit. The McGraw-Hill Dictionary of Electronics and Computer Technology supports this interpretation because it defines "power supply" as a source of electrical energy used to furnish the proper electric voltages and currents. Two power supply lines are required for current to flow from a power supply through an electric circuit. Furthermore, NeoMagic's own expert in electrical engineering testified that "power supply" commonly refers to a source of electrical energy that requires at least two power supply lines.

Nevertheless, the inventors could have intended the term "power supply" to mean something different in the context of their
invention. See Beachcombers v. Wildewood Creative Products, Inc., 31 F.3d 1154, 1158 (Fed. Cir. 1994) (stating that a patentee can be his own lexicographer provided the patentee's definition, to the extent it differs from the conventional definition, is clearly set forth in the specification); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992) ("Where an inventor chooses to be his own lexicographer and to give terms uncommon meanings, he must set out his uncommon definition in some manner within the patent disclosure."). In Lear Siegler, Inc. v. Aeroquip Corp., 733 F.2d 881, 889 (Fed. Cir. 1984), the United States Court of Appeals for the Federal Circuit stated:

So long as the meaning of an expression is made reasonably clear and its use is consistent within a patent disclosure, an inventor is permitted to define the terms of his claims. Nevertheless, the place to do so is in the specification of the inventors application, and the time to do so is prior to that application acquiring its own independent life as a technical disclosure through its issuance as a United States patent. The litigation-induced pronouncements of [the inventor], coming nearly at the end of the term of his patent, have no effect on what the words of that document in fact do convey and have conveyed during its term to the public.

In this case, the inventors did not set forth a definition of "power supply" in the specification or in the prosecution history of the '955 and '806 patents. The term is not even mentioned in the common specification of the patents in suit. NeoMagic argues that the language of canceled claims in the parent application demonstrates that the inventors intended "power supply" to refer to one of the power supply lines, V[DD], V[SS], or V[BB]. But the inventors did not define "power supply" in the parent application to have the uncommon meaning proposed by NeoMagic. Furthermore, interpreting power supply as it is commonly understood by one skilled in the art is consistent with the specification of the '955 and '806 patents which requires a second source of electrical energy ("an on-chip charge pump") to reverse-bias the substrate in order to solve the noise problem. Therefore, the court finds, as argued by Trident, that "power supply" refers to a source of electrical energy, such as a battery, that requires at least two power supply lines to deliver power in an electrical circuit.

1. Is AV[SS]/BIAS in Trident's split bias device a power supply?

The court has revisited the issue of the proper definition of the words "power supply" and has decided the court was correct to reject NeoMagic's proposed construction that a power supply is a source connection or line that may be at a particular voltage level. The court found the words should be given their plain, ordinary meaning as they are commonly understood by one skilled in the art. As argued by Trident, the court found "power supply" refers to a source of electrical energy, such as a battery, that requires at least two power supply lines to deliver power in an electrical circuit.

The issue raised by NeoMagic, in arguing that Trident's split bias device is a power supply, is that the device appears to fall within the court's definition, but is not what one of ordinary skill in the art would call a power supply. The split bias device has two or more terminals and is capable of providing power to a circuit. It is analogous to the substrate bias generator, in that it takes power from an off chip source, V[DD]/V[SS], and modifies the voltage of that power. As described in the patent, the substrate bias generator uses the +3.3 V[DD] volts to create the -1.5 V[BB] volts. Similarly, the split bias device uses V[DD]/V[SS] to create the voltage BIAS which varies between +2.0 and +2.2.

The court agrees with Trident that the split bias device is not a power supply within the ordinary meaning of that term. At this stage of the litigation, the court could revisit the subject of the proper construction of the words, or leave the issue to the jury. In leaving it to the jury, it appears that the dispute between the parties would not be whether the device is a power supply in its ordinary sense. Rather, the parties would be disputing whether the device fell within the court's definition. As the court intended to give power supply its ordinary meaning and as NeoMagic's argument shows the court has not accomplished this, it is more appropriate for the court to revisit the subject of the definition to insure that the one selected by the court accomplishes the court's purpose, which is to construe the claims to require a power supply as understood by one of ordinary skill in the art.

Trident has suggested that it is well-known to one of skill in that art that power supplies are designed and intended to deliver a constant source of power and that some power supplies can come closer to ideal than others. It argues that the court should construe power supply as a "constant voltage power supply." In advancing that argument Trident notes that there is evidence to show that voltage on the substrate bias generator varies plus or minus 0.5 volts around -1.5 volts. It argues that this
definition fairly draws the distinction between the substrate bias generator and the split bias device: the substrate bias generator is designed to produce as constant a voltage as possible, whereas the BIAS line is a signal line used as a control voltage line which changes in magnitude to keep the current sources in the digital-analog-converter at a constant value. Trident offered the testimony and affidavit of Robert J. Murphy to confirm that one of ordinary skill in the art would understand that a substrate bias generator is an on-chip power source that receives its power from the main power supply of the chip and delivers power in a converted form to the substrate. At the same time, one of ordinary skill in the art would not find that a bias or control voltage line is a power supply, as it controls sources of power in a manner to make them constant and independent of both power supply variations and temperature.

The court agrees with Mr. Murphy's testimony and finds a person of ordinary skill in the art would find the substrate bias generator is a power supply and the BIAS line in the split bias device is not. To the extent it is necessary to clarify the normal and ordinary meaning of the term, the court will adopt Trident's proposed definition.

Therefore, for the reasons set out by the court in its May 8, 2000 opinion as supplemented by this opinion, the court finds power supply in the asserted claims should refer to a source of electrical energy, such as a battery, that requires at least two power supply lines to deliver a constant voltage supply of power to an electrical circuit.

Turning to the '806 patent, the parties dispute the meaning of the terms "power supply" and "negative with respect to." Claims 7 and 18 of the '806 patent recite both a "first power supply" and a "second power supply." The specification does not provide a specific definition of power supply, and thus the term should carry its ordinary meaning in the art. Johnson Worldwide Assoc., Inc. v. Zebo Corp., 175 F.3d 985, 989-90, 50 USPQ2d 1607, 1610-11 (Fed. Cir. 1999); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1576-77 (Fed. Cir. 1996). NeoMagic argues that each individual power supply line is a "power supply." The district court held, and we agree, that one of ordinary skill in the art would understand power supply to mean "a source of electrical energy . . . that requires at least two power supply lines to deliver power in an electrical circuit." Markman Order, 98 F. Supp. 2d at 554. A power supply requires two lines because there must be both a source line and a return line in order for current to flow. In other words, because power cannot be applied to a circuit without both a source line and a return line, a "power supply," in order to function as such, requires at least two supply lines.

NeoMagic contends that this construction would exclude its preferred embodiment from the scope of the claims. NeoMagic asserts that its on-chip bias generator, which biases the substrate with a voltage VBB, has only one supply line. Thus, says NeoMagic, the inventors obviously could not have intended "power supply" to require anything more than a single supply line at a particular voltage. If this were an accurate description of the on-chip generator, it would be a powerful argument in favor of NeoMagic's construction. However, as admitted by NeoMagic's own expert, Mr. McAlexander, on-chip generators do have a return line in addition to the supply line. In fact, they have multiple return lines; so many that it is customary in the art not to draw them in diagrams or refer to them. When asked whether Trident's expert correctly described and drew an on-chip bias generator, McAlexander replied that Trident's expert had "generally described the construct of a substrate bias generator with respect to one terminal versus two versus three." He then explained that with respect to the number of terminals, the bias generator is typically viewed as a single-terminal output supply VBB, which in the classical sense with P-type substrate material, generates a negative voltage level that is below the classical understood VSS level of zero volts. But in terms of having a second terminal or a return, in all truth, the reason why designers don't draw it that way is because there's multiple returns. There's not any single return.

Because a substrate bias generator does contain at least one return line in addition to the supply line VBB, it would fall within a construction of "power supply" that requires at least two lines.

In the final iteration of its claim construction, the district court held that one of skill in the art would interpret "power supply" to provide a "constant voltage supply of power." NeoMagic, 129 F. Supp. 2d at 696. Trident proposed this "constant
NeoMagic argues, and we agree, that the court arrived at the constant voltage definition by examining the BIAS line of the accused device and, in effect, construing the claims to exclude it. It is well settled that claims may not be construed by reference to the accused device. SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1118, 227 USPQ 577, 583 (Fed. Cir. 1985) (en banc). Nevertheless, the error is harmless if the court's construction is correct and the term "power supply" does, in fact, require a constant voltage. However, Trident has pointed us to no probative evidence of record, either intrinsic or extrinsic, to support its proposed constant voltage construction. To the extent that evidence does exist in the record, it appears as part of an infringement analysis, i.e., as part of Trident's expert witness Mr. Murphy's testimony that the BIAS line would not be regarded as a power supply by one of skill in the art. It goes without saying that whether the accused device supplies a constant voltage or not is irrelevant to the proper interpretation of the claim term "power supply."

Unfortunately, on the record before us, we are unable to say with certainty whether or not one of skill in the art would understand that a power supply is designed to provide a constant voltage to a circuit. Given the complex technology involved in this case, we think that this matter can only be resolved by further evidentiary hearings, including expert testimony, before the district court. We note, however, that should the district court decide that the proper claim interpretation requires a constant voltage source, the court should take care to further define constant, since "constant voltage" is itself a somewhat ambiguous term. As the district court noted, "some power supplies can come closer to ideal than others" in terms of constant voltage supply, NeoMagic, 129 F. Supp. 2d at 696, and the court should consider the impact of the degree of fluctuation of the preferred embodiment, the on-chip substrate bias generator, on the definition of constant. 4 It is elementary that a claim construction that excludes the preferred embodiment "is rarely, if ever correct and would require highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583, 39 USPQ2d at 1578. Thus, while we affirm that power supply means "a source of electrical energy . . . that requires at least two power supply lines to deliver power in an electrical circuit," Markman Order, 98 F. Supp. 2d at 554, we vacate and remand for further proceedings that portion of the court's summary judgment holding that the "power supply" limitation requires a constant voltage supply.

4 The evidence of record on appeal suggests that the on-chip generator fluctuates by approximately 0.5 volts in either direction of its setting.

IV. DISCUSSION

In its May 9, 2003, Memorandum Opinion, the court construed the term "power supply" as a "source of electrical energy that requires at least two power supply lines to deliver power in an electrical circuit at a voltage to enable the junction between the well and the substrate to remain reverse-biased." Trident in its motion for clarification requests that the court insert the entire construction in the first sentence of the final paragraph of page 31 of the opinion. The court agrees that for clarity purposes the entire construction of the term "power supply" should be included.

NeoMagic requests the court to strike the portion of the opinion that refers to the "BIAS/AVSS device in the accused products does not deliver power to the circuit." (D.I. 355 at 2). However, the court actually stated that "the AVSS line does not deliver a voltage to the substrate in the accused device but grounds the substrate at 0 volts." Trident also requests that the court strike this sentence (D.I. 352 at 4).
With the inclusion of the entire construction of the term "power supply", the accused device has once again been reexamined to determine whether it contains all the limitations of the claimed invention. According to NeoMagic, the only remaining issue is whether the BIAS and AVSS supply lines, the split-bias device in the accused product, constitute the requisite claimed second power supply. As already stated in the previous Memorandum Opinion, in determining whether there is patent infringement, after the claims are properly construed, the second step is a factual determination of whether the accused product infringes, either literally or by equivalents, made by comparing the properly construed claims to the accused product. In order to prevail on a claim of literal infringement, "the patentee must show that the accused products contain every limitation in the asserted claims. If even one limitation is missing or not met as claimed, there is no literal infringement." Again as stated in the previous Memorandum Opinion, there must be two power supplies and each power supply must be "a source of electrical energy that requires at least two power supply lines to deliver power in an electrical circuit at a voltage to enable the junction between the well and the substrate to remain reverse-biased." Comparing the accused device to the properly construed claim, the alleged BIAS/AVSS power supply does not enable the junction between the well and the substrate to remain reverse-biased as required.

--- Footnotes ---

3 See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1365 (Fed. Cir. 2002).

NeoMagic asserts that the accused device and the preferred embodiment are exactly alike and provided diagrams in support of their interpretation. NeoMagic contends that both power supplies share AVSS which is connected to the substrate as required. However, NeoMagic omits to compare the second required line of the power supply. The second line of the alleged second power supply in the accused device, the BIAS line, connects to the capacitor whereas the second line of the preferred embodiment, the VBB line, connects to the substrate, as does the AVSS line. These are clearly not exactly alike. Based on those diagrams, the accused device is clearly not the same as the preferred embodiment as alleged by NeoMagic. NeoMagic continually refers to power supply lines instead of the required power supply as recited in the claims. The claims do not recite power supply lines, this issue was resolved by the Federal Circuit. Each power supply must enable the junction between the well and the substrate to remain reverse-biased. The split bias device does not meet this limitation of the claim, as asserted by Trident's expert and by NeoMagic's expert when the full context of their testimony is considered. As NeoMagic continues to remind the court, the claims may not be construed in light of the accused device. The court, as required, has compared the accused device to the newly construed claim and continues to hold, as did Judge McKelvie in his previous decision, that the split bias device is not a power supply. As stated in two previous decisions, Trident's accused products may achieve the same result, but they do it in a different way, using a single power supply, a grounded substrate and a triple-well construction.

--- Footnotes ---

5 Neomagic Corp. v. Trident Microsystems, Inc., 287 F.3d 1062 (Fed. Cir. 2002).
7 NeoMagic Corp., 129 F. Supp. 2d at 698; NeoMagic Corp., 287 F.3d at 1069.

NeoMagic has not presented any new evidence, the controlling law has not changed, no clear error of law or fact needs correcting or to prevent manifest injustice, and as such the court will not alter or amend its judgment.

However, for the reasons described above, the Memorandum Opinion will be clarified as follows. The final paragraph of page 31 should read:

To be considered a second power supply, the split-bias device must be able to deliver power to an electrical circuit at a...
voltage to enable the junction between the well and the substrate to remain reverse-biased. A split-bias device is simply a BIAS signal line that controls the current in the digital-analog-converter at a constant value, not a power supply, as held by Judge McElvain in his previous decisions. The split bias device does not influence the well voltage and does not enable the junction between the well and the substrate to remain reverse-biased. Because the accused device does not have the requisite second power supply, there can be no infringement, and no further arguments need addressing. n.115

n.115 Following the findings of this opinion, the Issues raised in the parties letter motions of December 30, 2002 (D.I. 347) and January 2, 2003 (D.I. 348) are moot.

In light of this clarification, the split bias device is not a power supply pursuant to the properly construed claim. GO BACK

3243

b. Personal computer power supply (Claims One, Four, Seven)

Streak proposes the following construction of personal computer power supply: "a component adapted to receive AC current and provide DC current to a personal computer, and expressly excludes redundant power supplies." Defendant argues the construction should instead read, "a device that receives AC current and provides DC current to the components of a personal computer." In its reply brief, Streak acceded to Alliance's preference for the word "device," as opposed to "component," at the beginning of the sentence. The parties also agree that "current to the components of a personal computer" means functionally the same thing as "current to a personal computer." The dispute here relates to whether Streak's suggested negative inference excluding redundant power supplies is supportable. A 'redundant' power supply is essentially a "back up" source of power used in the event that the main power supply becomes disabled. While the parties appear to agree that redundant power supplies are commonly associated with servers connected to multiple machines, and further agree that the '293 patent is directed toward personal computers, Alliance suggests it does not necessarily follow that a personal computer would never have or need a backup power supply.

Streak argues, first, that all patent documents refer to a main power supply and do not anywhere suggest a redundant, or "back up," embodiment. Moreover, Streak insists the inventors expressly disclaimed during prosecution any embodiments involving "redundant power supplies" in order to distinguish prior art. A prosecution disclaimer arises where the inventor "expressly relinquishes" an embodiment otherwise within the scope of a claim. See Omega Eng'g v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003) ("We indulge a heavy presumption that claim terms carry their full ordinary and customary meaning, unless the patentee . . . expressly relinquished claim scope during prosecution.") (internal quotation marks and citation omitted). As the Federal Circuit has emphasized, the doctrine of prosecution disclaimer is unavailable where the alleged disavowal of claim scope is ambiguous. Id. Rather, the Federal Circuit has "required the alleged disavowing statements to be both so clear as to show reasonable clarity and deliberateness, and so unmistakable as to be unambiguous evidence of disclaimer." Id. at 1324 (citation omitted).

Streak points to several statements from the prosecution history that it argues demonstrate the inventors' "clear and unambiguous" disavowal of redundant power supplies. First, Streak highlights a statement made in an Interview Summary on March 16, 2006, highlighting how the claimed invention sets forth "configurations that allow formation of cable assemblies in a way to allow selection and customization by the buyer of a single power supply unit." (Ex. 17: March 15, 2006 Interview Summary of 2/1/06 Interview, at 2.) Streak suggests the phrase "single power supply unit" is utterly inconsistent with the idea of a backup power supply. Alliance argues the sentence quoted is taken out of context. The complete paragraph, it points out, notes how the product is designed for individual users, rather than for large corporations that might need to purchase many units. Both explanations read comfortably from the paragraph. Accordingly, Alliance's suggestion that the statement's meaning is ambiguous is well-taken.

Streak turns next to statements it made to the PTO to distinguish the '293 patent from prior art. In a May 15, 2006 Request for Continued Examination ("RCE"), Streak argues the inventors "repeatedly distinguished" the claimed invention from the "entire category" of redundant power supplies. Alliance counters that Streak's inventors only disclaimed a particular type of redundant power supply: the rack mounted, external, backup power supply that was the subject of a Wiscohome patent. Streak emphasized how "the Wiscomonte patent expressly discloses and teaches that its power supply is for 'racked mounted' systems using 'redundant power supplies'—the present ['293] claims were amended to limit to personal computers." At
another point, it reiterated that "[t]he Wiscombe patent . . . addresses the problem with 'redundant power supplies' (not personal computer power supplies)." Streak reads these statements as a categorical disclaimer of all redundant power supplies from the claimed "personal computer power supply." This time, Streak's disclaimer does not suffer from the type of ambiguity discussed above. While Wiscombe's redundant power supply may have been of the rack mounted variety, it is apparent that the '293 inventors sought to disclaim more than this when they contrasted Streak's personal computer power supply from redundant power supplies. Moreover, every item of intrinsic evidence details the workings of a main power supply, whose function is essentially to supply DC current to a personal computer and its components. Accordingly, "personal computer power supply" shall be construed to include Streak's proposed limitation: "a device that receives AC current and provides DC current to the components of a personal computer, and expressly excludes redundant power supplies."

3244

(4) A Second Power Supply

The parties next dispute the meaning of "a second power supply," which also appears in claim 41 of the '364 patent. Square D argues that the phrase should be construed to mean simply "a second source of power"; EI argues that it should be construed to mean "a second, independent source of power distributed to the meter by executing a algorithm." Again, the claim language is clear and unambiguous, and nothing in the claims or the specification limits this second source of power as EI seeks to limit it. Indeed, the specification itself suggests that the first power supply and the second power supply need not be independent:

The power supply 715 supplies operating power to the revenue meter 700. . . . the power supply 715 is also designed to provide short term isolation of the meter operation from the power quality event. This is known as "Ride-Thru" and enables the revenue meter 700 to continue to quantify and/or record and report the power quality event throughout the duration of the event and before losing operating power due to extended power quality events.

U.S. Patent No., 6,792,364 B2, col. 12, lines 29-42. Significantly, figure 715 shows a single power supply, not two independent power supplies. The Court adopts Square D's construction and construes "a second power supply" to mean "a second source of power."

3245

2. "Power Supply Circuit"

Claims 28, 36 and 38 of the Reissue Patent incorporate a power supply circuit. The principle area of dispute, it appears, is the parties disagreement over whether terms such as "constant current" and "high impedance," as used in the context of the Reissue Patent, are too ambiguous and require a precise numerical value. In regards to the power supply circuitry of claim 28, Rockford argues that: (a) the term "constant current" is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation; (b) the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance; and (c) the phrase "increase electrical isolation between the first stage and the at least one return signal" lacks definite meaning because the first stage is not isolated from the return reference potential, and the patent provides no baseline for measuring increase. (Def.'s Markman Br. at 2-3, 32-44.)

Rockford argues that the terms "constant current" and "high impedance" require some absolute numerical value because they are ambiguous and indefinite. Id. at 23-27. According to Rockford, the term "constant current" of claim 28 of the Reissue Patent is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation. (Def.'s Markman Br. at 2.) Rockford also alleges that the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance. Id. Finally, Rockford concludes that the phrase "increase electrical isolation between the first stage and the at least one return reference signal" lacks definite meaning because the first stage is not isolated from the
return reference potential, and the patent provides no baseline for measuring an increase. Id. at 2-3.

Fiori counters that the intrinsic evidence clearly demonstrates that the claim language of the patents-in-suit were presented and approved by the PTO examiners, and therefore do not violate 35 U.S.C. § 112 (2) or require some absolute numerical value. (Pl.'s Markman Br. at 11.) Fiori asserts that "[t]he specification and Figures provide a complete definitional framework" for its claims. (Pl.'s Markman Br. at 20.) He contends that the Reissue Patent defines "constant current" as an exact current precisely metered through each transistor to operate the op-amps. Id. at 27. Fiori claims that the specification of the Reissue Patent teaches and defines that this power supply provides a current to the first stage preamplifier circuit that does not respond to changes in the potential of the supply pins of the op-amps (e.g., 38) so that the first stage is able to track the input reference signal without inducing any corrupting noise variations in the preamplifier circuit or in the return input reference signal current pathway. Id. According to Fiori, because the current is metered precisely, any changes and potential of the op-amp supply pins will have no bearing on the current delivered. Id. As a result, the effective impedance of the power supply is extremely high. n28 Id. Fiori further contends that "constant current," defined in the specification with precision, is a "degree term." (Pl.'s Markman Br. at 11 n.5.)

n28 Figure 3 in the specification similarly describes an alternative power supply for providing a constant current.

n28 The Federal Circuit has consistently held that terms of "degree" such as "high", "low", "substantially", "significantly", "approach each other", "close to", "substantially equal", and "closely approximate" are definite under 35 U.S.C. § 112 (2) and do not require further mathematical precision. See Seattle Box Co. v. Industrial Crating & Packing, 731 F.2d 818, 826 (Fed. Cir. 1984) (citing W.L. Gore & Assoc., Inc. v. Garlock, Inc., 721 F.2d 1540, 1557 (Fed. Cir. 1983), cert. denied, 469 U.S. 851, 105 S. Ct. 172, 88 L. Ed. 2d 107 (1984)) ("substantially equal" is a term of degree, and that its acceptability depends on "whether one of ordinary skill in the art would understand what is claimed . . . in light of the specification"); see also Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir. 1985) cert. denied, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985); N. Am. Vaccine, Inc., 7 F.3d at 1579; Hybritech, Inc. v. Monoclonal Antibodies, Inc., 802 F.2d 1367,1385 (Fed. Cir. 1986). As the Federal Circuit has noted in Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 821 (Fed. Cir. 1988), such words are ubiquitous in patent claims. Such usages, when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention, and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the Courts. See Rosemount Inc. v. Beckman Instruments, Inc., 727 F.2d 1540 (Fed. Cir. 1984). Furthermore, when a claim term is expressed in general descriptive words, the Court will not limit the terms to a numerical range that may appear in written description or in other claims. See Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996) (citation omitted). Accordingly, this Court finds that Rockford's interpretation that the terms "constant current" and "high impedance" require some absolute numerical value is unpersuasive. The general descriptive terms in which the terms are expressed are acceptable under the present state of the law.

In regards to the power supply circuitry of claims 36 and 38, Rockford argues that: (a) the location of the "constant current" in both claims is between the power supply and the first power supply circuit because claims 36 and 38 state that the first power supply circuit draws the current from the power supply; and (b) the elements of the voltage regulation means in claim 38 include a bias voltage circuit. (Def.'s Markman Br. at 2, 24-30.)

In its Markman brief, Rockford first contends that the ordinary meaning of the words of claims 36 and 38 place the "constant current" between the power supply and the first power supply circuit. Id. at 25. According to Rockford, analogous to a "farmer drawing n29 water from a well," the first power supply circuit performs the act of drawing and the power supply circuit draws current toward itself from the power supply. Id. at 26. Thus, Rockford believes that the location of the "constant current," as described in both claims, must be restricted because the limitations refer "to the particular water the farmer takes from the well" . . . and do "not refer to water used in the barn where animals drink." Id.

n29 "Draw" means "to cause to move after or toward on by applying continuous force." JOSEPH M. PALVELL, THE
This Court does not agree. As previously stated, "if the claims, read in the light of the specification, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed Cir.) cert. dismissed, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985) (quoting Georgia-Pacific Corp. v. U.S. Plywood Corp., 258 F.2d 124, 136, cert. denied, 358 U.S. 884, 79 S. Ct. 124, 3 L. Ed. 2d 112 (1958)). Here, the term "constant current," as described in claims 36 and 38, is specifically defined in the specifications and claims and is not required to be situated between the first power supply circuit and the power supply. As such, Rockford's construction of claims 36 and 38 is too narrow in scope and its "farmer and the well" rationale is tenuous and unpersuasive. Rockford further asserts that the "voltage regulation means" of claim 38 includes the voltage regulator circuitry found within the constant current circuits. Despite the parties stipulating that "voltage means" includes transistors 22, 24, resistors 21, 25, and op-amps 23 and 26, Rockford interprets the pertinent language of the specification to include elements 80, 82 and 84 and the op-amps requiring a bias voltage circuit. Id. at 2, 25, 27-30. According to Fiori, the first and second stage recitals of claim 38 are identical in scope to claim 36 and the power supply in claim 38 is recited as comprising a voltage regulating means for drawing the constant current from the first power supply with respect to the changes in the input source reference potential to isolate the first power supply circuit from the first stage. (Pl.'s Markman Br. at 29.) Moreover, Fiori contends that the specification describes the voltage regulation means as the transistors 47, 22, 50 and 24 in combination with the resistor and op-amps and zener diode 43 and 45. Id.

This Court does not agree with Rockford's position that claim 38 includes the voltage regulator circuitry found within the constant current circuits. Rockford fails to establish the relevance or materiality its assertion serves for the purpose of this Markman process. n31

Similarly, Rockford's argument that Fiori's claim constructions are unfounded in an effort to cover up the flaws of Plaintiff's case, is irrelevant for purposes of this Markman process. (Def.'s Rebuttal Br. at 25-30.)

IV. CONCLUSION

The Court concludes that the disputed terms have the following meanings:

1. "Input Portion" of claims 1 and 17 of the '148 Patent shall mean a specifically defined physical structure, connected to two conductors and recited as generating an intermediate signal.

2. "Output Portion" of claims 1 and 17 of the '148 Patent shall mean a physical structure, specifically defined as op-amp 65,
which is separate, independent and isolated from the input operational amplifier and recited as generating a destination signal and a corresponding destination reference signal.

3. "Second Stage" of claim 28 of the Reissue Patent shall mean a stage, operatively coupled to the first stage, n32 generating an output signal which is a sum of the at least one intermediate signal generated in the first stage minus a potential of the at least return reference signal plus an output return reference signal.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - - -

n32 There is no issue between the parties regarding the "first stage" of the Reissue Patent.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

4. "High Impedance" of claim 28 of the Reissue Patent shall mean a mathematically sufficient term of degree for providing a constant current power supply circuit coupled to said first stage to increase electrical isolation between the first stage and the at least one return reference signal.

5. "Constant Current" of claims 28, 36 and 38 of the Reissue Patent shall mean an exact, non-absolute numerically valued current, precisely metered through each transistor to operate the op-amps, and not required to be situated between the first power supply circuit and the power supply.

6. "Power Supply Circuit" of claims 28, 36 and 38 of the Reissue Patent shall mean a first stage preamplifier circuit that does not respond to changes in the potential of the supply pins of the op-amps (e.g., 38) so that the first stage is able to track the input reference signal without inducing any corrupting noise variations in the preamplifier circuit or in the return input reference signal current pathway.

3246

"power supply circuitry"

Claims 14 and 39 of the '185 Patent contain the term "power supply circuitry." ACQIS contends the term means "components and connections for the processing of electrical energy," while Defendants contend the term means "a battery."

The '185 Patent describes "power supply" as follows: "The primary power supply has sufficient capacity to power both the PCON and the ACM 100 for normal operations. Note that the ACM may include a secondary "power supply" in the form, for example, of a small battery." '185 Patent, col. 5:34-27. The term "power supply circuitry" is used in the claims as follows: "power supply circuitry having a stored energy capacity no greater than the energy required to power said CPU, memory and mass storage for 30 minutes of operation at the maximum rated speed of the CPU." ACQIS argues that even though a battery is a type of power supply, a power supply is not necessarily limited to just a battery. ACQIS further argues that Defendants' proposal ignores the word "circuitry" because a battery is only one component of a circuit, and thus the term "circuitry" implies more than just the power source.

Defendants' proposal limiting "power supply circuitry" to "a battery" is improper and inconsistent with the specification and claim language. Even devices using a battery as a power source include additional circuitry for voltage regulation purposes. Furthermore, Defendants' argument that the claims' reference to "stored energy capacity" restricts "power supply circuitry" to "a battery" is misplaced. To illustrate, a power supply circuitry often uses a capacitor bank at the output to provide auxiliary power during a main power outage. The capacitor bank "stores" electrical energy even though it does not deliver that energy while the power supply circuitry is receiving power. Thus, the Court rejects Defendants' proposal.

ACQIS's proposed construction would only add ambiguity where none exists. The claim language is clear and understandable to the fact finder and does not require construction beyond its plain and ordinary meaning. See Orion, 406 F. Supp. 2d at 738 (stating that "although every word used in a claim has meaning, not every word requires construction" in declining to construe claim terms). Thus, the term "power supply circuitry" does not require reconstruction.
8. "controller," "power supply controller," "system controller"

As to "controller," the parties have agreed to Power-One's proposal of "circuitry that controls the operation of one or more devices." As to the other terms, Power-One argues for the same construction, while Artesyn proposes "part of a distributed power control system that activates and at least partially programs and monitors a regulator and allows the output of the POL regulator to be transmitted to an external load circuit." The Court notes that a "power supply controller" is discussed in the '999 patent as follows:

Traditionally, POL regulators operate in conjunction with at least one power supply controller. The controller (1) activates and partially programs the POL regulator by providing data directly to the POL regulator, (2) monitors the output of the POL regulator by measuring data external to the POL regulator, and (3) allows the output of the POL regulator to be transmitted to an external load circuit by controlling an external switch.

Col. 1:34-42; see also '798 patent, col. 1:37-42. The Court finds that this language supports Artesyn's proposal and therefore, construes "power supply controller" and "system controller" as "part of a distributed power control system that activates and at least partially programs and monitors a regulator and allows the output of the POL regulator to be transmitted to an external load circuit."

7. "A power supply coupled to the first power signal port and to at least one of said modems to be powered by the power signal and for powering said modem"

This phrase also appears in claim 18 of the '280 patent, the terms of which are described above. SercoNet maintains that this term means: "The device receives a power signal and allows the transfer of the power signal with the modem and the power coupler." NetGear's proposed construction is: "The device receives power and data on the first wiring segment, and filters the power. The filtered power is used to power a modem."

Starting with the claim language, as with the previous claim, the plain language of the claim does not on its face describe a filtering of power from the data, as urged by NetGear. SercoNet's proposed construction of this term as a device that receives a power signal and allows the transfer of that signal with the modem and the power coupler. The plain language of the claim supports this reading, as the claim language simply describes a power supply powered by a power signal connected to a power signal port that powers a modem. In addition, other parts of claim 18 separately deal with the transfer of data, so this portion of the claim should not be construed to deal with data transfer.

Turning to the specification, NetGear again relies on the power/data splitter/combiner description in the specification which describes such devices as separating the power and data signals. See '280 patent at 5:63-66, 6:31-34. The specification does not, however, state that "filtering" is required. NetGear, therefore, imports an extraneous term that is not supported by the claim or specification. 1 While SercoNet's construction may not be perfect, it does not suffer from the same problems as NetGear's construction, as it does not import an unsupported extraneous term. And, as SercoNet points out, requiring that the device receive both power and data is incorrect, because the first SIC -- the one connected to the power supply -- does not necessarily receive both power and data.

1 In addition, as discussed above, certain alternative embodiments do not use a power/data splitter/combiner.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "A power supply coupled to the first power signal port and to at least one of said modems to be powered by the power signal and for
powering said modem" and construes the term as: "The device receives a power signal and allows the transfer of the power signal with the modem and the power coupler."

IX. "Power tool"

The Court next addresses the term "power tool" from claim 7 of the '059 patent.

A. The Parties' Proposed Constructions

Black & Decker proposes construing the term "power tool" as "an electrically powered tool." Bosch proposes that the term "power tool" means "a device that aids in accomplishing a task that is powered by an energy source."

B. The Parties' Arguments

The Court agrees with Black & Decker that Bosch's proposed construction is overly broad because it would cover devices such as a bicycle or a toothbrush. Bosch derives its proposed construction from the dictionary definition of the word "tool" (i.e., a device that aids in accomplishing a task). The Federal Circuit in its en banc decision in Phillips recently warned against using dictionary definitions to construe claims when the intrinsic evidence would be clear to one of ordinary skill in the art. Phillips, 415 F.3d at 1321 ("The main problem with elevating the dictionary to such prominence is that it focuses the inquiry on the abstract meaning of words rather than on the meaning of claim terms within the context of the patent").

The intrinsic record does not support the broad construction proposed by Bosch. The "Objects Of The Invention" section of the specification provides that: "It is yet another object to be able to power the radio with modular batteries normally used in professional portable power tools." ('059 patent, col. 1, ll. 55-57.) Further on, the specification states that the invention may include "an adapter engageable with a secondary direct current power source, such as a tradesworker's hand tool battery pack." ('059 patent, col. 2, ll. 28-30.) Black & Decker also points out that The New Shorter Oxford English Dictionary (1993) defines "power tool" as "an electrically powered tool." This confirms the understanding that one of ordinary skill in the art would have of the term "power tool" based on a reading of the intrinsic record, and specifically the specification. Accordingly, the Court construes the term "power tool" as "an electrically powered tool."

n10 Although this construction essentially recites the claim term itself, counsel for Bosch conceded at the Markman hearing that people understand what a "power tool" is. (Markman Transcript at 69:17-20.) Accordingly, the Court does not find it necessary to further define a term that the trier of fact will already understand.

5. "powered on"

Claim 1 of the '969 Patent describes the method of Claim 1 "wherein the step of opening the lid causes the AED to be powered ON." Philips contends that the term "powered ON" should be construed as "the AED is turned from off to on." Cardiac Science asserts that "on means on" and the phrase needs no further construction.

In support of its construction, Cardiac Science asserts that the patent describes a standby mode or quiescent state during which periodic and automatic self-tests of the AED components occur on a daily or weekly basis. ('969 Patent at c. 7, ll: 24-56.) Cardiac Science contends that these self-tests require electronics and power. Thus, Cardiac Science asserts that the AED is neither "on" nor "off" but rather in the standby mode. Then, when the AED is needed for a rescue, the user opens the lid
of the AED and the AED is turned from the standby mode to "ON." Philips, on the other hand, asserts that the specification of the '969 Patent does not describe such a "standby" state. Instead, Philips contends that the patent describes the lid as an on/off switch. (Id. at c. 4, ll: 57-58; c. 8, ll: 19-22.) Thus, Philips maintains that opening the lid controls whether the AED is powered on or powered off.

The Court finds that although the word "standby" never appears in the '969 Patent, the specification describes a dormant state of the invention whereby the device performs various self-tests without actually being "powered on." If the Court were to agree with Philips' construction that the device is powered "off until the lid is opened, it would imply that there is no functionality or power to the unit, and this is plainly not the case. For this reason, the Court agrees with Cardiac Science that opening the lid does not switch the device from "off to "on." Thus, the Court construes the term "on" to mean "on."

3251

B. "Preclude from Accessing"

1. Proposed Constructions

The parties dispute the proper construction of "preclude from accessing." The claim language at issue is found in claims 1 and 14 the 440 patent. Claim 1 reads: "circuitry operable to alter said BSY bit . . . to indicate said host computer is precluded from accessing said plurality of ATA command block register addresses"; claim 14 reads: "said status register including a BSY bit . . . that indicates when access by said host computer to said ATA command block register addresses is precluded." n10 Plaintiffs assert that the correct construction of these phrases is "the BSY bit indicates whether the host computer is permitted to access the command block registers"; defendants assert that "the BSY bit indicates when it is impossible for the host computer to access -- i.e., read or write -- the ATA command block registers." Defendants' 527 Br. at 16; Plaintiffs' 527 Br. at 13.

n10 Both parties agree that the limitations at issue refer to "precluding" the host computer from accessing the command block registers, not the command block register addresses, as stated in the claims.

Both parties are in agreement that the BSY bit is an indicator and does not itself operate to prevent the host computer from accessing the command block registers. However, they disagree over what the BSY bit indicates in the claims at issue. Plaintiffs, referring to the ATA specification, contend that the indicator is permissive, such that the BSY bit unset permits the host computer to access the command block registers and only indicates when the host computer should not access the command block registers. Defendants contend that the plain language of the claims makes it clear that the BSY bit indicates when the host computer is prevented from accessing the command block registers (i.e., it is impossible to access the command block register when the BSY bit is set). Plaintiffs on the other hand, argue the defendants' construction relies on a dictionary definition of "preclude." This reliance, they contend, is impermissible under Phillips.

Plaintiffs' protests aside, Phillips does not prevent a court from referring to a dictionary definition, so long as that definition is given the proper weight. See, e.g., Terlep, 418 F.3d 1379, 2005 WL 1950186 at *5 (citing Phillips, 415 F.3d at 1317).

Because the claim language and specification are unhelpful to determining the meaning of preclude, the court first attempts to discern the ordinary meaning of "preclude," which, as defendants assert, has the ordinary meaning of "to make impossible." American Heritage Dictionary, 4th Ed. 2000; Webster's Ninth New Collegiate Dictionary, 1988. Generally, a court may deviate from the ordinary meaning of a claim term in one of the following four circumstances. "First, the claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history." CCS Fitness v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). n11 The court discerns in neither the specification nor prosecution history any attempt to clearly set forth a definition of "precluded from accessing" that resembles plaintiffs' permissive construction. Indeed, "preclude" appears nowhere in the 440 patent, except in the claims. "Second, a claim term will not carry its ordinary meaning if the intrinsic evidence shows that the patentee distinguished that term from prior art on the basis of a particular embodiment,
expressly disclaimed subject matter, or described a particular embodiment as important to the invention." Id. Again, there is no indication that the patentee distinguished the implementation of the BSY bit in the claimed invention in any way from the prior art, or otherwise described an implementation as important to the invention that supports plaintiffs' construction of "precluded from accessing." "Third . . ., a claim term also will not have its ordinary meaning if the term chosen by the patentee so deprives the claim of clarity' as to require resort to the other intrinsic evidence for a definite meaning." Id. at 1367. The meaning of "precluded" is clear and does not conflict with the language of the claims or any description set forth in the specification. The fourth way cited by the Federal Circuit involves step-or means-plus-function format claims under 35 U.S.C. § 112 P 6, which is inapplicable to this case. Id. Based on this analysis, the court would conclude that the ordinary meaning of preclude obtains.

n11 CCS Fitness was couched in terms of an alleged infringer attempting to overcome the plain meaning of a term. CCS Fitness, 288 F.3d at 1366 ("An accused infringer may overcome this "heavy presumption" and narrow a claim term's ordinary meaning but he cannot do so simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history."). There is no reason why the same principles should not apply to a patentee advocating a construction that diverges from the ordinary meaning of the term.

The parties both argue that the following extrinsic evidence lends support to their respective constructions: the ATA specification n12 and the implementation of the OTI-11 chip, which is the commercial embodiment of the patent's preferred embodiment, see, e.g., 527 patent, Fig. 3a. They agree that the ATA specification and the OTI-11 both specify that requests to access the command block register are to be redirected to another location, the status register, when the BSY bit is set.

n12 The parties dispute whether the ATA specification is intrinsic or extrinsic evidence. Defendants characterize the ATA specification as extrinsic evidence. Plaintiffs, on the other hand, contend that it is intrinsic because it is referenced in the 440 patent specification and was submitted to the PTO during prosecution of the 440 patent. Plaintiffs' Resp. to Sur-reply at 9. They cite Phillips for support. 415 F.3d at 1317 ("The prosecution history, which we have designated as part of the intrinsic evidence,' consists of the complete record of the proceedings before the PTO and includes the prior art cited during the examination of the patent.").

Plaintiffs assert that this redirection to the status register demonstrates that defendants' construction requiring read and write access to be impossible when the BSY bit is set is not supportable. Even if writing to the command block register is precluded according to defendants' definition, plaintiffs contend that reading from the command block register is always possible. In particular, they argue the command block register not inaccessible when the BSY bit is set because it remains possible for part of the command block register (namely the status register) to be read. The redirect logic described above only sends the request to a different register in the command block, and that register is read instead. Defendants, on the other hand, argue that redirecting the request to another location is the same as precluding access to a command block register. Defendants essentially assert that because it is not feasible to physically preclude access to the command block registers, the redirect logic serves as the mechanism to make accessing the command block register impossible when the BSY bit is set.

The court agrees that, while access to the command block registers would technically be possible in the preferred embodiment because access is not physically prevented, reading from the command block register would only be accomplished by violating the rules established by the ATA specification or the logic of the OTI-11. Thus, the implementation described under either the ATA specification or implementation of the OTI-11, redirecting the read request away from the requested command block register when the BSY bit is set, would serve to make read access to the command block register impossible while the BSY bit is set.

Even assuming the ATA specification does not require the command block register to refuse access requests when the BSY
bit is set, the plain language of the claims nonetheless clearly indicates that the BSY bit indicates when the host computer is precluded from accessing the command block register. In this case, the use of the term "precluded" carries the ordinary meaning of "prevented." Plaintiffs present no evidence that "preclude" would have generally suggested an alternative meaning to one of skill in the art. The extrinsic evidence set forth above appears to support the plain meaning of the term. Thus, the court finds that "precluded" carries its ordinary meaning. The "precluded from accessing" limitation is construed such that "the BSY bit indicates when it is impossible for the host computer to access the ATA command block registers." "Precluding" includes redirecting the request to another location.

4. "predefined bandwidth"

The plaintiff contends that this term means "a TDM frame with a fixed number of time slots." The defendants argue that this term means "data transfer capacity fixed in advance of operation." Although the plaintiff cites to the abstract, the defendants' proposed construction embraces the definitions of "predefined" and "bandwidth" as used in the claims. The court adopts the defendants' proposed construction.

3253

1. "With each user being capable of having predefined characteristics indicative of multiple predetermined roles in the system." Used in Claim 1.

Blackboard proposes: "Each user can have multiple roles in the system such that each user identified can have one role in one course and another role in another course. The roles and some associated characteristics are set before the user can access data files of a course." D2L initially suggested "a user may be assigned more than one role. The roles contain properties that have been defined by the system, not by a user."

Initially, both parties invite inadvertent error because their proposed constructions focus on the standpoint of a user. Claim 1 is an apparatus claim. Thus, structural and functional limitations of the system are at issue. See '138 patent, col. 30, ll. 18-48. While a user interacts with the system, the user is not part of the system itself. The court's construction, therefore, must focus on system limitations, and must be based on the standpoint of the system.

Similarly, the parties invite additional error by agreeing that the court may instruct the jury that the claim should be defined as including a specific "such that" requirement, viz., "such that each user identified can have one role in one course and another role in another course." The parties agree that the claim term permits one user to assume more than a single role within the system. Nonetheless, for reasons not argued by the litigants, the court cannot wholly adopt Blackboard's proposal.

--- Footnotes ---

3 As noted at the outset of this section, D2L initially opposed this language. However, at the Markman hearing, D2L conceded that its competing proposal advocated in its responsive brief could be inappropriate because it might "actually capture those types of prior art where an individual could have different log-ons to access different courses." Tr. p. 36, ll. 17-19. Consequently, D2L further agreed at the hearing that the court should adopt the first sentence of Blackboard's proposed construction. Tr. p. 36, ll. 23-25.

--- End Footnotes ---

Blackboard argues that the court should adopt this construction because the specification identifies three separate roles, and states that these "roles may be mixed." See '138 patent, col. 4, ll. 7-11 ("...roles may be mixed; for example, when an instructor of one course, is also a student in another course."). This reference, however, is only an example of a limitation in an illustrative embodiment. See '138 patent, Figs. 5-6 and 39. To base the court's construction on it, therefore, runs afoul of the principle that limitations of preferred embodiments will not be read into claims. "Although the specification may aid the
court in interpreting the meaning of disputed claim language, particular embodiments and examples appearing in the specification will not generally be read into the claims.” Comark Commns., Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998); see also Varco, L.P. v. Pason Systems USA Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006) (“In examining the specification for proper context, however, this court will not at any time import limitations from the specification into the claims.”). If a specific limitation to a system wherein a user is assigned a teacher role within the system as to one course and assigned a student role within the system as to another course were intended, an express recitation of such a limitation could have been placed into the claims. But, such an express recitation is absent in the claim language itself. The court cannot depart from the plain meaning of the claim language and cannot add this limitation.

Additionally, Blackboard's proposed construction would be inconsistent with the remainder of the claim. Language at the end of the claim specifies that multiple user roles to which each user can be assigned are at least two but can be all three. See '138 patent, col. 30, ll. 28-34. The word "comprising" makes it permissible for a single user to be assigned to all three identified roles. Thus, a construction that limits assignment of a user to only one role in one course and another role in another course is not consistent with the open-ended recitation of "comprising at least two user's predetermined roles…."

The sole remaining issue, therefore, is how to properly interpret "predefined characteristics" and "predetermined roles in the system" (italics added). The operative and italicized words are interchangeable, but the patentee's decision to modify user roles with "predetermined," while using a different word, "predefined," to modify associated user characteristics, makes the phrase difficult to parse. Nevertheless, a plain reading of the patent language makes clear that "predefined" and "predetermined" are analytically synonymous. As commonly understood, each word denotes a coetaneous temporal limitation, and the parties do not suggest that one should be construed differently from the other. 4

There are discernible differences between user roles and characteristics associated with user roles. The patent does not indicate why the inventor modified roles with "predetermined" but modified characteristics with the commensurate term, "predefined." The court assumes that the language reflects a stylistic choice, perhaps intended to aid in preventing blurring of the subtle distinction between roles and associated characteristics.

The parties concur that "predefined" and "predetermined" impose temporal limitations. They disagree over when such limitations are imposed. D2L suggests an ab initio construction holding that limitations are set or specified by the framework of the system. In other words, D2L argues for an interpretation imposing role and associated characteristic limitations when the system is installed and begins operating. Blackboard, however, advocates an in medias res interpretation holding that user roles and associated characteristics can be created downstream, i.e., after the system is installed and operating. Blackboard's proposed construction requires only that limitations be set sometime before an established user can access course files.

Here, the claim language uses "predetermined" to indicate a finite set of separately identifiable roles within the system. See '138 patent, col. 30, ll. 25-34. The roles within the system framework, which have access levels associated with them, are assigned based upon a user's characteristics. See '138 patent, col. 30, ll. 21-34. Thus, the claim language suggests that predetermined user roles and associated characteristics are settled or decided in advance within the framework of the system.

The specification supports this view. It identifies a universe of roles that encompasses student, teacher and administrator. See, e.g., '138 patent, col. 4, ll. 7-11; '138 patent, col.7, ll. 58-59. The specification indicates that user access to system features is tied to the "predefined" role of the user within the system. '138 patent, col. 3, ll. 42-46 ("… a system that allows multiple types of users to access the features of the system as a function of their predefined role within the framework of the system (e.g. student, teacher, administrator).”). The specification further states: "Each user computer is associated with a user of the system having predefined characteristics indicative of a predetermined role in the system. Each role provides a level of access to data files associated with a course, and a level of control over data files associated with a course." '138 patent, col. 3, ll. 61-66.

Both the claim language and the specification describe a system in which discrete roles are set in advance within the
framework of the system. Nevertheless, Blackboard argues that a construction requiring that user characteristics and roles be established in advance within the framework of the system would be improper because it reads out a preferred embodiment disclosed in the specification. Blackboard points to the fact that an administrator (a user) can change accessible features associated with other users' particular roles within the system. See ‘138 patent, col. 12, ll. 61-63; ‘138 patent, col. 13, ll. 17-19. Blackboard maintains that if the court were to construe the claim as stated above, it improperly would eviscerate the administrator's clearly defined authority.

Blackboard correctly argues that a court generally cannot construe a patent claim so as to read out a preferred embodiment. See Vitronics, 90 F.3d at 1583 (reasoning that an interpretation that excludes a preferred embodiment is unlikely to be correct). Here, however, a construction that roles are predefined within the system does not read out a preferred embodiment. The preferred embodiment cited by Blackboard does not suggest that users (as opposed to system framework) establish predefined characteristics or predetermined roles. An administrator's ability to change access to features associated with particular user roles does not alter the fact that roles and features themselves are set in advance within the system. Rather, in the preferred embodiment scenario cited by Blackboard, the administrator simply works within his/her predetermined role in changing predefined accessible features. Stated differently, an administrator can limit accessible features for a student, but cannot change the student role itself.

"With each user being capable of having predefined characteristics indicative of multiple predetermined roles in the system" means "discrete roles and their associated characteristics to which a user can be multiply assigned are set in advance within the system."

Business Objects also challenges the district court's construction of the terms "predefined query language" and "predetermined query language." Absent any party dispute, this court construes these two terms as having the same meaning. The district court initially construed these terms to mean that a "query language that must be determined prior to the 'generating a query' step, but not necessarily prior to the associating step. Furthermore, the 'predefined [or predetermined] query language' must support the functions and operators contained in the associating step's SELECT clause." Construction Order 2003 U.S. Dist. LEXIS 26206 at *20. Business Objects disputes the portion of this claim construction requiring the predetermined language to support the functions and operators contained in the associating step's SELECT clause.

Business Objects argues that the district court's construction improperly imports the "associating step" from claim 1 into claim 4. To the contrary, this court agrees with both parties that the "query engine means" limitation of claim 4 is a means-plus-function limitation governed by 35 U.S.C. § 112, P6. This court also agrees with the parties that the corresponding structure consists of the algorithm described in column 4, lines 42-52; column 7, lines 48-54; column 8, lines 21-23; column 9, lines 14-40; and column 9, line 52 through column 13, line 2. One step of this algorithm is the generation of the SELECT statements by concatenating SELECT clauses associated with familiar names. ‘403 patent, col. 10, ll. 6-16. Because the query engine means of claim 4 must concatenate SELECT clauses associated with familiar names to generate SELECT statements in the predetermined query language, the predetermined query language must support the SELECT clauses associated with the familiar names. The district court's claim construction, therefore, is consistent with the structural limitations of the query engine means and does not improperly import the associating step limitation of claim 1. Consequently, this court affirms the district court's construction of the terms "predetermined query language" and "predefined query language."

In the instant case, the construction of claims 1 and 25 of the Lemon patent, which are included in all other claims of plaintiff's patent, are disputed by the parties. Claims 1 and 25 state: "A system for controlling the selection and dispensing of product coupons at a plurality of remote terminals located at predesignated sites such as consumer stores...." Defendant argues that "predesignated sites such as consumer stores" requires that the location of the terminal be pre-established in a specific location at the point of sale. Plaintiff argues that "predesignated sites" should be defined as "being places marked
out for the activity of selecting and dispensing coupons before such activity can take place," and "such as a consumer store" is merely an example of one possible location of the terminals, of which could include a person's home due to the ability to shop over the Internet.

"Predesignate" is defined as "to designate beforehand." Webster's New Int'l Dictionary 1785 (3rd 1986). "Site" is defined as "the original or fixed position of a thing." Webster's New Int'l Dictionary 2128 (3rd 1986). Accordingly, the ordinary and accustomed meaning of "predesignated site" in this context means "to designate beforehand the original or fixed position of a thing." The term "such as" is defined as "of a kind or character about to be indicated, suggested, or exemplified; for instance." Webster's New Int'l Dictionary 125, 2283 (3rd 1986). Accordingly, the ordinary meaning of "predesignated site" in this context means "to designate beforehand the original or fixed position of a thing." The term "such as" is defined as "of a kind or character about to be indicated, suggested, or exemplified; for instance." Webster's New Int'l Dictionary 125, 2283 (3rd 1986). The definitions of these terms demonstrate that the terminal must be placed at a place that has been designated beforehand, for example a consumer store. Therefore, the pertinent question is whether "such as a consumer store" is to be construed, narrowly, to mean "at the point of sale" or, broadly, to merely be an example of a possible location, such that the terminal could be placed anywhere.

The "Abstract" of the Lemon patent states: "A system for monitoring the distribution of product coupons from a plurality of remote terminals located at the point of sale is provided." (Emphasis added). The "Summary of the Invention" states that "by providing point of sale distribution …[a] stand alone coupon dispensing terminal is provided at each retail store … the present invention … benefits the consuming public by providing a convenient means of obtaining coupons at the point of purchase." (Emphasis added). The "Description of the Preferred Embodiments" states: "Each of terminals T is a stand alone unit to be placed at a remote location such as a retail grocery store." (Emphasis added).

During the prosecution of the Lemon patent, the inventors responded to the examiner's rejection of the invention, in part, stating, "The invention is a system for controlling the selection and dispensing of product coupons by stand alone terminals located in stores." (Emphasis added). In response to the second rejection by the Patent Office, the inventors stated, "The concepts of this invention go to the very core of couponing, beginning with the dispensing of coupons onsite and controlling coupons credibility by providing the ultimate in control over the origin of coupons." (Emphasis added). The inventors also included the declaration of Peter Engel in their response to the Patent Office's rejection of their patent. In the declaration, Peter Engel stated that the Lemon patent would have a substantial impact on the coupon industry because manufacturers would not have to mail coupons to homes or provide them in packaging of products sold because the "coupons may actually be offered on site to persons most likely to redeem them." (Emphasis added).

The claims, specification, and file history support defendant's reading of the claims. All of these sources indicate that the terminal is to be placed at a predesignated site at the point of sale, i.e., a consumer store. See Young Dental Mfg. Co. v. Q3 Special Products, Inc., 112 F.3d 1137, 1142-43 (Fed. Cir 1997) (specification and prosecution history support defendant's more narrow reading of the claim); Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) (rejecting broad definition of the term "when" because the specification provided overwhelming evidence of a narrower interpretation).

B.

While the phrase "located at predesignated sites such as consumer stores" appears only in the preamble of Claim 1, this language appears in both the preamble and body of Claim 25. Hence, the applicants specifically included this language in the claim not once, but twice. By virtue of its inclusion in the body of Claim 25, this phrase limits Claim 25. This court, therefore, must determine whether the district court's construction of the disputed phrase is correct as a matter of law.

In interpreting this language, the district court found that "predesignate" means "to designate beforehand," and that "site" means "the original or fixed position of a thing." Accordingly, the district court held that the ordinary meaning of "predesignated site" is "to designate beforehand the original or fixed position of a thing." The district court found that the term "such as" means "of a kind or character about to be indicated, suggested, or exemplified; for instance." The district court then considered whether the phrase "such as a consumer store" means that the terminals may be located anywhere or only "at the point of sale." The district court concluded that the terminals had "to be placed at a predesignated site at the point of sale, i.e., a consumer store."
Although agreeing with the dictionary definition of "predesignated site," Catalina argues that the predesignation of sites refers to "the connecting of and accepting of the terminal by the host computer." According to Mr. Wicker, Catalina's expert, "predesignated sites" "indicates that certain sites have been designated, and [] that they have been designated at a point in time prior to . . . 'the selection and dispensing of product coupons.'" Catalina further contends that the district court erred by equating "point of sale" with "consumer store." According to Catalina, the genus indicated by the species "consumer stores" is a "point of sale" location.

The district court correctly held that the ordinary meaning of "predesignated site" is "to designate beforehand the original or fixed position of a thing." Thus, the claim requires designation of a terminal site before location of a terminal at that site. Catalina's argument that "predesignated sites" refers to the recognition of a terminal by a host computer at some point before coupon selection ignores the physical dimension indicated by the phrase "located at" immediately preceding "predesignated sites." Recognition simply does not amount to predesignation. Thus, a coupon dispensing entity must designate a location for a terminal before placing it at that site. This claim language limits the scope of the claims.

The district court correctly found that the term "such as" means "of a kind or character about to be indicated, suggested, or exemplified; for instance." Despite correctly characterizing "such as" as exemplary language, the district court erroneously equated "point of sale" with "consumer store." "Such as" introduces an example of a broader genus rather than limiting the genus to the exemplary species. Moreover, the specification of the '041 patent uses the phrase "such as consumer stores" as an example of a possible point of sale location. See, e.g., '041 patent, col. 1, l. 67 - col. 2, l. 4, col. 2, ll. 32-38, and col. 4, ll. 65-67. As discussed above, the applicants stated during prosecution that their invention involved terminals "located in stores" for the dispensing of coupons "on-site." This descriptive language during the acquisition of the patent does not make the store location more than an example of a point of sale location.

This court thus holds that the phrase "located at predesignated sites such as consumer stores" requires designation of the physical site of the terminal before location of the terminal at a point of sale location.

6. "Predetermined"

Claim 1 of the '415 patent states that the LAS directs the carrier among a plurality of workstations, "each workstation adapted to conduct a predetermined test." (Filing 64-3, Ex. C, at 6:24-25.) In the '670 patent, claim 1 uses the term "predetermined" three times in the same sentence to modify a workstation, an order, and a test:

    said computer tracking movement of said first carrier along said conveyor, and directing the movement of said first carrier according to information in the database regarding the first specimen, to predetermined work stations in a predetermined order to conduct predetermined tests;

(Filing 64-4, Ex. D, at 6:4-9 (emphasis added).)

If a claim term is non-technical, is in plain English, and derives no special meaning from the patent and its prosecution history, then the court has no need to function as a thesaurus. . . . To do so could well encroach upon the factfinder's domain. The "ordinary" meaning of such terms should speak for itself, and the court should avoid merely paraphrasing claim language with less accurate terminology.

Federal Judicial Center, Patent Case Management Judicial Guide § 5.1.4.3, at 5-23 (2009); id. § 5.2.3.1.2, at 5-39 ("Where 'construing' a claim term would involve simply substituting a synonym for the claim term, it may be appropriate to allow the claim language to speak for itself."). See U.S. Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997) ("The Markman decisions do not hold that the trial judge must repeat or restate every claim term in order to comply with the ruling that claim construction is for the court. Claim construction is a matter of resolution of disputed meanings and technical scope, to clarify and when necessary to explain what the patentee covered by the claims, for use in the determination of infringement. It is not an obligatory exercise in redundancy.").

The evidence before me establishes that "predetermined" is used in the '415 and '670 patents in a non-technical sense to
The parties dispute the meaning of the term "predetermined," which appears in all of the asserted claims. O2 contends that the term needs no construction. TSE contends that the term means "fixed in advance or beforehand with intent or knowledge."

In support of its construction, TSE points to the district court's construction of a similar term in Koito Mfg., Ltd. v. Turn-Key-Tech, LLC, 381 F.3d 1142 (Fed. Cir. 2004). That case, however, is distinguishable. In Koito, the court affirmed the district court's construction of predetermined because the patentee failed to object. Moreover, the Federal Circuit observed that the invention in that case logically required the mold designer to know the flow direction of the plastic. By contrast, the court is not persuaded that the patents in this case require intent or knowledge as inherent limitations. At the same time, the
court disagrees with O2's primary position that no construction is needed. Therefore, the court construes predetermined in accordance with its ordinary meaning: "determined beforehand." Webster's Third International Dictionary, 1993.

3260

D. Predetermined

The plaintiff proposes that this term means "to know, anticipate, ascertain or determine beforehand." The defendants contend that predetermined must mean "determined before the route is created." The court defines "predetermined" to mean "determined beforehand."

3261

4. "Predetermined" (366, Claim 5, 19; '311, Claims 1, 16)

Broadcom argues that no construction is necessary for this term, while Agere seeks to construe it as "calculated before a bridging node transmits each succeeding beacon." Agere's only support for its assertion that the timing of each beacon must be calculated independently is found in the embodiments of the '366 patent. (See, e.g., '366 patent, col. 15, ll. 29-31, col. 19, ll. 18-31.) Although Agere appears to be correct in arguing that there are no embodiments that contradict its construction, there is also no language in the specifications indicating that such a construction is required. In other words, the claim term is broader than its preferred embodiments, and therefore the Court rejects Agere's proposed construction as an attempt to improperly limit the term to its specifications. In addition, Agere's argument that "predetermined" necessarily implies "calculated" is based on a tortured reading of Webster's Dictionary, which even Agere's expert admits does not define "predetermined" to mean "calculated." (See Goodman Rep. P 136 (citing Webster's dictionary definition of predetermine as "determine, decide, or establish ahead of time").) Thus, the Court finds that there is no factual support for Agere's proposed construction. Accordingly, in the absence of persuasive evidence indicating the need for a specific construction, the Court credits Dr. Acampora's testimony that both a person of skill in the art and a layperson would understand this term to have its customary meaning. (Acampora Rep. at 20.) Therefore, no construction is necessary. See W.E. Hall, 370 F.3d at 1350 (affirming district court determination that term "single piece" was "sufficiently clear to make even resort to the dictionary unnecessary").

3262

a. Do UEI's remote control devices execute a "predetermined action?"

UEI contends the words "predetermined action" in claims 1 and 6 can be read with their ordinary meaning and describe a single, specific, user-observable response by the appliance (such as channel up for a television) that has been previously determined at the time of manufacture and that the user is not free to define. In support of this construction, UEI notes, for example, that the specification at column 5, line 51, sets out the following description of the flow chart for a preferred embodiment of the program that is set out in Figure 5: "Next, the key data section of RAM 44 is automatically set to the predetermined response command. This command is a command which will cause some readily observable action to occur at the appliance to be controlled. For TV, VCR, and cable converter, the channel up command is used."

In addition, UEI notes the inventors use "predetermined" in other claims in a way that suggests it means determined by the manufacturer rather than by the user. For example, in claim 4 "predetermined" describes an intercommand time delay determined at the time of manufacture. In claim 3 "predetermined" describes the number of times a command signal will be sent before the command for the next appliance will be sent.

UEI also contends its reading of these words is consistent with how Rich used them in her Response to the Patent Office examiner's December 12, 1986 Office Action, where she wrote:
New claim 18 is the first method claim now on record. It distinguishes from German Patent DE 3313-493 in a number of important respects. The selected appliance is said to be one of a plurality of appliances of different categories as well as different manufacturers. The selected appliance is set to execute a predetermined action upon receipt of the response-evoking signal. In the DE 3313-493 patent the selected appliance does not have to be set to execute a predetermined action. Any one of the controllable actions will suffice. The German device, since it is only for different manufacturers and not for different categories, allows the trial and error signals (response command signals) to be available for every possible command. No matter which command in selected by the user, the German device will generate this command in the code of all the manufacturers covered by the remote control unit. It is already an inventive step to consider that it is not essential that this capability be available. The difficulty in setting the device to be receptive to the particular command is minimal. In many cases, simply turning on the power is sufficient.

UEI argues Rich's statement is an admission that claim 1 identified a remote control device that is preprogramed to send a particular response-evoking signal.

In response, Philips concedes that the specification's description of a preferred embodiment does provide that the response-evoking signal is predetermined by the manufacturer. Philips argues, however, that the preferred embodiment is simply one way of implementing the broad language of claim 1 and that the words "predetermined action" in claim 1 can be read as including actions determined by the user at the time he or she is stepping through the library of codes to elicit a response from the appliance.

Philips argues Rich's statement to the Patent Office spoke to the difference between the claimed invention of a remote device directed to more than one appliance and Telefunken's remote, which was dedicated to only one device. As a Telefunken remote for a television would not, for example, have buttons for a VCR such as pause or rewind, Rich was pointing out that a user of a Telefunken remote would not need to select a button from among a number of buttons to "predetermine" those that would apply to a television. For a Philips remote, he or she would first need to "predetermine" those buttons that applied to a television or VCR, before using that button to test for a response.

As used in the claims, the word "predetermined" can be read to express its ordinary meaning: to determine beforehand. While Philips contends "before hand" may only mean that the user selects the response-evoking signal before he or she presses the action button, a more logical reading of the claim suggests that what happens beforehand is that the manufacturer programs the device to use one action to test the signal structure. This is what the inventors described in the preferred embodiment, by noting that for a television the unit would be preprogramed to send the signal for channel up. That is consistent with one of the objectives the inventors listed in the summary of invention, to make the unit simple to operate. By programming the response evoking signal, the inventors have reduced the number of buttons to be pushed by the user, eliminated the need for the user to make a choice as to what signal to send, and have, therefore, simplified the operation of the unit. Rich's comments to the examiner support and are consistent with this construction. As used in claims 1 and 6, the phrase "predetermined action" is construed to mean an action that is determined by the manufacturer.

4. A Certain Predetermined Balance

The meaning of "a certain predetermined balance" turns on the intended meaning of the word predetermined. Webster's defines predetermined as "(1) (a) foreordain, predestine (b) determine beforehand (2) to impose a direction or tendency on beforehand." WEBSTER'S at 978. Although both parties agree that the correct meaning is "determine beforehand," they disagree about how far beforehand the certain balance must be determined. Fiala proposes that "a certain predetermined balance" means "a balance that is fixed and stated prior to crediting of the metered account." (Pl. Brief at 31.) SVS submits that the term means "a fixed value given to a card prior to shipment to retail merchants." (Def. Brief at 14.)

SVS contends that adopting Fiala's proposed construction of the phrase would render claim language superfluous. Every word in the claim is presumed to add meaning, and the claim should not be read in such a way as to render claim language superfluous. See Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1557 (Fed. Cir. 1995). According to SVS, any balance credited to the metered account must necessarily be determined before the account is credited with a dollar amount. For the word "predetermined" to add meaning to the claim, it must require the balance to be fixed at some earlier time. (See
SVS Resp. at 18.) SVS cites the specification as guidance for the precise time the balance must be determined.

In several instances, the specification refers to problems in the prior art surrounding the use of so-called "hot cards." See, e.g., U.S. Patent No. 5,918,909, Column 18:41-50, 18:51-54, 1:24-35. Hot cards are shipped with a metered account that is already activated; the balance on the account must, therefore, also be fixed. See id. That the prior art described cards with balances fixed before shipping, however, does not require that this definition be read into claim 29. In fact, a "predetermined balance" of this kind was part of the problem that the '909 invention sought to address.

Other aspects of the specification also contradict SVS's proposed meaning. "The metered account may have been credited with a certain predetermined balance when the metered account was entered into the digital computer [prior to shipping], but, if not, the digital computer will ... credit the metered account with a certain predetermined balance [when the card is activated by the store clerk at the time of purchase]." U.S. Patent No. 5,918,909, Column 20:1-5. The specification supports Fiala's construction and permits giving the card value either before shipment or at the time of activation. Claim terms are given their ordinary and customary meaning absent some contrary meaning indicated in the specification or the prosecution history. See Teleflex, 299 F.3d at 1324-25; Johnson Worldwide Assoes. v. Zebco Corp., 175 F.3d 985, 990 (Fed. Cir. 1999). As discussed above, the specification supports the ordinary meaning of predetermined as "determined beforehand." The prosecution history indicates no intent to vary from the ordinary and customary meaning. There is no indication that a person of ordinary skill in the art at the time of invention would have understood predetermined to mean determined before shipping as opposed to determined before the crediting of the account. Nothing supports the imposition of additional limitations not found in the claim language itself. The court, therefore, reads the claim language as supporting Fiala's interpretation rather than SVS's interpretation.

Having considered the claim language, specification and prosecution history, the court construes "a certain predetermined balance" to mean: "crediting the metered account with a balance that is fixed and stated prior to crediting of the metered account." The evidence before the court indicates that a person of ordinary skill in the art would have so defined "a certain predetermined balance" at the time the patent was prosecuted, and this interpretation is consistent with the clear meaning of the claim language.

2. Predetermined Condition.

The Court believes, contrary to Leviton, that the term "predetermined condition" is not clear on its face to one of ordinary skill in the art and that, therefore, it requires construction. The term "predetermined condition" is not specifically defined or described in the '766 patent. See The '766 Patent. The Defendants' initial proposed construction of the term is "the occurrence of a current imbalance from an actual or artificially induced ground fault." Defendants' Memo at 32.

In their initial memorandum in support of their proposed claim constructions, the Defendants' assert that the specification describes only three conditions in which the "circuit interrupting portion" would cause "electric discontinuity:" sensing an actual fault, pressing the test button, and pressing the reset button. See Defendants' Memo at 32; The '766 Patent, Col. 7, ll. 13-18; id. at Col. 7, ll. 19-23; id. at Col. 8, ll. 35-38; id. at Col. 6, ll. 8-12. The Court agrees that those are the only three conditions that the specification describes that would lead the circuit interrupting portion to cause electric discontinuity. See The '766 Patent. The Defendants, in their initial claim construction briefing, also maintain that those three conditions have one thing in common: they create a circuit imbalance from an actual or artificially induced ground fault. See Defendants' Memo at 32-33; The '766 Patent, Col 3, ll. 1-5; see id. at Col 3, ll. 21-31.

In further support of their construction, the Defendants cite Dr. De La Ere's testimony concerning the '558 patent. See Defendants' Response at 14. The Defendants point out that Dr. De La Ere testified that "predetermined condition" meant the same thing in U.S. Pat. No. 6,040,967 ("the '967 patent") and the '558 patent, see Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d at 1334 ("We presume, unless otherwise compelled, that the same claim term in the same patent or related patents carries the same construed meaning."); August 31 De La Ere Deposition at 68:17-20; id. at 69:3-6, and that he admitted that the term "test cycle," as used therein, was synonymous with "stimulating a ground fault," see Defendants' Response, Exhibit A, Deposition of Jaime De La Ere at 149:18 (taken December 14, 2004)("December 14 De La Ere Deposition"); id. at 150:2.
Leviton contends that the '766 patent incorporates by reference the language concerning "predetermined condition" contained in the '967 patent. See Leviton's Response at 11-12. The Court concurs. See The '766 Patent at Col. 1, 12-15. With regard to "predetermined condition," the '967 patent states: "Predetermined conditions include, without limitation, ground faults, arc faults, appliance leakage faults, immersion faults and a test cycle." The '967 Patent at Col.2, ll. 25-27. Leviton also contends that "arc faults" and "test cycles" do not necessarily create or require current imbalances. 1 See Leviton's Response at 12. The Defendants respond to that contention by noting that may be true, but pointing out that in such "open-neutral" test circumstances, the circuit interrupting portion does not cause electrical discontinuity -- because no electricity is flowing through the device -- and that the relevant claim expressly states: "A circuit interrupting portion configured to cause electrical discontinuity." Transcript at 53:9-54:18 (Fry); The '766 Patent, Claim 1. Essentially, the Defendants argue that the claim language effectively excludes "open-neutral test cycles" that do not cause current imbalances, and that, therefore, the "upon the occurrence of a current imbalance" portion of their proposed claim construction is correct. See id. The Court also notes that the proposed construction the Defendants presented at the Markman hearing replaced "ground fault" with "electrical fault," seemingly acknowledging that the '967 patent was incorporated by reference and that it allows for the possibility that the circuit interrupting portion may cause electrical discontinuity upon the occurrence of arc faults, appliance leakage faults, immersion faults, in addition to ground faults and test cycles. See Defendants' Presentation at 73.

1 Leviton does not discuss the circumstances surrounding such "arc faults," and thus fails to give the Court sufficient information to evaluate this element of Leviton's contention.

The Court believes that the term "predetermined condition" is not clear on its face to one of ordinary skill in the art and that, therefore, construction is required. The Court finds that the '967 patent is incorporated by reference in the '766 patent, and that, as a result, it is proper to use "electrical fault," rather than "ground fault." Defendants' Memo at 32; Defendants' Presentation at 73. Moreover, the Court notes that Dr. De La Ere has testified that, for purposes of the '558 patent, "test cycle" is synonymous with "stimulating a ground fault," see December 14 De La Ere Deposition at 149:18; id. at 150:2, and that it is not disputed that ground faults create and/or require current imbalances. Further, the Court agrees with the Defendants and finds that the claim language excludes "open-neutral test cycles" that would not create or require current imbalances. As such, the Court will adopt the Defendants' proposed claim construction for "predetermined condition."

3265

(5) "Predetermined Data Element"

EMC contends that a predetermined data element is a particular piece of data, of any size, that may be identified in some predetermined way, for example, by the address where it is stored. HP counters that a predetermined data element is a subunit of host data, such as a track or record, which is stored on the data storage system. The issue is, therefore, whether a predetermined data element includes subunits of data as well as the data on an entire data storage device.

Although the term "predetermined data element" as a whole means little, the plain meaning of each word in the phrase is instructive. The ordinary meaning of the word "predetermine" is "to determine beforehand." Webster's Third International Dictionary, 1786 (1981) and the word "element" means "one of the constituent parts, principles, materials, or traits of anything." Id. at 734. Thus, in the context of the subject patents, a predetermined data element is a part or unit of data the identity of which is determined beforehand and which is stored on the first or second data storage system. Nothing in that definition excludes the data contained in an entire data storage device. Indeed, such data has been identified beforehand as all of the data stored on a particular storage device. Moreover, that data is a part or unit of all of the data stored on all of the data storage devices (of which there may be hundreds) within a data storage system.

The explicit language of the Specification of the '347 Patent (set forth at length in the preceding section of this Memorandum) is also instructive here. See '347 Patent, Col. 7, In. 32 - Col. 8, In. 30; see also '347 Patent, Col. 3, ll. 19-32; Col. 7, ll. 13-31. Although the phrase "predetermined data element" is conspicuously absent from the Specification, if an "indicator", which indicates data validity, includes both invalid track and device level information, a predetermined data
element can also include data at the track level or the device level. Additionally, Figures 2 and 3 in the Specification of the '347 Patent illustrate that a predetermined data element can include both track level data and the data stored in an entire storage device.

Finally, EMC did not, explicitly or implicitly, limit the meaning of the term "predetermined data element" in the prosecution of the subject patents. Accordingly, the term "predetermined data element" will be construed to mean a part or unit of data, including the data on an entire storage device, which identity is determined beforehand and which is stored in the first or second data storage system.

3. "Predetermined database": A set of decision-making rules that incorporate a medical code classification system and expert medical clinical judgment and that are not programmed to be modified by the user. 8

7 The '164 patent claims 1, 2, 3, 10, 12, 13, 14, 15 and 16.8 The court rejects both parties' positions vis a vis this limitation as being either too broad (plaintiff) or too narrow (defendant). The court finds support for its construction in the specification of the '164 patent:

"The present invention uses a set of decision-making rules coupled to a knowledge base of facts and observations to assist the medical claims processor." ('164 patent, col. 3, ll. 30-32) "[A] set of rules developed for use of this program is now invoked. These rules were derived using the CPT-4 classification system, and from various medical procedures which were examined, classified, and possible combinations of procedures assessed by expert medical specialists. . . . Each of the rules was developed as a result of reviewing medical procedures by expert medical personnel and is consistent with the CPT-4 classification system. However, expert medical personnel also applied clinical judgment to situations where the CPT-4 classification system is not explicit or nonexistent." ('164 patent, col. 5, l. 67 - col. 6, l. 13)

2. The "Preventing" Step, "Means for Preventing," and "Prevention Means"

As stated in Section I of this Order, Gammino contends that the patents in dispute selectively block international access calls based on predetermined digits and do not require the blocking of all international calls. He asserts that the claims block only international access calls with dialing sequences that meet two criteria, namely, the third plurality of numbers within the sequence are (1) in a position to accomplish international dialing, and (2) are predetermined numbers. Further, he asserts that the claims do not automatically block all access calls but only a sub-category of access calls that are selected for blocking based on predetermined digits. Based on Gammino's proposed claim construction, his patented method would prevent the calls that cause fraudulent losses, and at the same time, continue calls that generate profits.

However, SWB contends that the claims block all international telephone calls at the payphone if the digits entered in the third plurality indicate that the telephone call is international. Gammino's claimed invention distinguishes international calls from non-international calls by analyzing the third plurality of digits. According to SWB, Gammino's solution successfully prevented fraudulent telephone calls at the Port Authority because it blocked all international dialing at the Port Authority? blocking both legitimate international telephone calls and fraudulent international telephone calls when the digits in the third plurality indicate the call is international.

Based on the intrinsic evidence and a reading of (1) the claims, (2) the specification of the patents, and (3) the prosecution history of the patents, the Court construes the terms "preventing" step, the "means for preventing," and the "prevention means" of disputed Claims 1, 15, 22, 35 and 42 of the '125 patent and disputed Claims land 3 of the '650 patent to require the blocking of all international calls if the third plurality of digits indicates that the telephone call is international. In other
words, based on clear intrinsic evidence, the Court defines the preventing function of the claims to require the blocking of all international calls.

The patents state that a device must block all international calls if the third plurality of digits indicate that the telephone call is international in order to be in accordance with the claimed invention. For example, Claim 1 of the '125 patent provides, in pertinent part,

means for evaluating said third plurality of dialing signals and for preventing establishment of said telephone call if said evaluated third plurality of dialing signals are determined to a) be in a location in said dialing sequence to accomplish international dialing and b) respective predetermined signals which are used for international dialing irrespective of said second plurality of dialing signals.

125 patent, col. 10, lines 34-41 (emphasis added).

During the prosecution of his patents, Gammino repeatedly distinguished prior art that did not block all international calls. The Patent Office rejected Gammino's patents eight times based on prior art call-blocking solutions which blocked some, but not all, international calls. In particular, the Patent Office determined that U.S. Patent No. 4,577,066 (the "Bimonte" patent) anticipated many of Gammino's claims because the Bimonte patent also blocked international calls. To distinguish his patents from Bimonte and other prior art, Gammino argued that his patents, unlike other prior art, blocked all international calls based on an analysis of the third plurality of digits. In so distinguishing his patents, Gammino made the following statements to the Patent Office:

"If the digits in the third plurality of digits are digits which are used for international dialing then the call is prevented."

"If certain dialing in the dialing sequence are DETERMINED to be used for international dialing, then prevent the call...If...certain dialing signals are DETERMINED not to be used for international dialing, then allow the call."

"Applicant is preventing international calls based upon a determination that the call is international. In this way, for example, international calling card fraud is prevented."

Therefore, according to Gammino, if a call is international, his claimed invention will block the call; otherwise, the call will be allowed. For example, Gammino distinguished the Bimonte patent by showing the Patent Office that his claimed invention, unlike Bimonte's patent, would block 1-800-950-1XXX-01. As he stated to the Patent Office,

To put the matter in simple terms, Applicant's claimed invention will prevent the call dialed with the following sequence: 1 800 950 lxxx 01. The digits 01 of course mean that the call is an international one. Bimonte will allow this call to go through because it does not prevent a call based on its determination that the call is international.

He then goes on to say,

In other words, Applicant's claimed invention 'looks for' international dialing digits. If Applicant's invention 'finds' international dialing digits, then establishment of the call is prevented.

Thus, based on his own statements to the Patent Office, if his invention "finds" international dialing digits, the call is blocked.

In addition, to overcome the examiner's rejections, Gammino submitted several news articles that highlighted the fact his claimed invention blocked all international calls. For example, Gammino submitted the July 1992 issue of Public Communications Magazine to show that New York Telephone was using his claimed invention, "permanently blocking international calls from several thousand of its payphones in the Port Authority Bus Terminal..." Likewise, he submitted a Port Authority memorandum to the Patent Office wherein Ken Philmus, a Port Authority official, acknowledged that Gammino's solution "blocked all international calls" and resulted in a "small down side" that legitimate calls would also be blocked.

In light of the evidence and arguments submitted to the Patent Office by Gammino, the examiner understood Gammino's
claimed invention blocked all international calls throughout the prosecution. This understanding is reflected by the examiner's following statement,

All appellant's statements regarding 'prevention of fraudulent international calls' are not exactly accurate because the invention prevents ALL international calls. In examiner's opinion, based on the declarations provided by appellant, the claimed invention does not solve the problem of fraudulent international calls, it solves the problem of having anyone making any international call from Port Authority Bus Terminal.

Gammino confirmed the examiner's understanding that his claimed invention blocked all international calls by stating,

The fact that Appellant's claimed invention will block ALL international calls is irrelevant to the decision of patentability of the claimed invention.

As SWB correctly notes, Gammino's confirmation and subsequent acquiescence to the examiner's understanding that his claimed invention prevents all international calls precludes him from now arguing that his claimed invention does not include the requirement of blocking all international calls. Phillips, 415 F.3d at 1317; Norian Corp. v. Stryker Corp. 432 F.3d 1356, 1362 (Fed. Cir. 2005)(a patentee cannot recapture broader claim interpretations after acquiescing to a narrower interpretation in distinguishing prior art); See also Glaxo Wellcome, Inc. v. Impax Laboratories, Inc., 356 F.3d 1348, 1357 (Fed. Cir. 2004).

In an attempt to overcome SWB's proposed claim construction, Gammino contends in his Claim Construction Reply Brief that the claims and specification in the 125 and '650 patents provide for the selective prevention of some but not all international calls. See '125 patent, col. 1, lines, 10-15. Although the claims and specification provide for the "selective disablement of telecommunications devices," Gammino ignores the fact that in distinguishing prior art, as stated above, he told the Patent Office on numerous occasions that his claimed invention blocked all international calls and acquiesced to the examiner's interpretation that his claimed invention blocked all international calls. Phillips, 415 F.3d at 1317; Norian Corp., 432 F.3d at 1362. In any event, the patents are anticipated under Gammino's interpretation as set forth in Section III of this Order.

In his Claim Construction Brief, Gammino also points to examples of calls that do not include international dialing digits in the third plurality to show that those calls are international and not blocked by his claimed invention. As stated above, Gammino's claimed invention distinguishes international calls from non-international calls by analyzing the third plurality of digits. The Court does not dispute that those calls are not blocked by his claimed invention? Gammino's claimed invention blocks calls based on an analysis of the third pluralities. Therefore, the Court finds Gammino's argument without merit. If the digits in the third plurality are used for international dialing, then as Gammino has stated, the call is prevented.

Based on the intrinsic evidence, particularly the prosecution history, Gammino understood his invention to block all international calls. Phillips, 415 F.3d at 1317. Therefore, he limited his invention in the course of prosecution to mean the blocking of all international calls. Id. The Court interprets the "preventing" function of the claims of the patents to require the blocking of all international telephone calls if the digits in the third plurality are digits which are used for international dialing.

3. Predetermined Signals or Digit Sequences Used For or To Accomplish International Dialing

For the reasons set forth in Section IV(A) (2) of this Order and discussed in this section, the Court construes "predetermined sequences [signals] which are used for international dialing" in disputed Claims 1, 22 and 29 of the '125 Patent and disputed Claim 1 of the '650 patent to mean "the set of all digits which are used for international dialing." Similarly, the Court finds that "predetermined digit sequences" in disputed Claim 3 of the '650 patent to mean "the set of all signals which are used for international dialing."

Gammino asks this Court to construe this language to mean any of the signals that can be used for international dialing. However, Gammino's arguments made during prosecution contradict this interpretation. In fact, Gammino recognized that his invention blocked all international calls when he stated that his invention is "particularly suited for locations where few legitimate calls are typically made to international locations," and therefore, his "claimed invention would probably not be used at an airport" where many legitimate international phone calls are made. Gammino also submitted to the Patent Office
a license agreement whereby he licensed his patent applications to Technology Service Group, Inc. ("TSG"). Gammino told the Patent Office that the dialing sequences (e.g., telephone numbers) listed in the TSG License Agreement correspond exactly to his claimed invention. The telephone numbers listed as Exhibit A in the license agreement are:

- 10xxx-01
- 950-10xxx-01
- 1800-xxx-xxxx-01
- 800-xxx-xxxx-01
- 950-10xx-809
- 1800-xxx-xxxx-809
- 800-xxx-xxxx-809

The numbers listed above represent all known telephone numbers for making international calls as of 1992 and as Gammino stated they correspond exactly to his claimed invention. Based on Gammino's statements to the Patent Office regarding the license agreement, "predetermined digit sequences [signals] which are used for international dialing" and "predetermined digit sequences" must mean "the set of all digit sequences which are used for international dialing." Therefore, the Court gives the terms their meaning as proposed by SWB and as supported by intrinsic evidence. Such an interpretation is consistent with the Court's construction set forth in Section IV (A) (2) of this Order.

F. Predetermined Digital Identification

Plaintiff contends that the "predetermined digital identification" can be known in advance or calculated at the moment it is verified. Conversely, Defendants argue that the "predetermined digital identification" cannot be calculated at the moment because it must be a unique preassigned data string that cannot be shared with others. (D.I. 268 at 11).

Defendants base their contention on language in the specification calling for the "predetermined digital identification" to be microcoded onto a subscriber's hardware key. (See '416 Patent, col. 6, ll. 54-55, col. 14, ll. 52-53). However, the language in Claims 1 and 24 does not require that the hardware key be microcoded with a "predetermined digital identification." Rather, Claim 1 refers to "at least one hardware key being adapted to generate a predetermined digital identification," with no specific limitation on when that information is generated. ('416 Patent, col. 35, ll. 47-48)(emphasis added). Moreover, Defendants' proposed construction would invalidate dependant claims 6 and 31, which each state that the first server computer can change the predetermined digital identification. ('416 Patent, col. 40, ll. 13-15).

In light of these considerations, and guided by the claim and specification language, the Court declines to import the specification limitation of microcoding into the claim language as Defendants propose. Instead, the Court construes the term "predetermined digital identification" to mean "digital data whose value is known in advance or calculated at the moment."

2. "time interval of predetermined duration"

The district court construed the "time interval of predetermined duration" limitation to mean that "the time interval of the recorded signal must be of a fixed duration determined prior to operation." Summary Judgment Opinion at 22. The district court defined "interval" as a "space of time between events or states," and "predetermined" as "to determine beforehand." Id. at 19 (citing Merriam Webster's Collegiate Dictionary 613, 917 (10th ed. 1993)). The district court explained that "predetermined duration" means that the space of time for receipt of the signal values was determined before the time interval began. Id. The court noted that the parties agreed that "'predetermined' refers to before the time the system begins storing signals—whether the company sets the time interval, or the user sets the time interval before watching." Id. The court went on to explain that the written description supports this construction because it refers to the amount of programming stored in the memory as "fixed," and that the prosecution history supports the construction because the applicant added the...
We recognize that the user can vary the buffer capacity and thus the amount of programming that may be stored by changing the buffer size. Amendment to overcome the cited prior art.

The district court rejected Pause's argument that "because the '801 patent contemplates that the actual or effective capacity of the buffer may change [based on the compression ratio], the time interval of predetermined duration necessarily must refer to a minimum capacity of the buffer—that is, the buffer must be sufficiently large to hold signals of the predetermined duration." Id. at 18 (internal quotations omitted). The court reasoned that "while the program capacity of the buffer can be increased by adjusting the compression ratio, the patent describes fixing the time interval for recording before recording begins." Id. at 21. The district court concluded that "in this way a predetermined and fixed amount of programming is stored in the buffer during operation, no matter what the compression ratio." Id.

Pause argues that determining the "time interval" of signal values entering the buffer is not equivalent to fixing the "time interval" of signal values entering the buffer. Pause contends that the time interval can change after the buffer begins receiving signals so long as the buffer stores at least the data received during the predetermined time period. Pause adds that the district court erroneously imported a limitation from an embodiment and erred in relying on prosecution history. TiVo responds that the time interval must be fixed prior to operation. Again, we agree with TiVo.

The claim recites that the "circular storage buffer [is] for storing those of said digital input signal values which were received during the immediately preceding time intervals of predetermined duration," '801 reissue patent, col. 6, ll. 13-16, and that the oldest signals are overwritten "so that said digital input signal values received during said immediately preceding time interval of predetermined duration are stored in said addressable memory," id., ll. 33-36. The parties agree that time interval refers to the space of time in which the signal values are received and that this space of time must be determined before the buffer begins receiving the signals. The parties agree that the determination can be made by either the manufacturer or the user of the system. The dispute is over what the claim requires to be determined. By arguing that the "time interval" can vary after the determination is made and the buffer begins receiving signals, Pause attaches no significance to the word "predetermine." In construing claims, however, we must give each claim term the respect that it is due. Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."). The written description explains that:

the memory subsystem 5 continually stores the incoming data [that was received during the immediately preceding time interval of predetermined duration], writing over the oldest data stored on the hard disk 7, so that a fixed duration or "time window" of prior recorded signals are recorded in the memory subsystem 5 at all times.

Using the remote control 13, or the connected computer 14, the user may select for viewing on the monitor 10 not only a particular incoming program but may select any point in time within the stored time window.

'801 reissue patent, col. 3, ll. 11-15 & 63-66 (emphasized). Pause argues that because the phrase "fixed duration or 'time window'" is in the disjunctive, the written description indicates that a time window is an alternative to a fixed duration of signals recorded in the buffer. However, the use of the quotation marks and the context of the surrounding text shows that this phrase does not specify two alternative time intervals but simply describes in different words the same interval. This supports an interpretation of the claim to require that signals received during the immediately preceding time interval—of a duration fixed prior to operation—be stored in the addressable memory.

The prosecution history is consistent with this construction. In a March 14, 1997 Response to an Office Action ("Response"), the applicant explained that:

applicants' invention particularly claims the use of a circular buffer in order to provide a continuous recording capability wherein only a specified interval of the most recently recorded material is retained. Among other advantages, this eliminates a specific drawback of prior art devices, such as that disclosed in the cited Goldwasser et al., whereby recording is stopped when the capacity of the storage medium, whether videotape or RAM, is reached.

Response at 2 (emphasis added). This indicates that the duration of the time interval in which signal values are recorded into the buffer is "specified" prior to operation. Id. As noted supra, the "time interval of predetermined duration" language was eventually added via Amendment to overcome the cited prior art.

We recognize that the user can vary the buffer capacity and thus the amount of programming that may be stored by changing
the compression ratio. '801 reissue patent, col. 6, ll. 20-21 ("the duration of said interval being selectable in response to said control commands"); id., ll. 64-65 (the "compression means is responsive to said processor means for varying the compression ratio"). However, a variation of buffer capacity by the user does nothing more than predetermine a new "time interval," which is then fixed prior to re-commenced operation.

For these reasons, we conclude that the district court properly construed "time interval of predetermined duration" to mean that the duration of the time interval for recording signals into the buffer memory must be fixed prior to operation.

1. "a timer circuit . . . for providing a time-out sequence of a predetermined duration"

O2 Micro proposes that the Court adopt the following construction: "a circuit that provides a predetermined amount of time before shutdown occurs." MPS, arguing that the timer circuit has no role in the circuit's shutdown process, proposes an alternative construction: "a circuit that measures a time period having a duration determined beforehand."

The claim language clearly provides that it is the protection circuit, not the timer circuit, that shuts down the power supply to the CCFL. See '382 patent, col.11:13-16. Thus, contrary to O2 Micro's argument, it is not necessary to include language calling for "shutdown" in the description of the timer circuit. At the claim construction hearing, O2 Micro agreed that the "time-out sequence" is a time period. Accordingly, the Court construes the language above as follows: "a timer circuit . . . that measures a time period having a duration determined beforehand."

2. "predetermined length of time"

While the parties point out flaws in their respective proposals, according to the parties' technology tutorials, the parties agree on the basic operation of the invention disclosed in the '689 specification. The '689 specification describes a preferred embodiment in which the predetermined length of time varies between 3.56ms and 7.12ms depending on when the SDENTR signal is asserted relative to the external clock. '689 Pat. at 8:30-47. Nonetheless, Defendants appear to argue that claim 5 requires that the predetermined length of time be an exact time, e.g. exactly 4ms, rather than a time period, e.g. 3.56ms-7.12ms.

Defendants point out that, as originally written, the patentee tried to claim a "predetermined minimum amount of time." Defendants argue that because these claims were abandoned or rejected, the patentee may not now reclaim subject matter that it abandoned during prosecution. Defendants' argument is misplaced for two reasons. First, by removing the word "minimum" the patentee broadened the scope of its claims; these amendments did not narrow claim scope. For example, a minimum amount of time would be "at least 5ms." A "length of time" may include, "exactly 5ms," "at least 5ms," "between 3ms and 7ms," or "up to 5ms." Second, although the prosecution history cited by Defendants shows that the patentee removed the word "minimum" from the claims, the patentee offered no explanation for why this change was made. This amendment does not clearly and unambiguously disclaim any claim scope, and it certainly does not disclaim the preferred embodiment. See Omega Eng'g, Inc., 334 F.3d at 1323. Accordingly, the Court rejects Defendants proposal to the extent that it limits the predetermined length of time to a predetermined exact time.

The Court finds that Saxon's construction does not clearly encompass the idea that the predetermined length of time refers to a time that may vary within a known time period. The Court finds that the proper construction of the term "predetermined length of time" is "a length of time within a known time period." Because this construction resolves the parties' claim scope dispute, the larger phrase "stopping said at least one output clock signal after a predetermined length of time after receiving said disable request signal" need not be construed. See O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1362 (Fed. Cir. 2008); Fenner Inv. Ltd. v. Microsoft Corp., No. 6:07-cv-8, 2008 U.S. Dist. LEXIS 65686, 2008 WL 3981383 at *3 (E.D. Tex. Aug. 22, 2008) (finding that a court need not construe a disputed term as long as it has resolved the claim scope dispute between the parties).

Blackboard proposes "providing access and control to course files over the network, where the level of access and control is set before the user can access or control course files." D2L suggests "the authority to locate, view, read, download, modify, add, move, and delete files associated with a course is provided by the system, not by a user."

The dispute is over how to construe "predetermined," and reproduces arguments of the parties regarding the identical word in Claim 1. Blackboard again argues that its construction accounts for a temporal limitation consistent with the plain meaning of the term. D2L again claims that "predetermined" references levels of access and control provided by the primal system framework and not by a subsequent user.
The term "predetermined" denotes that levels of access and control are set in advance. See 138 patent, col. 32, ll. 36-43; see, e.g., THE MERRIAM-WEBSTER THIRD NEW INTERNATIONAL DICTIONARY, UNABRIDGED (2002). Claim 36(c) refers to the level of access and control set within the system for users who have characteristics identifying the user as a student, while Claim 36(d) refers to the level of access and control set within the system for users who have characteristics identifying the user as other than a student. The claim language and the specification teach that each user's level of access and control to course files is tied to that user's predetermined role (e.g. student, instructor, administrator). See '138 patent, col. 32, ll. 25-27; '138 patent, col. 4, ll. 7-25. As determined earlier, a user's access to system features is based upon the user's role within the framework of the system. '138 patent, col. 3, ll. 42-46.

The court earlier drew a distinction between an administrator's ability to change access to features associated with a particular user's role and changing the role itself. That distinction also applies to this disputed term in Claim 36(c) and (d), i.e. "predetermined level of access and control." To repeat, the system itself, not an administrator, determines a user's level of access and control over the network to course files. An administrator cannot change the level of access and control, but may change some accessible features at a given user's level.

D2L's proposal embraces these ideas generally, but D2L adds language that unnecessarily limits the claim. There is no basis in the claim language to include the terms "locate, view, read, download, modify, add, move and delete" in place of "access and control."

"Providing a predetermined level of access and control" means "the level of access and control is set in advance within the system."

F. "predetermined match weight" / "predetermined mismatch weight"

These terms appear in claim 31: "when at least one of the attributes and the text match the stored case model, the score is increased by a predetermined match weight" and "when at least one of the attributes and the text does not match the stored case mode, the score is decreased by a predetermined mismatch weight." The specification does not use the terms "predetermined match weight" or "predetermined mismatch weight," but it does contain "match-weight" and "mismatch-weight":

The raw score of a stored case model may increase or decrease in differing amounts depending on the particular feature (i.e., attribute) being searched. Thus, if feature[1] matches, the raw score may increase by match-weight, while if feature[2] matches, the raw score may increase by match-weight[2]. Similarly, if feature[1] does not match, the raw score may decreased by mismatch-weight[1], while if feature[2] does not match, the raw score may decrease by mismatch-weight[2]. It is preferred that the match-weight of each feature is a positive number and that the mismatch-weight is zero.

('947 patent, 8:48-57) (emphasis added). Bright Response argues that "predetermined match weight" should be construed as "a predetermined factor controlling the degree to which a stored case model's score is increased by a comparison of text and attributes from a case model with those from a stored case model." Likewise, for "predetermined mismatch weight," Bright Response proposes "a predetermined factor controlling the degree to which a stored case model's score is decreased by a comparison of text and attributes from a case model with those from a stored case model." On the other hand, the defendants' proposed construction of "predetermined match weight" is "a predetermined factor which is added to a stored case model's match score when a feature from the stored case model matches text and attributes from the presented case model"; their proposal for "predetermined mismatch weight" is "a predetermined factor which is subtracted from a stored case model's match score when a feature from the stored case model does not match text and attributes from the presented case model."

The defendants argue that the plain language of claim 31, which states that the score is "increased by" and "decreased by" the predetermined weights, requires addition and subtraction. But the court is not persuaded that the claim language excludes other mathematical operations, such as multiplication and division. On the other hand, Bright Response's "controlling the degree" language is vague. Therefore, the court construes "predetermined match weight" to mean "a
predetermined factor that arithmetically increases a stored case model's match score when a feature from the stored case model matches text and attributes from the presented case model." The term "predetermined mismatch weight" is construed to mean "a predetermined factor which arithmetically decreases a stored case model's match score when a feature from the stored case model does not match text and attributes from the presented case model."

3274

3. "Predetermined Maximum Peak-to-peak Value."

The court shall apply the ordinary definition of the phrase "predetermined maximum peak-to-peak value." Thus, the phrase "predetermined maximum peak-to-peak value" shall be construed to mean "a predetermined value that the peak-to-peak voltage produced by the resistive divider will not exceed."

3275

5. Predetermined Number of Digital Bits

Each digital word in the digitized image consists of one or more bits of information, where the number of bits in each word is preselected and constant for a given set of broad band information.

3276

b. Claim 5

Claim 5 of the '892 patent reads (bracketed text and letters provided for ease of reference):

[Preamble] 5. A method of providing a bingo game comprising the steps of:

[A] providing a bingo operator for determining at least one winning bingo pattern;

[B] registering at least one bingo card bearing a plurality of bingo numbers with said operator;

[C] generating a predetermined number of random bingo numbers; and,

[D] identifying all registered bingo cards on which the generated random bingo numbers form one of said at least one [sic] winning bingo pattern and,

[E] awarding the holder of the winning bingo card an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed.

c. Defendant's Proposed Constructions

Defendant contends the Court should give the following terms the meaning they would have had to a person of ordinary skill in the art in light of the intrinsic record. In this regard, Defendant asserts that the following terms should have the following constructions

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.
The term "registering at least one bingo card" from paragraph [B]: Assigning each card an identify that will differentiate that card from all the others in play.

The term "a predetermined number of random bingo numbers" from paragraph [C]: The specific and predesignated quantity of random bingo numbers that will be played during a complete bingo game after which the game will end.

The term "an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed" from paragraph [E]: An award of any type in which the value of the award is not based upon how many cards have a winning pattern.

c. Plaintiff's Proposed Constructions

Plaintiff contends that, based upon the general acceptance of certain terms by the public and by using dictionary definitions, the following terms should be constructed as follows:

"Bingo game" - a "traditional" bingo game as that term is understood by the general public. In this regard, Plaintiff suggests that the Court construct the term "bingo game" within Claim 5 as:

a game simultaneously played by multiple players that contains the following elements: (1) displayed cards that bear numbers, (2) which must be daubed on each card when numbers are determined by random means during the game, and (3) which game is won by at least the first person to hold a card on which a previously designated arrangement of numbers has been covered.

"Predetermined number" of random bingo numbers: Plaintiff argues that the term "predetermined number" should be construed in accordance with the dictionary definition of "predetermined." In this regard, Plaintiff argues that the construction should be: "A number or range of numbers that is determined, decided, or established in advance."

"Registered": Plaintiff argues that the term should be construed as follows:

identifying a discrete bingo card chosen by a player, communicating the pattern of that card to the game operator, and having the game operator record the pattern of the card prior to play of a discrete bingo game.

III. CONCLUSION

Having carefully reviewed the text of Claim 5, the specification, and the prosecution history of the '892 patent, and having considered the parties' arguments presented at the Markman Hearing, the Court finds that the construction proposed by Defendant is, in all respects, proper. The '892 patent was proposed and amended in order to distinguish the patent from prior art. Plaintiff's proposed construction would have the opposite effect. Therefore, the Court finds as a matter of the law that the following terms from Claim 5 shall have the following constructions:

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.

The term "registering at least one bingo card" from paragraph [B]: Assigning each card an identify that will differentiate that card from all the others in play.

The term "a predetermined number of random bingo numbers" from paragraph [C]: The specific and predesignated quantity of random bingo numbers that will be played during a complete bingo game after which the game will end.

The term "an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed" from paragraph [E]: An award of any type in which the value of the award is not based
The parties disagree about the meaning of "predetermined" and "expected." Curiously, Innovatron urges a narrow reading under which, "predetermined operations and 'predetermined expected response' are technical terms and mean operations and responses, respectively, that are established at the time of design and do not change over time." Innovatron's Prop. Or.

Thomson, on the other hand, argues that:

'Predetermined' means 'determined beforehand.' 'Expected' means 'predicted' or 'to look forward to the probable occurrence or appearance of.' Neither word requires a determination at the time of the design of the electric device which cannot change over time.

Thomson's Prop. Or.

The ALJ adopted Innovatron's narrow construction. The Commission disagreed. "We find nothing in the specification or the claim that indicates that predetermined operations must be established at the time of design." ITC at 8. "We believe 'predetermined' should be construed to have its ordinary dictionary definition." ITC at 9. "We also disagree with the ALJ's construction that 'expected' means 'not changing over time.' We find no indication in the patent that expected should be construed other than in accordance with its ordinary dictionary meaning." ITC at 9.

The burden is on Innovatron to show that "predetermined operations" and "predetermined expected response" are technical terms narrower in scope than when used ordinarily. Innovatron argues that these "are not terms that one normally confronts in everyday conversation." Innovatron's Post-Hrg. Reply at 22. Innovatron argues that this observation justifies reliance on extrinsic evidence. Innovatron then relies on Dr. Kuc's testimony to support its argument.

The Court will not go down that path. Innovatron cites no authority for the proposition that a term not frequently used in conversation must be a term of art. On the contrary, "absent a special and particular definition created by the patent applicant, terms in a claim are to be given their ordinary and accustomed meaning." Renishaw, 158 F.3d at 1249. Nothing in the claim language, the specification, nor the prosecution history indicates that Moreno intended a "special and particular definition" to attach to these terms. Moreover, reading "predetermined" to mean "determined beforehand" and "expected" to mean "predicted" is entirely consistent with the purpose of the method and the specification.

Footnotes

7 Independently, the Court has considered and rejected two arguments that would support Innovatron's reading. First, it may have been that in 1978 "predetermined" meant at the time of design because the technology required that the system be hard wired. However, no persuasive evidence was introduced to compel that result. Second, the term "predetermined expected response" is potentially redundant when given its ordinary meaning. The term "expected" implies that a determination or prediction has been made prior to receipt of the response. That being so, "predetermined" only makes express a necessary implication of the term "expected." However, "predetermined" does not require "at the time of design," and the Court is persuaded that "predetermined" adds enough by requiring that the "expectation" arise from a conscious prediction to find that giving the terms their ordinary meaning does not produce a redundancy.

End Footnotes
Predetermined parameters

In its briefing, ConnecTel argued "predetermined parameters" should be construed to mean "those parameters whose values are fixed, vary over relatively long periods of time, or are set by external actions, e.g. user input." Cisco contended "predetermined parameters" "refers to parameters of the paths that are fixed and not measured." During the hearing, the parties agreed to construe "predetermined parameters" as "parameters of the paths that are stored in memory and not measured." The Court agrees that this is an appropriate construction and adopts it.

The plaintiffs propose "the immediate operand or the instruction that is accessed has a position, relative to the beginning or end of the instruction group that includes the operand or instruction being accessed, that is determined based on a portion of an accessing instruction that identifies an operation to be performed and without reference to operand or address bits in the accessing instruction." The defendants propose "the bits forming the accessed operand or instruction either begin or end at a position defined in relation to the boundaries of the instruction group in the instruction register rather than the currently executing instruction." The principal dispute is whether the instruction group refers to the group in which the currently executing instruction is located or whether it refers to the group in which the instruction or operand being accessed is located.

The plaintiffs argue that, during prosecution, the applicants referred to the predetermined position of the accessed operand or instruction. See Supplemental Amendment, February 5, 1998, at 6-8. The plaintiffs also argue that instruction location is determined based on the particular place for instructions of that type. In addition, the plaintiffs contend that the target address specified by the instruction has no effect on the decision to begin executing at the beginning boundary of a target group.

The defendants argue that the Abstract explains the meaning of this phrase. It states

A high-performance microprocessor system using instruction that access operands and instructions located relative to the current instruction group rather than located relative to the current instructions, as is the convention, is disclosed herein. '584 patent, Abstract.

The defendants also contend that the plaintiffs add limitations that are not supported by the intrinsic evidence.

In reply, the plaintiffs contend that the term "current" in the Abstract refers to the target group, not the accessing group. For example, one of ordinary skill in the art would, in the case of a BRANCH instruction, determine the target instruction relative to the boundary of the target group, not the accessing group.

A "predetermined position" refers to a position based on the instruction group being accessed. See '584 patent, 2:29-35. The Court construes the term to mean "the operand or instruction is accessed at a position defined in relation to the boundaries of the instruction group that includes the operand or instruction being accessed."

3. "predetermined protocol requirement"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>predetermined</td>
<td>a requirement of a defined</td>
</tr>
</tbody>
</table>
The primary dispute with regard to these terms is the meaning of the word "protocol." Both parties cite to the definition of "protocol" contained in the same dictionary. See IEEE Standard Dictionary of Electrical and Electronic Terms, The Institute of Electrical and Electronics Engineers, Inc., 1984 ("a set of conventions or rules that govern the interactions of processes or applications within a computer system"). At the hearing, the Court proposed a construction based on this definition, i.e. construing "verifying that said disable request signal satisfies a predetermined protocol requirement" as "confirming that said disable request signal satisfies a known set of rules." See Markman Hr'g Tr. at 46:18-20 (June 25, 2009). Saxon agreed to this construction. Id. at 47:7-8. Defendants argued that this construction is inconsistent with the patent specification. Id. at 47:12-24.

The Court begins its construction by consulting the claim language. Phillips, 415 F.3d at 1314. In this case, the plain and ordinary meaning of the term "protocol," as evidenced by the parties' dictionary definitions, is a known set of conventions or rules. Defendants argue that the Court's construction should diverge from this plain and ordinary meaning because the only disclosed example of a predetermined protocol requirement involves a series of sequential steps rather than a set of rules. Defendants cite to the patent specification, which states that "the predetermined protocol requirement may be a predetermined number of writes in a predetermined order to the at least two registers." '689 Pat. at 3:58-60. However, at most, this statement shows that the patent discloses one embodiment in which the predetermined protocol requirement involves a series of steps. Defendants have not cited any statements of disclaimer, or any other reason to import this limitation into the claim language. Liebel-Flarsheim Co., 358 F.3d at 913; Brookhill-Wilk 1, LLC, 334 F.3d 1294, 1301; see also Phillips, 415 F.3d at 1312-13.

Saxon's original proposed claim construction is similarly flawed. While the patent explains that the purpose of the predetermined protocol requirement is for protection from inadvertent entry into shut-down mode, '689 Pat. at 8:13-16, Saxon offers no reason to import this purpose into the claim as a limitation. Furthermore, the term "defined protection scheme" would be unnecessarily confusing for a jury.

Therefore, the Court finds that the proper construction for the term "predetermined protocol requirement" is "a known set of rules." Because this construction resolves the parties' claim scope dispute, the larger phrase "verifying that said disable request signal satisfies a predetermined protocol requirement" need not be construed.

GO BACK
The court construes "predetermined range," consistent with the previous constructions, to mean "a range determined beforehand."

2. Claims 1 & 5 -- "Predetermined Region"

The term "predetermined region" appears throughout the '170 patent and is another term crucial to the invention. Defendants argue that "predetermined region" is a region determined prior to user station installation, which region the user cannot change. CIVIX, on the other hand, contends that "predetermined region" is a bounded geographical region around a user station which is determined before a map is provided to the user, but which is not necessarily fixed prior to use by the user.

The parties do not disagree on the meaning of the word "region" which is defined as "a particular part of the world or universe." Webster's Third New Int'l Dictionary 1912 (3d ed. 1986). Nor do the parties appear to disagree with the definition of the word "predetermined" which Webster's defines as "to determine beforehand: settle in advance." Webster's Third New Int'l Dictionary 1786 (3d ed. 1986). Instead, the disagreement centers on when the region is determined. CIVIX argues that the geographical area surrounding the user station is necessarily decided before a map is provided to a user, and no other limitation should apply. CIVIX contends that Defendants are wrongly attempting to saddle the term "predetermined region" with the limitations in the preferred embodiment where the predetermined region is created by a master database and loaded into a kiosk located on a city sidewalk. This region is not determined by the user at the user station. However, CIVIX urges that it is legal error to thus saddle the phrase. The claim language, not the preferred embodiments define the scope and meaning of the phrase. Defendants, on the other hand, argue that the term "predetermined" in the '170 patent means that the region is determined prior to kiosk installation.

I disagree with both proffered interpretations. I conclude that "predetermined region" means that the region is determined prior to use by the user and thus cannot be changed by the user, but that it has the potential to be changed by those who maintain the user station by loading new information into the user station to reflect a new, altered, or broader region.

CIVIX' definition of "predetermined region" as a region determined before a map is provided to a user would render the term "predetermined" superfluous. Necessarily, any system providing a geographical representation to a user must determine such a region before providing a map. However, this broad concept of determination prior to provision of a map would allow for the system to flexibly select a region or a user to select such a region. Necessarily a region must be determined before a map is provided. This would be true even if the term "predetermined" were ignored. This is not the broad meaning to be given the term "predetermined region" in this context. CIVIX chose to limit the region to a "predetermined" region and I cannot read this limitation out of the claims. See Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1583 (Fed. Cir. 1996) ("[Plaintiff] need not have included this limitation in its claim. Having done so, it must live with the language it chose."); Exxon Chemical Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1557 (Fed.Cir.1995) (recognizing that the court "must give meaning to all the words in [the] claims").

Further, it is proper for me to refer to the specification in determining the meaning of the term "predetermined region." See Ethicon, 93 F.3d at 1578 ("the district court did not import an additional limitation into the claim; instead, it looked to the specification to aid its interpretation of a term already in the claim, an entirely appropriate practice."). CIVIX's embodiment of the purported invention is clear. Data for one region surrounding a user station is loaded into the user station's memory during installation. Specifically, the location of the new kiosk is entered into a primary database and a map is generated having the kiosk at the center. ( '170 Patent, Col. 3 lines 12-16). The perimeter of this map is then clipped to provide a circular shape. ( '170 Patent, Col. 3 lines 16-17). The transfer of this map is completed by being "physically carried to the new kiosk, and the information therein is loaded into the memory of the base station." ( '170 Patent, Col. 3 lines 22-24). This specification only contemplates a predetermined region loaded into the user station upon installation of each new user.
station. However, I conclude that the same process can be used to update the region periodically.

Furthermore, I cannot construe the '170 patent claims broadly, to cover an apparatus providing a user-specified region, because the prosecution file shows that the applicants added the term "predefined region" to the claims to distinguish them from prior art which provided user-defined regions. (CIV 000058 - 000061). In distinguishing the '170 patent from the Esparza patent, which taught the automated dispensing of maps of any one of a number of regions depending on user choice and regardless of user location, the '170 patent applicants noted:

The claims . . . call for identifying locations within a predetermined region of a selected group of this set relative to the location of a user station. The claims call for the data including an identification of the location for each subscriber in the predetermined region . . . .

(CIV 000063). Thus, "predetermined region" is not open-ended enough to include user-defined regions.

Finally, the inventors of the '525 patent have acknowledged that the '170 patent is limited in that it does not employ user-selected regions:

U.S. Pat. No. 4,974,170 ['170 patent] describes one system which includes a fixed kiosk with an internal memory for storing locations such as businesses and historical sites within a predetermined distance from the kiosk. . . . However, such a system is inflexible. The map generated by the system is predefined; and thus the user cannot access or select information about businesses and historical sites outside of the predefined map.

('525 Patent, Col. 1 lines 21-32) (emphasis added). These comments are relevant to the construction of the term "predetermined region" in the '170 patent because they are representative of comments of common inventors of both the '170 and '525 patents. I conclude that "predetermined region" denotes a region stored in the user station and determined prior to use by the user subject, however, to new information loaded into the base station memory, by the system developers, from time to time.

C. "predetermined response"

"Predetermined response" is found in claim 26: "retrieving one or more predetermined responses corresponding to the interpretation of the electronic message from a repository for automatic delivery to the source." The term is discussed throughout the specification, including in the passage quoted below:

When the automatic message reader 30 has classified the E-mail message 11 as being of the "automatic" type . . . , one or more predetermined responses . . . are retrieved from a repository . . . for automatic delivery to the source 52. . . . [T]he predetermined response is an appropriate response to the inquiry of the customer 50. It is understood that the predetermined response may be modified and/or altered in accordance with the interpretation of the E-mail message 11 if required to properly respond to a customer 50.

('947 patent, 9:24-35) (emphasis added). According to the plaintiff, "predetermined response" requires no construction. If this term must be construed, however, Bright Response proposes the following definition: "Responses prepared prior to the receipt of the electronic message. The responses may be modified and/or altered based on the interpretation of the electronic message." The defendants contend that this term means "responses prepared prior to the receipt of the electronic message."

Both sides agree upon the first sentence of the construction. The defendants also agree that the predetermined response may be modified or altered. But the defendants contend that Bright Response's proposed construction would allow alteration or modification at any time, such as before retrieval or after delivery of the response. The only time limitation imposed by the claim is based on the interpretation of the electronic message: "retrieving one or more predetermined responses corresponding to the interpretation of the electronic message." ('947 patent, claim 26). Because the predetermined response retrieval must occur after interpretation of the electronic message, the court construes this term to mean "responses prepared prior to the receipt of the electronic message. The responses may be modified and/or altered based on the interpretation of
3. Predetermined Signals or Digit Sequences Used For or To Accomplish International Dialing

For the reasons set forth in Section IV(A) (2) of this Order and discussed in this section, the Court construes "predetermined sequences [signals] which are used for international dialing" in disputed Claims 1, 22 and 29 of the '125 Patent and disputed Claim 1 of the '650 patent to mean "the set of all digits which are used for international dialing." Similarly, the Court finds that "predetermined digit sequences" in disputed Claim 3 of the '650 patent to mean "the set of all signals which are used for international dialing."

Gammino asks this Court to construe this language to mean any of the signals that can be used for international dialing. However, Gammino's arguments made during prosecution contradict this interpretation. In fact, Gammino recognized that his invention blocked all international calls when he stated that his invention is "particularly suited for locations where few legitimate calls are typically made to international locations," and therefore, his "claimed invention would probably not be used at an airport" where many legitimate international phone calls are made. Gammino also submitted to the Patent Office a license agreement whereby he licensed his patent applications to Technology Service Group, Inc. ("TSG"). Gammino told the Patent Office that the dialing sequences (e.g. telephone numbers) listed in the TSG License Agreement "correspond exactly to his claimed invention." The telephone numbers listed as Exhibit A in the license agreement are:

10xxx-01
950-10xxx-01
1800-xxx-xxxx-01
800-xxx-xxxx-01
950-10xx-809
1800-xxx-xxxx-809
800-xxx-xxxx-809
