In this instance, the specification explains, "UniPost Internet subscriber, generally indicated as 12, is in Japan and uses the local public switched telephone network 10 to contact the Tokyo UniPost Access Node 6." Then, according to the specification, "[a]fter proper identification of the subscriber, the Tokyo UniPost Access Node uses Internet 4 to access the electronic mailbox 30 of the subscriber and allows retrieval of the various contents of the various boxes." A "subscriber" can then retrieve messages using a computer and modem 12, a telephone 29, or a facsimile machine 31. '350 patent, col. 7, lines 27-47. Doing so allows a "subscriber" to retrieve messages using the Internet and a local PSTN connection:

It can also be appreciated that the example shown in FIG. 3 has allowed the subscriber 12 to form a relatively local connection using the public switched telephone network 10 to contact the Tokyo UniPost Access Node 6. This is then connected to the Toronto UniPost Access Node 6 and the electronic mailbox of the subscriber via an Internet or dedicated data communication channel. Information is retrieved from the mailbox and provided to the UniPost Access Node, also by this data communication channel provided by Internet. In contrast to a single UniPost Access Node, the multiple access nodes, shown in FIG. 3, advantageously use the dedicated data communication network to interconnect the access nodes and reduces the need for long distance telephone communications with a particular computer.

(c) The Embodiment of Fig. 4

The embodiment of Fig. 4, although also drawn to sending a facsimile message, is a bit different from Figs. 1-3. Once again, Fig. 4 is described as "an overview showing an effective manner for delivering a facsimile in a cost effective manner." '350 patent, col. 4, lines 21-22.

In this embodiment, facsimile machine 60 is illustrated as connected to PSTN 10 which in turn is shown as having connections to Toronto UniPost Access Node 6. Also, facsimile machine 62 is illustrated as connected to PSTN 10 which in turn is shown as having connections to Tokyo UniPost Access Node 6. Thus, this portion of the illustration is the same as for facsimile machine 14 in Fig. 1, and facsimile machine 31 in Fig. 3. In Fig. 1, a "non-subscriber" may use a "subscriber's" Personal Mailbox Telephone Number to leave a fax message on Toronto UniPost Access Node 6, which may then be
GET DRAWING SHEET 4 OF 5

The specification first explains that "[i]n this case, the transmission is sent from the facsimile machine 60 via the public switched telephone network 10 to the UniPost Access Node 6." ’350 patent, col. 8, lines 9-11. The specification at this juncture does not expressly say whether the "UniPost Access Node 6" is the one in Toronto or Tokyo. The next sentence, though, says "[t]he facsimile machine 60 can include add-on devices to cause this long distance call to be rerouted or the communication may first be made to the Tokyo UniPost Access Node and thereafter to the Japanese address." ’350 patent, col. 8, lines 11-15. Because Fig. 4 illustrates fax machine 60 connected through a local PSTN to Toronto UniPost Access Node 6, the reference to "this long distance call" suggests that "UniPost Access Node 6" refers to the Tokyo node. The specification does not describe the referenced "add-on devices." But whatever those devices are, according to the specification, they "cause this long distance call to be rerouted . . ." to the Tokyo UniPost Access Node and thereafter to the Tokyo UniPost Access Node. All of that suggests that a fax is being sent from fax machine 60 through the Toronto node to the Tokyo node and then to fax machine 62 -- as opposed to simply sending the fax to the Toronto node for later retrieval as illustrated in Figs. 1, 2 and 3.

How one does so is less clear. The specification, as noted above, says that "FIG. 4 shows how a facsimile transmission addressed to a particular address in Japan can effectively use the UniPost access system." ’350 patent, col. 8, lines 7-9 (emphasis added). The emphasized phrase suggests that the user must have access to the UniPost system. Although, as discussed above, non-subscribers may leave voice mails and facsimile messages which may thereafter be retrieved by subscribers, there is no disclosure in the ’350 patent of non-subscribers having the ability to otherwise "use" the UniPost access system. This portion of the specification thus suggests that in the embodiment of Fig. 4, the originator of the fax message is a "subscriber." Indeed, the next sentence in the specification says that "the user provides the direction to initiate the contact with the Toronto UniPost Access Node 6." ’350 patent, col. 8, lines 16-17 (emphasis added). The specification does not say here what that "direction" is. But again, the preceding sentence says "[t]he facsimile machine 60 can include add-on devices to cause this long distance call to be rerouted or the communication may first be made to the Toronto UniPost Access Node and thereafter to the Japanese address." ’350 patent, col. 8, lines 11-15. In any event, the fax is sent to the Tokyo UniPost Access Node and then to fax machine 62. ’350 patent, col. 8, lines 17-29.

Although the specification does not at the foregoing juncture say what "direction" a user provides, later the specification refers to this fax transmission in analogizing long distance voice communication: "The discount long distance voice messaging requires that each UniPost Access Node is able to accept and digitize voice calls. . . . As with long distance facsimile calls, the call originator will dial the local UniPost Access Node and enter his account and the number of the recipient. The UniPost Access Node will establish a packet path between the originating UniPost Access Node and the destination UniPost Access Node closest to the recipient. The destination UniPost Access Node will then place a local call to the recipient and deliver the voice message." ’350 patent, col. 9, lines 11-23. The reference to dialing the local UniPost Access Node and then entering an "account number" strongly suggests that the originator of the fax message in the embodiment of Fig. 4 must be a "subscriber."

Also, the disclosure strongly suggests that the originating and receiving "commercial access providers" must be UniPost Access Nodes -- or at least have the capabilities of such Nodes. Although "generic" Internet access providers may have the capability to establish a packet path from an originating node to a destination node, there is no disclosure that "generic" Internet access providers have the ability to place a local call to a recipient and cause the fax to be delivered to fax machine 62. It is less clear whether the recipient must be a "subscriber."

(d) The Embodiment of Fig. 5

Once again, Fig. 5 is described in the ’350 patent as "a schematic of how the system can be used to complete a voice communication channel to a telephone set in a distant geographical location." ’350 patent, col. 4, lines 23-26:

GET DRAWING SHEET 5 OF 5
The specification contains scant disclosure of Fig. 5. The specification once again discloses that:

FIG. 5 also shows how this UniPost system can be used for providing a direct telephone link using the data transmission network involving Internet. In this case, voice is transmitted digitally and a live communication is maintained between Toronto UniPost Access Node 6 and Tokyo UniPost Access Node 6. Each of these have formed a live communication with the originating telephone set and the receiving telephone set. This can thus provide the subscriber with a further cost advantage in completing his international communications or other long distance communications.

'350 patent, col. 9, lines 1-10 (emphasis added). The specification thus says that a "subscriber" is provided with a cost advantage, suggesting once more that the originator of the telephone call must be a "subscriber." That is reinforced by the following disclosure, which is the same disclosure discussed above in connection with Fig. 4:

As with long distance facsimile calls, the call originator will dial the local UniPost Access Node and enter his account and the number of the recipient. The UniPost Access Node will establish a packet path between the originating UniPost Access Node and the destination UniPost Access Node closest to the recipient. The destination UniPost Access Node will then place a local call to the recipient and deliver the voice message.

'350 patent, col. 9, lines 16-23 (emphasis added). The emphasized language again strongly suggests that the call originator must be a "subscriber." Once again, the specification says that "the subscriber is provided with a . . . Personal ID Number (PIN): 63265." '350 patent, col. 4, lines 42-45 (emphasis added).

Also, the specification discloses that "[t]he discount long distance voice messaging requires that each UniPost Access Node is able to accept and digitize voice calls," and as noted above, the destination access node places a local call to the recipient. That suggests that the originating and receiving nodes are UniPost Access Nodes -- or at least have the capabilities of such Nodes. There is no disclosure that "generic" Internet service providers have the ability to "accept and digitize voice calls" or make local phone calls in response to receiving a telephone number.

(4) eBay's "widely available" Arguments

eBay argues that the '350 patent discloses in the abstract that the system is "widely available" and provides "access to hundreds of millions of telephones," (Doc. No. 82 at 18) (citing col. 3, line 66 - col. 4, line 4, and col. 4, lines 58-62). eBay urges that "[t]he millions of ordinary telephone users can continue using their existing telephones and yet still take advantage of the significant cost savings and efficiencies of the Internet -- savings and efficiencies that are not available to conventional long distance calls routed through the PSTN." Id. eBay further cites to column 3, lines 35-38 disclosing that the "Internet becomes the transport backbone of a global voice and fax mail system and opens [the] Internet to transparent access by telephones, facsimile terminals and other non-subscriber devices," and col. 2, lines 30-33 that "[s]imilarly, the system is accessible to anyone wishing to leave a voice, facsimile, or other message for the subscriber by dialing the telephone number associated with the subscriber's electronic message mailbox. As a result, data networks, such as Internet, are accessible by devices other than computers, namely by telephones and facsimile terminals." (Doc. No. 82 at 18).

The portions of the specification that eBay cites to, however, relate to the messaging embodiments of Figs. 1-3. In those embodiments, as discussed above, non-subscribers using conventional telephone and fax machines may leave voice and fax messages for a subscriber which a subscriber can thereafter retrieve. In the embodiment of Fig. 5, on the other hand, a conventional telephone may be used to originate a call. However, as discussed above, the disclosure strongly suggests that the one originating a call must be a "subscriber."

(5) Prosecution History

eBay also cites to portions of the prosecution history in which eBay says that the "applicant repeatedly emphasized to the U.S. Patent and Trademark Office how the claimed invention, for the first time, opens up the efficiencies and cost benefits of the Internet to ordinary telephone users on a broad commercial basis." (Doc. No. 82 at 19). eBay makes similar arguments in its reply. (Doc. No. 91).

In actuality, during prosecution of the application maturing into the '350 patent, the applicant originally submitted a "Preliminary Amendment" dated June 4, 1996, that, inter alia, replaced the "Summary of the Invention" covering pages 2-6
of the specification. (Doc. No. 86-7 at 36). That new "Summary" included several paragraphs discussing "[a] method of establishing a long distance telephone communication between an initiating telephone device and a receiving device telephone . . . " which were not in the original "Summary." Id. at 38. In an Office Action dated September 9, 1996, the PTO initially required, in light of the material added in the Preliminary Amendment, that the application be redesignated as a continuation-in-part (CIP), as opposed to a continuation. Id. at 52. In a response dated February 10, 1997, the applicant did not redesignate the application as a CIP. Id. at 65. In an Office Action dated March 4, 1998, the PTO, inter alia, objected to the Preliminary Amendment under 35 U.S.C. § 132 as being drawn to new matter. The Office Action explained that "[a]s originally filed, the specification is directed to facsimile communications, there is no detailed description regarding long distance voice communications as added, such as using the telephone address to establish voice communications, the long distance [sic.] comprising three distinct segments, etc." The Office Action further provided that "Applicant is required to cancel the new matter in the reply to this Office Action." (Doc. No. 86-8 at 9).

The applicant responded on July 28, 1998, urging that Fig. 5 and the accompanying description provided support for the material added in the Preliminary Amendment, and the claims. The applicant argued that:

[1] The present invention allows long distance voice communications to be available to users of conventional telephones as the specialized protocols and procedures have been concentrated with the access nodes making the process simple and convenient and available to a huge number of telephone devices in a simple manner. [2] The prior art system discloses different arrangements for long distance voice communication over INTERNET but none of these systems make it available in the simple manner of the present invention where specialization and processing is resident at the commercial access provider nodes. This solution is in contradiction to the art and provides a new alternative to long distance real time voice communication. (brackets and numbers added)

In the next paragraph, the applicant argued that in the prior art "[t]he systems that are available for a normal telephone user require each user to have a computer and essentially, prearrange a telephone communication therewith, i.e., both systems have to be on line at the same time and this essentially requires each user to know of the desire to complete a telephone communication." Id. at 26.

eBay cites to the first sentence -- sentence [1] -- but does not refer to sentence [2] or the context of the prior art. (Doc. No. 82 at 19). In all events, this portion of the prosecution history does not assist eBay -- in fact, quite the opposite. First, the applicant did not argue or assert that users were not required to be "subscribers." Second, the applicant did point out that "specialized protocols and procedures have been concentrated with the access nodes." The specification, yet again, which the applicant reproduces in its response, provides that "the subscriber" realizes a "cost advantage in completing his international communications or other long distance communications," and that "the call originator will dial the local UniPost Access Node and enter his account and the number of the recipient," (Doc. No. 86-8 at 25). The reason for dialing the UniPost Access Node and entering an account number, of course, is so that the user of a conventional telephone can use the "specialized protocols and procedures" that have been "concentrated with the access nodes." In referring to making the process simpler, the prior art, as the applicant pointed out, required a computer, in addition to a telephone, and a prearrangement between the caller and the recipient.

The PTO was not convinced. In an Office Action dated September 4, 1998, the PTO again objected to the material added in the Preliminary Amendment, and required cancellation. In a response dated February 2, 1999, the applicant replaced the "Summary of the Invention" with the original content, i.e., the specification was returned to what it had been before the Preliminary Amendment. The PTO subsequently entered a Notice of Allowance.

The applicant also submitted a Rule 132, 37 C.F.R. § 1.132, declaration by Nuno Romao with the response of February 2, 1999, in arguing over certain rejections. eBay currently relies on statements made in that declaration. (Doc. No. 82 at 19).

The first is in paragraph 3 of the Romao declaration, which states in full:

3. The present invention makes it possible to have conventional telephones communicate using PSTN's to interact with commercial access providers (CAPS) associated with a digital network to complete long distance real time voice communications. This approach allows conventional telephones to take advantage of this technology without requiring any special arrangement between the conventional phones. As such, this technology becomes generally available and is not limited to specialized networks as is the case in the art cited by the Examiner and attached to this affidavit."
(Doc. No. 82-7 at 14). eBay in its brief uses an ellipses after "generally available." (Doc. No. 82 at 19). In context, it is clear that when Romao referred to being "generally available," he was referring to the prior art that used "specialized networks." That does not address whether the call originator must be a "subscriber."

eBay also refers to a portion of paragraph 2 of Romao's declaration (which actually includes several unnumbered paragraphs). Again, the entire paragraph that eBay points to says:

The above digital technology [referring to the prior art in which voice was digitized and transmitted] is then combined with a commercial access provider to receive instructions via a local PSTN and a conventional telephone to complete a long distance call to a particular destination which instruction is sent to a second commercial access provider. This second commercial access provider out dials to the particular destination. The commercial access providers function like the local area network with respect to the signals provided thereto, and the local PSTN's complete the communication. This arrangement makes it possible for the multitude of existing conventional telephones to utilize the system in a very simple manner.

eBay quotes and emphasizes the last sentence. (Doc. No. 82 at 19). In context, though, it is clear that Romao was referring to the prior art, and, indeed, was responding to the PTO's rejection under § 112(1) for lack of enablement. In context, Romao does not address whether the call originator must be a "subscriber."

(6) eBay -- IDT's Proposed Construction Limits Claims to a Business

In its reply, eBay further contends that IDT's proposed construction limits the claims to a "business," which, eBay argues, is nowhere described in the intrinsic record, and becomes "nonsensical" in light of the claims. For example, eBay points to claim 18 providing that the first and second "commercial access providers" exchange voice communications data over a packet-based computer network and convert a signal into a different form. eBay urges that "[p]lainly, computer systems, not 'businesses,' are exchanging this data over the computer network." (Doc. No. 91 at 5). eBay further argues that with IDT's proposed construction, claim 18 would require two different businesses. Id.

IDT's proposed construction does not limit the claims to a "business." In all events, however, the '350 patent speaks in terms of a "subscriber" and in the prior art "a subscriber typically contracts with a commercial access provider (CAP)." Also, the '350 patent explains that a "subscriber" is given (1) an e-mail address, (2) an account number or password, and (3) a "Personal Mailbox Number." '350 patent, col. 4, lines 47-50. The point of being a "subscriber" is that only "subscribers" can retrieve messages from UniPost Access Nodes in the message embodiments of Figs. 1-3, and, by the most reasonable interpretation, only "subscribers" can make telephone calls using the Internet (or digitized packet based network) in the embodiment of Fig. 5 to which the asserted claims are drawn. In the context of the disclosure of the '350 patent, a "subscriber" is given entree to the features and capabilities of the UniPost Access Nodes -- a "non-subscriber" is not.

As to eBay's second argument, IDT's proposed construction clearly "uses a computer system." Claim 18 is not rendered nonsensical. Such "computer systems" may communicate per the terms of claim 18.

(7) eBay -- Use by Non-Subscribers

eBay, in its reply, also argues that IDT's proposed construction vis-a-vis "subscription-based services," is contradicted by the specification which, eBay, argues "explicitly teaches that the invention can be used by 'non-subscriber' devices." (Doc. No. 9 at 6-7).

eBay's citations to the specification are the same as those discussed above -- i.e., references to the messaging system of Figs. 1-3. As discussed above, in those embodiments, "non-subscriber" originators may leave voice and fax messages which a "subscriber" can thereafter retrieve. The asserted claims, however, as eBay points out in its opening brief, are drawn to the embodiment of Fig. 5. (Doc. No. 82 at 10). Further, in describing the embodiment of Fig. 5, eBay says that "[s]uppose Alice, who is now back in Toronto, wishes to call Bob in Tokyo. Alice places a local call over the PSTN to a first commercial access providing computer in Toronto. '350 patent, col. 9: 16-18. Alice then enters Bob's telephone number. Id." (Doc. No. 82 at 10-11). What eBay omits from the cited disclosure at col. 9, lines 16-18 ("the call originator will dial the local UniPost Access Node and enter his account and the number of the recipient") is that Alice, after using the local PSTN to call the Toronto UniPost Access Node, must "enter[s] his [her] account" and then Bob's telephone number. The account number is
what gives Alice access to the UniPost Access Node and allows her to make the telephone call. And according to the specification, account numbers are provided to "subscribers."

c) Conclusion

In view of the foregoing, therefore, the Court concludes that:

The phrase "commercial access provider" in claim 1 and its dependent claims means "a service provider that provides subscription-based services and uses a computer system commercially available to telephone users that acts to provide an interface to or from the Internet." The phrase "commercial access provider" in the remaining asserted claims means "a service provider that provides subscription-based services and uses a computer system commercially available to telephone users that acts to provide an interface to or from a digitized packet based network."

IDT has used the phrase "subscription-based services" in its proposed construction and throughout the briefing. eBay has never asserted that phrase requires separate explanation in resolving the issues of infringement and validity (or any other issue) in this case. However, if that is -- or becomes -- an issue, the Court does not foreclose further consideration.

673

2. commercial insert video signal(s)

A "commercial insert video signal" is an analog video signal, 6 distinct from the programmed channel signal and local video signal, that contains commercial content that is to be inserted into a local time avail in the programmed channel signal. In the multi-channel setting, one commercial insert signal is transmitted from a remote control center to each video switch.

6 An "analog" signal is ready for broadcast, in contrast to a digital signal, which is stored for later playback.

Beam Laser argues that the commercial insert signal can be either analog or digital. The claims language does not expressly state whether the commercial insert signal is analog or digital. Defendants argue that because the commercial insert signal is generated at a remote site and there is no means specified in the patent for storing the commercial insert signal at the headend, the commercial insert signal must be analog. Moreover, Defendants assert that the specification in the '825 Patent makes explicit that the commercial insert signal is analog. See, e.g., '825 Patent, col.4, 11.15-16, 34-40 (referring to "analog commercial inserts").

Beam Laser responds by citing a specific reference in the '883 Patent specification to the source of the commercial insert video signals, in which it is stated that this video source "may be a multiple video laser disc, a video tape, or a digital video still frame, all operating in combination with an audio source." '883 Patent, col.6, 11.41-44. Even if these sources were not readily recognized as digital sources at the time the patent issued, Beam Laser argues, the use of digital technology would have been readily apparent to a person of ordinary skill in the art without undue experimentation, and therefore, digital signals would fall within the scope of enablement of the patent. See National Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1195-96 (Fed. Cir. 1999). The portion of the specification to which Beam Laser makes reference is in the description of the preferred embodiment. There, it is explained that the source of the commercial insert signal, which is located in the remote control center, generates the stream of commercial insert signals, which are then applied to a satellite up link interface, so that the signals can be transmitted to the switch system at the headend. Even if the generating source of the signal is digital, the signal must be converted to an analog signal before it can be input to the switch. The term "commercial insert video signal," occurring as it does in the claim governing the switch system, thus refers to a ready-for-broadcast signal, i.e., an analog signal.
7 Beam Laser argues that a digital form of commercial insert video signal is an "inherent disclosure" of the patent. The Federal Circuit has explained that the scope of enablement of a patent includes the "explicit disclosure"--that which is disclosed in the specification--together with the "inherent disclosure"--"the scope of what would be known to one of ordinary skill in the art without undue experimentation." National Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1196 (Fed. Cir. 1999).

Defendants argue that the term should be construed to include the additional limitation that the commercial insert signal is one advertisement belonging to a series of discrete commercial segments. It is clear that "commercial insert signal" refers to a single commercial. There is language both in the patent claims and in the specifications supporting this conclusion. Thus, for example, the '883 Patent distinguishes prior art as follows:

After sensing the [cue tone], this device inserts a local commercial generally by operating a video switch that selects a locally generated commercial insert video signal from one input of the video switch as opposed to selecting the programmed channel video at the other input. However, this prior art device is only capable of inserting one commercial insert in a single channel.

'883 Patent, col.1, 11.48-55. Clearly, "commercial insert video signal" is used here to refer to one commercial. In another reference, the patent refers to "a spot commercial or a commercial insert," in a way that makes clear the terms are used as synonyms. Id. col.10, 11.43-44.

Defendants nevertheless argue that the commercial insert signal must consist of a discrete commercial from a stream of commercials, because the patents consistently refer to it in this way. Thus, Defendants cite several instances in both patents where the commercial insert video signal is characterized as a "sequential stream" or a "continuous stream." E.g., id. col.3, 1.45; '825 Patent, col.6, 1.31.

Claim 1 of the '883 Patent addresses a single switch, while Claim 7 of the '883 Patent (and also Claim 14, which is not an asserted claim) addresses a plurality of switches. The specification of the '883 Patent describes the operation of the multiple switch system, which is the case in which a stream of commercial inserts is necessary. See supra § I.B (explaining the purpose of the invention). In the claims pertaining to the multiple switch system, the claim language expressly mentions that the commercial insert is one from a stream of inserts. See, e.g., '883 Patent, col.13, 11.36-37 (Claim 7); id. col.14, 11.61-63 (Claim 14). Thus, this additional limitation should not be read into the term, because it has clearly been added by the inventors when intended. The implication is that this limitation was not intended in Claim 1 of the '883 Patent. 9

8 Defendants assert that Claim 14 of the '883 Patent "equates" the terms "commercial insert video signal," "sequential stream of commercial insert video signals," and "stream of commercial insert video signals." SeaChange and Cox's Supplemental Markman Br., at 11-12. This assertion apparently rests on the fact that all three terms have been used in the claim. The court agrees that "sequential stream of commercial insert video signals" and "stream of commercial insert video signals" are used as equivalents, but does not find this significant. The court is inclined to believe that the one use of "commercial insert signal," in at least seven references to the commercial signal, reflects a careless lack of precision rather than an indication that "commercial insert signal" carries in it the notion that commercials are always part of a stream.

9 Contrary to Beam Laser's argument, the court does not find the doctrine of claim differentiation to be applicable here. The Federal Circuit has stated that "The concept of claim differentiation … states that claims should be presumed to cover different inventions. This means that an interpretation of a claim should be avoided if it would make the claim read like another one." Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) (internal quotation marks omitted) (alterations and emphasis in original). Regardless of the construction the court gives to "commercial insert signal," Claims 1 and 7 will be distinct.

Beam Laser argues that long-form commercials ("infomercials," which typically last about thirty minutes), and alternate
signals that are broadcast after the national broadcaster has gone off the air, could qualify as commercial insert video signals. However, this ignores the use of "insert" in the disputed term. The use of "insert" must be given effect, and it is clear from the specification that "insert" refers to the insertion of the commercial insert video signal into a local time avail. Therefore, the court concludes that a commercial insert video signal is a commercial spot that is inserted into a local time avail.

7. Commercial invoice n8

DE contends that "commercial invoice" means "a document that defines the basic terms of an international transaction including at least the description and total value of the product." Dell contends that the term should be construed as "an international shipping document that contains at least the information required by all applicable customs regulations."

The specification does not assist the court in determining the ordinary meaning of "commercial invoice," and the court must therefore consult the prosecution history. DE contends that the prosecution history supports its reading of the claim language. The inventor described a commercial invoice, which "serves as a document used by governments to control imports... In contrast, an invoice used in domestic trade is nothing more than a bill for the goods from the seller to the buyer." Prosecution History Files for Patent ’020, at DET05338. If the information specified was not included as part of the commercial invoice, the documents could not be used to control imports and exports, and would be no different from the distinguished "invoice" used in domestic transactions, which is "nothing more than a bill for the goods from the seller to the buyer." Id. In contrast, a typical commercial invoice was described by the inventor as including "information about the exporter, consignee, intermediate consignee, forwarding agent, bill of lading number, [and] export references." Id. Based upon these statements, the applicant "clearly and unambiguously disclaimed or disavowed" a broad construction of "commercial invoice" during prosecution history. See Safazar v. Procter & Gamble Co., 414 F.3d 1342, 1344 (Fed. Cir. 2005). In order for a "commercial invoice" to be differentiated from an invoice used in domestic transactions, the term must encompass more than merely a bill.

The court therefore finds that "commercial invoice" must be construed as "an international shipping document that contains at least the information in the form required under the applicable laws of the jurisdiction[s] through which the selected product travels."

C. Limitation 2: at least first and second spaced base regions

7. The next element of Claim 1 is as follows: "at least first and second spaced base regions of the opposite conductivity type to said one conductivity type formed in said wafer and extending from said first semiconductor surface to a first depth beneath said first semiconductor surface; the space between said at least first and second base regions defining a vertical common conduction region of one conductivity type at a given first semiconductor surface location; the concentration of carriers of said one conductivity type in said common conduction region at said first semiconductor surface being less than the concentration of carriers of said opposite conductivity type of said first and second base regions at said first semiconductor surface." In prior litigation involving the ’699 patent, the Court concluded that the "common conduction region" of ’699 claim 1 could be defined by an array of polygonal bases. International Rectifier Corp. v. SGS-Thomson Microelectronics, Inc., 1994 U.S. Dist. LEXIS 20943, 38 U.S.P.Q.2d 1083, 1085, P7 (C.D. Cal. 1994), aff’d without op. 56 F.3d 81 (Fed. Cir. 5/10/95). This element of Claim 1 would have been understood to require a number of separate "base"
regions of conductivity type opposite to that of the lightly doped layer (e.g., P type base regions diffused into a lightly doped N type epitaxial layer). The number of base regions is not constrained -- it can be arbitrarily large, so long as there are at least two of them. The material of the first conductivity type (i.e., the same conductivity type as the lightly doped major body portion) between these bases is defined in the claim to be the "common conduction region." In addition, because the patent defines the common conduction region to be the region between bases, and further requires that the drain conductive region both be remote from the common conduction region and separated from it by the relatively lightly doped major body portion, those of ordinary'skill would have understood that the device current would flow, upon exiting the channel, in a predominantly vertical direction through the common conduction region, and hence that the claims inherently describe a vertical-conduction structure. Because the base regions are diffused into the relatively lightly doped major body portion, the concentration of dopants (carriers) at the top surface of that relatively lightly doped region is inherently less than the concentration of dopants (carriers) at the surface of the bases.

8. A number of specific arguments have been directed to this claim limitation.

1. Enhanced Conductivity

9. IXYS argues that the phrase "common conduction region" should be construed as the region in the epitaxial layer located between the base regions, which is relatively highly conductive/doped compared to the conductivity of the epitaxial layer, and through which current flows between the channels and the drain region; and that the claimed "common conduction region" must be relatively highly conductive (or highly doped) compared to the conductivity of the relatively lightly doped major body portion.

10. The claim language does not support IXYS's argument that the claimed "common conduction region" must be relatively highly conductive (or highly doped) compared to the conductivity of the relatively lightly doped major body. Rather, the "common conduction region" is defined in the claim itself as the space between the bases or, put another way, the portion of the "relatively lightly doped major body portion" between the bases.

11. The doping concentration limitation IXYS would read into all claims is found only in claims IR has not asserted against IXYS: dependent Claims 2, 4 (claim cancelled), 9, 10, 15 and 21 (and claims depending from those claims): "said common conduction region is relatively highly doped compared to said relatively lightly doped major body portion". Asserted independent Claims 1 and 7 and dependent claims 3, 6, 8, 11, 12, 16, 17, 19, 20 and 22 through 29 do not include any such language. Because unasserted Claims 2, 9, 10, 15 and 21 -- which include the restriction that "said common conduction region is relatively highly doped compared to said relatively lightly doped major body portion" -- are dependent claims that add this additional element to the elements of the claims on which they depend, it would be unreasonable to construe the asserted independent claims as already containing that limitation. D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir. 1985).

12. For example, independent Claim 1 simply recites, in pertinent part: "the space between said at least first and second base regions defining a vertical common conduction region of one conductivity type at a given first surface location." Dependent Claim 2 adds the additional restriction that "said common conduction region is relatively highly doped compared to said relatively lightly doped major body portion . . .". If the "common conduction region" in the device of Claim 1 already was "relatively highly doped compared to said relatively lightly doped major body portion," then Claim 2 would not have recited that language as an added restriction on the "common conduction region" of Claim 1.

13. The Patent Office also recognized that the common conduction region of the independent claims is not required to be relatively highly doped compared to the relatively lightly doped major body portion. For example, the Patent Office examiner rejected Claim 1 during reexamination on the basis of a hypothetical device he asserted was obvious from the Takakuwa and Okabe references. Although that hypothetical device did not include a relatively highly doped region between the bases, the examiner nonetheless described it as "a plurality of polygonal base regions surrounded by a common conductive drain region." (Reexam. No. 90/003,490, Paper No. 6, pp. 14-18, copy attached as Exhibit F.) Throughout the Patent Office proceedings on the '699 patent, IR overcame this and all other rejections of Claim 1, but IR never argued that Claim 1 could be distinguished from the prior art because it requires that the common conduction region be relatively highly doped compared to the relatively lightly doped major body portion.

14. For these reasons, the "common conduction region" is properly construed as the semiconductor material of the first
The level of doping/conductivity of the "common conduction region" is not constrained to be higher between the bases than in the underlying "relatively lightly doped major body portion."

2. Spacing

15. IXYS also asserts that there is no "common" conduction region between bases where the two bases are far enough apart that they do not experience "significant FET pinch-off." Again, however, the claim language itself "defines" the "common conduction region" as "the space between said at least first and second base regions" without regard to the spacing between those base regions. While a person of ordinary skill in the art would understand that the bases preferably would be closely spaced to maintain breakdown voltage, the current from both bases will flow through the "space between" "base regions," which is "defined" to be the common conduction region -- whether or not those bases are close enough to generate "pinch off."

16. Similarly, the specification describes current flow from each channel only as flowing through the space between the bases: "Current from each source can flow through its respective channel (after the creation of the inversion layer defining the channel), so that majority carrier conduction current can flow through the bulk region and across the wafer or chip to the drain electrode." ('699 patent, 1:48-53.) The current from each channel flows through the current path defined by the space between bases (i.e., through the claimed "common conduction region"), whether or not those bases interact to generate "significant FET pinch-off."

17. Accordingly, a "common" conduction region is properly construed to refer to the portion of the "relatively lightly doped major body portion" between the bases. The amount of spacing between the bases is not constrained.

3. Admixing

18. IXYS also argues that statements in the '699 file history restrict the word common to a region wherein the current from two or more regions "admix." IXYS's reading of the prosecution history of the patents is incomplete. The comment on which it relies was immediately clarified during reexamination to make clear that no literal admixing is required:

Patentee would like to clarify certain of its remarks . . . filed March 24, 1995. In its remarks distinguishing the claimed invention from devices such as those disclosed, e.g., in the Plummer reissue patent and Scharf et al. and Plummer et al. articles, patentee stated that, in the claimed invention, current from the channels admixes and flows downwardly through the common conduction region . . . . Patentee's point is simply that current flow in the common conduction region is predominantly vertical, whereas current flow in a device [like Plummer's] with a surface drain disposed between the channels is predominantly lateral. Whether or not there is literal admixing of current in the common region is irrelevant to the invention." (Supplemental Response, Dated May 19, 1995, emphasis added.)

Footnotes

1 Likewise, IR pointed out during the reexamination of the '699 patent that "In paragraph 4 of footnote 4 of the Supplemental Response [in the '699 reexamination], the Patent Owner pointed out that the 'contributions' of the 'crowded electrical current' from each inversion layer of Lisiak et al. Figure 5, disposed along each wall of the 'V', do not combine until they reach the apex of the 'V' beneath the base. Patent Owner wishes to clarify for the record that this statement is not intended to imply, directly or indirectly, that the claims of the Lidow et al. '725 and/or '699 patents are limited to a structure in which there is admixing of current in the common conduction region. Patent Owner's point is simply that the recitation in the claims of a common conduction region between spaced bases does not and cannot read on a V-groove structure, in which the silicon occupying the space limited by the split portions of the base has been removed." (Supplemental Amendment Pursuant to 37 C.F.R. 1.550(b), served November 22, 1996 in Reexam. Nos. 90/003,490 and 90/003,900.)

- 1162 -
cannot meet the presently claimed vertical characterization because, as the Patent Owner explains on amendment page 15, conduction therebetween is horizontal in the main.

2 IXYS cites to testimony in prior cases by the inventors concerning the supposed requirement for commingling of current in a common region. While an inventor may in testimony explain the invention and its development, inventor testimony as to the meaning of claim language seldom should be considered in construing patent claims. Solomon v. Kimberly-Clark Corp., 216 F.3d 1372, 1379-81 (Fed. Cir. 2000). This is particularly true where, as here, that testimony is argued by IXYS to contradict the record of proceedings in the Patent Office. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996).

20. Those of ordinary skill would have understood that the current contribution from one '699 base tends to spread laterally as the current flows generally downwardly through the device. Since this is true of the other '699 spaced bases as well, the lateral components of these currents tend to cancel each other, resulting in a location between two given bases, (which Dr. Zommer referred to as the "zero current line") at which the net lateral current is zero. In other words, the current component going from left to right exactly matches the current component going from right to left at that point, so the net lateral current component is zero.

21. Electrons in a device such as a MOSFET move according to two principal phenomena. One is called "drift," and refers to the tendency of a charged particle such as an electron to move in response to an electric field or voltage. The other is called "diffusion," and refers to the motion of electrons and other particles according to local thermal conditions. A "zero current line" does not suggest that exactly zero electrons cross it. Instead, it suggests that the electric fields are arranged so that the net number of electrons crossing it is zero. If, for example, random thermal motion caused more electrons to cross the "zero current line" from left to right, that a voltage would be created that would be just sufficient to cause an equal number of electrons to cross from right to left. In this way, although electrons are moving constantly in all directions due to thermal conditions, a dynamic equilibrium is established so that the net flow across the "zero current line" tends to return quickly to zero.

22. This phenomenon is present in any MOSFET having two active base regions being held to (more or less) the same potential, such as those depicted in the '699 patent. When the channels are activated in that structure, the potential of the material near the channel will tend towards the voltage of the source electrode, while the material lower down in the device will tend towards a higher voltage (in an n-channel device, which voltage will be a function of the device current and on resistance). Under those conditions, there will be a "zero current line" at some point between the bases in the material defined in the claims to be the "common conduction region." Thus, there would be understood to be literal "admixing" of electrons at a "zero current line" in the devices depicted in the '699 patent, and in any other MOSFET device where opposing channels are held at (more or less) the same potential.

23. For these reasons, the claimed "common conduction region" is properly construed not to require any particular kind of interaction between the current flows emanating from the spaced bases.

32. The added element introduced by Claim 28 is as follows: "The device of claim 1 wherein said vertical common conduction region is continuous and uninterrupted." In the examples of the '699 patent, the common conduction region is a three-dimensional structure following a path corresponding to that of gate electrode 24 in Figure 1 and gate electrode 80 in Figure 8. In each instance, it is possible to transit from any point to any other point within that three-dimensional structure while staying entirely within the common conduction region. A "continuous and uninterrupted" common conduction region is properly construed to require that be possible to transit from any point to any other point within that three-dimensional structure while staying entirely within the common conduction region.

- 1163 -
10. "common data store"/"data memory accessible by each of said processors"

The term "common data store" appears in claim 10 of the 037 Patent. 037 Patent, 56:65. The term "data memory accessible by each of said processors" appears in claim 11. Id. at 57:21. In both claims, the claimed processors access the "data memory" or "common data store" to allow for the "storage and retrieval" or for the "transfer" of data between system components. Id. at 56:65-57:5, 57:21-23. Once again, plaintiff argues that no construction of these terms is needed. Defendant argues that both terms should be construed as "shared computer memory (as distinct from the mass storage device(s)) in which each of the facility processors can locate a unit of data to use in the process." 9

9 Although defendant initially contended that "every process" should have the capability of locating a unit of data in the common data store, defendant's responsive brief concedes that "each of the facility processors" better reflects with the language of the claims. See Def.'s Responsive Br. at 21-22.

The court again begins its analysis with the ordinary meaning of the claim language. Although neither the phrase "common data store" nor "data store" are defined in the IEEE Dictionary, the noun "storage" has a well-established meaning in the art of "electronic computation," which the IEEE Dictionary defines as "[a]ny device in which information can be stored, sometimes called a memory device," or "a section [of a computer] used primarily for storing information . . . sometimes called a memory or a store." Id. at 1112. The description of a "store" as memory is also consistent with the specification, which refers to the claimed data store as a "memory resource" in the preferred embodiment of the invention. 037 Patent, 13:40-41, 14:23. Indeed, the parties do not distinguish between the "common data store" recited in claim 10 and the "data memory" term in claim 11. Based on the ordinary meaning of the words "data store" and the disclosures in the specification, the court sees no reason to do so either. As the claim language makes clear, this memory resource is also "shared" or "common" to each to the filesystem facility processors in the claimed invention. See id. at 56:65-57:1, 57:21-23; see also id. at fig. 6 (depicting shared "memory" (18)). Based on this language, the court agrees that the adjective "shared" aptly describes the memory resource claimed in the 037 Patent.

Defendant urges the court to go one step further to require that claimed common data store (or data memory) allows "each of the facility processors can locate a unit of data to use in the process." However, to the extent that such a limitation is necessary, the surrounding claim language makes clear which processors can access the shared memory. For example, claim 11 expressly provides that "each of the said processors" can access the data memory "for the storage and retrieval of data blocks exchangeable between said processors." Id. at 57:21-23. Claim 10 similarly claims a network facility and a filesystem facility, each facility "providing for the transfer of data between said data store and said [facility]." Id. at 56:65-57:1. Thus, because these limitations are clear from the ordinary meaning of the other claim terms, the court declines to read these limitations into the "common data store" or "data memory" term.

Finally, defendant requests that the court construe the terms "common data store" and "data memory" to be "distinct from the mass storage device(s)." Defendant notes that in the specification, the preferred embodiment discloses a "memory resource" -- i.e, a "data store" -- that transfers data to and from a mass storage device (the "disk array resource"), thereby implying that the memory resource and mass storage device are separate and distinct. from each other. Id. at 13:34-50. While this may be true of the preferred embodiment of the invention, no such limitation appears in the language of the claims. The court cannot rewrite the claims to introduce one. Accordingly, the court construes "common data store" in claim 10 as "shared data memory." On the other hand, because it is clear from the term "data memory accessible by each of said processors" that the data memory is in fact shared by the processors that have access to it, the court declines to construe that term as it is used in claim 11 of the 037 Patent.
3. "Common Formats"

IBM argues that the phrase "common formats" requires that all of the instructions stored and provided by memory means have a "fixed" or "uniform" format, while Data General contends the phrase allows for more than one format of instructions but requires commonality.

Claim 1 provides that "instructions", now construed as S-Instructions which are a level below high-level language instructions and a level above conventional machine language instructions, have "common formats." See '797 Patent, col. 4, ll. 30-37.

Instruction format refers to the layout of the constituent parts of the instruction. An instruction typically begins with an operation code and is followed by operation code syllables known as Names. The length of operation codes and operation code syllables are measured in "bits." Data General suggest that two sets of instructions consist of instructions having common formats if the formats of one set are the same as, or a subset of, the formats of the other set.

IBM disagrees and asserts that the term "common formats" requires that all instructions share a "common" format in that every instruction has an operation code with a fixed length and operand syllables that have a fixed length within a procedure. In support of its proposed construction, IBM cites the following portion of the Common Specification which describes instructions as having a fixed format:

…the I-Stream has a fixed format: in the present embodiment, SOPs are always 8 bits long, and Names may be 8, 12, or 16 bits long. The length of Names used in a given procedure is fixed….

'602 Specification, col. 345, ll. 60-63. Based upon that and similar provisions of the Common Specification, IBM argues that all instructions must have a fixed format. It contends that because "common formats" does not have a commonly understood meaning in the art of computer science, IBM argues that it is necessary to depend upon the Common Specification to glean the meaning of that phrase.

Again, this Court is unpersuaded by IBM's argument for three reasons:

1. Although the phrase "common formats" does not have a generally accepted meaning in the art, the word "formats" does have such a meaning and the word "common" is not a term of art in computer science. "Common" has the same generally accepted meaning to one skilled in the art of computer science and to laypersons.

2. Even if it were necessary to rely solely on the Common Specification, it does not follow that limitations from the specification should be read into the claims. See Sjolund v. Musland, 847 F.2d 1573, 1581-82 (Fed. Cir. 1988).

3. To construe the phrase "common formats" to mean that all instructions have a single, fixed format contradicts the plain meaning of the plural "formats". The use of a plural indicates that instructions may have more than one format.

The phrase "said instructions" which are to have common formats refers to instructions containing operation codes belonging to more than one functionally different operation code sets. Instructions which are part of two separate sets of instructions must have identical formats. Although the formats in instruction sets of different S-Languages must be the same, Claim 1 does not require that only one fixed format may be used. This Court construes "common formats" as allowing for instruction sets to have more than one format, but requiring commonality.
Katz also proffers a definition for "common processing" as meaning "processing in which the logic underlying certain of the content and/or sequence of steps of the formats are the same or shared." Katz Brief at 36. Verizon does not offer a competing interpretation.

The Court adopts Katz's asserted interpretation to the extent it is consistent with the construction of the same limitation in the Joint Claim Construction and Prehearing Statement. See Moore 1/14/03 Decl.Ex. 13 at 3.

Static Display of Prices/Common Static Price Axis

The parties dispute the meaning of "static" in "static display of prices" and "common static price axis." Plaintiff argues that the price axis is static, or unmoving, in relation to a change in the inside market. Plaintiff further argues that the patents limit the movement of the price axis in order to increase the likelihood that a trader will not miss his price. Therefore, plaintiff encourages us to adopt a construction of "price levels that do not normally change positions when new market data reflecting a change in the inside market is received," Defendants urge adoption of their various constructions, all of which limit movement of the price axis to a manual re-centering or re-positioning command. At the center of this fight is the question of automatic re-centering-do plaintiff's patents cover automatic re-centering? Plaintiff answers in the affirmative and, not surprisingly, defendants answer in the negative.

Although our preliminary injunction construction aligned with plaintiff's view, such construction was, simply put, preliminary. Jack Guttman, Inc. v. Kopykake Enterprises, Inc., 302 F.3d 1352, 1361 (Fed.Cir. 2002) ("District courts may engage in a rolling claim construction, in which the court revisits and alters its interpretation of the claim terms as its understanding of the technology evolves"). Today we have a better understanding of the technology, and all parties have had the opportunity to flesh out their arguments.

We now choose to alter our initial construction, construing "common static price axis" as "a line comprising price levels that do not change positions unless a manual re-centering command is received and where the line of prices corresponds to at least one bid value and one ask value." We construe "static display of prices" similarly, as "a display of prices comprising price levels that do not change positions unless a manual re-centering command is received." Defendant eSpeed pointed us to MSN Encarta Dictionary to set forth the ordinary and customary definition of static: "motionless: not moving or changing, or fixed in position." Our search of Webster's II New College Dictionary yielded similar results: "Having no motion: at rest" While we recognize that Phillips teaches us that a dictionary definition should only be used for context. Phillips also teaches that the "words of a claim 'are generally given their ordinary and customary meaning,[..., which is] the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." 415 F.3d at 1312-13. Plaintiff has given us no reason to think that such a person of ordinary skill in the art would construe "static" as anything other than non-moving at the time of the invention.

n4 We do find it interesting that in all of plaintiff's filed exhibits with regard to claim construction, including two dictionary excerpts, plaintiff has never argued that the ordinary and customary meaning of "static" is something other than stationary or non-moving.

If "static" ordinarily means non-moving, then we cannot see how we can construe it any other way. The only exception can be the one explicitly stated in the specifications and prosecution history-movement due to receipt of a manual re-centering command. If we were to construe the term inclusive of additional unstated exceptions, such as automatic re-centering, we would not know where to stop. Defendant eSpeed aptly asks, "Why is a price display which automatically receneters after every two seconds 'static,' but a price display which automatically recenters after every five seconds is not? Why is a price display that automatically receneters when the inside market exceeds three ticks from the center price 'static,' but a price display which automatically recenters after every fifth tick is not?" (eSpeed's post-Markman brief, at 6, n4). Plaintiff's own argument raises the same questions. Plaintiff notes, "In fact, with eSpeedometer (which contains a slow drift recentering..."
component,) a price level never suddenly changes position under a trader's cursor causing him to miss his intended price. This is in contrast to the eSpeed product addressed by the Court at the PT hearing which provided for an instantaneous automatic recentering when the inside market moved off the top or bottom of the screen. Thus, eSpeedometer is more 'static' than eSpeed's previous product because it provides the trader with virtually a 100% guarantee that he will not miss his intended price" (plf's post-Markman brief, at 8-9, n5). n6 How can any movement be "more static"? What is static enough to fall within the ambit of plaintiff's static construction? Because we cannot say, we must construe the term "static" in its ordinary meaning, non-moving, and allow for the only exception plainly stated in the written description: manual recentering.

n5 It is possible that eSpeed's (or any other defendant's) product will be considered "static" under the doctrine of equivalents, even under the current construction. Such analysis, however, is reserved for a future date.

We find unpersuasive plaintiff's argument that the patent only increases but does not guarantee the user's likelihood of accurately selecting his desired price. Plaintiff's patents are designed to achieve simultaneous goals: speed and accuracy. With regards to accuracy, the patent specification states, "The 'Mercury' display and trading method of the present invention ensure fast and accurate execution of trades by displaying market depth on a vertical or horizontal plane, which fluctuates logically up or down, left or right across the plane as the market price fluctuates" ('132, 3:5-9; '304, 3:9-13) (emphasis added). Like defendants, we read such language as a guarantee. It is only with regard to speed that the patents cannot guarantee accuracy - it is impossible to know how quickly a trader will process a desired price, move his hand to the user input device, and select the bid or ask region. It is with that in mind that the patent states "[t]he faster a trader can trade, the less likely it will be that he will miss his price and the more likely he will make money" (132, 2:60-62; '304, 2:65-67). We find that the purpose of the patents' invention would be frustrated by the inclusion of any movement uncontrolled by the user. See Curtiss-Wright Flow Control Corp. v. Vclan, Inc., 438 F.3d 1374, 1379-81 (Fed. Cir. 2006) (limiting the claim term "adjustable" to the patent's consistent description that adjustment occurs during operation of the de-header system, in part because "[a]ny construction to the contrary is not consistent with the overall context of this invention and this field of art as described in the specification"). Thus, we are further convinced of our construction.

We take time to note that the construction of "common static price axis" includes the phrase, "where the line of prices corresponds to at least one bid value and one ask value." We do so to clarify that with regard to the 'Mine of prices," orientation of the axis is irrelevant - it can be horizontal, vertical or angled, for example. We find that use of the claim language "common," "corresponding to" and "aligned" are all used as synonyms for "in relationship with." See Id., 438 F.3d at 1380 ("this court has acknowledged that two claims with different terminology can define the exact same subject matter"). The specification's language states that "Mercury displays market depth in a logical, vertical fashion or horizontally or at some other convenient angle or configuration" ('304, 4:2-45, '132, 7:22-25). That market depth, which includes the best bid and the best ask, can be displayed on an angle gives further support to plaintiff's contention that "common" connotes no more than a relationship between the price axis and the bid and ask display regions.

We also note our use of the term "price levels" in the construction of both "common static price axis" and "static display of prices." While recognizing that the '132 patent does not use the term "price level" in the claims, as compared to the '304 patent, we find that the intrinsic evidence compels us to adopt such language in both constructions. We re-assert our preliminary injunction analysis regarding this issue: "the real issue is what 'static display of prices' means, and we understand that phrase to include price levels, which is where the prices are located and displayed. In other words, the display of prices is a region in which prices, represented by numbers, are shown." Trading Technologies Int'l. Inc. v. eSpeed, Inc., 370 F.Supp.2d 691, 699 (N.D.Ill.2005) ("Trading Technologies I"). We reject defendants' contention that "price levels" are synonymous with prices or representation of prices. The written descriptions of both patents consistently refer to "price rows" and "price levels." For example, "The market depth display shows the trader the interest the market has in a given commodity at different price levels" ('304, 6:17-19, '132, 5:50-52). "The status of each order is displayed in the price row where it was entered" ('304, 8:23-24, '132, 7:56-57). "Thus, a right click in the AskQ column in the 87 price row will send a sell order to market at a price of 87 and a quantity of 150" (304, 10:46-48, '132 10:8-10). "A left click would enter an order with a price corresponding to the price row clicked . . ." (304, 11:21-22, '132, 10:50-51). n6 Found in the preferred embodiment, it is clear that both patents intended to showcase a "price level" that was broader than simply price. Pfizer, Inc.
v. Teva Pharmaceuticals. USA, Inc., 429 F.3d 1364, 1374 (Fed.Cir. 2005) ("A claim construction that excludes a preferred embodiment...is 'rarely, if ever, correct'"). Thus, we define "price level" as "a level on which a designated price or price representation resides."

n6 Defendant eSpeed argues that the use of "price levels" with respect to Figure 2 ("The working bid and ask quantity for each price level is also displayed in columns 202 and 205 respectively" (304,5:27-29, '132, 5:23-25)), wherein 202 and 205 are on the same horizontal row, proves that "price levels" are synonymous with "prices." Plaintiff counters by arguing that Figure 2 docs contain "price levels" under its proposed construction - the trading screen has a level or region on which the price resides that does not extend across the entire row, as compared to patents' preferred embodiments-We find plaintiff's argument persuasive.

Analysis of a patent infringement claim is a two-step process. First, we construe the claims, an issue of law for the court to determine. Warner-Lambert Co. v. Teva Pharmaceuticals USA, Inc., 418 F.3d 1314, 1340 (Fed.Cir.2005). Second, we compare the accused product or process to the properly construed claims, an issue of fact for the fact-finder. Id. Plaintiff's patent infringement claim will be successful "only where the accused product or process contains each limitation of the claim, either literally or under the doctrine of equivalents." Id. (citing Deering Precision Instruments, L.L.C. v. Vector Distrib. Sys., Inc., 347 F.3d 1314, 1324 (Fed.Cir.2003)). Defendants argue that plaintiff is conflating the two steps. By arguing that defendants' products may still infringe on plaintiff's patents under a part-time infringement theory, eSpeed suggests that TT is putting the cart before the horse. eSpeed contends that "[t]he theory of part-time infringement is not a canon of claim construction and does not override the plain meaning of the claim or the disclosures in the specification and file history... It is the claim construction, which is derived from the plain meaning of the claim and intrinsic evidence, that dictates whether the theory of part-time infringement has any relevance to the infringement analysis. Under the plain meaning of the claim and the Court's claim construction, part-time infringement is inapplicable because a price axis that moves other than through a manual re-centering command is not a static one" (eSpeed response, at 5).

We agree with defendants that the analysis of part-time infringement is, as the name implies, one of comparison -- the second step of patent infringement analysis. Because there seems to be some confusion on the construction of the term "static," however, we will address the merits of plaintiff's arguments. Specifically, we will address whether the term "static" in "common static price axis" and "static display of prices" requires a permanent state of lack of movement.

Plaintiff's arguments center on two overlapping principles. First, plaintiff contends that Claim 1 of each patent-in-suit is an open claim, designated by the term "comprising" in its preamble. Plaintiff asserts that such a claim does not preclude the existence of additional unrecited features of an accused product or process. Second, plaintiff asserts that part-time infringement - infringement for any length of time, regardless of whether the accused product or process also has times of non-infringement -- covers its claims. Although plaintiff's briefs imply that the two arguments are part of the same theory, we are not so sure. TT's "comprising" argument seems to assert that automatic re-centering is an unrecited additional feature that is made possible by the fact that the price axis was already in a static condition (TT reply, at 2). We read that to mean that the automatic re-centering is separate from the static claim limitation. TT's part-time infringement theory, on the other hand, seemingly suggests that the mere presence of a static price axis -- regardless of whether it moves at some time -- is...
still infringing (id., at 1). In our view, such an argument suggests that automatic re-centering takes an accused product or process out of the purview of plaintiffs patent protection, but only for the split second that it is moving, so that the time when the accused product’s price axis is not moving, it is still infringing. Ultimately, however, plaintiffs arguments both suggest that the addition of movement does not preclude a finding of infringement.

We begin by assessing plaintiffs "comprising" argument. To do so, we must lay out Claim 1 of each patent-in-suit. Patent '304, Claim 1, reads:

A method for displaying market information relating to and facilitating trading of a commodity being traded in an electronic exchange having an inside market with a highest bid price and a lowest ask price on a graphical user interface, the method comprising:

[1] dynamically displaying a first indicator in one of a plurality of locations in a bid display region, each location in the bid display region corresponding to a price level along a common static price axis, the first indicator representing quantity associated with at least one order to buy the commodity at the highest bid price currently available in the market;
[2] dynamically displaying a second indicator in one of a plurality of locations in an ask display region, each location in the ask display region corresponding to a price level along the common static price axis, the second indicator representing quantity associated with at least one order to sell the commodity at the lowest ask price currently available in the market;
[3] displaying the bid and ask display regions in relation to fixed price levels positioned along the common static price axis such that when the inside market changes, the price levels along the common static price axis do not move and at least one of the first and second indicators moves in the bid or ask display regions relative to the common static price axis;
[4] displaying an order entry region comprising a plurality of locations for receiving commands to send trade orders, each location corresponding to a price level along the common static price axis; and
[5] in response to a selection of a particular location of the order entry region by a single action of a user input device, setting a plurality of parameters for a trade order relating to the commodity and sending the trade order to the electronic exchange.

Patent '132, Claim 1, reads:

A method of placing a trade order for a commodity on an electronic exchange having an inside market with a highest bid price and a lowest ask price, using a graphical user interface and a user input device, said method comprising:

[1] setting a preset parameter for the trade order
[2] displaying a market depth of the commodity, through a dynamic display of a plurality of bids and a plurality of asks in the market for the commodity, including at least a portion of the bid and ask quantities of the commodity, the dynamic display being aligned with a static display of prices corresponding thereto, wherein the static display of prices does not move in response to a change in the inside market;
[3] displaying an order entry region aligned with the static display prices comprising a plurality of areas for receiving commands from the user input devices to send trade orders, each area corresponding to a price of the static display of prices; and
[4] selecting a particular area in the order entry region through single action of the user input device with a pointer of the user input device positioned over the particular area to set a plurality of additional parameters for the trade order and send the trade order to the electronic exchange.

Plaintiff correctly notes that the addition of unclaimed unrecited elements does not traditionally defeat a finding of infringement where the patent uses an open transitional phrase such as "comprising." Free Motion Fitness, Inc. v. Cybex Int'l, Inc., 423 F.3d 1343, 1347 (Fed.Cir.2005); CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1235 (Fed.Cir.2005); Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1371 (Fed.Cir.2005). Therefore, when the term "comprising" appears in the preamble of the claim, as it does here, it is generally read to mean including, but not limited to, the following elements. Nazomi Communications, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed.Cir.2005) ("Comprising' is often synonymous with 'including"); Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, Inc., 246 F.3d 1336, 1348 (Fed.Cir.2001) ("In the parlance of patent law, the transition 'comprising' creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements").
limitation of a static or non-moving condition. n5 Any movement takes a product or process outside the scope of plaintiff's claim. See W.E. Hall Co., Inc. v. Atlanta Corrugating, LLC, 370 F.3d 1343 (Fed.Cir.2004) (where an accused product failed to meet each of the elements or limitations required by the claim language itself, a partially open transition term could not enlarge the scope of the claim); Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261 (Fed.Cir.1986) (the term "comprising" did not affect the scope of the particular structure recited within the method claim's step). Unlike Smith & Nephew, Inc. v. Ethicon, Inc., 276 F.3d 1304 (Fed.Cir.2002), failure to include movement of the static price axis in plaintiff's claims would not exclude a reasonable practice taught in the specification of the patent. And unlike CollegeNet, Inc., 418 F.3d at 1235, failure to include movement of the static price axis in plaintiff's claims would not be inconsistent with the problems the invention sought to redress. Rather, including movement of the static price axis would work against the patents' stated purpose: "If a trader intends to enter an order at a particular price, but misses the price because the market prices moved before he could enter the order, he may lose hundreds, thousands, even millions of dollars" (304, 2:61-65, '132, 2:57-61). It is a basic principle of patent law that an infringing use of a patented method or claim requires practice of every limitation of the claim or every step of the method. Zoltek Corp. v. U.S., 442 F.3d 1345, 1359 (Fed.Cir.2006). Addition of the term "comprising" does not remove the limitations that are present in the claim, Power Mosfet Technologies, L.L.C. v. Siemens AG, 378 F.3d 1396, 1409 (Fed.Cir.2004). Therefore, we do not read "comprising" as allowing some movement of the static price axis. Our earlier constructions remain, and we clarify that the price axis never changes positions unless by manual re-centering or re-positioning.

n5 We have already determined that "static" means non-moving. TT Markman I, 2006 U.S. Dist. LEXIS 80153, 2006 WL 3147697. In addition to the plain and ordinary meaning we focused on in TT Markman I, we also note several instances in the intrinsic record suggesting such a construction. See, e.g., '304, 7:65-67 ("The values in the price column are static; that is, they do not normally change positions unless a re-centering command is received..."); Amendment and Reply under 37 CFR § 1.111 (eSpeed Markman exhibits, Exh. E, at eS0000604873) (same); Notice of Allowability (id., Exh. OO, at eS0000604919) ("The static display, directed to the commodity price, does not change").

Once we determine that the term "comprising" does not allow for any movement of the static price axis, it is easy to dispose of plaintiff's part-time infringement argument. Plaintiff correctly points out that "an accused product that sometimes, but not always, embodies a claimed method nonetheless infringes." Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 622 (Fed.Cir.1995). The statute governing patent infringement, 35 U.S.C. § 271(a) (2003), also suggests that any infringement -- even de minimis infringement -- is actionable; the level of infringement is a question of damages, not liability. Embrex, Inc. v. Service Engineering Corp., 216 F.3d 1343, 1352-53 (Fed.Cir.2000) (Rader, J., concurring). Where, however, the claim limitation itself -- here, a static condition -- requires permanency, any movement (outside of manual re-centering or re-positioning) negates one of the specified claim limitations. Therefore, introduction of such movement takes an accused device out of the protection of plaintiff's patents.

The situation at hand is different from those cases finding part-time or de minimis infringement. For example, the court in Seal-Flex, Inc. v. Athletic Track and Court Const., 172 F.3d 836, 845 (Fed.Cir.1999) found infringement where defendant's customary method was non-infringing, and defendant only used plaintiff's patented method one time. Or, in SmithKline Beecham Corp. v. Apotex Corp., 403 F.3d 1331, 1341-42 (Fed.Cir.2005), the Federal Circuit affirmed the district court's determination that trace amounts of the patented compound found in the infringing device would infringe under the construction of the claims. Or, in Embrex, 216 F.3d 1343, the court found infringement when defendants engaged in testing for commercial purposes using plaintiff's patented technology. In this case, in order to literally infringe, defendants must practice all elements of plaintiff's patented technology. Zoltek Corp., 442 F.3d at 1359. Therefore, any movement of the static price axis leaves accused technology outside the protection of plaintiff's patents.

 Plaintiff makes various other arguments and points to various extrinsic evidence in support of its position that any period of a static condition falls within our construction of "common static price axis" and "static display of prices." None is persuasive. We have already determined the influence of the phrase "ensure fast and accurate execution" in the claim construction. Free Motion Fitness, a case cited by plaintiff to support its argument that the patents did not guarantee accuracy, tells us "to scrutinize the intrinsic evidence in order to determine the most appropriate definition" of a claim term. 423 F.3d at 1348-49. That is exactly what we did -- we turned to the specification, which suggested that the patented
technology would "ensure fast and accurate execution" to construe "common static price axis" and "static display of prices." Thus, we need not alter our construction. And the extrinsic evidence presented -- in light of our construction, based almost entirely on intrinsic evidence -- will not change our construction.

1. "Communicating a superseding signal to a bus coupled to said first computer and said at least one originally provided memory through a diagnostic/emulation port or harness coupled to said bus from an adapter module, said superseding signal to alter control of said engine by said first computer."

Plaintiff argues that this phrase should be read to mean "communicating or sending a signal, from an adapter module through a vehicle diagnostic/emulation port or wiring harness, to a bus connected to the vehicle computer, that alters the way the vehicle computer controls the engine." Defendants offer a competing interpretation: "communicating a superseding signal from the adapter module through the diagnostic/emulation port or harness to the vehicle computer, overriding the control signals that are simultaneously being sent from a first computer to the engine, resulting in the alteration of the control of the engine by the first computer." The essence of the parties' dispute is the definition of "superseding"; Defendants insist that this term requires that both the originally provided memory and the additional preprogrammed memory simultaneously send signals to the ECM, with the signal from the additional memory overriding the signal from the originally provided memory.

Mr. Lundell has recommended a construction of the disputed phrase as a whole but has not expressed an opinion on this particular issue. The Court notes, however, that Mr. Lundell's reading of claim 1, which the Court has adopted, permits the communication either of the contents of a memory or of the physical memory itself. If the physical memory contained in the adapter module is communicated to the ECM, replacing the originally provided memory (which, according to all parties, is transferred to the adapter module in this embodiment of the invention), then it is not possible for both memories to send signals to the ECM at once. The Court therefore adopts Mr. Lundell's recommended construction, which permits either simultaneous signaling or signaling only by the additional memory: "communicating a superseding signal from an adapter module to a bus coupled to the first computer and the originally provided memory, with the result of altering control of the engine by the first computer."

TERM # 13: "communicating at least one message associated with said submitted bid to said issuer's computer over said at least one electronic network" - As an initial matter, the majority of the terms used in this phrase have already been defined, as evidenced by the repeated use of the term "said", meaning, previously mentioned. Defendants' proposed claim construction requires that the bidder's computer do the communicating. And again, the intrinsic evidence to which they cite does not support such a construction. As plaintiff correctly points out, the patent contemplates that an auctioneer's computer could be used to coordinate the auction. Under such circumstances, the bid information could emanate from the auctioneer's computer. There is no support in the intrinsic record for importing the limitation proposed by defendants. As such, this phrase means: "a message associated with the submitted bid is sent to the issuer's computer over at least one network for
communicating data messages between said computers, including, but not limited to, the Internet."

The Special Master construed the phrase "communicating frames containing data between all of the nodes at a common communication capability" appearing in claim 31 of the 732 patent as follows:

I find that this phrase requires that each and every node in the network have the ability to communicate with the medium and hence with each and every other node in the network at the common communication capability, and that each node would be expected to use this ability at some time in the operation of the network. This means that in actual network operation, each node at some time can be expected to place data frames on the medium at the common capability and receive data frames from the medium at the common capability.

Datapoint asserts that the requirement that "each node actually use this ability at some time" is an extraneous limitation that controverts the specification and the claim language. According to Datapoint, the patents only require that each node have the ability to transmit and receive frames and either transmit or receive frames at the common communication capability. The Special Master determined that claim 31 of the 732 patent requires that the node not only be able to communicate at the common capability, but also that at some point each node actually do so, lest this method claim be inoperable. J.A. at 41 ("The mere fact that a node may have the capable hardware and/or software installed would not meet this method limitation if the network system organization precluded that node from using that communication capability in actual network operation.") (emphasis in original)); cf. Wang Labs, Inc. v. America Online, Inc., 197 F.3d 1377, 1383, 53 U.S.P.Q.2D (BNA) 1161, 1165 (Fed. Cir. 1999) (noting that claims should be construed to preserve their validity). This was not an erroneous construction.

Datapoint's position hinges on its belief that communication occurs when at least one node transmits and at least one node receives frames containing data, such as in a broadcast communication. But claim 31 recites "a method of communicating information frames between at least three nodes in a [LAN] comprising . . . communicating frames containing data between all of the nodes at a common communication capability and in accordance with a predetermined logical connectivity pattern . . . ." (emphasis added). And the specification explicitly defines what "communication" means for purposes of the present invention: "Communication between nodes occurs by sending and receiving frames. A frame is a series of signals applied to a medium." 732 patent, col. 10, lines 49-51 (emphasis added). Thus, to meet all of the limitations of method claim 31, each of the at least three nodes in the LAN must at some point during network operation interconnect as equal peers and send and receive a series of signals applied to a medium. Such a construction comports with the purpose of the invention and is proper when claim 31 is read in light of the specification as a whole.

After considering the arguments of counsel and the intrinsic record, the court concludes that the term "communicating with" requires no construction.

The phrase "the central server communicating with said content provider" - as used in the '498 Patent - means "the central server providing information to or receiving information from said content provider."

- 1172 -
A. "Communication"

Fortinet argues that "communication," as used in the '272 Patent, is limited to calls, while PAN contends that the patent imposes no such limitation, and "communication" should be understood as having its ordinary meaning. In light of how "communication" is used in the patent as a whole, the court agrees with PAN.

The words of the claims themselves shed little light on whether "communication" is limited to calls or can include other types of communication. According to Fortinet, the fact that claim 24, a dependent claim of claim 1, refers to "said call destination" when claim 1 only discusses how to determine the destination for a communication shows that "call" and "communication" are used interchangeably. See '272 Patent 12:59-13:4 (claim 1), 14:9-11 (claim 24). While this claim language is consistent with Fortinet's interpretation, it is also consistent with dependent claim 24 merely having a narrower scope than claim 1 (claim 24 being limited to calls, whereas claim 1 includes all communications).

The specification is the "single best guide to the meaning of the disputed term." Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005). The court thus looks to the specification for guidance as to how "communication" should be construed. The specification states that "[t]he classification method can be used for managing any type of communication. For example, the invention can be used to classify and/or route facsimile messages or other printed documents, electronic mail messages, instant electronic messages, or any other human readable or computer readable communication." '272 Patent 12:32-38 (emphasis added). The patentee thus expressly disclosed to the public that the "communication" referred to in the claimed invention includes "any type of communication," including facsimiles, printed documents, e-mail, instant messages, and more. Id. Further driving this point home, the specification refers to an embodiment using a "textual communication" and explains that "[r]outing of communications can be accomplished over electronic channels or through physical transportation of the communication." Id. at 12:40, 44-46. Construing "communication" to mean "call" would exclude such textual communications and communications that are routed through physical transportation, such as paper documents.

Fortinet contends that the claimed invention is limited to routing of calls because the "Field of the Invention" section of the specification states that "[t]he invention relates generally to management of telecommunications calls and more specifically to a method and apparatus for routing and managing telecommunications calls and for developing rules for accomplishing the same." '272 Patent 1:9-12. This statement only asserts that the invention relates to management of telecommunications calls and does not assert that it is limited to management of telecommunications calls. Moreover, even if this statement, standing alone, could be read as suggesting that the patentee only contemplated use of the invention for telecommunications calls, this statement should be read in the context of the patent as a whole. Elsewhere in the specification, the patent refers to "the management and routing of communications, such as telecommunications calls." Id. at 4:1-2. This usage suggests that "communications," as used in the patent, is not limited to telecommunications calls. In the context of the patent as a whole, particularly in light of the express statement that the invention can be used for "any type of communication," the statement in the "Field of the Invention" section is insufficient to limit the meaning of "communication" to calls. See Martek Biosciences Corp. v. Nutrinova, Inc., 579 F.3d 1363, 1380, 1383 (Fed. Cir. 2009) (finding that patentee's explicit definition of a claim term controls even when language in the "Field of the Invention" section suggests a more limited claim scope).

The fact that the preferred (and only) embodiment described in the patent deals with routing of telephone calls does not suggest that the claimed invention is limited to the management of calls. "[I]t is improper to read limitations from a preferred embodiment described in the specification -even if it is the only embodiment— into the claims absent a clear indication in the intrinsic record that the patentee intended the claims to be so limited." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 913 (Fed. Cir. 2004). In this case, not only is there no clear indication that the patentee sought to limit the claims to calls, the specification expressly states that the invention can be used for managing "any type of communication." '272 Patent 12:32-38. Additionally, with regard to the preferred embodiment, the specification states, "[t]he invention has been described through a preferred embodiment. However, the embodiment is not intended to be limiting to the scope of the invention as defined by the appended claims and legal equivalents." Id. at 12:54-57.

Fortinet argues that if "communication," as used in the '272 Patent, is not limited to calls, the patent would be invalid for lack of the required enabling disclosure. Though the court recognizes the maxim that claims should be construed to preserve their validity, the Federal Circuit has indicated that this principle should not be applied broadly and should be limited to cases where a claim remains ambiguous even after the court has applied all available tools of claim construction. Phillips, 415 F.3d at 1327; see also Liebel-Flarsheim, 358 F.3d at 911 ("unless the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous, the axiom regarding the construction to preserve the validity of
the claim does not apply”). In this case, the specification makes clear that "communication" has its ordinary and customary meaning. Hence, for the purposes of claim construction, the court need not determine whether such a construction would render the claims invalid.

The court finds that "communication" has its ordinary and customary meaning and is not limited to calls. Because the plain meaning is sufficiently clear from the claim language, there is no need for construction of this term.

Communication with the network; communicating/communication with an ASP; all forms of "communicate"

The term "communicate" appears, in some form, in Claims 1, 11, 12, and 13. MyMail proposes the term be construed to mean "the ability to exchange data" or the "exchange of data," depending on the context within the claims of the 290 patent. Implicit in MyMail's definition is the limitation that communication must be a two-way process. Defendants, citing two dictionaries, assert that "communicate" means "transmit information" and also argue that communication can be either one-way or two-way.

The specification describes a communications connection where the user and NSP transmit and receive data. See Col. 7:10-16. Communication cannot then be defined as transmitting information since it also entails receiving information. The Court thus rejects Defendants' proposed definition as being inconsistent with the specification. However, the Court must still determine whether communication, as defined in the 290 patent, includes one-way processes or must be limited to two-way processes.

The Court concludes that in the context of the 290 claim language, communication cannot be one-way since that would render the word "with" meaningless. The word "with" implies a two-way conversation. Had the patentee intended to include one-way conversation in his definition of "communicate," he would have replaced "with" with "to," or some other analogous word or phrase, in his claim language. The Court therefore substantially adopts MyMail's definition since "exchange" better reflects the two-way nature of communication.

The parties additionally dispute the meaning of the phrases "communication with the network" and "communicating with an ASP." MyMail proposes that "communicating with an ASP" be defined as "exchange of data with an ASP over a connection to the network." Defendants propose that "communication with the network" be defined as "transmission of information to a system of interconnected computers." The Court notes that MyMail's "over a connection to the network" limitation is already implicit in the definition of communication. For example, the Microsoft Press Computer Dictionary states that computer communication requires a connection or link between the computers. See MICROSOFT PRESS COMPUTER DICTIONARY 102 (3d ed. 1997). Thus, one skilled in the art understands that communication occurs over a connection to the network. However, a juror may not fully appreciate this nuance. Given that the purpose of claim construction is to "elaborate the normally terse claim language in order to understand and explain . . . the scope of the claims," the Court concludes that limitation is necessary to definitively express what is otherwise implied. Embrex, Inc. v. Serv. Engr. Corp., 216 F.3d 1343, 1347 (Fed. Cir. 2000). The Court therefore construes "communication" to mean "exchange of data," "communication with the network" to mean "exchange of data over a connection to the network," and "communication with an ASP" to mean "exchange of a data with an ASP over a connection to the network."

7. Communication

Genlyte asks the Court to construe the word "communication," which appears in claims 1 and 8, and the word "communicating," which appears in claims 8 and 14, to mean "digital communication" and "digitally communicating." While Genlyte argues that "the digital nature of 'communication' . . . was apparent to the U.S. PTO, and was (and is) apparent to one of ordinary skill in the Relevant Art," Lutron contends that because the inventors never claimed the digital nature of the communication as a feature of the invention in either the independent or dependent claims, the Court should
The Federal Circuit has unequivocally stated that (1) this Court cannot alter what the inventors chose to claim as their invention, (2) limitations appearing in the specification will not be read into claims, and (3) interpreting what is meant by a word in a claim is not to be confused with adding an extraneous limitation appearing in the specification, which is improper. See Bayer AG v. Biovail Corp., 279 F.3d 1340, 1348 (Fed. Cir. 2002) (internal citations omitted) (emphasis added). The parties do not disagree as to the communication that takes place in the '731 patent. The only disagreement regards whether such communication is digital in nature.

The specification at col. 2, ll. 30-33, states that one objective of the invention is to "simplify the installation of such a multi-room controller by utilizing digital rather than analog signal transmission between individual light controls and the multi-room controller." Additionally, at col. 5, ll. 30-35, the specification states that the individual light controls are adapted to communicate with the multi-room controller through "a digital signal comprising data codes to the controller 12 and receive instructions and data therefrom." The specification goes on to state at col. 5, ll. 45-50 that "because of the digital nature of communication, each light control 10 and the controller 12 are connected by twisted pairs 24 of telephone wire...capable of transmitting the digital signal at up to 1200 baud without measurable signal degradation."

Therefore, the specification clearly shows that the communication which takes place is "digital." While the claim does not specifically say "digital communication," one of skill in the relevant art would have understood that the communication at issue in the '731 patent is digital in nature. Therefore, "communication" in claims 1 and 8 and "communicating" in claims 8 and 14 mean "digital communication" and "digitally communicating."

D. "for communication between [the host device and the data transmit/receive device]"

Papst proposes that "for communication between" the computer and the data transmit/receive device should be construed to include one-way or two-way communication, or both. Papst's App. at 2. The Camera Manufacturers propose that the phrase "for communication between" means "for transmitting of information bidirectionally and actively between the two devices." CMs' PowerPoint Slides [Dkt. # 267] ("CMs' Slides") at 55.

As more fully explained above, the preamble to Claim One states, "[a]n interface device for communication between a host device . . . and a data transmit/receive device . . . ." '399 Patent, col. 12:42-45 (emphasis added); '449 Patent, col. 11:47-49 (same). "Communication between" implies bilateral interchanges. The specification describes active communication and data interchange between the host device and the data transmit/receive device via the interface device. See '399 Patent, col. 5:56-62 ("The data transmit/receive device itself can also communicate actively with the host device via the first and second connecting device . . . ."); '449 Patent, col. 4:55-61 (same); '399 Patent, col. 8:43-46 (an "important advantage of the interface device of the present invention" is the "extremely high data transfer rates by using, for data interchange, the host device's [sic] BIOS routines."); '449 Patent, col. 7:43-47 (same). Accordingly, the Court accepts, with slight modification, the construction proposed by the Camera Manufacturers, finding it consistent with the construction of the term "data transmit/receive device" to require bidirectional communication. "For communication between" the computer and the data transmit/receive device means "for transmitting of information bidirectionally between the two devices."

In this case, the only general term in dispute is "low voltage communication cable," which appears in Claim 17. While there was not much dispute over what "low voltage" means, there was significant dispute over the specific meaning of "communication cable." Accordingly, the Court limited its construction to "communication cable" specifically. For the reasons outlined in the Court's prior order, the Court construed "communication cable" to mean "any cable which carries any data or control signal from one point to another in a low voltage system -- i.e., that communicates between aspects or elements of a low voltage system."
2. "a first communication connection," "a first communication connection between a caller and a called party" & "a first communication connection between an institutional caller and an outside recipient"

a) The Parties' Proposed Construction and Arguments

T-Netix's Proposed Construction

"A first communication connection" means a telephone connection between an institutional caller and an outside recipient.

"A second communication connection" means a telephone connection between the outside recipient and another party.

T-Netix's PowerPoint presentation at the Markman Hearing, Slides 4 and 10.

Global's Proposed Construction

"a first communication connection between a caller and a called party" or "a first communication connection between an institutional caller and an outside recipient" means:

1. the telephone instrument of the caller,

2. the telephone instrument of the called party, and

3. all apparatus for maintaining an ongoing communication connection between the caller and the called party. Global's PowerPoint presentation at the Markman Hearing, Slide 10.

b) Discussion

The '533 patent is little help in interpreting "communication connection." The term appears only in the claims and not in the specification. The problem with following the rule of using the plain meaning is that both uses of the word "connection" come within the plain meaning, since both meanings are common. According to McGraw-Hill Dictionary of Scientific and Technical Terms, Fifth Edition, the term "telephone circuit" means:

"The complete circuit over which audio and signaling currents travel in a telephone system between the telephone subscribers in communication with each other."

This does not prevent the use of another term as a synonym. As an example, The IEEE (Institute of Electrical and Electronic Engineers) Standard Dictionary of Electrical and Electronic Terms, 1972, defines "telephone connection" as:

"A two-way telephone channel completed between two points by means of a suitable switching apparatus and arranged for the transmission of telephone currents, together with the associated arrangements for its functioning with the other parts of a telephone system in switching and signaling operations."

Global also makes the argument based on the formatting of the claims affecting the scope of the claims. It is a valid point. It would have been possible to move certain elements to the preamble rather than including them as claim elements. The '533 patent includes numerous references such as "a trunk management unit, which connects institutional telephones to outside telephone lines" from the Abstract and "Referring now to FIG. 4, a block diagram of one channel of a multichannel TMU 2 is shown. Generally, TMU 2 includes circuitry to selectively connect inmate phones with outside lines" from column 12, beginning with line 28. Similar phrases appear throughout the patent where some form of the word "connect" is used with "outside lines" or "outside telephone lines." We cannot, however, rewrite the claims. To interpret the claims as Global urges, does, however, create a disclosure problem. The figures used by Global at the Markman hearing add to Figure 1 of the '533 patent. Figure 1 stops at showing outside telephone lines 8. Global added blocks for "local central office" and "remote central office" and shows the called party and a telephone as well as a person representing a third person and the second
communication connection with a telephone. None of these items appear in Figure 1 or any figure of the patent. Figure 4 shows lines going to and coming from a central office, but that is all. There are, of course, reasons to not move some items to the preamble, such as patentability issues or measure of damages. Normally, however, we try to interpret ambiguous claims in a manner that supports validity. We can do that by either interpreting "communication connection" in a narrow sense, such as the dictionary definition put forward by T-Netix:

"3. anything that connects: connecting part; link; bond: a pipe connection."

In a normal landline connection between wired telephones, all of the wires, switches and telephones preexist before a "connection" takes place, so there is some logic to this claim construction. In the alternative, it could be said that the existence of telephones and telephone offices are so well known that no specific disclosure is needed for those features, in which case there is no disclosure problem. That seems to be the better logic in this case, since the construction urged by Global takes into account both the structure of the claims and the shift away from the more restricted language of the specification. Finally, it brings the term "communication connection" into agreement with the term "telephone connection" which is appropriate since the communication that the patent concerns is telephone communication.

c) Construction -- "a first communication connection between a caller and a called party"

In view of the foregoing, the Court concludes that:

d) The term -- "a first communication connection between a caller and a called party" and the term "a first communication connection between an institutional caller and an outside recipient" mean:

1. the telephone instrument of the caller,

2. the telephone instrument of the called party or outside recipient, and

3. all apparatus for maintaining an ongoing communication connection between the caller and the called party or outside recipient.

Consistent with the intrinsic evidence of the '508 patent, the phrase "communication connection is provided between said option connector and said second processor" shall mean "a two-way line of communication in which information may be sent from the option connector to the second processor or information may be sent from the second processor to the option connector."

C. "Communication Device"

"Communication device" is defined as, "An apparatus for the transmission of intelligence between two or more points." This definition accurately summarizes what a communications device would do -- it would communicate, by transmitting data.

Plaintiffs' proposed definition is, "A device having a receiver and a transmitter, or a device having a receiver, or a device having a transmitter." In other words, plaintiff defines a "communication device" as a receiver, or a transmitter, or a device that contains both a receiver and a transmitter. Plaintiff obviously takes this tack because its specifications designate a computer as the "device" that "communicates" -- and computers "communicate" with other computers.

But plaintiffs' disjunctive definition cannot possibly be correct, because it defines a "device having a receiver" (but no
transmitter) as a "communications device." A bare receiver (i.e., a device that can receive data, but not transmit data) cannot possibly be a "communications device," because "communication" requires the transmission of data. "Communicate" comes from the Latin word "communicare," which means "to impart." In the common parlance, the word is defined as, "To convey knowledge of or information about, to make known." WEBSTER'S NEW COLLEGIATE DICTIONARY, 228 (1977 ed.). In scientific and technical parlance, "communication" means, "The transmission of intelligence between two or more points…" McGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNOLOGICAL TERMS, supra, at 440. Both definitions comprehend the sending or imparting of data. A bare receiver cannot send or impart data. It can only accept data. Therefore, it cannot be a "communications device."

It is equally clear from the specifications that a bare receiver cannot be a "communication device" for purposes of the '725 patent. Here is how the contested language appears in context:

    Wherein the limitation or restriction is transmitted to a receiver from a communication device associated with an individual account holder. '725 patent, col. 48, line 29-31.

In this patent, in these claims, the communications device sends data (in the form of a limitation or restriction) to a receiver. Thus, in the context of the claims in suit, the communications device is the sending device, and the receiver is the receiving device. If a communications device could be "a device having a receiver" (but no transmitter), it would be incapable of "transmitting to a receiver." Thus, in the context of the claims in suit, the communications device cannot possibly be a bare receiver. It must, therefore, either be a transmitter, or be something that contains a transmitter.

I hasten to add that nothing in the definitions of "receiver" and "communication device" that I adopt rules out a computer or other input/output (I/O) device as being either a "receiver" or a "communications device."

F. "Communication Device Other Than an Internet-Connected Device" (910 Patent)

This term appears in both independent claims of the '910 patent. CashEdge seeks to construe this to mean "a device for sending or receiving information that does not communicate with the Internet either by wireless or non-wireless means," while Yodlee asserts that no construction is necessary. Alternatively, Yodlee advances a construction that would read "a device that is not connected to the Internet at the time the device receives the notification." CashEdge asserts that the prosecution history shows that the applicants added this language to overcome prior art by excluding all devices that are capable of connection to the Internet, regardless of whether they are not connected at the time of notification. However, the cited file wrapper language does not indicate that any device that can connect to the Internet is not included, it only shows that notification via e-mail would constitute notification via an Internet-connected device. CashEdge Ex. 12 at CE 00003344-45, 00003355. Furthermore, dependent claim 6 covers wireless communication devices that are "incapable of Internet connection." Where there are different words used in different claims, there is presumed to be difference in meaning. Tandon Corp. v. International Trade Com., 831 F.2d 1017, 1023 (Fed. Cir. 1987). The CashEdge construction goes against this presumption by construing "other than an Internet-connected device" as meaning the same thing as "incapable of Internet connection." The Court construes this term to mean "a device that is not connected to the Internet at the time the device receives the notification."

29. Bi-directional communication fabric

The phrase "bi-directional communication fabric" means "an interprocessor communications network allowing communication in both directions." The specification suggests that the patentee used "network" and "fabric" interchangeably. See 840 patent, col. 6, 11. 16-19. At least one programmable media processor is provided within the communications network for receiving, processing, and transmitting the at least one stream of unified media data over the bi-directional communications fabric.
Citrix asserts that this is a mean-plus-function pursuant to 35 U.S.C. Section 112, paragraph 6.

Use of the term "means" creates a presumption that the element is to be construed in accordance with Section 112, paragraph 6. This presumption may be rebutted, however, when claim element recites sufficiently definite structure or material to perform the claimed function. Absence of the term 'means' creates a presumption that the element is not to be construed in accordance with Section 112, paragraph 6. However, this presumption may be rebutted when the claim element does not recite sufficiently definite structure or material to perform the claimed function. In determining whether these presumptions have been rebutted by a preponderance of the evidence, the court may examine the intrinsic evidence and any relevant extrinsic evidence.

Schwartz, supra, § 5.III.C.

There are four permutations of "communication facility" at issue here, and Citrix asserts that all of them are subject to Section 112, paragraph 6. The court disagrees. The four permutations are as follows: 1) "Data Communication Facility"; 2) "Location Facility"; 3) Communication Facility"; 4) "Data Generating Facilities."

None of these four permutations use the word "means" and Citrix fails to rebut the presumption that this is not a means-plus function by a preponderance of the evidence. The court agrees that the specification provides a clear description of the "facilities" and particularly the "data communication facility" as a computer software product. Indeed, the specification provides that "a number of computer program facilities are described in this invention as separate facilities for the sake of describing the invention." '479 Patent, col. 10, lines 11-13. Therefore, the court concludes that 01 Communique's proposed construction is correct, which is "Computer software associated with the personal computer."

J) "a communication facility"

As explained in section E) above, the court agrees with 01 Communique that the appropriate construction is "Computer software associated with the remote computer."

1. "Communication Facility"

The parties have asked the Court to construe the term "communication facility." 1 The plaintiffs argue that although the term does not have a common meaning to one of ordinary skill in the art, 2 the meaning is clear from the claim language. The plaintiffs contend that because the purpose of the communication facility in the claims is to connect callers to the interactive voice application ("the Katz system"), the kind of communication facility is inconsequential and the Court should construe the term to mean "any telephone network that enables callers to make calls." (Pls.' Brief at 44-45).

--- Footnotes ---

1 The parties agree that the term "telephonic [or 'telephone'] communication system" is synonymous with "communication facility" and thus should be construed the same. The Court finds no reason in the claim language, specifications, or prosecution history of the patents which contain these terms to construe the two terms differently.

In addition to Claim 51 of the '309, the term "communication facility" or "telephonic [or 'telephone'] communication system" appears in the following claims: Claims 33, 44, 93, 104, 117 and 192 of the '707 patent, Claims 49, 50, 65, 79, 171, and 190 of the '863 patent, Claim 10 of the '309 patent, Claims 17, 20, 24, and 77 of the '285 patent, and Claim 15 of the
presented by the plaintiffs, the term "communication facility" does not require the involvement of the entire PSTN or thus,
construction of this term. Thus, I conclude that in light of the claim language, specifications, and prosecution history
not undermine this reading of the claim language and specification and do not lend support to the defendants' proposed
"communication facility," is consistent with this indication. The references to the specification made by the defendants do
network." This indicates that the communication facility may, but is not required to involve the entire PSTN. In addition, the
Katz states that "in the illustrative embodiment of the system, the communication facility C comprises a public telephone
The specification is more helpful in determining the scope of the term at issue. In Column 3, lines 55-59 of the '707 patent,
however, there is no indication from claim language itself that the communication facility must include the entire PSTN.
This Court concludes that the claim language does not shed much light on the scope of the communication facility; however, there is no indication from claim language itself that the communication facility must include the entire PSTN. The specification is more helpful in determining the scope of the term at issue. In Column 3, lines 55-59 of the '707 patent, Katz states that "in the illustrative embodiment of the system, the communication facility C comprises a public telephone network." This indicates that the communication facility may, but is not required to involve the entire PSTN. In addition, the prosecution history of '299 patent cited by the plaintiffs, in which Katz removed the word "public" from modifying "communication facility," is consistent with this indication. The references to the specification made by the defendants do not undermine this reading of the claim language and specification and do not lend support to the defendants' proposed construction of this term. Thus, I conclude that in light of the claim language, specifications, and prosecution history presented by the plaintiffs, the term "communication facility" does not require the involvement of the entire PSTN or thus,
all of its elements and processes.

To support their argument that "communication facility" is defined in the patents such that the Katz system must be operated only outside the PSTN or communication facility, the defendants point to the language of the preamble and claim limitations. The parties agree that because the terms "communication facility" and "analysis control system," which initially appear in the preamble, are referred to in the claim limitations, these terms should be considered as limitations in the claims. See Gerber Garment Tech., Inc. v. Lectra Sys., Inc., 916 F.2d 683, 689 (Fed. Cir. 1990). The preamble provides for "an analysis control system for use with a communication facility;" the defendants contend that this language, particularly the word "with," indicates that the Katz system, the analysis control system, is necessarily outside of the network. Further, the defendants argue that because the preamble indicates that the communication facility provides call data signals to the Katz system, this indicates that Katz was not referring to the internal routing signals that occur inside the telephone network.

Turning to the language of the claim limitations, the defendants point out that Katz used the phrase "coupled to said communication facility," which they argue indicates that the Katz system is something distinct from the communication facility because it is "coupled to" it. The defendants also contend that the limitation "interface structure coupled to said communication facility . . . including means to provide signals representative of data developed by said remote terminals and for receiving said calling number identification data and said called number identification data (DNIS) to identify one from a plurality of called numbers" indicates that the interface structure cannot be a switch inside the PSTN, because switches send DNIS, not receive it. 4 This, the defendants argue, is further proof that the Katz system cannot include any elements or processes which are inside the PSTN.

4 This limitation is not present in Claim 51 of the '309 patent, but it and similar limitations appear in other claims in which the term "communication facility" is used. See, e.g., Claim 171 of the '863 patent (dependent on Claim 93 of the '863).

In addition, the defendants refer the Court to Figure 1 in the specification. First, the defendants argue that the Katz system is represented as a "dead-end" or the place at which a call terminates, not as a mechanism by which calls are connected from one person to another, as is the function of the PSTN. Second, the defendants argue that pursuant to the Code of Federal Regulations, if an aspect of the invention is represented in the figure as a rectangular box, it indicates that that aspect is not essential to the understanding of the invention, citing 37 C.F.R. § 1.83(a). Thus, the defendants argue, the fact that the communication facility is represented in the figure as an empty box lends support to their position that the Katz system must be operated only outside the network.

Finally, the defendants point to the specification of the '707 patent at Column 6 at line 14, which provides that "individual callers would use the remote terminals T1-Tn to contact the central station D through the communication facility," as indicating that by using the word "through," Katz indicated that the Katz system must be operated only outside the PSTN.

The plaintiffs argue that the claim language is silent as to whether the Katz system must function only "inside" or "outside" the network. Further, the plaintiffs argue that there is nothing in the specification that requires that the Katz system function only outside the network. The plaintiffs maintain that although the communication facility is represented in Figure 1 as an empty box, certain parts that the defendants would consider to be "inside" the PSTN, such as the remote terminals and customer billing, are split out and shown as separate boxes in Figure 1. Thus, the plaintiffs contend that if customer billing and the remote terminals can be shown as separate empty boxes and still be "inside" the PSTN, there is no basis in Figure 1 for construing the Katz system, which is also represented by separate boxes, as "outside" the PSTN.

The Court concludes that there is no basis in the claim language, the specifications, or in Figure 1 to construe the term "communication facility" to mean that the Katz system must be operated only outside the communication facility. It appears that the essence of the defendants' argument here is that the Katz system cannot run on any of the equipment that is part of the communication facility, and thus, is "outside" of the communication facility. The Court is not persuaded that the words "for use with," "through," or "coupled to" indicates that the Katz system must be operated only outside the communication facility. The words "with," "through," and "coupled to" connote some type of relationship between two things; however, none of these terms means that the two things in the relationship cannot be considered part of the same system or entity.
Finally, the defendants argue that, claim language and specification aside, Katz clearly limited his invention to a system only existing outside the communication facility in his representations to the PTO during the prosecution of his patents. The defendants point to comments by Katz during the prosecution of the '075 patent regarding patents to DeBruyn, Riskin, Comella, and Daudelin. Specifically, the defendants point out that in an Amendment dated August 31, 1995, Katz stated that he amended his claim to recite "that processing of at least certain of the data developed by the terminals and the calling number identification data occurs in the Applicant's system" and that "neither DeBruyn nor Riskin teach this aspect of the Applicant's system, also neither patent teaches calling number identification data provided automatically by a communication system (for example, ANI or like signals)." (Ex. 51).

In addition, the defendants point out that in the same Amendment, Katz noted in part that Comella's system "replaces the function of an operator for certain types of calls, for example, collect calls, person-to-person calls, charge-to-third number calls and so on" and that the patent to Comella "is somewhat of background interest for its interface aspects." (Ex. 51). As for the patent to Daudelin, the defendants point out that Katz described it as "generally directed to an interface arrangement for reducing the load on telephone operators." (Ex. 51). Apparently, the defendants contend that if Katz had contemplated that his system could have operated inside the PSTN, he should have said a lot more than he did to adequately distinguish his invention from the Daudelin and Comella patents, which were inventions that were operated by the PSTN.

Whether Katz complied with his obligations before the PTO, however, is a question for another day; the question before the Court is whether Katz made any statements to the PTO that limited the scope of his claims. Considering the passages of prosecution history flagged by the defendants, the answer to that question is no: The Court concludes that the statements by Katz regarding these patents do not constitute a representation from him to the PTO that his invention could be operated only "outside" the communication facility.

Further, the defendants point to statements made by Katz to the PTO in the September 19, 1994 Supplemental Information Disclosure Statement ("IDS") during the prosecution of the '575 patent, which occurred while the application of the '707 patent was still being prosecuted. Specifically, the defendants point to a passage in which Katz referred to a patent by DeBruyn and stated in part that the patent to DeBruyn "discloses a lottery system that is integral with the 'Telephone Company,'" and that in Katz' system, "the 'Telephone Company' ('a communication facility') simply provides an interface, the lottery system being a separate and distinct capability." (Ex. 41). However, taking the statements highlighted by the defendants in context, Katz points out differences between his system and the DeBruyn system including that in Katz system the caller must enter "lottery and identification data," while in the DeBruyn system, the caller need not enter such information because the system is run inside the "Telephone Company" where the callers' telephone number is already known. These statements highlight that the Katz system requires that a caller enter certain data, which is not required by the DeBruyn system; the statements do not limit the physical or geographic location where the Katz system can or cannot operate.

Similarly, the defendants refer to another piece of prosecution history in which Katz discussed a patent to DeBruyn for a telephonic lottery system. (Ex. 46). In the September 30, 1994 IDS in the prosecution of the '120 patent, 5 Katz stated that DeBruyn was distinct from his system which received identification from a caller because the it was "integrated with the composite telephone system which could identify the subscriber's telephone number." The Court concludes that the statements of Katz in the September 19, 1994 Supplemental IDS and the September 30, 1994 IDS do not restrict or limit the term "communication facility" to mean that the Katz system must be operated only outside of it.

5 The '120 patent is related to the patents-in-suit; the defendants cite to this prosecution history because the claims at issue contain language regarding the communication facility which is similar to the patents before the Court. (Defs.' Brief at 34 n. 20).

The defendants argue that Katz also distinguishes his system from the routing and connection of telephone calls, which are integral functions of a telephone company, thereby establishing that his system was to operate only outside the network. The defendants point to a statement made by Katz regarding a patent to Riskin in the prosecution of the '075 patent. (Ex. 40). In
the Preliminary Amendment dated July 17, 1990, Katz stated that "recognizing that the Riskin patent discloses the utilization of ANI and DNIS signals to accomplish telephone routing, it is respectfully submitted that applicant's system involves entirely different philosophical considerations and structure." The defendants contend that because the Riskin patent was a system that was inside the telephone network, this statement by Katz indicates that his system was to be operated outside the PSTN. Similarly, the defendants argue that Katz distinguished his invention during the prosecution of the '929 patent 6 from a patent to Riskin by stating that his invention was outside the PSTN. (Ex. 37). In the Amendment dated August 1, 1990, Katz noted that in the Riskin patent, "functions are involved that are completely distinct from applicant's system . . . . Specifically, Riskin does not disclose an interface telephone system but rather discloses a connection system." The Court concludes that in these statements, however, Katz is discussing functional differences between the Riskin system and his system, not differences in the physical or geographic location of the elements of the systems.

Essentially, the defendants are attempting in their arguments regarding "communication facility" to put a non-infringement rabbit in their hat at the claim construction stage of the case; in their arguments, they expressly seek to include any and all of their equipment, wires, switches, computers, trunks, lines, databases, and so on in the definition of "communication facility" and then establish that the Katz system cannot by definition include any of those things or run on any of that equipment because his system must be "outside" the communication facility. The result of adopting such reasoning would be to restrict the definition of "communication facility" on the basis of who owned the computer or switch on which the Katz system was running or on the basis of the physical or geographic location of the particular computer or switch. The plain words of the patents will not support such a restricted definition.

Based on the foregoing inspection of the claim language, specification, and prosecution history, the Court construes the term "communication facility" in the Katz patents to mean: that part of a telephone network that enables a caller to connect to the Katz system. The Court concludes that there is no support for a construction of "communication facility" to require that the Katz system be operated only outside the entire PSTN nor that the "communication facility" encompass the elements or processes of the entire PSTN.

700
E) "data communication facility"

Citrix asserts that this is a mean-plus-function pursuant to 35 U.S.C. Section 112, paragraph 6.

Use of the term "means" creates a presumption that the element is to be construed in accordance with Section 112, paragraph 6. This presumption may be rebutted, however, when claim element recites sufficiently definite structure or material to perform the claimed function. Absence of the term 'means' creates a presumption that the element is not to be construed in accordance with Section 112, paragraph 6. However, this presumption may be rebutted when the claim element does not recite sufficiently definite structure or material to perform the claimed function. In determining whether these presumptions have been rebutted by a preponderance of the evidence, the court may examine the intrinsic evidence and any relevant extrinsic evidence.

Schwartz, supra, § 5.III.C.

There are four permutations of "communication facility" at issue here, and Citrix asserts that all of them are subject to Section 112, paragraph 6. The court disagrees. The four permutations are as follows: 1) "Data Communication Facility"; 2) "Location Facility"; 3) "Communication Facility"; 4) "Data Generating Facilities."

None of these four permutations use the word "means" and Citrix fails to rebut the presumption that this is not a means-plus function by a preponderance of the evidence. The court agrees that the specification provides a clear description of the
"facilities" and particularly the "data communication facility" as a computer software product. Indeed, the specification provides that "a number of computer program facilities are described in this invention as separate facilities for the sake of describing the invention." '479 Patent, col. 10, lines 11-13. Therefore, the court concludes that 01 Communique's proposed construction is correct, which is "Computer software associated with the personal computer."

The next disputed term "communication interface" appears in Claims 57 and 58 of the '554 Patent. Ricoh asserts that the proper construction for this term includes "any hardware and software that is used to connect two modules of a device or to connect two devices." (Chart at 11). Ricoh's construction is primarily based on the technical definition for the term "communication interface," and the opinion of its expert, James R. Adams, Ph.D. ("Adams"). (Tr. of Markman Hr'g at 42:4-10). Ricoh also points to the specification and Figure 1 and 2 of the patent.

In contrast, Pitney contends that the term means "hardware having an output coupled to the first end of a communication line and an input coupled to a processor to transmit state data over the communication line." (Chart at 11). Pitney bases its construction primarily on the claim language. Based on the parties' proposed constructions, the issue before the Court is whether "communication interface" is limited to the hardware or includes a combination of hardware and software.

The Court agrees with Pitney that "communication interface" refers to hardware. In Claims 57 and 58 which are apparatus claims, the communication interface is described as a component of the "office machine system." '554 Patent, Claims 57 & 58. In the specification and Figure 2, the patent describes the "interface" as part of the hardware for the present invention. The specification states:

FIG. 2 illustrates hardware features utilized to implement the present invention. All devices 10, 20, 30 have buses 1001, 2001, and 3001, which connect Interface Units 114, 214, and 314 respectively.

Id., col. 3, ll. 37-40. The Court finds no basis in the intrinsic evidence for including software in the construction. Consistent with Phillips, the Court attributes greater weight to the intrinsic evidence, rather than extrinsic, including technical dictionaries and expert testimony, which are the sources upon which Ricoh relies in support of its proposed construction. Thus, the Court adopts Pitney's construction. Accordingly, "communication interface" means "hardware having an output coupled to the first end of a communication line and an input coupled to a processor to transmit state data over the communication line."

The computer jukebox has a “communication interface for receiving” data from the central management system. Opening Brief, Ex. 1 at 8:59-61. Plaintiffs contend that this term means “a connection between components that allows communication from one component to the other.” Id. at 8. Defendants contend that the term means “the point at which data is received by or sent from the jukebox from or to the central management station.” Resp. Brief at 8. Defendants' construction would limit the communication interface to one that permits point-to-point communication between the jukeboxes and the central management station without intervening.
Defendants are again improperly attempting to read a limitation into the claim from the specification. They rely on the testimony of their expert, Dr. Sigurd Meldal, to argue that a person of ordinary skill in the art would understand that the communication interface is a point-to-point system because the central management system and the jukebox “use respective modems ... to maintain serial communication on the transmission link” and the transmission link “may be a cable system such as a public or private telephone lines or the like.” Resp. Brief, Ex. F at ¶¶ 37-40. However, as plaintiffs' expert, Dr. Bradley Dickinson, points out, a skilled artisan would understand that communication networks between computers do not require fixed transmission paths. Rather, “cable and telephone modems are regularly used to connect remote devices through multiple interconnections using networks that are not point-to-point.” Reply Brief, Ex. 21 at ¶ 32.

The Court need not base its construction on the experts' opinions, however, because it is plain that defendants rely too heavily on the diagram in figure 1 to the exclusion of the actual claim language. The fact that the diagram in figure 1 shows a line between the modem in the jukebox and modem in the central management system does not mean that intervening devices such as repeater stations, routers, firewalls, and nodes cannot be utilized. The specification also describes embodiments that routinely use intervening routing devices, such as cable and telephone systems. Opening Brief, Ex. 1 at 3:30-32. Moreover, to the extent that figure 1 shows the limitation inferred by defendants, it is part of the specification. Space Sys./Loral, Inc. v. Lockheed Martin Corp., 405 F.3d 985, 987 (Fed.Cir.2005) (written description requirement in specification includes “[w]ords, structures, figures, diagrams, formulas, etc., that fully set forth the claimed invention.”) (citation omitted). A limitation from the specification may not be imported into the claim in these circumstances. MBO Labs., 474 F.3d at 1334. The Court therefore construes “communication interface” as “the point at which data is received by or sent from the jukebox from or to the central management station.” The same construction applies to the term “communication interface” in patents 889, 189, 575, 398, and 834.

e. "Plurality of communication interface circuits"
Claim 1 discloses the following:

A plurality of communication interface circuits, one for each of said plurality of self-contained pieces of surgical equipment, each for transmitting data representing status of the associated surgical control head and for receiving remote commands for driving the associated self-contained surgical instrument.

'688 Pat. col.19 ll.57-62. Claim 10 makes a similar disclosure See id. at col.21 ll.17-20. As discussed at the Markman hearing, the Court construes this term as "two or more circuits, each of which enables communication between a single piece of surgical equipment and the central controller." 2 (See Hr'g Tr. 31, 84-85.)

--- Footnotes ---

2 The word "between" in this construction has its ordinary meaning. (See Hr'g Tr. 85.)

--- End Footnotes ---
means for selectively establishing a communication link with each mobile phone unit." Because this limitation is written in "means-plus-function" form, in accordance with 35 U.S.C. § 112, P 6, the claim must be construed to cover the structure disclosed in the specification as performing that function and equivalents thereof. Kahn v. General Motors Corp., 135 F.3d 1472, 1476, 45 U.S.P.Q.2D (BNA) 1608, 1610 (Fed. Cir. 1998). The first step of a 35 U.S.C. § 112, P 6 analysis is to identify the function of the claim limitation. Kemco Sales, Inc. v. Control Papers Co., 208 F.3d 1352, 1361, 54 U.S.P.Q.2D (BNA) 1308, 1313 (Fed. Cir. 2000). The second step requires identification of the structures disclosed in the specification and equivalents thereof that perform the claimed function. Id.

The district court observed that the claim recites the function of selectively establishing communication with each mobile phone. Based on that construction, it determined that the only structure described as performing that function corresponds to the structure found in embodiments describing selective and automatic establishment of communications for performing activation or programming of the debit phone via an electronic link. We find no error in the district court's claim construction.

We begin our analysis of this means-plus-function limitation by determining the function recited. In accordance with the plain language of the claim, the function "selectively establishing a communication link with each mobile phone unit" describes a communication established by the host processor. We cannot, as Telemac requests, read the plain language of that clause as encompassing communications established by the user, via the mobile phone. We are reminded that a construction that flies in the face of the express language of the claim is not preferred. Interactive Gift Express, Inc. v. CompuServe, Inc., 231 F.3d 859, 865, 56 U.S.P.Q.2D (BNA) 1647, 1652 (Fed. Cir. 2000). Unless something in the written description suggests that the patentee intended the unambiguous language to be construed in a manner inconsistent with its ordinary meaning, we are bound by that language. Nothing in the written description contradicts the plain language describing the function of that limitation. In light of that, we cannot agree with Telemac that the claim can be construed to encompass systems in which the user manually establishes communications with the host processor.

Next, we identify the structure described within the specification as performing the claimed function. In the preferred embodiment, activation of the phone is performed using an interlink receiver for machine-to-machine communications, thereby ensuring a secure transfer of information. '100 patent, col. 3, ll. 60-67. The '100 patent describes over the air updating of the rate table "at the initiation of the system provider." Id. at col. 14, ll. 14-19. The specification describes a transmission station for establishing a wireless link to the mobile phone for reprogramming the rate table over the air at the initiation of the host processor. Id. at col. 4, ll. 18-22; Id. at col. 6, ll. 32-39. The patent further states that the "system requires that a communication link be established between the host processor and the mobile phone unit and may require that the phone unit be physically connected to the host processor." Id. at col. 1, ll. 15-19. Thus, numerous passages from the specification identify the structure, each part of the host processor, for establishing a communication with a mobile phone.

As provided above, Telemac's challenge to the district court's construction, with an eye towards infringement, focuses upon whether the "communications means" should be construed to encompass embodiments describing communications established using toll-free calls placed by the user from the telephone. The function claimed, however, requires establishment of the link by the host processor, and not the mobile phone unit.

As a further challenge to the district court's construction, Telemac contends that embodiments describing user-initiated activation and replenishment meet the requirement that the host processor selectively establish a communication link because, in those embodiments, the host processor determines the identity of the phone establishing the communication. Telemac argues that those embodiments describe "selectively" communicating confidential information in accordance with the identity of that phone. Telemac would have this court interpret the term "selectively establishing" as a process by which the host processor checks the electronic serial number of the mobile phone that established the call. Moreover, Telemac suggests that the "selectively establishing" limitation of the claim can be found in the user-initiated embodiments, and that those embodiments should be encompassed within the scope of the claim.

On the record before us, we cannot agree with Telemac's assertions. As noted, both the plain language of the claim and the written description of the invention require that the link with the phone be "established" by the host processor, and not vice-versa. Telemac's reading of "selectively establishing," as encompassing a confidential communication protocol, ignores the remainder of the claim identifying the host processor as the device that initiates the communication. Thus, we conclude that Telemac's proposed construction, encompassing manually initiated communications, would render the phrase "for selectively establishing a communication link with each mobile phone unit" mere surplusage. Accordingly, we reject
Telemac's proposed interpretation of that language.

Telemac further argues that the court's construction is in conflict with the doctrine of claim differentiation. Under this doctrine, claims are presumed to be of a different scope. Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1366, 53 U.S.P.Q.2D (BNA) 1814, 1817 (Fed. Cir. 2000). Claim 3 provides that the host processor initiates the communication link at a "time" controlled by the system provider. Telemac contends that, under the district court's construction, the provisions of claim 3 would be negated by the court's construction limiting communications to those established automatically. We do not agree that the "time" limitation of claim 3 is negated by a construction of the "communication means" as limited to automatically established communications. Even accepting Telemac's assertions, we further note that claim 3 embraces additional limitations not encompassed within claim 1 including, "activating the communication of the record data of stored call charges from the mobile phone unit to the system provider." Therefore, the doctrine of claim differentiation does not lead us to reach a different construction.

Telemac further challenges the court's limitation of the claim to automatically established communications, on the basis that such an interpretation renders the claimed invention inoperable. First, Telemac notes that the court determined that the "communication means" performs activation and reprogramming exclusively, and that the "payment verification means" is used only for updating the account amount. Under that construction, Telemac argues, the host processor cannot automatically communicate with the phone, or perform activation or programming, until the phone has been initially programmed and assigned a telephone number. Telemac's argument, however, is contradicted by the preferred embodiment describing activation and programming via a direct connection. '100 patent, col. 8, ll. 36-38. Based upon the written description, we reject Telemac's assertions that the court's construction would render the claim inoperable.

We conclude that only those embodiments involving communications established by the host processor meet the functional requirement of the claim. Therefore, we agree with the district court's interpretation of the phrase "communication means for selectively establishing a communication link with each mobile phone unit" to require communications established by the host processor. As the district court concluded, the disclosed embodiments describing user-initiated communications could not provide the structure or equivalent structure for performing the claimed function in accordance with 35 U.S.C. § 112, P 6. Odetics, Inc. v. Storage Tech. Corp., 185 F.3d 1259, 1267, 51 U.S.P.Q.2D (BNA) 1225, 1229 (Fed. Cir. 1999).

706

a. "communication medium"

The parties dispute the meaning of the term "communication medium." Intel's proposed construction for the term "communication medium" is the collection of connections (generally, links between nodes) over which negotiation signals and other data in a communications system may be transmitted. According to Intel, the term is not limited to any specific type or arrangement of a communication medium. Intel claims that its proposed construction adopts the common technical meaning of the term, see, e.g., IEEE Standard Dictionary of Electrical and Electronics Terms 581 (4th Ed. 1988) (defining medium as "a vehicle capable of transferring data"), and "communication medium" is a term whose definition is clear on its face.

Broadcom claims the term "communication medium," as used in the claim, is a shared physical medium, such as a wire or a cable, over which data is transferred. In support of its reading, Broadcom points to language in the specification explaining that a "communication medium can be cable, fiber optics, radio channel or other medium of communication shared by the nodes." Col. 1:14-16.

Before construing this claim element, the court makes the following preliminary observations. First, the claim language itself, which is clear on its face, does not contain the word "shared" and does not seem to limit the term communication medium to a single shared link. Next, while the claim language should be interpreted in a manner that is consistent with the specification, it is improper to import limitations from the specification onto the claims. Intervet, 887 F.2d at 1053. Moreover, the Federal Circuit has repeatedly stated that it is improper to add a limiting adjective or adverb before a term that stands unmodified in the claim. See, e.g., Micro Chem., Inc. v. Great Plains Chem., Inc., 194 F.3d 1250, 1258 (Fed. Cir. 1999) (refusing to limit the term "weighing" from the claim to sequential and cumulative weighing); Johnson Worldwide Assocs. v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999) (collecting cases); Virginia Panel Corp. v. Mac Panel Co., 133
F.3d 860, 865-66 (Fed. Cir. 1997) (holding that term "reciprocating slide plates" could cover rotational reciprocation in addition to linear reciprocation, even though embodiment in patent was linear).

Claim 1 indicates the communication medium is the vehicle by which data is transferred between nodes on a network. The particular embodiment that is shown in Figure 1 consists of five conductive cables (labeled 1) over which electrical signals travel. The specification of the 830 patent demonstrates that links other than the cables shown in Figure 1 were contemplated by the inventors. Indeed, as noted by Broadcom, the specification states that "the communication medium can be cable, fiber optics, radio channel or other medium of communication shared by the nodes." Col. 1:14-16. Rather than limiting the definition of communication medium, as Broadcom argues, that phrase indicates that the definition of communication medium was intended to be broader than the preferred embodiment shown in Figure 1. As used in that sentence, the term communication medium is not limited to a "shared" communication medium in the sense that it must be a single cable or wire link that connects all of the nodes such that every transmission placed on the medium by one node is available to all other nodes simultaneously. The plain meaning of "shared" is not limiting. The word "shared" only indicates any communication medium that is covered is used to connect each node to the system. The fact that the patent expressly includes bridges and gateways as nodes supports this conclusion.

In sum, the court declines to adopt Broadcom's limiting construction. Therefore, the court finds, a communication medium is a collection of connections (generally links between nodes) in a communication system over which information may be transmitted.

2. "Communication module" (Claims 1, 2, 10, 11, 12)

The debate over this claim term concerns Agere's proposed construction of a "module" as "as self-contained" unit. This language is found in the definition of "module" in Webster's II New College Dictionary, and Broadcom does not object to it per se. 19 Broadcom asserts, however, that if the modifier "self-contained" connotes the ability to function independently, then it is inaccurate and in conflict with the claim language.

As the claim language makes clear, this patent describes removable, interchangeable modules that can function only when assembled into the base module. (See '705 patent, col. 38, ll. 26-27 ("The base module receiving the selected one of the plurality of communication modules in an assembled position.").) The "communication module," as this term is used in the '705 patent, is not an independently-functioning entity but rather a component that, once inserted into the base module, enables communication between the base processor and a wireless transceiver. (Id., col. 38, ll. 30-36.) Furthermore, the specification describes instances in which the communication module may access and utilize external components in the receiving device in order to function. (See, e.g., id. col. 4,ll. 8-12 (teaching that communication module, after having been inserted in to receiving device, may connect to external antenna located within the receiving device), col. 32, ll. 21-33 (describing embodiment wherein radio card accesses antenna in receiving device).) Finally, Agere's expert, Dr. Goodman, confirmed at the Markman hearing that his inclusion of the term "self-contained" in the construction was not meant to imply that the module was able to function independently, but rather that "it's all within one packaging of some sort." (R. at 269 (May 6, 2004).) Therefore, the claim language, specifications, and expert testimony demonstrate that the claimed "communication modules" do not function independently. Thus, the Court will adopt the following construction for communication module: "A self-contained assembly of electronic components and circuitry used for the transmission or reception of information. A communication module cannot function independently." 20

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

19 Webster's II New College Dictionary defines "module" as "a self-contained assembly of electronic components and circuitry, as a stage in a computer." WEBSTER'S II NEW COLLEGE DICTIONARY 705 (1999). The IEEE dictionary definition omits the modifier "self-contained." (See Goodman Rep. at 25 (citing IEEE at 817 ("any assembly of interconnected components which constitutes an identifiable device, instrument, or piece of equipment.").)

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

As the above indicates, this patent describes removable, interchangeable modules that can function only when assembled into the base module. (See '705 patent, col. 38, ll. 26-27 ("The base module receiving the selected one of the plurality of communication modules in an assembled position.").) The "communication module," as this term is used in the '705 patent, is not an independently-functioning entity but rather a component that, once inserted into the base module, enables communication between the base processor and a wireless transceiver. (Id., col. 38, ll. 30-36.) Furthermore, the specification describes instances in which the communication module may access and utilize external components in the receiving device in order to function. (See, e.g., id. col. 4,ll. 8-12 (teaching that communication module, after having been inserted in to receiving device, may connect to external antenna located within the receiving device), col. 32, ll. 21-33 (describing embodiment wherein radio card accesses antenna in receiving device).) Finally, Agere's expert, Dr. Goodman, confirmed at the Markman hearing that his inclusion of the term "self-contained" in the construction was not meant to imply that the module was able to function independently, but rather that "it's all within one packaging of some sort." (R. at 269 (May 6, 2004).) Therefore, the claim language, specifications, and expert testimony demonstrate that the claimed "communication modules" do not function independently. Thus, the Court will adopt the following construction for communication module: "A self-contained assembly of electronic components and circuitry used for the transmission or reception of information. A communication module cannot function independently." 20
20. Agere proposed this construction in its post-Markman brief. The Court finds that it is both accurate and responsive to Broadcom's concerns. (R. at 297 (May 6, 2004); see also Agere's Post-Markman Br. at 9.)

(2) Communication Pathway

Independent claims 1 and 11 include the term "communication pathway. The parties propose the following meanings to this term:

<table>
<thead>
<tr>
<th>Braun's Proposed Construction</th>
<th>VMI's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>A medium that carries coded data, such as commands and status information, between components.</td>
<td>A medium that carries a communication signal between components.</td>
</tr>
</tbody>
</table>

Braun argues that "[t]he claim language establishes that one role of the 'communication pathway' is to carry 'door operation commands' sent by the 'standard control module' to other components of the system. (Braun Claim Constr. Br. at 10). From this, Braun concludes that "the 'communication pathway' must be capable of carrying coded data," (id.) and that "a medium incapable of carrying 'coded data' cannot be a 'communication pathway,' (id. at 11).

VMI insists that nothing in the specification defines a "communication pathway" to include only "coded data." VMI maintains that "if Braun had intended to limit the claim to only those communication pathways that carry 'coded data' it would have used the term 'serial bus' instead of the broader term 'communication pathway.'" (VMI Resp. at 5.)

Braun's argument is plausible only if the term "door operation commands" means coded data commands. But, as explained above, the term cannot be so narrowly construed. There is no other strong basis in Braun's argument to conclude that a "communication pathway" is a medium that carries coded data between components. In fact the opposite is true. For example, the portion of the specification referring to the embodiment of a communication pathway in Figure 4 states that "[i]n one embodiment, the components of system 400 are operatively coupled together with electric conductive wires for communication by electrical signals." (The '628 Patent col. 5:39.) Accordingly, the Court adopts VMI's definition of "communication pathway": a medium that carries a communication signal between components.

7. "communication of control and monitoring data therebetween"

Power-One proposes this phrase refers to "sending control and monitoring data between the POL regulator and the data bus," while Artesyn proposes the phrase refers to "sending control and monitoring data between the POL regulators." The dispute here is whether the communication recited by the claims is between a POL regulator and the serial bus (Power-One's position) or between multiple POL regulators (Artesyn's position).

Claim 1 of the '916 patent describes

a plurality of point-of-load regulators . . . and
a bi-directional, serial data bus connected to each of said plurality of point-of-load regulators to permit communication of control and monitoring data therebetween, each one of said plurality of point-of-load regulators being adapted to initiate a communication cycle by providing a synchronizing signal onto said serial data bus followed by a multi-bit data message that includes at least one of an address set, a command set, and a data set.

The claim language calling for communication "therebetween" seems to refer to communication between the immediately preceding items, i.e., "said plurality of point-of-load regulators." Unasserted Claim 14 of the '916 patent provides for a "point-of load regulator having a serial data interface adapted to communicate control and monitoring data with other like point-of load regulators via a serial data bus . . ." Clearly, claim 14 contemplates communication of control and monitoring data between point-of-load regulators. See Phillips, 415 F.3d at 1314 ("Other claims of the patent, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term . . . Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims.").

Further, the larger context of claim 1 also supports communication between POL regulators. Claim 1 provides for POL regulators "being adapted to initiate a communication cycle by initiating a synchronization signal onto said serial data bus followed by a multi-bit data message that includes at least one of an address set, a command set and a data set." The address set can be used to identify the POL regulator that is providing the information or the POL that is being written to or read, while the command set can identify what the POL regulator is providing. See '916 patent, col. 4:43-48. Thus, the communication at issue is between the devices connected to the serial bus, rather than between a device and the serial bus to which it is connected. While the devices certainly communicate by way of the serial bus, they communicate with, or between, themselves.

Power-One cites to the statement in the '916 specification that the "present invention provides a system and method for using a serial bus to passively or actively communicate with a point-of-load regulator." Col. 2:55-57. Power-One also cites to Figures 2 and 3 which show, according to Power-One, control and monitoring information flowing between the POLs and the controller across the data bus. However, simply because a data bus is used to communicate or permits communication does not mean that communication is between the bus and the POLs or a controller. The specification of the '916 patent regularly speaks of communication "via," "by way of," or "over" the serial bus, rather than "between" the serial bus and a device. See, e.g., '916 patent, col. 3:42-44; col. 3:53-61; col. 3:66-67; col. 4:8-15. While a person can communicate over a telephone line, one does not typically refer to communication occurring between a person and a telephone line. Indeed, Figure 2 is discussed in terms of a controller communicating with a plurality of POL regulators (i.e., 220, 230, 230, and 250) via a serial bus 200. Col. 3:42-44 (emphasis added). Likewise, Figure 4 is described as a "method of communicating over a single-wire serial bus" and Figure 5 shows "how information can be transmitted over a serial bus." Col. 3:66-67; Col. 4:29-31. Finally, the specification discusses how POL regulators determine priority of communication where multiple POL regulators initiate a communication cycle simultaneously. Col. 4, line 59-63 ("Thus, a POL regulator can determine, by reading the start sequence 510 and address set 520 of a communication cycle 50 as it is being sent, whether another POL regulator is also attempting to send a communication cycle 50 at the same time. If multiple devices . . ."). Thus, the bus is the vehicle that allows communication between multiple POL regulators or other devices. For the foregoing reasons, the Court construes this term as "sending control and monitoring data between the POL regulators."

1. Communication platform

The court is persuaded that Judge Breyer's construction of "communication platform" in the Nortel case is correct. Accordingly, the court construes "communication platform" to mean "a general purpose computer system that operates under program control."

VI. "a call state, being at least one of the group consisting of active and hold states" / "a plurality of communication ports,
each supporting at least one of the group of switch connections consisting of video in, video out, audio in and audio out"

The two disputed phrases from the '500 patent are interrelated, and must be construed together. Claim 1 of the '500 patent is representative of the use of both phrases.

1. A teleconferencing system comprising:
   (a) a plurality of AV devices, each capable of
       (i) originating and reproducing
           (1) user related audio and video signals;
       (b) a plurality of communications ports, each supporting
           (i) at least one of the group of switch connections consisting of
               (1) video in, video out, audio in and audio out; and
       (c) at least one communication path,
           (i) arranged for transport
               (1) of audio and video signals,

   wherein the system is configured to
   (i) to control a communication connection
       (1) between two of the AV devices,
       (2) over the communication path,
   (ii) by creating,
       (1) as a result of a call request,
       (2) at least a first call handle,
           i. associated with one of the two AV devices and, thereafter,
       (3) at least a second call handle,
           i. associated with the other AV device,
       (4) each call handle defining,
           i. for its respective AV device,
           ii. a call state, being at least one of the group consisting of active and hold states; and
           iii. the port switch connections involved in the communications connection.

'500 patent at 41:51-42:11 (emphasis added).
The claims of the '500 patent relate generally to the mechanics of placing and connecting a videoconference call between two AV devices (CMWs) using the invention described in the Specification. The description of the preferred embodiment illustrates the general process for how a videoconference call is connected.

First, before a CMW can participate in a videoconference call, it must connect to the AVNM and register the types of collaborative services it provides—such as videoconferencing or data sharing—in a central directory, or "service server." Spec. at 20:66-21:1. During registration, the CMW can specify "the audio/video ports physically connected to the particular CMW into which the user is logged in." Id. at 21:18-19. Based on the information provided by the CMW, the AVNM creates a data record called a "port abstraction, wherein each port represents an addressable bidirectional audio/video channel." Id. at 20:42-44.

In the preferred embodiment, a CMW has four physical connections to the AV switch: video in, video out, audio in, and audio out. Id. at 20:35-41. A CMW need not make all four of these connections available in its port abstraction, however. Instead,

   [c]lient programs can specify which of the 4 physical connections on its ports should be switched. This allows client programs to establish unidirectional calls (e.g., by specifying that only the port's input connections should be switched and not the port's output connections) and audio-only or video-only calls (by specifying audio connections only or video connections only).

Id. at 20:57-63. Moreover, not all devices participating in a conference must support all four connections:

   The system architecture also accommodates the situation in which the user's desktop computing and/or communications equipment provides varying levels of media-handling capability. For example, a collaboration session -- whether real-time or asynchronous -- may include participants whose equipment provides capabilities ranging from audio only (a telephone) or data only (a personal computer with a modem) to a full complement of real-time, high-fidelity audio and full-motion video, and high-speed data network facilities.

Id. at 3:38-46.

When a user initiates a videoconference from a CMW, the caller's CMW sends a call request to the AVNM, specifying the address of the callee's CMW. The AVNM then looks up the callee in the service database. Id. at 22:3-17. If the callee has registered a videoconference service, the AVNM proceeds to create two "call handle" records, and associates one call handle with each CMW's port abstraction. Id. at 22:54-61. The call handle records include information about the state of the call. Id. 23:11-20. If a CMW is connected to a call, the call handle will have an "active" state. Id. If a CMW places a call on hold, the associated call handle will be changed to a "hold" state. Id. A CMW has a separate call handle for each videoconference call it engages in, and can have multiple call handles at any one time. Id. at 23:7-10 ("Each port can have an arbitrary number of call handles bound to it, but typically only one of these call handles can be active at the same time,"). For example, if a CMW is connected to one videoconference and has two more videoconferences on hold, the CMW will have a total of three call handles associated with its port abstraction.

Based on this overall understanding of how a call is placed in the preferred embodiment, the court now turns to the construction of the disputed terms.

A. "a call state, being at least one of the group consisting of active and hold states"

CPI argues that the phrase "a call state, being at least one of the group consisting of active and hold states" should be construed to mean "the call state of the call handle must have at least one of two possible states; active (in a call) or on hold (connected but not transferring images or sound)." Tandberg argues that the phrase should be construed as follows:

   Call State: the status of both audio and video connections indicating whether each connection is active or hold.

   Active State: a call state in which information is exchanged over a dedicated physical connection between the caller and the callee.
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Hold State: a call state permitting the caller to answer incoming calls or initiate new calls without releasing a previous call.

The parties' proposed constructions differ in two respects. First, the parties dispute whether a call state must have the ability to be simultaneously "active" and "hold," or whether the state may be either "active" or "hold" individually. Second, the parties dispute whether an "active" call is one where information is exchanged over a dedicated physical connection. The court has already concluded, in the context of construing "AV path," supra, that calls need not be connected over a dedicated physical connection.

Turning to whether the call state must be able to simultaneously be active and hold, the phrase "configured to" in claim 1 indicates that the following elements are a recitation of the claimed system's capabilities. n2 Claim 1 thus requires that the system have the functionality of creating a call handle which defines "a call state, being at least one of the group consisting of active and hold states." A system with the capability of creating a call handle with a call state of "active" would fall within the literal scope of the claim, as would a system with the capability of creating a call handle with a call state of simultaneously "active" and "hold." The phrase "at least" is most reasonably understood as broadening the claim to include systems with call states being simultaneously "active" and "hold," as well as either individually, rather than requiring the call state to be simultaneously "active" and "hold." The court's construction is consistent with the Specification, which clearly contemplates that the call state will toggle between "active" and "hold," but will not be both simultaneously. See Spec. at 23:11-20. The phrase "a call state, being at least one of the group consisting of active and hold states" is therefore construed to mean "a call state, which is 'active,' 'hold,' or both 'active' and 'hold' simultaneously."

n2 The court takes up the meaning of "configured to" in more detail in its order denying Tandberg's motion for summary judgment of invalidity under 35 U.S.C. section 112.

B. "a plurality of communication ports, each supporting at least one of the group of switch connections consisting of video in, video out, audio in and audio out"

The phrase "a plurality of communication ports, each supporting at least one of the group of switch connections consisting of video in, video out, audio in and audio out" appears only in the claims of the '500 patent, and is highlighted above. CPI argues that the phrase should be construed to mean "There are at least two communication ports in the video conferencing system (at least one for each AV device), and that at least one port at each AV device supports at least one of audio in, audio out and video in and video out." Tandberg argues that the phrase should be construed as follows:

A plurality of access points for entry or exit of audio and video signals to or from a communication device, each access point connected to at least one of an audio in, audio out, video in, and video out switch that may be individually opened or closed.

Switch Connections: audio in, audio out, video in, and video out circuits that may be individually opened or closed.

Communications Port: A set of access points for entry or exit of audio and video signals to or from a communication device.

The parties' constructions differ in two respects. First, Tandberg argues that the phrase requires that each communication port must be capable of all four modes of communication—audio in, audio out, video in, and video out. Second, Tandberg argues that each of the four modes of communication must be capable of being individually switched.

1. Modes of Communication

The claim language precludes Tandberg's proposed construction, as the claims only require that each port support "at least one of the group of connections consisting of... video in, video out, audio in and audio out." '500 patent at 41:56-58. This language is identical in structure to the phrase "a call state, being at least one of the group consisting of active and hold
"states," which the court has just construed. A port supporting "video in" alone thus falls under the scope of the claim, as does a port simultaneously supporting "video in" and "video out."

This construction is completely consistent with the use of the word "port" in the Specification. The Specification uses the word "port" in two different senses. The first sense is a physical connection to a device, such as a CMW. See Spec. at 15:61-64 ("camera 500 and microphone 600 capture and transmit outgoing video and audio signals into ports 801 and 802, respectively, of Add-on box 800."); id. at 15:64-65 ("Incoming video and audio signals (from another videoconference participant) are received across AV network 901 through Audio/Video I/O port 805."). Physical ports may support only a single type and direction of data, see port 801 of Figure 18A, or they may combine multiple types and directions of data, see port 805 of Figure 18B.

The second sense is a logical "port"—a data structure used by the AVNM to initiate and manage connections between devices. See id. at 20:41-44 ("For each device on the network, the AVNM combines these four connections into a port abstraction, wherein each port represents an addressable bidirectional audio/video channel."). There is not a one-to-one correspondence between inputs and outputs in a port abstraction and physical inputs and outputs in the system. Id. at 20:45-48 ("Different ports may share the same physical connections on the switch. For example, a conference bridge may typically have four ports (for 2.times.2 mosaicing) that share the same video-out connection."). Also, each port abstraction in the preferred embodiment is not required to have all four connection types: "Not all devices need both video and audio connections at a port. For example, a TV tuner port needs only incoming audio/video connections." Id. at 20:48-51. Finally, as discussed above, workstations participating in a videoconference need not support all four connection types. Id. at 3:38-46.

CPI's construction is flawed, however, in that it requires that only "at least one port at each AV device supports at least one of audio in, audio out and video in and video out." The claims require that "each" port support at least one of audio in, audio out and video in and video out. "The claim language does not require that each connection be individually switched. The claim language is "switch connection," not "switched connection." A "switch connection" is a connection to a switch, either digital or analog. See Spec. at 7:13-18 ("Further, as the current preferred embodiment uses analog networking for audio and video, it also physically separates the real-time and asynchronous switching vehicles and, in particular, assumes an analog audio/video switch. In the future, a common switching vehicle (e.g., ATM) could be used."); id. at 8:49-50 ("A/V Switching Circuitry 30 (whether digital or analog as in the preferred embodiment) provides common audio/video switching for CMWs").

The court therefore accepts CPI's construction, with the modification set forth above, and construes the phrase "a plurality of communication ports, each supporting at least one of the group of switch connections consisting of video in, video out, audio in and audio out" to mean "at least two communication ports in the video conferencing system (at least one for each AV device), each port supporting at least one of audio in, audio out and video in and video out connections to an analog or digital AV switch."

1. "Selective call receiver" (Claims 1 & 5)

   a. The Parties' Proposed Constructions

      | Motorola's Proposal | VTech's Proposal |
      |---------------------|------------------|
      | "A receiver that can respond to a radio signal communication that is specifically directed to it." | "A pager." |

   b. Discussion

   VTech argues the term "selective call receiver" should be limited to the preferred embodiment of the '391 patent, i.e., a
The '391 patent does not expressly define the term "selective call receiver." As noted by VTech, the brief specification of the '391 patent provides the following regarding a "selective call receiver." Figure 1, which contains a block diagram of a prior art selective call receiver, specifically refers to "pager circuitry." Under the section "Detailed Description Of The Invention" the patent states: "Referring to FIG. 1, pager circuitry 102…" (391, 1:63) (first emphasis added). The patent further states: "The selective call receiver shown in Fig. 1 is well known to those skilled in the art." (391, 1:67-68) (emphasis added).

According to VTech, the specification as well as the claim language, taken in context, describes the metes and bounds of the term selective call receiver as a pager. For instance, the claim language "plurality of function indicators in a selective call receiver capable of receiving a message" taken in conjunction with the disclosure in the specification shows that the term "message" in the context of the invention are messages received by pagers. (’391, 3:1-3). VTech asserts the patent does not enable, disclose, or even mention, any other technology.

The two instances where "pager circuitry" is used in the specification to describe prior art and the preferred embodiment do not necessarily limit a "selective call receiver" to a pager. The Court notes that subsequent to the ’391 Weitzen Patent, Motorola eventually adopted the phrase "radio pagers" for "selective call receiver" in the ’140 Wong patent. (’140, 1:15-17). The Weitzen Patent was filed in September 5, 1989 without equating the two phrases. The Wong Patent was filed later in November 23, 1992 with the statement "Radio pagers (also known as selective call receivers) having a plurality of alerts are well known," defining the terms to be synonymous. Id.

The Court is of the opinion Motorola did not initially limit selective call receivers to be only pagers. Around the time of the filing of the ’391 Patent, the industry terminology for pagers and paging systems was not necessarily "selective call receivers." For example, the pager patent U.S. Patent No. 4,845,491 referencing the Motorola product PMR2000 and the POCSAG standard does not contain the terminology "selective call receivers." Also, Motorola offered its PMR2000 product line brochure as a prior reference in the ’391 Patent. Motorola's 1986 - 1987 brochure introduces its PMR 2000 paging system product as a "personal message receiver," but the brochure does not mention "selective call receiver." (Motorola PMR 2000 Personal Message Receiver Product Brochure, 1986). The brochure suggests there is a wide array of terminology related to pagers, but none necessarily equated to "selective call receiver."

Similarly, the prosecution history does not limit a "selective call receiver" to a pager. VTech asserts that statements made in the prosecution history demonstrate the limited scope of the term "selective call receiver." On May 17, 1990, the Patent Office issued an office action rejecting Motorola's specification and claims based on non-enablement stating, inter alia, "[S]ince the Applicant does not show how to modify the prior art pager in order for it to accomplish the allegedly novel and unobvious functions, this specification is non-enabling." (VTech Ex. 10, pg. 30) (emphasis added). The Patent Office also stated that: "Although replete with functional language describing the display and selection, the specification must also comprise language describing how and through what means the pager performs the functions described in the flow diagram of figure 2, especially since the specification does not incorporate these hardware means by reference to a U.S. Patent. . . ." (VTech Ex. 10, pg. 29 ) (emphasis added). According to VTech, in response to this rejection, Motorola submitted a "variety" of selective call receivers to demonstrate what hardware it was referring to in the specification, which Motorola argued "are well known to those of ordinary skill in the art," (VTech Ex. 10, pg. 38), and every reference Motorola submitted is directed to pagers. (VTech Ex. 10, pg. 38). According to Motorola, the two exemplary references it submitted which were directed to pagers were intended to show how the preferred embodiment of a selective call receiver could be constructed.

The Court further finds VTech's argument regarding "disclaimer" improper in this instance. Prosecution disclaimer only applies where a disclaimer was clear and unambiguous. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). That is not the case here.

VTech next cites to the claim construction order entered in a past Motorola litigation against Qualcomm in the Southern District of California, asserting Motorola should be estopped from arguing a different definition now during its current litigation. In 1997, Motorola brought an action against Qualcomm, Inc. ("Qualcomm") for infringement of numerous patents, including the '391 Weitzen patent. See Motorola, Inc. v. Qualcomm, Inc., 989 F. Supp. 1048 (S.D.CA.)("Qualcomm litigation"). During the claim construction proceedings, Motorola submitted to Qualcomm its claim construction statement,
wherein it set forth its proposed interpretation of the preamble to claim 1 including the limitation "selective call receiver."

In response, Qualcomm submitted its claim construction statement whereby it agreed to Motorola's proposed interpretation of the preamble of Claim 1. (VTech Ex. 12, pg. 2). Following this exchange, the parties submitted a joint claim construction statement to the Court. (VTech Ex. 13). This document included the statement: "The parties agree that the preamble [to Claim 1] refers to a method for presenting function indicators in a selective call receiver capable of receiving messages, i.e. a pager" (VTech Ex. 13, pg. 2) (emphasis added) In its claim construction opinion, the court stated that "[t]he ['391] patent seeks to simplify the method by which user of a selective call receiver, or pager, accesses features of the pager." (VTech Ex. 14, pg. 2)(emphasis added) .

The Court disagrees with VTech that Motorola is judicially estopped from arguing a different definition in this litigation. Motorola explains that the Qualcomm court's reference to "selective call receiver, or, pager" was a passing reference to an uncontested term. VTech's emphasis on this reference is insufficient to judicially estop Motorola from arguing its current position. The Qualcomm litigation involved allegations of infringement of the '391 patent by a number of Qualcomm cellular telephones. According to Motorola, the parties did not dispute the term "selective call receiver" for purposes of that litigation because they clearly felt that the term was broad enough to cover pagers or telephones.

Finally, to the extent there is an enablement issue raised in the briefing, the Court finds the issue is more appropriately raised in the context of a motion for summary judgment.

c. The Court's Construction

Accordingly, the Court construes the term "selective call receiver" to mean: "A receiver that can respond to a radio signal communication that is specifically directed to it."

R) "communication settings associated with the data communication facility"

Citrix argues that this phrase should be construed to mean "Parameters that control the manner in which the data communication facility communicates with the server computer, including the Registration Routine 21." The court, however, agrees with 01 Communique that the appropriate proposed construction is "Settings that control some aspect of how the data communication facility works." Specifically, the court agrees with 01 Communique that Citrix's proposed construction does not encompass all the communication settings disclosed in the specification, and would therefore be an improper limitation. To wit, the data communication facility as described in the specification is not limited in its operation to communication with the locator server computer; Citrix's construction, however, would so limit it. Therefore, the court rejects Citrix's proposed construction and instead adopts that of 01 Communique.

A. "Communication System"

The parties dispute the meaning of the term "communication system," which is found in the '932 Patent, claims 1 and 18; the '561 Patent, claims 1 and 24; and the '052 Patent, claim 1. Sprint argues that the term should be construed to mean a plurality of network elements and connections forming a network to transfer information. In Vonage, the Court gave the term the same construction urged by Sprint here, which Vonage did not dispute. See 518 F. Supp. 2d at 1315. Big River seeks to construe the term to mean a plurality of network elements and connections forming a network to transfer a user communication over a communication path selected during call set-up. Thus, Big River essentially agrees with Sprint's definition, but seeks to add a limitation. As framed by the parties, the dispute centers on whether this term should be construed to incorporate the concept of a communication path established during set-up, with each packet traveling over the same path or route for the entirety of the call.
The parties note that this dispute is key to the issue of infringement because Big River's technology does not require that packets use a single route set up at the beginning of a call, but instead allows packets to travel over different routes during the same call.

Big River does not rely on the language of the claims themselves, as the claims contain no such limitation to the term "communication system". Instead, Big River, relying on Microsoft, argues that the '605 Family specification's repeated and consistent description demonstrates that such a path is fundamental to the invention. Big River points to the great number of references in the specification to the fact that communication systems establish paths. For instance, at the outset, the specification states that "[t]elecommunications systems establish a communications path between two or more points" and that "[c]ommunication control is the process of setting up a communications path between the points." (605 Family at 1:29-30, 36-37.) The summary in the specification makes clear that the invention separates communication control processing from the switches that form the connections or path. Big River notes that "signaling" is cited throughout the specification as a common method of communication control. Sprint has agreed that "signaling" is defined as a method to set up or tear down a call. Thus, Big River argues that the communication path must be set up before any data is transmitted during the call. Big River further notes that such connection-based systems are the only systems discussed, and that the specification contains no references to connectionless systems. Finally, Big River argues that in every embodiment described in the specification, the communication control processor (CCP) establishes paths before any packets are sent, even where the CCP shares such communication control with other network elements in the system.

Based on its review of the '605 Family specification, the Court rejects this argument and concludes that the specification does not sufficiently describe the invention with the limitation urged by Big River. Big River has not referred the Court to any particular language in the specification that actually describes the invention, or even an embodiment, as a system that sets up only a single path per call or that sets up the entire communications path before any data is transmitted. Thus, Microsoft and other cases in which the specification clearly described the entire invention as limited may be distinguished, as the specification at issue here contains no such clear description containing the limits argued by Big River. Instead, Big River relies on the specification's use of the singular noun "path"; it is not clear, however, that the patentee was not simply using that form for ease in describing what happens with respect to any particular path, but instead intended to limit the scope of the invention to a single path per telephone call. Similarly, Big River equates "signaling" with call set-up, but there is no clear language requiring an entire path prior to the transmission of any data. The specification does not mention these limits as a part of the invention, and the references to "path" and "signaling" are simply too oblique to effect limits on the claims' broad scope in the manner urged by Big River.

3 In this regard, the references in the specification are nothing like the specific descriptions of the '301 Family invention as an ATM interworking multiplexer, on which the Court relies in limiting the scope of the term "interworking unit". See infra Part IV.A; see also Vonage, 500 F. Supp. 2d at 1314-16.

It is clear from a review of the specification, and in particular the summary of the invention, that the patented invention is a method for separating communication control from the actual switches. The overall invention is not described otherwise. Big River essentially relies on references to path creation. Sprint concedes, as it must, that there must be communication paths on which information travels. Big River has not shown, however, that the specification describes an invention that imposes limits regarding the kind of path that is established. To the contrary, language in the specification that contemplates varied kinds of paths and varied ways to select paths (e.g., '605 Family at 5:16-23, 16:60) suggests that the inventor did not intend to limit the scope of the invention based on a particular type of communication path. Accordingly, the Court concludes that the specification does not support the construction urged by Big River.

The Court also rejects Big River's argument based on the doctrine of prosecution history disclaimer. Big River argues that the patent applicant distinguished prior art by describing the invention as one that uses signaling to control path creation. In
the cited excerpt, however, the applicant actually distinguished the prior art references on the basis of the present invention's separation of communication control from the path; the applicant did not distinguish those references by stating that the invention requires a single path or that the entire path must be completed before any information is transmitted. Thus, the cited prosecution history is not helpful to the Court's construction.

Nor is the Court persuaded by Big River's citation to extrinsic evidence consisting of testimony in which the inventor noted his ultimate rejection of connectionless systems. The inventor did not testify that the patent was intended not to encompass such systems, and at any rate, Big River has not cited any authority that would allow the testimony of the inventor concerning his invention to overcome the language of the patent claims. See Howmedica Osteonics Corp. v. Wright Med. Tech., Inc., 540 F.3d 1337, 1346-47 (Fed. Cir. 2008) (inventor's understanding of his invention does not equate to an understanding of the patent claims; "inventor testimony as to the inventor's subjective intent is irrelevant to the issue of claim construction"). Nor are Big River's citations to the '301 Family specification helpful.

In summary, Big River has not shown that the patent claims should be limited with respect to the term "communication system." The specification does not limit the scope of the invention or this term either by express language of disclaimer or by a consistent description of the entire invention with the limitation urged by Big River. Accordingly, the Court adopts its prior construction from the Vonage case, which Sprint urges here, and construes "communication system" to mean a plurality of network elements and connections forming a network to transfer information.

D. "Communication System"

Claim 1 of the '561 patent and claim 18 of the '932 patent recite the claim term "communication system." Sprint contends that this claim term should be construed to mean a plurality of network elements and connections forming a network to transfer information. In Vonage's response to Sprint's trial brief regarding claim construction, Vonage states that it does not dispute Sprint's proposed construction from the Vonage case, which Sprint urges here, and construes "communication system" to mean a plurality of network elements and connections forming a network to transfer information.

- "communication system" is construed to mean a system for communicating information. The Court's construction of this phrase is consistent with its plain meaning. Accordingly, further explanation for the Court's construction is not required.

Communication with the network; communicating/communication with an ASP; all forms of "communicate "

The term "communicate" appears, in some form, in Claims 1, 11, 12, and 13. MyMail proposes the term be construed to mean "the ability to exchange data" or the "exchange of data," depending on the context within the claims of the 290 patent. Implicit in MyMail's definition is the limitation that communication must be a two-way process. Defendants, citing two dictionaries, assert that "communicate" means "transmit information" and also argue that communication can be either one-way or two-way.

The specification describes a communications connection where the user and NSP transmit and receive data. See Col. 7:10-16. Communication cannot then be defined as transmitting information since it also entails receiving information. The Court thus rejects Defendants' proposed definition as being inconsistent with the specification. However, the Court must still determine whether communication, as defined in the 290 patent, includes one-way processes or must be limited to two-way processes.

The Court concludes that in the context of the 290 claim language, communication cannot be one-way since that would
Communication with the network; communicating/communication with an ASP; all forms of "communicate"

The term "communicate" appears, in some form, in Claims 1, 11, 12, and 13. MyMail proposes the term be construed to mean "the ability to exchange data" or the "exchange of data," depending on the context within the claims of the 290 patent. Implicit in MyMail's definition is the limitation that communication must be a two-way process. Defendants, citing two dictionaries, assert that "communicate" means "transmit information" and also argue that communication can be either one-way or two-way.

The specification describes a communications connection where the user and NSP transmit and receive data. See Col. 7:10-16. Communication cannot then be defined as transmitting information since it also entails receiving information. The Court thus rejects Defendants' proposed definition as being inconsistent with the specification. However, the Court must still determine whether communication, as defined in the 290 patent, includes one-way processes or must be limited to two-way processes.

The Court concludes that in the context of the 290 claim language, communication cannot be one-way since that would render the word "with" meaningless. The word "with" implies a two-way conversation. Had the patentee intended to include one-way conversation in his definition of "communicate," he would have replaced "with" with "to," or some other analogous word or phrase, in his claim language. The Court therefore substantially adopts MyMail's definition since "exchange" better reflects the two-way nature of communication.

The parties additionally dispute the meaning of the phrases "communication with the network" and "communicating with an ASP." MyMail proposes that "communicating with an ASP" be defined as "exchange of data with an ASP over a connection to the network." Defendants propose that "communication with the network" be defined as "transmission of information to a system of interconnected computers." The Court notes that MyMail's "over a connection to the network" limitation is already implicit in the definition of communication. For example, the Microsoft Press Computer Dictionary states that computer communication requires a connection or link between the computers. See MICROSOFT PRESS COMPUTER DICTIONARY 102 (3d ed. 1997). Thus, one skilled in the art understands that communication occurs over a connection to the network. However, a juror may not fully appreciate this nuance. Given that the purpose of claim construction is to "elaborate the normally terse claim language in order to understand and explain . . . the scope of the claims," the Court concludes that limitation is necessary to definitively express what is otherwise implied. Embrex, Inc. v. Serv. Engr. Corp., 216 F.3d 1343, 1347 (Fed. Cir. 2000). The Court therefore construes "communication" to mean "exchange of data," "communication with the network" to mean "exchange of data over a connection to the network," and "communication with an ASP" to mean "exchange of a data with an ASP over a connection to the network."
A. Communications Channel

The parties first dispute the meaning of the term "communications channel," used in claims 5, 7, and 8 of the '708 patent. Visto proposes the term means "a path or link by which information is passed between two locations. A communications channel can be a physical or wireless link." Seven suggests that the term means "a path or link by which information is passed between a remote computer terminal and a global server (i.e. second store) or between the global server and a first store within the firewall-protected corporate LAN. A communications channel may be a physical or wireless link."

The court adopts Visto's proposed definition, with slight modifications. As the parties' proposals suggest, a common area of disagreement which pervades the claim construction briefing is whether the inventions are limited to the preferred embodiments described in the specification. Seven's proposed definition, to illustrate, incorporates the limitations of a "global server" and a "firewall-protected corporate LAN." Seven thus urges that the patentee either explicitly or implicitly incorporated these requirements into the patents. The court rejects these arguments. The court defines "communications channel" to mean "a medium for transferring information. A communications channel can be a physical or wireless link."

M. Communications Channel Storage Means and Storage Means: These terms appear in claims 1 and 3. Independent claim 1 recites:

s较快 network members being remotely located from said central processing unit and connected thereto via a communication channel storage means containing identification of the network members.

(emphasis added). Independent claim 3 recites a "storage means containing the identification of the network members "(emphasis added). It is Defendants' contention that these terms are means-plus-function limitations subject to construction under Section 112, P 6, and that they fail to pass muster under that section.

Defendants assert that claim 1 recites two functions performed by the "communications storage means": (i) storing the identification of the network members and (ii) connecting the network members to the central processing unit; and they assert that the recited function of the "storage means" in claim 3 is to store the identifications of the network members.

1. Defendants' Contentions: According to Defendants the specification of the '328 Patent discloses only two structures capable of storing information, neither of which are suitable to store network member identities. According to the specification, the quotation system computer includes the following structures:

a random access memory for temporary storage of information, a read only memory for permanent storage of the computers [sic] configuration and basic operating commands, an input/output adapter for connecting peripheral devices and known input and interface devices, [and] a display adapter and display device.

Col. 6, ll. 35-42. Neither the random access memory ("RAM") nor the read only memory ("ROM") is identified as storing or containing the identifications of network members. The ROM could not store network member identities, because such identities are not for "permanent storage" and are not part of "the computer[']s configuration or basic operating commands." Moreover, network member identities could not be stored in ROM, because data in read only memory can be accessed, but not modified. Similarly, RAM is commonly understood to refer to volatile memory, i.e., memory that loses its data when power is disconnected from the system, and as such would also be unsuitable for storing network member identifications or other data that would need to be accessed on a more permanent basis.

No other memory or storage structures are described in the specification and there is no description or disclosure of a "communications channel storage means" or a "storage means" for containing identification of the network members. See
Defendants conclude that "[a]s stated in Amtel v. Information Storage Devices, 198 F.3d 1374, 1382 (Fed. Cir. 1999), the patentee must disclose the structure corresponding to the means in the specification in order to comply with the particularity requirement of 35 U.S.C. § 112, ¶ 2. Here, the specification is completely devoid of any structure that corresponds to the function of storing the identifications of the network members. Even if the only structures described in the specification for storing information were actually capable of storing the network member identities, . . . the specification fails to clearly link or associate those structures with the recited function." (Defs' Opening Br. at 25)

2. Discussion: SST advances two reasons why Defendants' position lacks merit. First, the claims are not in means plus function format. Second, if the storage means is in means plus function form, several corresponding structures are disclosed and linked.

Section 112, ¶ 6 provides that:

[a]n element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

A court first "must decide the subsidiary question of whether the claim element disputed by the parties invokes § 112, ¶ 6 in the first instance." Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999). In reaching that decision:

The word "means" is "part of the classic template for functional claim elements." Accordingly, in determining whether a claim element falls within § 112, ¶ 6, this court has presumed an applicant advisedly used the word "means" to invoke the statutory mandate for means-plus-function clauses."

Id. at 1302 (citations omitted).

This presumption can be overcome:

Two specific rules, however, overcome this presumption. First, a claim element that uses the word "means" but recites no function corresponding to the means does not invoke § 112, ¶ 6. Second, even if the claim element specifies a function, if it also recites sufficient structure or material for performing that function, § 112, ¶ 6 does not apply.

Id. at 1302 (citations omitted). SST contends that the language in question does not implicate § 112, ¶ 6 because it recites no function.

There must first be noted the distinct difference in the language construed in the case upon which the Defendants rely so heavily, WMS Gaming Inc., supra, and the instant case. In WMS Gaming the disputed claim language read:

means for assigning a plurality of numbers representing said angular positions of said reel . . .

means for randomly selecting one of said plurality of assigned numbers

Means for stopping said reel at the angular position represented by said selected number

That is classical means-plus-function language. It is to be contrasted with the language of the '328 patent under consideration here:

A computerized system for forming a computer based communications network of network members inclusive of network
buyers and or network vendors for processing requests for quotations for goods and services through at least one central processing unit including operating system software for controlling the central processing unit, said network members being remotely located from said processing unit and connected thereto via a communication storage means containing identification of the network members, means for network buyers to generate request for quotation for goods and/or services, etc.

Claim 1 (emphasis added).

A method for processing requests for quotation for goods and/or services from a party representing a buyer or supplier of goods and/or services through a computerized system forming a computer based communications network of network members for linking buyers to suppliers with the computerized system having at least one central processing unit including operating systems software for controlling the central processing unit and storage means containing the identification of the network members, wherein the method comprises the steps of, etc.

Claim 3 (emphasis added).

Defendants urge rejection of the declaration of Eric M. Dowling, Ph.D., E.E., asserting that he is not a person skilled in the art and that the substance of his declaration is irrelevant. The court finds that Dr. Dowling is highly skilled in the art and that the information he provides is relevant.

The pertinent means-plus-function language in WMS Gaming clearly must find its structure apart from the claim itself. In the '328 patent, on the other hand, the language to be construed is a noun. It is not pointing to something else; it is itself a storage means which contains identification of the network members. "Storage means" was recited in both the abstract and summary of the '328 patent. The summary states "and storage means containing the identification of the network members," (Col. 2, ll. 59, 60) and "storage means containing appropriate identity and other information about members of the network, means for potential buyers of product and/or services to transmit a request for quotation to said central processing unit. .." (Col. 3, ll. 10-14).

Used as a noun, "storage means" identifies a known structure, i.e., a device into which bits of information can be written and later recalled, such as a disk, ubiquitously found on computer systems. As stated by Dr. Dowling, "[t]o one of ordinary skill in the art, 'storage means' as used in Abstract and the above two citations, taken in light of the rest of the disclosure [], would mean 'one or more computer storage devices capable of storing computer files.' Typically, this would involve a disk, like a hard drive, but could involve other types of storage devices such as semiconductor disks implemented with RAM and/or ROM (EPROM) devices. Alternatively, the storage means could be a memory such as a RAM where data is temporarily stored so it can be manipulated upon a CPU." (Dowling Decl. para. 10).

In Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996) the district court held that words "detent mechanism" used in the following claim language was within § 112(6), P 6: "a radically enlarged wheel on said sleeve and said wheel and said one handle having a cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals." In addition the summary of the invention used "detent means." The Federal Circuit disagreed, with the district court, stating "... the fact that a particular mechanism - here 'detent mechanism' - is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of section 112(6). Many devices take their names from the functions they perform ... 'Detent' (or its equivalent, 'detent mechanism') is just such a term" Id. at 1583. The Court found no significance in the fact that the patent specification used on two occasions the words "detent means" rather than "detent mechanism." Further the Court noted that the patentee did not use the "means-plus-function" language.

The present case is similar to Greenberg. The terms in question, "storage means" and "communications channel storage means," are devices taking their names from the functions they perform, as "detent mechanism" did. The patentee in Greenberg enjoyed a favorable presumption: "... that the failure to use the word 'means' creates a presumption that § 112, P 6 does not apply," Personalized Media, 161 F.3d at 703-04. SST faces the opposite presumption: "... the use of the word 'means' triggers a presumption that the inventor used this term advisedly to invoke the statutory mandates form means-plus-function clauses." Id. at 703.

In Personalized Media, supra, the International Trade Commission construed the limitation "digital detector" as a means-
plus-function limitation under § 112, P 6. Rejecting this holding, the Federal Circuit referred to the presumptions, stating that "[i]n deciding whether either presumption has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of § 112, P 6." 161 F.3d at 704. The Court noted that the "'digital detector' limitation does not use the word 'means,' and therefore this limitation is presumed not to invoke § 112, P 6." Id. Following the reasoning of Greenberg, the Court concluded:

Even though the "detector" does not specifically evoke a particular structure, it does convey to one knowledgeable in the art of a variety of structures known as "detectors." We therefore conclude that the term "detector" is a sufficiently definite structural term to preclude the application of § 112, P 6

Id. at 705.

Although the limitations "storage means" and "communications channel storage means" are subject to the presumption of § 112, P 6 applicability, they convey to one knowledgeable in the art a definite form of structure and overcome whatever presumption that may exist.

SST urges another route to avoid § 112, P 6. "[W]here a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format even if the claim uses the term means." Sage Prods. v. Devon Indus., Inc., 126 F.3d 1420, 1427-28 (Fed. Cir. 1997). SST relies upon two cases to support its contention that Claims 1 and 3 themselves elaborate sufficient structure to perform entirely the recited function.

At issue in Wenger Mfg. v. Coating Machinery Systems, 239 F.3d 1225 (Fed. Cir. 2001), was the question whether § 112, P 6 applied to a claim limitation reading "means defining a plurality of separate product coating zones." The district court held that this limitation was not subject to § 112, P 6. The Court of Appeals agreed, concluding that in spite of the presumption of applicability "it is unclear whether there is any function recited that corresponds to the word 'means.'" Regardless of that consideration, the Court stated:

. . . we agree with Wenger that § 112, P 6 does not apply because the claim recites sufficiently definite structure for performing the function of "defining." See Rodime, 174 F.3 at 1302, 50 USPQ 2d at 1434 ("[E]ven if the claim element specifies a function, if it also recites sufficient structure or material for performing that function, § 112, P 6 does not apply.").

Id. at 1237. The Court then noted that "[t]he claim specifically recites structure including spray nozzles that are directed toward the sidewall of the reel, which 'define' (i.e., establish the boundaries of) the separate product coating zones that are longitudinally spaced along the reel." Id.

Rodime, supra, is to the same effect. The Federal Circuit held that § 112, P 6 was inapplicable even though (i) the claim used the term 'means,' (ii) there was therefore a presumption of applicability, and (iii) the claim language linked the means with a function. The claims in question used the limitation "positioning means." For example, in claim 3, the element at issue began, "positioning means for moving said transducer means between the concentrically adjacent tracks on said micro-hard disk," 174 F.3d at 1302. The district court held that this language invoked § 112, P 6. The Federal Circuit reversed, stating that although the first steps in the required analysis appeared to bring the claim element within § 112, P 6, "[t]he final step in the analysis, however, requires this court to determine whether the claim nevertheless recites sufficient structure for performing the moving function to take it outside the bounds of that provision." Id. at 1303.

The Federal Circuit examined the claim and noted that after the language in question, claim 3 further provided a list of the structure underlying means: "said positioning means including: two support arms . . . a pivot shift . . . a positioning arm . . . a bearing assembly. . . a stepper motor . . . means for operating said stepper motor . . . and a tensioned steel band . . .". In addition the claim recited the specific location and interconnection of each of these structural sub-elements. "This detailed recitation of structure for performing the moving function takes this claim element out of the scope of § 112, P 6." Id. at 1303-4.

In the present case if it were assumed that "storage means" were not a noun identifying itself and not referring to another structure, then either i) the claims themselves contain a detailed recitation of structure for performing the function so as to
take them out of the scope of § 112, P 6 or ii) the details contained in the claims themselves, together with the details contained in the specification constitute compliance with § 112, P 6.

Claim 1 calls for, along with a communications channel storage means, a computerized system for forming a computer based network and processing RFQs through at least one central processing unit including operating system software for controlling the central processing unit. Claim 3 calls for similar components. As Dr. Dowling stated:

By 1996 it was well known that various types of physical storage devices could be used to store computer files on a PC or central server. Commonly known and commonly used storage devices included, by 1996 and before: hard drives, floppy drives, magnetic tape drives, RAM-Disks (file system portion loaded into RAM to speed file system access performance), ROM-Disks (disk equivalent implemented using semiconductor ROM technology), and optical disks, among others. All such storage devices were well known and commonly used by 1996 to implement computer file systems, and would have been obvious design choices well known to those of ordinary skill in the art by 1996 or as early as 1993, or before.

(Dowling Decl. para. 14).

If the detail in the claims themselves were not sufficient to bring this case within Wenger and Rodime and the limitations at issue were held to be in means plus function form, the detail in the claims and in the specification is sufficient to comply with § 112, P 6. The specification states that RAM is used as the computer's temporary memory. (Col. 6, ll. 36-42). The claimed filter operates on the data in the storage means - "means for filtering the network members in said storage means" - which is the temporary storage for the RAM. As Dr. Dowling explained, a person ordinarily skilled in the art would understand that the computer leads the data into temporary storage RAM before operating on the data, and any filtering done with respect to the network members is done when they are stored in the RAM in accordance with the claim. (Dowling Decl. para. 16-17).

Fig. 5 of the '328 patent, labeled "CREATE EMPTY TABLE TO HOLD VENDORS THAT WILL BE SELECTED FOR THIS RFQ (tmp - SELECTED TABLE)," discloses that the storage means that holds the information upon which the filter means will operate is RAM. The RAM is storage means.

Further, at Col. 6, ll. 36-42 the specification reads: "The quotation system computer is schematically (sic) shown in Fig. 4 as the 'Central Office' and includes a random access memory for temporary storage, a read only memory for permanent storage of the computers configuration and basis operating commands, an input/output adapter for connecting peripheral devices and known input and interface devices." Commenting on this language, Dr. Dowling wrote: "One of ordinary skill in the art would thus understand that 'peripheral devices and known input and interface devices' would include a hard drive or any other storage device that could hold a computer file system. To one of ordinary skill in the art, it would be unmistakable that the 'Central Office' computer system includes the storage means recited in the abstract, summary, and claims and that 'storage means' could be implemented using 'known input and interface devices,' e.g., hard drive or any other well known device in common use for storing computer files." (Dowling Decl. para. 155).

The court concludes, however, that the better view is that the '328 patent storage means (including its use in "communications channel storage means" is not in means plus function format, but refers to a specific structure - the computer's permanent and temporary storage.

2. "Plurality of communications channels." Radio frequency communications channels, each channel including two distinct frequencies, one for communication to the mobile unit and the other for communication from the mobile unit. (554 patent, col. 4, ins. 51-60)

6. Claims 1, 17 & 26 -- "Communications Link"
Defendants contend that "communications link for communicating between a user of the system and the database" is a means-plus-function phrase and is thus limited by 35 U.S.C. § 112 P 6. CIVIX argues that this phrase should not be so limited.

35 U.S.C. § 112 P 6 and federal circuit case law dictate that "where a claim sets forth a means for performing a specific function, without reciting any specific structure for performing that function, the structure disclosed in the specification must be considered, and the patent claim construed to cover both the disclosed structure and equivalents thereof." Data Line Corp., 813 F.2d at 1201. Although not dispositive, the phrase at issue here does not use the word "means." See Cole, 102 F.3d at 531; see also Personalized Media, 161 F.3d at 703-704 ("failure to use the word 'means' creates a presumption that 35 U.S.C. § 112, P 6 does not apply").

I conclude that this phrase is not a means-plus-function limitation controlled by 35 U.S.C. § 112 P 6. "Communications link" is defined in the '525 patent as follows:

"Communications link" is used to denote means, including for example a telephone line for communicating between the database and the port. . . A communications link facilitates communications between a user of the system and the database. ('525 Patent, Col. 2 lines 5-7, 16-17). Other portions of the specification support CIVIX' contention that "communications link" is a connection allowing for the transmission of information between one or more databases and one or more ports. ('525 Patent, Col. 11 line 65 through Col. 12 line 7). The patent is careful not to limit itself to the recited forms that this structure might take.

The communications link 18 of the invention can take many forms. It is generally impractical to "hard-wire" each remote access port 16 to the database 12; so the form of the communications link 18 generally includes existing communications networks, such as one or more of the following: telephone lines, fiber-optic cabling, satellite communications, cellular communications, radio and microwave-frequency communicators, infra-red communicators, the facsimile mechanism, airphones, modems, the internet, co-axial cabling, television including interactive TV communications, and the like. These communications networks and subsystems are readily known to those skilled in the art without further reference hereto. ('525 Patent, Col. 5 line 63 through Col. 6 line 8). Furthermore, the phrase "communications link" is expressed throughout the '525 patent as a specific structural element. Accordingly, the phrase at issue is not subject to 35 U.S.C. § 112, P 6, and I will not analyze it as a means-plus-function element. Therefore, I reject Defendants' contention that the patent is limited to the means in the specification.

2.1.3 “Communications Medium”

Plaintiff proposes that “communications medium” means “a medium over which data communications travel.” Defendants propose that “communications medium” means a “network for transferring data,” and does not include the internet.

Plaintiff argues that “communications medium” should include the internet because “the ordinary meaning of the term ‘communications medium’ encompasses the Internet.” (Plaintiff’s Opening Claim Construction Brief 9:10-11.) Plaintiff also argues that the patent application discloses the internet by referencing “the Internet protocol TCP/IP” and “Compuserve, a thenexisting Internet service provider.” (Id. at 10:1.) Defendants respond that “communications medium” should not include the internet because, among other arguments, at the time of the invention, that term did not refer to the internet. The Court agrees with Defendants. Whether the original patent supports a definition of “communications medium” that includes the internet depends on whether a person of ordinary skill in the art, reading the patent in 1995, would have understood “communications medium” to mean the internet. See Phillips v. AWH Corporation, 415 F.3d 1303, 1312 (Fed. Cir. 2005) (“[T]he words of a claim are generally
given their ordinary and customary meaning,” which is “the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention.”) Plaintiff has offered no evidence that “communications medium” was understood to include the internet in 1995. Instead, Plaintiff has introduced dictionary definitions of “medium” from 1995 and 2000. Plaintiff’s “ordinary meaning” argument fails because it rests on an understanding of “communications medium” today, not in 1995.

Plaintiff’s argument that the patent application discloses the internet by referencing TCP/IP and CompuServe also fails. As Defendant RouteOne explains, the mention of TCP/IP protocol in the ‘841 Patent was not made in reference to the “communications network.” (Defendant RouteOne’s Reply Claim Construction Brief 22:19-25.) Further, in 1995, TCP/IP communications protocol was used on many computer networks other than the internet. Further, in 1995 CompuServe “commercially offered only a direct (non-internet) dial-up service.” (Id. at 21:24-25.) At that time, CompuServe was still in beta testing with its web browser, and its service was “not internet based.” (Id. at 22:5-17.) Thus, in 1995, a reference to either TCP/IP or CompuServe was not automatically a reference to the internet.

The specification supports the claim construction advanced by Defendants. For example, the ‘841 specification lists as examples of a “communications medium” a wide area network, a local area network, a satellite communications network, a commercial value added network, ordinary telephone lines, and private leased lines. (‘841 Patent 18:1-5.) The internet was not on this list. And, while it is improper for a court to limit a patent to its preferred embodiment, Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1374 (Fed. Cir. 2003), it is reasonable to assume that when a patent supplies a long list of examples like here, the list is exhaustive.

The prosecution history supports both Plaintiff’s and Defendants’ arguments. First, Plaintiff argues that the prosecution history shows that the term “internet” was disclosed in the original specification of ‘841 Patent. Plaintiff contends that the patent examiner of the ‘403 Patent determined that the term “internet” was disclosed by the ‘403 Patent, which “necessarily” implies that the term was disclosed in the ‘841 Patent, since the ‘403 Patent and the ‘841 Patent were originally identical. ((Plaintiff’s Opening Claim Construction Brief 11:1-4.) Plaintiff slightly overstates the strength of the argument. The patent examiner of the ‘403 Patent did not make an express determination that “internet” was disclosed by the ‘403 Patent. Instead, the examiner allowed, without comment, amendments to the patent that added the term “internet” to two places in the specification. (‘403 Patent Prosecution History, June 23, 1998, Notice of Allowability at FXPRS002339-002342.) This action implies that the patent examiner had determined that the addition of “internet” did not disclose new matter. See MPEP 608.04 (“No amendment may introduce new matter into the disclosure of an application.”).

On the other hand, Defendants argue that the prosecution history shows that the original patent did not support the internet as a communications medium of the invention. (Id. at 28:1-2.) Defendants point out that the ‘841 patent examiner refused to allow Plaintiff to add “Internet” to its meaning in a Preliminary Amendment to the ‘841 Patent. (Defendant RouteOne LLC’s Opening Claim Construction Brief 27:20-25.) Indeed, the ‘841 patent examiner rejected the very “internet” amendments that the ‘403 patent examiner allowed. Before granting the ‘841 Patent, the examiner required that the two references to the “internet” be removed from the specification. (‘841 Patent Prosecution History, Feb. 5, 2003, Notice of Allowability at FXPRS003175.) While the ‘841 examiner, like the ‘403 examiner, did not give reasons for his action, the action alone implies that the examiner had determined that the addition of “internet” disclosed new matter. See MPEP 608.04. Thus, the patent examiners made conflicting determinations.

Determinations by patent examiners are entitled to an “especially weighty presumption of correctness.” Brooktree Corp. v. Advanced Micro Devices, Inc., 977 F.2d 1555, 1574-75 (Fed. Cir. 1992). But this Court is faced with two opposite decisions by patent examiners in the same situation. In this circumstance, the Court relies on its own reasoning. Thus, the Court construes “communications medium” to mean a “network for transferring data,” not including the internet.
Q. "communications module"

Claim 5 describes a computer which comprises "a communications module for receiving transmitted reservation requests from any of the PCDs; . . . [and] a request processor coupled to the communications module . . . for determining a proposed reservation time. . . ." (col. 27, ll. 43-54) (emphasis added). Claim 17 contains similar language. The Defendants contend that "communications module" should be construed as a means-plus-function limitation under § 112, P 6. However, the term "means" is absent from the claims and, thus, there is a presumption that § 112, P 6 does not apply. In an effort to rebut the presumption, the Defendants claim that "communications module" lacks definite structure. But, as with "personal communication device," they present no evidence in support of this conclusory assertion. As the Federal Circuit has emphasized, determining if a term connotes sufficient structure depends on "whether the term is one that is understood to describe structure, as opposed to a term that is simply a nonce word or a verbal construct that is not recognized as the name of structure and is simply a substitute for the term 'means for.'" Lighting World, Inc., 382 F.3d at 1360. "Communications module," and even "module," represents more than a mere verbal construct serving as a "means for" substitute. For example, The American Heritage Dictionary of the English Language (4th ed. 2000), defines "module," in the electronics sense, as "a self-contained assembly of electronic components and circuitry, such as a stage in a computer, that is installed as a unit." See Lighting World, Inc., 382 F.3d at 1361 (dictionary definitions consulted to determine if "connector" has a reasonably well-understood meaning as a name for structure); Linear Tech. Corp., 379 F.3d at 1320 (technical dictionary aids determination that "circuit" is structural). Thus, "module" connotes definite structure, and when combined with "communications," which describes the module's operation, sufficient structural meaning will likely be conveyed to a person of ordinary skill in the art. In fact, the Plaintiff's expert testified that: "A person of ordinary skill in the art would recognize the structural connotation of the term Communications Module and would understand it to mean a [sic] electromagnetic transceiver and attendant software. An electromagnetic transceiver is capable of receiving and transmitting wireless signals such as RF, microwave and infrared radiation." (Frost Decl. P 5.) Consequently, the "communications module" limitation of claims 5 and 17 is not a means-plus-function limitation.

Because they contend that "communications module" is a means-plus-function limitation, the Defendants do not propose an independent construction of the term. The Plaintiff, however, claims that the term means "a transmitter/receiver designed for data transmission." This construction is consistent with the specification, which provides, for instance, that communication modules receive and transmit reservation requests and information. (col. 9, ll. 1-3; col. 10, ll. 4-11; col. 20, ll. 20-26.) The specification further states that the communications module "is implemented using wireless transmitter/receiver and attendant software." (col. 9, ll. 3-5; col. 10, ll. 9-10.) As such, the Court will adopt the Plaintiff's proposed construction of "communications module."

B. Communications Module

Visto proposes that the term "communications module," as used in claim 11 of the '192 patent, means "software routines or code that perform the task of communicating." Seven urges that the term means "a computer software module having routines for compressing data and communicating with a synchronization agent on a global server." Again, Seven has incorporated the limitations of a synchronization agent and a global server into its definition of communications module despite the fact that the claim language supports a broader meaning. Seven also asserts that the inventors defined this term by implication by referring to the communications module as having routines for compressing data. Definition by implication is a tough climb. Seven has not persuaded the court that the "communications modules" referenced in the claims necessarily include routines for compressing data as described in the description of the preferred embodiment. The court therefore adopts Visto's proposed construction of this term. "Communications module" means "software routines or code that perform the task of communicating."
3. Communications module

The term "communications module" appears in both the '201 patent and in the '542 patent. Seven defines this term to mean "software on the client for communicating." Visto proposes that the term means "a software module on the client that interfaces with the gateway computer/server computer. The communications module is based on an OLE connection technology. The communications module must be on a separate device from the session module."

Visto's definition is replete with limitations that are not found in the claims. The cited portions of the specification related to OLE connection technology demonstrate that OLE technology is clearly illustrative and not exclusive. See, e.g., '542 patent, col. 3, ll. 58-60 ("The new FormLogic client/server components described herein use an object management scheme and are preferably based on Microsoft's OLE technology.") (emphasis added). The court construed the term "communications module" as "software routines on the client for communicating."

I. Computer Based Communications Network: Defendants' proposed construction of computer based communication network is a presentation of their disclaimer contention in a different form. They note the use of the phrase in independent claims 1 and 3. Claim 3, for example, reads:

A method for processing requests for quotation for goods and/or services . . . through a computerized system forming a computer based communications network . . . for linking buyers with suppliers

(Col. 8, ll. 49-53) (emphasis added).

Defendants then observe that in various places in the specification where reference is made to a computer based network, there appears the language "No central database of goods, prices, etc. is involved" (Col. 2, ll. 35-42) or "[t]here is no central pricing database to limit the number of buyers and vendors of good and services or to limit the number of goods and services which can be processed." (Col. 3, ll. 55-62).

Relying on the claims, specification and prosecution history, Defendants urge that the proper construction of the term "computer based communications network" is "a computer network that does not include or use a central database that contains more information than is required to determine which network vendors should receive the buyer's RFQ." The court has already rejected this construction in its rejection of Defendants' disclaimer contention.

* * *

B. Disclaimer: In support of their definition of filter means Defendants contend that during the prosecution of the application leading to the issuance of the '328 patent the applicant disclaimed any central database that contained anything more than the information required to determine which vendors should receive the buyer's RFQ. SST contends that the applicant disclaimed a system wherein all of the information about all the items for sale from all the vendors was stored at the central database, so that a complete quote could be generated, and a transaction could be fully consummated, between the central database and the consumer, i.e., a central database storing anything less was not disclaimed.

The portion of the application file upon which Defendants rely gives some support to their argument.

In his February 5, 1998 Response to Office Action, the inventor summarized the claimed invention as follows:

Before turning to the specific rejections, it is believed that a brief review of the invention as claimed would be helpful. Applicant's invention comprises a central filter and broadcast means which receives RFQs, filters them to determine which particular vendor terminals may be able to service such requests, and sends the RFQs to those terminals. As explained in
applicant's originally submitted specification, this eliminates the problem of having a central database which, if it were to make available products from many worldwide vendors, would have to store hundreds of millions of entries. This would be inefficient and time consuming and thus, impractical.

The present invention solves the problem by not providing a central database which contains all of the information on all items to be sold. Rather, the invention uses a database with information regarding various vendors who may be able to supply classes of items. The central filter means then transmits the RFQ to appropriate vendors, and received back an appropriate quote from the vendors. The quote may include items such as delivery terms, price, etc., none of which are stored in the central database.

February 5, 1998 Response at 4, 5.

The inventor also stated:

In summary, none of the prior art teaches a system wherein the central database maintains information only sufficient to determine which sellers should receive the quote, and wherein the central database filters and sends that request for quote only to the appropriate sellers.

February 5, 1998 Response at 8.

The Examiner, when deciding to allow the claims of the '328 patent to issue, stated:

The systems of the prior art either maintain a central database containing all necessary information to answer an RFQ or they require that the buyer specify the vendor to deliver the RFQ to. Applicant's system represents a significant improvement over these systems in that the filtering means only maintains enough information to determine which vendors to send the RFQ to, without having to maintain data on all possible goods and services.

Notice of Allowability (Jan. 19, 1998) at p. 3.

At best from Defendants' point of view the Examiner's statement is ambiguous. He stated both that "[t]he systems of the prior art either maintain a central database containing all necessary information to answer an RFQ" and also that "[a]pplicant's system represents a significant improvement over these systems in that the filtering means only maintains enough information to determine which vendors to send the RFQ to . . ." He did not address the situation in which the central database does not contain all the necessary information to answer an RFQ but does contain more information than is necessary to determine which vendors to send the RFQ to.

For a prosecution comment or argument to narrow the ordinary meaning of claims there must be a clear, unambiguous, deliberate disavowal of claim scope. Any ambiguity must be resolved in favor of the patent owner. Middleton Inc. v. Minnesota Mining and Mfg. Co., 311 F.3d 1384 (Fed. Cir. 2002).

Apart from the ambiguous statement upon which Defendants rely, everything else in the prosecution history and in the specification and claims demonstrates that SST's contention is correct, namely, that the applicant disclaimed only a system wherein all of the information about all the items for sale from all the vendors was stored at the central database. He did not disclaim a central database that contained something more than the information required to determine which vendors should receive the buyer's RFQ but less information than that which is necessary to generate the entire quote and consummate the sale.

The file history preceding that portion upon which Defendants rely is replete with statements to the effect that the prior art discloses that all of the information on all of the items for sale is kept at a central data base, distinguishing prior art from applicant's invention, which does not store all of the information necessary to generate all of the quotes, e.g., First Office Action Response dated August 1, 1997, p. 8; Response of January 13, 1998, pp. 2-3.

The '328 patent specification refutes Defendants' assertion that the central data base can store nothing more than information required to determine which network vendors should receive on RFQ. The specification notes that the central database stores product information such as price versus time by product type, vendor profile data, password information, user
coordinates, etc. (Col. 4, ll. 43-60). The '328 patent provides a separate embodiment for "special sales" whereby a vendor can register certain products and their detailed specifications with the central office, and the central office will forward this product information to certain buyers (Col. 4, ll. 52-59). The central computer stores forms necessary to register as a member (Col. 5, ll. 3-6). This information is not filter conditions for selecting vendors, but it is stored on the same central computer.

The allowed claims of the '328 patent are inconsistent with Defendants' disclaimer contention. For example, the '328 patent claims a system wherein RFQ's are subjected to "a first set of filter conditions" to determine to which vendors the RFQ should be sent, and then the responding actual quotations are subjected to "additional filter conditions" to determine which subset of the quotes returned from the vendors should be sent on to the requesting buyer. (Col. 10, claims 17-19). The first filter conditions of claim 17 are different from the additional filter conditions of claim 17. Claim 17 recites that it is the first filter conditions, and not the additional filter conditions, that determine which sellers are to receive the RFQ. Thus the central computer must store more filter conditions than those required to determine which seller is to receive an RFQ.

These various factors compel rejection of Defendants' contention that by virtue of a disclaimer the claims do not cover a system wherein the central database stores anything more than the filter conditions to select which vendors are to receive RFQs.

GO BACK

728

Claim Construction: "Communications Network"

The primary dispute between the parties concerning the meaning of "communications network" in claim 1 centers on whether, as argued by IPXL, the term is broad enough to encompass packet switched networks, such as the Internet, or whether it encompasses only a single defined or dedicated path that is maintained for the duration of the transmission (such as a circuit switched network), which is Amazon's position. The Court concludes that IPXL's interpretation is correct because a person of ordinary skill in the art at the time of this invention would understand the plain meaning of the term "communications network" to encompass communications techniques of both the packet switched and circuit switched varieties.

Claim 1 requires a "communications network" and "terminal device selectively connectable to the central controller through the communications network." Although the written description does not expressly use the term "communications network," it does generally address the communication function of the system in the context of a "transaction network system." For instance, the specification explains that

The transaction network system preferably comprises one or more central control units or host processors 200, having associated database(s) or memories 300 and a plurality of transaction terminals 10 connected to one or more of the central control units 200 via communications link 400 in a known manner. An example of one known system and communications link is described in the '336 Patent. Other configurations may be used.

Col. 5, ll. 57-65.

FIG. 2 is a flow chart illustrating the operation of preferred embodiments of the present invention. For simplicity, the well known steps associated with the local controller communicating with a central controller are omitted.

Col. 8, ll. 6-19. Rather than specifically defining or describing the communication aspects of the invention, the written description simply refers to the manner in which the communication is accomplished using "a known manner" and "well known steps."

Amazon argues that because the claim language requires the terminal device to be "connectable" to the central controller, the Internet, being a "connectionless" medium, is not covered by the claim. This argument fails for at least two reasons. First, Amazon applies the language "connectable" out of context. A reading of the claim as a whole reveals that "connectable" does not modify "communications network" so as to limit the claim to only connection-oriented communications. Rather, the claim simply provides that the terminal device be "selectively connectable" to the central controller. Nowhere in the claim language, the written description, or the prosecution history does the patentee discuss the
difference between connection-oriented and connectionless in the context of the claimed communications network.

Second, the Internet is only connectionless in the sense that it is packet switched rather than circuit switched. Simply because the Internet is a packet switched network does not mean that it is incapable of establishing connections. When devices communicate using the Internet, logical connections are established between those devices. A reference in a claim to "connectable" devices, without any suggestion or context in the intrinsic evidence that would disclaim packet switched networks, does not by itself exclude communication over the Internet. Moreover, a person of ordinary skill in the art would consider the Internet to be a "communications network." 2

--- Footnotes ---

2 Indeed, Amazon's own flagship U.S. Patent No. 5,960,411 discloses "communications link(s)" as incorporating "transmission(s) over the Internet." '411 Col. 6, ll. 19-21. Similarly, Amazon's invalidity expert, Dr. Kreitzberg, has asserted U.S. Patent No. 5,664,110 to Green, et.al., as prior art to the '055 patent. Dr. Kreitzberg notes that

The DPU and DFTC in Green can communicate via telephone, cable, satellite, or fiber-optic data transmission. (4:61-5:6). Green also teaches using "known communication means" such as telephonic serial data transfer or the Internet. (5:7-21)

Kreitzberg May 10, 2004, report at p. 33. The Court notes such extrinsic evidence not to support its claim construction, but rather to highlight the inconsistencies in Amazon's own arguments regarding the nature of "communications network."

--- End Footnotes ---

For all of these reasons, the Court construes the term "communications network" as follows:

Any network, including the Internet, enabling communication between a terminal device and a central controller.

---

6. "a communications network electronically linking the computer workstations to the host computer network"

The parties similarly disagree about the meaning of the term "a communications network electronically linking the computer workstations to the host computer network" in claim 1. Without question, the plain meaning of the term communications network to one of ordinary skill in the art is consistent with the definition proposed by Manheim—namely, an "electronic connection between the users' computers and the host computer network that enables data transfer." (See Manheim Resp. Br. at 20; AMS Resp. Br. at 28.) But, this term must be construed in light of the claims as a whole. Given the Court's conclusion, supra, that the "means to send user commands" and the "means to receive and display … auction data retrieved and transmitted from the host computer network" require communications parameters capable of employing the X.25 network protocol, the Court adopts AMS's proposed definition. Therefore the term "a communications network electronically linking the computer workstations to the host computer network" shall mean "hardware and software forming an electronic connection between the users' computers and the host computer network that enables data transfer via the X.25 protocol."

---

1. "communicatively coupled"

The term "communicatively coupled to the gel layer" appears in Claims 1 and 2 of the '102 Patent. Cardiac Science asserts that this term should be construed as "configured to enable electrical connection to the gel layer." Philips contends that this phrase should be defined as "the wire is in direct contact with the gel layer, without the use of a conductive contact layer, such as an intermediate metallic layer." Philips renews its disclaimer arguments as set forth in Section II.D.1, above.
The Court construes "communicatively coupled" to mean "configured to enable electrical connection to the gel layer."

A. "Communicatively Coupled" Means "Connected in a Way that Permits Communication."

1. Ordinary Meaning

The term "communicatively coupled," which appears in asserted Claims 1, 6, 11, and 17, invariably describes the connection between a central information storage bank (the computer or array of computers that stores the universe of downloadable media content) and local units from which a user can download selected media. E.g., 823 Patent Claim 1 ("at least one local unit communicatively coupled to said central computer"); Claim 19 (same); Claim 6 ("a first interface to be communicatively coupled to the central computer"). The ordinary meaning of the term "coupled" is "connected," and the adverb "communicatively" suggests that the coupling is for the purpose of communication.

Digeo proposes a construction of " communicatively coupled " that reflects the term's ordinary meaning. Audible, however, contends that the term is limited to couplings on an "integrated closed network." At oral argument, Audible explained that an "integrated closed network" is a network that only preauthorized users can access. Audible does not contend that the "integrated closed network" limitation is inherent in the plain meaning of "communicatively coupled," nor could it. Audible must, therefore, point to evidence of a "clear disavowal of claim scope" through "words or expressions of manifest exclusion or restriction." ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1091 (Fed. Cir. 2003).

2. Specification

The claim language and specification provide no support for Audible's proposed construction, much less a "clear disavowal of claim scope" that would mandate a departure from the ordinary meaning of "communicatively coupled." When pressed at oral argument to point to any disclosure of a "closed" network in the specification, Audible suggested that the description of a customer opening an account and obtaining an identification card was evidence that the patent disavows any "open" network. The disclosure, however, simply notes that in a "point of purchase delivery system" embodiment, the customer would obtain an access card before downloading content. 823 Patent at 10:40-11:17. The court is not at liberty to restrict the scope of the claims to conform to the description of an embodiment. Dow Chem. Co. v. Sumitomo Chem. Co., 257 F.3d 1364, 1378 (Fed. Cir. 2001) ("It is axiomatic that claims, not the specification embodiments, define the scope of protection.") (internal citation omitted). Even if the court were to limit the claims in accordance with the point of purchase embodiment, the embodiment does not require a "closed" network. Nothing in the description prohibits a user from accessing content without preauthorization. Authorization is necessary only if the user decides to purchase content.

In contrast to the single inapposite disclosure in the specification that Audible identified, the specification repeatedly discloses the use of unrestricted networks over which local units and a central information bank are communicatively coupled:

Communication network links between the central information bank... and point of sale sites can be made utilizing one or a combination of many commercially available networks such as telephone, satellite or cable networks or any other medium suitable for transmitting information in a digitized format.

Id. at 5:21-27. The inventors also stated that one could use the internet as the "backbone" network for the invention. Id. at 5:28-30. The inventors never described the communication links between the central information bank and the local units as closed or restricted to preauthorized users. Instead, the means for protecting media content from unauthorized use are the encryption methods that the court will discuss later. See infra Part III.G; 823 Patent at 15:17-28. When the patentees wished to claim encryption methods, they did so by using explicit language covering encryption. The notion that the term "communicatively coupled" is limited to "closed" communication is inconsistent with the 823 Patent's written description and claim language.

3. Are Mr. Saigh's Pro Se PTO Communications Part of the Prosecution History?
The bulk of the support for Audible's proposed construction comes from the prosecution history. Before reviewing the history, however, the court must consider a dispute over whether it may consider certain communications from Mr. Saigh as part of the prosecution history. Each of the challenged communications is physically part of the prosecution history, in the sense that each is part of the public record. Nonetheless, Digeo urges the court to ignore at least some of the communications. Audible contends that the court cannot ignore them.

The court first reviews the context of the challenged communications. Mr. Saigh executed a power of attorney during the prosecution of the 120 Application, and a joint power of attorney with the other three inventors on the 056 Application. PH at 500-244-45 ('120), 500-442-45('056). Nonetheless, Mr. Saigh submitted "pro se" communications to the PTO on several occasions, in violation of PTO rules. See Manual of Patent Examining Procedure ("MPEP") § 403. In response, the PTO took actions suggesting that it ignored the pro se communications. E.g., PH at 500-321, 500-591. The PTO also suggested, however, that it substantively considered the communications. E.g., 500-597 ("Applicant's arguments filed 12/27/95 have been fully considered but they are not deemed to be persuasive."). In the interim, Mr. Saigh purported to revoke the power of attorney. PH at 500-590. It is not clear whether the PTO applied the revocation prospectively or retrospectively. There are other entries that further complicate matters, but the court will summarize the situation succinctly: the prosecution history with respect to Mr. Saigh's communications is a big mess.

Fortunately, the court need not serve as housekeeper. The court assumes for the purposes of claim construction that Mr. Saigh's communications are part of the prosecution history, and that the court should examine them as it would any other entry in the prosecution history. It will become apparent that considering Mr. Saigh's communications does not prejudice Digeo.

4. Prosecution History

The fuss over Mr. Saigh's communications with the PTO arises because he made statements that serve, in Audible's view, to sharply limit the scope of the claims, including the scope of the term "communicatively coupled." In a November 1995 office action, the PTO rejected all claims pending in the 056 Application because a disclosure in the October 1993 issue of the Heller Report (an educational technology newsletter) either anticipated the claims or made them obvious. PH at 500-572; Culbert Decl. Ex. A. In addition, the same office action contained a "Notice of References Cited," PH at 500-575, along with a notice that the "prior art made of record and not relied upon is considered pertinent to applicant's disclosure." PH at 500-573.

Although the PTO had not rejected any claims based on any prior art other than the Heller Report, Mr. Saigh chose to discuss every reference in the "Notice of Prior Art" when he responded to the November 1995 office action. In a section addressing United States Patent No. 5,221,838 (the "Gutman Patent"), Mr. Saigh offered several bases for differentiating his invention:

While the Gutman device is to be used in connection with an unrelated network for the transmission of data electronically, the Applicant Invention represents an integrated closed network for the electronic transfer of data representing intellectual properties composed of many bytes of data.

PH at 500-581 (emphasis added).

While the Gutman device is not physically configured to make it suitable for reading or viewing intellectual properties comprised of many bytes of data, the Applicant invention is a closed network whose principal purpose would be the
electronic transmission of such intellectual properties comprised of many bytes of data.

PH at 500-581 (emphasis added).

While it would be reasonable to assume that the Gutman device will be principally used by the end user to interface with electronic networks or devices of unrelated persons to receive, store and transmit data related to the user electronically, [sic] n4 Most likely, the Applicant invention would represent a closed integrated network for the transfer of intellectual properties for the creator or owner to one or more persons desiring to purchase or lease the use of the data being transferred.

n4 Mr. Saigh's communications to the PTO often contain typographical or grammatical errors. The court has attempted to reproduce them faithfully in its citations to the prosecution history.

PH at 500-582 (emphasis added). Audible contends that these disclosures limit the scope of the claimed invention, and the term "communicatively coupled," to communication over a "closed integrated network." Audible Br. at 13. Audible seeks to invoke the doctrine of prosecution disclaimer. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323-25 (Fed. Cir. 2003). When a patentee has made "clear and unmistakable" statements disavowing claim scope, a court must interpret claims consistently with the disavowal. Id. at 1326; see also NTP, Inc. v. Research in Motion, 418 F.3d 1282, 1309 (Fed. Cir. 2005) (requiring "words or expressions of manifest exclusion or restriction representing a clear disavowal of claim scope"). Ambiguous disclaimers do not limit claim scope. See Omega Eng'g, 334 F.3d at 1325-26; see also Sandisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1287 (Fed. Cir. 2005). A court can limit claim terms by prosecution disclaimer only when the patentee's "arguments to the examiner have no reasonable interpretation other than to disavow" claim scope.

Mr. Saigh did not clearly and unmistakably disavow claim scope when he used the term "closed integrated network" during prosecution. Ambiguity pervades his statements. Mr. Saigh used the phrase, or variations of it, three times. In the first instance, he arguably made a distinction giving meaning to the phrase "integrated closed network," but it is not the distinction or meaning that Audible urges. The Gutman Patent describes a handheld "Electronic Wallet" used to conduct consumer transactions electronically. When Mr. Saigh described his invention as "an integrated closed network," he was distinguishing it from the "unrelated network" over which the Gutman wallet would transmit data. PH at 500-581. Beyond the semantic difference between the phrases, it is unclear what distinction Mr. Saigh sought to draw. The court finds no basis, however, to conclude that he was limiting his invention to networks in which all access is preauthorized, much less that he did so clearly and unmistakably.

In the remainder of Mr. Saigh's effort to distinguish the Gutman Patent, the phrases "closed network" and "closed integrated network" most likely carry the same meaning as they did in the instance the court described above. Mr. Saigh noted that the Gutman device was not suitable for "reading or viewing intellectual properties composed of many bytes of data," and stated that his invention is a "closed network whose principal purpose" is to allow transmission of many bytes of data. PH at 500-581. Mr. Saigh thus distinguished the amount of data the two inventions were meant to transport; he imparted no additional meaning to the term "closed." Similarly, in noting that the Gutman wallet connected the "end user" to "unrelated persons," whereas his invention "represents a closed integrated network" for transfer between content owners and persons desiring to purchase or lease the content, PH at 500-581-82, Mr. Saigh distinguished his invention in a manner consistent with his initial use of the term "closed integrated network." The court therefore assumes that Mr. Saigh used the term as he had previously, to distinguish the "unrelated network" on which the Gutman wallet operates.

Audible contends that Mr. Saigh described his invention as operating on an "open-ended" network in the 120 Application, suggesting that his later adoption of the phrase "integrated closed network" was significant. The use of the term "open-ended," however, only injects more ambiguity into the prosecution history. In distinguishing a prior art reference, Mr. Saigh noted that the "system described in the [prior art] is a closed network, in that, for the most part, the system will be housed and operated within the same vicinity or building." PH at 500-332. By contrast, he deemed his invention an "open ended network," because "the data may be flowing into and out of the network from many diverse locations many of which may be quite far from each other (they could be half a world away)." Id. Mr. Saigh made the same distinction in discussions of at
least two other pieces of prior art. PH at 500-340, 500-343. Following Audible's logic, when Mr. Saigh later allegedly limited his invention to a "integrated closed network," he disavowed the practice of the invention on any network except one housed "in the same vicinity or building." Such a limitation is preposterous in light of the specification and the claims. Indeed, the illustration on the first page of the 823 Patent shows a network operating across the United States.

In examining another prior art reference in the prosecution of the 120 Application, Mr. Saigh declared that it did not matter whether his invention operated on a closed or open network. PH at 500-337 ("The Saigh Patent System could be Operated as part of an open access system or network or a closed computer system or network.") (emphasis added). This is consistent with the later entry in the prosecution history on which Audible urges the court to rely. PH at 500-582 ("Most likely, the Applicant invention would represent a closed integrated network for the transfer of intellectual properties . . .") (emphasis added).

Mr. Saigh's pro se contributions exemplify the Federal Circuit's observation in Phillips that the prosecution history "often lacks the clarity of the specification and thus is less useful for claim construction purposes." 415 F.3d at 1317. The court can only speculate about why Mr. Saigh addressed the Gutman Patent at all, given that the PTO had not rejected any claims in light of it. In addressing the Gutman Patent, he may or may not have used variations of the phrase "integrated closed network" to make a distinction, but that distinction is murky at best. The court has noted that his references are subject to numerous interpretations. Audible cannot prevail merely by offering its best interpretation of Mr. Saigh's statements, even if its interpretation is reasonable. Audible must show that Mr. Saigh clearly and unambiguously disavowed the practice of his invention on any network except one that required preauthorization before accessing it. It has not met that burden here.

For these reasons, the court interprets the term "communicatively coupled" consistent with its ordinary meaning and the specification of the 823 Patent. The term means "connected in a way that permits communication."

732

7. The '186 Patent

United States Patent Number 5,878,186, issued March 2, 1999, is a continuation in part of the '704 patent. Generally speaking, it relates to a method for synchronizing audio signals with transcribed text. The patent claims, in part,

1. A transcription system having a stenographic recorder that receives key-strokes representative of a group of spoken words that are spoken during a first time period, and said stenographic recorder generating, during a second time period, signals corresponding to the key-strokes received, wherein the first and second time periods are not in time synchronization, said transcription system comprising:

   a terminal, communicatively interconnected to the stenographic recorder, which transcribes signals generated by the stenographic recorder into corresponding alphabetic and numeric text;

   recording means for creating a recording of the group of spoken words;

   a link between said terminal and said recording means, said terminal operating across said link to create associations between recorded spoken words and corresponding alphabetic and numeric text; and

   analysis means for automatically identifying a third time period that provides better time synchronization with the first time period than does the second time period.

   * * *

3. A transcription system used to transcribe spoken words, comprising:

   a recorder for storing in sequential locations audible signals representative of spoken words as each of the words is spoken, and said recorder being capable of indicating a current storage location;
a terminal communicatively interconnected to said recorder;

input means responsive to manual input for generating input signals, and for delivering the input signals to said terminal as such signals are generated;

said terminal transcribes the input signals received from the input means, and, as the input signals are received, said terminal selectively associates current storage locations with the input signals;

said recorder also being controllable by said terminal to selectively access a portion of the stored audible signals based on the storage location of the portion; and

analysis means for adjusting the associated storage locations to provide better time synchronization between the input signals and the stored audible signals.

With respect to this patent, the parties dispute only the phrase "communicatively interconnected." The defendants argue that this language means that the communication links -- the link between the stenographic recorder and the computer terminal in claim 1 and the link between the recorder and the computer terminal in claim 3 -- must be two-way, in other words, that it contemplates a two-way data flow. Engate contends that neither link needs to be two-way. The defendants argue that their construction is supported by both the dictionary and the specification. But the dictionary, which defines "interconnect" as "to connect mutually or with one another" and "connect" as "to join, fasten or link together," Webster's Third New International Dictionary, Unabridged, 1177, 480 (1993), adds little to the mix. The specification section upon which the defendants rely indeed suggests that the CAT system must be able to communicate with the court reporter; it states: "if the absolute barrier is reached before identifying the beginning of a dead zone, the CAT system 13 first indicates to the court reporter that two units of speech by the same speaker have been indicated." U.S. Patent No. 5,878,186, col. 12, lines 12-18. But this language appears in the description of the preferred embodiment, and nothing in either the remainder of the specification or the claims suggests that this limitation should be written into the claims. Accordingly, we agree with Engate that the phrase "communicatively interconnected" reads on either one-way or two-way communication between the terminal and the stenographic recorder (claim 1) or recorder (claim 3).

GO BACK

b. "a compact, portable and interchangeable computer readable medium"

Claim 1 explains how the data storage assembly associated with the local processor assembly includes "a compact, portable and interchangeable computer readable medium." Rothschild suggest that this term be construed as "a computer readable medium that is small, can be carried easily and can be swapped." Citrix urges the following construction for this claim term: "[a] computer readable medium that is small, can be carried easily, and can be mutually substituted. Examples include a CD-ROM or a DVD. In contrast, the local processor assembly's hard drive is not a "compact, portable and interchangeable computer readable medium."

The parties' dispute over this claim limitation stems from Rothschild's proposal, stated in its reply brief and at the Markman hearing, that the "compact, portable and interchangeable computer readable medium" should encompass the local processor assembly's hard drive. Rothschild has argued that internal computer hard drives are interchangeable and swappable. Citrix contends that Rothschild's proposal directly contradicts the '534 Patent, which distinguishes between the claimed "data storage assembly," i.e., the local processor assembly's hard drive, and a "compact, portable, and interchangeable computer readable medium," such as a CD-ROM or DVD. For example, Citrix points to the following passages from the '534 Patent specification:

While the data storage assembly may include only a fixed/hard drive of the local processor assembly, preferably the data storage assembly of the interface system includes at least one compact, portable and interchangeable readable medium.

***
Preferably, the data storage assembly 30 includes a computer readable medium, and in the preferred embodiment of FIG. 1 preferably includes a computer hard drive or other fixed data storage assembly wherein a large quantity of data may be stored and contained. As will be described in further detail subsequently, however, the data storage assembly may also include a portable and/or interchangeable assemblies such as compact discs or other such writable and non-writable assemblies and the accompanying drives.

***

While the data storage assembly may include a computer hard-drive of the local processor assembly 25', in the preferred embodiment and potentially in addition to the computer hard-drive associated with the local processor assembly 25', the data storage assembly will include a compact, portable and interchangeable computer readable medium 36 and its associated external or internal drive 35, which can be configured to merely read data or to both read and write data.

Claim terms must be construed from the vantage point of one with ordinary skill in the art at the time the patent application was filed and who has read the patent specification. Regardless of whether internal hard drives in 2007 are compact, portable, and interchangeable, Rothschild has presented no evidence to show that this was the case 10 years ago when the patent was filed. Moreover, even if internal hard drives could have generally been understood as compact, portable and interchangeable computer readable media in 1997, the fact that the patent specifically distinguishes the disputed claim term from internal hard drives means that Rothschild's construction cannot be correct. Accordingly, the Court construes "a compact, portable and interchangeable computer readable medium" to mean: "[a] computer readable medium that is small, can be carried easily, and can be mutually substituted. Examples include a CD-ROM or a DVD. In contrast, the local processor assembly's hard drive is not a "compact, portable and interchangeable computer readable medium."

3 Indeed, Rothschild's expert testified at the Markman hearing that in the past, hard drives were not compact, portable or interchangeable. (4/13/07 Hearing Tr. at 161:15-162:7).

2. "Comparator"

ITW describes this word as: "software code or an electronic circuit that compares two values." Pl.'s Revised Proposed Order Regarding Claim Construction at 5. Ion argues that it means "a digital circuit running a software routine that accepts two binary input values and outputs a result to indicate whether or not the two input values are equal." Def.'s Proposed Order re Claim Construction for the '756 patent at 6.

Any claim construction of "comparator" must be consistent with the "comparing" step defined in claim 17. See Epcon Gas, 279 F.3d at 1030. The dictionary defines "comparator" as "any of various instruments for comparing a measured property of an object, such as its shape, color, or brightness, with a standard." American Heritage Dictionary of the English Language (4th 2000). This construction is overbroad for purposes of the '756 patent. To be consistent with claim 17, supra § I.A.3, and the intrinsic evidence, a "comparator" can only use a non-hardware-based system for comparing values. The proper construction is therefore "any non-hardware-based instrument that compares two values." 13

13 To avoid unnecessary repetition or inadvertent confusion, I will incorporate the constructions for "value" and "compare" previously described in § I.A.2-3.
Disputed Claim Language

"for input to a comparator circuit for providing an automatic noise threshold adjustment to said laser receiving section to facilitate discrimination between said returned laser pulses and said noise pulses"

Analysis

Plaintiff asserts that this disputed claim language should be read in accordance with its plain meaning and argues I should refer to Claim 18 of the '779 Patent for analysis. Plaintiff's Reply Memo, 32. But here, Plaintiff argues that this claim does not require obtaining a constant pulse firing rate as does Claim 18. Defendants contend that Claim 1 "includes several of the elements discussed above in connection with claims in the other two patents," specifically, "an automatic noise threshold adjustment" and "a comparator circuit." Defendants' Memo, 35. Apparently, Defendants ask me to refer to previous analysis of those components of this claim. Id.

A comparator "compares something to be measured with a standard measure." WEBSTER'S 3RD NEW INTERNATIONAL DICTIONARY 462 (3rd ed. 1986). By the plain language of Claim 1, this comparison provides a foundation for adjusting the noise threshold. Both parties refer me to Claim 18. There, I construed the noise threshold circuit to include a feedback loop composed in part of diode 316. Here, I do the same.

CONSTRUCTION: For input to a circuit that consists of a feedback loop composed in part of diode 316 for adjusting the noise threshold based on the noise environment in relation to reflected pulses received by the laser receiving section, before the noise signals are parsed out from the actual target signals. The circuit adjusts the noise threshold by comparing incoming pulse values with previously received pulse values to ascertain the noise environment.

VII. "Comparing"

The last clause of Claim 1 indicates that the patented technology "determin[es] the optimized path by comparing the default cost and the alternative cost." The parties are divided over whether this comparison is limited to the sort of quantitative, technical comparison that a computer would do, or whether "comparing" should be given its more ordinary meaning. Defendant claims that since the comparison is being made in the context of "a packet-switched computer-based communications network," the term "comparing" should be construed as "a computer operation examining whether one term is greater than, equal to, or less than another." Plaintiff argues that the term should be construed more generally as "to examine for likenesses or differences."

Defendant's effort to give this term a narrow technical definition cannot be squared with the construction of "cost" that the Court has adopted. As indicated above, the term "cost" refers to "the value of network communication performance metrics, in accordance with a practitioner's priorities and needs." Thus the "costs" that are being "compared" may not lend themselves to unidimensional greater-or-less-than determinations; rather, "comparing" may involve a more holistic assessment of the alternative paths in relation to the default path. As such, even though the comparison may at times involve an assessment of which of two values is greater, there is no reason to limit the definition of "comparing" to that sort of quantitative assessment.

The Court will therefore adopt plaintiff's proposed construction of this term.
Defendant Ion Beam argues the claim term "comparing" is indefinite. (Ion Beam P.&A. at 12:8-14.) Ion Beam cites Union Pac. Resources v. Chesapeake Energy Corp., 236 F.3d 684, 692 (Fed. Cir. 2001) to support its argument that the term "comparing" is indefinite. "Whether a claim is invalid under 35 U.S.C. § 112, P2 for indefiniteness is a question of law reviewed de novo." Id. (citing Personalized Media Communications, LLC v. Int'l Trade Comm'n, 161 F.3d 696, 702 (Fed. Cir. 1998)). "The definiteness inquiry focuses on whether those skilled in the art would understand the scope of the claim when the claim is read in light of the rest of the specification." Id. (citing Orthokinetics, Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986). "Even if the written description does not enable the claims, the claim language itself may still be definite." Id. (citing In re Hyatt, 708 F.2d 712, 714-15 (Fed. Cir. 1983)). "The amount of detail required to be included in claims depends on the particular invention and the prior art, and is not to be viewed in the abstract but in conjunction with whether the specification is in compliance with the first paragraph of section 112: 'If the claims, read in the light of the specifications, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more.'" Georgia-Pacific Corp. v. United States Plywood Corp., 258 F.2d 124, 136, 118 USPQ 122, 132 (2d Cir.), cert. denied, 358 U.S. 884, 79 S. Ct. 124, 3 L. Ed. 2d 112 (1958), cited with approval in Chemcast Corp. v. Arco Industries Corp., 854 F.2d 1328 (Fed. Cir. 1988).

Although the Union Pac. Resources court held the term "comparing" to be indefinite, the court in Georgia-Pacific Corp., 258 F.2d at 136 explained "[o]bjective indefiniteness must be determined by the facts in each case, not by reference to an abstract rule." Id. (emphasis added). "Patentable inventions cannot always be described in terms of exact measurements, symbols and formulae, and the applicant necessarily must use the meager tools provided by language, tools which admittedly lack exactitude and precision." Id.

In Union Pac. Resources, supra, 236 F.3d at 692, the court found the patentee failed to enable the patent, and the patent term "comparing" was void for indefiniteness. 24 Id. at 690-92. In Union Pac. Resources, the Federal Circuit found an oil drilling company failed to enable its method for calculating the location of a borehole because it failed to disclose all information about the computer programs used to perform the calculation. Id. The Union Pac. Resources court made the following observations:

According to the claims, the method for determining the location of a borehole relative to strata (or in the earth) comprises a step of "comparing" characterizing information. The precise meaning of the term "comparing" is not explained in the written description. The patent suggests, however, that "comparing" (which incorporates "rescaling" in Claim 1) involves the determination of TSD by correlation. As explained during trial, correlation is a process of stretching and squeezing a TVD log by carefully choosing assumed bed dip angles, until a portion of the TVD log matches a portion of the offset log. In other words, the "comparing" step presumably refers to a complex "correlation" step suggested (but not explained) in the written description.

Yet "comparing" could undoubtedly have other meanings to a person of skill in the art. For example, because the patent does not indicate that it is a technical or scientific term, the term "comparing" could simply mean "to examine in order to note the similarities or differences of." The American Heritage College Dictionary 283 (3d ed. 1997). Nothing in the specification describes "comparing" (or "rescaling") as a process of stretching and squeezing a TVD log by carefully choosing bed dip angles. Thus, the '951 patent does not define the means to "compare" the two sets of characterizing information. The district court correctly found that the "comparing" steps in claims 1 and 6 are indefinite.

Id. at 692. The instant case is distinguishable from Union Pac. Resources on several grounds. First, there is no "complex correlation step" suggested (but not explained) in the instant patent specification. Rather, the specification states that the data generated by switching magnet monitors and detectors is compared with data representing the type of beam requested by an operator. (See Rosenberg Decl. Ex. 2, the '518 Patent at 5:25-6:18.) Secondly, there is no reference to "rescaling" in the instant case, or any other similarly confusing cross-reference for the term "compare." (See id.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
24 As CHISUM explains, "definiteness" and "enablement" are not the same thing: "Definiteness means that the language of the claims must clearly set forth the area over which the applicant seeks exclusive rights. Enablement means that the specification must describe the manner of making and using the invention in such clear terms as to enable any person skilled in the art to make and use it." 3 DONALD S. CHISUM, CHISUM ON PATENTS § 8.03[2][a] at 8-24 (2003). The primary purpose of the definiteness requirement is "to provide clear warning to others as to what constitutes infringement of the patent. A secondary purpose is to provide a clear measure of the invention." Id. at § 8.03, 8-18.

The court in Union Pac. Resources was dealing with a more complex procedure than the one at issue in the instant case. For example, the Union Pac. Resources court complained about the indefiniteness of the word "compare" because, inter alia, "the patent does not explain that stretching and squeezing of the borehole log, as well as significant trial and error, are necessary to correlate (i.e., "compare" and "rescale") the logs. Nor does the patent describe how to select sections of the borehole log to stretch or squeeze, or how to select points to correlate." Union Pac. Resources, 236 F.3d at 691. In the instant case, on the other hand, the term "compare" refers to the comparison of two sets of data to see if they are in "agreement."

A patentee need not disclose the underlying source code or computer program that actually structures and performs the comparison. See id.; see also Dan Burk and Mark Lemley, Is Patent Law Technology-Specific?, 17 Berkeley Tech. L.J. 1155, 1164 (2002). In the instant case, it is difficult to imagine how the patentee could be more specific without disclosing the code or including actual software program used to perform the comparison. Accordingly, the court hereby finds the claim term "comparing" is sufficiently definite as used in the context of the '581 patent. It means, "to examine, check or note similarities or differences between two things." (See, e.g., Airhart Decl. Ex. H. at 125; compare Optivus P.&A. at 17:14-15, and Ion Beam P.&A. at 17:10-11.)

738
d. "Comparing a First of Said Selected Pixels to at Least a Second of Said Pixels"

This claim term appears solely in claim 15 of the 780 patent. IP proposes that we construe this term according to what it claims is the ordinary and customary meaning: taking selected pixels in an image, and within the group of them, comparing a pixel of the original image to at least a second of the selected pixels. Lexmark and Dell by and large agree with this construction, but they wish to add the phrase "electronically coded" or variants thereof to make the definition read as follows: taking the selected pixels of an electronically coded input image, and within the group of them, electronically comparing the pixel to be displayed to one or more of the surrounding selected pixels of the coded image.

As was the case with regard to the construction of "pixel" and "image element" discussed above, Lexmark and Dell's proposed construction unnecessarily adds limitations and features that are not supported by the specification, such as that the image be of the "electronically coded input" variety and that the comparator pixel be from the pixels "surrounding" the first pixel. The intrinsic evidence indicates that the addition of these terms would impermissibly narrow the scope of the claim. According to Lexmark and Dell, because the specification, particularly Figure 7, comports with their definition, we should import the limitations found in the specification into the claim itself. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 905 (Fed. Cir. 2004). While the sections of the specification to which Lexmark and Dell point undeniably illustrate and discuss one way in which the comparison can be accomplished, we disagree that the process described in the plain language of the claim term could only be effectuated in that way. In addition, the insertion of the phrase "the pixel to be displayed" is not consistent with the specification or the claims; it requires that any comparison must be with the pixel that is ultimately to be displayed. Lexmark and Dell's definition would erase the possibility of a new pixel being generated from the comparison of two existing pixels, which the language of the patent anticipates. See United States Patent No. 5,424,780, col. 5, Ins. 33-50.

Therefore, the court adopts IP's proposed definition: taking the selected pixels of an image, and within the group of them, comparing a pixel of the original image to at least a second of the selected pixels.
The parties also dispute the term "comparing a reference value with a difference between a slow spinning speed and a fast spinning speed of the drum," which appears in Claims 3 and 10. LG proposes construing the term to mean "comparing a reference value [i.e., a known value for measuring against] with a difference [i.e., change] between a slow spinning speed and a fast spinning speed of the drum." (Chart at 26.) Whirlpool proposes instead that the term be construed to mean "subtracting a slow measured drum speed from a fast measured drum speed and comparing the result with a standard value." (Id.)

According to the written description for Figures 5 and 6, "[t]he imbalance sensing operation is performed by calculating the difference between a speed X2 at which the drum spins fastest so that the laundry is placed on the top of the drum, . . . and the speed X1 at which the drum spins slowest so that the laundry is placed in the lower part of the drum, . . . and then comparing the calculated difference with a reference value in step 55S." ('731 Patent, col. 3, ll. 49-55.) Figure 5 shows this calculation in step 55S as "X[2] - X[1] > reference value."

The summary of the patent describes "a drying method for a drum-type washing machine, the method including the steps of . . . comparing a reference value with a difference between a slow spinning and a fast spinning speed of a drum . . . and based on a result of the comparing step, controlling a spinning operation of the drum." (Id., col. 2, ll. 44-53.)

Based on the patent's use of the term "difference" when describing the comparison of values X[1] and X[2], and its use of a subtraction calculation to describe the comparison performed, the Court agrees with Whirlpool that the term refers to the subtraction of the two values.

With respect to the terms "slow spinning" and "fast spinning," however, Whirlpool has failed to identify any intrinsic support for construing the terms to mean "slow measured" and "fast measured." With respect to Whirlpool's argument that the term "standard value" should apply, the Court also finds no basis to support that argument.

The Court will therefore construe the term "comparing a reference value with a difference between a slow spinning speed and a fast spinning speed of the drum" to mean "subtracting a slow measured drum speed from a fast measured drum speed and comparing the result with a reference value."

E. "Comparing An Output Of A Local Clock Signal Generator With Said Result Of Said Decoding Step"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendant's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using an operating computer or hardware logic to determine whether the local time indicated by the equipment at the user site is prior to, equal to, or after the expiration time indicated by the result of the interpretation of the data values that set an expiration threshold.</td>
<td>Comparing the output of a time-of-day clock generator at the user site with the result of the decoding step.</td>
</tr>
</tbody>
</table>

Neither party addressed this term during the Markman hearing, and the parties devoted little attention to this claim term in
their claim construction briefing. After reviewing this briefing, the only dispute the Court is able to discern is whether the "local clock signal" must come from only a "time-of-day" clock (Defendant's position) or not (Plaintiff's position). Based on the parties' proposed constructions, the parties agree that the "local clock signal generator" is located "at the user site."

In support of the position that the "local clock signal" is referring to a "time-of-day" clock, Defendant contends that the only embodiment described in the specification appears to use a time-of-day-clock. (See D.I. 63 at 18-19; see also, e.g., '402 patent at 4:37-38 ("In the case of a time limit, this comparison can be made with the time-of-day clock . . . ."). Plaintiff responds that this claim limitation can be referring to "more than 'time of day' but also may include any time and date that indicate a relevant time period." (D.I. 66 at 25.) Defendant's attempt to limit this claim limitation to a "time-of-day" clock is, Plaintiff contends, merely an attempt to import a limitation from the specification into the claims.

The Court agrees with Plaintiff that, although "time-of-day" clocks are mentioned in the specification, there is no good reason to limit the claims to this particular embodiment in the specification. Nevertheless, the Court will not adopt Plaintiff's proposed construction. Plaintiff's construction introduces unnecessary verbiage and limitations into the claims, including the use of "an operating computer program or hardware logic," and a comparison of whether the "local time" is "prior to, equal to, or after the expiration time." In the Court's view, none of this would illuminate the meaning of this claim term to one of skill in the art. Accordingly, the Court will construe "comparing an output of a local clock signal with said result of said decoding step" to mean "a comparison of a local clock signal with the result of said decoding step." This construction conforms most closely to the clear language of the claim, yet at the same time confirms that the "clock signal" is not limited to a "time-of-day" clock and further reflects the parties' agreement that the "local clock signal generator" is located at the "user site."

4. comparing bit patterns from a contiguous plurality of said output reconstructed bytes with bit patterns known to have comprised a like plurality of bytes of each of said contributory frames

FORE contends that this phrase requires "bit patterns from two or more adjacent reconstructed bytes to be compared with bit patterns known to have been present in two or more adjacent bytes in each of the contributory frames which have been multiplexed to form the bit stream." (D.I. 146 at 31 (emphasis in original)). FORE further contends that each contributory frame must both contain the pattern and contain it within two or more adjacent bytes of the contributory frame.

In response to FORE's construction, Bellcore contends that this phrase means "that the contributory frames each have a plurality of bytes like the bytes included in the compared 'contiguous plurality' of bytes." (D.I. 151 at 16). According to Bellcore, this phrase cannot mean, as FORE contends, that the compared contiguous plurality must exist within each contributory frame. According to Bellcore, the requirement for byte interleaving makes this arrangement impossible.

The Court agrees with FORE's construction of this phrase. This element of the patent concerns frame boundary detection after byte reconstruction, because as the claim recites, the comparison is made from a "contiguous plurality of output reconstructed bytes." (768 Patent, col. 12, line 12). Because this step is performed after the interleaved bytes are reconstructed, Bellcore's contention that the interleaving arrangement makes this interpretation impossible is incorrect. As the specification states:

Upon completion of the formatting of the high-speed serial data stream to a low-speed, properly synchronized byte-parallel data stream, there remains the problem of identifying the boundaries of each frame of the original transmission in order that the payload, as well as the relevant overhead information bytes, may be demultiplexed to the basis STS-1 level. For this purpose, the present invention relies upon the prescribed bit sequence of both the F1 and F2 framing bytes, of which each frame above STS-1 will have at least two, F2 bytes following immediately upon the final F1 framing byte as depicted in FIG. 2.

(768 Patent, col. 5, lines 41-52 (emphasis added)). The reference to Figure 2 here is only for the purpose of illustrating that the F2 bytes follow the F1 bytes. Accordingly, the Court concludes that "comparing bit patterns from a contiguous plurality of said output reconstructed bytes with bit patterns known to have comprised a like contiguous plurality of bytes of each of said contributory frames" means that two or more adjacent reconstructed bytes are compared with bit patterns known to
have been present in two or more adjacent bytes in each of the contributory frames which have been multiplexed to form the
bit stream. Each contributory frame must contain the bit pattern and each frame must contain the bit pattern within two or
more adjacent bytes of the contributory frame.

Disputed Claim Language

"comparing each of said assigned pulse values with other ones of said assigned pulse values"; "continuing to perform said
comparing step until a predetermined number of said assigned pulse values coincide within a specified precision"; and
"determining said actual return signal to be represented by said … values."

Analysis

Plaintiff argues that the these claim elements should be construed according to their plain meaning "to require comparing
pulse values until a predetermined number of the pulse values coincide within a specified precision and determining the
target signal to be the signal associated with a desired threshold of matching pulse values (as opposed to the random pulse
values associated with noise signals)." Plaintiff's Reply Memo, 7. Plaintiff contends that this construction is supported by
the '779 patent specification. I agree. "The specification is always highly relevant to the claim construction analysis.
Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Johnson Worldwide, 175 F.3d at 990.

Given the patent specification language referenced above ( '779 patent specification, col. 2, lines 22-29, 30-35, 50-62), I
conclude that pulse values are assigned to both noise and actual pulses. Therefore, when each pulse value is compared with
every other pulse value, logical relationships result. Noise pulse values are compared with other noise pulse values. Noise
pulse values are compared with actual, or target pulse values. Actual, target pulse values are compared with other actual
pulse values.

Accordingly, the plain language of the claim elicits the following construction. The device compares pulse values
continually until a large enough sample of pulse values is gathered that falls within a specific, limited degree of variation.
The actual target signal (representing the distance from range finder to target) corresponds to the pulse values within that
specified, limited degree of variation. Therefore, I agree with Plaintiff that the target signal is associated with the
"matching" pulse values that correspond within the specified limit.

This claim interpretation is consistent with the '779 patent specification. "A representative pulse value is assigned for each
of the possible reflected signal pulses with respect to the series of signal pulses transmitted to the target and each of the
representative pulse values is compared with other ones of the representative pulse values. Each of the representative pulse
values [is] compared until any predetermined number of the representative pulse values coincide within a specified
precision and the actual return signal is determined to be represented by the predetermined number of the representative
The nature of the claimed invention further supports my reading. Because the range finder emits multiple pulses of laser light, it receives multiple return signals. The device must sort them out and decide which of them are actual target signals. Assigning pulse values to each signal gives the machine "handles" with which to identify each signal for later grouping. When a group of very similar values grows to a large enough number within a user-specified range of pulse values, the device defines this group as representative of the target.

This makes sense. If the target is a certain, specific distance from the range finder, laser pulses emitted from the range finder will travel that same, specific distance to the target, and return that same, specific distance to the range finder. Variations in the topography of the target surface might cause slight variations in the target, or actual, signal travel distance. These subtle variations would seem to be of much smaller magnitude than random variations in signals reflected from noise-creating objects like dust or water droplets in the air that could be any distances from the range finder. Therefore, pulse values indicative of the target should be similar.

Defendants argue that "the element of the claim 'comparing each of said assigned pulse values with other ones of said assigned pulse values' … should be construed [so] each newly arrived pulse is assigned a pulse value that … is immediately compared at the time of arrival with previously stored pulses"; and "each newly arrived representative pulse value [is] compared with all previously assigned representative pulse values at the time the newly arrived pulse value [sic] is assigned its pulse value, and not at the end of the pulse transmission, pulse collection and pulse storage process." Defendants' Reply Memo, 10. I disagree. I "may not add a narrowing modifier before an otherwise general claim term that stands unmodified in a claim." CCS Fitness, Inc., 288 F.3d at 1365-68. While Claim 11 of the '779 patent recites the term "comparing," it says nothing about comparing immediately as Defendants suggest. And, nothing in the '779 patent specification or other intrinsic evidence supports the conclusion that comparisons must happen immediately instead of at the end of the pulse transmission, collection, and storage process.

At first, Defendants argued that Claim 11 does not instruct a person of ordinary skill in the art how to compare pulse values. Defendants' Memo, 29-30. Defendants argued that the claim element merely states the function of comparing. Id. Now, Defendants seem to acknowledge that the comparison requires discrimination "between actual returned reflected signals and noise signals." Defendants' Reply Memo, 9. Still, Defendants argue that the proper way to construe this claim language is to require "assigning pulse values for the laser pulses transmitted and the actual reflected pulses received (but not for noise pulses), comparing pulse values for a match and then halting the comparing upon finding a match to a selected precision." Defendants' Memo, 33. See also, Defendants' Reply Memo, 12 (arguing that Claim 11 requires "assigning pulse values to the return pulse (and not the noise pulses) and comparing each incoming pulse with previously recorded pulses").

I agree that actual reflected pulses receive pulse values. I disagree, however, that Claim 11 limits pulse values to actual-or target-reflected pulses. As Defendants acknowledge, without differentiating between noise and actual pulses, it would be impossible for the device to separate the wheat (the actual, target pulses) from the chaff (the noise). See id. As I have said, both noise and target pulses receive pulse values under Claim 11.

CONSTRUCTION: Comparison of pulse values--both noise and target--continually until a large enough number of pulse values is gathered that falls within a specific, limited degree of variation. The comparison is not necessarily an immediate one. The actual target signal represents the distance from range finder to target. It corresponds to the pulse values within that specified, limited degree of variation. The target signal is associated with the "matching" pulse values that correspond within the specified limit.

The parties dispute the proper construction of the limitation "comparing predictions obtained with the simulation using the model with observed manufacturing trends in the plant, and using the comparison to refine the model." ITI again asserts that the limitation need not be construed, but it provides the Court with the following construction should we determine one is necessary: reviewing similarities and differences between results of the simulation and factory information in order to improve upon the simulation. In this instance, defendants agree with ITI that many of the words in the claim phrase do not
need to be construed. The only truly contested term is "refine." Defendants contend that the proper construction is: using the comparison of predictions obtained from the model with observed manufacturing trends in the plant to change the model to improve the model so that it more accurately reflects the actual operations of the plant. In short, the parties agree that the goal of this step is to improve the model, but defendants believe their interpretation makes it clear that the purpose is to make sure the model more accurately reflects the actual operations of the plant.

The specification states that "predictions obtained with the simulation are compared with observed manufacturing trends in the plant. The comparison is used to refine choice of fundamental rules and parameters in the model." U.S. Patent No. 4,796,194, col. 5. lines 12-16. Defendants' reading is certainly an implicit goal of the invention, but as ITI notes, their proposed added language appears nowhere in the patent. Moreover, the additional language is unnecessary to convey the plain and ordinary meaning of "refine" as used in the patent. The Court construes the limitation to mean using the comparison of predictions obtained from the simulation with observed manufacturing trends in the plant to improve upon the simulation.

As noted, JCI's challenge to Lear's claim of patent infringement rests solely upon the premise that the Roddy patent requires a receiver that operates by performing encryption. If this is so, it readily follows, in JCI's view, that its HomeLink system cannot literally infringe the Roddy patent, as it is uncontested that the receiver in JCI's system performs decryption rather than encryption. This question of "encryption versus decryption," then, is the only issue of claim construction that the Court must address at the present juncture with respect to the Roddy patent.

The Court's inquiry on this point necessarily begins with the language of the patent claims themselves. Although Lear has asserted claims 4 through 7 of this patent, the parties agree that the relevant language appears in claim 1, upon which claims 4 through 7 are dependent. This claim provides in full:

1. A method of actuating at least one home security system remotely comprising the steps of:
   (1) providing a transmitter with encryption logic to send an encrypted signal, providing a receiver adapted to identify an expected encrypted signal, said receiver being adapted to actuate a home security system said encryption logic sending signals that change sequentially, and thus are different on each actuation of said transmitter, said changing sequentially different signals being predictable to said receiver;
   (2) sending an encrypted signal from said transmitter;
   (3) receiving said signal at said receiver, and comparing said received signal to an expected signal; and
   (4) actuating said system if said received signal is determined to be as expected in step 3.

(JCI's Motion, Ex. 1, Roddy Patent at 6:8-22.)

There is no question, and Lear readily acknowledges, that the transmitter described in this claim uses "encryption logic" to send "encrypted signal[s]." It is also clear, and Lear again agrees, that the receiver "receiv[es]" these encrypted signals, and necessarily must somehow "compar[e]" these "received signal[s]" to "expected signal[s]" in order to determine whether to actuate the relevant home security system at step 4 of the claim. The parties' dispute, then, focuses upon the nature of the "compar[ison]" referred to at step 3 of the claim. JCI argues that the receiver must perform encryption in order to generate the "expected signal" that it will compare to the received (encrypted) signal. Lear, on the other hand, contends that the
The Court finds that JCI has the better of the argument, for a number of reasons. First and foremost, if the "expected signal" referred to at step 3 could encompass either encrypted or unencrypted signals, as Lear contends, then such a construction seemingly would conflict with the reference at step 1 to a "receiver adapted to identify an expected encrypted signal." 3 Although this "expected encrypted signal" language is not repeated verbatim at step 3, but instead is shortened to "expected signal," the "receiver" referred to in the latter step plainly is the very same "receiver" whose general function is set forth at step 1 -- namely, a device "adapted to identify an expected encrypted signal." In this context, the Court finds that the "expected signal[s]" referenced in steps 1 and 3 are properly construed as one and the same -- i.e., as encrypted signals.

3 In its recitation of the pertinent claim language in its response to JCI's motion, Lear notably omits this passage from step 1 of the claim. (See Lear's Response Br. at 3.)

In addition, the Court believes that this construction better comports with the ordinary meaning of the word "compare." Plainly, this activity requires that the items in question must be susceptible of comparison -- e.g., converted into the same unit of measure. Lear's expert, Dr. Avi Rubin, acknowledged as much at his deposition, opining that there were three ways in which a receiver could perform the comparison referred to at claim 1, step 3 of the Roddy patent: (i) by "decrypt[ing] the transmission and compar[ing] it to an expected plain text value," (ii) by "tak[ing] the [expected] plain text value and encrypt[ing] it and compar[ing] it to what it received," or (iii) by "perform[ing] some operation that . . . performs partial encryption and then partial decryption and compar[ing] for some value in the middle." (Lear's Response, Ex. D, Rubin Dep. at 103-04.) Under this testimony, then, "comparison" is done only after the two values in question are made comparable, through some combination of encryption and decryption that the receiver performs on either the signal sent by the transmitter, a plaintext expected value, or both.

Yet, step 3 does not refer to any intermediate processing, calculation, or transformation of any sort that the receiver performs between receipt of the transmitted signal and comparison to an expected signal; rather, it states merely that the signal is received and then compared. This immediate juxtaposition of actions requires that the received and expected signals already be capable of comparison -- i.e., that both signals are encrypted. This reading of step 3 also comports with the above-cited language from step 1, providing that the receiver is "adapted to identify an expected encrypted signal." This specified adaptation, of course, obviates the need for the receiver to decrypt a received signal before comparing it to an expected value. Thus, while Dr. Rubin's testimony fairly characterizes the range of possible ways that a receiver could determine whether a received signal matches an expected value, the Court views the language of claim 1, read as a whole, as limiting the specified receiver to only one of these three means -- namely, a comparison between encrypted signals.

Still other portions of the language of claim 1 lend further support to this conclusion. Step 1 stipulates that the transmitter is provided with "encryption logic" that enables it to "send[] signals that change sequentially, and thus are different on each actuation of said transmitter." This step then provides that these "changing sequentially different signals [are] predictable to said receiver." Similarly, after performing the receipt and comparison required under step 3, the receiver proceeds at step 4 to "actuat[e] said system if said received signal is determined to be as expected." These various passages, read together, indicate that the receiver must be able to "predict[]" the sequentially changing -- and encrypted -- signals sent by the transmitter and activate the proper home security system upon receipt of an "expected" signal. Presumably, in order to "predict" the "expected signal[s]" that will emerge from a transmitter that is performing encryption, the receiver must be able to mimic the transmitter's operation -- i.e., it must also perform encryption.

Finally, the Court finds that the specification is fully consistent with and supportive of JCI's proposed construction of claim 1. At one point, for example, the specification states that "when the receiver receives a signal from the transmitter, it compares the received signal to the first expected signal to determine whether the newly received signal is an acceptable signal." (Roddy Patent at 4:41-44.) As with the language of the claim itself, this passage from the specification indicates that the receiver makes a direct comparison between a received (encrypted) signal and an expected signal -- a comparison which, as explained, is only possible if both signals are encrypted. Similarly, the specification later refers to the possible modification of an existing GDO by adding an "encrypted receiver unit" that is able to "recognize[] . . . encrypted signals."
The receiver's evident ability to perform encryption is made explicit in another portion of the specification. In particular, the specification describes a "particular preferred embodiment" in which "the receiver and transmitter are both provided with encryption logic that sequences through a great number of different encrypted signals." (Id. at 4:27-29.) As explained in the specification, this use of the same logic enables both the transmitter and receiver to "know[] the sequential encrypted signals," such that "the receiver is able to predict and recognize the encrypted signal" sent by the transmitter. (Id. at 4:10-14.) Presumably, if the receiver both "knows" and is "able to predict and recognize" the sequence of encrypted signals that the transmitter will send, it must be performing encryption operations in parallel with those performed by the transmitter.

Lear's arguments against this interpretation of claim 1 are not persuasive. First, Lear notes the absence of language at step 3 explicitly stating that the receiver performs an encryption operation in order to generate an expected encrypted signal that can be compared to the received signal. Yet, the Court has already explained why, in its view, it is most natural to read the "expected signal" at step 3 in para materia with the "expected encrypted signal" referenced in step 1. This being the case, it necessarily follows, whether step 3 expressly says so or not, that the receiver must perform an encryption operation in order to form an expected encrypted signal that may be compared to a received encrypted signal. Thus, the Court cannot accept Lear's contention that JCI's proposed construction would impermissibly insert a limitation that is not found in the claim language itself. Rather, the claim stipulates, at step 1, that the receiver is "adapted to identify an expected encrypted signal," thereby enabling the receiver to compare two encrypted signals (received and expected) at step 3.

Lear next points to certain portions of the specification as purportedly inconsistent with JCI's proposed construction. First, Lear cites the specification's reference to certain "[p]refered patented encryption technology [that] is available from United Technologies Automotive, Inc. of Dearborn, Mich." (Id. at 4:4-6.) While this preferred technology is not identified in the specification itself, inventor Timothy Roddy testified that the intended reference was to the technology disclosed in the Koopman patents that also are at issue here. (See Lear's Response, Ex. E, Roddy Dep. at 68-69.) Lear then notes that the specification for one of these patents, the '181 patent, refers to a receiver performing "decryption." (Lear's Response, Ex. F, '181 Patent at 4:27.) Juxtaposing all of this, Lear contends that JCI's proposed interpretation would take the preferred embodiment outside the scope of the Roddy patent, a construction which the case law recognizes "is rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996).

This contention fails to persuade, on a number of levels. First, JCI correctly notes the patent law principle that "[t]o incorporate material by reference, the host document must identify with detailed particularity what specific material it incorporates." Advanced Display Systems, Inc. v. Kent State University, 212 F.3d 1272, 1282 (Fed. Cir. 2000). The Roddy patent manifestly fails to meet this standard through its reference to unspecified "patented encryption technology . . . available from United Technologies." Indeed, JCI points to at least two other patents, apart from the Koopman patents, that would meet this description.

In any event, any suggestion of decryption that could be culled from the Roddy patent's reference to unspecified "patented encryption technology" is overcome by the language that immediately follows this reference. Specifically, in describing this "patented encryption technology" and its use in the preferred embodiment of the invention, the specification states that this technology calls for a transmitter and receiver alike to be "provided with logic that 'knows' the sequential encrypted signals," so that both "will know what encryption will be performed" upon each actuation of the system, and so that the receiver, in particular, will be "able to predict and recognize the encrypted signal" sent by the transmitter. (Roddy Patent at 4:8-14.) As discussed earlier, the Court reads this language as indicative of a receiver that performs encryption.

Lear next points to patent figure 3, a flow chart of the invention. This figure identifies the successive stages of the patented method as (i) send signal, (ii) encrypt, (iii) transmit, (iv) receive, and (v) compare acceptable. Lear reads this figure as dictating encryption by the transmitter, but as silent regarding the receiver's use of encryption, decryption, or some combination thereof in performing its comparison. Yet, as discussed earlier, any silence on this issue in figure 3, like the analogous silence in claim 1, step 3 as to the precise nature of the "compartment" to be performed, is overcome by language elsewhere in the claim and the specification that reflects a comparison between encrypted signals. Thus, even if the figure is deliberately open-ended in this regard, other portions of the patent -- most significantly, the language of claim 1 itself -- limit the operation of the receiver to encryption rather than decryption.

Finally, Lear points to the above-quoted testimony of its expert, Dr. Rubin, regarding the number of different ways that a
receiver could determine whether a received signal matches an expected value. As previously explained, however, this
catalog of possibilities is narrowed by the language in claim 1, step 1, which describes the receiver as capable of identifying
an expected "encrypted" signal. In addition, Dr. Rubin himself apparently draws a distinction between "comparison" and the
encryption or decryption necessary to enable such a comparison. As observed above, claim 1, step 3 evidently contemplates
that no such intervening operation need be performed between the receipt of a signal and the comparison of received
and expected signals, and this could only be so if the expected signal, like the received one, is encrypted. Accordingly, this
expert testimony -- which, as extrinsic evidence, plays a lesser role in the Court's claim construction effort, see Phillips, 415
F.3d at 1317 -- does not overcome the language in claim 1 itself. This language, in the Court's view, mandates a receiver that
performs encryption in order to compare received and expected signals.

5. "comparing said signals"

KLA argues for the first time in its responsive claim construction brief that "comparing said signals" should be construed to
exclude the operation of normalization and subtraction. D.I. 414 at 30. ADE does not state a proposed meaning.

In support of its construction, KLA quotes a paragraph from a statement made by the inventors during patent prosecution:
"Neither of the references teaches or suggest comparing scattered light intensities in different angular locations. As
discussed above, Quackenbos 5 normalizes and subtracts the signals from the two sensors 28 and 48 but does not compare
the levels of the signals. …" Id. From that snippet of information, KLA asks this court to exclude entirely the operations of
normalization and subtraction from the scope of the '525 patent when signals are compared.

--- Footnotes ---

5 Quackenbos (patent number 4,794,264) was listed in the "References Cited" portion of the '525 patent as a prior art patent.

--- End Footnotes ---

This court declines to do so. KLA has taken the quoted language out of context. The inventors merely stated that
Quackenbos "normalizes and subtracts … but does not compare the levels of the signals." Id. Viewed in this fashion, it is
clear that the inventors were not attempting to surrender the functions of normalization and subtraction but, instead, were
distinguishing their own invention by arguing that Quackenbos only "normalizes and subtracts" and does not also "compare
the levels of the signals." Therefore, this court will not construe the phrase "comparing said signals" to exclude the functions
of normalization and subtraction.

I. "Comparing The Bid To The Asks"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendant's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Examining a bid and ask in order to note similarities and differences.</td>
<td>A bid is compared to all of the submitted asks.</td>
</tr>
</tbody>
</table>

Defendant objects to Plaintiff's proposed construction as failing to confirm that this claim refers only to the comparison of a
single bid and the (plural) submitted asks. (See D.I. 50 at 24-25.) However, as explained above, the Court has declined to
construe the claims as being limited to only a single "bid" and more than one "ask." Defendant further objects to Plaintiff's
proposed construction as failing to confirm that the "comparing" is done to determine (1) whether the bid price and ask price are "equal" and (2) whether the bid quantity is less than or equal to the ask quantity. Defendant apparently maintains that the claim term should be construed in this manner because the claims explicitly include this requirement. (D.I. 50 at 25.) However, Defendant's own construction fails to include this requirement, and, in light of the claim language, it would be...
superfluous to include this limitation in the construction of this claim term. Accordingly, consistent with the Court's conclusion that the claims are not limited to plural "asks," the Court will construe the term "comparing the bid to the asks" to mean "examining a bid and one or more asks in order to note similarities and differences."

3. "Comparing [the] ion output current reference value [to an] actual ion output current value"

ITW defines this method claim as: "using either a software routine or a circuit element that accepts as one input the ion output current reference value and as another input a representation of the actual ion output current value and varies its output based upon whether the values are equal." Pl.'s Revised Proposed Order Regarding Claim Construction at 2. Ion argues that it is "using a software routine that accepts as one input the ion output current reference value and as another input a binary number that corresponds to the actual ion output current value and outputs a result based upon whether the numbers are equal." Def.'s Proposed Order re Claim Construction for the '756 patent at 3.

10 ITW agrees with Ion that the ion output current reference value is digitally stored. It also agrees that, to compare two values, those values must be in the same format, i.e. digital or analog. ITW argues, however, that the comparison of the reference and actual ion output current values at issue in this claim could be performed using either digital or analog representations of the respective values. Plaintiff also claims that nothing in the specification requires that the comparison occur when the values are in digital form. For these reason, ITW asserts, the court cannot conclude that the values are necessarily digital. Pl.'s Reply Claim Construction Br. at 3-7.

Like the construction of "value," the construction for "comparing" shall reflect limitations required by language from the specification. Nonetheless, for the reasons stated earlier, analysis of the disputed term should begin with the dictionary definition and the claim language.

The key word to be defined is "compare." 11 The common dictionary definition for the word "compare" is "to examine in order to note the similarities or differences of." American Heritage Dictionary of the English Language (4th 2000). Both Ion and ITW adopt the ordinary meaning of the word "compare:" each party's construction assumes that "comparing" is noting the similarities or differences between the actual ion output current value and the ion output current reference value. Nonetheless, both parties' definitions attempt to narrow this dictionary definition. One attempt involves a dispute over the plain meaning of the claim language. The other proposes to limit the ordinary meaning based on evidence contained in the specification.

11 The only other word the parties appear to dispute is "value," insofar as Ion seeks to limit this word to a digital representation of a numerical quantity. This dispute is moot in light of my discussion in § I.A.2 above. As stated above, the word "value" is to have one construction for the entire '756 patent.
consistent with the dictionary definition and the claim language.

The second disagreement requires reference to the specification. The parties' remaining dispute is over whether or not the "comparison" is performed using software or hardware. The patent's specification only describes a digital comparison performed by a microcontroller. See '756 patent, col. 7:53, col 8:12. As discussed above, limitations from the specification should be read into the claim language only when the ordinary usage conflicts with the specification. See CCS Fitness, 288 F.3d at 1367; SciMed Life, 242 F.3d at 1340-1341. Ion presents compelling evidence for why the dictionary definition of "compare" conflicts with the intrinsic evidence. Within the specification, plaintiff repeatedly emphasizes the improvements of the '756 system over prior systems that relied on hardware component values and hardware-based balancing systems. 12 '756 patent, col. 1:54-63, col. 11:17-34. Based on this intrinsic evidence, any "comparison" step in the '756 patent should be free from the earlier imperfections. The claim language, like the patent itself, thus can only use a non-hardware-based system for comparing (or balancing) values. Consequently, the terms "comparing the ion output current reference value to an actual ion output current value" mean: "using a non-hardware-based system to a) examine the actual ion current value and the ion output current reference value and b) note any similarity or difference between the two values."

--- Footnotes ---
12 The applicable specification language reads as follows:

As discussed above, conventional automatic balancing systems have hardware-based feedback systems, and suffer from at least the following problems:

(1) Such systems cannot provide very fine balance control, since feedback signals are fixed based upon hardware component values;

(2) The overall range of balance control is limited based upon the hardware component values.

(3) Quick and inexpensive modifications are difficult to make, since the individual components are dependent upon one another for proper operation. Conventional ion current control circuitry suffers from the same problems. In contrast to conventional systems, the software-based balance and ion current control circuitry of the present invention do not suffer from any of these deficiencies.

'756 patent, col. 11:17-34 (emphasis added).

--- End Footnotes ---

10. Claim 6: Step (e)

Text:

(e) comparing the outlines of the outer surface of the lesion of the said at least one ultrasound image with the outline of the outer surface of the lesion of at least one of the diagnostic images, whereby the position of the lesion with respect to the radiation therapy device may be verified to conform to a desired position of the lesion in the radiation treatment plan.

'026 Patent, col. 12, ll. 54-61.

NOMOS's Proposed Construction:

NOMOS submits that step (e) of claim 6 is clear on its face, and may be construed in accordance with the plain meaning which is not altered by the specification of the '026 patent.

NOMOS Opening Brief at 16 (citations omitted).
ZMED’s Proposed Construction:

This step requires comparing the computer generated line drawn along the surface of the lesion in the two-dimensional ultrasound image to the computer generated line drawn along the surface of the lesion in a two dimensional image from the treatment plan.

ZMED Opening Brief at 28.

Construction:

Step (e) means “comparing the two-dimensional outlines of the outer surface of the lesion generated from the at least one ultrasound image (which has positional data regarding the third dimension), with the three-dimensional rendering outline of the outer surface of the lesion generated from the at least one of diagnostic images, whereby the position of the lesion with respect to the radiation therapy device may be verified to conform to a desired position of the lesion in the radiation treatment plan.”

Commentary:

Since step (e) is not a means plus function claim, the analysis starts and ends, if possible, with the claim language. Looking at the claim language, I interpret the outlines in question to be two-dimensional outlines compared to a three-dimensional rendering outline from the "at least one of the diagnostic images."

The second outline must be three-dimensional because of a slight difference in language:

comparing the outlines of the outer surface of the lesion of the said at least one ultrasound image with the outline of the outer surface of the lesion of at least one of the diagnostic images . . . .

'026 Patent, col. 12, ll. 54-57 (emphasis added). A single "outline of the outer surface of the lesion" can only be a three-dimensional outline (the actual surface of a lesion cannot be two-dimensional). Therefore, the second "outline" must be, from the claim language, a three-dimensional rendering generated from the initial imaging device. The specification supports this interpretation. See, e.g., '026 Patent, col. 8, ll. 60-62.

The claim language in step (e) alone does not allow for a determination of whether the first "outlines" are two-dimensional or three-dimensional because the word is plural. However, I determine that the "outlines" being discussed in step (e) are in fact two-dimensional, drawn on specific two-dimensional ultrasound images which contain positional information regarding the third dimension, despite the fact that they could be combined to create a three-dimensional rendering.

As described above in claim 6, the ultrasound probe must be a conventional, commercially available ultrasound probe that generates a two-dimensional ultrasound image. It therefore makes sense that the first "outlines" must be on two-dimensional ultrasound images. Additionally, while it is conceivable that several three-dimensional rendering "outlines" would be compared to the single three-dimensional rendering "outline" of the outer surface of the lesion generated from the diagnostic images, comparing several two-dimensional "outlines" better explains the use of the plural "outlines." Finally, I make this determination in light of claim 16 of the '026 patent, which explicitly discusses comparing a three-dimensional rendering to a three-dimensional rendering. Under the doctrine of claim differentiation, claim 6 should be construed to mean something different than claim 16, since claim 6 uses different language. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) (explaining that different claims should be construed, when possible, to cover different inventions). 1

1 It is true that this construction is not in complete harmony with the specification, which describes converting the outlines into three-dimensional renderings. See, e.g., '026 Patent, col. 7, ll. 44-47, 52-54; col. 8, ll. 56-62. However, the claim language should control when there is an apparent conflict between the claim language and the specification.
4. STEP OF COMPARING (UID of stored license file to a record of assigned UID)

The comparing function, specified in the claim as occurring "upon locating said license file on said selected workstation," is described for the license transfer embodiment at 9:68 - 10:6 and for the license pool embodiment at 13:63 - 14:1. The comparison is identified in the claim as occurring "upon locating," a license file and the procedure delineated in the specification for ultimately comparing the located to the assigned UIDs consists of several discrete components, the Court therefore concludes that the step of comparing should be interpreted according to the mechanism of § 112 P 6. The relevant descriptions provided for the license transfer and pool embodiments are substantially the same, and yield the following construction:

"STEP OF COMPARING THE UID OF STORED LICENSE FILE TO RECORD OF ASSIGNED UID" refers to 1) asking the operating system for the UID for the license file (area of memory which contains a UID, which is on a disk and which is capable of storing at least one LICENSE) that the operating system caused to be stored in a record in the system memory at the local NODE; 2) decrypting the UID contained in the license file; 3) comparing the UID contained in the license file with the UID returned by the operating system. Equivalents of the process just described also are implicated.

1. "a plurality of comparison frames, each being a shifted version of one of the reference frame or the sample frame, is correlated with the other of the reference frame or the sample frame to produce a corresponding plurality of correlation values and ascertain motion in the directions along the first and second axes"

In PixArt, the Court did not construe the entire phrase, but instead referred the parties to the Court's construction of "frame" as "a single image in a sequence of images" and "the correlation being upon the values in all memory array locations that correspond to overlap between the comparison frame and the other of the reference frame or sample frame" as "the operation of comparing at least one shifted sample frame or at least one shifted reference frame with the other of a reference frame or a sample frame being upon all of the values stored in memory that correspond to the area shared between the frames. The comparison provides the degree to which the frames are related. The values that are being compared are numerical representations of the digitized photo detector outputs." Avago proposes that the claim language should be construed as "at least two frames, each generated by shifting a sample frame or a reference frame, are compared with the other of a reference frame or a sample frame to provide the degree to which the frames are related. Such correlations produce numerical representations of the degree of similarity between the frames. Such correlations are also used to ascertain motion in the directions along the first and second axes. A frame refers to a single image in a sequence of images." Elan proposes the following construction: "At least two different comparison frames (images captured by the complete array of photodetectors subsequent to a first image captured by a complete array of photodetectors) compared to either the reference frame (first image) or sample frame (subsequent image) to produce a corresponding number of correlation values and ascertain motion along either axis. Each comparison frame being shifted from the first image or subsequent images with some offset within the array."

Elan's proposed definition of "comparison frames" as "images captured by the complete array of photodetectors subsequent to a first image captured by a complete array of photodetectors" is not supported by the specification. As detailed in the specification, the device may track movement "by comparing a newly captured sample frame with a previously captured reference frame to ascertain the direction and amount of movement," and this comparison may be accomplished by the use of comparison frames where "the comparison frames are temporarily shifted versions of the sample frame." Col. 3, ll. 59-65 - Col. 4, ll. 29-33. In this embodiment, the comparison frames are not limited to the image captured by the complete array of photodetectors -- rather, the comparison frames may be the product of an internal operation so that what is captured by the array of photodetectors (a reference frame or a subsequent sample frame) may be correlated to the comparison frame, or the comparison frames may be correlated with each other.
Furthermore, Elan's definition of comparison frames excludes the prediction function disclosed in the specification: "For a
hand held mouse, several successive collections of comparison frames can usually be obtained from the (16x16) reference
frame taken at . . . This shifting to accommodate prediction throws away, or removes, some of the reference frame,
reducing the size of the reference frame." Col. 5, ll. 14-25. In the prediction operation the comparison frame is derived from
the reference frame and is thus neither a complete image, nor technically, an image captured by the array of photosensors.

Accordingly, the Court construes "a plurality of comparison frames, each being a shifted version of one of the reference
frame or the sample frame, is correlated with the other of the reference frame or the sample frame to produce a
corresponding plurality of correlation values and ascertain motion in the directions along the first and second axes" as "at
least two frames, each generated by shifting a sample frame or a reference frame, are compared with the other of a reference
frame or a sample frame to provide the degree to which the frames are related. Such correlations produce numerical
representations of the degree of similarity between the frames. Such correlations are also used to ascertain motion in the
directions along the first and second axes. A frame refers to a single image in a sequence of images."

12. "compatible with said scrambling means"

The plaintiff argues that no construction of the term "compatible with said scrambling techniques" is necessary. Joint Claim
Construction Brief, Exh. B. Defendant EchoStar argues the term means for each scrambling technique selected, there is a
single, corresponding unscrambling technique. The DIRECTV defendants argue it means for each scrambling technique,
there is a particular corresponding user exchangeable card that unscrambles according to that scrambling technique.

The term appears in the following context:

  Said unscrambling means being substantially replaceable with differing unscrambling circuits . . . compatible with said
scrambling means to remove the objectionable interference or distortion . . .

'066 Patent, col. 6, lines 40-47.

I agree with the defendants, and I construe the claim term "compatible with said scrambling means" to require that for each
scrambling technique there is a single corresponding unscrambling technique.

This construction finds support in the specification, which provides that each user card incorporates an "electronic circuit
for decoding one particular scrambled signal." '066 Patent, col. 3, lines 24-26 (emphasis added). The construction finds
further support in the specification, as follows:

  The master scrambling circuit 31 would be set for a particular type of coding at this same time the user would insert an
unscrambling card 150 incorporating a complementary decoding circuit into the decoding box . . .

Id. at col. 4, lines 26-29.

I reject the DIRECTV defendants' construction requiring that the single corresponding unscrambling technique be contained
in or on the exchangeable unscrambling card. The specification makes clear that in certain embodiments it is the user card
and the decoding box acting together which accomplish the task of unscrambling. '066 Patent, col. 4, lines 14-24 (describing
that in the very complex systems "the decoding box and card would each contain various parts of sophisticated electronic
circuits, all of which would be utilized in a certain arrangement to provide decoding").
The parties dispute the construction of the term, "compiling and merging a plurality of first end user inquiries." The term at issue appears in claim elements 1(f), 3(g), and 5 of the '025 Patent. (Herbst Decl. P 5, Ex. 3.)

Plaintiffs' proposed construction of the term is "collecting and combining the results of passively monitoring requests for information." Defendants' proposed construction of the term is "dynamic computer generation of information for a demographics database by continually analyzing, organizing and combining multiple related first end user inquiries to identify distinct trends that is more than maintaining a time record, count of the length of time, or number of user inquiries." In support of their respective constructions, Plaintiffs point to the claim language, the specification, and the prosecution history, while Defendants primarily rely on the prosecution history. The Court now turns to the claim language, the specification, and the prosecution history.

Turning to the claim language, in construing "compiling and merging a plurality of first end user inquiries," the Court is guided by general principles of claim construction and begins with the phrase's ordinary meaning. See Vitronics, 90 F.3d at 1583 (instructing the court to look first at the words themselves). The Court may look to other words in the claims to provide contextual support for the proper interpretation. Faroudja Lab., Inc. v. Dwin Elecs., Inc., 76 F. Supp. 2d 999, 1007 (N.D. Cal. 1999). At first blush, this phrase appears to lack any obvious "ordinary or customary meaning." See Wolverine World Wide, Inc. v. Nike, Inc., 38 F.3d 1192, 1196 (Fed. Cir. 1994). However, its meaning becomes slightly more evident when the Court considers the phrase in context.

The Court observes that the phrase at issue, in context of the claim language, essentially refers to what is done with the information collected from the passive monitoring of the end user inquiries encompassed by the preceding claim element 1(e). Although the parties contest the construction of the preceding claim element 1(e), the parties do not appear to dispute that the phrase at issue relates to the sequential step associated with the information collected from the end user inquiries and how a demographics database is generated therefrom. The claim language supports an interpretation that describes the particular step whereby the demographics databases are generated.

The '025 Patent specification tends to support this interpretation as described in Figure 1. (Herbst Decl. P 5, Ex. 3.) The description of this diagram illustrates that certain databases at issue "consists of all qualitative inquiries generated by viewers seeking more information on specific property profiles viewed on the disclosed system," (id., at col. 7, ll. 17-20), and are "generated by viewership of any property profiles wherein the viewer may or may not be interested in pursuing the transaction but has viewed the property," (id., at col. 7, ll. 20-23). In referring to related databases at issue, the specification describes it as "compris[ing] all qualitative inquires generated by viewers seeking more information on specific goods or services advertised on the disclosed invention," (id., at col. 7, ll. 23-26), and are "generated by viewership of any advertising message wherein the viewer may or may not be interested in obtaining more information about the advertiser's goods and/or services," (id. at col. 7, ll. 26-30). Accordingly, the specification contemplates that "respective databases" would consist of, and be generated by, first end user inquiries pertaining to property or advertisements. (Id. at col. 7, l. 31.)

However, the Court's review of the claim language and the specification does not appear to support a wholesale adoption of either parties' proposed construction. In following the canons of construction, the Court now addresses the '025 Patent prosecution history.

The '025 Patent prosecution history reveals that the inventor described the claim at issue to be one that generally "collects" inquiries. The inventor stated that the phrase at issue "compiles the inquires and from the inquiries, generates a demographics database, from which consumer trends can be ascertained . . . ." (Id. P 9, Ex. 7, Amendment After Final, submitted April 11, 1995 at p. 16.) Subsequently, the inventor stated that,

it is possible to collect data about the actual behavior of the end user, using the actual behavior of the end user. By collecting data about the end users actions, as they are "retrieving and viewing . . . data" it is possible to more accurately assess actual preferences of the end user. This is a collection of data that does not require active work by the end user, like answering a questionnaire. It is the collection of data by watching the actions of the end user . . . .

(Id. P 7, Ex. 5, Response to Office Action in Ex Parte Reexamination and Request for Continued Examination, submitted March 14, 2005 at p. 30) (emphasis added.) In further describing claim 1(f) the inventor stated that "[t]he features . . . state how to use data collected by assessing the user's actions." (Id. at p. 31) (emphasis added.) In light of the prosecution history, the Court finds that the phrase at issue necessarily means the process of "collecting the results of first end user inquiries."
Both parties urge the Court to include additional words and phrases in its construction of the phrase at issue. Plaintiffs request the Court to import the words, "collecting and combining" and "passively monitoring requests." Defendants ask the Court to import the phrases, "dynamic computer generation," "by continually analyzing, organizing and combining multiple related first end user inquiries," "to identify distinct trends that is more than maintaining a time record, count of the length of time, or number of user inquiries." The only proposed additional word offered by both parties is "combining." However, the Court finds the remainder of the parties' proposed extraneous words and phrases to be unnecessary.

Regarding Plaintiffs' proposed additional words, the Court finds it unnecessary to repeat language relating to information that is "passively monitored." Such a construction would be repetitive of the Court's construction of claim term 1(e). Next, regarding Defendants' proposed additional limiting phrases, the Court finds insufficient support in the record for their use here. See Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998) (citing Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 950, (Fed. Cir. 1993)) ("It is improper for a court to add 'extraneous' limitations to a claim, that is, limitations added wholly apart from any need to interpret what the patentee meant by particular words or phrases in the claim.") (quoting E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, (Fed. Cir. 1988)); see also Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) ("Where a specification does not require a limitation, that limitation should not be read from the specification into the claims.") (citing Lemelson v. United States, 752 F.2d 1538, 1551-52 (Fed. Cir. 1985)); cf. Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571 (Fed. Cir. 1988) (holding that the written description provided "no evidence to indicate that [ ] limitations must be imported into the claims to give meaning to disputed terms"). Defendant fails to identify applicable portions of the record that support the importation of additional limitations to the phrase at issue. For these reasons, the Court finds the parties' proposed additional language to be unnecessary.

Having considered the claims, the specification, the relevant patent prosecution history, and the parties respective use of the term, "combining," the Court construes "compiling and merging a plurality of first end user inquiries" as "collecting and combining the results of first end user inquiries."

31. Completing the execution of said branch instruction

This phrase appears in claims 1-12 of the '037 patent. Biax contends that this term means "delivering the target address of a branch instruction so that the target instruction will be the next instruction fetched for execution." ADI contends that the term means "delivering the branch target address of the next basic block to the instruction cache control." The dispute is whether the delivery must be to the instruction cache control. The court agrees with Biax that ADI's construction improperly limits the claim to the preferred embodiment. The court adopts Biax's construction for this term.

In reviewing the district court's analysis, we note that, consistent with the arguments of the parties, its claim construction was limited solely to an interpretation of claim 1. The district court concluded that, in accordance with the plain language of that claim, the host processor initiates communications with the mobile phone. Specifically, the court based its construction of the claim on the language requiring that "the host processor . . . selectively establishes a communication link . . . with" the mobile telephone. The court explained that an interpretation in which the customer initiates the claimed communication is contrary to the plain meaning of the claim. The court further rejected Telemac's argument that such a construction of claim 1 would render similar language in claim 3 duplicative, concluding that the dependent claim included limitations not found in claim 1 as construed.

Relying on both the language of the claims and the written description, the court next determined that the term "communication link" be construed to require "automatic communications." First, the court reiterated that the claim requires communications established by the host processor, not the customer. Looking to the written description, the court determined that in each embodiment in which the host processor establishes the communication, the communication is
established automatically. It further determined that in those embodiments, the communication is established to perform
activation and programming of a customer's phone. The court cited various portions of the specification in support of its
argument, including a description of the preferred embodiment in which activation of the phone is accomplished using "a
terminal interconnect" for direct machine-to-machine communication. Similarly, another section of the specification
describing "automatic" communications cited by the court recited reprogramming of the rate table over the air at the
initiation of the system provider. Thus, the court concluded that the "communication means" should be construed to
encompass automatically established communications initiated for the sole purpose of performing activation or
programming.

Rejecting Telemac's proffered construction, the court concluded that the embodiment relied on by Telemac, describing
manually established communications, functioned in accordance with the clause of the claim reciting the function of the
"payment verification means," not the "communication means." The district court also determined that whether or not the
structure of the claimed "payment verification means" uses some of the same technology employed by the "communication
means," the two means constitute distinct components of the claimed invention. Specifically, the court found that the
"communication means" functioned to establish the communication link for activating and programming the mobile phone,
whereas the "payment verification means" describes the process for updating the amount credited to the account. Based on
that reading of the specification, the district court rejected Telemac's arguments that the "communication means" should be
construed broadly to include structure for performing user initiated communications.

With respect to the claimed "complex billing algorithm," finding no clear meaning of this phrase evident from the claim
itself, the court turned to the written description to discern its meaning. The court concluded that the complex billing
algorithm is defined therein as a function that includes the means to store phone rates for local, long distance, international,
and roaming calls. The district court further determined that the algorithm includes means to identify the appropriate rate
category and to selectively apply those rates to each call.

In its February 1999 order, the district court also determined that the Wittstein patent disclosed each of the limitations
present in claim 1 of the patent as construed, as well as the limitations found in dependent claims 4, 6, 9, 18, 20-24, 29 and
30. Accordingly, the court granted Topp's motion for partial summary judgment of invalidity. In the order denying Telemac's
request for leave to file a motion for reconsideration, the district court acknowledge that "the Wittstein patent does not
expressly identify the four specific rate categories" required by the "complex billing algorithm." The district court explained
that the disputed features are necessarily present in the disclosure of the Wittstein patent.

On April 17, 1999, Topp filed a motion for summary judgment of non-infringement in which it argued that the claimed
"complex billing algorithm" and "communication means" were missing from the accused TRACFONE system. On July 1,
1999, the district court granted Topp's motion for summary judgment on the issue of non-infringement. The court found that
because the TRACFONE system, as manufactured and sold, blocks international calls, the accused device does not store
international rates in its memory and does not deduct values from the credit amount based on such rates. Instead, the court
noted that international calls cannot be completed unless the customer first calls an outside international carrier.
Accordingly, the court determined that the accused device lacked the "complex billing algorithm" limitation as construed.
The court further determined that because the accused device did not allow placement of international calls, it did not
perform substantially the same function in substantially the same way as the claimed algorithm. Thus, the court concluded
that the claims were not infringed literally or equivalently.

The court further found that the claimed "communication means for selectively establishing a communications link" was not
present in the accused device. According to the district court, the claims require communication means that automatically
establish communications with the phone via an electronic link, for performing activation and programming. In the
TRACFONE system, however, the programming and activation process is initiated manually by the user, not automatically
by the host processor using an electronic link. The court determined that the only automatic transmission of data present in
the TRACFONE system relates to replenishment of the user's credit amount, a function associated with the claimed
"payment verification means." The district court also rejected Telemac's argument that automatic and manual programming
are equivalent. The court determined that to reach such a finding, it would have to, in effect, vitiate the host initiated
automated communication requirements of the claims as construed. On August 25, 1999, the district court entered final
judgment pursuant to Rule 54(b) of Federal Rules of Civil Procedure, summarily holding the patent invalid and not
infringed. Telemac appeals the judgment of the district court.
STANDARD OF REVIEW

This court reviews a district court's grant of summary judgment without deference. Cortland Line Co. v. Orvis Co., 203 F.3d 1351, 1355, 53 U.S.P.Q.2D (BNA) 1734, 1746 (Fed. Cir. 2000). The moving party is entitled to summary judgment under Rule 56(c) "if the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits, if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law." In reviewing the district court's grant of summary judgment, this court draws all reasonable inferences from the evidence in favor of the non-movant. Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 255, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986).

Summary judgment is appropriate when it is apparent that only one conclusion as to infringement could be reached by a reasonable jury. ATD Corp. v. Lydall, Inc., 159 F.3d 534, 540, 48 U.S.P.Q.2D (BNA) 1321, 1324 (Fed. Cir. 1998). Summary judgment of noninfringement is appropriate where the patent owner's proof is deficient in meeting an essential part of the legal standard for infringement, since such failure will render all other facts immaterial. London v. Carson Pirie Scott & Co., 946 F.2d 1534, 1537, 20 U.S.P.Q.2D (BNA) 1456, 1458 (Fed. Cir. 1991).

DISCUSSION

I. Claim Construction

On appeal, Telemac argues that the court misconstrued two terms of the patent. Specifically, Telemac challenges the district court's construction of the "communication means" and the "complex billing algorithm."

A. "Communication Means"

Claim 1 of the patent claims a mobile phone system having a host processor. The host processor includes a "communication means for selectively establishing a communication link with each mobile phone unit." Because this limitation is written in "means-plus-function" form, in accordance with 35 U.S.C. § 112, P 6, the claim must be construed to cover the structure disclosed in the specification as performing that function and equivalents thereof. Kahm v. General Motors Corp., 135 F.3d 1472, 1476, 45 U.S.P.Q.2D (BNA) 1608, 1610 (Fed. Cir. 1998). The first step of a 35 U.S.C. § 112, P 6 analysis is to identify the function of the claim limitation. Kemco Sales, Inc. v. Control Papers Co., 208 F.3d 1352, 1361, 54 U.S.P.Q.2D (BNA) 1308, 1313 (Fed. Cir. 2000). The second step requires identification of the structures disclosed in the specification and equivalents thereof that perform the claimed function. Id.

The district court observed that the claim recites the function of selectively establishing communication with each mobile phone. Based on that construction, it determined that the only structure described as performing that function corresponds to the structure found in embodiments describing selective and automatic establishment of communications for performing activation or programming of the debit phone via an electronic link. We find no error in the district court's claim construction.

We begin our analysis of this means-plus-function limitation by determining the function recited. In accordance with the plain language of the claim, the function "selectively establishing a communication link with each mobile phone unit" describes a communication established by the host processor. We cannot, as Telemac requests, read the plain language of that clause as encompassing communications established by the user, via the mobile phone. We are reminded that a construction that flies in the face of the express language of the claim is not preferred. Interactive Gift Express, Inc. v. CompuServe, Inc., 231 F.3d 859, 865, 56 U.S.P.Q.2D (BNA) 1647, 1652 (Fed. Cir. 2000). Unless something in the written description suggests that the patentee intended the unambiguous language to be construed in a manner inconsistent with its
We reject Telemac's assertions that the court's construction would render the claim inoperable. In the preferred embodiment, activation of the phone is performed using an interlink receiver for machine-to-machine communications, thereby ensuring a secure transfer of information. The '100 patent describes over the air updating of the rate table "at the initiation of the system provider." The specification describes a transmission station for establishing a wireless link to the mobile phone for reprogramming the rate table over the air at the initiation of the host processor. The patent further states that the "system requires that a communication link be established between the host processor and the mobile phone unit and may require that the phone unit be physically connected to the host processor." Thus, numerous passages from the specification identify the structure, each part of the host processor, for establishing a communication with a mobile phone.

As provided above, Telemac's challenge to the district court's construction, with an eye towards infringement, focuses upon whether the "communications means" should be construed to encompass embodiments describing communications established using toll-free calls placed by the user from the telephone. The function claimed, however, requires establishment of the link by the host processor, and not the mobile phone unit.

As a further challenge to the district court's construction, Telemac contends that embodiments describing user-initiated activation and replenishment meet the requirement that the host processor selectively establish a communication link because, in those embodiments, the host processor determines the identity of the phone establishing the communication. Telemac argues that those embodiments describe "selectively" communicating confidential information in accordance with the identity of that phone. Telemac suggests that the host processor checks the electronic serial number of the mobile phone that established the call. Moreover, Telemac suggests that the "selectively establishing" limitation of the claim can be found in the user-initiated embodiments, and that those embodiments should be encompassed within the scope of the claim.

On the record before us, we cannot agree with Telemac's assertions. As noted, both the plain language of the claim and the written description of the invention require that the link with the phone be "established" by the host processor, and not vice-versa. Telemac's reading of "selectively establishing," as encompassing a confidential communication protocol, ignores the remainder of the claim identifying the host processor as the device that initiates the communication. Thus, we conclude that Telemac's proposed construction, encompassing manually initiated communications, would render the phrase "for selectively establishing a communication link with each mobile phone unit" mere surplusage. Accordingly, we reject Telemac's proposed interpretation of that language.

Telemac further argues that the court's construction is in conflict with the doctrine of claim differentiation. Under this doctrine, claims are presumed to be of a different scope. Claim 3 provides that the host processor initiates the communication link at a "time" controlled by the system provider. Telemac contends that, under the district court's construction, the provisions of claim 3 would be negated by the court's construction limiting communications to those established automatically. We do not agree that the "time" limitation of claim 3 is negated by a construction of the "communication means" as limited to automatically established communications. Even accepting Telemac's assertions, we further note that claim 3 embraces additional limitations not encompassed within claim 1 including, "activating the communication of the record data of stored call charges from the mobile phone unit to the system provider." Therefore, the doctrine of claim differentiation does not lead us to reach a different construction.

Telemac further challenges the court's limitation of the claim to automatically established communications, on the basis that such an interpretation renders the claimed invention inoperable. First, Telemac notes that the court determined that the "communication means" performs activation and reprogramming exclusively, and that the "payment verification means" is used only for updating the account amount. Under that construction, Telemac argues, the host processor cannot automatically communicate with the phone, or perform activation or programming, until the phone has been initially programmed and assigned a telephone number. Telemac's argument, however, is contradicted by the preferred embodiment describing activation and programming via a direct connection. Based upon the written description, we reject Telemac's assertions that the court's construction would render the claim inoperable.
We conclude that only those embodiments involving communications established by the host processor meet the functional requirement of the claim. Therefore, we agree with the district court's interpretation of the phrase "communication means for selectively establishing a communication link with each mobile phone unit" to require communications established by the host processor. As the district court concluded, the disclosed embodiments describing user-initiated communications could not provide the structure or equivalent structure for performing the claimed function in accordance with 35 U.S.C. § 112, P 6. Odetics, Inc. v. Storage Tech. Corp., 185 F.3d 1259, 1267, 51 U.S.P.Q.2D (BNA) 1225, 1229 (Fed. Cir. 1999).

B. "Complex Billing Algorithm"

The district court determined from the written description that the claimed "complex billing algorithm" requires storage of phone rates for, at a minimum, local, long distance, international, and roaming calls. It further determined that the algorithm required means for identifying the appropriate rate category for each telephone call and for the application of those rates to calculate the call charges.

Initially, we note that the claim provides "program means including a complex billing algorithm and rate data for internally calculating call charges as calls are made." Because the term "complex billing algorithm" does not have an ordinary meaning, and its meaning is not clear from a plain reading of the claim, we turn to the remaining intrinsic evidence, including the written description, to aid in our construction of that term. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996); Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 955, 55 U.S.P.Q.2D (BNA) 1487, 1490 (Fed. Cir. 2000). The written description of the '100 patent states, "the basic complex billing algorithm calculates the call charges for the basic categories of local calls, long distance calls, international calls and roaming calls" and can be "expanded to incorporate other categories." '100 patent, col. 17, ll. 1-8. Because the district court properly followed the intrinsic evidence, we agree with the district court's construction of "complex billing algorithm."

10. Compliance signal (Claim 30)

As with other limitations related to a means plus function limitation, defendants argue that a compliance signal must be construed as the output of the corresponding means for the related means plus function term "compliance signal means." Here too, the Court rejects defendants' proposed construction. The specification clearly discloses a signal that is generated based on the whether the audience member's usage of the device has been in accordance with the predetermined usage criterion. Therefore, plaintiff's proposed construction is adopted as follows: "A signal that indicates device usage in accordance with a predetermined usage criterion."

Compliant, Compliant Layer, Compliant Material

The term "compliant" appears in the intrinsic record several times to describe materials or layers of materials with differing functions, and the parties have developed sharply divergent constructions as a result of the term's broad use. Tessera suggests that "compliant" should be defined as, "yielding to applied force," but Defendants argue that Tessera's definition is unhelpful because all materials in the universe yield to applied force, and submit that "compliant" should be defined as, "[a] layer/material, such as soft rubber, that can be appreciably compressed in the direction toward the chip sufficient to accommodate tolerances in typical semiconductor components and test equipment."

The Court finds that Tessera's construction would not provide sufficient guidance to a juror struggling to understand "compliant." See Sulzer 358 F.3d at 1366. If all known materials yield to an applied force, the term compliant provides no limitation and is effectively read out of the patent, rendering its presence superfluous and potentially confusing to a jury. See Curtiss-Wright Flow Control Corp v. Velan, Inc., 438 F.3d 1374, slip op. at 9 (Fed Cir. 2006) (rejecting a construction so
broad as to render the limitation "nearly meaningless"). In addition to being unhelpful and possibly confusing, Tessera's construction is simply a modified dictionary definition, which after Phillips, is suspect in cases where the ordinary meaning of the claim language is not readily apparent to those not skilled in the art. Phillips, 415 F.3d at 1314; see also Brown v. 3M, 265 F.3d 1349, 1352 (Fed. Cir. 2001). Here, the meaning of the term compliant is not readily apparent because the patentee has used the term idiosyncratically and the Court must look to the claims, specification, and prosecution history to determine what a person skilled in the art would understand compliant to mean. Phillips, 415 F.3d at 1314; Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1116 (Fed.Cir. 2004).

However, arriving at an appropriate and reasonably precise construction of compliant is not easily done because the construction must be exclusive enough to be helpful while successfully accommodating the myriad of uses of the term in the patents in suit. For example, a compliant layer can facilitate movement of the terminals in a parallel or perpendicular direction with regard to the chip (ITC Order at 154; 977 Specification at 7:57-61; 977 Patent Figure 3); a compliant encapsulate allows the flexible lead to facilitate the movement of the terminal relative to the chip as the interposer buckles and wrinkles during thermal cycling (977 Specification 11:13-17); compliant material may include elastomers or elastomeric material (Id. at 17:40-42, 977 Claim 3), a compliant layer may incorporate adhesives (Id. at 22:1-2) or be incorporated by a flexible sheetlike element (977 Claims 1-2), and compliant materials can even include intermittent holes (977 Claim 4). Tessera's construction does not exclude any of these uses, but its wording is overly broad and unhelpful.

Although much of Defendants' construction is unnecessary and confusing, the concept that compliance requires compressibility is born out by the intrinsic evidence. Despite their differences, both parties' constructions embrace the idea that a compliant material or layer must yield because compliance is closely related to movement, and the Court agrees that this concept is at the heart of compliance. After reviewing the intrinsic evidence, the Court finds that compliance necessarily requires compressibility in a direction perpendicular to the substance's surface.

Tessera disputes that compliance necessarily implies compressibility, and points out that the 977 specification provides for a "compliant, compressible layer." 977 Prosecution History, 10:43-44. If compliance necessarily implied compressibility, Tessera argues, "compressibility" would not have been included. Further, 627 Claim 4 provides, "[a] chip assembly as claimed in claim 1, wherein said dielectric element includes a compliant layer of a low modulus material, said compliant layer being disposed beneath said terminals," and Claim 7 provides, "[a] chip assembly as claimed in claim 4, wherein said compliant layer is formed from a compressible foam." When a dependent claim contains a limitation, a presumption arises that the limitation was not present in the independent claim. Phillips, 415 F.3d at 1314-1315; Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). However, "that presumption can be overcome if the circumstances suggest a different explanation, or if the evidence favoring a different claim construction is strong." Medrad, 358 F.3d 910. Here, claim 7 adds the additional limitation of specifying the type of compliant material -- namely foam. Thus, Tessera's claim differentiation argument is without merit. Moreover, in this case, the evidence favoring a different construction is sufficiently clear to overcome any presumption and Tessera's reference to a "compliant, compressible layer" in the 977 specification.

Specifically, the Defendants highlight evidence from the prosecution of the parent application to the patents-in-suit and a divisional of that parent application whereby Tessera repeatedly defined that materials and layers are compliant because they deform by compressing in the direction perpendicular to their surfaces. For example, Defendants point to the prosecution history and specification of a divisional of the parent to the patents in suit, U.S. Patent No. 5,346,861 ("the 861 patent"). In Tessera's Response to the PTO distinguishing the Saito reference, it expressly defined compliant as, "compressible in the directions perpendicular to its first and second surfaces." App. No. 865,984 -- 10/26/92 Amendment and Response at 8. See also, App. No. 673,020 -- 1/10/92 Amendment and Response at 10-11 (explaining to the examiner that an ordinary sheet of note pad paper, placed atop the examiner's desk, was flexible, but not compliant because it was not appreciably compressible to forces applied perpendicular to its surface.). The 861 patent specification further provides that, "soft materials and foams provide a highly compliant interposer, i.e., an interposer which is readily compressible in the directions perpendicular to its surfaces and which therefore permits movement of the terminals in these directions." 861 Specification 14:40-46.

Defendants' evidence is express and on point, and the claims and specification require the same conclusion. It is clear that compliance is inextricably intertwined with movement, and that while compliant materials and layers can be flexible, they must be appreciably compressible in order to facilitate movement by some means other than just flexibility. Based on a thorough reading of the patents in conjunction with the express guidance in the prosecution history regarding
compressibility. The Court is of the opinion that compliance necessarily implies compressibility, and construes a compliant layer/material to mean, "a layer/material that is appreciably compressible in a direction perpendicular to its surface."

The Court finds that "comply," consistent with its ordinary meaning, means to act in accordance with standards or requirements.

B. Component

Leader's Construction

A computer-related entity, either hardware, a combination of hardware and software, software, or software in execution

Facebook's Construction

The term "component" should be construed in reference to three specific components identified in the asserted claims: "tracking component"; "storage component"; and "context component"

The term "component" appears in Claims 1-3, 5, 9, 17, 23, 29, and 32. Leader contends that its proposed construction of "component" is identical to the definition in the specification, which is dispositive because the patentee can act as his own lexicographer. (D.I. 179, at 8.) Facebook does not provide a proposed construction for the term (see D.I. 191, at 25), and does not dispute that the patentee has defined the term "component" in the specification as follows: "As used in this application, the terms "component" and "system" are intended to refer to a computer-related entity, either hardware, a combination of hardware and software, software, or software in execution." '761 patent, col. 5:54-57. Rather, Facebook contends that "component" is never used in isolation, and always appears in the phrases "context component," "tracking component," and "storage component". According to Facebook, all three terms are means-plus-function claim terms, and all three terms are indefinite because the specification fails to identify algorithms to perform the claimed functions. (D.I. 191, at 26-30.) Therefore, the parties' dispute centers on whether means-plus-function treatment is appropriate. 1

Footnotes

1 Facebook also states that the explicit definition of "component" in the specification is so "broad and amorphous . . . as to render it almost entirely meaningless." (D.I. 191, at 25.) While the definition is expansive, it is well-settled law that a patentee is free to be his or own lexicographer as long as "any special definition given to a word [is] clearly defined in the specification." E.g., Markman v. Westview Instruments, Inc., 52 F.3d 967, 980 (Fed. Cir. 1995). To the extent Facebook contends that the Court should disregard the patentee's definition of "component" solely for its breadth, Facebook has provided no authority to support such a contention.
35 U.S.C. § 112(6) provides that "an element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof; and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112(6). Section 112, P 6 applies only to "purely functional limitations that do not provide the structure that performs the recited function." (DePuy Spine, Inc. v. Medtronic Sofamor Danek, Inc., 469 F.3d 1005, 1023 (Fed. Cir. 2006) (citing Phillips, 415 F.3d at 1311). In determining whether a claim element is subject to Section 112, P 6, a court considers the phrasing of the element. Use of the word "means" creates the presumption that a claim is employing means-plus-function language, and therefore, that Section 116, P 6 applies. Id. Its absence creates a presumption to the contrary. Id. The presumption that a claim term is not a means-plus-function term "can be rebutted 'by showing that the claim term element recite[s] a function without reciting sufficient structure for performing that function." Id. (citing Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000)).

Facebook recognizes that the term "means" is not used with these terms in any of the claims, which gives rise to the presumption that none of the three terms are means-plus-function terms. (D.I. 191, at 26, 28, 29.) However, Facebook contends that the presumption is overcome because "component" is a generic term that does not connote structure to one of ordinary skill in the art, and the modifying terms "context," "tracking," and "storage" do not provide additional structural identification. (Id.) In response, Leader contends that Facebook ignores both the specification and the claim language in that the patentee explicitly defined "component" in the specification, and described each of the three types of components in the claims. (D.I. 196, at 5.) Further, Leader contends that the patentee explicitly used means-plus-function language in Claim 22, and therefore, would have done so with respect to these three terms if they were intended to be means-plus-function terms. (Id. at 5-6.)

The Court concludes that Facebook has not overcome the presumption against means-plus-function treatment, and that "context component," "tracking component," and "storage component" should be not construed as means-plus-function terms. With respect to the term "context component," Claim 1 claims "a computer-implemented context component of the network-based system." '761 patent, col. 20:65-66 (emphasis added). Claim 23 claims "a computer-implemented context component of a web-based server." '761 patent, col. 23:22-23 (emphasis added). With respect to the term "tracking component," Claim 1 claims "a computer-implemented tracking component of the network-based system." '761 patent, col. 21:7-8 (emphasis added). Claim 23 claims "computer-implemented tracking component of the web-based server." '761 patent, col. 23:31-32 (emphasis added). With respect to the term "storage component," Claim 9 claims "the data and metadata stored on a storage component of the web-based computing platform." '761 patent, col. 21:44-46 (emphasis added). Claim 17 claims "storing in a storage component ordering information." '761 patent, col. 22:28 (emphasis added). Claim 23 claims "storing the context data as metadata on a storage component of the web-based server," and "storing the change information on the storage component [of the web-based server] as part of the metadata." '761 patent, col. 23:27-29, 35-36 (emphasis added). Upon consideration of the phrasing used in the Claims, the Court concludes there is sufficient structural identification for each of the three terms. Because means-plus-function treatment is not appropriate, "component" is explicitly defined in the specification, and Facebook has not otherwise proposed a construction for the term, the Court concludes that "component" means "a computer-related entity, either hardware, a combination of hardware and software, software, or software in execution."

760

The parties dispute whether "component" is a means-plus-function term. The surrounding claim language indicates that the component is software that is downloaded onto a computing device.

Verimatrix argues that "component" is a generic term and the claims in which it is found are subject to 35 U.S.C. § 112(6). Verimatrix further argues that the word "component" requires context to have sufficient structure and the claims do not provide the needed context. Widevine argues that surrounding claim language provides sufficient structure to "component" and that it should be construed as "a downloadable software component." The specification's description of a decryption shim is consistent with the claims' use of the term "component." Unlike "device," "component" does not refer to a general purpose computer that is programmed to perform specified functions. "Component" refers to software that is an element of the "computer-readable storage medium" of Claim 9 or an element of the "encryption bridge" of Claim 1. The Court finds
that the claim provides sufficient structure to "component," as recited in the '831 Patent, Claims 3, 4, 11, and 12, and is therefore not governed by 35 U.S.C. § 112(6). "Component" means "a downloadable software component."

GO BACK

761

E. "Component Identifier"

Plaintiffs seek the following claim construction for the term "component identifier":

A "component identifier" is a device that identifies, recognizes, or selects, the type of component stored in a compartment with or without analyzing indicia of the component or compartment.

(Docket Entry No. 40, p. 19). Universal argues that the term "component identifier" is in means-plus-function format and covers every possible means for identifying components. Universal seeks construction of this term under section 112, P 6. Plaintiffs respond that the term "component identifier" has a generally well-understood meaning in the art, a similar argument to that made for the terms "location indicator," "error indicator," "individual visual indicator," and "information processor."

Because the two claims involving the term "component identifier," claims 1 and 13, do not use the term "means," this court presumes that section 112, P 6 does not apply. Universal can rebut this presumption by showing that "component identifier" fails to recite sufficiently definite structure or recites a function without reciting sufficiently definite structure to carry it out. Apex, 325 F.3d 1364, 2003 WL at *5. "[T]his presumption can collapse when a limitation lacking the term 'means' nonetheless relies on functional terms rather than structure or material to describe performance of a claimed function." Id. (citing Micro Chem. Inc. v. Great Plains Chem. Co., 194 F.3d 1250, 1257 (Fed. Cir. 1999)).

Unlike "location indicator," the term "component identifier" is not defined in technical dictionaries. Plaintiffs cite the use of the term "component identifier" in a publication by the Institute for Printed Circuits entitled "Sectional Requirements for Shop-Floor Equipment Communication Messages (CAMX) for Printed Circuit Board Assembly" as showing that the term "component identifier" has a well-understood meaning in the art. (Docket Entry No. 49, Ex. A, Ex. 10, pp. 37-38). In that reference, the term "componentId" is defined as the "unique component identifier" in the section of the document entitled "Dictionary of Attributes." The "componentId" is defined as a "string." The manual describes a "unique component identifier," or "componentId," as a string of characters in a computer program that identifies a particular component. Different types of components are identified by different "componentId's" within the computer program. This is consistent with the definition of the term "identifier" in the IBM DICTIONARY OF COMPUTING (10th ed. 1993) as "(1) one or more characters used to identify or name a data element and possibly to indicate certain properties of that data element; (2) in programming languages, a token that names a data object such as a variable, an array, a record, a subprogram, or a function." Unlike the definition of "detector" found in the technical dictionaries, this definition of "identifier" is not connotative of physical structure. Nor did this court find the term "identifier" in the MCGRAW-HILL ELECTRONICS DICTIONARY (6th ed. 1997). Plaintiffs' proposed construction of "component identifier" is in functional terms. Plaintiffs' expert witness, Thomas Rhyne, was unaware of any structures that bear the name "component identifier." (Docket Entry No. 49, Ex. A, Ex. 6, Deposition of Thomas Rhyne, at p. 164, 1.11-1.12).

"[T]he fact that a particular mechanism . . . is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of section 112, P6." Greenberg, 91 F.3d at 1583. The present case is distinguishable from Greenberg. The Greenberg court determined that the term "detent mechanism" was not a means-plus-function claim, even though it was defined in functional terms. The court stated that the term "detent" "denote[d] a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms." Id. Dictionaries defined "detent" as "a mechanism that temporarily keeps one part in a certain part relative to that of another, and can be released by applying force to one of the parts." The court found that so defined, "detent," "as a term for structure, ha[d] a reasonably well-understood meaning in the art." Id. (citing RANDOM HOUSE UNABRIDGED DICTIONARY 541 (2d ed. 1993)). The term "component identifier," in contrast to the term "detent," does not "denote a type of device." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY (1983) defines "identifier" as simply "one that identifies." This definition does not connote structural meaning, as did the dictionary definitions of "detent." The technical definitions of the terms "identifier" and "component identifier" do not imply a
Universal contends that this function is carried out by the information processor in the four-element version of the

The construction of "component identifier" is also distinguishable from the construction of the term "digital detector" in Personalized Media, 161 F.3d at 705. In that case, the term "detector" did not evoke a particular structure. The term did convey to one knowledgeable in the relevant art a variety of structures known as "detectors," based on technical definitions of the term. By contrast, the technical definitions of "identifier" and "component identifier" do not connote a particular structure or a variety of structures. Rather, the term "component identifier" could be any device that identifies a component. See Mas-Hamilton, 156 F.3d at 1214 (finding that a claim for a 'lever moving element' was a means-plus-function claim). The term "component identifier" cannot be construed as covering every conceivable way of identifying components. Id.

As to the term "component identifier," Universal has rebutted the presumption that means-plus-function analysis is inapplicable. Plaintiffs define "component identifier" in functional terms and the term itself is not connotative of structure. The term recites a function without reciting sufficient structure for performing that function. Section 112, ¶ 6 applies to the term "component identifier."

Claims subject to means-plus-function analysis are interpreted to cover the structure set forth in the specification and its equivalents. 35 U.S.C. § 112, ¶ 6; Kahn, 135 F.3d at 1476. A court must identify the claimed function and the structure in the written description necessary to perform the claimed function. Micro Chemical, 194 F.3d at 1258. A court must not incorporate structure from the written description beyond that necessary to perform the claimed function and must not adopt a function different from that explicitly recited in the claim. Id.

The written description of the '943 Patent states that the component identifier serves two primary functions: it "acquires information concerning the type of component held in a compartment," and it "passes the information along to the position indicator." ('943 Patent, col. 4,1.20-1.23). The written description states that "in one embodiment, [the] component identifier is a device that identifies components by optically or magnetically reading indicia accompanying the components or indicia of the components themselves." (Id. at col. 4, 1.23-1.27). The function of determining the proper location of a component or a component compartment after it is identified by the component identifier is distributed between the component identifier and the location indicator in the three-element embodiment and is located in the information processor in the four-element embodiment. (Id. at col. 4, 1.58-1.61; col. 5,1.55-1.59).

To carry out the functions of acquiring information about the type of component held in a compartment and to pass that information to the location indicator, the component identifier must contain an optical or magnetic reader, as well as software or electronic logic. In claim 1, the component identifier analyzes indicia of the components or component compartments to determine the type of component to be positioned. However, claim 13 does not state that the component identifier operates by analyzing indicia of the components or component compartments to determine the type of component being positioned. Claim 1 contains a limitation that claim 13 does not.

Unless a patent provides otherwise, a claim term cannot be given a different meaning in the various claims of the same patent. Georgia-Pacific Corp. v. U.S. Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 1999); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570 (Fed. Cir. 1995). Claim 1 requires the component identifier to analyze indicia of the component or component compartment in question; claim 13 does not expressly contain this limit. However, because the "component identifier" means-plus-function claim in claims 1 and 13 covers only the structure recited in the written description, the component identifier of both claims 1 and 13 is limited to optical and magnetic readers.

Universal contends that under the written description, the component identifier of claim 1 must contain a computer that determines whether a particular component is valid for the product assembly. 6 Universal cites the language describing the proposed algorithm for the use of the invention. The written description states that "[i]n a preferred embodiment, [the] component identifier . . . is a bar code reader (connected to the computer's serial port or keyboard) reading a bar code from a reel of electronic components." (943 Patent, col. 14,1.48-1.51). That information is sent to the computer, which "compare[s] [the part] against a list of parts for the current product of manufacture." (Id. at col 14,1.53-1.54). The computer then determines whether the part belongs in the product being assembled and proceeds accordingly. (Id. at col. 14, 1.54-1.59).

--- Footnotes ---

6 Universal contends that this function is carried out by the information processor in the four-element version of the
The claims do not, however, require the component identifier of claim 1 to perform the function of determining whether the component is a valid component for assembling the product, or that the invention use the particular algorithm presented in the written description. The written description in the claims clearly states that the component identifier's two primary functions are to "acquire information concerning the type of component held in a compartment" and to "pass the information along to [the] position indicator" or the information processor. (Id. at col. 4, 1.19-1.23, col. 5, 1.50-1.52). These two functions are met by construing the component identifier as an optical or magnetic reader or equivalent, which identifies, recognizes, or selects the component or component compartment to be placed in a specific location in the assembly process. It is not necessary to have a computer running the algorithm described in the written description for the component identifier to carry out its two primary functions. Requiring a computer as part of the component identifier would adopt a function different from that explicitly recited in the claims. Plaintiffs' proposed construction gives a consistent meaning to the claim term "component identifier" throughout the '943 Patent.

GO BACK

The '451 patent describes a system and method that allows for multiple tasks to be performed upon one command from the client, such as a broad user command to "plan a trip" which causes the system to make airline, hotel, and car reservations on its own and return the results of these completed tasks to the user.

The patent uses the term "component tasks" in both its independent claims (claims 1 and 8). Yodlee construes "component tasks" to mean "individual tasks that make up a multi-component task," while CashEdge construes it to mean "the distinct sub-tasks of the multi-component task." The dispute thus centers around the word "distinct." It is not clear to the Court how the addition of the word "distinct" clarifies the meaning of the term "component tasks." The prosecution history cited by CashEdge does not support the addition of the word "distinct." Accordingly, the Court adopts Yodlee's definition.

"Multi-component task" also appears in both independent claims of the '451 patent. Yodlee defines "multi-component task" as "an overall task that is made up multiple individual tasks." CashEdge defines it as meaning "a task that is accomplished by performing two or more distinct sub-tasks in unrelated areas that is more than simply gathering information and presenting the information to the end user." Again, CashEdge cites to prosecution history that does not support its addition of the words "unrelated areas that is more than simply gathering information and presenting the information the end user." There is nothing in the intrinsic evidence to support the limiting language proposed by CashEdge. The Court adopts Yodlee's definition.

GO BACK

The term "composed image" appears in the sixth, eighth, ninth, and eleventh elements of independent claim 28. Adobe contends that "composed image" has the same meaning as "composed image" in claim 27, i.e., the image that results from blending two images in dependence on at least one control image, where the control image specifies the relative contribution of each input image and where the control image contains more than two possible values for specifying those relative contributions.

The court concludes that the term "composed image" appearing in claim 29 has the same meaning as the term "composed image" appearing in claim 27, i.e., a "composed image" is the image that results from compositing two images using a control image that has more than two values. The sixth element of claim 29 explicitly recites at least three values for the control image: "storing a frame of said first control pixel signals in a third addressable memory as signals having a first
value for pixels of a composed image based on one of said first pixel signals and said second pixel signals, a second value for pixels of said composed image based on the other of said first pixel signals and said second pixel signals, and intermediate values for pixels of said composed image based on combining proportions of said first pixel values and said second pixel values." See col. 16, lines 28-36 (emphasis added).

2. "Composite Gesture Action" ('053 patent, claims 1, 6)

The second term in dispute is "composite gesture action." Plaintiff's proposed construction is "a gesture action (as defined above) in which movement results from a contribution of two or more gesture actions." Defendant's proposed construction is "a gesture action (as defined above) that involves movement of several joints."

Defendant's construction is supported by the fact that the phrase "composite gesture action" appears only in claims 1 and 6 of the '053 patent, not in the specification, and the phrase found its way into those claims through an amendment that plaintiff itself introduced during the procurement process to distinguish prior art. See Tr. at 14-17, 123-24. At that time, plaintiff suggested that a "composite gesture action" is an action that "govern[s] a plurality of movements at a corresponding plurality of joints," Pl. Ex. 2 ("'053 Prosecution History") at NYU004019-20, and defendant's construction largely tracks this language. In introducing the amendment, plaintiff made no claim that "composite gesture action" meant "two or more gesture actions," and relied on the assertion of control over several joints to distinguish prior art. See Tr. 14-17, 123-24.

Plaintiff responds that regardless of the prosecution history, defendant's construction renders the clause "composite gesture action" meaningless because, as plaintiff's expert testified, a mere "gesture action," alone, may entail the movement of several joints, and the word "composite" must therefore be read to indicate "two or more gesture actions" in order to avoid redundancy. See Tr. at 13; see also Tr. at 18, 64. But the prosecution history supports defendant's construction and does not accord with plaintiff's definition. The fact that defendant's construction arguably results in a partial (but far from total) redundancy--and plaintiff's expert did not testify unequivocally on this point, see Tr. at 70-71--is an almost unavoidable function of the less than perfect precision of common English usage and therefore, of itself, an insufficient reason to reject it when the plain meaning is otherwise clear. See Tr. at 19. Moreover, plaintiff offers no other rationale for rejecting defendant's construction, see Tr. at 18 (The Court: "Why shouldn't the plaintiff be bound by the definition it gave?" Dr. Badler: "I'm not sure I have a response to that.").

Accordingly, the Court hereby adopts defendant's proposed construction of "composite gesture action."

2. "Comprehensive surveillance of a predetermined area." Used in Claims 1, 18, and 25.

E-Watch argues that no construction is needed because the term is plain and ordinary on its face. In the alternative, E-Watch suggests "careful, close, continuous, thorough, or extensive watching of a predetermined area." March Networks argues that the definition should be: "the area under surveillance has sensors with some sensors having overlapping zones of detection."

This claim language is in the preamble of Claim 1 and could be interpreted to merely state an intended use or a desired result. It might be said that the phrase does not "breathe life and meaning" into the claim or any part of it, and is not a required antecedent of any of the actual paragraphs (a)-(c). However, both parties believe the phrase is important enough to argue over, see Tr. pp. 34-35, so the court will construe it.

Defendant's construction is too limited. The "pre-determined area" is not specifically defined in the claims or specifications. In the context of the patent, it is the entire area of the facility to be protected. Nothing in the drawings or specifications requires overlap of sensors or sensor appliances, so long as all of the area is covered or monitored by at least one sensor appliance or conventional sensor. See ' 183 patent, col. 6, ll. 9-18. In other words, there could be one sensor appliance with video coverage of a court room, another with coverage of the judge's chambers, a third with coverage of the hall, and a heat
and smoke detecting unit covering the crawl space above these rooms. There is no overlap, but the entire area is monitored or protected.

E-Watch argues that "comprehensive surveillance" includes the storing of data. The specifications indicate that storage, and other uses of data occurs in the server or in the sensor appliance. ’183 patent, col. 7, ll. 38-40. The term being defined is "surveillance" of an area. The other functions are accomplished by the total system, but that does not make them part of the surveillance function.

The claim itself requires a plurality of sensor appliances,’183 patent, col.45 ll.49-50, so there must be more than one. n4
The appliances may, but do not have to, overlap in their coverage of parts of the "predetermined area." n5

-n4 For the reasons stated in Bilstad v. Wakalopulos, 386 F.3d 1116, 1122 (Fed. Cir. 2004), the court concludes that "plurality," as used in this patent, means "two or more."

-n5 Counsel for both sides agreed to this. See Tr. pp. 39-41.

The court will define this term as follows:

"Comprehensive surveillance of a predetermined area" means: "Using at least two sensor appliances, and in some cases one or more conventional security sensors, to monitor or observe the area protected by the system, so that all parts of the area are monitored or observed, although some or all parts of the area may be monitored or observed by only one sensor appliance or sensor."

GO BACK

I. "compression rate" 2

2 The term "compression rate" is contained in claims 1, 2, 13, and 25 of the '104 patent and claims 1 and 9 of the '158 patent.

Defendants contend that the specification distinguishes between the term "compression rate" and "input data rate." REPLY at 3. Defendants further contend that the term "compression ratio" is not "subsumed" in "compression rate" because Plaintiff gave up that subject matter during prosecution. Id. at 4. Defendants argue that the only way to increase the effective data storage rate, as disclosed in Claim 1 of the '104 patent is by compressing the data at a compression ratio that is greater than 1, and therefore claims reciting "compression rate" are indefinite. Id.

Plaintiff contends that despite Defendants' arguments that this term is indefinite, Defendants nevertheless propose a construction showing that the term is not indefinite. RESPONSE. at 3. Plaintiff argues that the specification illustrates a proper construction for this term and even Defendants' expert has used the term in his own articles and patents. Id. at 5-6. Finally,
Plaintiff contends that claims 1 and 2 of the '104 and '158 patents use the term consistently. Id. at 8.

Claim 1 of the '104 patent discloses:

1. A program storage device readable by machine, tangibly embodying a program of instructions executable by the machine to perform method steps for providing accelerated data storage and retrieval, said method steps comprising:

   receiving a data stream at an input data transmission rate which is greater than a data storage rate of a target storage device;

   compressing the data stream at a compression rate that increases the effective data storage rate of the data storage device; and

   storing the compressed data stream in the target storage device.

'104 patent at 18:41-52 (claim 1). Claim 2 of the '104 patent depends from claim 1 and discloses:

2. The program storage device of claim 1, wherein the compression rate is at least equal to the ratio of the input data transmission rate to the data storage rate so as to provide continuous storage of the input data stream at the input data transmission rate.

'104 patent at 18:54-58 (claim 2). Claim 1 indicates that the "compression rate" is a rate at which a data stream is compressed, such that the effective data storage rate of the data storage device is increased. Claim 2, however, indicates that the "compression rate" is the ratio of the input data transmission rate to the data storage rate. As Defendants point out, a rate is not the same as a ratio. MOTION at 6.

Moreover, the specifications of the '104 and '158 patents, as well as the prosecution history, indicate that the patentee intended these terms to have different meanings—the meanings one of ordinary skill in the art would attribute the terms. '104 patent at 3:8-13 ("the method for providing accelerated data storage and retrieval utilizes a compression ratio that is at least equal to the ratio of the input data transmission rate to the data storage rate"); id. at 5:28-32 ("the rate that data blocks from the input data stream may be accepted by the data storage accelerator 10 is a function of the . . . the compression ratio achieved [in addition to other factors]"); id. at 9:57-65 (noting a compression ratio of 3:1 and a storage rate of 30 MB/sec); see also '158 patent at 3:36-42; 11:10-17. As these portions of the specification indicate, a ratio is a unit-less indicator of relative magnitude, while a rate is expressed in terms of data per unit of time. '104 patent at 9:57-65 (noting a compression ratio of 3:1 and a storage rate of 30 MB/sec). This conclusion is also supported by the parties' agreed construction of "compression ratio." CLAIM CHART at 11-12 ("ratio of the number of bits in a data block input to an encoder to the number of bits in that data block output from that encoder").

When the application for the '104 patent was filed, claim 2 originally disclosed:

2. The program storage device of claim 1, wherein the compression ratio is at least equal to the ratio of the input data transmission rate to the data storage rate, so as to provide continuous storage of the input data stream at the input data transmission rate.

MOTION, EXH. F at FH00006208 (emphasis added). 3 The PTO rejected the claim as being obvious, and in response, the applicant amended the claim to disclose a "compression rate." Id. at FH00006206-08; see also id. at FH00006208 (amending claim 1 from "compressing the data stream at a compression ratio which provides a data compression rate that is greater than the data storage rate" to "compressing the data stream at a compression rate that increases the effective data storage rate of the data storage device") (emphasis added).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 The '104 patent issued from application no 09/266,394 ("the '394 application"). The '158 patent was a continuation-in-part of the '394 application.
In addition to acknowledging the difference between "rate" and "ratio," in the specifications of the '104 and '158 patents the applicant specifically disclosed the intended meaning of compression ratio. The specification of the '104 patent discloses:

"In order to achieve continuous data storage acceleration, the data storage accelerator 10 must be configured to compress a given input data block at a rate that is equal to or faster than receipt of the input data. Thus, to achieve optimum throughput, the rate that data blocks from the input data stream may be accepted by the data storage accelerator 10 is a function of the size of each input data block, the compression ratio achieved, and the bandwidth of the target storage device. For example, if the data storage device 45 . . . is capable of storing 20 megabytes per second and the data storage accelerator 10 is capable of providing an average compression ratio of 3:1, then 60 megabytes per second may be accepted as input and the data storage acceleration is precisely 3:1, equivalent to the average compression ratio."

As to claim 1 of the '104 patent, the prosecution history supports this conclusion. Claims 1 and 2 were initially rejected by the PTO as being obvious in light of the Adiletta reference. MOTION, EXH. F at FH00006203. The prosecution history indicates that the patent applicant considered the increase in the effective data storage rate as the point of novelty which made the invention patentable over Adelitta. This is because Adelitta discloses a data compression scheme which compresses all the data before storing it to memory. MOTION, EXH. F at FH00006205-06. Although Adelitta does provide a decrease in the required memory storage space, an increase in the effective data storage rate may not result because the time required to compress all of the data and subsequently store all the data could be greater than or equal to the time to merely store the uncompressed data. Id. ("the Adiletta system may realize a decrease in storage, but such system will not realize 'accelerated data storage' as contemplated by the present invention"). The applicant's modification of the language in claims 1 and 2, in light of these arguments, reflects the importance of the time required to compress the data and make it available for storage. So unlike the compression ratio, the compression rate takes into account the time period it takes to compress a certain amount of data.

The use of the term "compression rate" in claim 1 of the '104 patent is consistent with this conclusion. There, the data throughput of the compressor is great enough that it increases the effective storage rate of the data storage device. '104 patent at 18:41-53 (claim 1) ("compressing the data stream at a compression rate that increases the effective data storage rate of the data storage device"). Claims 13 and 25 of the '104 patent, along with claims 1 and 9 of the '158 patent similarly use the term "compression rate" to refer to compressor throughput at a given compression ratio. The use of term "compression rate" in claim 2 of the '104 patent, however, is not consistent with the use of the term throughout the remainder of the patent and prosecution history. Claim 2 indicates that the "compression rate" is "at least equal to the ratio of the input data transmission rate to the data storage rate." '104 patent at 18:54-58 (claim 2). As previously noted, this is inconsistent with the remainder of the claims, specification, and prosecution history.

Plaintiff argues that the term "compression rate" provides information about the amount of input data a compressor can compress per unit of time, the amount of compressed data a compressor can output per unit of time, and the amount of data that is compressed—the compression ratio. RESPONSE at 8. In other words, Plaintiff argues that the term "compression ratio" is subsumed within the term "compression rate." However, this contention is refuted by the specification, as previously noted, because the patentee explicitly distinguishes between "rates" and "ratios." See '104 patent at 3:8-13 ("the method for providing accelerated data storage and retrieval utilizes a compression ratio that is at least equal to the ratio of the input data transmission rate to the data storage rate"); id. at 5:28-32 ("the rate that data blocks from the input data stream may be accepted by the data storage accelerator 10 is a function of the . . . the compression ratio achieved [in addition to other factors]"); id. at 9:57-65 (noting a compression ratio of 3:1 and a storage rate of 30 MB/sec); see also '158 patent at 3:36-42; 11:10-17; MOTION, EXH. F at FH00006208 (amending claim 1 from "compressing the data stream at a compression ratio which provides a data compression rate that is greater than the data storage rate" to "compressing the data stream at a compression rate that increases the effective data storage rate of the data storage device") (emphasis added). Therefore, with respect to claims 1, 13, and 25 of the '104 patent and claims 1 and 9 of the '158 patent, the Court finds that
the term "compression rate" is not indefinite and is properly construed as "compressor throughput as a measure of the amount of input data a compressor can compress and make available for storage per unit of time at a given compression ratio."

However, as previously noted, the use of the term "compression rate" in claim 2 is inconsistent with the remainder of the claims, specification, and prosecution history. It is nonsensical and one of ordinary skill would understand it as such. The limitation is directed at a "compression ratio," but discloses a "compression rate." While patents are presumed valid and claims may only be declared invalid based on clear and convincing evidence, the term "compression rate" is amendable to only one reasonable construction, rendering claim 2 nonsensical. The Court must construe the claim as the patentee has drafted it. Process Control Corp. v. Hydreclaim Corporation, 190 F.3d 1350, 1357 (Fed. Cir. 1999) ("[w]here, as here, the claim is susceptible to only one reasonable construction . . . . we must construe the claims based on the patentee's version of the claim as he himself drafted it"). As such, courts may not redraft claims to make them operable or to sustain their validity, regardless how the patentee wished they had drafted it. Chef America, Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1373-74 (Fed. Cir. 2004). As a result, claim 2 of the '104 patent is invalid as being indefinite because it is not "amenable to construction," Exxon Research, 265 F.3d at 1375, and it is insolubly ambiguous and no narrowing construction can properly be adopted." Id.; see also Honeywell, 341 F.3d 1332 at 1338-39.

"Comprised of"

The district court found that the meaning of "comprised of" has not been clearly resolved in patent-specific precedent, and therefore the court held that the "ordinary and customary meaning" should be used. The court ruled that "comprised of" does not have the same open-ended meaning as "comprising," which also appears in claim 1, and that "comprised of" should be construed as a closed-end term that excludes the presence of all elements beyond those presented in the "comprised of" clause. Thus the court defined "comprised of" as "a limiting description of composition," reasoning that "[i]t is consistent with the claim construction preserves the distinction between 'comprised of' and 'comprising,' the latter of which in fact is a patent term of art when used in a transitional phrase. . . ."

We conclude that this ruling is not correct. Although "comprised of" is not used as regularly as "comprising," and "comprised of" is sometimes used other than as a "transition phrase," nonetheless it partakes of long-standing recognition as an open-ended term. See generally 3 Chisum on Patents § 8.06[1][b], at 8-180-82 (2007) (claims usually are structured with a preamble, a "transition phrase," and the elements or steps that are necessary to the right to exclude). The usual and generally consistent meaning of "comprised of," when it is used as a transition phrase, is, like "comprising," that the ensuing elements or steps are not limiting. The conventional usage of "comprising" generally also applies to "comprised of."

Alliance argues that several judicial decisions have used "comprised of" to mean "consists of." However, these rare usages do not remove from "comprised of" its conventional meaning when used as a transition term. The only patent case that illustrates this casual usage appears to be Glaxo Grp. Ltd. v. Apotex, Inc., 376 F.3d 1339, 1343 (Fed. Cir. 2004), where the invention was a "highly pure amorphous form of CA [cefoxime]," and the opinion described the accused product as "an amorphous 'co-precipitate' comprised of 90% CA, 9% sorbitol, and 1% zinc chloride by mass." This usage of "comprised of" was not as a claim transition term, but was the court's description of the defendant's product; there was no issue of whether "comprised of" was a limiting term in patent claim style. Similarly, in Aro Mfg. Co. v. Convertible Top Replacement Co., 365 U.S. 336, 348, 81 S. Ct. 599, 5 L. Ed. 2d 592, 1961 Dec. Comm'r Pat. 635 (1961) the Court stated: "The decisions of this Court require the conclusion that reconstruction of a patented entity, comprised of unpatented elements, is limited to such a true reconstruction of the entity . . . ."; this linguistic usage is not concerned with claim drafting; and, if anything, it is open-ended and non-limiting.

The other cases to which Alliance directs us are not patent cases, and the usage is simply as descriptive text. An example is Admiral Fin. Corp. v. United States, 329 F.3d 1372, 1377 (Fed. Cir. 2003), where the court wrote that "Admiral . . . seek[s] total restitution in the amount of $ 14,395,075, comprised of $ 11,072,075, representing capital contributions to Haven, and $ 3,323,000, representing the amount that Admiral claims it saved the government." Similarly in Nissho Iwai Am. Corp. v. United States, 982 F.2d 505, 506 n.1 (Fed. Cir. 1992) the court explained that: "The parties estimated that the cars would be comprised of 57.45% Japanese-made components and 42.55% American-made components." These cases raise no issue of
the conventional patent claim meaning of "comprised of."

In the patent claim context the term "comprising" is well understood to mean "including but not limited to." In Vivid Techs., Inc. v. Am. Sci. & Eng'g, Inc., 200 F.3d 795, 811 (Fed. Cir. 1999) the court explained that patent claims "use the signal 'comprising,' which is generally understood to signify that the claims do not exclude the presence in the accused device or method of factors in addition to those explicitly recited." In Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999) the court explained that "the terms 'comprise' and 'consist' have different meanings: . . . 'comprising' . . . is inclusive or open-ended and does not exclude additional, unrecited elements or method steps . . . . From these definitions it is clear that 'comprise' is broader than 'consist.'" Similarly, our predecessor court explained that this usage of "comprising" also embraces "comprises" and "which comprises." Application of James F. Hunter, 288 F.2d 930, 48 C.C.P.A. 887, 1961 Dec. Comm'r Pat. 289 (CPA 1961) (the term "comprises" does not limit the claim to the steps that are listed).

The contrast, in patent lexicography, is with "consisting of," not with variations of "comprises." It is equally well understood in patent usage that "comprising of" is closed-ended and conveys limitation and exclusion. See Norian Corp. v. Stryker Corp., 363 F.3d 1321, 1331 (Fed. Cir. 2004) ("comprising of is a term of patent convention meaning that the claimed invention contains only what is expressly set forth in the claim . . . [however] it does not limit aspects unrelated to the invention"); In re Gray, 53 F.2d 520, 19 C.C.P.A. 745, 1932 Dec. Comm'r Pat. 85 (CCPA 1931) (the use of the claim term "consists" is limited to the claim's enumerated alloy metals without other elements, unlike the term "comprising" which permits the inclusion of other metals than those claimed"). Robert A. Faber, Landis on Mechanics of Patent Claim Drafting § 2:5, 2-15 (5th ed. 2006) also elaborates that "[o]ther words, less often used, have been given the same meaning in patent claim interpretation as 'comprising': 'including,' 'having,' 'containing,' and even 'wherein.'"

District court cases illustrate this routine construction of "comprised of" in the same way as "comprising," as meaning "including but not limited to." E.g., SKW Americas v. Euclid Chem. Co., 231 F. Supp. 2d 626, 637 (N.D. Ohio 2002) ("Because the hydraulic cement mix is 'comprised of' the four elements listed . . . it may include other elements as well."); B.F. Goodrich Flight Sys., Inc. v. Insight Instruments Corp., 22 USPQ2d 1832, 1840, 1992 WL 193112, at *9 (S.D. Ohio Feb. 25, 1992) ("Use of the term 'comprised' renders this claim an 'open' claim which will read on devices which merely add additional elements or steps."); aff'd, 991 F.2d 810 (Fed. Cir. 1993) (Table); Univ. of Fla. Research Found., Inc. v. Orthovita, Inc., No. 1:96-CV-82-MMP, 1998 U.S. Dist. LEXIS 22648, 1998 WL 34007129 (N.D. Fla. Apr. 20, 1998) ("comprised of" is broader than "consisting essentially of" when used in patent claims).

These cases reflect the general understanding and usage of "comprised of" in patent convention as having the same meaning as "comprising." For patent claims the distinction between "comprising" and "consisting" is established, along with the meaning of "comprised of" as related to "comprising," not "consisting of." Correctly construed, "comprised of" does not of itself exclude the possible presence of additional elements or steps.

Applying an incorrect construction of "comprised of," the district court ruled that "unique authorized information . . . comprised of machine-readable code elements coded according to a detectable series" is limited to coding by a detectable series, and that since the Alliance code systems include a "secret" series along with a detectable series, the limit imposed by "comprised of" bars infringement. On the correct construction of "comprised of," this reasoning does not support the court's ruling as to "secret" series. However, as we shall discuss, the prior art and prosecution history served to limit the scope of "unique authorized information" to a "detectable series" and to exclude a series that included "secret" information.

As to DDI's second argument, we acknowledge that the term "comprising" raises a presumption that the list of elements is nonexclusive. See Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997). However, "[c]omprising' is not a weasel word with which to abrogate claim limitations." Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1380 (Fed. Cir. 1998). "Comprising" appears at the beginning of the claim- "comprising the steps of"-and indicates here that an infringing process could practice other steps in addition to the ones mentioned. Those six enumerated steps must, however, all be practiced as recited in the claim for a process to infringe. The presumption raised by the term "comprising" does not reach into each of the six steps to render every word and phrase therein open-ended especially where, as here, the patentee has narrowly defined the claim term it now seeks to have broadened. The district court's limitation of the claim scope to exclude
processes that produce some irregularly shaped particles is correct.

A method for specifying a computer system comprising:

The parties initially disputed the meaning of "comprising." Dell proposed: "including, but not limited to." Lucent argued that no construction was required. The parties subsequently agreed on the construction of this term. Based upon the agreement of the parties, the court construes "comprising" as follows:

"including, but not limited to."

When a patent claim uses the word "comprising" as its transitional phrase, the use of "comprising" creates a presumption that the body of the claim is open. In the parlance of patent law, the transition "comprising" creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements. See KCI, 223 F.3d at 1356.

The transition "having" can also make a claim open. Regents of the Univ. of Cal. v. Eli Lilly & Co., 119 F.3d 1559, 1573, 43 U.S.P.Q.2d (BNA) 1398, 1410 (Fed. Cir. 1997). However, the term "having" does not convey the open-ended meaning as strongly as "comprising." "Having," for instance, does not create a presumption that the body of the claim is open. Therefore, this court examines the claim in its full context to determine whether Crystal's use of "having" limits claim 1 to its recited elements.

The language of claim 1 itself does not limit the term "having" to a closed meaning. The '483 patent discloses a capacitor structure that shields the sensitive plate of the capacitor from stray noise. The "Background of the Invention" describes typical prior art capacitors with a two-plate structure. Col. 1, ll. 58-68. The top plate served as a "sensitive 'virtual ground' capacitor plate" while the bottom "shielded the sensitive node from substrate noise." Id. These two-plate capacitors were "still susceptible to noise coupling onto the sensitive top plate through passivation and packaging dielectrics." Id. at 66-68. The claimed tri-layered structure improves noise shielding. The first and third layers are connected together and operate "to shield . . . the second conductive layer, from noise resulting from external sources or from the semiconductor substrate." Col. 2, ll. 19-24; col. 4, ll. 8-11 ("The upper metal plate 38 is operable to shield the shielded plate 36 from noise resulting from signals that are disposed above the plate 38.").

E. "Computer-Implemented Method/Steps."

The term "computer-implemented method" appeared in the preamble of each of claims 1-43 of the '381 patent. The preamble recited "[a] computer-implemented method for renting movies to customers." The term "computer-implemented steps" was recited in the preamble of independent claims 1, 16, and 31 of the '450 patent. Each of those claims recited "[a] method for renting items to customers, the method comprising the computer-implemented steps of . . . ."

(1) Limiting Claim Preambles.

The first issue is whether the preamble to these claims is limiting. "In general, a preamble limits the invention if it recites essential structure or steps, or if it is 'necessary to give life, meaning, and vitality' to the claim. Conversely, a preamble is not limiting where a patentee defines a structurally complete invention in the claim body and uses the preamble only to state a purpose or intended use for the invention." Catalina Marketing Intl., Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002) (internal citations omitted). Clear reliance on the preamble in prosecution history transforms the preamble into a
claim limitation because it indicates that the patentee used the preamble to define the claimed invention. Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1367 (Fed. Cir. 2003).

The file history of the '381 patent is instructive in this instance. In an office action dated October 29, 2004, the examiner rejected the application under 35 U.S.C. 101 for being drawn to non-statutory subject matter. The examiner explained (Ramani Decl. Exh. 11):

In the present case, claims 55-94 only recite an abstract idea. The recited steps of establishing, causing to be delivered, selecting and updating does [sic] not apply, involve, use or advance the technological arts since all of the recited steps can be performed in the mind of the user or by use of a pencil and paper. The terms "computer-implemented" and "Internet," as claimed, do not obviate this line of reasoning . . . . The computer need not be present to execute these steps, and if executed may merely be given by hand (digital data) or orally.

It is worth noting that the phrase "computer-implemented" was present from the beginning of the prosecution of the '381 patent; it was not added in response to this rejection. The applicants traversed the examiner's rejection in the remarks saying that the examiner did not heed the express limitation that all steps of the process were performed by a computer. Specifically, they argued (id. at Exh. 12):

Technology is used to provide electronic digital information that causes attributes of movies to be displayed to the user, to establish multiple, electronic movie rental queues each associated with a particular customer, to store the movie rental queue information, to update the movie rental queue, and to cause the selection of movies to be delivered to the customer, all without any human mediation on the part of the renting enterprise.

With this statement, the applicants disclaimed any inventions teaching the use of anything other than electronic means to carry out the claimed steps.

Blockbuster argues that the specifications of both patents show that the method is not limited to rental using computers. They quote ('450 patent at col. 14:24-34; '381 patent at col. 12:54-64):

In the foregoing specification, the invention has been described as applying to an implementation anticipating Internet-based ordering and mail or other long- distance delivery of the items, where the special advantages of the method are very attractive. However, the same invention may be applied in a more conventional video, games, or music rental-store setting, where subscription customers may be allowed rentals of a specified number of movies, games, or music selections at any time, and/or in one subscription period, without rental return due dates, in exchange for a periodic rental subscription fee.

It is true that Netflix has not limited itself to ordering and delivery over the Internet. The above passage anticipates having the customer input information to the system in ways other than from their own computer. It does not indicate that any of the claimed steps of selecting items, causing items to be sent, etc., are performed by anything other than a computer. This passage addresses ordering and delivering the items; these are steps performed by the customer, not by the system. Accordingly, this order holds that the preamble reciting "computer-implemented method/steps" adds a limitation to the claims.

Blockbuster argues that some of the steps, such as delivery, cannot be performed by a computer, so the preamble should not be held to be a limitation on all of the recited steps. Defendant misstates the claims. Modern technology has of course not developed a computer that can physically deliver a DVD by itself. A computer can, however, cause a DVD to be delivered and it can select a DVD to be delivered as taught in the '381 patent. It can even provide a DVD by giving an order for it to be sent to a customer, as taught in the '450 patent.

(2) Construction.

Secondly, as with the disputed term "electronically updating," parties disagree over whether the updating function is performed by the provider's computer or by some other device under someone else's control. As with "electronically updating," it is clear that the information is coming in from the customer. The claims and the specification do not make clear that the steps are being carried out by the provider's computers. Again, Netflix reads a limitation from its preferred embodiment into the claims. Netflix's argument omits a crucial step. It contends that because all the steps occur after
information is received from a customer, it necessarily follows that the steps are performed by the provider's computer. The argument fails because the specification and the claims did not exclude the use of all other computers in performing the steps. Accordingly, this order will not import that limitation into the meaning of "computer-implemented."

Finally, Blockbuster argues that the Court should define the term "computer," another commonly-used word from the English language. As such, the term is understood to mean a programmable device that can electronically process, store and retrieve information. Merriam-Webster, Ninth New Collegiate Dictionary, 1984. Blockbuster's proposed definition would cause more confusion than it would clear up. The above definition of "computer" will be used. "Implemented" is generally understood to mean "carried out" or "accomplished."

Accordingly, this order holds that "computer-implemented" adds a limitation to each element of the claims in which it appears in the preamble. "Computer-implemented" will have its ordinary meaning, but will not be confined to the provider's computer.

(b) ... comprising the steps of...

The parties disagree whether the phrase "comprising the steps of" mandates the steps that follow to be taken in the order they are listed within the claim. The recited steps are:

a. establishing a charge for paying the lifetime payments after the account value reaches zero in accordance with the guarantee;

b. using a computer:

1. determining an initial benefit payment;

2. determining a subsequent periodic payment; and

3. periodically determining the account value;

c. periodically paying the initial payment and the subsequent payment and reporting the account value to the beneficiary.

The Defendant does not address the established usage of the phrase "comprising the steps of." Rather, it argues that the steps make sense only if they are carried out in the listed order. The Plaintiff counters this assertion by submitting a specific meaning of the phrase and by insisting that no certain order is mandated by the logic or grammar of the steps.

Generally, absent specific recitation of order, steps of a method are not construed to have particular order. See Altiris, Inc., 318 F.3d at 1369-71 (Fed. Cir. 2003). Barring the steps of determining the amount of payments, paying the payments, and determining the account value, Claim 1 is not an exception to this rule. The logic of the steps does not mandate the order in which the payments are determined. For example, there is no inherent requirement to determine the subsequent payments only after the amount of the initial payment is decided. The amounts of these payments are dependent variables but can be set in any order. Similarly, the charge for paying the lifetime payments after the account value reaches zero can be set either before or after the initial and subsequent payments have been determined. Of course, following a certain order to determine the amount of payments and charges may make better business sense, but that is different from a mandated order. A requirement for a valid patent is that it is functional, not that it is perfect.

That the order of the steps is not set in stone is also confirmed by the ordinary meaning of the phrase "comprising the steps of." This phrase connotes an open ended claim that allows additional steps. See Medichem, S.A. v. Rolabo, S.L., 353 F.3d 928, 933 (Fed. Cir. 2003) ("The transition 'comprising' in a method claim indicates that the claim is open-ended and allows for additional steps."). Since the claim is not foreclosed to additional steps, the steps themselves are not foreclosed from being carried out in a different order than stated in the claim.
1. The term "in response" in claims 3, 8, 9, 19, 20, and 25 is construed to mean "as a consequence of." 1

2. The term "off" in claims 3 and 20 is construed to mean "the lowest power state of the monitor or circuit that can be achieved by the power management system where the monitor is still able to reactivate itself."

3. The terms "general purpose computer" or "computer" in claims 9, 14, and 24 are construed to mean "a programmable electronic device that can store, retrieve, and process data."

U.S. Patent No. 5,648,799

1. The term "in response" in claims 1, 36, 85, 98, 103, 107, 139, and 150 is construed to mean "as a consequence of."

2. The terms "general purpose computer" or "computer" in claims 1, 36, 73, 80, and 136 is construed to mean "a programmable electronic device that can store, retrieve, and process data."

12. "Computer" & "Browser"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Browser/web browser&quot;</td>
<td>Plain and ordinary meaning. Alternatively, this term means &quot;an application for browsing a network, such as the web&quot;</td>
<td>A device having a processor for processing data</td>
</tr>
<tr>
<td>&quot;computer&quot;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The Cell Phone Defendants separately propose the construction of few terms. The first dispute is over the scope of the "computer" terms. 6 Fotomedia points out that the specification discloses "any other computer capable of running a standard web browser." '774 patent, at col. 6 ll. 44-53. The Cell Phone Defendants seek to limit the term "computer" to a "personal computer" wherever it is used. The Court finds this limitation is unwarranted.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 The parties dispute the construction of the terms "computer," "receiving computer," and "sending computer." For each of these terms, the Cell Phone Defendants seek to limit its scope to a "personal computer."

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

A "computer" is "a device that processes data."

With regard to the "browser" terms, the Cell Phone Defendants seek to import two different limitations to the construction of the term "browser" - a personal computer and HTML documents. In response, Fotomedia notes that the specification discloses images (such as GIF or JPEG) that are also viewable in a web browser. See '774 Patent at col. 12 ll.30-33. Further, the specification discloses a Java-enabled browser. A Java-enabled browser would be capable of displaying more than just HTML pages. At a minimum, such a browser could display applications written in a version of Java. Therefore, the Court rejects the defendants' proposed construction of this term.
A "browser" is "a computer application for browsing a network, such as the internet."

1. "computer" and Related Terms

The issues regarding these terms are (1) whether the court should include a limitation, as the defendants suggest, indicating that a computer cannot be a microprocessor or microcontroller, and (2) whether all four terms should have the same general construction.

Regarding the defendants' limitation, the defendants argue that the patentee expressly disclaimed embedded microprocessors and microcontrollers. In support, they cite portions of the prosecution history in which the patentee attempts to distinguish the present invention from U.S. Patent No. 5,841,865 ("the Sudia patent"). See Ex. 16-17 of Defs.' Claim Construction Brief. The Sudia patent discusses RNGs that are interfaced to microcontrollers. See the Sudia Patent, col. 13, ll. 35-65. In response to the examiner's discussion of the Sudia patent, the patentee declared, "[a]n embedded microprocessor, or microcontroller, taught in Sudia '865, is designed for a specific task to control a particular system. The embedded microcontroller of Sudia '865 is supposed to conduct specifically programmed functions related to encryption and decryption and is not operable to conduct other functions." See Ex. 17 of Defs.' Claim Construction Brief.

Claim 1 of the '242 patent contemplates a RNG interfacing with a general-purpose computer. See '242 Patent, cl. 1. As indicated by the prosecution history, the present invention does not contemplate a scenario in which the RNG directly interfaces only with a microprocessor that performs only one function and is divorced from a general purpose computer. Indeed, both parties concede that a stand-alone microprocessor is not a computer. The operative fact of the disclaimer contained within the prosecution history is the scope of the capabilities of the microprocessor, not the fact that it is embedded, stand-alone, or otherwise. The disclaimer does not preclude an interface with a microprocessor capable of performing multiple tasks or one that is part of a general-purpose computer.

The court will not typically define a term in the negative, but in light of the parties' stipulation and the discussions contained within the prosecution history, the court will do so in this instance. See Hutchins v. Zoll Med. Corp., 492 F.3d 1377, 1381 (Fed. Cir. 2007). Such construction falls squarely in line with the court's duty to define the scope of a term, as well as its meaning, when both are contested. See O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351 (Fed. Cir. 2008).

The second issue is whether all of the "computer" terms have the same meaning. Quantum relies on a claim differentiation argument, while the defendants, again, cite to portions of the prosecution history. See Ex. 17-19 of Defs.' Claim Construction Brief. The court concludes that "computer" and "general purpose computer" mean the same thing. In addition, "personal computer" and "general purpose personal computer" should be construed consistently.

Accordingly, the court defines "computer" and "general purpose computer" as follows: "a programmable machine that is operable to conduct a wide variety of tasks using a variety of applications programs that can be accessed and operated. The term does not include a microprocessor or microcontroller that is operable to conduct only a single, specific task."

The court defines "personal computer" and "general purpose personal computer" as follows: "a computer designed for use by one person at a time, such as a desktop PC or a laptop."

G. "computer readable medium," as used in claims 9, 10, and 14.

In the claimed invention, a "computer readable medium" is the device in which http clients and servers house executable
program instructions and state information. In the course of the September 25, 2009 claim construction hearing, the parties sensibly agreed that "computer readable medium" means "storage device." Importantly, this construction is fully supported by the plain and ordinary meaning of the claim term, read in light of the specification. See Phillips, 415 F.3d at 1313. For example, claim 14 makes clear that storage is the key function of the computer readable memory; it houses both state information in the form of a state object and executable program instructions. See also '670 Patent Specification col. 5 11. 5-10 (confirming storage function). Accordingly, "a storage device" is an appropriate claim construction for "computer readable medium." 19

--- Footnotes ---

19 It is worth noting that both parties' initial proposed constructions run afoul of settled claim construction principles. Specifically, defendants' proposed construction, "a magnetic or optical mass storage device," relies on a specification passage that teaches: "The server will typically include . . . a computer readable medium, such as a magnetic ("hard disk") or optical mass storage device." '670 Patent Specification col. 2 11. 41-44 (emphasis added); see also id. col. 5 11. 5-10. Significantly, the use of "such as" signals the use of an example; it does not indicate that the patentee is providing a definition. See Catalina Mktg. Int'l v. Coolsavings.com, Inc., 289 F.3d 801, 811 (Fed. Cir. 2002) ("'[S]uch as' introduces an example of a broader genus rather than limiting the genus to the exemplary species."). This rule dovetails with the well-established principle that the specification cannot be used to limit patent claims. See Nazomi, 403 F.3d at 1369.

On the other hand, plaintiff's proposed construction, "memory," contravenes the presumption "that the use of . . . different terms in the claims connote different meanings." CAE Screen Plates v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308, 1317 (Fed. Cir. 2000). Here, claim 14 refers to both "a memory coupled to said processor" and "a computer readable medium coupled to said processor." '670 Patent Claim 14. The claim further directs that a state object be stored "in one of said memory and said computer readable medium." Id. Consequently, the claim term "computer readable medium" cannot mean "memory" because such a definition would render part of the claim language superfluous and redundant. See In re Gabapentin Patent Litig. 503 F.3d 1254 (accepting district court's construction because it "gives full meaning to every word of the entire claim term"); Bicon, Inc. v. Straumann Co., 441 F.3d at 950 (refusing construction that would leave a claim term with no meaning).

--- End Footnotes ---

A. Claim Construction

Pickholtz argues that the district court erred when it construed the term "computer" to exclude peripherals. He urges that whether a "computer" includes peripherals is unanswered by the intrinsic evidence and that we should therefore turn to the extrinsic evidence that supports his broader construction. He argues that "computer system" and "computer," as used in his patent, are synonymous. He further argues that the court's construction is wrong because a computer without peripherals would be incapable of accepting input or yielding output and therefore would be useless.

Pickholtz also contends that the court misconstrued the phrase "located in the computer" to mean "in the CPU, main memory or on the CPU circuit board, but excluding connected peripherals." First, he argues that the court's construction is inconsistent with the claims' requirement that the PRN generator device be in a sealed casing, with the specification's teaching that the PRN generator device is installable by the user on-site, and with the depiction in Figure 1 of the PRN generator device 22 as being separate from the CPU 12 and the main memory 14. Secondly, he argues that the court's construction of the phrase "located in the computer" is inconsistent with the court's construction of the term "computer" because the latter does not include the CPU circuit board. Thirdly, he urges that he did not distinguish his invention over Thomas during prosecution on the basis of the location of the PRN generator device.

Rainbow responds that the court's construction is the unambiguous result of the intrinsic evidence. Rainbow draws attention to the fact that the patent claims refer to a "computer," whereas the specification describes a "computer system" with reference to Figure 1. Thus, according to Rainbow, a "computer" is something less than a "computer system." Rainbow also defends the court's construction of the phrase "located in the computer" by arguing that it is consistent in part with the
In summary, we construe the phrase "located in the computer" to mean "located in the CPU, main memory, the CPU or main proximity to the CPU. Certainly such a peripheral, as it indisputably connects substantially directly to the CPU circuit board and is in close proximity to the CPU, or else the phrase "in" would become meaningless. A peripheral distinctly connected reasonably cannot be "in the computer." Therefore, not everything somehow connected to a CPU can be a peripheral in the sense of being part of the "computer." At the very least, however, the term "computer" encompasses peripherals that are within a reasonable proximity to the CPU and its main memory and directly connected to the CPU or the CPU circuit board. We need not, and indeed cannot, attempt to precisely define which peripherals may be part of the "computer" as used in the '353 patent for all cases. See EMI Group N. Am. v. Intel Corp., 157 F.3d at 887, 895, 48 USPQ2d 1181, 1187 (Fed. Cir. 1998) ("It is irrelevant whether the district court achieved a technologically perfect definition, because there is no dispute that the corresponding step of the Intel process is within the literal scope of [the claim limitation]. Thus we do not attempt to decide, de novo, the correct meaning of [the claim limitation]."). The accused device in this case is certainly such a peripheral, as it indisputably connects substantially directly to the CPU circuit board and is in close proximity to the CPU.

In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vitronics Corp. v. Conectronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1577 (Fed. Cir. 1996). Only if a disputed claim term remains ambiguous after analysis of the intrinsic evidence should the court rely on extrinsic evidence. 90 F.3d at 1583, 39 USPQ2d at 1577. We agree with Rainbow that the proper construction of the term "computer" follows without ambiguity from the intrinsic evidence; however, that construction is not as Rainbow contends. Instead, we agree with Pickholtz that the '353 patent uses the terms "computer" and "computer system" as synonyms. Although we would typically be inclined to give meaning to the word "system," rather than regard it as surplusage, see Elekta Instrument, 214 F.3d at 1307, 54 USPQ2d at 1913, the patent in this case provides no indication that the two terms mean different things. Instead, the patent uses the term "computer system" in the specification and the term "computer" in the claims; nothing in the patent itself explicates their relationship or indicates any difference in meaning.

The remaining intrinsic evidence, the prosecution history, does not compel a different result. Pickholtz originally submitted the claims in vastly different form, referring to the invention as part of a "data processing system" and reciting "a pseudorandom number generator at the data processing system." Pickholtz changed the claims into their allowed form after the PTO rejected the claims as being obvious in light of the Thomas patent. Although Thomas clearly uses the terms "computer" and "computer system" in a part-whole relationship, '519 patent at fig. 2, col. 5, ll. 18-25, Pickholtz did not distinguish his invention over Thomas on the basis of any difference between a "computer" and a "computer system." Despite Pickholtz's argument to the PTO that Thomas lacks a "[PRN] generator device located in the computer," Thomas clearly discloses PRN generating software, and that software is located in the core "computer" part of Thomas's "computer system." '353 patent at col. 4, ll. 37-48 (disclosing that the PRN generator is software loaded into the working memory and executed by the CPU). Pickholtz's argument, although inaptly stated, can only be understood to mean that he considered Thomas's software to not contain a PRN generator at all. Thus, although Pickholtz may have been casual and gratuitous in amending his claims and making arguments to distinguish over the Thomas patent, nothing in the prosecution history convinces us that the terms "computer" and "computer system" in the '353 patent have different meanings, even if they might have in the Thomas patent.

Accordingly, the district court erred when it concluded that the intrinsic evidence unambiguously imparted different meanings to the terms "computer" and "computer system." On the contrary, they are used interchangeably in the '353 patent. Because the meaning of the term "computer" can be resolved from the intrinsic evidence alone, we need not rely on any extrinsic evidence, see Vitronics, 90 F.3d at 1582, 39 USPQ2d at 1577, which in any event is not conclusive. While Pickholtz advanced a number of technical dictionaries defining "computer" as inclusive of peripherals, as well as expert testimony to the same effect, Rainbow disputed the meaning of those technical dictionaries and offered contrary expert testimony.

Furthermore, as the patent's specification includes one peripheral, a disc "reading means," as part of the "computer system," '353 patent at col. 6, ll. 11-12; fig. 1 (disc 18), the synonymous term "computer" in the claims must include at least some peripherals. However, the term "computer" cannot be so unbounded as to include all devices connected in any way to the CPU, or else the phrase "located in the computer," and particularly the word "in," would become meaningless. A peripheral distinctly connected reasonably cannot be "in the computer." Therefore, not everything somehow connected to a CPU can be a peripheral in the sense of being part of the "computer." At the very least, however, the term "computer" encompasses peripherals that are within a reasonable proximity to the CPU and its main memory and directly connected to the CPU or the CPU circuit board. We need not, and indeed cannot, attempt to precisely define which peripherals may be part of the "computer" as used in the '353 patent for all cases. See EMI Group N. Am. v. Intel Corp., 157 F.3d 887, 895, 48 USPQ2d 1181, 1187 (Fed. Cir. 1998) ("It is irrelevant whether the district court achieved a technologically perfect definition, because there is no dispute that the corresponding step of the Intel process is within the literal scope of [the claim limitation]. Thus we do not attempt to decide, de novo, the correct meaning of [the claim limitation]."). The accused device in this case is certainly such a peripheral, as it indisputably connects substantially directly to the CPU circuit board and is in close proximity to the CPU.
memory circuit boards, or qualifying peripherals” as indicated above. In view of that construction, it necessarily follows that the Rainbow dongle, when attached to a computer port, is such a peripheral and is therefore "located in the computer." No reasonable juror could conclude otherwise.

II. "[C]omputer"

Plaintiffs fail to provide a distinct definition of the claim term "computer." (R. 82, Pls.' Mem. at 15-16.) Instead, they ask the Court to construe the term "principal market maker . . . computer," and propose the following definition: "a computer that independently performs each and every function of the principal market maker (as construed) separate from and without being incorporated into any other clearing or trading system, computer or engine (including the GLOBEX and Project A systems)." (R. 82, Pls.' App., Ex. 1.) The Court finds that this definition is not only circular with respect to its construction of the term "computer," but also seeks to import limitations that are not located in the claim language.

In support of their position, Plaintiffs first draw the Court's attention to the '923 patent's specification and argue that language contained in the specification require the "principal market maker . . . computer" to perform its functions "separate from and without being incorporated into any other clearing or trading system, computer or engine." (R. 82, Pls.' Mem. at 15.) Plaintiffs' argument fails as it improperly seeks to import a limitation from the written description. See Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 906 (Fed. Cir. 2005) ("The court must take care in its analysis, when locating in the written description the context for a disputed term, not to import a limitation from that written description. It must use the written description for enlightenment and not to read a limitation from the specification."). Their argument based on the patent figures and their accompanying text is similarly unavailing as it impermissibly attempts to use a preferred embodiment to limit the claims without an express declaration by the patentee. See id. at 907-08 ("Claims of a patent may only be limited to a preferred embodiment by the express declaration of the patentee"). Plaintiffs do not to point to such an express declaration by Garber, and fail to do so for good reason: Garber clearly stated that the descriptions provided in the specification were "illustrative rather than limiting." '923 patent col. 10, l. 45.

Claim terms are generally given their "ordinary and customary meaning," which is the meaning the term would have to a person of ordinary skill in the art in question at the time of the invention, i.e., as of the effective filing date of the patent application. Phillips, 415 F.3d at 1312-13. In some cases, "the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314 (citing Brown v. 3M, 265 F.3d at 1352). Where the ordinary meaning is readily apparent, the Federal Circuit has noted that general purpose dictionaries may be helpful in construing a claim term. Id.; see Vitronics, 90 F.3d at 1584 n.6 (Judges may "rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents.").

Here, the Court finds that the claim term "computer" has a readily apparent meaning. As such, the Court will rely upon general purpose dictionaries and will construe "computer" as follows: "a programmable electronic device that can store, retrieve, and process data." 14

14 The Court relies upon the most relevant definitions found in the following two general purpose dictionaries: (1) Webster's Third New International Dictionary 468 (1981) (defining "computer" as "a programmable electronic device that can store, retrieve, and process data"); and (2) Merriam-Webster's Collegiate Dictionary 256 (11th ed. 2003) (defining "computer" as "a programmable usu. electronic device that can store, retrieve, and process data").
A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. #292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>

780

I. "computer"

Although "computer" is found without a modifier in many instances throughout the specification and claims, the term appears to be used interchangeably with "attraction computer." This conclusion is supported by the figures and the specification. In Figure 1, which is "a block diagram of a system according to the present invention," col. 4, ll. 7-8, the only computers included are attraction computers. (See also col. 5, ll. 2-4.) Similarly, Figure 6 illustrates the manner in which the attraction computer operates in accordance with the present invention. (col. 4, ll. 50-51.) As more direct evidence that the terms are synonymous, where "computer" is used in the specification instead of "attraction computer," the reference is to "computer 101" which corresponds with the attraction computer in Figures 1, 2, and 6. (col. 11, l. 66; col. 12, ll. 38, 47-48; col. 13, l. 19; col. 17, ll. 1, 35-36, 43, 57; col. 18, ll. 5, 16, 26; col. 19, l. 51.) Furthermore, in the section titled "Attraction Computer Operation," the specification alternates between "attraction computer" and the shorthand reference to "computer," thereby evidencing the fact that the two terms are interchangeable. (col. 20, l. 5 to col. 22, l.51.) Therefore, the ordinary meanings of "computer" and "attraction computer" are identical in the context of the present invention.

The specification essentially defines this term by stating that attraction computers are implemented with: (1) a microprocessor or central processing unit (CPU); (2) random-access memory; (3) disk storage; (4) input device such as a keyboard or mouse; and (5) output device such as a display screen; and (6) wireless communication hardware and software. (col. 5, ll. 15-29.) Additionally, the specification provides that the attraction computers may be: (1) components of a single computer system or group of computer systems wherein each component may be a distinct processor or processing node within the computer or group; or (2) separate computers that are physically disposed at or near the associated attractions. (col. 5, ll. 5-12.) Despite the fact that the specification describes two acceptable structures for the attraction computer, the Defendants' proposed construction limits the "attraction computer" to "a stand-alone computer physically disposed near one of the attractions." n5 On the other hand, the Plaintiff's proposed construction is consistent with the specification: "a computer system including one or more processors, storage devices, and associated hardware/software/peripheral
components, where the peripheral components may be distinct processors or processing nodes capable of processing information." Therefore, modifying the Plaintiff's construction to reflect the specification more accurately, the Court construes "computer" and "attraction computer" as "a computer system including a processing unit, random-access memory, disk storage, input and output devices, applicable wireless communication hardware and software, which may be implemented as: (1) a distinct processor or processing node within a computer system or group of computers; or (2) a separate computer physically disposed at or near its associated attraction."

n5 The Defendants do not propose a construction of "computer," deeming it inappropriate to do so out of context.
2. "computer"

This term appears in both the '366 patent and the '408 patent. It appears in the '366 patent claims 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 29, 30, 31, 32, 33, 34, 35, 37, 38, 39, 44, 45, 46, and 47; and in all claims 1-17 of the '408 patent.

Rackable contends that "computer" means "general purpose computer including a main board and additional components, such as a server." Supermicro contends that "computers" means "a device capable of processing information to produce a desired result."

The essence of this dispute is whether, as Rackable contends, "computer" refers to a general purpose computer like a server, or whether it is even more generic, as argued by Supermicro.

Rackable argues that the patent specification clarifies that the patent targets problems related to densely packed data centers. Because computers in data centers are general purpose computers, it asserts that its construction is consistent with the specification. Rackable contends that Supermicro's construction is contrary to the patent. It asserts that according to defendant, "computer" would include all processing devices -- not just computers in a data center environment.

Supermicro argues that its construction is consistent with the specification, and that several technical dictionaries support its construction as well. It contends that Rackable seeks to improperly read limitations into the claim terms that do not exist. It further notes that the phrase "general purpose computer," as urged by Rackable, does not exist anywhere in the specification, in a dictionary; nor is it supported by expert testimony.

At the October 4, 2006 hearing, the court indicated that it did not find either parties' constructions convincing. The court noted that Supermicro's definition was too generic, and that Rackable's attempt to limit the definition to a "general purpose" computer, a phrase not employed by or defined by the specification, was also problematic. However, because the court believed that construction is a matter for the parties in the first instance, it afforded the parties an opportunity to meet and confer regarding the term in light of the court's stated concerns. The parties subsequently notified the court that they were unable to reach an agreement regarding construction of "computer."

Accordingly, the court declines to adopt either parties' construction, and construes "computer" as a computer that functions as a server. For the reasons noted on the record at the hearing, Supermicro's construction is too generic. As for Rackable's proposed construction, it not only improperly reads in limitations from the specification, but it inserts language that improperly modifies the term "computer." Because there is nothing in the intrinsic evidence to suggest the ordinary meaning of "computer" was not meant to apply, the court finds no need to further define "computer" other than that it should function as a server.

"Computer"

The Court adopts Soverain's construction and defines "computer" to mean "a functional unit that can perform substantial computation, including numerous arithmetic operations, or logic operations without human intervention." This definition reflects the ordinary meaning to one skilled in the art. See IEEE Standard Dictionary of Elec. & Elecs. Terms, at 192 (6th ed. 1996). The Court rejects Amazon's proposed definition, which limits a "computer" to a single device, because it is inconsistent with the IEEE definition and the specifications, which do not require the computers to be dedicated to a single unique function.
A. "Computer"

Claim 1 repeatedly uses the term "computer:" (1) col. 6, 1. 4-5 ("for use with a computer"); (2) col. 6, 1. 12 ("located in the computer"); (3) col. 6, 1. 13-14 ("located in the computer"); and (4) col. 6, 1. 23 ("located in the computer").

1. The disputed constructions

Plaintiff urges the Court to construe "computer" to mean "one or more processing units and the memory, peripherals and other devices connected electronically to and communicating with the processing units." (Emphasis added).

Defendant proposes that "computer" be defined as "the CPU and main memory on the CPU's circuit board, which, taken together, form a part of a dedicated microprocessor system capable of executing instructions on data, and which exclude connected peripheral devices." (Emphasis added).

The primary distinction between the two definitions is that plaintiff interprets "computer" to include devices electronically connected to the processor, such as printers, servers, keyboards, and monitors, while defendant's definition excludes such "peripherals."

2. Analysis

"Computer," as used in claim 1, does not include peripherals.

First, defendant's construction is consistent with the specification. Figure 1 in the specification includes a CPU (central processing unit) and main memory (which together constitute defendant's definition of "computer") as well as a disc drive (no. 18 on Fig. 1). The entire device in Figure 1 is described as a "computer system." Col. 2, 1. 66 (emphasis added); see also Col. 3, 1. 4-5 (the CPU and main memory are "preferably components of a computer system") (emphasis added); Col. 3, 1. 10-11 ("Operation of such a system is described . . .") (emphasis added). The claim, however, consistently refers to a "computer" rather than a computer "system." Thus, the plain language of the patent suggests that a "computer" is different from a "computer system."

Second, the claim also repeatedly uses the term "located in the computer," for example, the pseudorandom number ("PRN") generator device is "located in the computer." If "computer" is interpreted as broadly as plaintiff urges, "located in the computer" is unnecessary; the PRN generator device must be located in the computer, that is, it has to be connected electronically to the controller and main memory. Thus, computer as used in claim 1 cannot simply mean connected electronically to the controller and main memory.

Third, Figure 1 shows the PRN generator "located in the computer" as defendant defines the term, that is, as part of the microprocessor system.

In sum, the intrinsic evidence unambiguously demonstrates that "computer" as used in claim 1 of the '353 refers to the microprocessing system and not the microprocessing system and everything electronically connected to it, including printers, disk drives and similar devices. Since the intrinsic evidence, that is the ordinary meaning of the term as used in the patent, is unambiguous and "answers the question," the Court need not consider plaintiff's extrinsic evidence.

Plaintiff's extrinsic evidence, in any event, is ambiguous, unpersuasive or supports defendant's definition of computer. For example, plaintiff identifies a patent examiner's report dated May 1, 1991 rejecting one of defendant's own patent applications as evidence of the meaning of "computer." The examiner's report, however, confirms that "computer" in the context of the '353 is not as broad as plaintiff contends. The examiner describes the '353 as

permanently establishing a first key in a hardware device (external memory 18 of Figure 1), providing and storing a second key in a hardware device . . ., connecting the hardware device having the first key and the second key stored therein into a computer . . . for establishing a communications path between the hardware device and the computer.
May 1, 1991 Report at 3 (Exhibit 21 to Pickholtz Decl.) (emphasis added). Thus, the examiner distinguished between the hardware device (a peripheral) and a computer. One could not connect external memory into a computer if the external memory is the computer. Similarly, one cannot establish a communications path between external memory and a computer if the external memory is the computer; that would be establishing such a path between the computer and itself. Thus, this extrinsic evidence confirms the Court's construction of "computer." See also id. (stating that a person of ordinary skill in the art would have been motivated to use conventional structure for "connecting a peripheral component such as external memory to a computer") (emphasis added).

Plaintiff also contends that because the patent refers to a book, "Microprocessors and Microcomputers," col. 3, l. 12 ("Operation of such a system is described in detail in a number of available references . . ."), the definition of digital computer in the book is intrinsic evidence supporting plaintiff's broad construction of "computer." Plaintiff's argument fails.

First, the definition in the book is inadmissible extrinsic evidence which contradicts the ordinary and unambiguous meaning of "computer" as gleaned from the language of the patent. See Key Pharmaceuticals, 161 F.3d at 717. Plaintiff cites no authority for the proposition that because a patent specification states that the operation of some device is described in some book, the contents of the book convert from extrinsic to intrinsic evidence.

Second, the reference to the book in the '353 actually states that the operation of a computer system is described in detail in the book. Thus, the patent is referring the reader to the book for a definition of a computer system (as is described in Fig. 1 of the '353), not the definition of "computer" as used in Claim 1.

3. COMPUTER

Defendants object to the use of a plain meaning approach to defining computer because of a lack of specificity, pointing to questions which would not be resolved by such a general definition, such as whether a computer necessarily must be "at a workstation." Defendants are correct that a general definition of "computer" does not answer this question or many other specific questions concerning the attributes of computers. Nor does the Patent provide an answer to such questions; nor must this Court. Defendants have pointed to no instance in the specification where the term "computer" is given anything other than its ordinary meaning, notwithstanding references to the specification where the computer in Fig. 1 thereof is described as having a CPU, system memory, and an operating system. None of these attributes constitute a usage of the word "computer" which falls outside the word's normally accepted usage, requiring the Court to adopt the preferred embodiment as an idiosyncratic definition. Nor does it appear so clearly that the drafter was attempting to circumscribe the definition of "computer" with regard to each usage of the word that he should be perceived to have been exercising his role as a lexicographer.

As explained by the court in In re Paulsen, 30 F.3d 1475, claims construction does not properly involve "a post hoc attempt to redefine the claimed invention by impermissibly incorporating language appearing in the specification into the claims." The Paulsen court explains further:

Although "it is entirely proper to use the specification to interpret what the patentee meant by a word or phrase in the claim, … this is not to be confused with adding an extraneous limitation appearing in the specification, which is improper. By 'extraneous,' we mean a limitation read into a claim from the specification wholly apart from any need to interpret … particular words or phrases in the claim."

Id. at 1480 quoting E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, (Fed.Cir. 1988). Conveniently, the plain meaning definition for "computer" also is found in In re Paulsen, 30 F.3d 1475 (Fed.Cir. 1994):

The term "computer" is not associated with any one fixed or rigid meaning, as confirmed by the fact that it is subject to numerous definitions and is used to describe a variety of devices with varying degrees of sophistication and complexity. However, despite the lack of any standard definition for this ubiquitous term, it is commonly understood by those skilled in the art that "at the most fundamental level, a device is a computer if it is capable of carrying out calculations."
A COMPUTER is a device capable of carrying out calculations.

A. A computer-aided design process for designing

Ricoh contends that the term means "during manufacture of a desired application specific integrated circuit (ASIC) chip . . . a process of designing the desired ASIC using a computer." Aeroflex Inc. and Synopsys, Inc. ("Aeroflex") state that the term means "a process that uses a computer for designing, as distinguished from a computer-aided manufacturing process, which uses a computer to direct and control the manufacturing process." In essence, the parties' fundamental disagreement revolves around whether the computer-aided design process described in claim 13 also encompasses the ASIC manufacturing process.

Ricoh bases it proposed construction on the text of the patent specification. Specifically, Ricoh directs the Court to language in the specification that states that "the present invention, for the first time, opens the possibility for the design and production of ASICs by designers, engineers and technicians who may not possess the specialized expert knowledge of a highly skilled VLSI design engineer." '432 patent, col. 2:15-20 (emphasis added). Ricoh also emphasizes that the present invention produces a "physical chip layout level description [that] provides the mask data needed for fabricating the chip." '432 patent, col. 1:42-44; see also '432 patent, col. 3:68 - 4:4 ("FIG. 1c illustrates a physical layout level representation of an integrated circuit design, which provides the detailed mask data necessary to actually manufacture the devices and conductors which together comprise integrated circuit.").

Aeroflex argues that Ricoh's proposed construction is contrary to the '432 patent's claims and specifications. Specifically, Aeroflex focuses on the claim language that provides that the invention is a "computer-aided design process for designing . . ." '432 patent, col. 16:34. Aeroflex also directs the Court to specification language that states the invention "relates to the design of integrated circuits, and more particularly relates to a computer-aided method . . . for designing integrated circuits." '432 patent, col. 1:9-12.

Ricoh's proposed definition is problematic because it clearly attempts to blur the line between the process of designing integrated circuits and the process of manufacturing integrated circuits. Nothing in the claim language supports Ricoh's attempt to broaden the claims to include a manufacturing process for a desired ASIC. Rather, the claim language describes a "computer-aided design process for designing an [ASIC] . . ." '432 patent, col. 16:34-35. Likewise, the specification consistently describes a design, rather than a manufacturing, process. In fact, the term "manufacture" does not appear in the claim or specification language. 3 While the "netlist" may be required to "produce the particular [ASIC]." see '432 patent, col. 2:44-49, that does not compel the conclusion that the '432 patent's design process is inherently a part of the manufacturing process of the actual ASIC chips. Given the Court's "focus . . . on the objective test of what one of ordinary skill in the art at the time of the invention would have understood the term to mean," Markman, 52 F.3d at 985, the Court finds that the "computer-aided design process" described in claim 13 does not include a manufacturing process for ASICs.
3 In its reply, Ricoh focuses solely on the specification language that states "the present invention, for the first time, opens
the possibility for the design and production of ASICs by designers, engineers and technicians who may not possess the
specialized expert knowledge of a highly skilled VLSI design engineer." '432 patent, col. 2:15-20 (emphasis added).
However, this language, standing alone, does little to persuade the Court that the present invention was intended to
encompass the ASIC manufacturing process. Rather, a fair reading of this language is that the present invention simply
opened up the "possibility" that non-experts could produce or manufacture ASICs at some point in the future, but not that
the present invention currently encompassed such a process.

4 This conclusion is also bolstered by the language in claim 14. Claim 14 describes "[a] process as defined in claim 13,
including generating from the netlist the mask data required to produce an integrated circuit having the desired function."
'432 patent, col. 16:66-68. This language clarifies that the generation of the netlist (the final step in claim 13) and the
production of the integrated circuit are two distinct processes.

Given these considerations, the clearest reading of "A computer-aided design process for designing" is a process that uses a
computer to direct and control the design of an ASIC chip.

1) "computer-assisted method" (Preamble to Claim 1)

There are two disputes with respect to this term: whether this phrase, appearing in the preamble, should be read as a
restriction of what the claim covers, and whether "computer-assisted" necessarily requires the participation of a human
being.

As to the first question, whether the words of a preamble may be considered "limiting" depends on the function of the
Cir.1997)):

"In general, a preamble limits the invention if it recites essential structure or steps, or if it is 'necessary to give life,
meaning, and vitality' to the claim. Conversely, a preamble is not limiting 'where a patentee defines a structurally complete
invention in the claim body and uses the preamble only to state a purpose or intended use for the invention.'

Read in context, it is clear that the term "computer-assisted" is a critical feature of Claim 1, in the absence of which, Claim 1
is structurally incomplete. Thus the preamble gives "life, meaning and vitality" to the claim. Id. "Computer-assisted,"
therefore, should be read as a limitation. See id.

As to the second question, I find nothing in the claim language, specification or elsewhere to indicate that the claim requires
human involvement; a computer assisted method, for example, would well be understood by one skilled in the art to be one
in which the computer assists another device. All that the claim term suggests is that the method is one that requires some
activity by or with a computer.

After examining the term in context, see Phillips, 415 F.3d at 1314, I construe "computer-assisted method" to mean: "a
series of steps performed in part by a computer."

B. "user initiable computer … being programmed to vary the temperature of said heating and cooling system and thereby
to vary the temperature of said plurality of chambers in accordance with said polymerase chain reaction protocol upon
This claim is not in means-plus-function form. The presumption against such construction arising from the absence of the word "means" is not rebutted because the claim discloses to one skilled in the art sufficiently definite structure for programming a computer to vary the temperature of a heating and cooling system in accordance with a polymerase chain reaction protocol, namely, a computer programmed to vary the temperature of a heating and cooling system in accordance with "multiple cycles of the steps of thermal denaturation of double-stranded DNA, primer hybridization to single-stranded DNA, and template-dependent primer extension by a DNA polymerase." '493 Patent, col. 56, ll. 58-62. The prosecution history further contains evidence demonstrating that one skilled in the art would reasonably understand how to program a computer in accordance with a PCR protocol. See Applera Markman Declaration [Doc. # 678] Ex. 7 at PP 6-8, Ex. 8 at P 7.

D. '716 Patent

Claim 3 of the '716 patent is representative in pertinent part of all of the independent claims of the '716 patent at issue in this claims construction. Claim 3 reads:

A computer program product that identifies an unknown base in a sample nucleic acid sequence, comprising:

1. computer code that receives a first set of signals corresponding to a first set of probe intensities, each probe intensity in said first set indicating an extent of hybridization of a nucleic acid probe with a reference nucleic acid sequence, and each nucleic acid probe differing from each other by at least a single base;

2. computer code that receives a second set of signals corresponding to a second set of probe intensities, each probe intensity in said second set indicating an extent of hybridization of a nucleic acid probe with said sample sequence, and each nucleic acid probe differing from each other by at least a single base;

3. computer code that performs a comparison of at least one of said probe intensities in said first set and at least one of said probe intensities in said second set;

4. computer code that generates a base call identifying said unknown base according to results of said comparisons said sequence of said nucleic acid probe; and

5. a computer readable medium that stores said computer codes.

The central issue with respect to construction of the '716 patent claims concerns whether or not the disputed terms should be interpreted as "means-plus-function" terms according to 35 U.S.C. § 112, P 6. Although the disputed terms are not explicitly recited in "means-plus-function" language, Hyseq argues that claiming "computer code" followed by the function performed by the computer code still subjects these claim terms to 35 U.S.C. § 112, P 6. If § 112, P 6 is applied to the disputed terms, the terms would be limited to the specific structures or steps disclosed in the specification and their equivalents. Upon considering all of the arguments of both Hyseq and Affymetrix, the Court finds that § 112, P 6 does not apply to the terms recited in the form, "computer code that [performs x function]."

Because the disputed claim terms are not expressly recited in "means for" language, there is a presumption that § 112, P 6 does not apply. Mas-Hamilton Group v. La Gard, Inc., 156 F.3d 1206, 1213 (Fed. Cir. 1996). However, this presumption may be overcome if the terms are determined to be purely functional, without the additional recital of specific structure or material for performing the stated function. Id.; see also, Al-Site Corp. v. VSI Int'l, Inc., 174 F.3d 1308, 1318 (Fed. Cir. 1999). Hyseq asserts that "a computer code that receives a first set of signals," "a computer code that receives a second set of signals," "a computer code that performs a comparison," and "a computer code that generates a base call" are all purely functional recitations of claim elements. Specifically, Hyseq argues that "computer code" does not recite any definite structure necessary to escape § 112, P 6.

Although it is a close question, the Court disagrees with Hyseq. To overcome application of § 112, P 6, a claim term must
identify some specific structure that performs the stated function. Al-Site Corp., 174 F.3d at 1318. In Mas-Hamilton, for example, the Court held that "lever moving element" does not recite adequate structure, because a "moving element" could be any device that causes the lever to move. Mas-Hamilton, 156 F.3d at 1214. In contrast, the Federal Circuit has found that sufficient structure is recited to escape application of § 112, P 6 when the claim terms identify a type of structure that performs the stated function. See Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996) (holding "detent mechanism" denotes a type of device with a generally understood meaning in the mechanical arts); Personalized Media Communications, LLC v. International Trade Commission, 161 F.3d 696, 704-05 (Fed. Cir. 1998) (holding "digital detector" connotes structure and is not a generic structural term such as "means," "element," or "device," nor is it a coined term lacking a clear meaning, such as "widget" or "ram-a-fram").

The Court finds that "computer code" is not a generic term, but rather recites structure that is understood by those of skill in the art to be a type of device for accomplishing the stated functions. Hyseq's own expert, speaking during the tutorial that preceded the Markman hearing, clearly indicated that he understood that "computer code" is a type of device for programming a computer. (Markman hearing transcript at 89:3-24). In this way, "computer code" is more similar to terms like "detent mechanism" and "digital detector," than "element," "means," or "device." Hyseq has failed to provide any evidence or caselaw to support the proposition that "computer code" is a generic term. Rather, Hyseq has only identified cases in which application of § 112, P 6 was presumed because the claims had been recited in means-plus-function format. See WMS Gaming, Inc. v. International Game Technology, 184 F.3d 1339, 1347 (Fed. Cir. 1999); Nilssen v. Motorola, Inc., 80 F. Supp. 2d 921, 929 (N.D. Ill. 2000).

Furthermore, the Court rejects Hyseq's argument that computer code lacks any structure because it consists of data with no physical dimensions. Hyseq has cited no cases to support this proposition. Moreover, Hyseq's proposition improperly would subject every software patent and many electronics patents to § 112, P 6. When, as here, the "means for" language is absent from a claim, the accused infringer has the burden of overcoming the presumption against application of § 112, P 6. Hyseq has failed to meet its burden. The Court therefore finds that "computer code" has sufficient structure to escape application of § 112, P 6. Hyseq concedes that, if the Court finds that § 112, P 6 does not apply to these terms, the terms should be construed according to their plain and ordinary meaning, and no further construction of these terms is required. Accordingly, the Court adopts the plain and ordinary meaning of these terms.

2. "a computer connected to control the ultrasound imaging system"

Plaintiffs' construction: no construction necessary

Defendant's construction: a remote computer linked to the ultrasound imaging system, used to provide control for the ultrasound imaging system

Plaintiffs argue that this term is clear on its face and requires no further construction. Defendant believes that the term is vague and does not accurately convey limitations included in the patent specification. I agree with plaintiffs that the term requires no additional construction. The patent specification imposes no explicit limitations on the term. Instead, the specification indicates that data may be sent from the network "to help" control the ultrasound imaging system, '447 pat. at col. 2, Ins. 19-28. Moreover, Figure 1 demonstrates that the ultrasound imaging system includes a central processing unit, which, presumably, is what receives this "help."

Court's construction: No construction necessary

III. Claims 26 and 32

Claims 26 recites a "computer displaying, in response to the scanner sensing a document, a plurality of user-selectable
Similarly the function and structure for claim 32 is identical to that of claims 1 and 20 discussed above.

Similarly, the function and structure for claim 26 is: "in response to placement of a document in the scanner, displaying a plurality of user-selectable options for processing said image data." Id. at 25:40-45. Similarly, claim 32 recites a "computer displaying, in response to said placement, a plurality of user-selectable options for processing said image data." Id. at 26:1-4. Keyscan argues that both of these claims should be construed as means-plus-function claims because "computer" is a generic term. These claims do not use traditional "means" language; consequently, they are presumptively not means-plus-function limitations.

Soque contends that the term "computer" is not a generic term, rather it denotes a particular type of device with a generally understood meaning in the mechanical arts, comparable to terms that the Federal Circuit has found sufficiently definite. For instance, Soque claims that in Linear Technology Corp. v. Impala Linear Corp., 379 F.3d 1311, 1320 (Fed. Cir. 2004), the Federal Circuit held that the claim term, "circuit," standing alone, sufficiently connoted structure. Soque is wrong. In Linear Technology, the Federal Circuit specifically relied on the recitation of the respective circuit's operation in sufficient detail to suggest structure to persons of ordinary skill in the art." Id. at 1320-21. There, "[t]he contextual language describe[d] the objective of the 'circuit,' 'monitoring a signal from the output terminal,' and the desired output of the 'circuit,' 'generat[ing] a first feedback signal.'" Id. at 1320. This structure, recited in the claim limitation, saved the claim from being treated as a means-plus-function claim. Soque claims sufficient structure is disclosed here because the limitations of claims 26 and 32 both state that the computer: 1) communicates with the scanner; and 2) displays user-selectable options. Neither limitation, however, states how the computer communicates with the scanner, or how the computer determines which user-selectable options to display. Soque's other support is similarly unpersuasive. In Personalized Media Comm'n's v. ITC, 161 F.3d 696, 704-05 (Fed. Cir. 1998), the court held that "detector" recited sufficient structure because the term "had a well-known meaning to those of skill in the electrical arts connotative of structure, including a rectifier or demodulator." Id. The court said nothing about the term "computer." The same goes for Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996), which construed the term "detent mechanism."

Keyscan contends the presumption--that claims 26 and 32 are not means-plus-function claims--is overcome because the term "computer displaying" does not provide a definite structure, but rather refers to a generic computer and describes the computer purely by its function. If the claims were computer-implemented means-plus-function claims, they would have to disclose enough of an algorithm to make them understandable. Specifically, "[i]n cases involving a computer-implemented invention in which the inventor has invoked means-plus-function claiming, [the Federal Circuit] has consistently required that the structure disclosed in the specification be more than simply a general purpose computer or microprocessor." Aristocrat Techs. Austl. Pty Ltd. v. Int'l Game Tech., 521 F.3d 1328, 1333 (Fed. Cir. 2008). This is because "[f]or a patentee to claim a means for performing a particular function and then to disclose only a general purpose computer as the structure designed to perform that function amounts to pure functional claiming. Because general purpose computers can be programmed to perform very different tasks in very different ways, simply disclosing a computer as the structure designated to perform a particular function does not limit the scope of the claim to 'the corresponding structure, material, or acts' that perform the function, as required by section 112 paragraph 6." Id.; FINISAR CORP. v. DIRECTTV GROUP, INC., 523 F.3d 1323, 1340-41 (Fed. Cir. 2008) (a computer-implemented means-plus-function claim must disclose enough of an algorithm to make it understandable); NetMoney, Inc. v. Verisign, Inc., 545 F.3d 1359, 1367 (Fed. Cir. 2008). A patent owner, however, may express the algorithm in "any understandable terms." FINISAR CORP., 523 F.3d at 1340-41.

A reference to a "computer" provides no basis to distinguish the structure from any other general purpose computer; thus, "computer" does not adequately describe a specific structure. Aristocrat Techs. Austl. Pty Ltd., 521 F.3d at 1333; FINISAR CORP., 523 F.3d at 1340-41; NetMoney, Inc., 545 F.3d at 1367. The same logic applies here--if "computer" is insufficient structure for a "means" limitation, the naked term "computer" cannot describe sufficient structure when recited directly in the claim limitation. An algorithm of some nature--that discloses how the plurality of user-selectable options is generated--is necessary to save this claim from indefiniteness. Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed Cir. 1999) ("claims should be so construed, if possible, as to sustain their validity"). Here, the language of claim 32 is identical to the language in claim 1, except that "means for" has been replaced with "computer." Since no corresponding structure is taught by claim 32, the claim cannot escape means-plus-function status. Claim 26 suffers from the same flaw. Accordingly, these claims must be construed as means-plus-function claims.

The function for claim 26 is: '"in response to' placement of a document in the scanner, displaying a plurality of 'user-selectable options for processing image data.'" Id. at 26:1-4. The structure is identical to that of claims 1 and 20 discussed above. Similarly, the function and structure for claim 32 is identical to that of claims 1 and 20 discussed above.
A. Computer-Implemented Method

The Plaintiff argues that this term does not require construction, but submits "method implemented using a computer" if construction is required. The Defendants propose "a method where the steps are automatically performed by a computer without human intervention." The parties agree that the preamble of the claim is limiting.

The parties disagree whether this term requires a construction that limits the computer-implemented method to one that is "automatically performed" and that is performed "without human intervention." Advocating automatic performance and lack of human intervention, the Defendants argue that the Plaintiff's definition is so broad that it is meaningless. The Court finds the Defendants' argument unpersuasive. The Defendants are attempting to add limitations into the language of the claim. Nowhere in the phrase "computer-implemented method" is it stated or implied that a computer implements the method without human intervention or that the computer automatically implements it. The Plaintiff points to FIGS. 3B and 4A-F in the specification to show that the user is involved in the computer-implemented method. The Plaintiff also points to the specification in col. 7: 57-63, which describes the user performing actions such as selecting a communications port, capturing test results, and clicking a button.

The language in the prosecution history cited by the Defendants is also unpersuasive. In the prosecution history language quoted - from ATSER_R_0000807 - the patentees responded to the Examiner that he did not point to evidence in a Martinez reference that gave a motivation to modify the reference to meet the teachings of independent claims one or thirteen. The patentees characterized "the claimed invention of claim one and thirteen of sending information collected from the material mixture to the server; applying one or more test methodologies to the collected information; generating one or more reports from the test methodologies; and sending the one or more reports to a project manager." This is merely a repetition of the claim language of claim one and does not add in the limitations that the Defendants request. Tying claim thirteen to the broad language of claim one, without the supposed link even adding any distinguishing limitation, does not add a limitation to claim one.

Each claim in a patent is presumed to have a different scope. AllVoice Computing PLC v. Nuance Communs., Inc., 504 F.3d 1236, 1248 (Fed. Cir. 2007) (citations omitted). Claim thirteen is directed to "a system for performing quality control on a pavement construction material mixture." The disputed phrase from claim one is "computer-implemented method." Claims one and thirteen have differing scopes as shown by the different language used in each.

The Defendants also claim support from several places in the specification - the description of a system that uses one centralized resource (col. 2:34-36), that the program is run on a computer (col. 3:1-4), and that FIG. 2 shows a process on the server (col. 4:1-3). These citations do not support limiting claim one to automation and a lack of human intervention. 1 The specification supports user interaction. Col. 2:34-35 ("system allows a user to analyze material testing data from beginning to the end using one centralized resource"); col. 2:37-38 ("allows the user to control and monitor progress relating to the analysis of the materials"); col. 2:43-44 ("also highly responsive to user requests"); col. 4:3-4 ("browser based user interfaces are used to collect test result inputs"); col. 7:30 - 8:7 (as discussed above). Further, FIGS. 3, FIGS. 4A-F, and the description of those figures shows embodiments that include user interaction. Col. 7:30 - 8:7. Even without those embodiments, it would ordinarily be improper to import a claim limitation from an embodiment when that limitation is not found in the broader claim language itself. Tate Access, 222 F.3d at 966.

1 The Defendants also argue that the language the patentees used in col. 8:15-24, where the patentees stated that the invention has been described in detail to comply with the patent statutes, limits the invention to the embodiment in FIG. 2.
This argument is unconvincing since the embodiments in FIGS. 3 and 4A-F are also included in the detailed description in the specification. This is not a case where a single preferred embodiment is specifically described as the whole of the invention and so limits the claims.

The Defendants also argue that claim one is different from the embodiment shown in FIGS. 3 and FIGS. 4A-F because those embodiments apply test methodologies to "construction materials" instead of "collected information." These embodiments connect test equipment to a sample where the equipment takes measurements, which are used in the test that are run. The Defendants seek to distinguish this from a situation where the test methodologies are applied to information entered by the user. This argument is contradicted by the language of the patent. It states, for example, that the user sets up a communication port with the equipment that he has selected and selects a test type, and clicks a button to enter the information when he is ready to run a test. Col. 7:30-49. It is information that is sent in the communications port. It is information collected from the construction material that is tested. There is no requirement in the claim that the user collect the information and then let the computer implement the testing.

Construction: A method where the steps are performed using a computer.

C. The District Court's Claim Construction

The claim limitation at issue on appeal is the "computer means" limitation. The parties agreed that this limitation is a means-plus-function clause encompassed by 35 U.S.C. § 112, P 6. The district court noted that the function recited in this limitation is "correcting automatically for discrepancies between oven temperatures and desired sample temperatures." Trial Tr. at 2346. The court determined that the description in the Babil patent of the structure that performs this function "includes the calibration, the correction, and the memory means, all within the computer means." Trial Tr. at 2346. The court therefore construed this claim limitation as "including the function of interpolation." Trial Tr. at 2347-48.

Perkin-Elmer contends that the "computer means" limitation must be construed by determining what structure disclosed in the Babil patent performs the function of "correcting automatically for discrepancies between oven temperatures and desired sample temperatures." Perkin-Elmer argues that this function is performed by the circuitry shown in Figure 1 of the Babil patent, or by a microprocessor implementing this circuit. It further argues that the district court improperly construed the "computer means" limitation by adding an interpolation function to the limitation. Perkin-Elmer asserts that claims 2 and 3 of the Babil patent, which recite calibration and interpolation, demonstrate through the doctrine of claim differentiation that the "computer means" of claim 1 is not required to perform these steps.

TA responds to these arguments by asserting that the Babil patent uses the phrase "correcting automatically for discrepancies between oven temperatures and desired sample temperatures" to refer to the process of determining the correction factor for a given temperature by applying the interpolation function to the correction factors of the calibrated temperatures. Thus, TA argues, the district court correctly construed the "correcting automatically" function as requiring calibration, correction and memory, and as including interpolation. TA asserts that the structure disclosed in the Babil patent that corresponds to the "computer means for correcting automatically . . ." is the device of Figure 3, which includes the circuitry of Figure 1, a memory device, and a processor that performs the interpolation routine.

Claim construction is a question of law that we review de novo. See Markman, 52 F.3d at 979, 34 U.S.P.Q.2D (BNA) at 1329. As a preliminary matter, we agree with the parties and the district court that the "computer means" limitation is encompassed by 35 U.S.C. § 112, P 6. See Kemco Sales, Inc. v. Control Papers Co., 208 F.3d 1352, 1360, 54 U.S.P.Q.2D (BNA) 1308, 1312. Whether the language of a claim is to be interpreted according to 35 U.S.C. § 112, P 6, . . . is . . . a question of law, reviewed de novo."). In accordance with that statute, the limitation must be "construed to cover the corresponding structure . . . described in the specification and equivalents thereof." 35 U.S.C. § 112, P 6 (1994). We therefore must determine what structures described in the specification of the Babil patent perform the function of "correcting automatically for discrepancies between oven temperatures and desired sample temperatures."
The specification of the Babil patent describes two structures that perform this function. The first structure is the "automatic calibration means" shown in Figure 1. As described in the Babil patent, this structure cycles the device through the steps of commanding the oven to reach a selected temperature, permitting the sample temperature to stabilize, and comparing the sample temperature to the selected temperature, etc., until the sample temperature reaches the selected temperature. See Babil pat., col. 3, ll. 40-47, col. 3, l. 56 - col. 4, l. 5. This structure "corrects automatically for discrepancies between oven temperatures and desired sample temperatures" by adjusting the temperature the oven is commanded to reach until the sample experiences the selected temperature.

The second structure that performs the recited function is the structure shown in Figure 3, which automatically calculates a corrected temperature for each selected temperature. This structure includes the automatic calibration system of Figure 1, the memory 36 of Figure 1, and a processor that applies the interpolation function to determine the corrected temperature corresponding to each selected temperature. See id. at col. 5, l. 36 - col. 6, l. 13. This structure calibrates the device at the calibration temperatures, stores the correction factors for each calibrated temperature, interpolates a corrected temperature for each selected temperature, and commands the oven to reach the corrected temperature corresponding to the selected temperature. See id. at col. 6, ll. 1-13. This structure "corrects automatically for discrepancies between oven temperatures and desired sample temperatures" by calculating a corrected temperature corresponding to the selected temperature and commanding the oven to reach the corrected temperature so that the sample experiences the selected temperature.

Although the district court was reluctant to construe claim 1 as encompassing both the type of automatic correction performed by the automatic calibration system of Figure 1 and the type of automatic correction performed by the automatic calculation system of Figure 3, see Trial Tr. at 2346-47, claim 1 itself supports such a broad construction. The function recited in the claim is "correcting automatically," and there is no limit on how this function is performed. The specification describes two structures that perform this function, the structure of Figure 1, which corrects automatically without interpolation, and the structure of Figure 3, which corrects automatically using interpolation. Both of these structures are corresponding structures for the recited "computer means . . ." under 35 U.S.C. § 112, P 6. See Smiths Indus. Med. Sys., Inc. v. Vital Signs, Inc., 183 F.3d 1347, 1357, 51 U.S.P.Q.2D (BNA) 1415, 1422 (Fed. Cir. 1999) (noting that it is the recited "function alone that serves as the touchstone for identifying the disclosed, corresponding structure").

Because the district court's judgment of noninfringement of the Babil patent was based on an erroneous claim construction, we vacate that judgment and remand for further proceedings consistent with this opinion.

--- Footnotes ---
7 In so doing, we reject Perkin-Elmer's argument that we can reverse the judgment of noninfringement based on the proffer Perkin-Elmer made as to the accused device. Even if there is no dispute as to the operation of the accused device, infringement of a claim under section 112, paragraph 6, is a question of fact, see Odetics, Inc. v. Storage Tech. Corp., 185 F.3d 1259, 1268, 51 U.S.P.Q.2D (BNA) 1225, 1230 (Fed. Cir. 1999), that we will not decide in the first instance. Moreover, as TA emphasizes, TA has not had an opportunity to present any evidence on any defenses to Perkin-Elmer's infringement counter-claim. Accordingly, a reversal would not be appropriate on the present record.

--- End Footnotes ---

2. "Computer Means" Limitation

In the asserted claims, "computer means" is introduced as a means for performing a certain function, i.e., a means for controlling the store and forward facility. ('926 patent, claim 55; '302 patent, claim 24.) Catch Curve argues that the phrase "computer means" should not be construed according to the strictures of § 112, P 6, because any presumption that it is a means-plus-function limitation is rebutted by the word "computer," which recites a sufficiently definite structure for performing the claimed function.

In support of this proposition, Catch Curve argues that the term "computer" had a particular definition at the time that the '926 patent was filed. However, the Court finds that because a physical item listed has a specific definition, the structure...
requirement is overcome. In order for the means-plus-function presumption to be rebutted, the claim itself must recite sufficient structure, material or acts to perform claimed function. Apex, Inc., v. Raritan Computer, Inc., 325 F.3d 1364, 1371-72 (Fed. Cir. 2003). While every computer may have a defined structure, it does not follow that every computer has structure sufficient to control the operation of a store and forward facility. See WMS Gaming Inc. v. Int'l Game Tech., 184 F.3d 1339, 1349 (Fed. Cir. 1999) ("in a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm.")

Here, Catch Curve has not met the burden of demonstrating that the claims recite sufficient structure to perform the claimed function of operating the store and forward facility. Moreover, Catch Curve's reliance on the technical dictionary definition of "computer" falls within the Texas Digital line of cases that is disfavored post-Phillips. See generally Phillips, 415 F.3d 1303, 1321-22. Accordingly, the Court finds that "computer means" is a means-plus-function phrase.

C.2.d. "computer means"

The parties disagree as to whether "computer means" should be interpreted as a means-plus-function element. Although computer connotes structure, it is insufficient, Verizon alleges, to perform the recited function of connecting calls to an operator terminal. See Verizon Brief at 75.

C.2.d.1. Applicability of Mean-Plus-Function Analysis

As discussed above, use of "means" in claim 1 of the 065 patent invokes a presumption that "computer means" is a means-plus-function element and, thus, places the burden on Katz of going forward with evidence to rebut the presumption. Apex, 325 F.3d at 1372. As Apex instructs the analysis must focus on "whether the claim term recites no function corresponding to the means or recites sufficient structure or material for performing that function." Id. Here, the claim language clearly recites at least one function to be performed (e.g., "connecting an incoming call by a caller to said operator terminal based on a condition"), requiring an identification of the claimed function(s) and analysis as to whether the claim element recites sufficient structure for performing the function(s). Rodine, 174 F.3d at 1302-03; Apex, 325 F.3d at 1373.

The structure recited in the claim element, a computer, does not appear to be sufficient, standing alone, to perform the recited functions. The functions associated with the computer means appear to include: 1) connecting an incoming call by a caller to said operator terminal based on a condition, and 2) visually displaying customer data on a selected customer. Verizon alleges that the recitation of structure in claim 1 of the 065 patent is insufficient as transmission lines are further required to connect incoming calls to the operator terminal. Katz appears to contend that the analysis should end upon the determination that "computer" connotes sufficiently definite structure. 13 See Katz Reply Brief at 26. Although a computer is sufficient to detect a condition and visually display customer data, a computer standing alone does not appear to connote sufficient structure necessary to connect incoming calls to an operator terminal. Rather, it appears that a transmission line between the computer and the interface terminal is required to connect -- i.e., join or link -- incoming calls to the operator terminal. See Waite 1/14/03 Decl. P 33; Lucantoni 1/14/03 Decl. Exs. 4, 5 (definitions for "connect"). Accordingly, "computer means" in the context of the claim appears to refer to some computerized means of performing the recited functions and therefore invokes application of 35 U.S.C. § 112, P 6. 14

13 Here, the term "computer" connotes sufficiently definite structure to one of ordinary skill in the art. However, as Apex and the cases it cites instruct, where an element uses the term "means" and recites a function to be performed, a determination must nevertheless be made whether the structure is sufficient to perform the recited functions. See 325 F.3d at 1373 ("The threshold issue for all the limitations involving the term "circuit" is whether the term itself connotes sufficient structure to one of ordinary skill in the art to perform the functions identified by each limitation.") (emphasis added). At the Claims Construction Hearing, Katz alleged that Apex supported its position since the Federal Circuit did not address the function corresponding to interface circuit once "sufficient structure" was found; however, in Apex, it appears that there was little or no question that an "interface circuit" connotes sufficient structure for receiving signals from peripheral devices.
The Court does note that the practical result of requiring transmission lines is rather curious, as the mere absence of the word "means" would most likely have changed the analysis and outcome entirely. However, the Court cannot ignore the term "means," the presumption it entails, and the requirements the Federal Circuit has set out for rebutting this presumption.

--- End Footnotes ---

2. Computer Network.

Next, the parties dispute the term "computer network." The plaintiff contends that "network" means "a group of two or more computer systems linked together." The defendants contend that term means "any set of devices or subsystems capable of linking a plurality of terminals to a host." Although the court concludes that the plaintiff's proposed construction is nearly correct, the concept of a computer network suggests the interconnection of a plurality of computers for the exchange of data or information. The court defines a computer network to mean "a plurality of computers interconnected for purposes of exchanging information."

2. Computer Network

The parties also dispute the terms "computer," "computer network," and "multinode computer network," although the parties agree that the latter two terms should be construed consistently. The plaintiff argues that the terms need no construction and, alternatively, that if the court elects to construe the term "computer," then the court should actually focus on the term "network" rather than computer. In its brief, the plaintiff urged the court to adopt a definition of computer network to mean "at least two interconnected computers." At the claim construction hearing, the plaintiff argued that based on certain invalidity positions taken by the defendants, the court should construe computer network to mean either "two computers interconnected by something other than a telephone network" or "two computers interconnected that send packets that contain computer network addressing." (Transcript of Claims Construction Hearing, at 16).

The defendant urges the court to adopt a definition of computer in connection with the definition of computer network and, in doing so, to define computer to include all devices that include a central processing unit ("CPU"). The defendant argues that the plaintiff could have chosen a narrower term when it prosecuted the patent had it desired a more focused definition.

The terms used in the claims bear a "heavy presumption" that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art. Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002); citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002); K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1362-63 (Fed. Cir. 1999); Johnson Worldwide Assoc.s., Inc. v. Zebo Corp., 175 F.3d 985, 989 (Fed. Cir. 1999); Specialty Composites v. Cabot Corp., 845 F.2d 981, 986 (Fed. Cir. 1988)). At the approximate time of the patent application, a "computer network" was generally understood to be "a complex consisting of two or more interconnected computer systems, terminals, or communications facilities." Webster's New World Dictionary of Computer Terms 74 (4th ed. 1992). That same source defines "network" to mean (1) the result of two or more computers being connected together to allow them to share the same software and information or (2) a system of interconnected computer systems and terminals. Id. at 278. Those of skill in the art referred to computer networks as "an interconnected collection of autonomous computers." Andrew S. Tanenbaum, Computer Networks 2 (Prentice Hall, 2d ed. 1989). Tanenbaum explains that the computers were "interconnected" if they were able to exchange information. Id. Finally, in this context, a "node" meant "an individual computer (or occasionally another type of machine) in a network." Michael Covington & Douglas Downing, Dictionary of Computer Terms 212 (Barron's 2d ed. 1989). Thus, the ordinary meaning of "computer network" or "multinode computer network," at the time of the patents in suit, would be "a system of two or more interconnected computers;" the computers were "interconnected" if they were able to exchange information.
Determining the ordinary meaning of a claim term is just the first step. The court must also review the specification to determine whether the patentee intended to define, expressly or by implication, the claim term in a manner other than according to its ordinary meaning. In this case, the court has examined the specification and discerns no such intent. A review of the specification confirms that the patentee used the terms according to their ordinary meaning. The description explicitly refers to two types of geographically-defined computer networks. In the context of Figure 5, the description states that personal computer 18 is "connected to a local area or wide area network 60 having other PCs, file servers, printers, and any other desired combination of computers and peripheral devices." '546 patent, Col., 4, ll. 55-59. These are specific types of computer networks subsumed by the ordinary meaning of the term. Accordingly, the court defines computer network and multinode computer network to mean "a system of two or more interconnected computers;" the computers are "interconnected" if the computers are able to exchange information.

The defendants urge the court also to define "computer." According to the defendants, the court should define "computer" to include any device having a CPU. In the court's view, such a construction is unnecessary. In the context of these patents, the reference to computer cannot be divorced from the reference to network, and the court is persuaded that it is more appropriate, given the intrinsic record and, specifically, the reference to local and wide area networks, to adopt instead a definition of "computer network" as set forth above.

798

B. "Computer Software"

Claim 1 uses the phrase "computer software" as follows: (1) col. 6, l. 6 ("an external memory device having computer software and a first authorization code and a second authorization code"), (2) col. 6, l. 17-19 ("said first authorization code being read prior to execution of said computer software"), and (3) col. 6, l. 32-24 ("with the second authorization code for enabling execution of the computer software stored in said external memory device").

1. The disputed definitions

Plaintiff interprets "computer software" to mean "one or more instructions for execution on a computer, and may include associated data."

Defendant construes "computer software" to mean "[a] set of instructions for execution on a computer and a header which identifies the first program instruction, and may include associated data."

The parties' primary dispute is whether the "computer software" can consist of a single instruction, such as "halt," or whether it must include a "set of instructions." Defendant also contends that the software must contain a "header" which identifies the first program instruction in the "set of instructions."

2. Analysis

Defendant's interpretation of "computer software," with respect to the requirement of a "set" of instructions, is more reasonable in the context of the '353. The "computer software" referred to in Claim 1 is computer software in an "external memory device." While "software" in the abstract might consist of only one instruction, the Court's obligation is to interpret terms in the claims of the patent as they are used in the patent, and not in the abstract. The expressed purpose of the '353 is to prevent the unauthorized use of computer software, that is, software that would require protection. As plaintiff conceded at the claim construction hearing, there is little practical value to protecting single instruction software. One reading Claim 1 of the '353 would have understood that the patent refers to software that might require protection, that is, software that consists of more than a single instruction.

Moreover, plaintiff's definition of "computer software" is at odds with the parties' agreed to definition of "execution of software." The parties agreed that "execution of computer software" means "to perform, run or carry out the instructions in the computer software." Exhibit 2, Pickholtz Decl. (emphasis added). The definition does not refer to one or more instructions, but rather to instructions plural; it assumes that the "computer software" has more than one instruction.

The Court declines to adopt defendant's interpretation of "computer software" as requiring a "header" to identify the first
instruction. Nothing in the intrinsic evidence supports defendant's construction and, in fact, it has not identified anything in
the extrinsic evidence either. Instead, defendant simply states, without citation, that a header is required. Such a bald
statement is insufficient to support the construction urged by defendant.

2. "Computer System"

NetApp's construction
A system containing one or more
computers coupled in a network.

Sun's construction
A system that includes at least one computer
and that may contain a number of computers
coupled in a network.

The parties agree that this term should receive the same construction in all of the claims of the '683 and '249 patents. See
also Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1119 (Fed. Cir. 2004) ("Unless otherwise
compelled, when different claims of a patent use the same language, we give that language the same effect in each claim.").
The parties also agree that a "computer system" contains one or more computers. The parties disagree, however, on whether
that system must always be networked. The sole dispute involves the instance where the computer system includes just one
computer, and whether in that instance, that computer must be "coupled in a network." Sun concedes that a computer system
containing multiple computers is coupled in a network, but asserts that a system containing one computer need not be
networked. In this invention, there are two different aspects of networking. The monitored computer system may be coupled
to other monitored computers in that same system via internal connections. In addition, the monitored system may be
coupled to another computer system, e.g., the monitoring computer system. The latter type of connection is at issue here.
Sun maintains that a single computer need not be connected to a monitoring system, while NetApp contends that it must.

As an initial observation, the patent uses the phrase "computer system" rather than the term "computer." As NetApp notes,
the specification uses the terms computer system and computer differently. See, e.g., '249 patent at 3:66-4:2 ("The
monitored [computer] system includes at least one computer and typically includes a plurality of computers."). NetApp
argues that Sun's proposal erroneously construes computer system, because Sun's construction defines a single-computer
system as a "computer," ignoring the "system" language in the claim term. NetApp's point is well taken.

NetApp's main argument is that the claimed invention of the '683 and '249 patents only makes sense if the computer system
is connected or networked to other computer systems. NetApp Op. Brief at 7:15-17. Turning to the claim language, NetApp
is correct that the majority of the claims require some type of communicating or monitoring between computers.
Independent claim 1 of the '683 patent requires a first computer system that communicates diagnostic data to a second
computer system. The next independent claim, claim 16, requires that the computer system be "monitored." Independent
claim 19 refers to a monitoring computer system. Independent claim 25 requires a "monitored computer system" and a
"monitoring computer system."

The independent claims of the '249 patent, however, do not all contain this communication language. See, e.g., claims 1-4
and 6-8 of the '249 patent. Sun's expert notes that claim 7, for example, uses the term "general computer system." Dr. Smith
argues that the fact that the monitored computer contains a network is irrelevant, as the claim addresses what is contained in
a modifiable static tree structure representing a general computer system. Smith Decl. P 48. However, Dr. Smith does not
explain how the claimed method would be able to represent the computer system without communicating. In addition, all of
these claims are method claims, which are not meant to spell out the system structure. 4 Furthermore, the '249 patent
incorporates by reference the '683 patent, which refers to monitoring in each independent claim, and independent claims 10
and 16 of the '249 patent require a "monitoring computer system."
connection between a monitored computer system and the monitoring system. The specification makes clear that regardless of whether computers "coupled in a network" relates to the connections between computers in a monitored system, as opposed to the network, and in fact expressly state that a network connection is only a preference. However, the above discussion of network connections is not the only relevant consideration. Sun argues that the patents do not define computer system as including a single computer coupled in a network, because "diagnostic data from monitored system 102 is received from modem 114 . . . "'249 patent at 4:1-4:4, 4:9-13; '683 patent at 2:14-15; '683 patent at 1:52-53, 2:9-10. The summary of the invention of the '249 patent provides that "the present invention provides a method, apparatus and computer program products to generate alerts indicating predetermined conditions exist in a computer system," id. at 2:28-30, and that a person of ordinary skill in the art would understand from this description that a connection is a required part of the computer system of the patents. Long Decl. PP 33, 35-38. According to NetApp's expert, such a system would not work without connections between systems. Id. P 38. Sun does not refute this point, and Professor Long's conclusion that connections between systems are required is persuasive.

In addition, the only embodiment disclosed in the specification includes a network connecting the monitoring and monitored computer systems. See figures 1a and 1b of both patents. In figure 1b, for example, even if one single computer were substituted for the plurality of computers "coupled in a network," that single computer would still be "connected" to the monitoring system.

At the hearing, NetApp also argued that an inventor, Mr. Chu, conceded at his deposition that the invention needs two systems. The inventor was discussing the term "remote" in the title of the patent and what he understood it meant. He was not interpreting the "computer system" phrase at issue as one skilled in the art would understand it. Sun notes that Mr. Chu did not specify whether he was referring to the claimed invention generally or to a preferred embodiment. While the Court may consider this inventor testimony only insofar as it relates to how one skilled in the art would understand the term "remote" in the context of remote monitoring, this testimony lends some further support to NetApp's assertion that even a single computer must be connected in such a way to allow remote monitoring. See Howmedica Osteonics Corp. v. Wright Med. Tech., Inc., 540 F.3d 1337, 1346-47 n.5 (Fed. Cir. 2008) (inventor testimony may be pertinent as to understanding the established meaning of particular terms in the relevant art, but inventor testimony concerning the scope of the claims is irrelevant to construction).

Sun also contends that its proposed construction is supported by the specification. However, Sun fails to distinguish internal versus external types of networking in its analysis of the specification. Specifically, Sun maintains that the patents provide near-verbatim recitation of its construction: "The monitored system includes at least one computer and typically includes a plurality of computers 104, 106, 108, 110, and 112 coupled in a network as shown in FIG. 1b . . . In exemplary computer system 100, which includes one or more computers and associated storage areas, preferably coupled in a network, incoming diagnostic data from monitored system 102 is received from modem 114 . . . "'249 patent at 4:1-4:4, 4:9-13; '683 patent at 3:44-46, 3:51-54. Sun argues that the patents do not define computer system as including a single computer coupled in a network, and in fact expressly state that a network connection is only a preference. However, the above discussion of computers "coupled in a network" relates to the connections between computers in a monitored system, as opposed to the connection between a monitored computer system and the monitoring system. The specification makes clear that regardless
of whether or not the single computer system is coupled in a network, that single computer must be able to receive incoming data "via email" or "direct modem connection" or "other communication channels." '249 patent at 4:10-17. In sum, the passages of the specification relied on by Sun merely state that the invention does not require a network between multiple computers in a monitored system, but it is the external type of connection between the monitored and monitoring systems that is in dispute here.

NetApp notes that this connection should be described as being "coupled in a network," as both parties use this phrase in their constructions and it is the term used in the art to refer to connections between computers. Sun does not argue that another term like "connected" should be used in lieu of "coupled in a network," should the Court agree that the disputed term requires connections between systems. Whenever computers communicate, they are connected by a network. Long Decl. PP 33-35; see also Microsoft Press Computer Dictionary at 327 (3d ed. 1997) (defining network as a "group of computer and associated devices that are connected by communications facilities") (Nathan Decl., Ex. 9 at NAC0109648). However, in light of potential jury confusion, and in light of the difference between connections between the monitoring and monitored system, the Court finds that using the phrase "coupled in a network" could mislead the jury. Rather, the construction should make clear that where a computer system contains only one computer, that computer must be able to communicate via email or a dedicated modem connection or another communication channel to allow remote monitoring. See '249 patent at 4:14-18.

In sum, NetApp is correct that the invention requires that even a single computer be networked or otherwise able to communicate with a monitoring system. Otherwise, the remote monitoring that is claimed would not be able to work. Sun does not tackle this argument head on. Rather, Sun argues that NetApp confuses the meaning of a "computer system" with the passing of information between two computer systems. Smith Decl. P 49. Dr. Smith notes that NetApp appears to be confusing the term "computer system" with the need for the monitored computer system to communicate with the monitoring computer system. Smith Decl. PP 47-49. However, Sun does not grapple with NetApp's point that the invention requires communication between the monitoring and monitored systems. In addition, both parties' constructions address the connections of the computers in the computer system, and the Court finds it appropriate to address these connections in construing this term. Accordingly, the Court construes "computer system" as: "A system that includes at least one computer and that may contain a number of computers coupled in a network. Even where a computer system contains only one computer, that computer must be able to communicate via email or a modem connection or another communication channel to allow remote monitoring."

800

computer system

The parties disagree on the meaning of a "computer system." Dell proposed: "an information handling system which can be designed to give independent computing power to one user or a plurality of users." Lucent proposed: "a complete, working computer that includes not only the computer, but also any software (including an operating system) and peripheral devices that are necessary to make the computer function."

The court agrees with Dell's proposed construction and concludes that the term should be construed as follows:

"an information handling system which can be designed to give independent computing power to one user or a plurality of users."

801

1. a computer system (Claim 1)
Keystone proposes the term "computer system" be given its ordinary meaning. Keystone contends that the inventor did not in any way redefine the term "computer system" in the patent claims or the specification. If the Court deems construction of the term necessary, Keystone's proposed construction is "a device with a processor to execute instructions." Defendants' proposed construction of the term is "a flexible, general purpose personal computer capable of running a variety of operating systems and application programs." They argue that these limitations have been defined by the inventor in the provisional application to the USPTO and in the prosecution history.

First, defendants argue that the inventor, Mr. Hindman, has defined the computer system of his invention as both flexible and general purpose. For support they point to the provisional application, wherein the inventor states in his "enabling disclosure" that the design of his invention is based on "a personal computer based architecture," and "is capable of running Microsoft Windows 3.1 and any desired software program." See U.S. Provisional App. No. 60/038,078. Further, defendants point to the patent that states that the invention augments the current capabilities available to the mobile user and facilitates the use of a variety of line replacement units ("LRUs"). See '123 Patent, 2:10-12. They argue that such architecture can only be achieved by a flexible computer. Further, defendants contend that the inventor repeatedly distinguished the architecture of the claimed computer system over the prior art during prosecution of the patent application, highlighting the flexible nature of the invention. Specifically, defendants point to the inventor's response to the examiner's rejection over U.S. Patent No. 4,758,959 ("Thoone").

Thoone's invention is not a comparable system to applicant's invention since its configuration is inflexible and predetermined... Figures 4 and 5 of applicant's invention disclose a general mobile computer platform with a flexible input/output management system... None of these specific features and functions are taught by Thoone.

1'23 File History, Response to Non-Final Office Action, at SIR0133860 (Sept. 25, 2000); see also id. at SIR0133863-64 ("Each of these patents referenced by the Examiner teaches away from Applicant's invention and away from an infinitely flexible architecture.").

The inventor repeated these argument in response to a second rejection by the examiner in light of the Thoone prior art, as well as the Haroun prior art. See '123 File History, Response to Non-Final Office Action, at SIR0133892-95 (Mar. 20, 2001). Therefore, defendants argue that the scope of this limitation should be narrowed per the inventor's own statements to the PTO. The Court agrees. See Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1021 (Fed. Cir. 1987) ("Claims may not be construed one way in order to obtain their allowance and in a contrary way against infringers.").

Keystone argues that these statements do not refer to the "computer system" limitation and are not unequivocal disavowals of scope. It contends that the statements could refer instead to just the I/O management component or to the computer architecture. Therefore, it argues, any ambiguity in the prosecution history must be resolved in favor of the inventor. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). However, as the Federal Circuit has held, prosecution history must always receive consideration in context. Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366 (Fed. Cir. 2008) (noting that where a patentee has "expressly defined a term in the specification," that definition would control over broad remarks during prosecution). There is nothing in the specification of the '123 patent that would lead the Court to consider the distinctions argued in the prosecution history to be ambiguous. Here, the inventor distinguished his invention from the prior art several times, focusing on the flexibility of the entire invention, including the computer system. Keystone's arguments that these statements referred only to the flexibility of the computer architecture or the input/output management system are not persuasive. The Court adopts the defendants' construction as below: "A flexible, general purpose computer capable of running a variety of operating systems and application programs."

GO BACK

802

Computer System

Claims 1, 13-16, and 18-19 of the '516 Patent contain the term "computer system." Individual Networks contends the term means "one or more general purpose computing devices performing server and/or client functions, including a storage medium." Apple contends "computer system" means "a computer in which the client is collocated with the server." The parties disagree whether "computer system" requires the client to be located at the server.
The claims define the relationship between the computer system and the user. The claims set forth that customized media and a customized media list are stored at a computer system. The claims also set forth that the customized media list is "not stored at the user" and that the customized media is not stored "local to the user." '516 Patent, col. 13:49-14:4, col. 14:56-15:5. This language clarifies that the "computer system" is not located at the user, but the language does not limit the client to collocation with the server. Therefore, while the claims require that both the client and the server are located separate and apart from the user, the claims do not require that the client and server are collocated.

The specification of the '516 Patent discloses that "[t]he computer system 200 includes the client 235, server 225, and the server storage medium 205, or, in alternative embodiments, separate computer systems contained remotely at the client location and the server location." '516 Patent, col. 9:16-19. The specification further states that "[t]he general purpose computer, in one embodiment, acts as either the server 225 or client 235 of FIGS. 2-4, or both." '516 Patent, col. 11:23-29. In this manner, the specification provides written description support for a collocated client and server, but clearly explains that this structure is merely one embodiment of what may be covered by the claims. The embodiment provided in the specification is exemplary and does not limit the claims to a computer system wherein a client and a server are collocated. See Electro Med. Sys., S.A. v. Cooper Life Scis., Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994). In fact, the word "collocated" cannot be found anywhere in the specification. The specification, therefore, does not provide any compelling evidence for restricting the "computer system" to an arrangement wherein the client is located at the server.

Apple improperly attempts to limit the claim based on the doctrine of prosecution disclaimer. However, ambiguous prosecution history cannot be used to trump the clear terms of the claims and specification. Phillips, 415 F.3d at 1317; Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003)("[W]e have . . . consistently rejected prosecution statements too vague or ambiguous to qualify as a disavowal of claim scope . . . . Rather, we have required the alleged disavowal statements to be both so clear as to show reasonable clarity and deliberateness, and so unmistakable as to be unambiguous evidence of disclaimer.") (citations omitted).

Apple derives the term "collocated" from arguments made by the Applicant in the prosecution history of the '516 Patent. During prosecution, the Applicant and the Examiner argued at length regarding patentability of the claims over the Logan prior art reference (U.S. Patent No. 5,721,827), which disclosed a structure where the client was located at the user. In particular, Applicant argued as follows:

In contrast, Applicant discloses an embodiment of a method and system for distributing personalized information where the client functionality is collocated with the server functionality, both of which are accessed by a user through a network.

'516 Patent file history, Third Supplemental Amendment, Nov. 20, 2004 at 11-12 (APP 0199-0200). Applicant set forth this argument as one embodiment covered by Applicant's claims that distinguished its claims from the Logan reference. Applicant did not, however, limit its claims to this singular embodiment. In other words, the fact that a client and server may be the same computer does not require such a result.

The manner in which Applicant limited its claims during prosecution is most clearly demonstrated by its final amendment to the claims during prosecution. In particular, Applicant added the following language to the claims in its final amendment to obtain allowance: "and wherein the customized media list is not stored at the user" and "without storing the customized media local to the user." '516 Patent file history, Response After Final With A Request for Continued Examination, Oct. 21, 2005 at 2 (APP 0261). This amendment covers the embodiment of a computer system wherein the client and server are collocated, but also covers and embodiment of a computer system wherein the client and server are located at separate and distinct network locations as long as neither the client nor the server resides at the user. In other words, the Applicant did not include and the Examiner did not insist that the Applicant include the positive limitation "collocated" to distinguish the claims from Logan. Instead, the Applicant sought to distinguish Logan with negative limitations that require the computer system to store the customized media and the customized media list at a location other than at the user. It was this final amendment, not ambiguous arguments made earlier during prosecution, that caused the claims to finally be allowed over the Logan reference. The Applicant's arguments during prosecution do not amount to a clear and unmistakable disavowal of claim scope.

For these reasons, Apple's proposed construction overly limits the term "computer system." The Court adopts Individual Networks' proposed construction and construes the term "computer system" to mean "one or more general purpose computing devices performing server and/or client functions, including a storage medium."
A. Computer Usable Medium (Claim 14)

HP contends that the term means "a tangible medium, such as a computer readable media (for example, diskette, CD-ROM, ROM, or fixed disk) or a medium for transmission to a computer system via a modem or other interface device using communications lines (for example, optical or analog communication lines) or wireless techniques (for example, microwave, infrared or other transmission techniques)." Intergraph contends that the term means "material on which computer readable code is recorded for use by a computer."

HP's proposed construction is taken directly from language in the embodiment of the patent. See '028 Patent, col. 17:11-24. HP states that the term, as used in claim 14, refers to the medium on which or through which the computer readable program code comprising the computer is delivered. HP concludes that this delivery must be through a transmission, and should include physical media and transmission media.

Intergraph offers the Court very little argument to support its proposed construction of the term. Intergraph states that the term is defined in Claim 14 as "having computer readable program code thereon." '028 Patent, col. 19:10-11. Intergraph also directs the Court to a portion of the specification that provides that "the system may be implemented as a computer program product for use with a computer system. Such implementation may include a series of computer instructions fixed either on a tangible medium such as a computer readable media . . . or transmittable to a computer system." '028 Patent, col. 17:12-18.

HP argues that Intergraph's proposed construction merely states what the computer usable medium contains - "computer readable code thereon." The Court agrees. Intergraph's proposed construction does not help explain the function or characteristics of the "computer usable medium." It is important to note that both parties direct the Court to a particular section of the specification - col. 17:12-18. It is well accepted that the specification can act as a dictionary when it expressly or impliedly defines terms used in the claims. In col. 17:13-23, it appears that the patentee has acted as a lexicographer and the Court will respect the meaning given to "computer usable medium" found therein. Therefore, the Court construes "computer usable medium" as a tangible medium, such as a computer readable media (for example, diskette, CD-ROM, ROM, or fixed disk) or a medium for transmission to a computer system via a modem or other interface device using communications lines (for example, optical or analog communication lines) or wireless techniques (for example, microwave, infrared or other transmission techniques).

6. "computer using an n-bit architecture" / "Computer using a m-bit architecture"

SuperSpeed proposes the term means "a computer whose general purpose registers are n-bits wide." 4 IBM proposes the term means "a computer that uses an address that has a length of 'n' bits to address data stored in main memory." SuperSpeed cites to the intrinsic record to support its proposal: "[t]he presently preferred embodiment of the invention uses remote disks that are connected by the Open VMS VMScluster and VAXcluster software. The VMScluster software is operable on 64-bit or 32-bit architecture computer systems. The VAXcluster software only permits 32-bit computers." ['244 Patent, 3:26-30]

--- Footnotes ---

4 The same analysis applies to "m-bit architecture." The court will refer to "n-bit architecture" for simplicity's sake.

--- End Footnotes ---

SuperSpeed has presented extrinsic evidence supporting that the "VAXcluster software," not surprisingly, was typically used...
on VAX computers that had general-purpose registers that were 32-bits wide. These computers, however, used an address with only 28 bits to address data stored in main memory. Bennett Dec., P 43. The Alpha AXP computer referred to in the specification, which had a "64-bit architecture," used an address with only 48 bits to address data stored in main memory. Bennett Dec., P 44. SuperSpeed points to other relevant extrinsic evidence to prove that it was well understood in the art that a computer having a 32 or 64 bit architecture meant the computer had general purpose registers that were 32 or 64 bits wide respectively. See Bennett Dec., P 42; see also Hennessey & Patterson's Computer Architecture: A Quantitative Approach. This is the bit-length through which a computer manipulates data in its CPU. For example, Hennessey and Patterson describe the IBM System 360 as a "32-bit machine" even though they note that it "had a 24-bit address space." Hennessey & Patterson at 148.

The intrinsic and extrinsic record support that a computer with an "n-bit architecture" or a "m-bit architecture" refers to a computer's general purpose register through which it manipulates data. The terms "computer using an n-bit architecture" and "computer using an m-bit architecture," therefore, mean "a computer whose general purpose registers are n-bits wide." and "a computer whose general purpose registers are m-bits wide," respectively.

A computerized method of selling parts for particular equipment specified by a customer

Defendants urge the Court to construe this term as "a method each step of which is performed by the computer." This limitation is not required by the claim language or the specification. Further, Defendants do not argue that "computerized method" is not likely to be understood by lay jurors. Accordingly, the Court determines that this term does not require construction.

X. "concatenating" 24

The parties dispute the meaning of the term "concatenating" in claim 1 of the '612 patent. The '612 patent specification explicitly defines "concatenation" to mean "that one bit field is juxtaposed to another." '612 patent at 4:6-7. Based on the definition provided in the specification, the parties generally agree that the claim term requires that the bit fields be linked together, the parties dispute, however, whether "concatenating" requires that the items be directly adjacent.

PACid contends that this term has a clear meaning, but if construed, should reflect the full scope of the claim term as it is commonly used in computing. OPENING at 18. PACid maintains that the Defendants' proposed construction improperly limits the claim to the manner it is used in a preferred embodiment. Id.

Defendants offer that in requiring that one bit field be placed "directly next to" another one, they are proposing a construction that comports with the patent's explicit definition. RESPONSE at 22. Referring to a dictionary definition, Defendants explain that "juxtapose" means "to place things side by side." Id. (citing CHAMBERS 21ST CENTURY DICTIONARY 737 (1996)). Defendants further cite language in the specification that implicitly describes the constant value
being placed next to the encrypted information file. Id. (citing '612 patent at 2:67-3:3; 6:61-64).

For this term, the express definition provided in the specification unquestionably governs. Phillips, 415 F.3d at 1316 (explaining that in instances where the inventor has clearly defined his own terms, the inventor's lexicography will govern during claim construction); CCS Fitness Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). Identifying the inventor's definition for "concatenating" to be "one bit field juxtaposed to another," the remaining issue is whether the accepted meaning of "juxtapose" requires the bit units to be directly next to one another.

Defendants identify language in the specification describing the constant value being concatenated "at the beginning of the encrypted information file," and thus conclude that "the constant value must be directly next to the encrypted information file." RESPONSE at 23 (citing '612 patent at 6:61-64 (emphasis added)). This conclusion, however, restricts the scope of the claim to the manner in which it is used in a preferred embodiment. Even where a patent describes only a single embodiment, claims will not be read restrictively unless the patentee has demonstrated a clear intention to limit claim scope." Innova/Pure Water, 381 F.3d at 1117 (internal citation omitted). Failing to identify any language of manifest exclusion, the Court finds Defendants' restrictive reading of claim 1 to be incorrect.

The patentee does not offer a clear meaning for "juxtapose," therefore the specification term will be given its ordinary meaning as established through extrinsic evidence. See Phillips, 415 F.3d at 1318 ("We have especially noted the help that technical dictionaries may provide to a court "to better understand the underlying technology" and the way in which one of skill in the art might use the claim terms.") (citing Vitronics, 90 F.3d at 1584, n.6). Defendants offer a dictionary definition that understands "juxtapose" to mean "side by side," but even if afforded this definition, common use of either "juxtapose" or "concatenate" does not preclude intervening bit fields. Instead, "concatenating" is understood broadly to account for bit fields that are "side by side," but not necessarily directly next to each other in a group of side by side bit fields.25 Incorporating this understanding of "juxtaposed," the proper construction of the term "concatenating" is "placing one bit field side-by-side with another." The Court notes, however, that side by side does not require that such bit fields be directly next to one another.

25 This concept is fully illustrated through an example. In other words, if "1," "2," and "3" are "concatenated" as "123," then "1" and "3" are still "juxtaposed" within the group of numbers.

4. "to conceal a correlation"

The dispute as to the phrase "to conceal a correlation" mirrors the disagreement between the parties with regard to the terms "reduce," "restrict," and "inhibit." One party contends that "conceal a correlation" means "concealing any relationship." Another party contends that the phrase means "decorrelate."

The claimed methods of the '661 patent are designed only to reduce the signal to noise ratio "thereby increasing the number of observations required by an attacker to compromise the key." Col. 3, 1. 67 -- Col. 4, 1. 1. As used in the written description, "conceal" does not refer to a complete concealment: "This high-entropy permutation combines several previously-described aspects of the present invention, including without limitation order randomization (thus being neither input-ordered nor output-ordered) and blinding techniques (to conceal further the data being permuted)." Col. 11, ll. 34-39.

The plain and ordinary meaning of "conceal" is more than de minimus. In discussing clock skipping, the '661 patent acknowledges: "Of course, small temporal alignment variations may not be able to conceal signal characteristics that are of large amplitude or of long duration." Col. 6, ll. 57-59.

Consistent with the stated purpose of the invention in using "leak minimization and obfuscation" as "useful for improving security," '661 patent, col. 14, ll. 6-9, the Court construes "conceal a correlation" to mean "hiding a correlation, so as to
Concurrencies (claims 1 and 6); a plurality of instructions which are concurrently executable (claims 14 and 15)

The parties agree that the terms "concurrencies" and "a plurality of instructions which are concurrently executable" have the same meaning. They further agree that the terms have no special meaning in the computer field. The parties' definitions differ, however, with respect to two elements. Defendant defines the two terms as follows: "Instructions (1) for which it is determined that zero [alpha] and [beta] dependencies exist and the required functional units are available, and (2) that can be simultaneously issued for execution." Accordingly, defendant's definition of concurrencies comprises two elements: (1) the absence of [alpha] and [beta] dependencies, and (2) the availability of appropriate functional units.

Plaintiff's definition, on the other hand, requires only that the instructions be free of dependencies. Specifically, plaintiff defines the disputed terms as: "a plurality of instructions that are ready to be issued because they are dependency free." Therefore, plaintiff's definition does not refer to any particular dependencies (such as [alpha] and/or [beta] dependencies), nor does it require the availability of appropriate functional units.

The Court agrees with plaintiff's definition. First, there is no basis in the patent or the prosecution history to read the terms as requiring that the instructions be in any particular format or have a particular set of fields. Nor is there a basis to read the terms as requiring that the instructions be free of any particular type of dependency, as requiring that any particular type of dependency have previously existed, or as requiring that dependencies have been removed in any particular manner. Indeed, the Court has already construed the term "instruction" broadly to mean "an expression that specifies one or more operations and identifies the applicable operands"; this construction includes instructions which never had false ([beta]) dependencies, in which case there is no need to "determine" that no false dependencies exist.

Application of the doctrine of claim differentiation also supports this view. For example, dependent claim 7 specifies false dependencies and is thus differentiated from independent claim 6 from which it depends. Likewise, dependent claim 16 specifies false dependencies and is thus differentiated from claim 15 from which it depends. While the Court is aware that claim differentiation is not a rigid rule, see Comark, 156 F.3d at 1187, here, application of the doctrine is fully consistent with the patent as a whole.

Next, there is no basis to conclude that an appropriate functional unit must be available before instructions may constitute "concurrencies" or "a plurality of instructions which are concurrently executable." Rather, for an instruction to be ready to be executed it must simply be dependency free. This construction is supported by the separation of the detecting function and the issuing function in the means-plus-function claims (independent claims 1 and 14). In these claims, the detecting function concerns the detection of instructions which are ready to be executed because they lack dependencies. The issuing function operates on instructions which have been determined to be dependency free; the issuance of such instructions to appropriate and available functional units is a distinct function performed by a distinct structure. Similarly, the method claims (independent claims 6 and 15) describe a two-step process: first, detecting dependency free instructions, and second, issuing them to available functional units.

Plaintiff also refers the Court to the plain meaning of the words "concurrently" and "executable." The Oxford English Dictionary Online (Oxford University Press, 2003) 9 ("OED") defines concurrently as "in a concurrent or concurring manner; in concurrence." The OED definition of concurrent includes "occurring together, as events or circumstances," and the definition of concurrency includes "a running together in place or time." OED defines executable as "that can be executed, performed, or carried out." Thus, applying the ordinary meaning of the words, the terms refer to two or more instructions which are in a state of readiness to be carried out at the same time. The ordinary meaning of the words is thus consistent with the patent and supports the Court's construction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 The Court is aware that this source is not contemporaneous with the patent; however, there is no reason to believe that the meanings of these non-technical words has altered since the time of the patent, nor does defendant dispute the ordinary
meanings of these words.

Accordingly, the Court reads "concurrenties" and "plurality of instructions which are concurrently executable" as meaning "a plurality of instructions that are ready to be executed at the same time because they are dependency free."

A.1.g.3. "concurrent processing"

Verizon alleges that "concurrent processing" means "processing at the same time." Verizon Brief at 24. "Concurrent processing," according to Katz, means "processing two or more calls in parallel." Based on the parties' comments, at the Claims Construction Hearing, concerning their asserted interpretations of "concurrent processing," the parties appear to agree on the substance or essential meaning of "concurrent processing," just not the words that should be used to further define it.

The term "concurrent processing" means processing two or more calls at the same time or in parallel (simultaneously). The Court's interpretation is consistent with the plain meaning of the term. See Webster's Ninth New Collegiate Dictionary at 273 (defining concurrent as "operating or occurring at the same time . . . running parallel"). The specification does not suggest a contrary interpretation. In fact, the written description of the 734 patent uses the term only twice in unrelated contexts, but in a manner consistent with its ordinary meaning. See 734 patent, Col. 8:61-64 ("In the disclosed embodiment, concurrently with the operation of further informing the caller, the interface processor 26 actuates the random number generator 40 to provide a random address for the question memory 38."); Col. 9:37-40 ("Note that in the interests of human perception, a printed record may be developed concurrently with the qualification of lottery participants."). The Court's interpretation is not intended to suggest that processing of calls associated with different formats must begin and end at the same time. See 734 patent, Col. 8:27-38 ("With the entry of a call into the common phase, the line carrying the call is connected through the coupler 24 (FIG. 1) to the interface processor 26. That is, depending on the call mode, the call is passed through one of the audio response units 18, 20 or 22 and the coupler 24 to the interface processor 26. Note that as indicated above, each of the audio response units 18, 20 and 22 is capable of accommodating a large number of asynchronous calls. Similarly, the coupler 24 is capable of connecting lines from the audio response units 18, 20 and 22 (LB1, LB 2 and LB3 respectively) to the interface processor on an individual basis through lines 37 and 39."); Col. 8:39-41 ("The interface processor 26 may comprise a relatively substantial computing capability for processing many individual calls with programmed variations.").

Microsoft contends that the concurrent limitation should include the restriction that each thread must be interrupted after a predetermined timeslice and that no thread may execute with interrupts disabled. This condition would, however, mean that the preferred embodiment disclosed by plaintiff's patents is not concurrent, because in this embodiment the editor is not interrupted after a predetermined timeslice when processing a keystroke, but is allowed to run until the keystroke is processed. To adopt the interpretation urged by Microsoft, therefore, would be to determine that plaintiff's patents are invalid by introducing a fatal disconnect between the claims and other elements of the specification.

Clearly, plaintiff intended the condition that multiple threads operate "concurrently" to mean that the user perceive them to be operating at, essentially, the same time. The question is whether this condition goes beyond a perception by the user to a requirement that no thread may control the CPU for as long as required to finish its task. The court concludes that plaintiff did not intend "concurrently" to mean that no thread could control the CPU, with interrupts disabled, while executing its task. Rather, plaintiff intended "concurrently" to be a measure of the user's perception. Consider claim two of the '603 patent, which states in part:
whereby said one thread executes interactively with the user in the foreground while another thread of the same program executes in the background concurrently with said one thread with control of the central microprocessor repeatedly switching back and forth between threads, and wherein said fast efficient preemption provided by said direct access by the threads to said memory address space enables control of the central microprocessor to be switched between the threads so rapidly that an interactive user perceives the foreground and background threads to be executing simultaneously and without any perceptible interference by the background thread with the user's interaction with the foreground thread.

The patents clearly contemplate that the modifier "concurrently" focuses on the user's perception. "Concurrently" thus refers to: A mode of operation wherein control of the CPU is alternated among executing threads of the same program at so rapid a rate that the multiple threads of execution appear to be executing simultaneously to the computer user.

EMC asserts that the term "concurrently" means operating in parallel while HP argues that it means at the same time. The term "concurrent" is defined as "running parallel" and "occurring, arising, or operating at the same time often in relationship, conjunction, association, or cooperation." Webster's Third International Dictionary, 472 (1981). Although both proposed definitions appear to be correct, the most appropriate construction depends upon the context in which the term is used.

Claim 1 of the '347 Patent states, in relevant part, said first data storage system enabling transfer of said data to said second data storage system, concurrently with said data received from said host computer, so as to nearly simultaneously maintain a concurrent copy of data stored on said first data storage system . . . .

'347 Patent, Col. 8, ll. 60-64 (emphasis added). Because the use of both "concurrently" and "concurrent" refer, generally, to the copying of data by the first data storage system to the second data storage system after such data is received from the host computer, they should be construed uniformly. See Epcon Gas, 279 F.3d at 1030-31 (where the same claim term is used consistently throughout a claim or claims, it should be given the same meaning throughout).

Given the context in which both terms are used, it is illogical to define "concurrently" and "concurrent" as "at the same time" because the phrase "nearly simultaneously" already describes the time element in the relevant claim. Moreover, to define the subject terms as "at the same time" would contradict the phrase "nearly simultaneously" because the latter term implies that one event occurs at almost the same time as another but not exactly at the same time. Accordingly, the claim terms "concurrently" and "concurrent" will be construed to mean "in parallel with" and "parallel" respectively.

Claim 11 includes the limitation "concurrently, but independently, processing within said computer specific portions of invoked ones of said routines for each of a plurality of said processes." Apple and Sun contend that this phrase means "for
each of two or more independent processes, processing specific portions of the invoked routines in an overlapped fashion during the same specified interval of time, where the processing of the specific portions is not contingent upon one another. Gobeli believes that this phrase means "the independent performance of two or more data processing tasks within a specified interval." Again, neither side is completely correct.

During the Markman hearing, the parties generally agreed with what "concurrently" meant in the world of computer processing, but could not reach agreement as to how to define the term. Basically, both parties agree that if there is a single processor, the computer cannot process more than one set of instructions at exactly the same time. Instead, the computer splits the time into very small increments and cycles between different sets of instructions. The parties agreed, however, that if there were multiple processors, then a computer could execute more than one set of instructions at exactly the same time.

The largest area of disagreement concerned whether there must be overlap between the specific portions of the invoked routines or whether these portions could be run in seriatim as long as they are executed within a specified time interval. Contrary to the Plaintiff's argument, serial processing does not comport with the specification or the general understanding of the term "concurrently."

Based on the foregoing, the Court construes the phrase "concurrently, but independently, processing within said computer specific portions of invoked ones of said routines for each of a plurality of said processes" means "the independent performance of two or more specific portions of the invoked routines wherein at least one part of the two portions are run in an overlapping fashion."

GO BACK

6. “Said processing being performed by said page server while said Web server concurrently processes said other requests”
“Said processing being performed by said page server while said Web server concurrently processes said other requests” is utilized in asserted claims 1 and 11 of the ‘554 Patent and 1, 15 and 29 of the ‘335 Patent. The Plaintiff asserts that the “said processing…” phrase does not need construction. Alternatively, if construed, the Plaintiff asserts that the proper construction is “said processing being performed by said page server while said Web server processes said other requests at the same time.” The Defendants assert that the phrase should be construed as “said processing being performed by said page server while said Web server executable processes other requests literally at the same time on a different machine.”

Three main points of distinction exist between the parties: the inclusion of “executable” with regard to the use of Web server, the inclusion of “literally” with regard to the “same time” language, and the inclusion of the concept of the Page server and Web servers being on different machines. With regard to the term “Web server” as utilized within the “said processing…” phrase, the Court finds that the construction the Court provided above for “Web server” is applicable, and thus the inclusion of the term executable does not need to be re-addressed with relation to the “said processing…” phrase. Similarly, with regard to the concept of different machines, the Court has addressed that concept above and does not need to re-address that concept here.

With regard to “concurrently,” both parties agree that this term includes the concept of something occurring “at the same time;” however, there is still a dispute as to whether it must be “literally at the same time.” The Defendants argue that “concurrently” should be analyzed in the context of the discussion in the patents of the prior art time-interleaved multi-threading techniques. Accordingly, the Defendants argue that if concurrently is not read to be “literally at the same time” the claims would read on time-interleaved multi-threading techniques. Once again, such arguments are more suited for invalidity assertions. Moreover, it is noted that in the passage in which the patents utilize the term “concurrently” to describe the Web server and the Page server operations, the patents also describe this concept as “to simultaneously process.” Col. 6:21-27. With regard to the prior art time-interleaved multi-threading discussion (which the Defendants assert is not literally at the same time) the patent also uses the term “simultaneously.” Col. 4:48-51. The patents do not distinguish one use of the term simultaneously from the other by the inclusion of the literal concept. The Court does not find support in the intrinsic evidence to support a requirement that “at the same
time” must be “literally at the same time.” Thus, the court construes “said processing being performed by said page server while said Web server concurrently processes said other requests” to mean “said processing being performed by said page server while said Web server processes said other requests at the same time.”

The Court is of the opinion that the findings and conclusions of the Magistrate Judge are correct. Therefore, the Court hereby adopts the Report of the United States Magistrate Judge as the findings and conclusions of this Court.

The parties generally agree on the proper construction of this phrase. OPTi contends that the construction should be "while at least one of the data units is moving from the secondary memory to the bus master." nVidia's construction is similar: "while at least one of the data units is moving directly from the secondary memory to the bus master." Thus, the only dispute between the parties for the aforementioned phrase is whether the movement from the secondary memory to the bus master is limited to a direct transfer.

There is no requirement in the claims that the transfer be direct. Further, what support nVidia relies on in the specification relates to the preferred embodiment. The Court will not read limitations of the preferred embodiment into the claims. Accordingly, the Court adopts OPTi's construction.

a. "condition proportional"

Ecolux construes "condition proportional" to mean directly proportional or having "the same or constant ratio." Ecolux believes this construction requires the invention's temperature sensor 16 to be located on the LED circuit board, as opposed to somewhere else in the invention's circuitry. Relume argues that this locational requirement is an unnecessary limitation on the claimed invention. Relume believes that the scope of "condition proportional" includes temperature sensors that are sensitive to the ambient temperature surrounding the LEDs.

Claim 1 does not recite a limitation on the location of its sensor. It describes the "sensor" as performing two functions: "sensing a condition proportional to said luminous output of said LED (12) and…producing a luminous output signal." '909, 7:1-3. This language limits the possible universe of conditions that could be sensed by the sensor to those that have a "proportional" relationship to the light output of the LEDs. 17 Webster's most relevant definition of "proportional" is "having the same or a constant ratio;" this is, in fact, Ecolux's proposed definition. 18 The key to understanding its scope is in the meaning of "ratio." Webster's defines it as "the fixed or approximate relation of one thing to another." Therefore all that claim 1 requires its sensor to do is sense a condition that has a "fixed relation" to the light emitted from the LEDs; this function does not imply a locational requirement for the invention's temperature sensor.
17 A related point regarding the "condition" sensed: the claim language does not limit it to the temperature of the LEDs as Ecolux has also argued. It is worth repeating that the only limit on the "condition" sensed is whether it is "proportional to the luminous output of the LEDs." 18 Ecolux's definition comes from its expert, Barry N. Feinberg. (See Ecolux's Mem. in Support of Mot. for Summ. J. of Non-Infringement at 7 & Ex. D.) He states without explanation that it is the definition given to "proportional" by those in engineering and mathematics. (See id.) To the extent that I accept "having the same or a constant ratio" as the definition of "proportional," I do so because it is the ordinary meaning of the word (as indicated in Webster's) and not because it is the opinion of Feinberg. Furthermore, in adopting this definition, I do not also adopt the alternative, "direct proportion" definition proposed by Ecolux. The claim language uses "proportional" without any qualification.

Despite the fact that the language of claim 1 neither explicitly or implicitly recites a location for the sensor, Ecolux nevertheless argues that such a requirement exists because the preferred embodiment diagram of the temperature sensor depicts it on the LED circuit board. Aside from this diagram, I find no support in the patent's specification for a locational requirement. Ecolux's argument is therefore an attempt to restrict claim language that is broader in scope than the preferred embodiment. The rules of claim construction do not permit this. See Electro Med. Sys. S.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054 (Fed. Cir. 1994) ("particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments").

Accordingly, I hold that a person of ordinary skill in the art of LEDs would understand "condition proportional" to mean that the sensor must sense a condition that has some fixed relationship with the LEDs' light output, but would not understand the phrase to require a certain location for the sensor.
with the selected format if any conditions associated with that format are satisfied. The term in itself does not connote what happens to the call if the format conditions are not satisfied, other than the call will not be interfaced with the format.

The specification provides that after the tests have been performed, "if the call is accepted, the process moves to initiate the selected format interface as indicated by the block 40. Conversely, if the call is to be rejected, the process moves to the step indicated by block 32, i.e. reject the call as with a message and release the line." Column 6, lines 34 through 41 of the '150 patent; Column 8, lines 4 through 6 of the '285 patent (identical provision). Figure 2 of the '285 and '150 patents, which are flow diagrams illustrating the operating process of the system, indicate that if the tests are not correlated, i.e. the conditions are not met ("No" at 48), the call flows in the direction of the arrow to 32, and the caller receives a reject message (32) and the line is released (34).

The specifications indicate that one possible result from a call in which the conditions associated with the selected format are not satisfied is that the call will be rejected and the line released. However, there is nothing in the specifications or the claim language that requires a call to follow the disclosed embodiment in Figure 2 and the specifications reciting the embodied result of rejecting the call and releasing the line. Further, the term "conditionally interfacing" does not in itself raise the question as to what happens to the call if the conditions are not satisfied other than that the call is not interfaced with a format, and there is no other language in the claims that otherwise restricts what happens to a call if the conditions of a format are not satisfied. The Court will not import the limitation on the claim language proposed by the defendants from the specification because there is no "hook" in the claim language on which such a limitation can hang. See Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1248, 1252 (Fed. Cir. 1998). Thus, the Court concludes that the claims do not require that the call be terminated if the conditions are not satisfied and the call is not interfaced.

Based on the foregoing, the Court construes the term "conditionally interfacing" to mean: connecting a call to the selected format once any conditions associated with that format have been satisfied.

The parties agree that the phrase "conditioning the signal for transmission to a remote receiver" means "converting the signal . . . for transmission to a remote receiver." The dispute is over whether a conversion into a radio frequency (RF) "format" is necessary.

Plaintiff argues that the specification discloses transmission of tire pressure data by radio waves and contemplates use of an RF signal. See '516 patent, Figs. 10a-10c; col. 2, ll. 64-67; col. 13, ll. 26-56 (discussing various aspects of the invention related to RF transmissions). Further, plaintiff points out, the specification discloses an communication protocol utilizing pulse width modulation (PWM). See id. at col. 15:33-61. Therefore, plaintiff argues, the invention disclosed in the '516 patent is directed solely to a RF-based TPMS.

The defendants argue that MHL's attempt to read a limitation into the claims should be rejected. They note that the phrase "a radio frequency (RF) format" does not even appear in the specification. Defendants argue that the specification discloses several embodiments for "conditioning the signal for transmission to a remote receiver" and, therefore, this term is entitled to a broader scope. See '516 patent, col. 9, ll. 2-5, ll. 25-31; col. 12, ll. 38-65; col. 15, ll. 17-20, 33-61.

It is clear from the specification that the invention is based on the use of RF signals alone. Each of the embodiments disclosed makes use of a RF signal for transmission. Given that the focus of the invention is to be able to use the wheel of the vehicle as an antenna, the Court finds that converting the signal into an RF one is an essential component of the invention. The Court construes this term as follows: "converting the signal into a radio frequency (RF) signal to be transmitted to a remote receiver."

4. "(1.2) Conducting a coarse frame synchronization over a plurality of said time slots which comprise a frame"
First, HTC contends that this "limitation is incapable of construction for failure to comply with paragraphs one and two of 35 U.S.C. § 112 because the phrase 'over a plurality of said time slots which comprise a frame' is insolubly ambiguous." Chart at 1-2. Section 112 provides:

The specification shall contain a written description of the invention and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same, and shall set forth the best mode contemplated by the inventor of carrying out his invention.

The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

"Because a claim is presumed valid, a claim is indefinite only if the "claim is insolubly ambiguous, and no narrowing construction can properly be adopted."” Honeywell Int'l, Inc. v. Int'l Trade Comm'n, 341 F.3d 1332, 1338-39 (Fed. Cir. 2003) (quoting Exxon Research, 265 F.3d at 1375). Claims are held to be indefinite only where a person of ordinary skill in the art could not determine the bounds of the claim. Halliburton Energy Servs. v. M-I LLC, 514 F.3d 1244, 1249 (Fed. Cir. 2008). "[C]laims are not indefinite merely because they present a difficult task of claim construction." Id. Finding a claim invalid on indefiniteness grounds requires "clear and convincing evidence that a skilled artisan could not discern the boundaries of the claim based on the claim language, the specification, and the prosecution history, as well as [the accused infringer's] knowledge of the relevant art area." Id. at 1249-50; accord Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1377 (Fed. Cir. 2001).

The Court declines to find that the cited phrase is incapable of construction. The parties agree that a "plurality" means two or more. Tr. 2/16/10 at 51 (IPCom) & 52 (HTC); see also Cybersettle Inc. v. Nat'l Arbitration Forum, Inc., 243 Fed. Appx. 603, 606 (Fed. Cir. 2007)(the term "plurality" means two or more). The inventors have instructed that "[t]here are eight time slots to a TDMA frame." '216 Patent at 1:64-65. Thus, "a plurality of said time slots" means two or more of the eight time slots which comprise a TDMA frame.

IPCom proposes that the referenced terms be construed to mean "[c]ontrolling a process to bring the mobile station's frame timing into at least approximate step with the base station's frame timing, such as by identifying a range within which the beginning of a frame falls." Chart at 1-2. As an alternative to its indefiniteness argument, HTC proposes "[c]ontrolling a first frame synchronizing process that utilizes a corrected phase course of a detected frequency correction burst to identify a range within which the beginning of a frame falls." Chart at 2.

The '216 Patent makes clear that it is necessary "to detect approximately the frame beginning for a particular channel" in order to achieve coarse frame determination and frame synchronization. '216 Patent at 5:57-58. As described in the specification, a frequency correction burst is first recognized and converted to baseband; then the I and Q components are sent to the analog to digital converter, and thereafter to the synchronization processor. Id. at 4:66-5:15; see also id. at 6:44-45 ("[w]hen the I and Q components are measured [for coarse frame synchronization], the received signal has been converted to the baseband"). "All of the synchronization routines which take place with the help of the synchronizing processor 28 are based on the processing of the phase angles calculated from the I and Q components," Id. at 5:11-15 (referring to Fig. 2); see also id. at 6:12-14 ("the corrected phase course of the received frequency correction burst 12 makes possible the determination of the beginning of a frame") (referring to Fig. 1).

The specification explains how to determine the beginning of a frame. First, the I/Q components' incoming signals must be analyzed to locate the frequency correction burst and determine generally when the frequency correction burst began. The specification discloses that "a simple criterion for the search algorithm for recognition of the beginning of the frequency correction burst 12 is provided, as shown in Fig. 5," which "shows how the corrected phase course of the received frequency correction burst 12 makes possible the determination of the beginning of a frame." Id. at 6:8-14 (referring to Fig. 1). Figure 5 depicts a "steadily rising line [that] can be calculated back to show that the burst began at the beginning of the interval marked 1 in Fig. 5," with the time region shown below the graph. Id. at 6:36-40. "From the beginning of the burst, the
beginning of a TDMA frame can be determined with reference to the time slot assigned to the mobile telephone, when necessary." Id. at 6:40-43. Because the frequency correction burst occurs in a known time slot of a frame, knowing the beginning of that burst allows the mobile station to determine when the frame itself began.

From these statements in the specification, the Court concludes that HTC has offered the better construction. The phrase "(1.2) conducting a coarse frame synchronization over a plurality of said time slots which comprise a frame" is construed to mean "controlling a first frame synchronizing process that utilizes a corrected phase course of a detected frequency correction burst to identify a range within which the beginning of a frame falls."

3. "Conducting a coarse frequency synchronization"

This phrase comes from substep (1.1) and may not be needed if the cell phone detects a carrier's signal that has "sufficient precision of . . . frequency tuning." Id. at 5:48-49. If the carrier signal is lacking sufficient precision of frequency tuning, this substep entails a "first frequency estimation . . . by means of the high frequency reception portion 21 of the radio receiver." Id. at 5:33-36 (referring to Fig. 3). "The result produces information of whether the frequency of the discovered carrier lies within or outside of a tolerance region TR (compare FIG. 3)." Id. at 5:36-39. "The tolerance region is variable, 10 so that the precision of the frequency estimation increases with a shrinking of the region for any particular data stream (compare FIG. 3 again)." Id. at 5:44-48. In laymen's terms, this means that the stronger the frequency signal, the more likely that frequency tuning between the mobile station and the base station occurs without substep (1.1).

10 See '216 Patent at 3:53-56 ("It is also possible . . . for the precision of the coarse frequency synchronization to be variable across the phase tolerance region (TR).")

IPCom proposes that the term be construed to mean "controlling a process to bring the mobile station's frequency into at least approximate step with the base station frequency, such as by selecting and tuning to a carrier frequency." Chart at 1. HTC counters with "having already tuned (selected) a carrier frequency, controlling a first frequency synchronizing process that estimates and refines the mobile station's frequency to within a tolerance region so as to be in approximate step with the base station's frequency." Id.

According to the '216 Patent, coarse frequency determination and synchronization do not entail "refining" the mobile station's frequency but, instead, "determin[ing]." '216 Patent at 5:31, whether a detected frequency signal from a carrier has "sufficient precision" already, id. at 5:48, or is "within or outside of a tolerance region TR," id. at 5:38, to be usable for communication. "[T]uning the coarse frequency determination" is not necessary when there is "sufficient precision of carrier frequency." Id. at 5:48-49. The parties disagree over whether, in this context, "determining" and "synchronizing" are the same thing; HTC says they are and IPCom says they are not. The Court concludes that they convey different actions. The high frequency reception 21 of the cell phone first "determines" whether the signal it detects is sufficient and then, if need be, "tunes," or synchronizes, to that signal.

The Court construes the phrase "(1.1) conducting a coarse frequency synchronization" to mean "having detected a carrier frequency, controlling a process to bring the mobile station's frequency into approximate step with the base station frequency, such as by tuning to a carrier frequency."

6. "(1.4) Conducting a fine frame synchronization over said plurality of time slots which comprise a frame"
The specification explains the need to achieve fine frame synchronization: to determine any "frame shift" resulting from delay in a signal reaching the mobile station. See '216 Patent at 2:33-42, 7:54-55, 8:20-25. "A bit accurate frame determination is possible by a pattern correlation procedure," id. at 7:24-26, which may be conducted by evaluating "the phase course of the training sequence within the synchronization burst 13." Id. at 7:35-37 (referring to Fig. 1). By matching the measured and expected phase courses of the synchronization burst, a "setting magnitude for bit synchronization" can be provided to "the central control unit 31." Id. at 7:33-34 (referring to Fig. 2); id., Figs. 4A & 4B. These procedures produce "necessary synchronization parameters (frame . . . shift)." Id. at 8:23-25. By determining how much to "shift" bits encoded in the base station signals, the mobile station ensures it can properly decode the information.

HTC first protests that this phrase is incapable of construction for failure to comply with paragraph 2 of 35 U.S.C. § 112 because the phrase "over said plurality of time slots which comprise a frame" is insolubly ambiguous. The Court rejects this argument as the claim can be construed as described below.

In the alternative, HTC proposes that the phrase be construed to mean "[c]ontrolling a second frame synchronizing process that conducts a pattern correlation of a measured phase course relative to a reference phase course to achieve a bit-accurate determination of the frame beginning." Chart at 2. IPCom proposes, instead, that the proper construction is "[c]ontrolling a process to bring the mobile station's frame timing into step with a desired operating accuracy with the base station's frame timing, such as by producing bit synchronization setting parameters." Id.

The Court finds its construction in the language of the specification provisions described above: "(1.4) conducting a fine frame synchronization over said plurality of time slots which comprise a frame" means "controlling a second frame synchronizing process that achieves bit-precision frame synchronization by recognizing and evaluating the training sequence within the synchronization burst." 823

9. "(3.2) Conducting a fine frame synchronization with fine frequency synchronization"

This phrase is the second step of extended synchronization, which "provide[s] synchronization of a mobile radiotelephone to neighboring cells of a cellular mobile radio communication system as a cell boundary is approached and crossed." '216 Patent at 8:5-7. By this process, "it is basically assured that upon leaving one radio cell the base station of that cell will not interfere with the continuation of the connection." Id. at 8:15-17. In other words, this process ensures that the on-going telephone call will not be dropped because the user is changing cell towers. Extended synchronization is provided as a "background procedure (process having lower priority) which produces the necessary synchronization parameters (frame and frequency shift) for the nearby cell in contemplation of a crossing from one cell to another." Id. at 8:21-27.

In particular, the synchronization procedure during normal operation performs a coarse frame synchronization (frequency burst beginning) 13 and a fine frame synchronization with fine frequency synchronization in which the synchronization burst 13 is used for the frame and frequency synchronization.

The relevant algorithms for the above steps correspond essentially to those designated 1.2, 1.3, 1.4 and 2.1 above, although more bits are involved in the extended training sequences.

Id. at 8:27-37.

and neighboring base station's frame timing in step within a desired operating accuracy while bringing the mobile station and neighboring base station's frequency in step within a desired operating accuracy, such as by producing frame shift and frequency correction parameters." Id.

The specification for the '216 Patent provides, "The relevant algorithms for [extended synchronization] correspond essentially to those designated 1.2, 1.3, 1.4, and 2.1 above, although more bits are involved in the extended training sequences." '216 Patent at 8:34-37. Since the two steps for extended synchronization "correspond essentially" to steps 1.2, 1.3, 1.4, and 2.1, the construction of the terms should also correspond. Accordingly, the Court construes "(3.2) conducting a fine frame synchronization with fine frequency synchronization" to mean "controlling a process to monitor and maintain the frame timing in step between the mobile station and neighboring base station while also maintaining the frequency within a desired operating accuracy between the mobile station and the neighboring base station, by producing frame shift and frequency correction parameters when crossing a cell boundary."

--- Footnotes ---

11 HTC conceded at the Markman hearing that the reference to "0.1 ppm" could be deleted from its proposed construction. Tr. 2/16/10 at 126 (HTC) ("I actually would be fine with striking that out."). See Conoco, Inc. v. Energy & Envtl. Int'l, L.C., 460 F.3d 1349, 1358 (Fed. Cir. 2006) ("When a claim term is expressed in general descriptive words, [courts] will not ordinarily limit the term to a numerical range that may appear in the written description or in other claims.").

--- End Footnotes ---

7. "2.1 Conducting a frame synchronization with fine frequency synchronization"

The parties jointly seek a construction of this phrase from Claim One of the '216 Patent. See '216 Patent at 9:37-38. It comes from Step 2 of the method, normal synchronization, substep 2.1, "frame synchronization with fine synchronization." Id.; see also id. at 7:45-47. HTC suggests it means "[c]ontrolling a process that, by evaluating each normal burst, produces both frame and frequency shift synchronization parameters for that burst to bring the frame timing and frequency of the mobile station in step with the base station." Chart at 2-3. IPCom prefers "[c]ontrolling a process to monitor and maintain the mobile station and base station's frame timing in step while having the mobile station and base station's frequency in step with a desired operating accuracy, such as by producing frame shift and frequency correction parameters." Id.

The patent discloses that "continuous monitoring and maintaining of the frame and frequency synchronism by the
evaluation of training [sic] sequence [sic] within the normal burst 14" assures "an error free decoding." '216 Patent at 7:49-52 (referring to Fig. 1). The "encrypted bits . . . serve to identify the training sequences." Id. at 7:53-54. "[A]ny frame shift is first determined" because the "value produced (timing pulse shift) is a necessary parameter in order to mark the pattern sequence with bit-accuracy within the data packet or sentence." Id. at 7:54-58. Because IPCom's proposal follows the specification more closely, the Court construes "(2.1) conducting a frame synchronization with fine frequency synchronization" to mean "controlling a process to monitor and maintain the frame timing in step between the mobile station and base station while also maintaining the frequency within a desired operating accuracy between the mobile station and the base station, by producing frame shift and frequency correction parameters." 12

12 The Court does not adopt IPCom's proposal to use the phrase "such as," i.e. "such as by producing frame shift and frequency correction parameters." Chart at 2-3. As HTC pointed out at the Markman hearing, "when you put "such as" in there it doesn't have to be practiced so it doesn't mean anything. In order for it to be a limitation, in order for it to mean something for the claim you have to remove the "such as" . . . ." Tr. 2/16/10 at 128 (HTC). This is distinguishable from the construction of "(1.1) [c]onducting a course frequency synchronization," above, where "such as" is appropriate because "tuning" may not be needed if the frequency signal has sufficient precision already.

Claim One of the '216 Patent provides for three steps to be carried out in the mobile radiotelephone: (1) initial synchronization; (2) normal synchronization; and (3) extended synchronization. '216 Patent at 9:4-20. In step (1), Claim One provides for "conducting an initial synchronization by means of a frequency correction burst." '216 Patent at 9:4-5. The purpose of the initial synchronization is "to provide the initial connection between a mobile radiotelephone and a fixed station." Id. at 5:23-24. The specification gives background information:

A base station sends signals on a broadcast control channel to enable a mobile station to synchronize itself to the base station and if necessary correct its frequency standard so as to put it in line with that of the base station. The signal[s] sent by the base station for these purposes are (a) frequency correction bursts and (b) synchronization bursts. A burst is defined as an interval within which the radio frequency carrier is modulated by a predetermined data stream.

Id. at 2:7-15.

The parties dispute whether the initial synchronization is conducted before or after the mobile station (i.e., cell phone) has selected a carrier 8 frequency. HTC maintains that initial synchronization is conducted after the cell phone has selected a carrier frequency, asserting that the correct construction is: "[h]aving selected a carrier frequency, synchronizing during initial connection by performing the claimed steps (1.1), (1.2), (1.2), and (1.4) on frequency correction burst 12." Chart at 1 (referring to Fig. 1). 9 IPCom proposes a broader construction: "[c]ontrolling a process to achieve an initial, synchronized connection between a mobile station and a base station through use of one or more frequency correction bursts." Chart at 1.

8 The "carrier" is the telephone service provider.
At times, the specification refers to the components of the invention by numbers shown in Figures 1 and 2.

HTC's definition will not suffice because it requires substep (1.1), i.e., "conducting a course frequency synchronization," see '216 Patent at 9:24-25, while the specification explains that substep (1.1) is not always necessary. Once the receiver in the cell phone detects a carrier frequency, it immediately makes a "first frequency estimation" to determine "whether the frequency of the discovered carrier lies within or outside of a tolerance region TR (compare FIG. 3)." Id. at 5:34-39. "With sufficient precision of carrier frequency tuning[,] the coarse frequency determination which is burst-independent can be dispensed with; in consequence the synchronization steps designated 1.2, 1.3 and 1.4 above then suffice for the initial synchronization."Id. at 5:48-52.

Moreover, HTC's definition fails because it states that the four substeps are performed on "frequency correction burst 12" when in fact not all of the four substeps utilize a frequency correction burst. Substep (1.1.), course frequency synchronization, is "burst-independent." Id. at 5:49-52. Substep (1.4), fine frame synchronization, also does not use a frequency correction burst; instead it "takes place by the recognition and evaluation of the training sequence in the synchronization burst." Id. at 7:22-24.

"Conducting an initial synchronization by means of a frequency correction burst" is construed to mean "controlling a process to achieve an initial synchronized connection between a mobile station and a base station through use of one or more frequency correction bursts and a synchronization burst."

With regard to the various "conductive" terms, plaintiff contends that the only term that the Court needs to construe is the very term "conductive." Defendants, on the other hand, contend that the term "conductive" should not be construed in isolation. Instead they propose constructions for "conductive wheel" and "conductive portion of the housing."

Plaintiff argues that because the '516 patent invention is directed to a high frequency RF-based TPMS, alternating current ("AC") conductive paths must be included in the term "conductive" or "conductive wheel." Where the specification uses "electrical conductivity," MHL argues that a person with ordinary skill in the art would understand this term to include both direct and alternating current. MHL argues that the inventors disclosed and anticipated AC current flow from the sensor to the wheel that acts as an antenna. The plaintiff argues that the specification makes multiple references to "impedance" and "impedance matching," which would only be relevant to an AC conductive contact. Therefore, MHL argues that even plastic that may be considered a good insulator can be the dielectric material of a capacitor, thereby being "conductive" of the high frequency current envisioned by the invention of the '516 patent.

5 Plaintiff points out that the '516 patent specification discloses an "impedance matching" circuit that compensates for undesired extraneous capacitive coupling effects due to, for example, the wheel standing in water. '516 Patent, col. 12, Il. 56-65. MHL contends that unless there was a capacitive contact between the sensor and the wheel, there would be no reason to compensate for undesired extraneous capacitive coupling effects. Both an impedance matching circuit and a capacitive coupling are only relevant to alternating current -- in this case the high frequency RF signal that is to be transmitted from the sensor.

Defendants argue that it is the "housing" and the "wheel" that are "conductors." 6 According to the defendants, MHL's construction makes every material a conductor because every material allows alternating current to pass to some degree. Defendants insist that plastic is non-conductive, and the mere potential to be used as a dielectric in a capacitor does not make a material "conductive."
6 Defendants note that the IEEE dictionary defines "conductor" as "a substance or body that allows a current of electricity to pass continuously along it." See THE IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS 176 (3d ed. 1984).

Volkswagen separately argues that the Court should adopt the understanding of the term "conductive" and "non-conductive" as disclosed by the specification. '516 patent, col. 10, ll. 12-14 ("Preferably, housing 154 is made of a lightweight, electrically conductive material, such as aluminum or the like."); see also id., col. 9, ll. 54-57 ("Non-conductive cap 122 includes a non-conductive spacer 130 made of a suitable material, such as plastic"). Volkswagen further points to various technical dictionary definitions of the term "conductive" as being a "material that offers a low resistance to the passage of electric current."

The Court finds plaintiff's argument persuasive with regard to conduction of high frequency AC signals in the patented invention. There is clear support in the specification that the inventor intended both the use of alternating current being conducted to the wheel and a elastomeric seal being used in the path of the current. 7 Further, the Court is not convinced that a construction that allows both DC 8 and AC 9 to pass would necessarily read out the term "conductive" from the claim. See Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."). Further, given that the disclosed embodiment uses an alternating current, the Court finds no need to mandate that "conductive" be required to conduct direct current as well. See Intel Corp. v. U.S. Int'l. Trade Com'n, 946 F.2d 821, 836 (Fed. Cir. 1991) ("Where a specification does not require a limitation, that limitation should not be read from the specification into the claims." quoting Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988)).

7 Further, plaintiff has presented the Court with engineering drawings done by the inventors at the time of the invention. See Plaintiff's Reply, Keane Decl., Ex. E. The drawings confirm the inventors' understanding, at the time of the invention, that the patented system anticipated a capacitor element, Cx, introduced by "Paint, Primer, Anodize, etc." along the path of the A/C signal being transmitted to the receiver. Id. These figures, however, were not disclosed as part of the patent application and are, therefore, not a part of the intrinsic evidence that Court relies upon in coming to its construction.

8 By defendants' own proposed construction, the term "conductive" allows direct current to pass.

9 The Court appreciates the fact that a dielectric used in a capacitor may not in itself be a conductor of either type of electric current. However, it is undisputed that the path between the sensor and the wheel has to allow an alternating current to "pass" for the patented invention to work as disclosed. Therefore, the term "conductive" has to be inclusive of allowing AC to "pass."

10 For instance, Volkswagen proposes a construction for "conductive" as a "material, such as aluminum or the like." Ordinarily, aluminum would conduct both types of current.

The terms "conductive wheel," "conductive portion of the housing," and "conductive portion" may be defined based on the construction of the term "conductive."

828
1. "conductive connection means communicatively connected to said gel layer"

Claim 1 of the '884 Patent describes first and second disposable electrodes including "conductive connection means communicatively connected to said gel layer." Cardiac Science maintains that this phrase should be construed as "configured to enable electrical connection to the gel layer." Philips, on the other hand, asserts that this is a means clause subject to 35 U.S.C. § 112, P 6, and that the functions of the clause are communicatively connecting to the gel layer and extending outwardly through the envelope. Further, Philips asserts that the structure corresponding to this function is a round wire covered by an electrically insulating material, such as polyvinyl chloride, that (1) is in direct contact with the gel layer, without the use of conductive contact layer, such as a homogenous, thinly deposited metallic layer, a conductive ink material, or a flexible metal mesh; and (2) starts inside the package, and continues through and beyond the package periphery. n7

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n7 Philips asserts that this term should be construed consistently with the terms "electrically interconnected to the conductive gel layer" and "communicatively coupled to the gel layer" from the '919 and '102 Patents, respectively. Thus, some of the Court's discussion of these terms will include language regarding all three patents -- the '884, '919, and '102 Patents -- and thus will overlap.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Philips is correct in asserting that Figures 13 and 14 are the only designs disclosed in the '884 Patent that use two electrodes that are placed together in a face-to-face relationship, consistent with the language of Claim 1. ('884 Patent at sheet 4.) In this embodiment, electrodes 128 and 129 each have two layers. Electrode 128 consists of non-conductive base layer 130 and conductive gel layer 131; electrode 129 consists of non-conductive base layer 133 and conductive gel layer 134. (Id.) The two layers are sandwiched together and separated by resistive layer 137. (Id.) In these drawings, the insulated lead wires 132 and 135 connect directly to conductive gel layers 131 and 134. (Id.)

The principal dispute regarding this term, and the somewhat corresponding terms of the '919 and '102 Patents, is whether these terms are restricted to two layers, as represented in Figures 13 and 14 of each of the patents. Philips argues that during the prosecution of the '884 and '919 Patents, Cardiac Science surrendered its claims for electrodes with a conductive layer between a base and conductive gel layer, and thus the construction of these terms is limited to a two-layer embodiment.

During the prosecution of the '884 Patent, the patent examiner specifically withdrew claims of electrodes with "a second conductive layer" because they were "drawn to a non-elected species." (Axtell Ex. 25 at CSI 000076-77.) After that withdrawal, the applicants cancelled the "second conductive layer," a.k.a., the "three-layer" claims. (Id. at CSI 000105.) The applicants then added the so-called "two-layer" claims, which required the "connection means" to be "communicatively connected to said gel layer." (Id. at CSI 000087.) The application with these changes issued as the '884 Patent.

A divisional application was also filed just before the '884 Patent issued. The PTO restricted the application (Axtell Ex. 23 at CSI 0001081), and the applicants elected to prosecute claims directed to Figures 13 and 14. (Id. at CSI 0001084.) The PTO responded by stating that none of the claims read on the elected species. (Id. at CSI 0001088.) The PTO requested further clarification, stating, "Each of the independent claims recite an electrode comprising a base layer, a conductive contact layer overlying the base layer and a gel layer overlying the contact layer. The elected species does not show or disclose this three layer combination." (Id.) The applicants amended the claims to remove the additional conductive contact layer. (Id. at CSI 0001090-93.) Similar to the '884 Patent, the claims were also amended to include an insulated lead wire "electrically interconnected to the conductive gel layer." (Id. at CSI 0001090-1094.) This application issued as the '919 Patent.

Just before the '919 Patent issued, the applicants filed a continuation-in-part application that included additional text and drawings. (Axtell Ex. 27 at CSI 000302.) The application recited the same two-layer claims as the previous applications. (Id. at CSI 000322-29.) This application issued as the '102 Patent.

Philips asserts that Cardiac Science's proposed construction of the terms "communicatively connected," "electrically interconnected," and "communicatively coupled" to the gel layer are too broad. To some extent, Philips is asking the Court
to engage in an infringement analysis, as Philips asserts that its electrodes are comprised of three layers and that Cardiac Science disavowed a three-layer construction during the prosecution of the '884, '919, and '102 Patents. Cardiac Science asserts that its responses to restrictions were not disavowals of claim scope.

At least one court has held that if the record demonstrates that the PTO examiner restricted the species elected, the applicant's "subsequent election of claims may constitute an avowed understanding that those claims were directed to that subject matter." R2 Med. Sys., Inc. v. Katecho, Inc., 931 F. Supp. 1397, 1439 (N.D. Ill. 1996). The Court recognizes that R2 is not binding precedent, and that the Federal Circuit has not yet confronted this issue. And, disavowal or not, the Court has "broad power to look as a matter of law to the prosecution history of the patent in order to ascertain the true meaning of language used in the patent claims[.]" Markman, 52 F.3d at 980.

The Court has reviewed the prosecution history of the patents at issue. Here, the examiner expressly identified the elected species as being limited to two-layer embodiments, and the applicants subsequently elected two-layer claims. Although Cardiac Science did not contest the PTO's restriction or request for clarification redirecting the inventors to claims that matched Figures 13 and 14, the election of the broader, two-layer elected species did not constitute an express disavowal or disclaimer of the more specific, three-layer embodiment. See Omega Eng'g, Inc., 334 F.3d at 1323-26. Yet, the Court can consider the prosecution history to determine how the PTO and the inventor understood the patent. Philips, 415 F.3d at 1317. The Court finds that here, the claim language at issue does not require the Court to incorporate into the construction of the terms at issue whether an express disavowal of the three-layer claims occurred. This discussion will be more appropriate for an infringement analysis than directed to claim construction of the terms that are at issue.

Thus, the Court returns to the claim construction of "conductive connection means communicatively connected to said gel layer." The Court finds that this phrase is not in a means-plus-function format because there is no clearly identified function. See York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1574 (Fed. Cir. 1996)(absent an identified function, the term "means" does not trigger 35 U.S.C. § 112, ¶ 6). The "conductive connection means" describes the structure of the invention that is in contact with the electrode's gel layer. In the only embodiment of the '884 Patent that describes the two-electrode system, this phrase specifically refers to the leads that extend from the conductive gel layers. ('884 Patent at c. 7, ll: 30-47.) "Communicatively connected" refers to the manner in which the leads link the current loop from the electrodes to the AED, so that the viability of the electrodes may be tested without opening the electrode envelopes. (Id. at c. 7, ll: 48-51.) The Court finds that "conductive connection means communicatively connected to said gel layer" should be construed as "a conductive lead or leads that are configured to enable electrical connection to the gel layer."

For the purposes of this discussion, the disputed claim language can be roughly broken up into three parts. First,
"conductive leads," are identified, then the relationship between the "conductive leads" and the "electronic device" is described, and finally the relationship between the "conductive leads" and the "conductive traces" is described. In each relationship, the "conductive leads" "electrically couple" or are "electrically coupling," with the "conductive traces" and "electronic device," respectively. Properly understood, the entire phrase describes "conductive leads" acting as electrically conductive bridges between the "conductive traces" and the "electronic device." That understanding may be gained from the plain and ordinary meaning of the language, and even if it were not, the Court would not adopt Tessera's construction because it offers no more guidance than the claim language itself.

Tessera's construction tracks the three part structure described above. In describing the relationship between "conductive leads" and "an electronic device," Tessera's construction provides that "conductive leads" are "used as input/output (I/O) for connecting the package body to an external device." Compare 8:1-2 ("conductive leads for electronically coupling with an electronic device."). Essentially, Tessera substitutes "connecting" for "electrically coupling," which would not offer much assistance to a juror. See Sulzer Textil A.G. v. Picanol N.V., 358 F.3d 1356, 1366 (Fed. Cir. 2004).

The construction goes on to say that "[t]he conductive leads are connected to the conductive traces (emphasis added)" and then clarifies that the purpose of that connection is "to provide an electrical current path between the leads and the traces." Compare 8:2-3 ("conductive leads electronically couple to said conductive traces."). Here, Tessera has broken up the phrase "electrically couple" into two phrases that are longer, but not significantly more helpful, than the phrase itself. Tessera's construction is not incorrect or confusing, but it simply reorganizes the claim language without offering more guidance than the claim language itself, which makes Tessera's construction unhelpful, and therefore, improper. Sulzer, 358 F.3d at 1366.

The Court will now address the parties' arguments regarding the construction of "conductive leads." The basic disagreement concerns Tessera's requirement that "conductive leads" be "long and thin, not shaped as a mass." Micron insists that the patent does not restrict the physical shape or size of the "conductive leads," but Tessera argues that Figures 2 and 3 depict "conductive leads" as long and thin, and further argues that one skilled in the art at the time the patent was issued would understand "conductive leads" to be "long and thin, not shaped as a mass." However, the claim language does not explicitly support such a limitation, nor do the specification or extrinsic evidence compel the conclusion that "conductive leads" must take on any particular physical form.

The specification implicitly refers to the "conductive leads" only three times, calling them "input/output (I/O) leads" or just "I/O leads." 2:24-26; 3:57-60; 4:45-48. Like the claim language, the specification focuses on the role "conductive leads" play, rather than their form. 2:24-26 (describing pads on the upper surface of the shelf being electrically coupled with conductive traces which attach to input/output (I/O) leads); 3:57-60 and 4:45-48 (describing coupling traces with I/O leads by means such as side brazing). Although Figures 2 and 3 depict "conductive leads" as long and thin, the Court declines to read that limitation into the claim. Burke, Inc., v. Bruno Indep. Living Aids, Inc., 183 F.3d 1334, 1341 (Fed. Cir. 1999).

Tessera also argues that, without regard to how the term "leads" is used within the patent, the meaning of "lead" was
independently established at the time this patent issued, and any person skilled in the art would understand that "leads" were "long and thin, not shaped as a mass." Micron disputes Tessera's understanding, and the Court finds that the extrinsic evidence is not clear enough to support Tessera's limitation.

In support of its limitation, Tessera cites several patents issued around the time the '328 patent was issued that contain embodiments where "leads" are shown as relatively long and thin. However, the fact that these leads are long and thin does not necessarily require that leads in general must be "long and thin, not shaped as a mass." Tessera goes on to argue that the common understanding of "leads" excludes masses, bumps, or balls, pointing out that chip packages employing solder balls are known as "leadless packages" in the packaging industry. Micron counters that the common understanding of the word lead is much more inclusive, citing the 1989 Edition of the Electronic Materials Handbook, which defines "lead" as "[a] conductive path, usually self-supporting. That portion of an electrical component used to connect it to the outside world."

Electronic Materials Handbook, Vol. 1 at 1148 (1989). This definition is consistent with the patent's treatment of the "conductive leads," which was based primarily on the function of the "conductive leads" rather than their form. As the extrinsic evidence is conflicted, the Court is reluctant to rely on that evidence to justify Tessera's more restrictive construction of "conductive leads." Phillips v. AWH Corp., 415 F.3d 1303 (Noting that extrinsic evidence is "less reliable than the patent and its prosecution history in determining how to read claim terms."

The last point of contention concerns Micron's use of the phrase "on the outside of the body." Tessera objects to this language on the basis that "conductive leads" cannot be, at once, a part of a body and outside of that body. The Court disagrees with the logic underlying Tessera's argument, and finds that the additional language is consistent with the claim language and specification. The claim language describes a self-contained die package with "conductive leads for coupling with an electronic device (emphasis added)." The electronic device is separate from the claimed logic component, and the leads couple the package with the outside device. Thus, in order to couple with a separate device, it is seemingly necessary that the leads be on the outside of the body. The specification reinforces this understanding of the placement of the conductive leads. 3:57-59 ("the traces have means for coupling with I/O leads on the outside of the ceramic body."); 4:45-47 ("The traces have means for coupling with I/O leads on the outside of the body). Accordingly, the Court construes "conductive leads" to mean "conductive input/output (I/O) elements on the outside of the body."

830

A. "a plurality of conductive lines having inherent distributed capacitance"

The '811 patent claim mentions "conductive lines" several times. Defendant contends that the term refers only to word lines in memory arrays; plaintiff asserts that it can also refer to any line capable of conducting current. In determining the meaning of "conductive lines," the Court will not apply section 112(6) because "conductive lines" are not the structure corresponding to the selecting, voltage pulse generating, transfer, or switching means. Rather, the Court is guided by normal principles of claim construction. Perceiving no "ordinary or accustomed meaning" of "conductive lines," see Wolverine World Wide, 38 F.3d at 1196, the Court turns to the specification, which supports plaintiff's broader construction. It states that:

Although this disclosure has been made with reference to raising the voltage on a word line in a memory array, those skilled in the art will recognize that other lines, such as y-lines, select lines and write lines may be pumped up to higher voltages by use of this invention.

'811 Patent, 7:28-31. Figure 4 of the specification, moreover, shows the charge pump circuits connected not only to word lines, but also to y-lines, write lines, and a sense line. '811 Patent, Fig. 4, 7:42-8:3.

Defendant argues that the phrase "conductive lines having inherent distributed capacitance," incorporated into the claim from the preamble, requires "conductive lines" to be construed as "word lines." According to this argument, capacitance is only "distributed" if it results from contact with transistors evenly spaced along the line; word lines are the only kind of conductive lines that have evenly spaced transistors. Because the specification defines the meaning of "conductive lines," however, the Court may not consider defendant's extrinsic evidence about the meaning of "distributed capacitance" and the spacing of transistors along various kinds of lines. See Vitronics, 90 F.3d at 1584. Accordingly, the Court holds that "conductive lines" refers not only to x-lines, but also to other lines that conduct current.
The parties agree that the term "plurality" means "two or more." Noting that this is the common meaning of the word, see York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1575 (Fed. Cir. 1996), the Court adopts the parties' construction.

Claim 1, with emphasis added, is representative of the asserted claims and reads as follows:

1. A capacitive displacement sensor, comprising a vessel having a wall including at least two adjacent conductive wall segments,

   means for electrically insulating said wall segments from each other,

   a dielectric coating on the interior of at least one but not all of said wall segments, the interior of at least one conductive wall segment being exposed,

   a conductive liquid-like medium contained inside said vessel covering a variable part of at least one wall segment with said dielectric coating and at least one wall segment without said dielectric coating, and electronic means electrically connected to at least one wall segment with said coating and at least one wall segment without said coating for producing an output related to the capacitance between said liquid-like medium and said one wall segment with said dielectric coating,

   whereby displacement of said vessel causes relative movement between said vessel and said liquid-like medium and a concomitant detectable change in the capacitance between said liquid-like medium and the wall segment with the dielectric coating.

Ekchian filed suit against Lucas alleging that the Lucas "Accustar" inclinometers infringe every claim of the '140 patent. The accused device uses a vessel partially filled with liquid and has a thin film coating on an interior wall. Lucas denied infringement, claiming that the liquid in the accused device acts as a dielectric across which an electric field is generated and that, in any event, its liquid is not sufficiently conductive to be covered by the claims of the patent.

On Lucas's motion for summary judgment, the district court construed the claim term "conductive liquid-like medium" as requiring a conductivity similar to the examples contained in the specification, which exceed the conductivity level of the liquid in the accused device. The court held that in light of its claim construction and based upon prosecution history estoppel, the accused device did not infringe the patent, literally or under the doctrine of equivalents.

DISCUSSION

Determining whether a patent claim has been infringed requires a two-step analysis: "First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device or process." Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1576, 27 U.S.P.Q.2d (BNA) 1836, 1839 (Fed. Cir. 1993). Claim construction is a question of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 983-84, 34 U.S.P.Q.2d (BNA) 1321, 1333 (Fed. Cir. 1995) (in banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384, 38 U.S.P.Q.2d (BNA) 1461 (1996). In construing the claims, the court looks to the patent itself, the prosecution history, and, if necessary, extrinsic evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2d (BNA) 1573, 1576-77
Application of a properly construed claim to an accused device is a question of fact. On appeal from a grant of summary judgment of noninfringement, we must determine whether, on the patentee's version of the facts, the district court correctly concluded that the patentee had failed to show that a reasonable jury could find infringement. See Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986); Conroy, 14 F.3d at 1575, 29 U.S.P.Q.2D (BNA) at 1377 ("The moving party . . . may discharge its burden by showing the district court that there is an absence of evidence to support the nonmoving party's case.").

In construing the claims of the '140 patent, the district court declined to adopt Ekchian's proposed definition of "conductive" as "the slightest ability to carry a current" because it concluded that such an interpretation would render the limitation meaningless, essentially reading the term "conductive" right out of the claims. Because Ekchian's proposal would "include virtually all liquids (and, indeed, all materials) on the planet," the district court sought a narrower definition that would render the term meaningful. The court concluded that, as a matter of law, the claimed conductive liquid-like medium did not extend to the liquid in the accused device. In particular, it determined that the liquid in the accused device "is vastly less conductive" than the preferred liquid mentioned in the patent specification and that the two liquids appear to be used for different purposes, the invention employing a liquid as a capacitor plate and the accused device employing a liquid as a dielectric.

Ekchian argues that the district court erred in its claim construction by reading the conductivity of the preferred embodiment into the claims. Ekchian contends that the patent does not impart any special meaning to the term "conductive" and therefore that the term's ordinary meaning to those skilled in the art should control. Lucas, on the other hand, contends that the district court properly interpreted the claim in light of the specification and that the patent defines "conductive liquid-like medium" as being limited to liquids having a conductivity equal to or greater than the examples listed in the specification. To support its proposition, Lucas relies on the following sentence in the specification which states, "Accordingly, the label 'conductive liquid-like medium' used herein shall refer to materials of whatever kind whether liquid or not, meeting the foregoing requirements of flowability, conformity, horizontal surface retention and conductivity." '140 patent, col. 5, line 66 - col. 6, line 2.

Lucas argues that the examples of conductive liquids in the specification are the only "foregoing requirements of . . . conductivity" disclosed in the patent and therefore must be read as limiting the claim term. We do not agree. Contrary to the assertion by Lucas, the expression "the foregoing requirements" also refers to the enumerated requirements immediately preceding the quotation, which include, "in addition, all points beneath the horizontal upper surface of the liquid medium must be conductive, preferably but not necessarily uniformly conductive." '140 patent, col. 5, lines 60-63. The statement thus is not a reference only to the stated examples, as Lucas asserts.

More importantly, Lucas identifies nothing further to support its contention that the term "conductive" is limited to the conductivity levels inherent in the disclosed examples. While examples disclosed in the preferred embodiment may aid in the proper interpretation of a claim term, the scope of a claim is not necessarily limited by such examples. See Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 U.S.P.Q.2D (BNA) 1289, 1299 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."); Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563, 231 U.S.P.Q. (BNA) 833, 835 (Fed. Cir. 1986) ("This court has cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification."). We therefore conclude that the term is not so limited.

Because the specification does not use the term "conductive" in a special or unique way, its ordinary meaning to one skilled in the art controls. See Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580, 36 U.S.P.Q.2D (BNA) 1162, 1165 (Fed. Cir. 1995) ("The words of a claim will be given their ordinary meaning to one of skill in the art unless the inventor appeared to use them differently."); cf. Texas Instruments, Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558, 1564, 39 U.S.P.Q.2D (BNA) 1492, 1497 (Fed. Cir. 1996) ("Although the dictionary broadly defines 'conductor' as any substance that conducts an electrical charge, the patent itself belies such a broad construction.").

Ekchian contends that those skilled in the art would recognize that the term "conductive liquid-like medium" in the context of the claimed invention refers to any material that is sufficiently more conductive than the dielectric so that a capacitor is formed. We agree. There is nothing in the patent specification that suggests that Ekchian intended to limit the meaning of
that term to a specific range of conductivity. This does not mean that the claim term "conductive" is meaningless or superfluous. Both Lucas and Ekchian agree that the term "conductive" ordinarily means the ability to transport electric charge. Furthermore, it is undisputed that the specification and prosecution history both state that the liquid must act as a capacitor plate, which must necessarily store electric charge. Therefore, one skilled in the art of capacitor design would recognize that the term "conductive" modifies "liquid-like medium" in the claims to indicate that the liquid must act as a capacitor plate, i.e., that it must be sufficiently more conductive than the dielectric material so that it stores electric charge. Accordingly, we hold that the district court erred in its claim construction by incorrectly limiting the degree of conductivity permitted by the term "conductive liquid-like medium." Within the context of this patent, "conductive liquid-like medium" means a medium sufficiently conductive to perform its function as a variable capacitor plate.

2. "conductive semi-liquid gel layer"

Claim 1 of the '884 Patent discloses a "conductive semi-liquid gel layer." Philips asserts that this term should be construed as "a thickness of semi-liquid material having low resistance." Cardiac Science asserts that the term should be defined as "a thickness of conductive semi-liquid materials."

The specification refers to several brand-name compounds that share the characteristics of the conductive gel layer, as contemplated by the patent. ('884 Patent c.5, ll: 6-9.) The specification states that "generally, these compounds have low resistivities." (Id. at c. 5, ll: 6-7.) However, the Court finds no support in the patent specification to limit the conductive gel layer to a certain low resistance, as Philips suggests. (Tr. at 214.) And the term "conductive" speaks for itself. Thus, the Court finds that the term "conductive semi-liquid gel layer" is appropriately construed as "a thickness of conductive semi-liquid materials."

C. The "Conductive Shield" of a "Coaxial Cable"

The meaning of "conductive shield" is the final dimension of the parties' dispute over the meaning of a "coaxial cable having a center conductor and a conductive shield." Plaintiff proposes that "conductive shield" simply means "an enclosing conductor that reduces interference." Quest describes the shield as "an outer conductive tube that is concentric with the center conductor' and reduces the effect of external electrical interference on the voltage varying electrical signal transmitted on the center conductor.'" 9 The parties thus dispute whether the conductive shield must be a concentric conductive tube or can merely be an enclosing or outer conductor.

9 In their responsive brief, Quest offered the compromise construction of "reduces the effect of . . .," a modification of their earlier construction that the conductive shield "minimizes the effect of . . ." and Monster Cable has agreed to this clause.

The claim language does not describe the conductive shield as a tube. Rather, it only requires that the conductive shield is outside and surrounding the center conductor. The ordinary meaning of the relational terms "inner" and "outer" used in the claims, combined with this court's claim construction that conductors must share an axis, makes it clear that the center conductor passes through the conductive shield. However, the patent or the intrinsic evidence thereto does not include any further specification about the shape of the conductive shield. Nor does the ordinary meaning of the word "shield" in the context of audio electrical engineering specify that the outer conductor must be a tube or that it must be concentric with the inner conductor. See, e.g., The Audio Dictionary, Masur Decl., Exh. J (defining "shield" as "an enclosure which protects its contents against the influence of magnetic fields or electrostatic fields or both"). The outer conductor thus need not be shaped as a tube.
Adding a further limitation onto the relative location of the inner conductor or the shape of the conductive shield based on the preferred embodiment or other assumptions about the standard shape of a conductive shield would attach unwarranted limitations into the patent claims. See E-Pass Techs., Inc., 343 F.3d at 1364 (holding that where "preferred aspects" of an invention are subject to variability, references to them should not be understood as limitations on the ordinary meaning of claim terms). As discussed, the lack of a concentricity limitation on the coaxial cable element, particularly in light of the presence of the helical shape of the outer conductor in the 787 Patent's coaxial cable, demonstrates that the conductive shield need not be concentric with the inner conductor.

Thus, for the reasons stated above, the court construes the conductive shield as an "outer conductor that reduces the effect of external electrical interference on the voltage varying electrical signal transmitted on the center conductor."

3. "the conductive wire portion of which contacts said gel layer"

Claim 2 of the '884 Patent describes the "connection means" of Claim 1 as an insulated wire, "the conductive wire portion of which contacts said gel layer." Cardiac Science maintains that "conductive wire portion of which contacts said gel layer" should be construed as "electrically connected to the gel layer." Philips contends that this phrase should be construed as "conductive wire portion of insulated wire is in direct contact with the gel layer, without the use of a conductive contact layer, for example an intermediate metallic layer." Philips also renews its disclaimer arguments, as discussed in Section II.D.1, above.

The Court finds that "conductive wire portion of which contacts said gel layer" should be construed as "the conductive wire portion of the insulated wire that is in contact with the gel layer." The phrase needs no further construction.

3. Conductor

Plaintiff one or more conducting media connecting said amounts
Defendant a single conductor (rather than two or more conductors) that connects the oxidizable and reducible species and upon which the entire amounts of the oxidizable and reducible specie in each device rest, have access to, or are carried

The parties agree that the claim term "conductor" refers to a conducting medium. The parties dispute whether "conductor" means a single, common conductor, as defendant contends, or whether "conductor" means one or more conducting media, as plaintiff asserts.
The Court agrees with plaintiff's proposed construction. Contrary to defendant's proposed construction, there is nothing in the claim language that specifically states that only one conductor may be used. For example, claim 46(c) states:

one or more conducting media connecting said amounts of said oxidizable species and said reducible species, all of said amounts of said oxidizable species and said reducible species having access to a conducting medium . . . .

This claim refers to "one or more conducting media" and "a conducting medium" -- not "the conducting medium," as one would expect under defendant's proposed construction. ('014 Patent, col. 11, lines 45-58 (emphasis added).) Therefore, the Court construes the claim term "conductor" in the '014 patent to mean "one or more conducting media."

ii. Die Pad as a Conductor
Defendants argue that there can be no literal infringement of Claim 12 because their devices are not attached to a "conductor," as the Court defined the term. 6 Again, TI's response ignores the Court's claim construction. TI contended throughout trial that a conductor was "anything capable of conducting electricity and which actually functions to conduct electricity." See, e.g., TI's Revised Proposed Jury Instructions, filed May 5, 1995, p. 32. The Court rejected this definition, concluding that the term conductor was not used in this generic or "dictionary" sense in the '027 or '764 patents, but had a much more specific meaning. TI's response to Defendants' motion points to the testimony of Mr. McAlexander and Dr. Seiling as sufficient evidence of literal infringement, even under the Court's construction. The Court cannot agree.

6 Claim 12 requires "mechanically attaching a portion of [the] device to at least one of the conductors for support." PX 2, 12:29-31. The Court defined "conductor" as "those portions of the [lead frame] assembly that extend from inside the package to the outside, and connect the semiconductor device to an external circuit." Jury Charge, p. 14.

Had the Court accepted TI's proposed claim construction, the cited testimony would have been sufficient. Under the Court's construction, however, the testimony falls short. It is undisputed that, after trimming, none of Defendants' lead frames have die pads that extend from inside the plastic encapsulation package to the outside. 7 At that stage, the die pad thus cannot be a conductor under the Court's definition.

7 The testimony on this issue was somewhat confusing, due to differing definitions of what constitutes a "pinned out" die pad. In one form of pin out, which Mr. McAlexander apparently recognized, Tr. 690:1-7, the tie bar extends into a lead which goes outside of the package. This type of pin out would meet the Court's definition of a conductor, assuming the lead connected the device into an external circuit. The only example of this type of pin out shown to the jury was PX 140.22(b), a TI lead frame. Mr. McAlexander testified that Defendants did not pin out their die pad in this way. Tr. 690:1-7. Dr. Rodgers testified to the same effect. In the face of this evidence, no rational juror could conclude that Defendants used pinned out lead frames in which the die pad extended out as a lead.

Dr. Seiling, however, testified that 2/3 of Defendants' lead frames were "pinned out" or used down bonding. There is no inconsistency, because a review of the exhibits cited, see, e.g., PX 626, and the testimony, demonstrates that Dr. Seiling used a different definition, describing pin out as meaning that "the die bond pad is connected to a conductor in the central region, which will eventually end up as one of the pins on the outside of the package." Tr. 1128:22-25. Dr. Seiling made clear that the connection was by means of a whisker wire. Tr. 1129:1-5. This type of pin out does not meet the Court's definition of the term conductor, because the die pad itself does not extend from inside the package to the outside. It is merely connected to a structure that does.

The testimony becomes even more confusing however, because what Dr. Seiling calls pinning out, Mr. McAlexander calls down bonding. Tr. 616:17-25. And what Dr. Seiling calls a down bond (i.e. a whisker wire connection from a terminal to the die pad, Tr. 1127), Mr. McAlexander calls a "wire to top side bond." Tr. 626:14. The Court will adopt Dr. Seiling's terminology for the remainder of the opinion, because the evidence demonstrates that Defendants employ no other form of pinning out than that which he described.

Before trimming, it is true that the die pad does extend from inside the package to the outside, because it is connected to the rest of the lead frame. However, Mr. McAlexander's testimony that the lead frame, including the die pad, functions as a conductor during manufacture by preventing static electricity from damaging the semiconductor does not establish literal infringement under the Court's definition. Nothing in Mr. McAlexander's testimony shows that the die pad's conductivity during manufacture connects the die to an external circuit. Indeed, the import of his testimony is that during manufacture the die pad prevents the die from being connected to an external circuit. Tr. 591-92.

The remainder of Mr. McAlexander's testimony, regarding the conductive function of the die pad in conjunction with down bonding, pinning out and substrate pumps, does not and cannot establish literal infringement, because none of these techniques utilize a die pad that extends from inside to outside of the package. The fact that a whisker wire may connect the
die pad to a lead is not sufficient to establish literal infringement, because, as Mr. McAlexander conceded on cross
examination, whisker wires are not conductors within the meaning of the patent. Tr. 753:5-12. Whether Mr. McAlexander's
testimony is sufficient for infringement under the doctrine of equivalents is discussed below.

Defendants' remaining arguments in favor of JMOL on the issue of literal infringement of Claim 12 are without merit.
Contrary to Defendants' contention, Claim 12 does not require that the die be entirely on one side of the plane formed by
the conductors (as Claim 14 does), but only that it be generally on one side. Compare Jury Charge at 15 with Jury Charge at 17-
18. There was sufficient evidence for the jury to find that Defendants' devices were generally on one side of the plane, and
that the gate was located on the other side of the plane, notwithstanding Defendants' depressed die pad.

837

a. The "Connecting the Device to a Conductor" Limitation of Claim 12 of the '027 Patent and Claim 16 of the '764 Patent

Both parties agree that claim 12 of the '027 patent and claim 16 of the '764 patent require the semiconductor device to be
connected to a "conductor." 4 The district court construed the term "conductor" to include "those portions of the [lead
frame] assembly that extend from inside the package to the outside, and connect the semiconductor device to an external
circuit. In other words, [conductors] are leads." Texas Instruments Inc. v. Cypress Semiconductor Corp., Civ. No. 3-90-
CV1590-H, slip op. at 10 n.6 (N.D. Tex. Sept. 6, 1995). On appeal, TI argues that the court misconstrued the term
"conductor." In particular, TI asserts that a "conductor" encompasses any element capable of conducting electricity.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

4 The process in claim 12 requires "mechanically attaching a portion of said device to at least one of the conductors for
support." The process in claim 16 also requires "conductively connecting one face of a semiconductor wafer to one of said
conductor strips in the central region."

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

We disagree. Although the dictionary broadly defines "conductor" as any substance that conducts an electrical charge, the
patent itself belies such a broad construction. See Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580, 36 USPQ2d 1162,
1165 (Fed. Cir. 1995) ("The words of a claim will be given their ordinary meaning to one of skill in the art unless the
inventor appeared to use them differently.").), cert. denied, 116 S. Ct. 1567, 134 L. Ed. 2d 666 (1996). Claim 12 states that the
"ends of the conductors extend[] from the mold cavity" and are held during the encapsulation process. In addition, claim 16
requires "enclosing the . . . assembly in plastic insulating material to surround the [semiconductor device] and parts of the
conductor strips." Thus, both claims indicate that a "conductor" for purposes of the invention extends beyond the plastic
encapsulation. The specification further supports the district court's claim construction. Figure 8 of each patent illustrates
the completed encapsulated semiconductor devices made by the claimed processes, with the conductors extending from the
device. In discussing these completed devices, the specification states that "the respective conductor wires can subsequently
be cut away to a customer's specification so that any arrangement of leads . . . can be provided for integration into
substantially any circuit." '027 patent: Col. 7, ll. 3-7; '764 patent: Col. 6, ll. 54-58 (emphasis added). Thus, the patentee did
not use the term "conductors" in the claims as the term is defined in the dictionary, i.e., any structure capable of conducting
electricity; instead, the patentee used the term in the claims to mean leads that "extend from inside the package to the
outside, and connect the semiconductor device to an external circuit." Texas Instruments, slip op. at 10 n.6. The court did
not err in so construing the claims.

838

2. "Through conductors" means "through any electrically conductive material."

The phrase "through conductors" appears only in Claim 1 of the 059 Patent. The claim covers a defibrillator maintenance
method including a step that "periodically deliver[s] a test pulse in a defibrillator from an energy source through conductors

- 1309 -
Philips urges the court to construe "through conductors" to mean "through any electrically conductive material." Defibtech insists that the "conductors" in the phrase are limited solely to the "patient electrode leads," which are the wires connecting the defibrillator to the electrodes used to shock a patient.

The claim language establishes that the claimed conductors are a pathway between an "energy source" and a "patient simulator." There is no express or implicit requirement that the conductors lead to defibrillator electrodes. Indeed, no claim of the '059 Patent mentions "electrodes." The written description, on the other hand, frequently discloses "conductors" between the electrodes and other components. E.g., '059 Patent at 3:27 ("Conductors leading from at least two electrodes"), 3:53-54 (same), 4:9-10 (same). The written description also admits that the invention applies only to medical instruments that use electrodes. '059 Patent at 9:2-6.

Nothing in the remainder of the specification, however, requires that the electrodes and the patient electrode leads be part of the pathway between the energy source and the patient simulator. Several disclosures indicate otherwise. The schematic diagrams illustrating the invention ('059 Patent Figs. 1, 2) demonstrate connections between the patient simulator and various energy sources that do not pass through the patient electrode leads. The written description discloses that "[o]ther suitable tests" will be apparent to persons of skill in the art ('059 Patent at 3:42-43), and these may be tests that do not require the patient electrode leads. In addition to testing for various electrode related problems, the invention is capable of diagnosing problems with the "defibrillator circuit itself," a test that would not necessarily involve the electrodes. '059 Patent at 4:30-38. Because the written description shows conductive pathways that do not include the electrodes, and because there is no "clear disavowal" of conductors between the energy source and the patient simulator other than the patient electrode leads, the court declines to limit Claim 1. Liebel-Flarsheim, 358 F.3d at 908. Accordingly, "through conductors" means "through any electrically conductive material."

1. "conference controller," "through a conference controller"

<table>
<thead>
<tr>
<th>NICE's Construction</th>
<th>Witness's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>A component that initiates, enables and/or establishes a conference call.</td>
<td>Device that initiates, establishes and enables a conference call.</td>
</tr>
<tr>
<td>By use of a conference controller.</td>
<td>The data packet transmissions of the IP data session pass through the conference controller.</td>
</tr>
</tbody>
</table>

The parties dispute the meaning of "conference controller" and "through a conference controller," as used in claim 1. NICE contends that the specification shows that a "conference controller" initiates, enables, and/or establishes a conference call, but all three functions only in "exemplary" situations, citing col. 5:6-col. 6:32. NICE also contends that nothing in the specification requires a "conference controller" to be limited to a device or hardware and to exclude software. Witness contends that the disputed term must initiate, enable, and establish a conference call, citing Figure 3 as demonstrating a conference controller performing all three functions.

With respect to "through a conference controller," NICE contends that Witness's proposal that data packets physically flow into and through conference controllers makes no sense based on how one skilled in the art would understand the specification. Witness contends that the use of both "through" and "using" in the claim language means each should have distinct meanings, and that "through" should not then be construed to mean "by use of." Further, Witness contends that NICE consistently used the term "through" to mean "flow through" during the prosecution, and in particular in distinguishing Rust prior art, citing '106 Pros. Hist., Resp., 21 n.5, dated Sept. 11, 2005. NICE responds that Witness's use of prosecution history is tortured and inaccurate, and that Figure 1 and the specification support its construction, citing col. 7:13-16 ("implementing the data session as a conference call through a conference controller such that said first and second communication devices are connected."). NICE further contends that the claim language and specification make clear that the conference controller serves to implement the connection of the two communication devices before there is any information flowing between them.
The Court construes "conference controller" to mean "a component that initiates, enables and/or establishes a conference call." Figure 3, which Witness bases its construction on, clearly "shows an optional flow of operations." (col. 6:17-23.) Moreover, even in Figure 3, the enabling function is only preferable. (Id., "[c]onference controller 30 enables recording device 24 to participate in the conference call, as well as preferably enabling the conference call itself.")

The Court construes "through a conference controller" to mean "the data packet transmissions of the IP data session pass through the conference controller." While NICE demonstrated that Witness's reliance on the prosecution history was misplaced, it failed to respond to Witness's contention regarding the use of both "through" and "using" in the claim language. In light of the claim language itself and the specification, the Court concludes that Witness's construction is the correct one.

III. "conferencing control" / "central control manager"

The phrases "conferencing control" and "central control manager" appear in claim 15 of the '654 patent:

15. A method of conducting a teleconference among a plurality of participants, comprising the steps of:

(a) initiating a video conference, from one of a plurality of workstations, using a video conferencing control included within each of the plurality of workstations, the video conferencing control establishing communication with a central control manager to set up AV paths along a first network over which the video conference can be conducted;

(b) capturing video images and spoken audio of the participants for transmission in the form of AV signals over the AV paths during the video conference;

(c) reproducing the video images and spoken audio on at least one first monitor, positioned near each workstation, from the AV signals received over the AV paths during the video conference;

(d) initiating a data conference, during the video conference, using a data conferencing control included within each of the plurality of workstations, the data conferencing control establishing communication with the central control manager to set up requested data paths along a second network over which the data conference can be conducted; and

(e) sharing data, among the plurality of participants, during the data conference, such that data received over the data paths is displayed on at least one second monitor included within each workstation.

'654 patent at 43:20-44:23. As the two terms are related to each other, the court will construe them together.

A. "conferencing control"

CPI proposes that the phrase "conferencing control" should be construed to mean "video or data conferencing software and/or hardware at a workstation." Tandberg proposes that the phrase should be construed to mean "software executed by the workstation that initiates all collaborative sessions by setting up appropriate services and paths via the central control manager." The parties' constructions differ in two respects. First, Tandberg's construction requires that the conferencing control set up all services and paths via the central control manager. Second, CPI's construction allows the conferencing control to be made up of hardware and/or software, while Tandberg's construction requires that the control be made up exclusively of software.

The phrase "conferencing control" does not appear anywhere in the specification of the patent. The parties agree, however, that the element in the preferred embodiment corresponding to the conferencing control is the Collaboration Initiator. See Spec. at 18:51-52 ("The central component of the Collaborative Multimedia Workstation software is the Collaboration Initiator 161.").
Tandberg argues that CPI's proposed construction is too vague because it says nothing about what the conferencing control does. Without some further restriction, "video conferencing software and/or hardware" might encompass any part of the workstation that is involved in a videoconference: the keyboard, the monitor, the camera, the CPU, and the operating system, as well as any special-purpose software or hardware associated exclusively with videoconferencing. CPI's construction is indeed too broad because it fails to account for the claim language. The phrase "conferencing control" has two elements. First, the term relates to "conferencing"-both videoconferencing and data conferencing. Second, the term encompasses the notion of "control." The surrounding claim language indicates that the control, at a minimum, must include setting up video and data conferences. See id. at 43:25-28 ("the videoconferencing control establishing communication with a central control manager to set up AV paths along a first network over which the video conference can be conducted") (emphasis added); id. at 44:5-9 ("the data conferencing control establishing communication with the central control manager to set up requested data paths along a second network over which the data conference can be conducted") (emphasis added). Moreover, "control" has broader meaning than "initiation"; the conferencing control is used to facilitate as well as initiate calls. See Spec. at 18:35-41 ("[conference control] Software 160 allows the user to initiate and manage (in conjunction with the server software) videoconferencing, data conferencing, multimedia mail and other collaborative sessions."). The court therefore finds that the conferencing control must be able to "control"-i.e., initiate and facilitate-video and data conferences.

Tandberg is also correct in arguing that the "conferencing control" must "set[] up appropriate services and paths via the central control manager." The claim language already expressly includes this limitation, however, and adding it to the definition of "conferencing control" would be redundant. See '654 patent at 43:25-28, 44:5-9.

Turning to whether the control may consist of hardware or software, the specification clearly indicates that videoconferencing functionality may be implemented in hardware as well as software. See Spec. at 18:5-8 ("Given the proximity of Side Mount device 850 to the user, and the direct access to audio/video I/O within that device, various additional controls 820 can be provided at the user's touch (all well within the capabilities of those skilled in the art)."

The "Side Mount" device is, in the preferred embodiment, a piece of additional hardware which is connected to a desktop computer or workstation. Id. at Fig 18B. Limiting the phrase "conferencing control" to software would exclude this disclosed embodiment, which is disfavored unless the claims present a compelling reason to do so.

Finally, the court notes that the hardware and software comprising the conferencing control must be present at each workstation. '654 patent at 43:23-24.

The court therefore construes the phrase "conferencing control" to mean "hardware and / or software at each workstation which is used to initiate and facilitate videoconferencing, data conferencing, and other collaborative sessions."

841

K. "wherein the interface device is configured by the processor and memory to include a first command interpreter and a second command interpreter"

The Camera Manufacturers propose that the phrase "wherein the interface device is configured by the processor and memory to include a first command interpreter and a second command interpreter" in the '399 Patent means that "the processor of the interface device runs a program from its memory to determine the data transfer parameters of the interface device for the first and second command interpreters." CMs' Slides at 115. The Court will adopt this construction.

After initially proposing no construction for this phrase, at the Markman hearing Papst proposed that it be interpreted to mean that "the interface device has first and second command interpreters and that they are implemented by the processor and the memory." Papst's PowerPoint Slides [Dkt. # 244, Ex. A] ("Papst's Slides") at 79; see Tr. 2:59 (Papst). Papst contends that the use of the passive voice, in the phrase "the interface device is configured by" does not suggest the active running of a software program. But as the Camera Manufacturers note, "the first and second command interpreters have to know how to communicate with the data transmit/receive device. They have to know how to make that data transfer occur and presumably it could be different for any particular data transmit/receive device." Tr. 2:63 (CMs). Moreover, even Papst's proposed construction recognizes that the command interpreters are "implemented" by the processor and the memory, implying that the processor runs a program from its memory.
Papst argues that the Camera Manufacturers' construction would render dependent Claim Eight meaningless, and thus it should be disfavored. See Cytologix, 424 F.3d at 1173 (if possible, a court should avoid an interpretation of one claim that renders another meaningless). "[A] claim in dependent form shall contain a reference to a claim previously set forth and then specify a further limitation of the subject matter claimed. A claim in dependent form shall be construed to incorporate by reference all the limitations of the claim to which it refers." 35 U.S.C. § 112. In other words, a dependent claim incorporates all of the limitations of the claim from which it "depends" and adds something new; thus, a dependent claim has a narrower scope than the claim from which it depends. Further, "the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Phillips, 415 F.3d at 1315. Claim Eight provides:

An interface device according to claim 7, wherein the virtual files comprise a configuration file in text format which are stored in the memory means and using which the user can configure the interface device for a specific data transmit/receive device.

'399 Patent, col. 13:37-41. Papst contends that because Claim Eight addresses the idea of configuring the interface device, Claim One must not deal with configuring the device. Tr. 2:60 (Papst).

Papst's argument fails. Claim Eight is unrelated to the construction of the "wherein" clause regarding configuration of the interface device to include command interpreters. Claim Eight merely refers to a separate mechanism, "configuration files," that can be used to configure the interface device "on the fly." Tr. 2:65 (CMs). The phrase "[w]herein the interface device is configured by the processor and memory to include a first command interpreter and a second command interpreter" as used in the '399 Patent means that "the processor of the interface device runs a program from its memory to determine the data transfer parameters of the interface device for the first and second command interpreters."
Honeywell asserts that Sandel is again attempting to improperly limit the claim language by using the patent specification. Sandel argues that its proposed construction is consistent with the specification, as well as dictionary definitions.

In its brief, Honeywell cites two dictionary definitions which sufficiently describe "configurable." The court rejects Sandel's proposed construction because it is too narrow, and imports a limitation from the specification which is not present in the claim language.

GO BACK

843

4. Configuration state

Claim 2 of the 651 patent imposes the limitation that the step of configuring further includes "receiving input from a configuration user" and "validating said input based on said definition, said set of relationships, and a current configuration state. . . ." The parties dispute the meaning of "configuration state."

Trilogy defines "configuration state" as "the status of the elements in the current configuration." Selectica contends that "configuration state" is defined by three types of state information-"selected," "selectable" and notSelecteable"-that track the state of parts in the configuration. Selectica argues that the patent uses "current state" and "configuration state" interchangeably and that the patent explicitly defines "current state" at col. 10, line 25:

The current state is defined by three types of state information that track the state of parts in the configuration. The current state is visible to the user. The three state types are: selected, selectable, and notSelectable.

According to Selectica, all parts options necessarily fall within one of these configuration states. Those included in the current configuration are "selected" parts. Those which could be added to the current configuration are classified as "selectable" parts. Those which cannot be used in the current configuration fall in the classification of "notSelecteable." Selectica thus contends that its definition captures all of the logical options available for the "configuration state."

Selectica's construction imports too many limitations from the preferred embodiment. After considering the parties' positions, the court construes "configuration state" to mean "the status of the elements in the current configuration."

GO BACK

844

1. "configuration table"

HP asks the Court to construe this term as: "A data structure used to organize information regarding the assignment of certain operating parameters of the storage system." EMC proposes: "A table organized on a logical unit by-logical unit basis containing, for each logical unit, one or more data fields related to the logical unit."

The meaning of "configuration table" is unclear from the language of claim 1, which indicates that a "configuration table" may contain "entries governing one or more interactions between the logical units and the two or more host computing systems" and "an access field entry for each logical unit." Claim 3 includes a further potential characteristic of a configuration table: "a host mode entry for each logical unit."

The written description states that "the configuration tables store information relating to which host connection a particular
logical unit should communicate with, any LUN numbers offsets employed by the logical unit to communicate with a particular host, and any special host modes' employed by the array controller in communicating with a particular host."

979:3/64-4/2. Thus, the claim language and the specification indicate that the configuration table contains data that govern the interactions between logical units and host computing systems. The specification and the claims include examples of the specific types of data contained in a configuration table, including "access fields," "offset fields," and "host mode fields." See e.g., 979:4/3-36 & 5/21. However, such examples need not be imported as limitations for the purposes of defining this particular term. Indeed, claim 1 explicitly does not include an "offset field entry" limitation or a "host mode entry" limitation (these are found in dependent claims 2 and 3). Using the doctrine of claim differentiation as a guide to claim construction, Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991), it would be inappropriate for the Court to specify particular types of entries in its construction of "configuration table."

HP's proposal also is ambiguous and potentially is too broad. Under HP's construction, the configuration table would contribute to organization of "information regarding the assignment of certain operating parameters of the storage system." However, the claim and the specification indicate that the configuration table is limited to data that govern the interactions between the logical units and the host computing systems. It is unclear from the intrinsic evidence what "assignment of certain operating parameters" means. According to a dictionary cited by HP itself, "a table is a data structure used to organize information." Langraff Decl., Separate Appendix, vol. 7, p. 1221. Notably, HP concedes that "the configuration table must specify information that governs aspects of the interaction between the logical units of the storage system and the host computing systems connected to the storage system." HP's Opening Brief, pp. 39-40.

At the same time, EMC's proposal is too narrow. While certain data relating to logical units obviously are contained within the configuration table, nothing in the claim language or the specification requires limiting the configuration table to a certain internal organization ("a table organized on a logical unit by-logical unit basis").

Accordingly, the Court construes this term as "a structure organizing data that governs the interactions between logical units and host computing systems."

1. "interacting with a graphical user interface to configure said imaging system"

Plaintiffs' construction: setting up the imaging system via a graphical user interface to control the association with a remote device

Defendant's construction: inputting commands via a graphical user interface to select or activate particular functions of the imaging system to control the association with a first remote device

At the claim construction hearing, the parties agreed that the following construction of this term would be acceptable: "interacting with a graphical user interface to control the association with a first remote device." I will adopt the parties' agreed upon construction.

Court's construction: interacting with a graphical user interface to control the association with a first remote device

5. "the second end configured for electrical interconnection to a defibrillator"

Claim 1 of the '919 Patent describes an insulated lead wire with two ends, "the second end configured for electrical interconnection to a defibrillator." Claims 2, 12, and 17 contain similar language. The parties dispute the meaning of this term. Cardiac Science contends that it refers to a "wire configured to enable electrical connection to the defibrillator." Philips asserts that it should be construed as "the second end of the insulated lead wire having a connector designed to be plugged into a defibrillator."
Philips contends that the terms at issue here relate to the '919 Patent's requirement that the packaged electrodes be "interconnected to the defibrillator" -- or "pre-connected" -- prior to use. Philips relies on a decision from the United States District Court for the Central District of California, which held that the '919 Patent's claims were likely to be found invalid because the claimed invention of pre-connecting the electrode to a defibrillator was not described in the '919 Patent specification. Cardiac Science v. Zoll Med. Corp., Case No. 02-2514 SVW (CTx)(N.D. Ca. Jul. 15, 2002).

The Court finds that the decision in Cardiac Science v. Zoll Med. Corp. is neither relevant nor binding to this Court's claim construction of this term. The Court further finds that the language of the claim and the specification does not require that the insulated lead wire have a connector that can plug into a defibrillator, as Philips contends. The Court finds that the plain language of the claim merely requires that the second end of the insulated lead wire allows for electrical interconnection to the defibrillator.

2. "Configured to Encrypt"

The parties also seek an interpretation of "configured to encrypt." The ordinary meaning of this phrase is "capable of encrypting." The specification reinforces this meaning when it notes that the invention's "delivery systems have the capability of performing dynamic encryption of data as the data is downloaded onto a user's storage media." Id. at 15:11-13 (emphasis added). Audible suggests that encryption is mandatory, but the court finds no support for that contention in the intrinsic evidence.

As Digeo noted at oral argument, it might be preferable to encrypt all data transferred to an end user, but nothing in the patent requires it. "Configured to encrypt" means "capable of encrypting."

4. Construction of "Configured to Operate in either the Presence or Absence of a Bandwidth Encompassing Modem Signal"

Plaintiffs contend that the claim language "configured to operate in either the presence or absence of a bandwidth encompassing modem signal" needs no construction. Defendants contend that this claim language should be construed as requiring that the claimed invention "[be] capable of working both with and without a modem attached." n8 (Def.'s Handout p. 40.)

n8 This proposed construction differs from the one set forth in Defendant's claim construction brief. (See Def.'s Cl. Constr. Br. p. 19 (providing that this claim language should be construed as "limit[ing] the claimed invention to a device that is capable of working both in the presence of a modem signal and in the absence of a modem signal, i.e., the device must be able to work without a modem attached just as well as when a modem is attached and is in use.").)
an adequate discussion of modem signals that are bandwidth encompassing. For example, in the context of distinguishing a prior art reference, the applicant noted:

The configuration will not work if modern high speed modems are substituted since the spectrum used by modern high speed modems utilize the complete standard 300 to 3400 Hz bandwidth of a typical telephone channel (bandwidth encompassing) and would randomly trigger the detection even though a 440 Hz SAS signal may or may not be present.

(Dec. 12, 2002 Amendment p. 5.) In the context of explaining the frequency spectrums associated with "modern modems," the applicant provided:

Similarly for the above modem the 387 Hz, 1200 Hz and 2200 Hz frequencies are far enough from 440 Hz that the published configuration would work with this modem but not a modern modem (such as a US Robotics 56K which utilize the total bandwidth of a telephone channel i.e. bandwidth encompassing).

(Id. at p. 7.) Finally, in the context of explaining why their invention is novel, the applicant stated:

[B]y qualifying signals (filtering) based on duty cycle or cadence coupled with level and frequency indication to decide what signals have been encountered reliable operation is guaranteed since modern modems utilize all of the standard 300 to 3400 Hz bandwidth of a telephone channel and that includes the 440 Hz SAS frequency.

(Id.); see also Irdeto Access, 383 F.3d at 1300 ("It is well-established that the patentee can act as his own lexicographer, so long as he clearly states any special definitions of the claim terms in the patent specification or file history.") (citation omitted).

Defendants do not adequately address the prosecution history of the '771 Patent when suggesting that the meaning of the claim phrase "bandwidth encompassing modem signal" might be uncertain to one of ordinary skill in the art. (See Def.'s Handout p. 44 ("The specification is utterly silent about any 'bandwidth encompassing modem signal'") (emphasis added); see also id. at p. 45 (focusing on prosecution history remark that "[n]o modems are required.").) As noted above, the prosecution history provides considerable discussion of the "bandwidth encompassing modem signal." In addition, when read in context, there is no basis for concluding that the remark that "[n]o modems are required" limits the scope of the claim in the manner suggested by Defendants. (See Dec. 12, 2002 Amendment pp. 2-13); see also Nystrom v. TREX Co., Inc., 424 F.3d 1136, 1142 (Fed. Cir. 2005) ("The person of ordinary skill in the art views the claim term in the light of the entire intrinsic record . . . the prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention . . . .") (emphasis added) (internal quotation marks and citations omitted).

Defendants also presented the following argument at the Markman hearing: (1) it is impossible to have a modem signal without a modem; therefore, (2) the phrase "the presence or absence of a bandwidth encompassing modem signal" means "the presence or absence of a modem." This argument fails for two reasons. First, the argument is based on faulty logic. It does not follow from the fact that, for example, it is impossible to have a modem signal without a related power source, that the phrase "the presence or absence of a bandwidth encompassing modem signal" also requires "the presence or absence of a power source for a modem signal." Second, the argument impermissibly removes the term "signal" from the claim language. The limitation at issue says nothing about operating in the presence or absence of a modem; instead, it focuses on operating in the presence or absence of a particular type of modem signal. See, e.g., '771 Patent, Col. 14, ll. 61-63 ("wherein the apparatus is configured to operate in either the presence or absence of a bandwidth encompassing modem signal") (emphasis added). There is simply no support in the intrinsic record for deleting "signal" from this claim limitation.

In sum, this Court rejects Defendants' argument that the claim language "configured to operate in either the presence or absence of a bandwidth encompassing modem signal" means that the claimed invention must "be capable of working both with and without a modem attached." Therefore, this Court concludes that no further construction of this claim language is necessary. This claim language is found in claims 1, 6, and 9 of the '771 Patent.
The Court agrees with Ciena’s proposed construction and construes the term as “programmed to supply service channel optical signals.” Ciena argues that the term should not be construed but offers its proposed construction in the alternative. Nortel argues that the term should be construed as “programmed to periodically supply service channel optical signals.” Nortel argues that the specification requires that each network element of the invention “periodically” transmits information to the other node control processors in the network. Nortel cites the abstract, the field of the Invention section, and the detailed description section of the ‘392 patent in support of its argument. See e.g.,Cols. 1:60-67; 7:11-19. However, a preferred embodiment of the invention indicates that the service channel optical signals are not always supplied periodically. Column 7, Lines 28 through 34 of the specification state,

Assuming that a break occurs in fiber 68, [Service Channel Modem] 26 and 32 detect the break and set the fault bit in an LSP to signify that a break has occurred. The LSP is next passed from SCM 32 to SCM 36, and from SCM 26 to SCM 22. If additional network elements were included in the span, the LSPs would be successively passed from SCM to SCM down the span until the terminals were reached.

This excerpt from the specification indicates that signals for service are sometimes sent episodically sent when a problem arises as opposed to exclusively being sent periodically. Nortel’s construction excludes this preferred embodiment. “The Court must always read the claims in view of the full specification. A claim construction that excludes a preferred embodiment . . . ‘is rarely, if ever, correct.’” SanDisk, 415 F.3d at 1285 (citing and quoting Vitronics, 90 F.3d at 1582-83). Accordingly, the Court construes “configured to supply service channel optical signals” as “programmed to supply service channel optical signals.”

850

2. "configuring a flash memory storage module" (claims 1 and 6)

The plaintiff asks the court to construe this term to mean "preparing the flash memory chip to receive and respond to commands" and the defendant asks the court to construe the term to mean "setting up physical storage media and its internal data structure." The specification does not mention the term "configuring."

The defendant argues that the plaintiff's proposed construction is identical to the meaning of "initialization" as used in claim 4 and thereby violates the principle of claim differentiation. The parties agreed to a define "initialization operation" (from claim 4) to mean "an operation that prepares the data processing system and the external storage device to read and write data." The court does not agree with the defendant that the plaintiff's proposed construction is merely a restatement of the parties' construction for "initialization operation."

The defendant devotes most of its argument with respect to this claim term to attacking the plaintiff's proposed construction rather than advocating its own proposal. The defendant's proposed construction is close to a verbatim quote of the specification at col. 4, ll. 15-16. However, the defendant does not explain why the court should adopt that language as its construction apart from arguing that by "reading the claim language as a whole and in context" the "configuring limitation clearly refers to setting up physical storage media of the external storage device and its internal data structure." Defs. Resp. Brf. at 18, 21.

The original application included both method claims and device claims. Claim 21 of the original application was a device claim. App. Ser. No. 09/687/869. All claims were cancelled and the method claims were elected for prosecution and claims 21-33 were added. Claim 21 included both a "configuring clause" and an "arranging" clause as follows:

21. An electronic flash memory external storage method, wherein comprises [sic] steps

configuring a portable external storage device, which comprises an USB or IEE [sic] 1394 interface, a microprocessor, a flash memory storage module and the firmware built-in said microprocessor for implementing and controlling the request of data access operation [sic] corresponding to with USB or IEEE1394 interface standard between the flash memory storage module and data processing system;
arranging internal data storage structure of the flash memory storage module according to an uniform data block unit. . . .

April 28, 2003 Amendment.

Prosecution claim 21 was cancelled and prosecution claims 24-46 were added. Issued claim 1 corresponds to prosecution claim 34. See Sept. 2003 Amendment; Oct. 2003 Amendment. The plaintiff argues that the arranging portion of prosecution claim 21 was cancelled, so the "arranging" portion claim 21 was eliminated so that limitation should not be imported into the construction of "configuring." This position is supported by the '672 patent specification.

The specification does not disclose building blocks of memory or forming blocks of memory. Instead, the specification identifies specific chips that are manufactured by third parties that can be used to practice the '672 patent. See col. 8, ll. 19-23; col. 11, l. 50-col. 12, l.14. The intrinsic record is clear that the language "method of setting up physical storage media of the external storage device and its internal data structure" from column 4 of the '672 patent does not mean that "configuring . . . module" includes physically arranging the data setting up the storage media and its internal data structure. The defendant's proposed construction could be interpreted to include that limitation, which was disavowed by the patentees and is not supported by the specification.

In light of the intrinsic record and the plain meaning of "configuring "the term "configuring a flash memory storage module" is defined to mean "preparing a flash memory chip to receive and respond to commands." 851

"Confined multipath [transmission] environment"

The Court adopts CSIRO's proposed construction and construes the term "confined multipath [transmission] environment" to mean "an indoor environment." Buffalo argues that the Court should interpret the term more expansively to mean "a defined environment with boundaries wherein direct and/or reflected paths may be taken by radio frequency signals from a transmitter to a receiver." Though Buffalo does not dispute that "indoor environment" is consistent with the plain meaning of the claim language and concedes that the specification contains references to such an environment, Buffalo contends that neither the claim language, the specification, nor the file history limit the term's construction to only an indoor environment.

CSIRO argues that its proposed construction comes from the claims' plain meaning as well as their context in light of the specification and prosecution history, whereas Buffalo's construction is ambiguous and baseless.

Although on its face the term "confined" does not seem limited to an indoor area, that term clearly refers to an area with fixed boundaries—an attribute that Buffalo's proposed construction does not adequately capture. "Confined" and "defined" are hardly synonymous, and Buffalo's inclusion of the term "boundaries" in its construction conceivably includes anything that reflects radio waves creating an indirect transmission path—even a meteor trail or satellite. Without further narrowing of its proposed "defined environment," Buffalo's construction of "confined multipath environment" is too broad to permit one of ordinary skill in the art to understand the term's meaning.

The specification describes the specific multipath signal problem that the invention was designed to address. The specification notes how the invention was designed to ameliorate problems that occur more acutely in a wireless LAN multipath "office or indoor environment" and "typical rooms" than with telephone or long distance radio communications. 069 Patent, cols. 4:58-59,5:3-15, 8:38-40. Buffalo contends that reliance on this language improperly reads an extraneous limitation from the specification into the claims, but the specification language simply defines an existing limitation and deriving interpretive guidance from such language is proper. See Phillips, 415 F.3d at 1317 ("It is . . . entirely appropriate for a court, when conducting claim construction, to rely heavily on the written description for guidance as to the meaning of claims").

The prosecution history also shows that the patentees linked "confined multipath environment" to an indoor environment. After the patent examiner rejected the patentees' original claims filed with their 1993 application as obvious in light of the prior art, the patentees amended their claims and distinguished the prior art as being designed to operate over long distances instead of within "a room of an office building or the like, unlike the present invention." July 1995 Amendment to U.S. Patent Application 157,375, at 26. The prior art did not "appear[] to describe radio transmissions in a confined multipath
environment.”” Id. at 27. The prosecution history thus links "confined multipath environment" with an indoor environment. Accordingly, the Court construes "confined multipath environment" to mean "an indoor environment."

The parties dispute when this phrase calls for the invention to confirm that the hardware key is connected to a subscriber client computer. Defendants propose that it occurs "after initial authentication, but before session termination," or, in other words, during re-authentication only. Plaintiff contends that the "to thereby confirm" limitations in claims 1 and 24 are broad enough to allow the hardware key's connection to be confirmed during both initial authentication and re-authentication.

As discussed in the preceding section of this Memorandum Opinion, the specification teaches that the "identity data" of the subscriber client computer is comprised of a subscriber's username, password and, in the case of two-factor identification, a hardware key's predetermined digital identification. (Id. at col. 35, ll. 48-50). Per Claims 1 and 24, the first server computer is adapted to forward the "identity data" of the subscriber client computer "at the beginning of an operating session." (Id. at col. 35, ll. 36-40). Consistent with the Court's construction of "operating session," once the identity data is confirmed, including confirmation that the hardware key is connected, an operating session begins. It therefore follows that the claim limitations requiring forwarding of the predetermined digital identification during an operating session do not read on initial authentication.

The '416 Patent describes that the invention initially authenticates subscribers, and then re-authenticates them throughout the operating session. Initial authentication occurs at login, and results in initiating an operating session. Re-authentication occurs after initial authentication but before the operating session terminates. Therefore, pursuant to the patent language and teachings, the phrase "to thereby confirm that said hardware key is connected to said subscriber client computer" only applies to the system's efforts to confirm that the hardware key is attached during re-authentication. Accordingly, the Court construes this phrase to mean "to verify after initial authentication, but before session termination, that the hardware key remains connected to the subscriber client computer."

"congestion" is construed to mean "the occurrence of more work than can be handled in a specific period of time."

Lucent contends that this term means "the occurrence of more work than can be handled by the facility in a specific period of time." (D.I. 396 at 15.) Extreme contends that this term means "the occurrence of more work than can be handled in a specific period of time due to the formation of many paths or circuits for routing the packets at the switch node." In support of its contention, Extreme points to Lucent's discussion of congestion in the background of the patent. ('811 patent at 2:5-11.)

The Court finds that the description of the causes and results of congestion do not serve to limit the claim term. Rather, the Court adopts Lucent's proposed construction and modifies it to eliminate the reference to the term "facility," which does not appear in the claim. The Court's construction is supported by Lucent's definition of "congestion of a facility" in the specification. (Id. at 2:10-11.)

"evaluating congestion at the switch node" is construed to mean evaluating congestion anywhere within the switch node. According to Newbridge, a construction of this phrase "requires a determination of the congestion at the point in the switch node at which the dropping decision will be made on a data packet which has been prepared for transmission from the switch node." (D.I. 547 at 25). After reviewing the claim language and the specification, the Court concludes that the phrase
is not limited in the manner in which Newbridge suggests. The phrase "at the switch node" indicates that this evaluation takes place at the switch node, but does not require that the evaluation be at a specific point at the switch node. Moreover, the specification suggests that there are nodes with multiple queuing points such that independent congestion evaluations at multiple buffers within the node are not excluded. (811 Patent, col. 1, ll. 53-61). Accordingly, the Court declines to limit the phrase in the manner suggested by Newbridge.

The plaintiff contends that the terms do not need to be construed. To the extent that a construction is needed, the plaintiff proposes that "coupling" be construed as "connecting" and "connectable" be construed as "capable of being connected." The defendants propose that both terms be construed as "capable of being placed in data communication." The court has consistently construed the term "coupled" to mean "directly or indirectly connected." Accordingly, "for coupling" means "for directly or indirectly connecting." Furthermore, the court agrees with the plaintiff that "connectable" means "capable of being connected."

The term "connected" is used extensively throughout the specification and the claims. It does not appear to have a different meaning other than its plain and ordinary meaning. The Court rejects Defendants' construction to include the language "not isolated," which is a negative construction on a term that does not require a negative construction. Further, Defendants are blending separate concepts, as "isolated" is a separate term that has no relevance to the word "connected." "Connected" is simply not synonymous with "not isolated." Further, the Court finds that a "direct" connection is not required. The Court agrees with SynQor that one of ordinary skill in the art, based upon the specification and the claims, would understand the term "connected" to mean an indirect or direct electrical connection. See Texas Instruments, Inc. v. Linear Tech. Corp., No. 2:01-cv-03, Dkt. No. 133 at 13 (E.D. Tex. April 3, 2002). Thus, the Court construes the term "connected" to mean "electrically connected, directly or indirectly."

Claim 1 recites that the invention is comprised of "at least one hardware key connected to the subscriber client computer," and Claims 1 and 24 require that the subscriber client computer "forward [a] predetermined digital identification to [the] first server computer to thereby confirm that [the] hardware key is connected to said subscriber client computer." The parties agree that "hardware key" is used synonymously with the terms "access key" and "hardware access key" in the specification. (D.I. 266 at 27, D.I. 268 at 7). However, they disagree over whether the specification uses the term "connected" interchangeably with "attached."

Plaintiff contends that the hardware key does not need to be an external device, but could also be built into the subscriber
client computer. Plaintiff further contends that "connected," as used in the '416 Patent, means only that the access key interface can read the digital ID from the access key. Plaintiff contends that the patent does not require any specific kind of connection between the hardware key and the access key interface.

Defendants contend that a "hardware key connected to the subscriber client computer," as used in the context of the specification, is an external device that physically attaches to the subscriber client computer. (D.I. 268 citing '416 Patent at col. 21, ll. 39-45, col. 7, ll. 61). They further argue that Plaintiff's proposed construction, that the hardware key can be built into the computer, would eliminate the need for the invention to verify the presence of the access key.

After reviewing the term "hardware key" in the context of the specification, the Court concludes that the specification requires that the hardware key be an external hardware device. ('416 Patent, col. 21, l. 40). The Court declines to adopt Plaintiff's proposal that the key can be built into the computer, because the "major function of the [hardware key] is to uniquely identify a user," and the specification teaches that the key should be something "which is known to have been assigned and given to a specific person." n2 (Id., col. 21, ll. 45-46, col. 22, ll. 4-5). A hardware key built in to a computer is computer-specific, not user-specific.

--- Footnotes ---

n2 Plaintiff also supports its argument that the hardware key can be built into the computer by pointing to the following language in the specification: "Generally, two factor authentication provides that something is known, such as the name and password and something is held, such as the physical key that is attached to the computer, or built into the computer." (D.I. 266 at 28, citing '416 Patent, col. 21, ll. 49-53; see also Transcript of Markman Hearing, held November 9, 2006 at Pg. 44, l. 5).

This sentence, however, is a general description of two-factor authentication. As such, the sentence explains to the reader of the patent that two factor authentication is comprised of something which is known and something which is either held or built into the computer. By using the descriptive phrase "such as the physical key that is attached to the computer," in this sentence, the patentee indicated that this invention uses the combination of something held and something known-the physical key attached to the computer that had been referenced throughout the paragraph. (See id., col. 21, l. 37 - col. 22, l. 5).

--- End Footnotes ---

After reviewing the term "connected" in the context of the specification, the Court concludes that it is not synonymous with physical attachment. Though the invention's preferred embodiment involves a hardware key that is physically attached to the subscriber client computer via a port interface, the specification also lists acceptable alternatives to the preferred embodiment which need not be physically attached, including "a credit card, a key, an ATM card, or the like which is known to have been assigned and given to a specific person." (Id., col. 22, ll. 1-5). Therefore, the Court finds that the specification anticipates hardware keys which are not physically attached.

Moreover, even though the inventors did not describe any embodiment of a hardware key that connects wirelessly to the computer, patent claims are not limited to only those features described in the specification, and later-developed technology is commonly allowed to be covered by broad claim terms. Varco, L.P. v. Pason Sys. USA Corp., 436 F.3d 1368, 1375-76 (Fed. Cir. 2006)(citing Sri Int'l v. Matsushita Elec. Corp. Of Am., 775 F.2d 1107, 1121 (Fed. Cir. 1985) ("The law 'does not require than an applicant describe in his specification every conceivable and possible future embodiment of his invention.'") (en banc)). Thus, wireless devices are anticipated by the broad language in the claims and specification. Accordingly, the Court construes "connected" to mean "in communication with, inserted in, or attached to."

--- End ---
"connected and connectable" -- These terms mean "directly joined to one another within the same unitary piece of equipment without any intervening equipment."

"unified structure" -- Although not a claim term, the Court defines the term "unified structure" to mean "a consolidated structure with all components directly connected to one another."

"bypass" -- "Bypass" means "a structure and path by which data channels completely go around and in no respect go through the TST switch."

"control store" -- "A 'control store' is included within a single unified DRTST switching unit that includes a memory, processor, and operating software that determines (1) which data circulating on the network loop is to be selected and diverted to the TST switch of a given switching node; (2) how that data passes through the TST switch; (3) which data is output from the TST switch back onto the network loop; and (4) which data is to bypass the TST switch of that node."

"means for measuring" -- The Court finds that this term is not capable of construction.

"direction of the timing adjustment interval" -- This term means "[t]he timing adjustment control command signal is fed in a reverse direction from the data signal; that is, from a downstream digital switching unit to an upstream digital switching unit, in a direction opposite the data flow."

"connected" ( '181 patent, claims 1 and 12; '664 patent, claims 1 and 3; '768 patent, claims 1 and 19)

Defendants assert that the term "connected" refers to structures that are physically connected. However, nothing in the specification or claim language of the patents limits that term to physical connections. Absent such a limitation, it makes sense to give the term its ordinary meaning of "joined" or "linked," whether physically or otherwise. In term of function, since the claim language refers to means connected to each other for the purpose of data transfer, the definition of "connected" is simply joined or linked with the capacity of transferring data.

--- Footnotes ---

1. Defendants' argument that the term "connected" in claim 12 of the '181 patent needs to be distinguished from "in communications with" in claim 13 of the '181 patent does not lead to the conclusion that "connected" refers exclusively to a physical joining or linkage. Claim 13 refers to a "web browser in communications with the Internet connection." See the '181 patent, col. 60, 11. 50-51. It simply makes no sense to talk about a web browser "joined or linked" to the Internet connection, whether physically connected or not.

--- End Footnotes ---

"connected" is construed to mean to join. Newbridge proposes a construction of the term "connected" which limits the term to mean "electrically connected," i.e. "jointed together in a manner that allows electrical signals to flow between the components." (D.I. 547 at 48). After reviewing the specification, the Court concludes that the specification refers to both electrical and physical connections, and therefore, the Court declines to limit the term "connect" to a definition with only electrical implications. (136 Patent, FIG. 1, col. 10, ll. 6-7 (describing connection of physical cables, trunks and lines); col. 10, ll. 4-5 (describing "electrical connection" between controller and port circuits). Accordingly, the Court concludes that the construction of the term "connected" should be given its ordinary, plain meaning.

--- End Footnotes ---
Although the parties agree that "connected" and "coupled" have the same meaning, they dispute whether those terms require that electrical components be connected without intervening circuitry. MOSAID contends that "connected" may include intervening circuitry; the Defendants contend that "connected" requires that there be no intervening circuitry.

The analysis begins by ascertaining the ordinary meaning of the disputed term. Both parties submit dictionary definitions that allegedly support their proposed claim construction. Defendants submit the following dictionary definitions for "connected:"

"1. united, joined, or linked. 2. having a connection. 3. joined together in sequence; . . . ." The Random House Dict. of the English Language 431 (2d ed. 1987).

"1. conjoined; fastened or linked together." The Oxford English Dict. 745 (2d ed. 1989).

MOSAID defines "connect" as "to join, fasten, or link together usually by something intervening." Webster's Third New Int'l Dict. 480 (1986). MOSAID latches onto the phrase "something intervening" and extracts from it that two items may be connected if any number of components intervene. However, contrary to MOSAID's assertion, the Court does not believe that this dictionary definition supports MOSAID's open-ended construction. Instead, the definition uses "something intervening" to describe the means by which two things are joined, fastened or linked together. For example, two items may be connected if they are physically joined, e.g., the halves of a ziploc bag pressed together, or if they are fastened together by something intervening, e.g., a memory cell access transistor connected to a bit line by a wire. See '602 patent. Fig. 1. In fact, the dictionary even provides an example of two items that are connected by something intervening - "a bus line connects the two towns." Webster's Third New Int'l Dict. at 480.

Nothing in MOSAID's definition suggests that two items may be considered connected if there are any number of intervening components. Taken to an extreme, MOSAID's interpretation of "connected" would mean that every electrical component on a DRAM chip is connected to all the other components no matter how many millions of intervening components there are. That interpretation does not coincide with the ordinary meaning of the term.

Consequently, the ordinary meaning of the term "connected" is "united, joined, or linked together."

Next, one looks to the intrinsic evidence to see if "connected" takes on a meaning that is different than its ordinary meaning. Claim 1 of the '602 patent includes the following pertinent language:

Memory cells connected to the bit lines and word lines, each memory cell being comprised of an access field effect transistor (FET) having its source-drain connected between a bit line and a high logic level voltage V[dd] bit charge storage capacitor, the field effect transistor having a gate connected to a corresponding word line . . . . '602 patent, claim 1 (emphasis added).

Looking at Figure 1 of the '602 patent, it is clear that the claim consistently uses the term "connected" to mean that components are linked together without any intervening circuitry, a fact that MOSAID does not dispute.

The specification of the Lines and Foss patents supports the ordinary meaning of "connected." For example, in the Lines specification, the patentee states:

The output of NAND gate is connected through an inverter 9 to the gate of an N-channel FET 10. FET 10 has its source connected to ground and its drain connected to control node 8A. '602 patent, col. 2, 11. 51-54 (emphasis added).

In the second sentence, it is clear that "connected" was used to mean without any intervening circuitry. Indeed, the first sentence shows that when there was intervening circuitry, the patentee would use the phrase "connected through." The Foss specification also uses "connected" in a consistent manner:
With reference to FIG. 3, a capacitor 15 is connected in a series circuit between ground and through an N-channel field effect transistor 16, configured as a diode, with gate and drain connected to a voltage source V[dd]. '620 patent, col. 3, ll. 35-38 (emphasis added).

MOSAID contends that a broader interpretation of "connected" is warranted by how it is used in claim 1 of the '620 patent. According to MOSAID, '620 claim 1 uses the term "connected" to mean "through intervening components." MOSAID focuses on the portion of claim 1 that states the "switching circuit alternately connecting the first terminal of the boosting capacitor to the voltage supply and to the capacitive load." '620 patent, claim 1 (emphasis added). MOSAID asserts that if one looks at the embodiment set forth in Figure 3 of the '620 patent, the switching circuit connects the right side of boosting capacitor 27 to the voltage supply through transistor 23, and connects the right side of boosting capacitor 27 to the output terminal 19 through transistor 24. Thus, argues MOSAID, the boosting capacitor is connected through intervening circuitry, and if the Court adopts Defendants' narrow construction of without intervening circuitry, '620 claim 1 would not cover the preferred embodiment depicted in Figure 3.

Although MOSAID's argument may appear to be correct at first, upon closer inspection it simply does not hold up. Contrary to MOSAID's assertion, claim 1 of the '620 patent clearly supports defining "connected" as directly linked when the excerpt that MOSAID focuses on is looked at in the appropriate context. Claim 1 states in relevant part:

[A] switching circuit including a first switch between one level of the voltage supply and the first terminal of the boosting capacitor and a second switch between the first terminal of the boosting capacitor and a capacitive load, the first and second switches being driven by clock signals, the switching circuit alternatively connecting the first terminal of the boosting capacitor to the voltage supply and to the capacitive load. '620 patent, claim 1 (emphasis added).

Focusing on the relationship between the boosting capacitor and the voltage source, it is clear that the claim does not state that they are connected. In fact, the plain meaning of "alternately connecting" is that unless the switching circuit performs the act of connecting, the two components are normally disconnected. If the Court were to adopt MOSAID's construction, however, it would turn the plain meaning of the claim on its head because "electronically connected with or without intervening components" would mean that the boosting capacitor and voltage source are always connected. If they are always connected, the requirement that the switching circuit alternately connect them would be meaningless and the Foss pump would be inoperative. Accordingly, MOSAID's definition is inconsistent with the plain language of the claim.

Contrary to MOSAID's assertion, when the ordinary meaning of the term "connected" is used in '620 claim 1, the claim includes the embodiment set forth in Figure 3. The claim clearly states that the switching circuit connects the boosting capacitor to the voltage source. Inserting the ordinary meaning of "connects" into the claim, it would read that the switching circuit, i.e., a first switch or transistor 23, directly links the boosting capacitor to the voltage source without any intervening circuitry. That is exactly what Figure 3 depicts. Thus, adopting a construction that excludes intervening circuitry does not exclude the embodiment depicted in Figure 3.

The remainder of the intrinsic evidence does nothing to evince a different understanding of the term "connected." Accordingly, based on the ordinary meaning and plain language of the patent claims, the terms "connected" and "coupled" shall be construed as meaning "directly united, joined, or linked together."
one which is not interrupted by any "significant electrical characteristics" while Pericom argues that it is a connection with no intervening structures or devices. There is nothing in the claims, specification or prosecution history that defines the meaning of "connected directly," therefore extrinsic evidence must be used to define the term.

Both parties submit dictionary definitions of the word "directly." Pericom cites Webster's Unabridged Third New World Dictionary which defines "directly" as "without any intervening agency or instrumentality or determining influence: without any intermediate step." This definition, particularly the second part, supports Pericom's assertion that a direct connection is one unencumbered by any intervening elements or structures. Quality cites Webster's Ninth Collegiate Dictionary which defines "directly" as "having no compromising or impairing elements." This definition somewhat supports Quality's belief that a direct connection is one which is uncompromised by significant electrical characteristics; "compromising or impairing elements," however, could apply to intervening structures or elements as well.

Again, Quality provides the testimony of the device's inventor and Crisp to support its position. When asked what type of connection would not be considered direct, Wyland explained that a connection is direct unless "it introduces any other significant electrical characteristic beyond providing . . . an electrical connection between the two [points]." Wyland Dep. at 154:18-20, Heit Opp. Decl., at Ex. D. Similarly, Crisp states that "to a person of ordinary skill in the art, an integrated circuit's terminals would be considered connected directly to a package pin if a bond wire, among other things, are part of the signal path." Crisp Decl., at P 5. Although expert testimony may be appropriate where the patent and prosecution history shed no light on the meaning of a term in the claim, Vitronics, 90 F.3d at 1583, as noted by the Bell court, the testimony of the inventor is entitled to little or no consideration since it is often a "self-serving, after-the-fact attempt" to broaden the scope of his or her patent. Bell, 132 F.3d at 706. As before, the court views Wyland's testimony to be particularly self-serving in this instance.

In contrast to claims 4 and 6, claims 1 and 5 specify that the terminals are "connected to" the nodes, omitting the word "directly." Pericom argues that because different language is used, the phrase "connected directly to" is presumed to convey a different meaning from "connected to." Tandon Corp. v. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed.Cir. 1987). Although this assertion is correct, it sheds little light on the meaning of the word "directly." Of paramount importance are the words of the claim itself, which should generally be given their "ordinary and customary meaning." Vitronics, 90 F.3d at 1582. Although "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning," he or she may do so only if "the special definition of the term is clearly stated in the patent specification or file history." Id.

The ordinary meaning of the word "direct" connection does not encompass a connection that follows a circuitous route through multiple intervening physical structures. The testimony of the device's inventor and Quality's expert implies that no matter how many physical structures intervene between the nodes, as long as none of those structures introduce electrical resistance of their own the connection is direct. This view does not fit the dictionary definition or the way in which the word "direct" is commonly used. Therefore this court finds that "connected directly" means a connection between two points that is unimpaired by an outside electrical force and uncompromised by any intervening physical structures other than a structure that connects the two points. This finding does not preclude the possibility that the accused device infringes the patent in question based on the doctrine of equivalents, however this court does not reach this question.

C. "Electrically connected directly between said busses" (claim 1, asserted claim 5)

Claim 1 teaches that the capacitor is "electrically connected directly" between the busses. The parties dispute whether in this "direct" electrical connection, there can be any device between the capacitor and the bus. According to AMD, a "direct" connection does not preclude "passive" devices, such as resistors. AMD proposes the following definition: "The bus and the capacitor are connected without any intervening active devices, such as transistors." Samsung construes the phrase as follows: "Connected through a direct and physical electrical connection, which includes no intermediate devices, to the Vcc current bus and the Vss bus." In other words, Samsung contends that in a "direct" electrical connection, there are no intermediate devices -- active or passive.

The intrinsic evidence does not clarify whether a "direct" connection exists when a passive device such as a resistor is
located between the capacitor and bus. The specification summarizes the invention as "an improved integrated circuit structure [that] comprises a Vcc bus and Vss bus having capacitance means coupled between the busses and distributed along the length of the busses." 2:23-26. Similarly, Figures 3A and 3B illustrate the invention with no device between the bus and the capacitor.

The prosecution history cited by AMD also fails to resolve this issue. AMD cites statements the patent applicants made to the PTO after the initial rejection of their application. The applicants attempted to distinguish the '830 patent from prior art by stating that the prior art references "disclose coupling one plate of a capacitor to the source or drain of the switching device [i.e. transistor] in a memory cell while the other plate is connected to the Vcc line." Fahrenkrog Decl., ex. L (Jan. 8, 1986 Amendment) at 8-9. In other words, the applicants claimed that the prior art was distinguishable because the prior art disclosed a capacitor connected to a transistor. The applicants emphasized this point when they wrote:

While the capacitors of the memory cells of the [prior art] references each have an upper plate connected to the Vcc (power) bus, the lower plate of their memory capacitors . . . is connected directly to the . . . transistor . . ., not to the Vss (ground) bus. While the Office Action generically refers to [the prior art] . . . as connecting [the] . . . capacitor to another bus . . ., the "connection" is only an indirect capacitive coupling through a dielectric to a signal bus . . . not to the Vss (ground) bus. Applicants' capacitance, on the other hand, is connected directly between the power busses, not to the signal busses.

Id. at 9-10 (emphasis original). In this statement, the applicants pointed out that when a capacitor connects to a bus through a transistor, there is an indirect connection between the capacitor and the transistor. These statements merely demonstrate that during prosecution of this patent, the applicants considered a connection indirect when it is interrupted by a transistor. This prosecution history is not instructive because the parties agree that the presence of a transistor renders a connection indirect. There is no evidence that the patent applicants intended their "direct" connection to encompass a connection that has a resistor between the capacitor and the bus.

As the intrinsic evidence is inconclusive, the Court turns to the extrinsic evidence. AMD's expert, Eby G. Friedman, opines that one skilled in the art would interpret a connection to be "direct" so long as "there is no 'active device' (which, in the context of an integrated circuit, means a transistor, which often acts as a switch) between the two end points of the line." Friedman Decl. P 24. Samsung's expert, Marwan Hassoun, contends that one skilled in the art would understand a "direct" connection "to be a point-to-point electrical connection. If a passive device, such as a resistor, intervenes between two points, the connection is no longer point-to-point, and therefore not direct." Hassoun Decl. P 32. These competing opinions about the meaning of "directly" in the context of an electrical connection do not help resolve the dispute. However, AMD's expert also points out that "[e]very conductor that connects two points electrically necessarily has some resistance and could be thought of as a resistor." Supp. Friedman Decl. P 7. Samsung's definition would therefore mean that no connection could ever be direct and would render the insertion of the word "directly" in claim 1 meaningless. The Court finds this testimony convincing and agrees that the presence of a passive device does not render a connection indirect.

Accordingly, the Court adopts AMD's construction.

"Connected to"

The Court construes "connected to" to mean "having a link to . . . to send or receive data." Amazon's proposed definition requires the things that are "connected to" one another be directly joined. This is too limiting. Although the parties agree that the claims require the shopping cart computer to modify the shopping cart in the shopping cart database, there is no basis to require the computer and database be directly connected. All that is required is a link between the computer and database over which to send or receive data. See IEEE Standard Dictionary of Elec. & Elecs. Terms, at 203 (6th ed. 1996) (defining "connection" (software) as "an association established between functional units for conveying information").
Claims 26, 28, and 31

Independent claim 26 of the '541 patent, from which claims 28 and 31 depend, is directed to a combination motor and controller. The controller of claim 26 has, inter alia, a microprocessor "wherein said microprocessor produces an actuation signal to direct a proportional-integral-derivative (PID) filter connected to said microprocessor." Id. col. 2, ll. 19-23 (Reexamination Certificate). The disputed claim limitation is "connected to." During trial, the district court accepted the parties' stipulation that the jury employ the ordinary meaning of the term "connected to." The court also accepted the parties' agreement that they would argue to the jury what the ordinary meaning of "connected to" was. Animatics Corp. v. Quicksilver Controls, Inc., No. C99-05133 WHA, slip op. at 2-3 (N.D. Cal. Nov. 6, 2002) ("Fourth Claim Construction Order"). When the jury was unable to decide whether claim 26 was infringed, the district court was left to construe the "connected to" limitation.

The issue, as explained by the district court in its post-trial order, is "whether the phrase requires that the PID filter and the microprocessor be two separate (but electrically connected) circuits as opposed to . . . a PID software algorithm running inside the microprocessor." Post-Trial Order at 6. In other words, the issue is whether the PID controller can be an integral part of the microprocessor, or whether the claim language requires that the controller and the microprocessor be physically separate circuits.

The district court ruled that the limitation "calls out two separate physical circuits-a microprocessor and a PID filter-which must be 'connected to' each other." Id. at 6-7. The district court thus construed the limitation as requiring "two separate circuits" that "must be electrically 'connected to' each other." Id. at 7. The circuits "can reside on the same chip . . . so long as they are electrically connected." Id.

In support of this construction, the court first relied on what it perceived to be the plain language of the claim. The district court also appeared to rely heavily on the file history, noting that the original claim 26 did not have a PID filter requirement. Id. The PID filter requirement appeared in original dependent claim 29 of the '541 patent, which was incorporated into claim 26 during reexamination. The district court thus reasoned that the original claim 26 could not have contemplated a microprocessor that included a PID function and, for this reason, the microprocessor and PID filter are required to be two separate circuits. Id. at 9.

The district court also noted that the verb "connect" was consistently used elsewhere in the '541 patent to refer to the joining or linking of "physical objects." Id. at 9 (emphasis in original). Finally, the court stated that "independent claims 70, 71 and 73 provide an instructive counterpoint." Id. at 10. The district court noted that these claims "all recite identical relevant language of the microprocessor 'having' a PID filter and software." Id. The district court thus reasoned that this "demonstrates that when the patentees wanted to claim a PID filter on par with software inside a microprocessor, they did so." Id.

Animatics argues that "connected to" should have its plain and ordinary meaning. Animatics points to Merriam-Webster's Collegiate Dictionary for a dictionary definition of "connected" as "(1) joined or linked together; or (2) having the parts or elements logically linked together." Webster's Seventh New Collegiate Dictionary at 244 (1976). Animatics contends that "the patent provides no basis to infer that the patentee discarded the broad ordinary meaning of the term 'connected' and chose to use the 'special definition' of the term imposed by the court-restricting the term 'connected' to mean 'physically separate' and 'physically and electrically connected.'" For this reason, Animatics argues that the district court erred in its construction of the claim 26 term "connected to."

We agree with Animatics that the district court erred in requiring that the microprocessor and the PID controller be physically separate circuits that are electrically connected. Claims are generally given their plain meaning unless the patentee chooses to be his own lexicographer. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). There should be a "clear and unambiguous disclaimer" of a software implemented PID filter in order to support the district court's interpretation. See Inverness Med. Switz. GmBH v. Princeton Biomeditech Corp., 309 F.3d 1365, 1372 (Fed. Cir. 2002).
A PID controller may be implemented in a number of different ways. First, the PID filter may be an analog circuit. An analog PID filter would be a completely separate circuit from the digital microprocessor. The analog feedback signals from the motor would pass through the analog PID filter. The filtered analog signal would be passed to an analog-to-digital (A/D) converter, and then to the microprocessor for analysis.

Second, the PID filter may be a digital circuit. In this case, the analog feedback signal from the motor is first digitized with an A/D converter. The feedback signal is then passed to the PID filter, and/or the microprocessor. If the PID filter is a digital circuit, then the physical line between the microprocessor and the filter becomes blurred because the parties agree that "microprocessor" would be construed as "a device that is capable of performing digital calculations and storing digital data for positioning a motor." First Claim Construction Order at 11. A digital filter certainly performs digital calculations on the feedback data and could conceivably be located on the same chip as the microprocessor.

Finally, the PID filter may be implemented using only software. The operation of the filter is represented by a software algorithm. As with the digital circuit, the feedback from the motor is digitized with an A/D converter. The software algorithm then operates directly on the digital data to produce the desired output. If the PID filter is implemented purely in software, then the physical line between the microprocessor and PID filter completely disappears.

We find no indication in the intrinsic evidence (claims, specification, or prosecution history) clearly indicating that the inventor intended to exclude a software-only implemented PID. Indeed, there is no indication as to which of the above methods is used. In the portion of the specification entitled "Best Mode for Carrying Out the Invention," the PID filter is explicitly referred to only twice. In both instances, the PID filter is described as being included in, or part of, the microprocessor. First, the '541 patent recites "the controller 49 houses a microprocessor 50 including a proportional integral derivative (PID) filter." '541 patent, col. 3, ll. 22-25. Later in the same section, there is the statement that "the microprocessor 50 includes a proportional integral derivative (PID) filter 53 which receives information from the encoder 48 to servo control the rotor." Id. col. 5, ll. 6-10. Neither of these descriptions excludes a software implemented PID filter.

Moreover, FIG. 1 shows that the link between the microprocessor and the PID filter is different from the links between other elements of the motor-controller. In FIG. 1, the PID filter and the microprocessor are shown adjacent to each other, while the other elements of the motor controller are connected by a line presumably representing an electrical connection. Thus, FIG. 1 provides no justification for limiting the term "connected to" to being "electrically connected," as opposed to "logically connected."

Claim 26 itself supports Animatics' assertion that the district court's construction was too narrow. Claim 26 refers to "the second housing" being in "mating relation to the first housing and electrically connected to the rotor position encoder." Id. col. 2, ll. 6-7 (Reexamination Certificate) (emphasis added). This indicates that the patentee did not limit the term "connected to" to mean "electrically connected." Indeed, neither the claim nor the specification describes the connection between the microprocessor and PID filter as being electrical. Furthermore, the claim limitation does not, as the district court suggested, "call out two separate physical circuits." Indeed, the word "circuit" is not mentioned in claim 26 or in any of the embodiments described in the specification. In short, the claims, figures, and specification of the '541 patent appear to support Animatics' contention that the claim term "connected to" was too narrowly construed by the district court.

Referring to the file history, the district court correctly noted that "the meaning of 'microprocessor' and 'PID filter' did not morph together" and that the "independent meaning of these terms persisted" after the reexamination. Post-Trial Order at 9. However, we do not think this sufficient reason to assume that the "connected to" language necessarily excludes a PID filter that is purely implemented via software. Indeed, the definition of microprocessor adopted by the court, and not challenged by the parties, does not exclude a microprocessor that includes a PID filter. First Claim Construction Order at 11. The district court merely defined a microprocessor as "a device that is capable of performing digital calculations and storing digital data for positioning a motor." Id.

For the foregoing reasons, we conclude that the district court erred in construing the claim limitation "connected to" as requiring two physically separate circuits that are electrically connected, thereby precluding a software-only implementation of the PID filter. Accordingly, we reverse the JMOL of non-infringement with respect to claims 26, 28, and 31. Because, as the district court noted, "it is undisputed that, in the accused products, PID is carried out via software running in the microprocessor," Post Trial Order at 7 n.1, the case is remanded to the district court for entry of judgment of infringement of claims 26, 28, and 31 in favor of Animatics.
3. "connected to"

As before, Pulse urges "connected to" is a commonly understood term and has an apparent meaning that can be readily applied such that no construction is needed. As an alternative, Pulse offers that "connected to" means "joined together via something intervening." Mascon suggests that since claim 1 of the ‘347 patent appears to mimic Figure 2 (with a line between components), the court should construe a "direct" connection between the components as drawn. Specifically, Mascon asks that "connected to" be construed to mean "in direct contact, through a zero impedance electrical conductor, with" or "in direct contact, through an electrical conductor whose impedance is independent of frequency," or a construction that combines both of these, "in direct contact with, through a zero impedance electrical conductor or an electrical conductor whose impedance is independent of frequency." 7

--- Footnotes ---

7 Only the first of these three options was included in the parties' Joint Claim Construction Worksheet; the others were offered in Mascon's Opening Claim Construction Brief.

--- End Footnotes ---

Defining "connected to" in its ordinary sense or as meaning "joined together via something intervening" expands the claim scope beyond what is contemplated in the specifications and claims. Pulse cites to the intrinsic evidence, arguing the instances where "connected to" is used with "via" something "intervening" show that "connected to," even without a specified intermediary, necessarily includes "something intervening." However, throughout the specifications and claims, where "connected to" is used without an intervening object, one skilled in the art would recognize the contemplated connection would utilize standard electrical conductors such as wire or solder and not additional electrical components such as inductors or capacitors. (See, e.g., '347 Patent, Col. 4, ll. 51-63.) Even where "connected to" is used with an intervening object, that object is generally wiring, pins, or a plug, not a circuit component. Pulse admits as much, stating "one of ordinary skill in the art would understand that any such connection requires 'something intervening' in order to join the two components (e.g., wire, solder, PCB traces, etc.)." (Doc. No. 34 at 14.) This observation is supported by the fact that a "first-order low-pass filter section," formed by two inductors, becomes a "second-order low-pass filter section" by adding a single component (a capacitor). (Compare '347 patent, Fig. 2, with '992 patent, Fig. 5.)

At the opposite end of the spectrum, Mascon's interpretations are more narrow than what is contemplated by the intrinsic evidence and do not account for real-world aspects of building a circuit. As noted during the parties' oral arguments, any wiring or other suitable connector would have an inherent degree of impedance or frequency dependence. In addition, as before, Mascon's constructions add technical terminology, unsupported by the specification, that may not serve to enlighten the jury or clarify the scope of the claims.

For these reasons, the court adopts the following construction: "connected to" means connected without interposition of additional circuit elements, such as inductors, capacitors, or resistors.
"Connected to" means joined together or linked. See Lucantoni Decl. PP 9-11, Exs. 4, 5; see also Webster's Ninth New Collegiate Dictionary at 278 ("connected" means "joined or linked together . . . having the parts or elements logically linked together."). "Connected to" does not require that the call distributors must be physically separate from the "interface switching structures" or the "operator terminal." See Rexnord, 274 F.3d at 1342 ("unless compelled to do otherwise, a court will give a claim term the full range of its ordinary meaning as understood by an artisan of ordinary skill.")(citations omitted). However, it appears from the context and plain meaning of the language in claim 21 that at least one of the interface switching structures must be physically separate from the operator terminal, since the claim refers only to a single operator terminal and requires that the interface switching structures be disposed in different geographic locations.

HP asks the Court to construe this term as follows: "The first receiving circuit is connected to and receives electricity or is currently capable of receiving electricity from the first feed circuit and the second receiving circuit is connected to and receives electricity or is currently capable of receiving electricity from the second feed circuit." EMC proposes: "The first receiving circuit is physically connected to and is receiving electricity from the first AC feed circuit. At the same time, the second receiving circuit is physically connected to and is receiving electricity from the second AC feed circuit." Essentially, the parties dispute the meaning of the phrase "energized by." HP asks the Court to construe "energized by" as "receives electricity or is currently capable of receiving electricity." EMC argues that the correct construction is "is receiving electricity." Under EMC's proposal, claim 1 would not protect an invention in which the receiving circuit is not currently receiving electricity from its respective AC feed circuit.

The meaning of "energized by" in the claim language is ambiguous. The Court thus turns to the specification for clarification. The written description indicates that the "AC mains [are] feed circuits which provide voltage," 253:3/9-10, and that "when both AC mains are energized, all three power supplies receive voltage," 253:3/34-36. Thus, for the purposes of the claim, a person of ordinary skill in the art would understand "energize" to mean "to provide voltage to." "Energized by" thus generally means "receives voltage from."

The claim states that a receiving circuit is "connected to and energized by" a feed circuit. Accordingly, a receiving circuit is "connected to and receives voltage from a feed circuit." Nothing in the claim language indicates that a receiving circuit must constantly receive voltage from the same feed circuit. Indeed, the claim language as a whole describes a situation in which both receiving circuits are energized by the second feed circuit "in the event the first feed circuit is de-energized." The specification also suggests that a feed circuit might not always provide voltage to a receiving circuit. For example, an AC main might fail, in which case it could not provide voltage to a receiving circuit. See, e.g., 253:3/29, 4/6-14, & 4/34-45. While the prosecution history shows that the patent examiner found the term "capable of being energized" indefinite, the meaning of "energize" in the context of the claim and the specification must include scenarios in which the receiving circuit is not always energized by the same feed circuit. There is no evidence in the prosecution history that the patentees stated that a certain feed circuit must continually energize a receiving circuit. Rather, the evidence suggests that they rewrote the claims to clarify that "the receiving circuits of claim 1 . . . are connected to and energized by the respective feed circuits." See Landgraff Decl., Separate Appendix, vol. 3, p. 0386. In other words, they did not intend to claim continual energizing, but rather to clarify which circuit energizes the receiving circuit for the purposes of subparagraph (b) of claim 1.

EMC also contends that, based on the claim language and the prosecution history, the two receiving circuits must be energized "at the same time." While it is true that the patentees argued that their "invention keeps at least two load circuits energized at all times, regardless of whether one energy source fails or not," id. at 0388, nothing in the disputed claim language requires that the two be energized at the same time by distinct AC feed circuits. The claim language merely indicates that the two receiving circuits are connected to and energized by feed circuits. As noted, the receiving circuits may not always be energized by their respective feed circuits. Although EMC's argument initially appears consistent with subsection (b) of the claim and the relevant prosecution history, it nonetheless does not make sense to require the two receiving circuits to be energized at the same time by respective feed circuits because, if a receiving circuit ceases receiving voltage from a feed circuit, "automatic switching capability" permits the invention to keep at least two receiving circuits energized "at all times" through a different, functioning feed circuit. Id.
The Court thus construes this term as: "The first receiving circuit is connected to and receives electricity or is capable of receiving electricity from the first feed circuit and the second receiving circuit is connected to and receives electricity or is capable of receiving electricity from the second feed circuit."

E. Limitation 4: Source electrode

31. The next element of Claim 1 is as follows: "source electrode means connected to said source regions." Again, various examples of this are described in the '699 written specification and drawings, including source electrodes 81 and 82 in Figures 7 and 8. The specification also notes that "In carrying out the above invention, it should be noted that any type of contact material can be used to make the source and gate contacts. By way of example, aluminum could be used for the source electrodes . . . ." ('699 patent, col. 6, lines 59-62.) This element of Claim 1 is properly construed to embrace any aluminum or other contact to the source regions.

32. The claims specify that the "common source electrode" or "common source electrode means" must be "connected to" the source regions, but do not constrain the means by which such electrodes are so "connected." Claim 1 merely requires "source electrode means connected to said source regions." ('699 patent, col. 7, lines 64-65.) The claim does not require or preclude any particular structure for "connecting" the source electrode to the annular source.

D. What is a Composite Gate Electrode?

Finally, the parties interpret differently the location and method for connecting the first and second gate electrodes. Claim 1 requires, in relevant part:

- connecting each of said second gate electrodes to an individual adjacent first gate electrode to form a composite electrode for a charge coupled element.

This claim language does not restrict the manner or location of the connection. The connection, however, must form a composite gate electrode.

Figures 9, 11, and 13 in the specification depict connection of adjacent first and second gate electrodes. The specification describes forming a conducting layer over exposed portions of the first and second gate electrodes to electrically connect them. In other embodiments, the specification describes etching off portions of the second insulation layer to create an electrical connection. These illustrative examples depict connection of the first and second gate electrodes over the active region of the device, either by forming the second gate electrodes on exposed portions of the first gate electrodes or by forming a conductive layer over exposed portions of both gate electrodes. The specification does not limit the manner or location of the connection.

During prosecution of the '674 patent, in an amendment, dated May 14, 1975, Loral distinguished its connection of electrodes from United States Patent 3,735,156 ("the Krambeck reference"). The figures in the Krambeck reference show every first gate electrode connected to one bus line and every second gate electrode connected to another bus line. Consequently, Krambeck did not connect adjacent gate electrodes. In other words, Krambeck clocked adjacent gates differently.

In the remarks section of the amendment, the inventor argued: "In the present invention, an individual first gate electrode is connected to an adjacent second gate electrode to form a composite gate electrode . . . . The composite gate electrodes may be connected together in any desired pattern, e.g., in a one-phase, two-phase or three-phase clocking arrangement." The inventor distinguishes the invention because it "includes the unique and distinctive steps of connecting a single first gate
electrode to a single adjacent second gate electrode to form a composite electrode." This remark shows that the inventor considered a composite gate electrode to be adjacent gate electrodes clocked together and nothing more. The inventor made no statement to the examiner about the method or location of the connection. In sum, the prosecution history does not limit the claim to a particular manner or location of connection.

Dr. Wen testified about the understanding of one skill in the art relative to connecting adjacent gates. He persuasively recounted that the Krambeck reference does not connect adjacent first and second gate electrodes to form a composite gate electrode. He also noted that, at the time of the '674 patent, those skilled in the art knew several ways to connect electrodes together. This testimony underscores the absence of any limit in the claims on the way to make connections. Transcript at 244-48.

Consequently, the court concludes this limitation describes a process step which connects each second gate electrode to one, but not both, adjacent first gate electrodes.

1. "Connecting Electronically"

Simplification's Construction
Physically or logically coupling by way of devices, circuits, or systems utilizing electron devices.

Block's Construction
The act of establishing communication between computerized devices automatically without manual intervention from the user.

Neither party offers a great deal of assistance as to the meaning of "connecting" in the term "connecting electronically." Block relies on general purpose and technical dictionary definitions that are either undated or appear to postdate the filing of the patents-in-suit. (See D.I. 79 at 21-22.) Simplification points out correctly that the specification explains that electronic connections are established over "electronic links." (D.I. 80 at 19.) Thus, Simplification offers a construction that it contends comports with a "[n]on-limiting" list of "electronic links" provided in the specification. (Id. at 20; see also '052 patent at 5:67-6:6 (listing, for example, modem, Internet, and computer-readable medium as "electronic links").) Notably, the parties have agreed on the meaning of "electronic link," jointly defining it to be "an electronic means of communicating digital information bidirectionally." (D.I. 79 at 5.) In the Court's view, Block's proposed construction of "connecting electronically," which focuses on the establishment of "communication," aligns most naturally with this agreed upon definition. The Court further notes that Simplification's definition demands only "physical" coupling by way of an "electron device." As above, the Court finds this definition to be overbroad. Accordingly, the Court concludes that "connecting electronically" means, as Block contends, "establishing communication between computerized devices without manual intervention from the user."

J. Communication Link & Processor

The Plaintiff construes "communication link" to refer to "the connection between computers that enables data transfer" citing Microsoft Computer Dictionary 98 (4th ed. 1999). The Plaintiff defines a "processor" to be "a unit comprised of hardware and/or software that processes computer-readable instructions." The Defendants did not propose an alternative to the Plaintiff's suggested constructions of "communication link" and "processor". In the hearing, the Defendants suggested that I adopt the Plaintiff's unopposed construction, so long as I also adopt their unopposed constructions of various other terms in the other claims. Since the scope of this construction is limited to terms in dispute in Claims 1 and 12, I need not consider the proposed constructions for other terms in the other claims. But, I will adopt the Plaintiff's constructions for "communication link" and "processor". Given the Defendants' concerns with respect to local memory, however, I adopt the Plaintiff's construction of "processor" with the caveat that it is a unit of the user's computer as distinct from the "remote
server." (col. 2, l. 8)

Construction: (connecting device) a network connection, such as the Internet, used for transferring data between computers

Construction: (processor) a unit of hardware and/or software, distinct for the remote server, that processes computer-readable instructions

Connecting to the network; providing to the user a connection to the network; all forms of connect

The parties differ as to whether a connection to the network is establishing a computer on the network (MyMail's proposed definition) or establishing a link to the network (Defendants' proposed definition). The Court adopts neither definition. MyMail's definition rolls the process of a user connecting to the network into the subsequent processes of a user's presence on the network being authenticated and the user being assigned a unique IP address. The specification teaches that the process of connecting is distinct from those two very closely related subsequent steps. See Col. 7:7-19; 11:31-33. Defendants' definition improperly substitutes "link" for "connection." Although a link may be the ordinary meaning of a connection, Claim 3 of the patent uses those two words differently.

The claims of the 290 patent in which these terms appear all deal with establishing network connections between the user's computer and the network. Upon completing a network connection, the user's computer is on the network. Once on the network, the user's computer has the ability to communicate with other computers on the network. Thus, the Court defines the above family of terms as "establishing the ability to communicate with the network" since the act of connecting, in the context of the 290 patent, establishes the ability to communicate with the network.

IV. "CONNECTING TOGETHER THE CIRCLES OF ADJACENT FAMILIES OF CIRCLES HAVING AN IDENTICAL INDEX TO FORM ISOLOOPS"

The limitation at issue here, found in claims 14 and 35, is "connecting together the circles of adjacent families of circles having an identical index to form isoloops." The parties' proposed constructions are as follows:

Plaintiff's Proposal
creating loops that contain
arcs of circles with the
same index from neighboring
circle families

Defendants' Proposal
Selecting circles that have been assigned
developmental indexes and using a smoothing
technique to connect those circles to form
sets of closed loops consisting of pieces
of the original circles and smooth curves
or lines joining those pieces. Although
the resulting isoloops are used in
generating the tool path, they are not the
toolpath itself.

Plaintiff argues that neither the claim language nor the specification requires a particular technique for connecting circles to form isoloops. Although Plaintiff's position is supported by the "bare" text in claims 14 and 35, some of the limitations proposed by Defendants are supported by language elsewhere in the patent. This language is particularly relevant because the term "isoloop" did not exist until this patent was drafted. It was coined by Defendant Evan Sherbrooke to describe the method claimed by the '013 patent. See generally Altiris v. Symantec Corp., 318 F.3d 1363, 1370 (Fed. Cir. 2003) ("[T]he claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history.")
Based on the analysis set forth below, the Court adopts the following construction of the contested terms, which differs somewhat from the tentative construction it circulated at the Markman hearing:

connecting together the circles of adjacent families of circles having an identical index to form isoloops -- Selecting circles that have been assigned identical indexes and connecting those circles to form sets of loops consisting of pieces of the original circles and curves or lines joining those pieces.

Each section of the analysis below begins with text from Defendants' proposed construction.

A. The Connected Circles Must Have Identical Indexes

"Selecting circles that have been assigned identical indexes . . . ."

Plaintiff's construction describes connecting circles with the "same" index. Defendants describe connecting circles with "identical" indexes. The parties thus agree on this part of the Court's construction, and neither party objected to it at the Markman hearing.

B. A "Smoothing Technique" and "Smooth Curves" Are Not Required

". . . and using a smoothing technique to connect those circles to form sets of closed loops consisting of pieces of the original circles and smooth curves or lines . . . ."

At the Markman hearing, Plaintiff's only objection to the Court's tentative construction was that it included a requirement that the method use a "smoothing technique," and that the pieces of the original circles be joined by "smooth curves or lines." Plaintiff's arguments at the hearing have persuaded the Court that including this requirement would be an improper importation of a single preferred embodiment's features.

1. The Sixth Preferred Embodiment

The claim language -- "connecting together the circles of adjacent families of circles having an identical index to form isoloops" -- does not refer to any smoothing requirement. Defendants thus rely on the specification's Sixth Preferred Embodiment, which states that

After creating the circle graph, the circles of each family are indexed by numbering the circles from the outside in an ascending scale. The circles having the same index are then joined together into isoloops, so called because the isoloops are created by joining circles of the same index together. The joining process creates some combination of arcs (pieces of the original circles) and blends joining those pieces together. FIG. 22 is an illustration of the circle families being joined by the isoloops.

Preferably, the lines joining two circles together are constructed by: [here, a technique and formulas are described] . . . . One skilled in the art would recognize that other blending techniques that would maintain a tangent continuous tool path could be used to connect the circles.

('013 patent 20:28-53) (emphasis added). Previously in the specification, before any of the preferred embodiments are described, the patent's "Definitions" section defines "tangent continuous" as "forming a smooth curve." ('013 patent 5:30). It defines "smooth curve" as "a curve in which the unit tangent to the curve is continuous at every point along the curve." ('013 patent 5:21).

Defendants argue that because the Sixth Preferred Embodiment states that "[o]ne skilled in the art would recognize that other blending techniques that would maintain a tangent continuous tool path could be used to connect the circles," and because "tangent continuous" is defined earlier as "forming a smooth curve," the patentee meant to limit its claim to methods that use a "smoothing" technique. Defendants also argue that the connections in Figure 22, which is referenced in the Sixth Preferred Embodiment, are tangent continuous and thus smooth.

The Federal Circuit has repeatedly warned against relying solely on a single embodiment to limit the scope of a claim, and
Defendants have not pointed to other sections of the patent that would compel the conclusion that a smoothing technique is required. See Saunders Group, Inc., 492 F.3d at 1332; Intamin, Ltd., 483 F.3d at 1333; Phillips, 415 F.3d at 1323. Cf. ICU Med., Inc. v. Alaris Med. Sys., Inc., 558 F.3d 1368, 1374-76 (Fed. Cir. 2009) (adopting narrow construction of claim term where specification "repeatedly and uniformly" used the narrow definition); Kinetic Concepts, Inc. v. Blue Sky Med. Group, Inc., 554 F.3d 1010, 1017-19 (Fed. Cir. 2009) (adopting narrower construction where all of the numerous examples in the specification used the narrower meaning); iLOR, LLC v. Google, Inc., 550 F.3d 1067, 1073-75 (although claim language was itself clear, for sake of argument court notes that the specification repeatedly used narrow construction of term, and prosecution history disavowed broader construction); Amazin' Raisins Int'l, Inc. v. Ocean Spray Cranberries, Inc., 306 Fed. Appx. 553, 556-58 (Fed. Cir. Oct. 31, 2008) (unpublished decision limiting claim term based upon specification's detailed description of the invention, which appeared before any preferred embodiment was discussed).

But even if the Sixth Preferred Embodiment alone provided a basis for limiting the claim language, the text upon which Defendants rely does not in fact limit the preferred embodiment to a smoothing technique or smooth connections. It states that "[o]ne skilled in the art would recognize that other blending techniques that would maintain a tangent continuous tool path could be used to connect the circles." That language does not require or imply that only techniques maintaining a tangent continuous tool path could be used to connect the circle pieces. Nor does the Sixth Preferred Embodiment define "isoloops" in a manner that compels Defendants' construction. The closest it comes to stating a definition is the statement, "[t]he circles having the same index are then joined together into isoloops, so called because the isoloops are created by joining circles of the same index together." ('013 patent at 20:30-32.) That description of "isoloops" does not require smoothing, and the next sentence does not clearly supplement the meaning of "isoloops." Defendants also point to what they argue are tangent continuous connections illustrated in Figure 22, which is referenced by the Sixth Preferred Embodiment. But it is not at all clear to the Court how Defendants determined that the lines in the illustration are tangent continuous, particularly in light of Sherbrooke's statement in his declaration that the scale of the figure is too small to tell even whether the connections are straight lines.

--- Footnotes ---

5 The next sentence reads, "The joining process creates some combination of arcs (pieces of the original circles) and blends joining those pieces together." ('013 patent at 20:32-34.) As discussed below, "blending" is a technique for creating smooth curves.

The Sixth Preferred Embodiment later discusses a method for implementing the step of "generating the tool path by blending between the isoloops." Although this section of the Embodiment says that "[t]he blends are generated using the same exact blending function used . . . above," that function is described as a "preferabl[e]" embodiment. ('013 patent at 20:37, 20:54-55.)

--- End Footnotes ---

2. Claim language

Turning to the claim language itself -- the most important source of a term's meaning -- Plaintiff points out that in contrast to the next limitation in claims 14 and 35 ("generating the tool path by blending between the isoloops"), this limitation does not mention "blending." It is reasonable to assume that if the patentee had intended to require blending in this limitation, it would have said so explicitly. Even if this were not the case, there is nothing in the claim language that supports Defendants' position.

3. Purpose of the invention

Finally, Defendants provide an illustration generated by Defendant Evan Sherbrooke that purportedly shows that connecting circles without a "smoothing technique" would allow "bizarre" loops including "self-intersections, sharp corners, and wildly varying engagement angles." Sherbrooke Decl. II at 8-9, Fig. D. Sherbrooke contends that this output would be "fundamentally contrary to the invention." But as noted above, the Court is not in a position to evaluate whether such an output would be "fundamentally contrary to the invention." Even if it were, without some basis in the text of the patent or the prosecution history, that assertion alone is not enough to justify the importation of limitations from one preferred embodiment.
For these reasons, the Court concludes that it is not appropriate to include the "smoothing" requirements in its construction of this limitation.

C. It is Not Necessary to State that the Loops Must Be Closed

"... to form sets of closed loops . . ."

Plaintiff's expert argued against incorporating this language. He cited a dictionary definition of "loop" and made the observation that "since the isoloops are connected to other isoloops in the blending step, it would be unnecessary and superfluous to require that they be 'closed.'" Potel Decl. II P 18. The Court found this argument persuasive, and omitted the language from its tentative construction. Defendants did not object at the Markman hearing to the omission, and the Court will not include it.

D. It is Not Necessary to State that Isoloops are "Not the Toolpath Itself"

"Although the resulting isoloops are used in generating the tool path, they are not the toolpath itself"

Defendants contend that the next step listed in claims 14 and 35 makes clear that the isoloops are not part of the tool path because it states that the tool path is generated by "blending between the isoloops." (emphasis added). They also assert that the Sixth Preferred Embodiment supports this conclusion, as does the prosecution history. The Court was not persuaded by these arguments and omitted the language from its tentative construction. Defendants did not object at the Markman hearing to this omission, and the Court will not include it.

GO BACK

3. connectionless communications network (claims land 3-5)

Plaintiff's Construction: A network in which data packets are routed through devices independently, based on a destination address for the packet

Defendant's Construction: A network in which data packets are forwarded through devices independently, based on a destination address for the packet.

The parties dispute one word: are data packets "routed" or "forwarded" in a connectionless communications network? Neither party explains the difference between these two terms; presumably, "routed" means that a router is used and "forwarded" is used as a more general verb that includes "routing" but is not limited to that method. In any event, the specification supports plaintiff's construction: "in a connectionless communications network, data packets are routed through devices . . ." '042 pat., col. 3, lns. 35-36. Defendant cites other passages in the patent discussing other methods of sending messages, but none of them is defining a "connectionless communications network" as is the passage cited by plaintiff. Accordingly, I will adopt plaintiff's construction: "a network in which data packets are routed through devices independently, based on a destination address for the packet."

GO BACK

"one or more connections for coupling to transmission media"

The term "one or more connections for coupling to transmission media" means at least one point of connection to a transmission media such as the PSTN that is different from the "one or more connections for coupling to a telephony server and a local area network."

Claim 1 of the '639 patent describes three connections: (1) a connection from the user communications device at the remote
site to the VPS at the corporate office through the transmission media (e.g., PSTN); (2) a connection from the VPS to the telephony server (e.g., PBX); and (3) a connection from the VPS to the LAN. 156 Claim 14, which is dependent on claim 1, necessarily requires the same three connections. Claim 39 describes the first connection.

--- Footnotes ---

156 '639 patent, col. 25, line 31-col.26, line 6.

--- End Footnotes ---

Plaintiff argues that even though the three separate connections are shown in the embodiments to the '639 patent, claims 1 and 14 uses only the phrase "one or more connections for coupling" and that three distinct connections are not required. 157 Plaintiff urges that the specific phrase "one or more connections for coupling" means only "at least one point of connection for a data communications path." 158 The Court cannot agree. The claims themselves require connections and the claims describe distinct connections. Claim 1 requires that the remote user dial up, using the transmission media (e.g., PSTN), the "virtual presence server communication device" (e.g., one or more modems or one or more ISDNs) to establish a connection with the VPS. 159 The VPS is separately connected to the LAN and separately connected to the PBX. 160 The connections are most significant to the '639 patent in part because the examiner distinguished prior art based on the nature of the connections. 161

--- Footnotes ---

157 Plaintiff's proposed findings of fact and conclusions of law do not address the connections in claim 39 regarding this issue. Docket no. 104 at 19-20.

158 Docket no. 104 at 19-20.

159 '639 patent, col. 2, lines 38-40 and figs. 1 and 2.

160 '639 patent, col. 25, lines 44-49.

161 Dx 2 at 3, Notice of Allowability, Nov. 13, 1997 ("The prior art cited by both applicant and the examiner requires the remote user to connect through the telephony server.") The patent specification distinguished the prior art based on the fact that the '639 patent did not claim a connection through the PBX: "It is noted that the system shown in FIGS. 1 and 2 does not include a key system or PBX intervening between the [VPS] and the remote users" ( '639 patent, col. 5, lines 45-48).

--- End Footnotes ---

5. "Connections over the telephone network."

USA Video proposes "Associations between two or more endpoints on a telecommunications network for the transfer of data." Time Warner suggests "Point-to-point calls, each call to a single intended recipient over telephone lines, which calls are established before transmission of the requested program, and do not involve broadcast cable techniques." The court construed the term "telephone network" in Part III(1) supra; therefore, the court will focus on the construction of "connections" here.

USVO argues that "connection" should be given its ordinary meaning. It cites to the 1999 Edition of the IEEE Standard Dictionary, which defined "connection" as "an association established between two or more endpoints or the transfer of data." The Authoritative Dictionary of IEEE Standards Terms, Pl. Claim Const. Br., Ex. C, at 220 [Doc. # 149, p. 4 of 4]. USVO's expert, Dr. Beckmann, stated that such a definition is consistent with the way that the term was used in 1990-92. Time Warner argues that even if the court were to agree that this was how the term was used at the time of the invention, the applicants disclaimed a definition of "connection" that was this broad.
For instance, Claim 1 states that both the request and distribution interfaces are connected to the telephone network, '792 Patent, col. 7, ll. 45-46, 50-51. In order to overcome a prior art reference during prosecution, which recited a system in which video programs were transmitted over a fiber optic cable and sent to multiple recipients, the applicants stated:

The system of Claim 25 [later Claim 1 of the '792 Patent] is directed to a system which has a central data facility for storing video programs. A request interface is provided, which receives call in requests over the telephone network. A distribution interface then initiates a call to a remote unit, and transmits a compressed video program to it.

Amendment of 5/22/91, Def. Claim Const. Br., Ex. 1-A at 8 [Doc. # 152, p. 9 of 12]. The applicants go on to state that the "distribution interface initiates all calls to remote units before transmitting the video programs to them…the claimed system sends a program only to a single intended recipient." Id. The applicants clearly distinguished their own invention over the prior art on the basis of transmission to a single recipient and repeatedly used the word "call" when referring to the program requests and transmissions. 6 At the hearing, USVO agreed that the requested program is transmitted to a single customer. Tr. at p. 109, ll. 5-8.

--- Footnotes ---
6 For a discussion of this part of the prosecution history, see USA Video Tech. Corp. v. Movielink LLC, 354 F. Supp. 2d 507, 513-520 (D. Del. 2005)(construing "initiates" as "begins" and holding that the central facility initiates the new connection).
--- End Footnotes ---

While "call" is frequently used by applicants in the prosecution history, the court's concern is that jury confusion may result from its use in claim construction. A "call" implies that some voice component is involved, which is not true with respect to the program sent by the distribution interface to the remote unit. A jury is naturally inclined to assume "call" and "telephone call" are synonymous, when they clearly are not in this case. At the hearing, Time Warner suggested using the term "data call" rather than "call," Tr. at p. 109, ll. 17-19, while USVO stated that "communication" would be less confusing than "call" or "data call." Tr. at p. 109, ll. 19-23. The court is of the opinion that "communication" has the advantage of being clearer than "call" or "data call," and would also alleviate Time Warner's concerns that USVO's proposed construction attempts to re-claim subject matter surrendered during prosecution. The court will define this term as follows:

"Connections over the telephone network" means "Communications to a single intended recipient over the telephone network."

---

IV. Claim Phrase of "connections through the Internet"

In the Memorandum, Windy and AOL indicate that they disagree as to how the phrase "connections through the Internet" should be construed in the '491 Patent. (Mem. 20,27). Windy contends, with respect to Claims 1 and 40 of the '491 Patent, that the phrase "connections through the Internet" should be construed as follows:

A communications path between the controller computer device(s) and each participator computer. The communication path passes through, or by way of, the Internet. In other words, the Internet forms at least one link in the chain of the overall communication path between the controller computer device(s) and each participator computer. The Internet is an electronic communications network that is formed by the interconnection of public and/or private networks and organizational computer facilities around the world.

(Mem. 20-21). AOL disagrees with Windy's proposed construction and argues that the phrase of "connections through the Internet" should be construed as the "use of non-propriety, platform-independent applications and protocols for communicating over the public, global series of interconnected TCP/IP networks independent of the control of any particular limited audience Internet service provider." (Mem. 21,27). Specifically, AOL contends that in the context of '491 Patent, the phrase "connections through the Internet" should be construed as "requiring" the "use platform independent, non-
propriety applications." (Mem. 27-31). Windy argues that AOL "has attempted to rewrite the claim language" in this regard and has proposed a construction which adds "limitations" to the claims. (Mem. 21-24).

The Federal Circuit has clearly stated that a court may examine the "interpretative context" of claims "from the specification and the prosecution history," but that a court "may not read limitations into the claims." Rambus Inc. v. Infineon Technologies Ag, 318 F.3d 1081, 1088-1089 (Fed. Cir. 2003); see also Northern Telecom Ltd. v. Samsung Electronics Co., Ltd. 215 F.3d 1281, 1290 (Fed. Cir. 2000)(stating that this "court has repeatedly and clearly held that it will not read unstated limitations into claim language."). In addition, the Federal Circuit has found that it is "improper for a court" to "add 'extraneous' limitations to a claim." Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 950 (Fed. Cir. 1993)(quoting in part E.I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, (Fed.Cir. 1988)).

In support of AOL's position that Claims 1 and 40 require that "connections through the Internet" can only be made through platform independent, non-propriety applications, AOL cites to numerous dictionaries and treatises which define and interpret the word "Internet." (Mem. 27-28). AOL further contends that the specification of '491 Patent "confirms" its position with regard to the phrase "connections through the Internet." (Mem. 28). However, the evidence submitted by AOL has failed to provide the court with any basis to construe that Claims 1 and 40 require that "connections through the Internet" can only be made through platform independent, non-propriety applications. Further, since Claims 1 and 40 of the '491 Patent do not even mention whether "connections through the Internet" can be made through platform independent, non-propriety applications, we decline to add this limitation. Hoganas AB, Inc., 9 F.3d at 950.

In accordance with the guidance provided in Texas Digital, we shall utilize a dictionary to ascertain the ordinary meaning of the term "Internet" at the time the '491 Patent was "issued" in 1999. Texas Digital Systems, Inc., 308 F.3d at 1203. In 1999, the time period in which the '491 Patent was issued, the Merriam-Webster's Collegiate Dictionary defined the term "Internet" as "an electronic communications network that connects computer networks and organizational computer facilities around the world." Merriam-Webster's Collegiate Dictionary 612 (10th ed. 1999). Therefore, the phrase "connections through the Internet" shall be construed, for purposes of the '491 Patent, as a "connection through an electronic communications network, known as the Internet, that further connects computer networks and organizational computer facilities around the world."

13. Connectors.

Intergraph argues this term carries its ordinary meaning to a person skilled in the art. Intel contends "connectors" lacks a commonly understood meaning as used in the context of the claims. Relying upon Fig. 10, Intel defines "connectors" as a series of instruction word paths with regard to "first set of connectors" and a series of pipeline pathways with regard to "a second set of connectors." The Court construes "connectors" as conductors or terminals for making connections.'028 patent at 10:3-9.

The Court is of the opinion that its resolution of the meaning of the above terms resolves the parties' disputes with regard to the '028 patent and that any remaining terms need not be construed.

B. "Consisting Essentially of"

The first term to construe is "consisting essentially of and is found in the preamble of claim 2. Digital Angel argues that the phrase is a term of art in patent law that has a well established meaning. Accordingly, Digital Angel avers the term is "a non-limiting transition phrase used to indicate that the invention necessarily includes the listed claim elements and is open to unlisted claim elements that do not materially affect the basic and novel properties of the claimed invention." Joint Claim Constr. Statement, App. A at 1. By contrast, Defendants argue that the term means "including only those elements recited in the claim, and no additional elements that materially affect the characteristics of the claimed invention." Id.
Both parties refer to PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351 (Fed. Cir. 1998) for support. In PPG Indus., the Federal Circuit stated:

"Consisting essentially of is a transition phrase commonly used to signal a partially open claim in a patent. Typically, "consisting essentially of" precedes a list of ingredients in a composition claim or a series of steps in a process claim. By using the term "consisting essentially of," the drafter signals that the invention necessarily includes the listed ingredients and is open to unlisted ingredients that do not materially affect the basic and novel properties of the invention.

156 F.3d at 1354. In the '129 patent, claim 2 begins "[a] transponder for syringe implantation into a host animal, consisting essentially of:" and then lists materials included in the transponder. '129 patent, col. 13:41-60. "Consisting essentially of" is construed in accordance with the Federal Circuit's construction of the term in PPG Indus. to mean "the invention necessarily includes the listed claim elements but is open to unlisted claim elements that do not materially affect the basic and novel properties of the claimed invention."

882

8. Supports consisting essentially of electrically conductive interconnects (claims 22, 33, 35)

Plaintiff contends that this term does not need to be construed, while Defendants contend that it means "the supports are made out of electrically conductive material and not electrically non-conductive material." The parties' primary dispute is whether the patentee limited "consisting essentially of" to mean "consisting only of" during prosecution.

Both parties acknowledge the general rule that "consisting essentially of" usually signals that the claim "is open to unlisted ingredients that do not materially affect the basic and novel properties of the invention." PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351, 1354 (Fed. Cir. 1998); Plaintiff's Opening Brief at 22; Defendants' Opposition Brief at 23. Defendants argue, however, that the inventor unequivocally disavowed a certain meaning to obtain his patent. Defendants' Opposition Brief at 23-24 (citing Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003)).

Specifically, Defendants rely on an examiner interview summary dated November 18, 1996, where the patentee and the examiner discussed "[c]laims amended and/or added relating to the limitation regarding the mechanical support [consisting] solely (or essentially) of electrically conductive connections" in response to a rejection based on the Higashi et al. prior art reference. Defendants' Ex. 7 at 305. Subsequent to that interview, Defendants argue, the patentee amended claim 22 and stated that "[i]t is well known in the art that silicon nitride is an insulator, not a conductor. Higashi et al. do not teach or suggest a structure [having] supports that consist essentially of electrically conductive interconnects." Defendants' Ex. 7 at 323 (November 25, 1996 Amendment). Contrary to Defendants' argument, however, neither of these statements approaches a clear and unmistakable disclaimer of claim scope or an unequivocal disavowal of the ordinary meaning of "consisting essentially of." Indeed, the patentee distinguished Higashi et al. on the basis that the reference does not teach or suggest a structure having supports that consist essentially of electrically conductive interconnects. Id. Neither of the statements upon which Defendants rely purports to limit "consisting essentially of" to "consisting solely of."

Because a jury will readily understand the meaning of this term as drafted, and because the patentee did not alter the ordinary meaning of this term during prosecution of the patent, the court finds that this term does not need to be construed.

See U.S. Surgical Corp., 103 F.3d at 1568.

883

1. "consisting of a steady-state component and a transient component subsequent to said arbitrary time" ('326 patent, claim 1)

AVID contends that this term should be construed as "consisting of, after the arbitrary time, a component in which one or more characteristics exhibit only negligible change over time (i.e., a steady state component) and a variable component that
The Defendants argue that the term means "consists of a component corresponding to a condition in which circuit values remain essentially constant (i.e., a steady state component) and a component caused by a sudden change in conditions and which persists for a relatively short time after the change (i.e., a transient component)." After carefully considering the parties' proposed constructions and the '326 patent, the Court is persuaded that AVID's proposed construction is correct and adopts it.

"console"

Various asserted claims of the patents-in-suit contain the term "console." ACQIS contends the term means "an enclosure with internal power and data connections for housing computer modules and other computer system components to the extent recited in the claims." Defendants originally contended the term meant "a chassis with a motherboard that connects several components of the computer system, capable of operation as a computer only upon connection to a computer module." However, at the claim construction hearing, Defendants deleted the phrase "with a motherboard" from their proposed construction. Also at the hearing, ACQIS acknowledged that it would agree to construing a "console" as "a chassis that connects several components of the computer system," but would not agree to the portion of Defendants' proposal that imports a negative limitation into the claims. Thus, the parties' dispute centers around the inclusion of "capable of operation as a computer only upon connection to a computer module."

ACQIS argues that the intrinsic evidence shows that the computer module requires a connection to a console for the computer module to operate as a computer system, but there is nothing that prevents the console itself from functioning as a computer system on its own without a computer module. ACQIS contends that the real purpose behind Defendants' proposal is to add functionality to the backplanes or chassis structures of their systems to avoid infringement. The claims themselves specify the division of a personal computer into two subsystems: the ACM and the PCON. However, the claims use the open-ended transition term "comprising," and thus an accused "console" may have additional computer functionality, yet nevertheless be a "console" as specified by the claims. Because there is nothing in the claims that limits the functionality of a console, Defendants' proposal which imports a negative limitation into the claims is improper. Accordingly, the Court construes the term "console" to mean "a chassis that connects several components of the computer system."

- "incrementing the count in the accumulator by a constant" is construed to encompass a constant whose range is typically between 0 and 1000. Newbridge contends that the constant referred to in this phrase must be a non-zero constant. After reviewing the claim language and the specification, the Court concludes that Newbridge's construction is contradicted by the specification which states that the constant can be a value between 0 and 1000. (810 Patent, col. 7, ll. 12-21). Accordingly, in the Court's view, its construction of this phrase is consistent with the express language of the specification.

2. "Power Supply Circuit"
Claims 28, 36 and 38 of the Reissue Patent incorporate a power supply circuit. The principle area of dispute, it appears, is the parties disagreement over whether terms such as "constant current" and "high impedance," as used in the context of the Reissue Patent, are too ambiguous and require a precise numerical value. In regards to the power supply circuitry of claim 28, Rockford argues that: (a) the term "constant current" is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation; (b) the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance; and (c) the phrase "increase electrical isolation between the first stage and the at least return signal" lacks definite meaning because the first stage is not isolated from the return reference potential, and the patent provides no baseline for measuring increase. (Def.'s Markman Br. at 2-3, 32-44.)

Rockford argues that the terms "constant current" and "high impedance" require some absolute numerical value because they are ambiguous and indefinite. Id. at 23-27. According to Rockford, the term "constant current" of claim 28 of the Reissue Patent is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation. (Def.'s Markman Br. at 2.) Rockford also alleges that the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance. Id. Finally, Rockford concludes that the phrase "increase electrical isolation between the first stage and the at least one return reference signal" lacks definite meaning because the first stage is not isolated from the return reference potential, and the patent provides no baseline for measuring an increase. Id. at 2-3.

Fiori counters that the intrinsic evidence clearly demonstrates that the claim language of the patents-in-suit were presented and approved by the PTO examiners, and therefore do not violate 35 U.S.C. § 112 (2) or require some absolute numerical value. (Pl.'s Markman Br. at 11.) Fiori asserts that "[t]he specification and Figures provide a complete definitional framework" for its claims. (Pl.'s Markman Br. at 20.) He contends that the Reissue Patent defines "constant current" as an exact current precisely metered through each transistor to operate the op-amps. Id. at 27. Fiori claims that the specification of the Reissue Patent teaches and defines that this power supply provides a current to the first stage preamplifier circuit that does not respond to changes in the potential of the supply pins of the op-amps (e.g., 38) so that the first stage is able to track the input reference signal without inducing any corrupting noise variations in the preamplifier circuit or in the return input reference signal current path. Id. According to Fiori, because the current is metered precisely, any changes and potential of the op-amp supply pins will have no bearing on the current delivered. Id. As a result, the effective impedance of the power supply is extremely high. n28 Id. Fiori further contends that "constant current," defined in the specification with precision, is a "degree term." (Pl.'s Markman Br. at 11 n.5.)

--- Footnotes ---

n28 Figure 3 in the specification similarly describes an alternative power supply for providing a constant current.

--- End Footnotes ---
This Court does not agree with Rockford's position that claim 38 includes the voltage regulator circuitry found within the constant current circuits. (Def.'s Markman Br. at 2, 24-30.)

In its Markman brief, Rockford first contends that the ordinary meaning of the words of claims 36 and 38 place the "constant current" between the power supply and the first power supply circuit. Id. at 25. According to Rockford, analogous to a "farmer drawing water from a well," the first power supply circuit performs the act of drawing and the power supply circuit draws current toward itself from the power supply. Id. at 26. Thus, Rockford believes that the location of the "constant current," as described in both claims, must be restricted because the limitations refer "to the particular water the farmer takes from the well" . . . and do "not refer to water used in the barn where animals drink." Id.

In regards to the power supply circuitry of claims 36 and 38, Rockford argues that: (a) the location of the "constant current" in both claims is between the power supply and the first power supply circuit because claims 36 and 38 state that the first power supply circuit draws the current from the power supply; and (b) the elements of the voltage regulation means in claim 38 include a bias voltage circuit. (Def.'s Markman Br. at 2, 24-30.)

This Court of Appeals does not agree. As previously stated, "if the claims, read in the light of the specification, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed Cir.) cert. dismissed, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985) (quoting Georgia-Pacific Corp. v. U.S. Plywood Corp., 258 F.2d 124, 136, cert. denied, 358 U.S. 884, 79 S. Ct. 124, 3 L. Ed. 2d 112 (1958)). Here, the term "constant current," as described in claims 36 and 38, is specifically defined in the specifications and claims and is not required to be situated between the first power supply circuit and the power supply. As such, Rockford's construction of claims 36 and 38 is too narrow in scope and its "farmer and the well" rationale is tenuous and unpersuasive. Rockford further asserts that the "voltage regulation means" of claim 38 includes the voltage regulator circuitry found within the constant current circuits. Despite the parties stipulating that "voltage means" includes transistors 22, 24, resistors 21, 25, and op-amps 23 and 26, Rockford interprets the pertinent language of the specification n30 of claim 38 to include elements 80, 82 and 84 and 85 and the op-amps requiring a bias voltage circuit. Id. at 2, 25, 27-30. According to Fiori, the first and second stage recitals of claim 38 are identical in scope to claim 36 and the power supply in claim 38 is recited as comprising a voltage regulating resistor and op-amps and zener diode 43 and 45. Id.

n30 The op-amps provide the biasing necessary for the transistors to conduct exactly that current required to produce that voltage across the resistors that match the biasing voltages produced by zener diodes 80 and 85 in combination with resistors 82 and 84. The Reissue Patent, column 5, line 18-27. Capacitors 81 and 86 are included to further reject any interference which may be present on the power supply as provided by contacts 91, 89 and 90. In this way, an exact current is precisely metered through each transistor to operate op-amps 13, 16, 38 and 41. Id. The op-amps provide the biasing necessary for the transistors to conduct exactly that current required to produce that voltage across the resistors that match the biasing voltages produced by zener diodes 80 and 85 in combination with resistors 82 and 84. Id. Capacitors 81 and 86 are included to further reject any interference which may be present on the power supply as provided by contacts 91, 89 and 90. Id. In this way, an exact current is precisely metered through each transistor to operate op-amps 13, 16, 38 and 41. Id.
constant current circuits. Rockford fails to establish the relevance or materiality its assertion serves for the purpose of this Markman process. n31

n31 Similarly, Rockford's argument that Fiori's claim constructions are unfounded in an effort to cover up the flaws of Plaintiff's case, is irrelevant for purposes of this Markman process. (Def.'s Rebuttal Br. at 25-30.)

IV. CONCLUSION

The Court concludes that the disputed terms have the following meanings:

1. "Input Portion" of claims 1 and 17 of the '148 Patent shall mean a specifically defined physical structure, connected to two conductors and recited as generating an intermediate signal.

2. "Output Portion" of claims 1 and 17 of the '148 Patent shall mean a physical structure, specifically defined as op-amp 65, which is separate, independent and isolated from the input operational amplifier and recited as generating a destination signal and a corresponding destination reference signal.

3. "Second Stage" of claim 28 of the Reissue Patent shall mean a stage, operatively coupled to the first stage, generating an output signal which is a sum of the at least one intermediate signal generated in the first stage minus a potential of the at least return reference signal plus an output return reference signal.

n32 There is no issue between the parties regarding the "first stage" of the Reissue Patent.

4. "High Impedance" of claim 28 of the Reissue Patent shall mean a mathematically sufficient term of degree for providing a constant current power supply circuit coupled to said first stage to increase electrical isolation between the first stage and the at least one return reference signal.

5. "Constant Current" of claims 28, 36 and 38 of the Reissue Patent shall mean an exact, non-absolute numerically valued current, precisely metered through each transistor to operate the op-amps, and not required to be situated between the first power supply circuit and the power supply.

6. "Power Supply Circuit" of claims 28, 36 and 38 of the Reissue Patent shall mean a first stage preamplifier circuit that does not respond to changes in the potential of the supply pins of the op-amps (e.g., 38) so that the first stage is able to track the input reference signal without inducing any corrupting noise variations in the preamplifier circuit or in the return input reference signal current pathway.

An appropriate order follows.
interpreted include claim terms 15 and 15a ("constant") and claim terms 9 and 31 ("continuously"). The terms as shown on
the Joint Claim Chart, in simplified form, are as follows:

9. "transmitting said electromagnetic signal continuously"
15. "constant electromagnetic signal with time"
15a. "constant calibration signal with time"
31. "whereby the depth of the boring tool can be continuously monitored as it moves from said first point to said second
point"

First, the Court looks to the terms as they appear in the context of the claims themselves. As the context of the claim terms
is particularly important for these claim terms, the Court quotes heavily from the language of the claims. Claim 1 of the '258
Patent includes the following language:

1. In a method for locating a boring tool that moves through the ground from a first point to a second point in directions
dependent on the roll orientation of the boring tool and during which time the roll orientation of the boring is controllably
changeable throughout 360 degrees of roll orientation in order to steer it between said first and second points, said method
using (1) a transmitter and power supply carried by the boring tool within an electrically conductive housing for
transmitting to an above ground location an electromagnetic signal containing information which is used in obtaining the
location of the boring tool and (2) a receiver located at said above ground location for receiving and processing said
electromagnetic signal whereby to determine the location of the boring tool, the improvement comprising the steps of:

transmitting said electromagnetic signal continuously as said boring tool moves from said first point to said second
point independent of the roll orientation of the boring tool at any point throughout its 360 degree of roll orientation,
whereby the transmitter is able to transmit and the receiver is able to receive said information containing signal irrespective
of the roll orientation of the boring tool so that the depth of the boring tool can be determined regardless of its direction of
movement from said first point to said second point; and

maintaining the strength of said signal substantially constant with time at any given point relative to said transmitter as
the signal is being continuously transmitted,

whereby the depth of the boring tool can be continuously monitored as it moves from said first point to said second
point.

(emphasis added). Similarly, Claim 4 of the same patent includes the following language:

4. In a method for locating a boring tool that moves through the ground from a first point to a second point, said method
using (1) a given transmitter . . . and (2) a receiver . . . whereby to determine the location of the boring tool, the
improvement comprising the steps of:

(a) providing a specific positional relationship between said transmitter and receiver and, while maintaining that
positional relationship, transmitting a CONSTANT electromagnetic signal with time from said transmitter and receiving
said CONSTANT signal from said receiver;

(b) obtaining distance and electromagnetic signal field strength measurements (i) based on said positional relationship
between the transmitter and receiver and (ii) based on the transmission and reception of said constant signal by said
transmitter and receiver, respectively, and using those measurements, establishing a proportionality constant k of said dipole
FOR SAID GIVEN TRANSMITTER AND RECEIVER . . .

(c) thereafter, using said proportionality constant and a CONSTANT electromagnetic signal with time, causing said
receiver to determine the depth of said boring tool.

(emphasis added). Finally, in regards to claim term 15a, Claim 9 of the same patent contains the following language:
9. In a method for locating a boring tool that moves through the ground from a first point to a second point during which time at least the roll orientation of the boring tool changes, said method using: (1) a given transmitter . . . and (2) a given receiver . . . whereby to determine the location of the boring tool, the improvement comprising the steps of:

(a) providing a specific positional relationship between said transmitter and receiver and, while maintaining that positional relationship, transmitting a CONSTANT electromagnetic calibration signal with time from said transmitter and receiving said CONSTANT signal from said receiver;

(b) obtaining distance and electromagnetic signal field strength measurements (i) based on said positional relationship between the transmitter and receiver and (ii) based on the transmission and reception of said constant signal by said transmitter and receiver, respectively, and using those measurements, establishing a proportionality constant k of said dipole FOR SAID GIVEN TRANSMITTER AND RECEIVER . . .

(c) thereafter, using said proportionality constant and a CONSTANT electromagnetic signal, causing said receiver to determine the depth of said boring tool.

(emphasis added).

Plaintiff would have these terms be limited to a continuousness or constancy of spatial orientation, in other words that the transmitter simply be capable of transmitting a signal throughout the entirety of its roll. Defendant, on the other hand, argues for an interpretation of these terms in a temporal sense. Defendant argues that "continuously" should mean that the electromagnetic signal is transmitted without interruption, and that "constant" should mean that the signal is uninterrupted and of unchanging magnitude.

The Court finds that the parties' interpretations are both in part correct and in part incorrect. First, claim term 9 "continuously" is presented in the following context: "transmitting said electromagnetic signal continuously as said boring tool moves from said first point to said second point independent of the roll orientation of the boring tool at any point throughout its 360 degree of roll orientation." '258 Patent, Claim 1 (emphasis added). The context in which the word "continuously" is found thus indicates that it relates to the spatial orientation of the boring tool. This is consistent with certain parts of the specification and prosecution history in which the inventor describes the prior art, which involved a window through which the signal could be transmitted. This design was inferior to the present design (using "slots" or "apertures") because the former design had a "blind spot" through twenty degrees of its rotation during which depth information could not be obtained, and a variation in signal strength depending on the roll angle of the boring tool. See '589 Patent, Col. 5:61 - Col. 6:4; Prosecution History of the '258 Patent, 11/19/98 Amendment at 5 (Pl's Hearing Ex. 9) ("the location of the boring tool is continuously available throughout the entire 360 degrees of its roll orientation, that is, it is independent of roll orientation."). Thus, the Court interprets the term "continuously" to mean that the signal is always available throughout the roll angle of the boring tool, in other words that the transmitter is capable of transmitting and the receiver is capable of receiving the electromagnetic signal independent of the roll angle of the boring tool.

The Court interprets claim term 31 in a similar fashion. In its proper context in Claim 1 of the '258 patent, it is clear that this claim term is describing a method in which the boring tool depth may be monitored without regard to the roll angle of the boring tool. This is shown most aptly by the language in the claim itself prior to the language of the claim term: "at any point throughout its 360 degree of roll orientation," "irrespective of the roll and orientation of the boring tool." As these claim terms are found within the same claim, they should be construed consistently. Claim term 31 refers to continuousness in a spatial sense.

Nevertheless, this interpretation does not compel an identical interpretation of the claim terms that include the word "constant." There is a distinction to be drawn between a signal that is "continuously transmitted" and one that is of "constant strength." The first instance of this word is in Claim 1 of the '258 Patent, which states: "maintaining the strength of said signal substantially constant with time at any given point relative to said transmitter as the signal is being continuously transmitted." (emphasis added). In Claims 4 and 9 of the same patent, the following phrase is seen: "transmitting a CONSTANT electromagnetic signal with time from said transmitter and receiving said CONSTANT signal." Here, the language of the claims, taken in the proper context, indicates that the signal is constant. The Court does not know how else to read the term "constant with time" other than to say that the signal remains constant with time. With a standard dictionary
definition of the word "constant" being "a value that does not change during a particular process," McGraw-Hill Dictionary of Scientific and Technical Terms, 468 (6th ed. 2003), this term does not appear to allow for a signal that is on-off keyed, such as a pulsed signal.

Other sources, both intrinsic and extrinsic, support this construction. The specification, for example, touts the invention's ability to provide the user with "precise and continuous depth and periodically updated orientation measurements." '589 Patent, Col. 6:24-26. This is consistent with DCI's own literature, describing its device as providing "depth shown continuously" (emphasis in original) and "roll updated every 1/4 second." See Def's Hearing Ex. 227. Further, this is consistent with the testimony of Dr. Mercer, both in his deposition taken during a prior case against Radiodetection Corp., and his testimony given during the claim construction hearing. First, during the Radiodetection case, Dr. Mercer was asked about the "constant electromagnetic signal with time" and how such a signal might not be constant. He replied "It could be varying on and off." Mercer Dep. 09/13/00 at 286-87. More convincing, however, is his testimony during the hearing. When asked about the carrier frequency, he explained:

Basically there is a characteristic of the signal that is unvarying with time and rotation angle. And based on that unvarying component of the signal that's being received we can determine the depth because of the one-to-one relationship between depth and signal strength.

All of the above evidence, both intrinsic and extrinsic, indicates that the terms "constant electromagnetic signal with time" and "constant electromagnetic calibration signal with time" mean that they are uninterrupted signals over time. This necessarily excludes signals that are pulsed or on-off keyed. These constructions are also consistent with the Court's interpretations of the means plus function claims above, as well as the constructions concerning the electromagnetic signals.

II. "constant value"

6 The term "constant value" is contained in claims 1, 6, and 12-16 of the '646 patent and claims 1 and 7 of the '612 patent.

6 The term "constant value" is contained in claims 1, 6, and 12-16 of the '646 patent and claims 1 and 7 of the '612 patent.

Alternatively, "a value that does not change for any given instance of generating an encryption key"

The patents-in-suit both contain the claim term "constant value." PACid advocates that a plain reading of the claims and patents-in-suit illustrates that a "constant value" is "not a universal and immutable value that does not change." OPENING at 5. Should a construction be necessary, PACid suggests: "a value that does not change for any given instance of generating an encryption key." PACid supports its alternative construction with language in the '612 specification describing examples of a constant value as having "several different components that can be changed." Id. (citing '612 patent at 6:6-21). Using the E-Key Seed ID as an example, PACid contends that the constant value can differ amongst host systems and that "different values can have different lengths." OPENING at 5.

Defendants dispute this approach, arguing for the dictionary definition of "constant value," meaning "[a] value that does not change." RESPONSE at 26. Defendants contend that the patentee never choose to be his own lexicographer and their proposed construction ascribes a meaning to "constant" that aligns with the commonly accepted meaning of the term.
short, Defendants maintain that the value does not deviate based on circumstances. Id.

As an initial matter, the differences articulated between PACid and Defendants' proposed constructions indicate uncertainty as to the claim term's scope, which is properly resolved through claim construction. O2 Micro, 521 F.3d at 1361 ("A determination that a claim term 'needs no construction' or has the 'plain and ordinary meaning' may be inadequate when a term has more than one 'ordinary' meaning or when reliance on a term's 'ordinary meaning does not resolve the parties' dispute."). The application of "constant" throughout the patents does not indicate that the patentee chose to ascribe a special meaning to this term. Therefore, in the absence of any "special definition," one of ordinary skill in the art would understand "constant" to mean what it means in a dictionary: "unchanging, permanent, or fixed." See Comaper Corp. v. Antec, Inc., 596 F.3d 1343, 1348 (Fed. Cir. 2010) (where the patent specification does not assign or suggest a particular meaning to the claim term, the claim is to be construed as it would be understood by a person of ordinary skill in the art in light of a general dictionary definition) (internal citation omitted); see also AM. HERITAGE COLLEGE DICTIONARY 298 (3d ed. 1993).

As such, the Court finds the Defendants' proposed construction uncontroverted by the intrinsic record and affirmatively supported by the extrinsic record.

Although clearly presented, Defendants' proposed construction does not account for the particular context in which an encryption key is generated. In order to decipher the scope of the claim term, it is proper to evaluate the particular circumstances required to generate the key. See Therasense, Inc. v. Becton, Dickinson and Co., 593 F.3d 1289, 1323 (Fed. Cir. 2010) (recognizing that "patentees frequently use terms idiosyncratically," which is why persons of ordinary skill must look to the full context in which a term is used) (citing Phillips, 415 F.3d at 1314). In other words, while "a value that does not change" is an accurate depiction of how "constant value" is used throughout the patents, it is also appropriate to clarify how this general term is understood in light of the process disclosed in the claims. To that end, the Court finds that the patents-in-suit only require that the "constant value" be constant for the purpose of generating a given encryption key (regardless of how many times the key is produced), and once that key is generated, another constant may be used to generate a different encryption key.

The meaning of "constant" in the asserted claims is only fully understood through the patents' description of the larger encryption/decryption process. 7 This is unambiguously borne out in the '612 patent specification at column 6, lines 6 through 21, as well as Figure 6. The described examples, using references to the E-Key Seed ID, show that a "constant value" has different components that can be changed, and thus, disclose a different "constant value" for each encryption key. In particular, a "constant value" can include an E-Key Seed ID, and the user may choose to assign another E-Key Seed ID. See '612 patent at 6:13-18 ("When the constant value 11 is first being formed, the E-Key Seed ID is automatically entered as that of the host system. A user is prompted, however, to either accept the ID or assign another. In this manner, files may be shared between PCs, workstations, and workgroups that normally use different E-Key Seeds.").

7 The importance of the circumstances underlying this term can be aptly analogized to familiar "constant values" like Pi or the acceleration of gravity. While Pi is an immutable constant that does not vary with context, the acceleration of gravity depends upon location because gravity varies with contextual facts such as altitude and local properties of the Earth (e.g., density and shape). Yet, both Pi and the gravitational pull are true constant values. Like gravity, the constant value in these patents depends upon circumstances such as the length byte and E-Key Seed ID.
3. "power or power-spectral-density constraint"

With regard to the third disputed claim term, Plaintiff does not offer a proposed construction, but rather asserts that it is indefinite and invalid. Plaintiff interprets Defendants' proposed construction as one that is "effectively synonymous" with the meaning of "power mask." (Pl.'s Reply at 11). Based on the claim language and specification, Plaintiff asserts that the terms "power- spectral-density constraint" and "power mask" cannot be synonymous. (Pl.'s Reply at 11; Tr. at 19:15-20:5).

Plaintiff is correct. It is clear, however, that Defendants do not propose that "power constraint" and "power mask" mean the same thing. At the hearing, Defendants described the system as having a "power constraint" which serves as an overall limit to the transmitter, as well as a "power mask" which limits the power in each individual carrier. (Tr. at 17:9-13, 18:1-2).

Further, the plain language of Claim 1 clearly differentiates between the terms "power mask" and a "power or power-spectral-density constraint." Moreover, the specification also differentiates between these terms:

When given a set of initial SNR estimates of the orthogonal carriers of a multicarrier communication system, a set of target bit error rates for the carriers, and an arbitrary transmit power mask together with an overall transmit power constraint, the present invention provides a method of determining the initial bit and energy allocations, and therefore the corresponding bandwidth.

'447 Patent, col. 7, 11. 11-17 (emphases added). Therefore, these terms are not interchangeable.

Regarding the proper construction of "power or power-spectral-density constraint," Defendants propose that the term should be read in the disjunctive. Specifically, Defendants argue that the transmitter is subject to either a "power constraint" or a "power-spectral-density constraint." 7 (Tr. at 16:13-24). A plain reading of the claim language supports this proposition.

Defendants submit that "power constraint" refers to "an absolute limit on the transmitter power," and "power- spectral-density constraint" is "one that may vary by frequency." (Id.). Defendants noted at the hearing that this definition for "power constraint" directly originates from the specification. The basis of Defendants' definition for "power-spectral-density constraint," however, is unclear.

The Court agrees with Defendants' construction of "power constraint" as a limit of maximum power based on the specification. A preferred embodiment of the invention, as explained in the specification, describes an algorithm associated with the initialization procedure. This states that the mathematical term E\(_{\text{target}}\) equals the "total input energy, or power constraint at the transmitter," and E\(_{\text{max}}\) is the "maximum energy, or power, allowable in [a] carrier due to the transmit power mask." '447 Patent, col. 8, 11. 17-22; col. 9, 11. 49-54. Thus, it appears that E\(_{\text{target}}\) is the maximum amount of energy at the transmitter and E\(_{\text{max}}\) is the maximum energy that can be used by each individual carrier. Additionally, the specification states that "in no event is \(E_{\text{target}}/k\) (k being the number of used carriers) greater than the allowable amount of individual carrier transmit energy due to the power mask." '447 Patent, col. 8, 11. 25-27. This description comports with Defendants' proposed construction for "power constraint."

The Court is then left to determine the proper construction of "power-spectral-density constraint." In defining this term, the record is limited to several dictionary definitions cited by Defendants, the claim language, specification, and the opinion of Defendants' expert, Tim A. William, Ph.D. ("Dr. Williams"). Defendants' proffered construction is based on a series of dictionary definitions. Such definitions, however, are taken from dictionaries that were published well after the patent issued. The Federal Circuit noted that reliance on dictionaries and treatises should be limited to those that are contemporaneous with the patent. Brookhill-Wilk, 334 F.3d at 1299 (declining consideration of references published after the date of the patent grant because they did not reflect the definitions that would have been given to them by a person of ordinary skill in the art). In the present case, the '447 Patent was filed in May 1993 and issued in December 1995.
Defendants submitted references dated between 1998 and 2004. As such, the Court will not consider these references in its claim construction analysis.

The claim language and specification is devoid of a clear meaning for "power-spectral-density constraint." As a result, the Court is left with the expert opinion of Dr. Williams for insight as to how a skilled artisan would interpret this term. Dr. Williams opines that a person of ordinary skill in the digital communications field would interpret "power-spectral-density constraint" to mean "a limit for the maximum transmit power allowed at particular frequencies." (Williams Report, P 140). In light of the absence of contradictory evidence in the claims and the specification, the Court will accept Dr. Williams' opinion as indicative of the proper construction.

Therefore, based on the evidence set forth in the record, the Court will adopt Defendants' proposed construction for this term. Accordingly, disputed term [3] "power or power-spectral-density constraint" means "an absolute limit in the transmitter power or a limit in maximum transmit power allowed at particular frequencies."

5. "constructing a data representation of a lifetime of the telephone call using data regarding telephony events associated with the telephone call segments of the telephone call"

The parties dispute the meaning of "constructing a data representation of a lifetime of the telephone call using data regarding telephony events associated with the telephone call segments of the telephone call," as used in the '570 patent (claim 6) and '345 patent (claim 14). NICE contends that disputed terms beyond "data representation of a lifetime of the telephone call," "telephony events," "telephone call segments," and "telephone call," should be accorded their plain meaning. NICE further contends that Witness has simply rearranged words used in the claim phrase and improperly inserted a limitation to preclude the use of "an identifier or key" to form the data representation. Witness contends that its proposed construction tracks the precise definition NICE used to disclaim prior art in its prosecution history, citing '345 Pros. Hist., 2nd Prelim. Amend., 9-10. In response, NICE contends that the cited prosecution history is taken out of context and does not constitute a clear and unmistakable disavowal.

After considering the specification, relevant prosecution history, and the Court's earlier constructions, the Court concludes that "constructing a data representation of a lifetime of the telephone call using data regarding telephony events associated with the telephone call segments of the telephone call" does not require construction. The Court's construction of "data representation of a lifetime of the telephone call," in particular, obviates the need to further construe the disputed language.

3. "constructing a data stream"

Claim 8 of the '094 Patent provides in relevant part:

In a method for broadcasting data to a television set using a carrier signal such as a television or commercial radio carrier signal, the improvement comprising:
constructing a data stream from the records of a transmission database. . . .

'094 Patent, col. 22, lines 21-25 (emphasis added).

The plaintiff claims that the term "constructing a data stream" as used in claim 8 means creating a series of information. Joint Claim Construction Brief, Exh. A. The defendants, by contrast, argue that "constructing a data stream" means extracting records from the transmission database and forming a single, serial signal. Id.

The briefing on this issue is not particularly informative. The issue, as explained at the Markman hearing, is as follows:

Well, the difference is, Your Honor, you can do what is described, taught, enabled in the 094 patent, which is you can take some data, you can take every little piece of that data, you can send it in a serial way, you can load it up on the television signal, and it will go out in that--in that sort of--it's a simple, more--you know, less sophisticated technology. That's all this patent talks about.

There are other technologies where you do create many multiple streams. You don't set it up that sort of single serial sort of way. You have--you take your data, and maybe you put it into 10, 15, 20 different streams, and it all goes out there, and with the advent of huge computer power and enormous advances in technology, you can then reconstruct all that--you take all that data stream . . . and then it can be put back together at the other end . . . . So that's the difference. And that type of technology is not described.

Record, at pp. 82-83.

The defendants argue that "although patent claims are not necessarily limited to the preferred embodiment described in the specification, 'claims may be no broader than the supporting disclosure, and therefore . . . a narrow disclosure will limit claim breadth.'" Joint Reply Brief of Defendants . . . Regarding Claim Construction for the '094 Patent, at p. 16 (quoting Gentry Gallery, Inc. v. Berkline Corp., 134 F.3d 1473, 1480 (Fed. Cir. 1998)). The defendants argue further that because the '094 Patent does not "disclose or enable a multi-stream system, the scope of the purported invention is properly limited to a single, serial transmission."

As discussed earlier, there is a "heavy presumption" that the claim terms carry the ordinary and customary meaning that would be attributed to them by one skilled in the relevant art. Texas Digital, 308 F.3d at 1202; Johnson Worldwide, 175 F.3d at 989. Here, that ordinary and customary meaning is that a "data stream" is "a sequence of data elements." The Dictionary of Computing, 127 (4th ed. 1996).

The defendants' restrictive construction is an attempt improperly to limit the scope of the claim to the preferred embodiment or specific examples disclosed in the specification. Ekchian, 104 F.3d at 1303. Although the invention may be described at times in the specification as transmitting a "sequential data stream," (col. 4, lines 39-40), or "processing . . . the serial data stream," (col. 5, lines 43-44), the specification does not always or necessarily limit the data stream to a single, serial data stream. For example, the specification discloses at col. 4, lines 13-26, a data stream that is not necessarily sequential or serial, but could be multiple:

The datacast network utilizes television signals to convey digital information for the text display at the receiver stations. In this respect, the central station generates a stream of data which is encoded into datacast packets as defined by the World Standard Teletext specification and know [sic] as Packet 31 data. This data stream is inserted into the vertical blanking interval (VBI) of the television broadcast signal transmitted from the central station and is subsequently broadcast over the ether to be received by the receiver stations at which are located display screens, such as television receiver sets or video monitors on which selected groups of received information can be displayed, and remote user interface devices, such as keypad controllers or the like.

Remembering that a patentee need not describe in the specification "every conceivable and possible future embodiment of his invention," CCS Fitness, 288 F.3d at 1366, I adopt the construction of the term "constructing a data stream" urged by the plaintiff, and I construe the term to mean creating a series of information elements.
10. "Consumable Participation Key" and "Limits on Use"

The parties have presented the terms "consumable participation key" and "limits on use" to the Court for construction. "Consumable participation key" appears in Claim 51 of the '309 patent and reads in context "qualification structure controlled by said record structure for testing caller data signals provided by a respective one of said individual callers to specify a consumable participation key for restricting the extent of access to said system to limit data stored from said respective one of said individual callers on the basis of entitlement." The term also appears in Claim 65 of the '863 patent and reads in context "qualification structure for testing caller data signals provided by at least one of said individual callers to specify a consumable participation key, said consumable participation key for use during a single predetermined period of time for restricting the extent of access to at least a portion of said system by said one of said individual callers on the basis of entitlement." The term "limit on use" or "limits on use" appears in Claims 33, 44, and 93 of the '707 patent and Claims 79 and 190 of the '863 patent. Claim 33 of the '707 patent recites in part a "qualification structure controlled by said record structure for testing said calling number identification data to specify a basis for entitlement defining a limit on use, for restricting the extent of access to said system for a respective one of said certain of said individual callers. . . . An analysis control system according to claim 26, wherein said limit on use relates to a dollar amount." The other claims in which "limits on use" appears are substantively the same; Claim 44 of the '707 is representative and reads "providing products carrying participation numbers specifying limits on use to entitle individual callers to access said operations of the interface with said telephonic communication system."

The parties agree that "consumable participation key" should be defined as a number or word that allows a caller access to a service or part of a service a predefined limited number of times and which cannot be refreshed or recharged. While the ordinary meaning of the claim language gives some indication of the meaning of "consumable participation key," the specification makes it clear. In Column 9, lines 31 through 35 of the '707 patent, the specification provides that "for example, a list may be preserved by a use-rate calculator to implement a consumable key operation. That is, a user is qualified to a specific limited number of uses during a defined interval."

The parties disagree, however, on the meaning of "limits on use." The plaintiffs argue that "limit on use" means "a control imposed on the degree or extent to which callers may avail or utilize a service or one or more operations of a service." (Pls.' App. at 74). The plaintiffs contend that a limit on use can be any one of a range of restrictions including "limits based on the total number of permitted accesses, the time of day for permitted accesses, limits on use based on a dollar value, [and] limits on use based on a predetermined period of time." (Pls.’ App. 75-76). The defendants argue that this term has the same meaning as consumable participation key in that it is a control on the number of times a caller may enter a format in the Katz system. The defendants agree that a limit on use can be fixed by a set number of uses or a set dollar amount. However, the defendants argue that a limit on use does not perform a metering function in that it does not effect the duration of access to a format; consequently, it cannot disconnect a caller during a format for exceeding a set period of use.

The place to begin is the claim language. Claim 33 of the '707 patent provides for a limit on use that relates to a dollar amount. The plaintiffs argue that this Claim clearly shows that limit on use is not restricted to only the number of calls or accesses into the system. Although this claim does not explicitly recite that the limit on use would be a duration of time linked to the set dollar amount, e.g. $ 10.00 limit at $ 2.00 per minute, it does not explicitly recite that the dollar amount could only be linked to a set number of accesses, e.g. $ 10.00 limit at $ 2.00 per access.

The defendants argue that the limits on use are used to qualify callers for access to the operations of the interface, which necessarily has to occur before the caller enters into the Katz system. However, claim 44 of the '707 patent provides for a further step of "invalidating on-line said participation numbers after said limits on use specified by said participation numbers are reached." This claim calls out a step of utilizing the limit on use at a later point in the process after the qualification step.

The specification confirms that "limit on use" should not be restricted to set number of accesses to the Katz system. In Column 12, lines 52-57 of the '707 patent, Katz describes how a calling number may be "checked by the use-rate calculator
to determine the number of times it has been used in excess of a predetermined number of calls or dollar value to participate in the lottery during a current interval of monitoring." (emphasis added). Similarly, in Column 12, lines 22 through 26 of the '707 patent, Katz describes how a lottery format may use a limit on use and states that "for example, a person might be entitled to play the lottery a limited number of times or to the extent of a limited dollar value during a predetermined interval." (emphasis added).

Contrary to the defendants' assertion, the Court concludes that Katz does not equate all limits on use to consumable participation keys. In Column 9, lines 32 through 35 of the '707 patent, the specification provides that "a list may be preserved by a use-rate calculator to implement a consumable key operation. That is, a user is qualified to a specific limited number of uses during a defined interval." The use of the phrase "limited number of uses," which accurately describes a consumable participation key, does not indicate that all "limits on use" are consumable participation keys. Thus, it is clear from the claims and specifications that a consumable participation key is only one kind of a limit on use.

There is no indication in the Katz patents of a method of measuring a limit on use based on a dollar value. That is, neither the claims nor the specifications require that the limit on use based on a dollar value be decremented by the number of accesses to the system, i.e. $2.00 for each access. The claims and the specifications leave open the possibility that the dollar amount could be decremented by some other method of measurement, such as time spent in the Katz system; i.e. $2.00 for 10 minutes, such that the limit on use served a metering function.

The statements made by Katz in the prosecution history cited by the defendants do not require a different construction than what is clear from the plain language of the claims and specifications. During the prosecution history of the '707 patent, certain of Katz's pending claims, including pending claim 47, were rejected by the examiner in an office action as unpatentable over two patents and an article of Turbat. (Ex. 51). In an Amendment dated August 31, 1995, Katz amended pending claim 47 by substituting the phrase "one time use" with "limit on use." Katz also argued against the examiner's rejection of his pending claim 47 in a section entitled "Discussion of the Rejections of Claims 32, 37, 40, 41 and 47 under 35 U.S.C. § 103." In that section, Katz distinguishes the rejected claim 47 on the basis that "applicant's system, as claimed, is independent of both time (Barger and DeBruyn) and value (Turbat)." However, this discussion was clearly directed toward the rejection of the claim as originally written, which called for "a basis of entitlement defining a one time use," as evidenced by Katz's statement at the end of the discussion section that "the rejected claims are urged to be distinct for the reasons presented above." Based on this review of the prosecution history, the Court concludes that Katz's statements about a claim that read "one time use" do not limit the claims that were eventually accepted, which read "limit on use."

Based on the foregoing the Court concludes that "consumable participation key" means: a number or word that allows a caller access to a service or part of a service a predefined limited number of times and which cannot be refreshed or recharged. The Court concludes that "limit on use" means: a control that limits a caller's access to a service based on some predefined method of measuring the level of use. The term "limit on use" is not restricted to a specific method of measuring use, such as a limited number of accesses into the Katz system.

4. "Consumer" and "Consumer Account"

The plaintiff argues that these terms do not need construction. Alternatively, the plaintiff proposes that "consumer" means "a person or entity that acquires or uses goods or services" and that "consumer account" means "an account associated with a consumer." The defendant argues that that "consumer" means "an individual that purchases goods or services" and that "consumer account" means "an account unique to an individual." The dispute is whether the terms are limited to an individual or whether it includes businesses and organizations.

The defendant contends that the term is limited to an individual because the specification refers to a consumer's Social Security number and birth date. See '116 patent, 3:5-8. According to the defendant, an entity cannot have Social Security numbers or birth dates.

The court rejects the attempt to limit the construction to the preferred embodiment. The court construes "consumer" to mean "a person or entity that acquires goods or services for direct use or ownership rather than for resale or use in production and

- 1354 -
4. "Consumer" and "Consumer Account"

The plaintiff argues that these terms do not need construction. Alternatively, the plaintiff proposes that "consumer" means "a person or entity that acquires or uses goods or services" and that "consumer account" means "an account associated with a consumer." The defendant argues that that "consumer" means "an individual that purchases goods or services" and that "consumer account" means "an account unique to an individual." The dispute is whether the terms are limited to an individual or whether it includes businesses and organizations.

The defendant contends that the term is limited to an individual because the specification refers to a consumer's Social Security number and birth date. See '116 patent, 3:5-8. According to the defendant, an entity cannot have Social Security numbers or birth dates.

The court rejects the attempt to limit the construction to the preferred embodiment. The court construes "consumer" to mean "a person or entity that acquires goods or services for direct use or ownership rather than for resale or use in production and manufacturing." The term "consumer account" needs no additional construction.
Regarding conductivity, PMT denies that the contact layers described in the Chen Patent are limited to p+ and n+ contact layers because the claim language speaks only of a "conductivity type," meaning genus p-type or n-type, and does not specify a particular species of conductivity. (R. 26 at 20 to 27 at 22; R. 234 at 12-24). Further, PMT points out that as originally filed, the first and second contact layers were called regions, and all regions were disclosed as either p-type or n-type or simply as the species p or n. (R. 23 at 2-9) (referencing, e.g., original claim 1, Application at 15). PMT concedes that no contact layer described in the specification is other than p+ or n+, but argues that an absence of an embodiment in the specification does not build a limitation into the claims. (R. 233 at 4-12).

Thus, PMT argues that "contact" layer should be defined in terms of its function (contact) and so may include several components in one functional area, as long as everything has the same conductivity type and same function. (R. 28 at 8 to 29 at 4; R. 72 at 1-7; R. 234 at 25 to R. 235 at 11). PMT offers, by way of example of a "contact layer," items 3 and 4 from Figure 4 of the Chen Patent. (R. 73 at 19-24). PMT concedes, however, that item 2 would not be included in the "contact layer" because it is of a different conductivity type. (R. 71 at 25 to R. 72 at 1-4).

PMT urges the Court to reject defendants' proposed definitions first on the ground that a heavy doping requirement violates the doctrine of claim differentiation. (R. 231 at 22-23). Specifically, PMT contends that if the Court were to adopt a heavy doping limitation on "contact layer", claim 11 would be indistinguishable from claims 12 and 13, and claim 14 would be indistinguishable from claims 15 and 16. (R. 231 at 24 to R. 232 at 15). PMT asserts that defendants' rebuttal that claim 13 can be distinguished from claim 11 because claim 13 includes a specific polarity fails because it does not take into account claim 12, which specifies the opposite polarity. (R. 300 at 11-23). PMT thus contends that dependent claims 12 and 13, considered as a pair, cannot be differentiated from independent claim 11. Id.

PMT asserts that Chen's attack on breakdown voltage in the patent can only be reconciled with a general p-type or n-type contact layer. (R. 233 at 18-22). PMT rebuts defendants' argument that its proposed definition is indefinite by pointing out that "contact layer" in the claims is always accompanied by language specifically locating it within the device relative to the voltage sustaining layer. (R. 235 at 12 to R. 236 at 5) (referencing, e.g., Chen Patent, col. 7, In. 62-63). PMT distinguishes "contact layer" from "voltage sustaining layer" on the basis that prior art devices contain components that are not heavily doped, but which nevertheless are part of the contact layer because they take on charge from an outside source when the device is turned on. (R. 236 at 14 to 237 at 8) (referencing Coe Patent, Figure 13). PMT explains that it is a predominant function test: if the structure functions predominantly to avoid breakdown, then it is a contact layer; if it function predominantly to sustain voltage, then it is a voltage sustaining layer. (R. 237 at 3-8). In the alternative, PMT distinguishes "contact layer" from voltage sustaining layer on the basis that the voltage sustaining layer must contain alternating regions; therefore, everything above and below the area of alternating regions is contact layer. (R. 230 at 20 to R. 231 at 2) (referencing, e.g., Chen Patent, col. 7, In. 66-68).

In rebuttal of Infineon's contention that a layer must be continuous and extend over the entire device, PMT directs the Court to the figures in Chen depicting processed devices, like Figure 4, and notes that Chen describes these figures as representing his invention, and points out that they contain discontinuous contact layers. (R. 295 at 1-22) (referencing Chen Patent, col. 5, In. 19-20; col. 5, In. 50-51). Noting that the terms "continuous" or "uninterrupted" do not appear in the patent, PMT further points out that the contact layers are uninterrupted when deposited and argues that they do not have to remain uninterrupted in the finished device. (R. 296 at 17-21; R. 295 at 8-10) (referencing, e.g., Chen Patent, col. 5, In. 56-67). PMT rebuts Infineon's argument regarding the use of "layer" in association with unprocessed devices (i.e., Chen, Figures 2 & 7) versus the use of "regions" with processed devices (i.e., Chen, Figures 4, 5, & 6) on the ground that the difference goes back to the original filing and illustrates that the drafter meant the terms to be interchangeable but, just to make the orientation easier to understand, recast vertical areas as "regions" and horizontal areas as "layers." (R. 295 at 23 to 296 at 14; R. 298 at 14-23). Finally, PMT contends that Infineon's position regarding "contact layer" is inconsistent with its position on "voltage sustaining layer", which Infineon accepts as being made up of multiple regions. (R. 297 at 1-4).

In rebuttal of defendant ST's arguments under Festo, PMT argues that Festo is inapplicable to the construction of the disputed claim terms because Festo does not alter literal infringement analysis, and PMT seeks only a literal interpretation, not any equivalency. (PMT Resp. to ST Festo Br. at 2, 4) (citing Festo, 56 U.S.P.Q.2d at 1-6). PMT argues that claim terms are to be construed from the viewpoint of one of ordinary skill in the art, not from narrow definitions culled from lay dictionaries, and that Festo does not teach otherwise. (Id. at 2-3). Specifically, PMT argues that "contact layer" is literally understood in the art of semiconductor technology as not necessarily continuous, and "contacted all" is literally understood...
to denote electrical and/or physical relationships. (Id. at 5). Finally, PMT argues that Festo is also inapplicable in this case because it requires that the prosecution history "reflect a clear and unmistakable surrender of subject matter," and PMT asserts that the prosecution history is completely devoid of any such assertion. (Id. at 6) (quoting Festo, 56 U.S.P.Q.2d at 14, § III.B) (internal punctuation omitted).

2. Defendants' Interpretation 4

--- Footnotes ---

4 To the extent that the parties may have changed their positions about the meanings of some of the disputed claim terms, the Special Master has ignored earlier positions and focused instead on the parties' latest positions, represented by the arguments pressed during the August 28-29, 2000 Markman hearing. Although the Special Master restates some of the parties' latest and most relevant arguments regarding the disputed claim terms, this is not intended to be exhaustive. However, all of the arguments from the three rounds of pre-hearing briefing, the arguments presented at the Markman hearing, and the Festo supplemental briefing have been considered in this recommendation.

--- End Footnotes ---

Because independent claim 14 has been asserted against Infineon, but not against ST, Infineon's proposed definition contains elements additional to ST's proposed definition, and Infineon presents arguments in addition to the defendants' common arguments. A hybrid definition incorporating the elements common to both defendants would be, "a heavily doped layer forming an interface with the voltage sustaining layer." 5 Defendants' common arguments are addressed first, followed by Infineon's definition and additional arguments.

--- Footnotes ---

5 Infineon's specific proposed definition is, "a single thickness of n+ or p+ semiconductor material lying over or under the voltage sustaining layer." (R. 105 at 7-10). ST's specific proposed definition is, "a heavily doped layer forming an interface with the voltage sustaining layer and extending to an external surface of the semiconductor material." (ST slide # 41).

--- End Footnotes ---

Regarding conductivity, defendants argue that a "contact layer" must be heavily, as opposed to lightly, doped because a lightly doped layer would sustain voltage, i.e., have the same function as the voltage sustaining layer. (R. 107 at 10-25; R. 183 at 10-24). Thus, if a lightly doped condition were included in the definition of "contact layer," there would be no functional difference between the terms "contact layer" and "voltage sustaining layer." (R. 107 at 10-15; R. 183 at 10-24). Defendants also point out that all the embodiments in the Chen Patent, such as Figure 7, items 4 and 8, illustrate a heavily doped layer. (R. 107 at 15-19; R. 184 at 9-11). Further, Infineon claims that the only conductivity species discussed throughout the specification are the n+ and p+ species; there is no mention of n or p, or -- or p-layers. (R. 109 at 12-16). Finally, defendants urge that the Court reject PMT's proposed definition as vague or overbroad in that "capable of electrical contact" would describe every structure in the device. (R. 117 at 5-12; R. 184 at 15 to 185 at 6). Therefore, that definition would not enable one to differentiate a "contact layer" from any other structure in the device and thus read "contact layer" out of the claims, violating the principle that every word in a claim has meaning.  Id. Defendants rebut PMT's contention that their proposition that a contact layer must be heavily doped violates the principle of claim differentiation on the ground that claim 13 imposes a further limitation over claim 11 in that it identifies the specific polarity of the conductivity types. (R. 285 at 18-25).

In addition to those elements of a proposed definition it asserts in common with ST, Infineon further asserts that a contact layer should be defined as "a single thickness of n+ or p+ semiconductor material." (R. 105 at 7-10). Infineon distinguishes "layer" from "region," 6 by taking "region" to mean "a generic term for any structure on a semiconductor." (R. 11 at 14-15). In Infineon's understanding, "all layers are regions," but "only regions that extend across the entire device can be layers." (R. 112 at 5-6). By way of illustration, Infineon offers Figure 4, item 4 of the Chen Patent as an example of a layer and Figure 4, item 3, as an example of a region. (R. 112 at 10-14). Regarding the composite buffer layer (referred to in the Chen patent as the CB-layer), which it describes as comprising alternating regions of opposite conductivity, Infineon contends that "layer" does not imply a single conductivity type and can be constructed of regions. (R. 271 at 13-22). Therefore, its
definition of "contact layer" does not conflict with its definition of "voltage sustaining layer." (R. 270 at 21 to 271 at 12).

6 ST denies PMT's assertion that it proposes that a "contact layer" must physically touch the voltage sustaining layer. (R. 185 at 17-24; R. 199 at 4-19).

In support of its proposition that a "layer" should be restricted to a single thickness, Infineon points first to the amendment made during prosecution of the Chen Patent wherein the inventor added the term "layer," and, defendant contends, adopted Figure 7 as the embodiment properly illustrating "layer." (R. 105 at 23 to 106 at 2). Prior to amendment, the patent contained no reference to "layer," only to "regions," (R. 105 at 1-4), and Infineon argues that the inventor knew that the terms were not interchangeable and intentionally chose to use the ordinary, and narrower, meaning of "layer." (R. 110 at 8-12). Since the change was made in an amendment responding to a rejection of all the original patent claims in light of prior art, Infineon argues that it is implicit that the change was made specifically to overcome prior art. (R. 106 at 11-21; R. 107 at 1-9; R. 116 at 17-24). Thus, by choosing to designate the areas above and below the voltage sustaining layer as a "layer," Chen gave up the broader meaning of "region." (R. 105 at 2 to 107 at 8; R. 273 at 13-18). Infineon urges the Court to adopt the ordinary and plain meaning of "layer": "one thickness, course, or fold laid or lying over or under another." (Infineon Br. at 10) (citing WEBSTER'S NEW COLLEGIATE DICTIONARY (9th ed. 1975)). Infineon points out that all of the claims refer to a contact layer in the singular, rather than the plural, form, whereas original claims had referred to "regions" in the plural. (R. 265 at 17-24). Finally, Infineon points out that the embodiments show only a single thickness "layer," such as items 4 and 8 of Figure 7, (R. 110 at 19-22), and that the examiner chose Figure 7 showing a single thickness "layer" to put on the patent cover as representative of the invention, (R. 115 at 23-25).

In support of its proposition that a layer must extend horizontally over the entire device, Infineon points to the descriptions in claims 11 and 14 of the "contact layers" contacting all the first and second regions of the voltage sustaining layer. (R. 266 at 19-20; R. 270 at 1-5) (referencing Chen Patent, col. 7, In. 68 to col. 8, In. 5). Infineon contends that only two figures in the Chen Patent illustrate an arrangement where the second contact layer (i.e., item 8) contacts all the regions, and those are Figures 2 and 7. (R. 267 at 10-19).

In addition to the arguments it pressed at the Markman hearing, Infineon submitted supplemental briefing arguing that the Federal Circuit's recent ruling in Festo mandates adoption of its proposed definition of "contact layer." In sum, Infineon argues that the addition by amendment of the elements "layer" and "all" narrowed the scope of "contact layer" from a meaning that, as originally filed, arguably could have been construed to include discontinuous regions 2 and 3 in Figure 5 to one that, in the claims as issued, can only include a continuous layer like that represented by items 4 and 8 in Figure 7. (Infineon Supp. Br. at 1, 5-6). Specifically, Infineon argues that substitution of the singular "layer" for the plural "regions" eliminates the possibility that the first and second contact layers can be made up of more than one element (i.e., discontinuous), or of more than one conductivity type. Id. at 7. In addition, Infineon asserts that the substitution of "contacting all" or "contacting with all" for "contacted with" to describe the interfaces between the first and second contact layers and the voltage sustaining layer restricts the formation of those interfaces to "continuous and uninterrupted contact of the respective first and second layers with the alternating p and n regions of the CB-layer" because the adjective "all" requires continuous contact and, under Festo, precludes any equivalency (i.e., discontinuity). Id.

The Special Master recommends that "contact layer" 8 be defined as "the semiconductor material between the metal contacts and the voltage sustaining layer that is designed to perform two contacting functions: (a) permit ohmic contacts to be formed at the terminals (e.g., the source or emitter contacts) and (b) provide a connection between the metal contacts".
and the voltage sustaining layer such that the reverse voltage across the device terminals is sustained primarily across the 
voltage sustaining layer." (See, e.g., Chen Patent, col. 5, In. 56-61; col. 6, In. 22-26 and In. 33-36; col. 1, In. 13-16).

8 The discussion of "contact layer" and "contacting" is very limited in the patent specification because the focus of the 
patent is on the point of novelty of the invention, the design of the CB-layer.

9 For example, the source contacts in the MOSFET devices and the emitter contacts in the bipolar devices.

10 It is well known to one of ordinary skill in the art that there will be some voltage drop across the ohmic contacts and the 
contact layers.

Contact layer is defined in terms of the function that it performs in the device. The "contact layer" may include multiple 
regions that need not be continuous or contiguous, or even of the same conductivity type, unless so limited by the claims. 11 
This is illustrated by the different embodiments in the specification, where the "contact layer" is designed differently in the 
various embodiments but performs the specific functions outlined above, regardless of whether the embodiment is a vertical 
MOSFET, a bipolar transistor, or a static induction transistor. For example, see regions 3 of the contact layers in Figs. 4, 5 
and 6, and region 11 in Fig. 8, all of which are discontinuous, and the contact layers in Figs. 2 and 7 which are continuous.

11 Note that the claims of the Chen Patent do specifically limit a contact layer to a single conductivity type. (See, e.g., Chen 
Patent, col. 7, In. 59-60; col. 8, In. 27-28).

In the field of semiconductor technology, a layer is commonly understood to mean semiconductor material that is disposed 
onto a semiconductor substrate or created by standard semiconductor processing techniques, such as epitaxy, diffusion, or 
implantation. When a layer is processed, for example, by etching followed by oxide deposition, it becomes further defined 
into regions. 12 Because a layer is so processed into these regions, however, does not mean that layer ceases to have any 
meaning. These processed regions are part of the same layer. Such an understanding of layer is consistent with how that 
term is used in the patent in connection with the terms "contact layer" and "voltage sustaining layer," as both are layers that 
are further processed so that, internally, they are made up of regions. (Chen Patent, col. 5, In. 26-26; col. 5, In. 32-36).

12 For example, in Figure 1, the patentee describes the formation of layer 3, then further processing it to form regions 2 
(and so also regions 3). (Chen Patent, col. 5, In. 24-26). Similarly, in Figure 4, the patentee describes forming layer 5, then 
further processing it to regions 6 and 7 of the voltage sustaining layer. (Chen Patent, col. 5, In. 52-55).

Festo does not require a different interpretation in this situation. It is true, as Infineon states, that "an amendment that 
narrows the scope of a claim for any reason related to the statutory requirements for a patent will give rise to prosecution 
history estoppel with respect to the amended claim element." Festo, 56 U.S.P.Q.2d at preamble. "Related to the statutory 
requirements for a patent" include amendments in response to a § 112 rejection, any voluntary amendment that narrows the 
scope of a claim for a reason related to patentability, and "unexplained" amendments. Id. The Festo court held that when 
prosecution history estoppel applies, the patentee can get no equivalents for the amended elements and is restricted to literal 
infringement. Id. Any voluntary amendment, however, must evidence an intent to surrender subject matter. Id. at § III.B.

However, substituting "layer" for "regions" as the patentee did during prosecution, did not narrow the claims under the 
proposed understanding of those terms. The patentee's remarks accompanying the amendment make it clear that the patentee
made this change to "better claim the present invention" in order to overcome the § 112 objection. (Chen Patent, Amendment at 9). Later remarks about the additions of the non-uniform dopant distribution and dielectric layers to distinguish over Coe and Ploog in order to overcome the § 102(b) and § 103 rejections reinforce the conclusion that the change involving the use of "layer" was not directed to those rejections, and so the patentee was not relying on the change from "regions" to "layer" to overcome prior art. (Chen Patent, Amendment at 10).

Further, the amendments during the prosecution of the Chen patent may be deemed to have expanded the scope of the claims instead of narrowing them. In the claims which issued, the first and second contact layers are not explicitly restricted to n+ or p+ regions, as they are in the original claims. (referencing Chen Patent, original claim 1, Application at 15; issued claim 11, col. 7, In. 59 to col. 8, In. 6). In addition, the original claims as filed use a narrower term, "CB-layer", which is then amended to recite a broader term, "voltage sustaining layer." (compare, e.g., original claim 1, Application at 15, and issued claim 11, Chen Patent, col. 7, In. 62-63).

The parties dispute the proper construction of the terms "contact region," (and "electrical contact region"), "semiconductor body," and "opening." As the terms are set forth in the claims, and as evidenced by the parties' arguments regarding the proper construction of these terms, there is a strong interrelationship between them, and therefore the Court considers it appropriate to construe these terms simultaneously.

1. "contact region" (and "electrical contact region"), "semiconductor body" and "opening"

The parties argue: (1) that the term "contact region" means "an electrically conducting space or area to which another electrical conductor may be connected so as to allow current to pass"; (2) that the term "semiconductor body" means "any semiconductor material"; and (3) that the term "opening" means "a hole or void; an open space." Atmel argues: (1) that the term "contact region" means "a region of the semiconductor substrate to which electrical contact is made"; (2) that the term "semiconductor body" means "the underlying material upon which a device, circuit or epitaxial layer is fabricated" (i.e., the substrate or the silicon wafer); and (3) that the term "opening" means "a contact hole, that is, a hole in the first dielectric layer that exposes the silicon surface." The essential difference between the parties' constructions is that Atmel apparently wishes to construe the claim terms such that the claims cover only openings above contact regions which are contained within the substrate or the silicon wafer, whereas Agere wishes to construe the claim terms such that the claims cover openings above contact regions which are formed in or on any semiconductor material, including but not limited to the substrate or silicon wafer.

Agere's proposed constructions more closely comport with the general and ordinary meaning of these terms. For example, Agere provides a dictionary definition of the term "contact," which provides, in pertinent part: "the junction or touching surface of two electrical conductors through which a current passes." Webster's Third New Int'l Dictionary 490 (1986). Also, Agere provides a dictionary definition of "opening," which provides, in pertinent part: "an unobstructed or unoccupied space or place ... a void in solid matter: a gap, hole, or aperture." Random House Dictionary of the English Language 1357 (2d ed. 1987).

Moreover, the specification indicates that Atmel's proposed constructions are too narrow. The "Background of the Invention" provides:

Making electrical contact to semiconductor regions such as, e.g., source, drain, and gate regions of a field-effect transistor typically involves the deposition of a metallization over a dielectric which has been patterned to produce openings.
(windows, holes, vias) to the underlying semiconductor structure.

'827 Patent at col. 1:14-19. In addition, the "Detailed Description" of the specification provides:

Contact openings may be, e.g., to source or drain regions of field- effect transistors, or to contact regions intended for device interconnections. Typically, in the latter case, contact is made to silicon in polycrystalline form.

'827 Patent at col. 2:30-34. According to the explanation provided by Agere's expert witness, this language makes clear that the patentee contemplated using the patented process not only for contact regions which are contained within the silicon substrate (such as source and drain regions), but also for contact regions which are not contained within the silicon substrate (such as gate regions). See Tr. 12/5/02 at 94-99. Thus, Atmel's proposed construction of "contact region" as "a region of the semiconductor substrate" is too narrow, as the contact region need not be contained within the substrate.

In addition, the patent does not provide that openings must be in the first dielectric layer and must expose the silicon substrate or wafer, but only that openings must expose an "underlying semiconductor structure." '827 Patent at col. 1:18-19 (emphasis added). The patentee's decision to use the term "semiconductor structure" in the specification and the term "semiconductor body" in the claims, and not to use the term "semiconductor substrate" in either the specification or the claims, indicates a specific intention not to limit the claimed process to openings that are formed in the first dielectric layer above the silicon substrate.

Accordingly: (1) the term "contact region" is construed as "an electrically conducting space or area to which another electrical conductor may be connected so as to allow current to pass"; (2) the term "semiconductor body" is construed as "any semiconductor material"; and (3) the term "opening" is construed as "a hole, void, or open space."

B. Contacting

1. Plaintiff's Interpretation

Plaintiff PMT asserts that "contacting" should be defined as "capable of electrical contact." (R. 41 at 20-21). PMT contends that "contacting" can include physically touching, but denies that it requires physically touching, (R. 45 at 8-25; R. 59 at 19-25), on the basis that then nothing could act as a buffer or intermediate between a contact layer and any of the regions in the voltage sustaining layer, (R. 38 at 5-9). PMT argues further that any requirement for physical touching is indicated in the claims by use of the phrase "directly contacting." (R. 41 at 22-25) (referring to Chen Patent, col. 6, In. 59-60; Chen Patent, col. 8, In. 38-39); see also R. 59 at 19-24; R. 241 at 19-22). According to PMT, if "contacting" meant only "physically touching," then "directly" would be superfluous, wherein every term in a patent has meaning. (R. 42 at 1-5). Instead, PMT asserts that almost every use of "contacting" or "contact" in the Chen Patent makes sense only in the context of electrical contact and that such meaning is necessary to be consistent with the meaning of "contact layer." (R. 42 at 25 to 43 at 18; R. 240 at 21-23). Further, PMT points out that the IEEE Dictionary defines "contact" as "conducting parts that co-act with another conducting part to make or break a circuit." (R. 43 at 19-23 (citing IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS 185 (Frank Jay, ed. 1984) (ANSI/IEEE Std 100-1984)). Specifically, PMT contends that the phrase "contact layer contacting" does not preclude a condition where the contact layer is electrically contacting the voltage sustaining layer through a less doped intermediate layer. (R. 243 at 15 to 244 at 19).

PMT characterizes defendants' proposed construction of this term as an impermissible attempt to back-load a limitation from the specification into the claims. (R. 43 at 23-25). Plaintiff rebuts the defendants' argument that its definition of "contacting" is indefinite on the basis that each time it is used in the claims, it is accompanied by language that structurally orients it by making clear that it means linking the voltage sustaining layer to a contact layer. (R. 241 at 9-15) (referring to Chen Patent, col. 6, In. 56-60; col. 7, In. 68 to col. 8, In. 4; col. 8, In. 35-40). Finally, PMT rebuts defendants' argument that "contacting" is limited to meaning "touching" by the prosecution history by explaining that the examiner's referenced comment can be interpreted to mean electric contact because a dielectric layer would block both physical and electric contact. (R. 44 at 15-25).
2. Defendants' Interpretation

Defendants assert that "contacting" should be defined to mean "touching." (R. 120 at 18; R. 185 at 25 to 186 at 1). They argue that the Court should reject PMT's definition on the basis that it is vague because, in an electrical device, all elements co-act with one another. (R. 120 at 20-25; R. 198 at 3-7 and ST slide # 51). Infineon explains that there is a fundamental distinction between plaintiff's and defendants' proposed definitions, that distinction being that plaintiff would have the Court adopt electrical definitions, while the defendants urge structural or physical definitions. (R. 121 at 1-4). Infineon argues for structural definitions because it regards the patent as disclosing a new structure of an electrical device. (R. 121 at 4-13).

Defendants also urge the Court to reject PMT's definition on the ground that it is erroneously based on how the noun "contact" is used in the patent in the context of a metal contact, and not on how the verb "contacting" is actually used in the patent. (R. 123 at 15-24; R. 185 at 21 to 186 at 1). Further, defendants argue that PMT is limited to "touching"as the definition of "contacting" because the examiner based a § 112 rejection upon that meaning of "contacting", and Chen acquiesced because he made no attempt to correct the examiner. (R. 124 at 1-13). Finally, ST argues that the dielectric of claim 2 prevents physical contact between the first contact layer and the second semiconductor regions and this is why claim 1 omits "contacting." (Infineon Resp. Br. at 10) (referencing Chen Patent, col. 6, In. 56-64). Therefore, "contacting" must mean physical contact. Id. ST argues that the use of "directly" in conjunction with "contacting" in certain of the claims does not alter this interpretation because there is no structural distinction for using it to describe the top interface. (R. 193 at 2-17).

3. Recommended Interpretation

The Special Master recommends that "contacting" be defined in terms of its relationship with the term "contact layer" as "permitting or enabling contact." Thus, "contacting" is not limited to physical contact and can also include electrical contact.

Throughout the claims, "contacting" is always used in conjunction with "contact layer" in the specific phrase "contact layer contacting," indicating that it is meant to describe the function of the "contact layer." (See, e.g., Chen Patent, col. 6, In. 56-67; col. 7, In. 68). The term "contacting" is never used in the claims independently, without the words "contact layer" preceding it. Read in light of the disclosure, we see that this "contacting" function of the contact layer is to permit ohmic contacts at the terminals (See, e.g., source "S" in Figure 4 or emitter "E" in Fig. 8) and to contact the voltage sustaining layer from either side (i.e., the top and bottom side). (See, e.g., Chen Patent, col. 5, In. 56-61). This is most apparent in the inventor's description of the CB-layer and its relationship to the contact layer: "Each n-region and each p-region of the CB-layer has two surfaces contacted respectively with the n+-region and the p+-region." (Chen Patent, col. 2, In. 8-10) (emphasis added). This language clearly demonstrates that "contacting" refers to the function and relationship of the contact layers to the voltage sustaining layer.

This interpretation is supported by how the term "contact" is used in the field of semiconductor technology. Specifically, "contact" is defined as, "[a] conducting part that acts with another conducting part to make or break a circuit." THE NEW IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS 249 (Christopher J. Booth ed., 5th ed. 1993) (IEEE Std 100-1992) (emphasis added). 13 As can be seen, this definition does not restrict "contact" to physical contact.

--- Footnotes ---

13 See also RUDOLF F. GRAF, MODERN DICTIONARY OF ELECTRONICS 148 (5th ed. 1977) ("To join two conductors or conducting objects in order to provide a complete path for current flow.").

--- End Footnotes ---

Defendants' "slippery slope" concern that electrically contacting is too vague a meaning because, in an electrical device all elements co-act with one another, becomes irrelevant because the definition outlined above limits itself to the specific kind of "contacting" that results from the introduction of the contact layers on either side of the voltage sustaining layer. Considered in this context, "contacting" describes the function of the "contact layer", which contacts the voltage sustaining layer on one side of the contact layer and permits ohmic contacts at the other side of the contact layer. (See, e.g., Chen Patent, col. 2, In. 8-10). As noted above, the contact layer provides a connection between the terminals of the device and the
voltage sustaining layer and sustains the reverse voltage applied between the device terminals, primarily across the voltage sustaining layer. In other words, "contacting" has meaning only when read together with the term "contact layer" as in "contact layer contacting."

Similarly, Infineon's contention that "contacting" must mean "physically touching" to distinguish Chen's claim 14 over the Lidow patent, U.S. Patent No. 4,593,302, is unpersuasive because there are other elements to claim 14 which distinguish over the prior art.

5. "Contacting Relationship"

The bringing step calls for bringing "said corresponding contact surfaces of said electrically conductive terminals into contacting relationship with said corresponding contact surfaces of said conductor elements." Thomson argues that "contacting relationship" means "physical contact;" Innovatron argues that the term is one of art, meaning "a position favorable for correct alignment and electrical contact." The Commission held:

We agree with the ALJ's construction that a contacting relationship is not established at the instant of physical contact, but instead when the card terminals and card reader elements reach a position favorable for making contact, that is, when they are roughly centered with regard to each other.

This Court is to interpret "contacting relationship" as one skilled in the art in 1978 would have understood the term. If the meaning were "physical contact" that meaning would be expressed far more readily by the phrase bringing the surfaces on the terminals "into contact" with the surfaces on the elements rather than "into contacting relationship." The term "relationship" adds a limitation. The Court holds that one skilled in the art would understand "contacting relationship" to mean that the terminals and elements are positioned favorably for good electrical contact. See also Tr. (July 2, 1998, a.m.) at 31 (testimony of Dr. Kuc).

13. a hard disk drive contained within said hand-held housing

The plaintiff contends that no construction is needed. The defendants propose "a hard disk drive fixedly or removably located within said housing." The defendants' proposed construction reads in limitations from the preferred embodiment. Accordingly, the court agrees with the plaintiff and concludes that this phrase requires no construction.

5. "Containing"

Claim 1 of the '641 Patent uses the term "containing" as follows:

1. A modular jack to be mounted on a circuit board, said modular jack comprising:

- a printed board containing an electronic element for suppressing noise;
- a contactor for contacting with a plug, said contactor being electrically connected with the electronic element by a wire on the printed board;
a terminal for contacting with the circuit board, said terminal being electrically connected with the electronic element by a wire on the printed board; and

an insulating housing for encasing the printed board.

Murata argues that "containing" means "including as a component." Murata's Opening Brief, at 28. Bel Fuse argues that "containing" means "held by or mounted on." Bel Fuse's Responsive Brief, at 23. The difference between these constructions is that Bel Fuse argues that the electronic element for suppressing noise must be physically "held by or mounted on" the printed board whereas Murata argues that "containing" is not so limited.

Bel Fuse argues that each of the three disclosed embodiments shows that the element for suppressing noise is "held by" or "mounted on" the printed board. Again, this court is wary of placing too much emphasis on the disclosure of the preferred embodiments, particularly where the specification contemplates modifications to the disclosed embodiments, because doing so may lead to improperly importing limitations from the specification into the claims. Phillips, 415 F.3d at 1323 (stating that courts should avoid "reading limitations from the specification into the claim").

Bel Fuse also argues that its construction is necessarily correct because the electronic element must be mounted on the printed board to be electrically connected to the printed wires on the printed board. However, because the court has rejected Bel Fuse's construction of "wire on the printed board" which would have required the wire to be printed, this argument no longer holds any force.

Murata's proposed construction of "containing" is supported by the Federal Circuit's decision in Mars, Inc. v. H.J. Heinz Co., L.P., 377 F.3d 1369 (Fed. Cir. 2004). In Mars, the Federal Circuit held that the term "containing" is an open-ended term which does not exclude additional, unnamed elements. Id. at 1375-76. Citing a general purpose dictionary, the court also stated that "containing" is synonymous with "comprising" and "including." Id. In this case, Bel Fuse is attempting to transform the term "containing" into a structural requirement, namely, that the printed board physically hold the component or that the component be mounted on the board. There is no indication in the patent that such a requirement is present. Rather, consistent with the Federal Circuit's holding in Mars, the court finds that "containing" is simply an open-ended term that denotes that the electronic element for suppressing noise is simply one component of the printed board. Thus, the court adopts Murata's proposed construction and holds that "containing" means "including as a component."

The critical claim in this matter is Claim 1. Claim 1 provides that the invention has a "main body portion" that "contains" an "FM transmitter" and "power/charging circuitry." '085 Patent col.6 11.1-6. "Contains" is the critical word in this claim, and nothing in the claim terms defines "contains." Furthermore, "contains" does not appear to be a technical term, and common-use dictionaries might illuminate possible relevant meanings for this every day, commonly understood word. "Contain" means "to keep within limits," "to have within," and to "enclose, bound." Merriam-Webster Online Dictionary, http://www.m-w.com/ dictionary/contains (last visited May 17, 2006); accord Webster's Seventh New Collegiate Dictionary 180 (1970). In light of these definitions, Claim 1 describes a product in which the FM transmitter and the power supply/charging assembly are "enclosed," "bound," or "kept within" the same housing unit.

This definition does not conflict with the other relevant evidence. The patent's entire content reflects that the invention has the FM transmitter and power supply/charging assembly within one unit. The patent's other language states that "[t]he present invention provides an integrated FM transmitter and power supply/charging assembly for an MP3 player." '085 Patent col.2 11.64-66 (emphasis added). "Integrated" shows that this invention's critical feature is that the FM transmitter and the power supply/charging assembly are housed within one unit. Such language is consistent with Claim 1's "contains."

This construction is also consistent with the prosecution history. In his "Reasons for Allowance," the patent examiner stated he approved the '085 Patent because the patent application described, unlike other patent applications, a product that contained the FM transmitter and power/charging circuitry within one main body. Thus, that single unit allowed not only "FM transmission . . . of audio content when played by the MP3 player in the docking cavity," but also the "transmi[ssion of] electrical power through the modular docking unit . . . for charging of a battery of the MP3 player and/or powering of the
MP3 player, as specified in the claim.” (Birdwell Decl. Ex. 16 at 4.) Thus, in communicating his reasons for allowing the patent, the patent examiner focused on the single, integrated unit having two separate functions. In light of this evidence, Claim 1’s plain language as illuminated by dictionaries, and the patent’s entire content, the ’085 Patent protects an invention where one module houses, contains, or holds within itself two separate functions: a fully functioning FM transmitter and power supply/charging assembly.

I. "[C]ontent"

A. The Special Master's Recommended Construction

The Special Master recommended that the term "'content' . . . should have the meaning provided in the glossary, namely, 'any form of digital data stream that may be supplied or sent to a computing system such as a personal computer,' and may include window object size and position information." (R&R at 140 (emphasis added to reflect the language added by the Special Master)); see also, e.g., '493 Patent col. 5 ll 46-48. The Special Master also interpreted the intrinsic evidence to exclude, from the scope of "content," data that was not sent from a server to the client computer system. (See R&R at 137-38 (stating "the patentees have used the term 'content' to broadly connote most if not all data sent from the server to the client").) Accordingly, under the Special Master's proposed construction of the term, any "size and position information provided by a user via module controls does not appear to be 'content.'" (Id.)

B. The Parties' Objections

The parties object to the Special Master's proposed construction and propose greatly varying interpretations of the term "content." CA "proposes 'content' be construed to mean 'any form of digital data stream that may be supplied or sent to a computing system such as a personal computer, regardless of the source of that data.'" (CA's Claim Construction Objections at 10.) In essence, though CA agrees with the Special Master's adoption of the glossary definition of the term "content," they disagree with the Special Master's additional restriction that "content" does not include "'size and position information provided by a user via module controls does not appear to be 'content.'" (Id. at 9-10 (quoting R&R at 138).)

Simple asserts that the meaning attributed to "Content" in its patent glossary should not be applied consistently throughout the entire patent. Instead Simple would have the Court apply the glossary definition of "content" only to instances where the capitalized term "Content" is used and apply "its ordinary and customary meaning in the context of the specification" every time the un-capitalized term "content" is used. (Simple's Claim Construction Objections at 4-5). Specifically, Simple urges that "content" be limited to "text, graphics, or 'media information such as news, data, weather, sports, and the like . . . , things that are displayed within a window object.'" (Simple's Claim Construction Objections at 5-6.) Having summarized the Special Master's proposed construction and the parties' corresponding objections, the Court will put forth its own analysis.

C. Analysis

The Court's analysis of the term "content" will entail the following steps: (1) constructing the term based upon a review of the claim language and the specifications of the patents in suit; (2) addressing the Special Master's additional language and modification of the term to exclude size and position information provided by a user; and (3) addressing the arguments raised by the parties.

1. According to the Claim Language of the Patents In Suit, the Term "content" Cannot Be Limited to the Information Displayed on Screen

The claim language of the patents in suit clearly establishes that content must include: (1) window object attributes such as size and location; (2) the address of a network client source; and of course, (3) information displayed in a content manifestation environment. According to claim 1 of the '493 Patent, "content" is processed to produce a window object. In this context, "content" includes the attributes of a window object such as size and window position which have been loaded into the host database and then sent to the client side to determine the appearance of the window object itself. E.g., '493
The system according to claim 1, wherein said associated content includes at least one address of a network content source that is configured to download information to said data processing system via said electronic data network, said information to be manifested within said at least one window within said content manifestation environment.

'493 Patent Cl.4 (emphasis added). The emphasized claim language clearly indicates that "content" is more than the information displayed on screen. A step-by-step analysis of claim 4 indicates that: (1) a user on a network client receives "content" from a remote server system over the Internet, as per claim 1; (2) this "content" includes the "address of a network content source" and other information that may be displayed on screen; (3) the network client accesses said address and downloads information; and finally (4) the received information is then displayed within a window object. Having reviewed the claim language of the patents in suit, the court will supplement its construction of the term "content" by referring to the specifications of the '493, '563, and '882 Patents.

2. According to the Specifications of the Patents in Suit, the Term "content" Cannot Be Limited to the Information Displayed on Screen

The specifications of the '493, '563, and '882 Patents indicate that: (1) "content" should not be limited to information "displayed within a window object" and (2) it can be received from any source. The specifications of the patents in suit state that "content" can include "window object instructions, content, data, and content stream data." '493 Patent col.7, ll. 64-67; '563 Patent col. 7, ll. 31-40; '882 Patent col.7, ll. 64-67. The specifications of the '493, '563, and '882 Patents also state that "content" can be "received via an electronic data network, from a local hard disk, etc." '493 Patent col. 8, ll. 57-59; '563 Patent col. 8, ll. 30-32; '882 Patent col. 8, ll. 57-59. The use of the term "etc." is noteworthy because it indicates that the patentees' list was not meant to be exhaustive. Consequently, content can be received from other sources besides "an electronic data network . . . [or] a local hard disk." An example of this additional source would be "a stream of position data coming from a mouse interface while the user moves the mouse to drag a . . . [window object] around the claimed content manifestation environment. (See CA's Claim Construction Objections at 10.) Having reviewed the relevant intrinsic evidence, the Court will define the term "content."

3. "[C]ontent" Defined

The intrinsic evidence before the Court, compels the adoption of the glossary definition of "content," specifically, "any form of digital data stream that may be supplied or sent to a computing system such as a personal computer." E.g., '493 Patent col. 5 ll 46-48. According to the patents in suit, "content" includes but is not limited to: (1) information delivered to a user; (2) window object attributes such as size and location; (3) the address of a network client source; and (4) window object instructions. In fact, the claim language of the '493, '563, and '882 Patents indicates that information displayed on screen is merely a part of what is considered "content." Additionally, "content" can be received from various sources including, but not limited to, an electronic data network and "a local hard disk." E.g., '493 Patent col. 8, ll. 57-59. Since the foregoing descriptors fall within the glossary definition of "content" found in the '493, '563, and '882 Patents, the Court will let the patentees' lexicography stand. Having construed the term "content," the Court will discuss why it disagrees, in part, with the Special Master's recommended construction and address the parties' objections.

4. The Special Master Unnecessarily Added Language to the Patentees' Glossary Definition of "content" and Then Incorrectly Modified His Definition of "content" to Exclude Data Supplied By a User

The Special Master was correct in adopting the glossary definition of "content" but his use of clarifying language is superfluous and raises the possibility of confusion. The Special Master recommended that the term "Content" . . . should have the meaning provided in the glossary, namely, 'any form of digital data stream that may be supplied or sent to a computing system such as a personal computer,' and may include window object size and position information." (R&R at 140 (emphasis added).) Although the Court agrees that the term "content" should have the meaning provided by the identical glossaries found in the '493, '563, and '882 Patents, the additional phrase "and may include window object size and position information" is counterproductive because it could be misconstrued as limiting the glossary definition of the term.
"content." Indeed, the phrase "any form of digital data" already includes "window object size and position information."

The Special Master also improperly limited the term "content" to exclude data supplied by a user. (R&R at 137-38; Special Master's Report and Recommendation Regarding Anticipation and Obviousness (Dkt. No. 592)) ("Anticipation and Obviousness R&R"). At 76.) According to the Special Master, "the patents-in-suit indicate that size and position information provided by a user, e.g., through minimizing and resizing, is not 'content' . . . [because it's] size and position information from a user is not part of a digital data stream that may be supplied or sent to a computing system such as a personal computer." (Anticipation and Obviousness R&R at 76 (quoting '493 Patent col.5, ll. 46-48); R&R at 137-38.) The Special Master also seems to narrow his definition of "content" to data sent from a server to a client over an electronic data network. (R&R at 137 (stating "the foregoing demonstrates that the patentees have used the term 'content' to broadly connote most if not all data sent from the server to the client").) However, the Special Master's focus on an electronic data network as a source of content directly contradicts statements in the specifications of the '493, '563, and '882 Patents, which provide that "content" can be "received via an electronic data network, from a local hard disk, etc." '493 col. 8, ll. 57-59; '563 Patent col. 8, ll. 30-32; '882 Patent col. 8, ll. 57-59.

The use of the phrase "received via an electronic data network, from a local hard disk, etc." is critical because it demonstrates that the patentees did not intend to limit the sources from which "content" could be received by the network client described by the patents in suit. First, the patents in suit clearly state that "content" can be received from "a local hard drive." If "content" originates from a local hard drive, it is already on the host client/computer and need not have been transferred over an electronic data network. Rather, the "content" could have arrived on the local hard drive: (1) as a result of data entry; (2) after being transferred from a CD ROM or other data storage device; or (3) as a result of certain data processing functions performed on the local hard drive. 10 The foregoing list is in no way exhaustive and could include numerous other entries. In short, "content" found on a local hard disk, as used in the context of the patents in suit, need not be transferred over an electronic data network, such as the Internet. In addition, the word "etc." indicates that: (1) the patentees did not list every source from which "content" can be received and (2) it is possible for "content" to be "supplied" by a user action such as dragging a window object across its content manifestation environment or even resizing it. 11 As the Court has just shown, explicitly listing every source from which "content" can be received would likely be an exercise in futility. As such, the Court finds that the Special Master incorrectly limited the scope of "content" by indicating that it must be sent over an electronic data network and that it cannot be supplied by a user.

--- Footnotes ---

10 An example of this data processing could be when calculations are performed, which produce a great deal of coordinates and data points as output. These coordinates and data points could then be displayed on screen as a graph or chart.

11 Dragging a window object across its content manifestation environment would produce a string of coordinates, indicating its new position. The coordinates would change for every new location of the window object. Accordingly, dragging a window object can produce a stream of "content" in the form of multiple position coordinate values. For example, a window object can initially be positioned at a value of 100 on the "X" or horizontal axis and 100 on the "Y" or vertical axis. If the new X and Y coordinates were 50 and 50, the act of dragging a window object across a screen would produce coordinate position values from 100 down to 50 for both the X and Y axes.

In addition, when a user resizes a window object, its size information changes. For example, if a window object has size values of: (1) length = 10 and (2) width = 10, these values would be altered every time a user adjusted the size of a window object. However, a user will not likely be able to instantly shrink the size from values of (1) length = 10 and (2) width = 10, to values of (1) length = 5 and (2) width = 5. Rather the data values will likely change incrementally from 10 to 5.

--- End Footnotes ---

According to the Special Master, "the patents-in-suit indicate that size and position information provided by a user, e.g., through minimizing and resizing, is not 'content'. . . . [because] size and position information from a user is not part of a digital data stream that may be supplied or sent to a computing system such as a personal computer." (Anticipation and Obviousness R&R at 75-76 (citing '493 Patent col.5, ll. 46-48) (emphasis in original); R&R at 137-38.) The Court sees no reason to find that the position and size information attributed to a particular window object is no longer "content" once it is altered by a user. (Contra Anticipation and Obviousness R&R at 76 (stating that "... [S]ize and position information from a
5. CA's Arguments and Proposed Construction

The Court agrees, almost entirely, with CA's objections to the Special Master's construction of the term "content," but will not go so far as to stray from the patentees' lexicography. CA is correct in asserting that "content:" (1) can include any form of digital data stream and (2) can be sent from any source. (CA's Claim Construction Objections at 9-10.) However, adding the phrase "regardless of the source of that data" is unnecessary since it is already subsumed within the glossary definition of "any form of digital data stream that may be supplied or sent to a computing system such as a personal computer." E.g., '493 Patent col. 5, ll. 46-48.

6. Simple's Arguments

Simple's assertion that "content" should be defined differently when it is capitalized is inconsistent with the '493, '563, and '882 Patents. To wit, the capitalized term "Content" is only used four times in the '493 Patent. One instance is the glossary entry for "Content" and another instance is the glossary definition of "Content Manifestation Environment." The other two instances are as the first word of a sentence. However the un-capitalized term "content" is used hundreds of times throughout the '493 Patent. This pattern of usage is also consistent with the '563 and '882 Patents. Were the Court to apply Simple's reasoning, the only time "content" would have the meaning assigned to it would be the entry in the patent glossary which defines it. In other instances, one of ordinary skill in the art would be left to guess whether "content" had its ordinary meaning or the special definition ascribed to it in the patent specification.

In support of their assertion that the term "content" should be treated differently when it is capitalized, Simple cites Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998), for the proposition that "[w]ithout an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning." (Simple's Claim Construction Objections at 5.) However, this reliance is misplaced because Renishaw expressly provides that "where there are several common meanings for a claim term, an inventor's claim terms take on their ordinary meaning." 158 F.3d at 1250. Indeed as Simple has acknowledged, Renishaw also states that a patentee's own lexicography should govern when she has defined a term "with reasonable clarity, deliberateness, and precision." (Simple's Claim Construction Objections at 5 (citing Renishaw, 158 F.3d at 1249)); see also Phillips, 415 F.3d at 1316; Durel Corp. v. Osram Sylvania Inc., 256 F.3d 1298, 1303-04 (Fed. Cir. 2001); Sinorgchem, 511 F.3d at 1136-39; Abraxis Bioscience, Inc. v. Mayne Pharma Inc., 467 F.3d 1370, 1376 (Fed. Cir. 2006); PC Connector Solutions LLC v. SmartDisk Corp., 406 F.3d 1359, 1363 (Fed. Cir. 2005). In this instance, the patentees have clearly defined their terms in a glossary. As such, the Court must look to this definition when faced with the "several common meanings" which can be attributed to "content."

D. The Court's Ruling on the Term "content"

CA's objection to the Special Master's construction of "content" is granted in part while Simple's objection is denied. The Court defines "content" exactly as the glossaries of the '493, '563, and '882 Patents do, to wit, "any form of digital data stream that may be supplied or sent to a computing system such as a personal computer." E.g., '493 Patent col.5, ll.46-48.

6. "Content instructions": Plaintiff has proposed the construction "Instructions to select data required by an application program from the electronic form of a document." Joint Claims Chart, Dkt. # 134-2, p. 11. Plaintiff cites as intrinsic evidence a section of specification titled "Summary of the Invention." Placed in context, the cited portion reads,

The invention provides an application program interface which inputs a diversity of hard copy documents using an automated digitizing unit and which stores information from the hard copy documents in a memory as stored document
information. Portions of the stored document information are selected in accordance with content instructions which define portions of the stored document information required by a particular application unit. Selected stored document information is then formatted into the transmission format used by the particular application program based on transmission format instructions. The transmission formatted selected stored document information is then transmitted to the particular application program. The hard copy documents may contain textual information or image information or both.

'697 Patent, col. 2, lines 48-62. The bolded section is the language cited by plaintiff.

The Court finds that the language of the specification cited by plaintiff contains sufficient definition of the term. That is, content instructions are "instructions which define portions of the stored document information required by a particular application unit."

D. "Content of Information"

This term appears in all claims of the '511, '382, and '392 patents, as well as claims 11-26 of the '617 patent and claims 19-23 of the '694 patent. In each claim where the term "content of information" appears, the term is used in the context of obtaining information about the data structure of a data source by "automatically accessing content of information stored" in the data source. See, e.g., '511 patent, claim 1 (emphasis added).

Timeline's proposed construction of "content of information" is "information in a data source such as data values, information about structure or other information." ProClarity's proposed construction is "value and type of data."

Timeline argues that ProClarity's proposed construction is too narrow because it limits "content of information" to two specific categories of data (data value and data type), and would not include information about data structure. Timeline maintains that "because every claim in which the phrase 'content of information' appears in the patents requires that information about data structure be obtained by accessing the 'content of information stored in [first] data source,' 'content of information' must include 'information about data structure.'" Pl.'s Opening Brief at 7. Timeline points to language in the '694 patent specification which states that "a procedure is first done in which all or a majority of the data and structure in the data source is accessed and saved to the new databases."'694 patent, Col. 13:67 -- 14:3 (emphasis added); see also '511 patent, Col. 11:63-66 (same). Timeline also observes that the specification describes a procedure in which "general information is loaded" and where "general information includes information about the structure of the data in the data source." '694 patent, Col. 16:27-39; see also '511 patent, Col. 13:46-58 (same).

Ex. A to Pl.'s Opening Brief at 4.

In response, ProClarity correctly observes that Judge Coughenour's ruling is not binding on this court. However, Judge Coughenour's construction may be regarded as instructive and is not inconsistent with the proposed construction offered by
ProClarity also contends that the prosecution history contradicts Timeline's proposed construction. ProClarity argues that the term "content of information stored in said [first] data source" was added to distinguish the '511 patent from a piece of prior art, which the parties refer to as the "Lu" patent. Timeline acknowledges that this term was added to overcome Lu. During the prosecution of the '511 patent, Timeline argued that Lu obtained information about data structure by using information about a data source's "format," rather than its content. Therefore, Timeline maintains that it added the term "content of information" to clarify that the invention did not solely access information about a data source's "format" to obtain information about a data source's structure. See, e.g., Dkt. No. 73, '511 patent history at 91 ("obtaining information about data structure involves obtaining information about the content of the database, not just its format.") (emphasis in original).

As noted earlier, prosecution history is generally less useful for claim construction purposes than the claims and specification. A court should limit claims based on prosecution history only if the "alleged disavowing actions or statements made during prosecution [are] both clear and unmistakable." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1326 (Fed. Cir. 2003). Here, the prosecution history does not clearly and unmistakably show that Timeline limited the term "content of information" to simply mean "value and type of data."

The court also agrees with Timeline's position that the term "content of information" should be construed to include information such as data values and information about structure. Both sides agree that the term encompasses data values. In addition, Timeline's argument that the term includes information about structure finds support in the intrinsic evidence. As discussed above, the specifications indicate that "[a] procedure is first done in which all or a majority of the data and structure in the data source is accessed and saved to the new databases." '694 patent, Col. 13:67-14:3 (emphasis added); see also '511 patent, Col. 11:63-66 (same). This suggests that "content of information" includes both data and information about structure.

Therefore, the Court construes the term "content of information" to mean "information in a data source such as data values and information about structure." Although Timeline seeks to include the words "and other information" at the end of this phrase, the court omits those words because they add nothing of substance.

Step 2

The parties' dispute over construction of Step 2 mirrors their dispute over construction of Step 1. Step 2 provides for "creating content profiles for each data source of said data, said content profiles indicating the degree of content of said predetermined characteristics in data from each data source." Amazon's proposed construction of "content profiles indicating the degree of content of said predetermined characteristics in data from each data source" parallels its "customer profile" construction rejected by the court. Amazon construes this phrase to mean "a list of mathematical values indicating the degree to which predetermined characteristics that describe the contents of data are contained in the data provided by each data source."

Amazon relies on two general dictionaries, its expert witness, and the specification. As above, "profile" is defined as "a formal summary or analysis of data, often in the form of a graph or table, representing distinctive features or characteristics." Def. Mem. at 18 (quoting The American Heritage Dictionary of the English Language (4th ed. 2000)). "Content" means "the topics, ideas, facts, or statements in a book, document or letter" and "the amount of specified material contained, present or yielded." Id. (quoting Webster's Third New International Dictionary of the English Language Unabridged (Philip Babcock Gove et al. eds, 1993)). Amazon modifies these general definitions with reference to its expert witness' declaration: "in content-based filtering, . . . a content profile of an item is a set of mathematical values representing the degree to which the item contains particular characteristics." Id. (citing Resnick Decl. at P 58). Amazon also contends the patent specification lends support by describing "content profiles" as "a collection of mathematical values representing the weighted significance of several predetermined characteristics." Def. Mem. at 19, Ex. 1, Col. 10.

Amazon's construction is not limited to the phrase "content profile." Amazon also interprets the phrase "degree of content." According to Amazon, "degree" means "a grade or point marking the attainment or existence of more or less of a quality,
acquiescence or aspect: [its] relative intensity." Def. Mem. at 20 (quoting Webster's Third New International Dictionary of the English Language Unabridged (Philip Babcock Gove et al. eds., 1993)). Amazon contends that "degree" cannot mean "presence," but instead signifies measurement of a certain characteristic, such as violence, on a range of 0-10. Amazon relies on the claims of the '722 patent in which presence is purportedly distinguished from degree: "said content profile indicating at least one of the presence and the degree of content of said predetermined characteristics in data of each of said data object[,]" Def. Mem. at Ex. 2, Col. 53-43, Claim 1 (emphasis added). Amazon's construction also relies on the foreign prosecution history of the '722 patent counterpart.

Pinpoint's proposed construction of "content profile" also parallels its proposed construction of "customer profile." Pinpoint construes "content profiles for each data source of said data, said content profiles indicating the degree of content of predetermined characteristics in data from each data source" as "data that describes the significant characteristics of a data source, indicating the degree to which predetermined characteristics are contained in the data from the data source." Pl. Opp. Mem. at 15. Specifically, Pinpoint contends a "content profile" is a "profile of the data source of said data" and contains "information that describes the significant characteristics of the item of interest." Id. Pinpoint uses the patent specification to support this proposed construction. Pinpoint emphasizes that the specification does not restrict "content profiles" to mathematical values or constructs, but rather includes other non-mathematical values not indicative of a range, such as "the director of a program, . . . the rating given to a movie by a third -party, such as the MPAA . . . [or] whether a stock is owned by a customer." Id. at 15-16 (citing Def. Mem. Ex. 1, Cols. 11, 51).

Pinpoint disputes Amazon's construction of "degree of content," contending that "presence is . . . a special case of degree." Pl. Opp. Mem. at 17. Pinpoint refers to the patent specification in support of this construction. Id. at 16, citing Def. Mem. Ex. 1, Col. 11 ("Of course, as in the Strubbe system, the values could simply be '0' or '1' to indicate the presence or absence of a characteristic"). Pinpoint refutes Amazon's claim that the '722 patent distinguishes presence from degree with reference to the prosecution history. According to Pinpoint, the inventors merely sought to clarify the claim language: "Claims 1 and 11 [of the '722 patent] have been amended to recite that the content profiles indicate either the 'degree of content' or the 'presence' of predetermined characteristics in the data." Id. at 17, App. 8 (AMZN 002689-90). Pinpoint argues that the foreign prosecution history actually supports its proposed claim construction of "degree of content." Specifically, the foreign examiner noted "the claim is silent as to how this 'degree' of measure is obtained. A simple on/off measure (e.g., binary flag representing presence or absence) is also included within the scope of these extremely broad terms." Id. at 18, App. 9 (AMZN 030073) (emphasis added).

Amazon's proposed construction of "content profiles" fails on the same grounds as its construction of "customer profiles." Simply put, neither the claim language nor the patent specification supports Amazon's contention that a "content profile" is always a "mathematical construct." A comparison of the claim language of the asserted claims to the claim language of non-asserted claims is instructive. Compare Def. Mem. at Ex. 1, Col. 52, Claim 1 ("relating said selected customer profile with the content profiles for the data available from each data source to the customer at a particular time by determining the distance between a customer profile and a content profile in a characteristic space by calculating an agreement scalar for common characteristics, ac, between said selected customer profile, cv, and said content profiles, cp, in accordance with the relationship: . . . ") with Claim 43 ("relating said at least one customer profile with the content profiles for the data available from each data source to the customer"). See Vitrinos, 90 F.3d at 1582 ("first, we look to the words of the claims themselves, both asserted and nonasserted, to define the scope"). The patent specification also supports a construction broader than "a list of mathematical values;" neither a program director nor stock ownership is a mathematical value.

Amazon's proposed construction of "degree of content" is flawed. Contrary to Amazon's assertion, the patent specification supports a broader reading of "degree." As Pinpoint argues, the specification contemplates content profiles containing information describing the range of a particular characteristic, like violence of a particular program between 0-10, as well as information describing the presence or absence of a particular characteristic. Def. Mem. Ex. 1, Col. 13 ("Of course, other simpler techniques such as one which simply determines the presence or absence of particular characteristics may be used within the scope of the invention"). Pinpoint's construction of "degree" as including "presence" is bolstered by the specification; Amazon's unsupported construction must therefore fail. Vitrinos, 90 F.3d at 1582 (specification "is usually dispositive; it is the single best guide to the meaning of a disputed term"). Indeed, the specification buttresses Pinpoint's contention that adding the term "presence" to the '722 patent claims was merely for clarification purposes. Moreover, the foreign patent prosecution history actually lends itself to Pinpoint's construction. Accordingly, the court construes "creating content profiles for each data source of said data, said content profiles indicating the degree of content of said predetermined characteristics in data from each data source" as "data that describes the significant characteristics of a data source, indicating the degree to which predetermined characteristics are contained in the data from the data source."
source, indicating the degree to which predetermined characteristics are contained in the data from the data source.

A. Context

<table>
<thead>
<tr>
<th>Leader's Construction</th>
<th>Facebook's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>A collection of interrelated webs</td>
</tr>
</tbody>
</table>

The term "context" appears in Claims 1-8, 23-26, 29, and 31-34. Leader contends that the meaning of the term "context" can be understood by reference to the intrinsic evidence. (D.I. 179, at 6-7.) Specifically, Leader contends that the terms "context" and "environment" are used interchangeably throughout the specification. (Id.) Facebook responds that "context" and "environment" are not used interchangeably in the specification, and further, that the doctrine of claim differentiation dictates that these two terms must have different meanings. (D.I. 191, at 13-14.) Facebook contends that the specification actually supports its proposed construction, and makes clear that "contexts" are used to organize the interrelated webs that sit beneath them. (Id. at 13.)

In the Court's view, Leader's proposed construction has stronger support in the specification. In describing Figure 9, the specification states, "[u]nder the context level 904 is the web level 906 that associates one or more of the webs with one or more of the contexts of the context level 904." '761 patent col. 12:10-20. Facebook argues this supports defining "context" to mean "a collection of interrelated webs."

While the specification clearly dictates that the one or more of the contexts of the context level associates with one or more of the webs of the web level, it is not clear that the associated webs must be "interrelated," or that there must be a "collection" of webs. In contrast, Leader's proposed construction of "context" is supported by this language in the specification:

'[W]hen a user logs-in to the system 100, user data 102 is generated and associated with at least the user and the login process. The user automatically enters into a user workspace or a first context 104 (also denoted CONTEXT.sub.1) or environment. This environment can be a default user workspace, or a workspace environment predesignated by the user or an administrator after login, for example.

'761 patent, col. 6:26-333. Facebook focuses on the word "or" to contend that the three terms are not used as synonyms, but rather, as different constructs. Facebook's position is untenable, however, when this portion of the specification is read as a whole.

Turning to Facebook's claim differentiation argument, the doctrine of claim differentiation is "based on 'the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scopes.'" Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1369 (Fed. Cir. 2007) (citing Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999)). The Federal Circuit has observed that two considerations generally govern the doctrine of claim differentiation when applied to two independent claims: "(1) claim differentiation takes on relevance in the context of a claim construction that would render additional, or different, language in another independent claim superfluous; and (2) claim differentiation 'can not broaden claims beyond their correct scope.'" Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1381 (Fed. Cir. 2006)(citing Fantasy Sports Props. v. Sportsline.com, 287 F.3d 1108, 1115-15 (Fed. Cir. 2002)).

In relevant part, Claim 1 of the '761 patent claims:

1. A computer-implemented network-based system that facilitates management of data, comprising:

   a computer-implemented context component of the network-based systems for capturing context information . . . created by user interaction of a user in a first context of the network-based system, the context component dynamically storing the context information in metadata associated with the user-defined data . . .; and
a computer-implemented tracking component . . . for tracking a change of the user from the first context to a second context of the network-based system . . . wherein the user accesses the data from the second context.

'761 patent, col. 20:63-321:21 (emphasis added). In relevant part, Claim 9 of the '761 patent claims:

9. A computer-implemented method of managing data, comprising computer-executable acts of:

creating data within a user environment of a web-based computing platform via user interaction with the user environment by a user using an application . . .;

dynamically associating metadata with the data, . . ., the metadata includes information related to the user, the data, the application, and the user environment;

tracking movement of the user from the user environment of the web-based computing platform to a second user environment of the web-based computing platform; and

dynamically updating the stored metadata with an association of the data, the application, and the second user environment, wherein the user employs at least one of the application and the data from the second environment.

'761 patent, col. 21:38-58 (emphasis added).

Facebook contends that, under the doctrine of claim differentiation, the use of different terms in these Claims indicates that the terms "context" and "environment" should have different meanings. (D.I. 191, at 14.) Leader responds that Claim 9 refers to "user environment," not simply "environment." (D.I. 196, at 7.) Further, Leader notes that dependent Claim 4 requires that "context information" includes "user environment." '761 patent, col. 21:22-24. According to Leader, because Claim 1 is necessarily broader than Claim 4, "context" (i.e., "environment") is broader than, and not identical to, "user environment." (D.I. 196, at 7.)

The Court is not persuaded that Leader's proposed construction runs afoul of the doctrine of claim differentiation. First, if every reference to "context" in Claim 1 is replaced with "environment," the scope of Claim 1 does not appear to be broadened. Second, if every reference to "context" in Claim 1 is replaced with "environment," Claims 1 and 9 do not appear to be totally identical in scope. As noted by Leader, Claim 9 specifically references "user environment" rather than merely "environment," and dependent Claim 4 dictates that "context" information (or "environment" information, if Leader's proposed construction is adopted) includes a relationship between the user and user environment. Third, even if independent Claims 1 and 9 were made to have similar scopes as a result of construing "context" to mean "environment," case law suggests that the doctrine of claim differentiation does not necessarily prevent two independent claims which use different terminology from having similar scopes. See Hormone Research Found., Inc. v. Genentech, Inc., 904 F.2d 1558, 1567 n.15 (Fed. Cir. 1990)(noting that, although the doctrine of claim differentiation is well-established, it "cannot overshadow the express and contrary intentions of the patent draftsman. It is not unusual that separate claims may define the invention using different terminology, especially where (as here) independent claims are involved.") Finally, claim differentiation is "not a hard and fast rule and will be overcome by a contrary construction dictated by the written description of prosecution history." Seachange Int'l, Inc. v. C-COR, Inc., 413 F.3d 1361, 1369 (Fed. Cir. 2005). For the reasons set forth above, the Court concludes that construing "context" to mean "environment" is dictated by the specification, and thus, the specification should prevail over claim differentiation principles. Accordingly, the Court concludes that "context" means "environment.

908

Context

Claims 1, 2, 3, 4, 15, 16, 18, 19, 20, 21, 24, 27, 28, 30, 31, 32, and 40 contain the term "context." Though this term was originally disputed, during the hearing both sides agreed that the definition of the term is "information already existing within the system that becomes relevant upon the occurrence of an event." This definition is in conformity with the claim language, specification, and prosecution history and is adopted accordingly.
21. Context free

The next term in dispute is "context free." This term appears in claims 11, 13, and 32 of the '755 patent and in claim 33 of the '945 patent. Claim 11 of the '755 patent is illustrative and recites "a plurality of individual context free processor elements (PEs)." The plaintiff defines a "context free processor element" to mean that "the processor element does not retain execution state information from execution of prior instructions and that execution state information is directly accessible by other processor elements." Intel and ADI argue that context free means "containing no execution state information from the execution of previous instructions."

In the original specification, the patentees included the following language:

The term "context free" means that the processor elements contain no state information, e.g., condition codes, registers, program status words, flags, etc.

The corrected specifications omit this language. Intel and ADI contend that the court should nevertheless use this definition of "context free" in the construction of claim 11.

The court disagrees. The applicable portion of the specification attached to the issued patent does not include the language relied upon by the defendants. During prosecution, the patentees described the "context free" concept of the invention and stated:

The present invention further executes the basic blocks containing the added intelligence on a system using a plurality of identical processor elements each of which is incapable of retaining execution state information from prior operations. Hence, all processor elements are context free and this feature is not found in any of the above references . . . .

(Petition to Make Special, attached to Defendants' Responsive Brief, Exh. W, p. 22).

The court accordingly defines "context free processor element" as "a processor element that retains no execution state information from prior operations."

(1) contiguous

The crux of the dispute over the construction of this term is whether "immediately" is warranted as a limitation. N-Data argues that the inclusion of "immediately" improperly limits the term and finds no support in either the claims or specification. Dell argues that, without the limitation, there would be no distinguishing characteristics between "contiguous" and "noncontiguous." Both N-Data and Dell point to Figure 11 of the '261 patent for support; indeed, the interpretation of what the patentee intended Figure 11 to represent provides the ultimate enlightenment as to the meaning of the present term.

The court agrees with Dell. As discussed in the claims construction hearing, it is the court's opinion that N-Data's proposed definition does not distinguish between "contiguous" data 458 and "non-contiguous" data 456. The '261 patent states as follows:

Referring to Table I, and FIG. 11, after the output of the first 4 bits of Ethernet data 452, there will be a wait of 0.2441 sec (during which, isochronous data 454 will be output). This pattern will be repeated six times 456, after which, there will be a transmission of five nibbles of Ethernet data contiguously 458. Thereafter, there will be another wait of 0.2441 sec 460 and so forth. '261 Patent, col. 7, ll. 54-61.
As the previous passage suggests, there is a distinction between contiguous and noncontiguous data transfer, a distinction not captured in N-Data's proposed construction. Under N-Data's construction, e.g., the data transferred on 450 would be contiguous with the data that is transferred at the first part of 458, something obviously not intended by the specification.

As such, the court defines "contiguous" as "immediately preceding or following in time and sequence."

3. continually detecting the instantaneous flow rate

This phrase is found in Claims 3 and 24 of the '802 Patent and Claims 9, 44, and 53 of the '193 Patent.

Phrase: continually detecting the instantaneous flow rate

Construction: Without interruption, creating a signal corresponding to the flow rate at a particular point of time.

Reasoning: At its core, there is little dispute between the parties as to the meaning of this phrase. Both parties agree that the computer circuitry detects the instantaneous flow rate by creating a signal corresponding to the instantaneous flow rate. The real dispute between the parties is over the meaning of "flow rate", which we have already construed above.

16. The next element of Claim 3 is: "said lattice being continuous and uninterrupted." An example of a "continuous and uninterrupted" lattice is shown in Figures 3 and 4 of the specification, where the semiconductor material in the space between the hexagonal base regions forms the continuous and uninterrupted three-dimensional lattice. "Continuous and uninterrupted" means that it is possible to travel from any point to any other point within the claimed lattice (the semiconductor material between the bases of the first conductivity type) while staying within the lattice.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 The language "continuous and uninterrupted" was added to the claims during the first reexamination of the '725 patent in response to the examiner's argument that the Yoshida et al. reference otherwise included a lattice. The examiner viewed Yoshida et al. as an array of square base regions, but with each corner of each square base overlapping (i.e., merged at) the corner of each adjacent "square" base. (Reexam. Control No. 90/002/478, Order Granting Request for Reexam., pp. 4-5; Reexam Interview Summary Form dated 9/11/92.) Because what the examiner viewed as square base regions overlapped one another, in reality there was only one base region and the space not occupied by the overlapping square bases consisted of separate regions isolated from one another by the overlapping square bases. (Reexam. Interview Summary Form dated 9/11/92.) Thus, in Yoshida et al. as viewed by the examiner, the space not occupied by the overlapping square base regions was not continuous and uninterrupted. Yoshida et al is comparable to a checkerboard, where the regions of the first and second semiconductor type were laid out like the red and black squares (except that the "black squares" representing the base were slightly oversized so that they overlapped each other at the corners). It was impossible to move from one "red square" of this checkerboard to another "red square" at the first surface without traveling through a "black square."

10 The phrase "continuous and uninterrupted" has the same meaning in Claim 10 of the '767 patent; and the above construction is equally applicable to that phrase in Claim 8 of the '725 patent and Claim 11 of the '767 patent, but with the substitution of the phrase "surface of said common conduction region" for the word "lattice."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
Continuous source of illumination

The phrase "continuous source of illumination" appears in the '823 and '302 patents. Gekko's proposed construction is "illumination with an uninterrupted source of current." Gekko contends that for illumination to be continuous, the source of current must be uninterrupted. Gekko offers no intrinsic evidence to support its construction; it only offers its expert's assertion that "[Gekko's definition] is consistent with the specification of the '823 and '310 patent specification."

An expert's conclusory allegations are entirely unhelpful to the Court. Phillips, 415 F.3d at 1317. Because neither Gekko nor its expert offers any supporting evidence to show how its construction is consistent with the specifications, the assertion is conclusory and unhelpful.

Gekko's proposed construction would render the '823 patent's Claim 1 incompatible with dependent Claim 2. Although Claim 2 is not asserted, it is helpful in construing this phrase. See Phillips, 415 F.3d at 1314 (usage of a term in one claim can often illuminate the meaning of the same term in other claims). Claim 2 is dependant upon Claim 1, which requires the light elements' illumination level to be controlled using pulse width modulation ("PWM"). '823 patent, Col. 31:2-17. Neither party disputes that PWM involves interrupting the power current. Claim 2 requires the light elements to provide a "continuous source of illumination." Id. at Col. 31:18-20. Applying Gekko's construction of "uninterrupted current" would render Claim 1 incompatible with Claim 2.

Gekko's construction focuses on the power source for the illumination, but the intrinsic evidence does not support this view. The proper focus is the visible effect not the power source. The specification discusses controlling visible effects, such as "strobing," "dimming," "pulsation," and "pattern generation." See id. at Cols. 19:7-52; 20:36-38. In one embodiment, the specification teaches "the lighting assembly 4600 can provide continuous light or, if applicable, various lighting effects." Id. at Col. 22:40-44. The positioning of continuous light as an alternative to "various lighting effects" further supports that the specification focuses on the effect as perceived by the eye and not on the power source.

The specification does not prescribe a special meaning for "continuous source of illumination." As Gekko stated in its moving papers, one skilled in the art of photography lighting would readily understand this phrase. Also, a lay juror would have no problem understanding what "continuous source of illumination" means. Therefore, the Court does not construe this term.

5. The term "CONTINUOUSLY" (claim 1) means that the tonal frequency changes constantly as the quantity being measured changes.
10. The network client according to claim 6, wherein said content includes at least one address of a network content source that is configured to download information to said data processing system via said electronic data network, said information to be dynamically and continuously manifested within said at least one corresponding window object within said content manifestation environment.

'563 Patent Cl. 10. In short, the Special Master's recommended construction of the phrase "continuously manifested" is at issue.

A. The Special Master's Recommended Construction

The Special Master recommended that "said information to be dynamically and continuously manifested within said * * * window object" be interpreted to mean "that the display of information or content changes over time and . . . [that] information is displayed without interruption within 'said * * * window object' while the 'content display section' of the 'window object' is visible." (R&R at 143 (emphasis added).) The Special Master interpreted the relevant intrinsic evidence to mean that information is to be "manifested" within the content display sections found in window objects. (Id. at 142.) The Special Master then used a common dictionary definition of "manifest" as being "readily perceived by the senses and especially by the sight." (Id. at 143 n.58. (using an Internet based dictionary to define the term "manifest").) Although the dictionary used by the Special Master did not explicitly limit manifestation to visual perception, the Special Master chose to do so. (Id. at 143.)

'Manifest,' of course, simply means 'readily perceived by the senses and especially by the sight,' and in the context of the claim, the information is to be displayed, i.e., visually manifested to the user. For the information to be displayed, the 'content display section' must be visible to the user. To meet that particular limitation of the claim, therefore, (1) the 'content display section' of the 'window object' must be visible, and (2) the information must be displayed therein. Put another way, the information is to be manifested within the window object while the content display section is visible.

(Id. (footnotes omitted.) Based on this analysis, the Special Master required that information in a content display section be "visible to the user" in order for it to be manifested. (Id. at 142-43.) Having summarized the Special Master's recommended construction of "continuously manifested," the Court will summarize the parties' corresponding objections and counter arguments.

B. Simple's Objection and CA's Counter Argument

Simple asserts that the Special Master "improperly limits the 'continuously manifested' requirement on a durational basis to the period while the content display section is visible without any explicit support in the intrinsic record." (Simple's Claim Construction Objections at 15.) Simple goes on to argue that the proper definition of "continuously manifested" should be "displayed without interruption." (Id. at 16.) Conversely, CA argues that the Special Master's recommended construction is supported by (1) the plain meaning of the terms at issue and (2) the specifications of the patents in suit. (CA's Resp. to Simple's Objections to Claim Construction R&R (Dkt. No. 583) ("CA's Claim Construction Response"), at 16-17.) Having summarized the parties arguments, the Court will put forth its own analysis.

C. Analysis

The Court's analysis of the phrase "continuously manifested" will entail the following steps: (1) constructing the term based upon a review of the claim language and the specifications of the patents in suit; (2) addressing the deficiencies in the Special Master's interpretation of the phrase; and (3) addressing the arguments raised by the parties. The Court will focus its analysis on whether the Special Master correctly emphasized the visual aspect of content manifestation. Indeed, this issue lies at the heart of resolving Simple's objection.

1. The Intrinsic Evidence Before the Court Indicates That Manifestation Should Not Be Limited to a User's Visual Perception

A step-by-step analysis of claim 5 of the '493 Patent indicates the following process: (1) a user on a client side network client receives content from a remote server system over the Internet; (2) this content includes the address of a network content source; (3) the network client accesses said address and downloads information; and finally (4) said information or a
portion thereof is continuously manifested within a window object. None of the relevant claim language makes any mention of whether or not information must be seen to be manifested. Accordingly, the Court must turn to the specifications of the patents in suit to determine whether or not information or content must be seen to be manifested.

The manifestation of information should not be confined to visual perception since: (1) user actions may lead to the manifestation of sound; (2) the parties do not dispute that window objects can manifest sound (see R&R at 115 (citation omitted)); and (3) window objects are equipped to manifest content which may extend beyond what can be shown at one specific moment. The specifications of the '493, '563, and '882 Patents state that the "manifestation of content is a broader concept than simple screen display." E.g., '493 Patent col. 9, ll. 22-30. For example, a window object may display a hyperlink within its content display section, "to invite a user click to cause sound to be manifested." Id. Since neither party disputes this finding, it also follows that a window object can deliver sound as content. See id. Additionally, the specifications of the '493, '563, and '882 Patents all describe window objects equipped with a scrolling functionality that allows for the manifestation of content which may extend beyond the visible portion of a content display area. E.g., '563 Patent col. 8, ll. 55-61 (specifically mentioning the use of "OCX files and systems to derive a customized WWW browser...[capable of supporting] an 'overflow:auto' CSS (cascading style sheet) property which applies to facilitate scroll bars, . . . to allow management of content that extends beyond a bottom edge of a visible area of a selected module"). In short, the specifications of the '493, '563, and '882 Patents clearly indicate that manifestation is more than what is seen.

2. "[C]ontinuously manifested" Defined

The Court interprets the phrase "continuously manifested" to mean: delivered without interruption. Accordingly, the phrase "said information to be dynamically and continuously manifested within said * * * window object" will be interpreted to mean that the display of information or content changes over time and that information is delivered without interruption within "said * * * window object." This construction is based on the fact that content need not be seen to be manifested. The patents in suit indicate that content is "any form of digital data." See '493 Patent col. 5, ll. 46-48; '563 Patent col. 5, ll. 32-34; '882 Patent col. 5, ll. 49-51. To assume that: (1) content cannot include audio as well as visual media and (2) that content must be seen to be delivered, would contradict the term's clearly established glossary definition as well as the scrolling functionality taught by the patents in suit. Accordingly, the concept of content delivery as opposed to a mere visual representation is more appropriate in the context of the '493, '563, and '882 Patents.

D. The Court's Ruling on the Term "continuously manifested"

Simple's objection is granted in part because the Special Master's construction seems to limit content manifestation to visual perception. The Special Master's application of the dictionary definition of "manifest" is countered by the patent specifications, which should be given greater weight in claim construction. Phillips, 415 F.3d at 1316, 1318. Nonetheless, instead of adopting Simple's proposed construction, the Court will use the term "delivered" because the specifications of the '493, '563, and '882 Patents indicate that the manifestation of content is more than what appears on screen. Indeed, content delivery better comports with this conception of manifestation than the visual emphasis placed on the term by the Special Master or the term "display," as suggested by Simple.

916

Claim Element 1c

coupled for continuously providing

The parties disagree on the meaning of "coupled for continuously providing."

Dell proposed: "providing multiple times daily."

Lucent proposed: "inputting at all times."

The court construes "coupled for continuously providing" as follows:
"continuously connected such that the first user can update the web site as new information becomes available."

The parties disagree on the meaning of "continuously updating." Dell proposed: "maintaining current by multiple daily updates." Lucent proposed: "bringing up to date at all times."

The court construes "continuously updating" as follows:

"bringing up to date as new information becomes available."

Claims 7 and 8 refer to downloading or licensing under "control" of the respective components. NCI argues directly for the equation of the terms "control" and "coordinate," essentially contending that the terms have no functional difference within the context of the patent. Alternatively, NCI argues that "control" means "to direct, guide or manage the transfer or delivery of electronic data." Microsoft again argues for an interpretation that includes the exercise of a dominating influence in the download or licensing process.

The Court finds that the terms "coordinate" and "control" can not be equated. NCI used different language in different claims. The difference is presumed to be intentional, and therefore should be given effect. Yet the Court finds nothing in the claim language, patent specification or prosecution history that mandates such a narrow, limited definition as that proposed by Microsoft.

The Court therefore adopts NCI's alternative definition. To "control" means to direct, guide or manage the transfer or delivery of electronic data. This is an active term, not a passive one. This interpretation is consistent with the ordinary meaning of the claim language, the patent specification, and dictionary definitions submitted by NCI. Fisher Decl. Ex. M.

"Control," in plaintiff's view, is "the authority to guide or manage." "Possession" is "to have and to hold as property." Plaintiff maintains that these terms should be accorded these meanings wherever used, including when they are used in combination or separately.

Defendants, on the other hand, seek to have each of the following phrases construed as meaning the same thing: "controlling use and possession," "in control and possession," "in possession and control," "controlling," and "controlling use." These must each be construed, in defendants' view, to mean "in physical control and ownership." Therefore, there are two disputes here which are interwoven. The court must determine what the terms mean and whether they are being used interchangeably.
Initially, it must be noted that both Sightsound and CDnow offer definitions for each term. "Control" in defendants' view is "physical control" while "possession" is "ownership." These terms may be measured against Sightsound's proposed definitions, and then the question whether they are being used interchangeably in the patent may be addressed.

A useful starting point for construing these terms is Claim 1 of the ‘573 patent:

1. A method of transmitting a desired digital audio signal stored on a first memory of a first party to a second memory of a second party comprising the steps of:

   - transferring money electronically via a telecommunications lien [sic] to the first party at a location remote from the second memory and controlling use of the first memory from the second party financially distinct from the first party, said second party controlling use and in possession of the second memory;
   - connecting electronically via a telecommunications line in the first memory with the second memory such that the desired digital audio signal can pass therebetween;
   - transmitting the desired digital audio signal from the first memory with a transmitter in control and possession of the first party to a receiver having the second memory at a location determined by the second party, said receiver in possession and control of the second party; and
   - storing the digital audio signal in the second memory.

(Docket # 69, Tab J, Claim 1) (emphasis added).

The dictionary defines "control" as meaning "exercise authority or influence over: direct" (Docket # 69, Exhibit E, The 1995 Webster's II New College Dictionary). "Possess" is defined as "to hold as property or occupy in person; have as something that belongs to one; own" (Webster's New World Dictionary, Third College Edition, 1988). "Possession" is defined as "a possessing or being possessed, as by ownership or occupancy; hold" (Id.). That these dictionary definitions offer slight but important variations of the meaning for the term "possess," only comports, in the court's view, with the common understanding of this prosaic term. One can "possess" one's house as a renter, with a possessory interest assertable against the whole world except, under some circumstances, against the owner, who also enjoys a possessory interest. "Possession" thus does not mean "ownership"; it means "holding as property."

The dispute with respect to "control," however, is whether or not the patents require that physical control be exercised over a particular object, or if the authority to direct the use of the object is sufficient. A review of the claims in suit does not reveal any support for defendants' assertion that physical control over any particular object is required as opposed to the authority to direct the use of that object. Therefore, physical control is not a requirement where the term "control," or any derivation thereof, is used in the claims-in-suit. 12

12 Defendants also make the argument that referring to the "plain meaning" of the terms used would end in an absurd result (which, in any event, defendants profess would be acceptable to them). Specifically, defendants allude to the third paragraph of Claim 1 of the ‘573 patent, where the receiver "is in possession and control of the second party." A "plain reading" of this language, in defendants' view, would require the receiver to possess and control the second party, rather than the other way around (Docket # 65 at 21-22). The court disagrees. At most, defendants have pointed out the infelicitous placement of a verb. This does not, however, establish that the meaning of the terms in issue are ambiguous. Rather, a reader of normal skill in the art, and with a normal understanding of the English language, will not be confused by the claims which place (or misplace) the terms "possession" and "control." In fact, it does not take one skilled in any art, past a common understanding of English, to understand that "a transmitter in control and possession of the first party" means that the first party controls and possesses the transmitter.

The issue of the interchangeability of the terms is largely disposed of by recognition that the terms do have generally
accepted meanings which are distinct. Thus, in Claim 1 of '573 patent, the first party has "controlling use" of the first memory, while the terms possession and control are used together with respect to the first party vis-a-vis a transmitter, and the second party vis-a-vis both the second memory and a receiver. The claim clearly makes a distinction, with respect to possession, between the first party's memory and the first party's transmitter.

Indeed, being in control of a thing, however, is not the same as being in possession of that same thing. The language of the '573 patent does not indicate to the court, nor would it to one skilled in the art, that the party is "in physical control and ownership" when the party is merely "controlling use" of the first memory.

In the court's view, the fact that the terms control and possession have common meanings which are not identical, and that they are not used jointly in all of the relevant patent claims, is strong evidence that each term is intended to convey its own meaning. Also, the dispute is limited in this case to several instances where the first party is asserted to be either "controlling" or "controlling use" of the first memory.

13 Defendants also assert that the term "controlling" is used individually with respect to the second party controlling the second memory in Claim 3 of the '573 patent (Docket # 65, Appendix B at 3. However, that claim is a dependent claim, which includes the limitation from Claim 1 that "said second party controlling use and in possession of the second memory." (Emphasis supplied). Thus, Claim 3, by definition, includes the restriction that the second party controls the use and possesses the second memory. This is, therefore, a non-issue with respect to Claim 3 of the '573 patent.

In Claim 4 of the '734 patent, by contrast, the phrase "possession and control" is used only once, and that is in reference to the second party possessing and controlling the second memory (Docket # 66, Exhibit 2 at Claim 4, column 10, lines 3-5). Claim 11, by contrast, places the first memory "in possession and control of the first party," and the second memory "in possession and control of the second party." (Id., Column 10, lines 54-56).

Defendants point to the '734 patent specification where it is stated that "the receiver is in possession and control of the second party. The receiver is placed by the second party at a second party location determined by the second party." (Docket # 66, Exhibit 2, '734 Patent at 5:56-59). Defendants argue that this, too, evidences that control and possession are required when either term is used in a claim. However, defendants fail to note that this language is used in describing the preferred embodiment of the invention. Indeed, the first portion of the first sentence cited by defendants reads in relevant part "preferably having the second memory while the receiver is in possession and control of the second party," (Id., 5:54-55). Further, the cited portion of the specification is addressed to the second party and the second memory. As noted above, the only disputed used of "control" are with reference to the first party and the first memory. Thus, this is not persuasive evidence supporting defendants' argument.

Further, to the extent that any ambiguity might exist, resort to the prosecution history establishes that the examiner, a person skilled in the art, understood "control" to mean "authority to guide or manage." (Docket # 70, '573 File History, Tab 13 at 3). This was expressed in the course of explaining the term "control" in light of prior art, the Lightner patent. Likewise, the term "possession" was explained by the applicant in 1991, in the course of distinguishing the patent from the Hughes patent:

[The] Hughes' receiver, although located in the user's home is taught to be owned by the owner of the transmitter and is thus 'in possession' of the owner.

(Id., Tab 34 at 9). Thus, the prosecution history also informs the court that control and possession are separate terms, that possession has an element of holding as property attached to it, and that physical control is not necessary.

The court therefore agrees that the terms control and possession have the meanings of "authority to direct" and "holding as property," respectively. Further, the court finds that the terms are not used interchangeably in the claims in suit.
4. "control . . . information," "control data"

Having considered the parties' proposals, the Court disagrees with both proposals. Thus, the Court construes these terms as "data specifying a desired operation by a POL regulator." See '125 patent, col.6:44-55.

3. "Control apparatus" in claims 1 and 7

IMS contends that the district court erred when, based on the preambles of claims 1 and 7, it limited those claims to a "control system for machine tools rather than an entire machine tool apparatus." To the extent that the district court's claim interpretation precludes a finding of infringement by a machine tool apparatus that includes the claimed control-related limitations, we agree that the district court improperly limited the claims.

"[A] claim preamble has the import that the claim as a whole suggests for it." Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620, 34 U.S.P.Q.2D (BNA) 1816, 1820 (Fed. Cir. 1995). If the preamble adds no limitations to those in the body of the claim, the preamble is not itself a claim limitation and is irrelevant to proper construction of the claim. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 U.S.P.Q.2D (BNA) 1161, 1165-66 (Fed. Cir. 1999). That is the case here. The phrase "control apparatus" in the preamble merely gives a descriptive name to the set of limitations in the body of the claim that completely set forth the invention. Its use does not limit the claims, as Haas contends, to a control apparatus that is separate from the machine tool. The claim is infringed by any apparatus encompassing all of the limitations in the body of the claim. Such an infringing apparatus may be a machine tool apparatus that includes the claimed control features or a control apparatus that is separate from and communicates with a machine tool apparatus.

The prosecution history is consistent with this interpretation. In a restriction requirement, the PTO recognized that the claimed invention, a machine tool control, was part of a machine tool. In sum, the applicant's choice to elect claims directed to machine tool control rather than machine control structure does not limit the scope of the claims to a control apparatus that is separate from the machine tool itself.

1. "Control apparatus for displaying a computer-generated image" (claims 17, 21, 38, 41)

PolyVision's proposed construction
A controller for displaying a computer generated image.

Smart's proposed construction
Asserts that plain and ordinary meaning is: Hardware and/or software for displaying a computer-generated image.

PolyVision argues that this phrase requires construction because the term "control apparatus" is not defined anywhere in the specification, although it is clear that claim 1 is directed to the controller 3 referenced throughout the specification (for example in Fig. 1). Smart contends that the language is clear and its plain and ordinary meaning must, under Federal Circuit law discussed above, include hardware and/or software for displaying the image. Although Smart contends that PolyVision's construction improperly limits the claim to structure, when the controller must also include software, the Court concludes that PolyVision's construction correctly identifies the control apparatus as the "controller 3" without excluding the software for the controller from the scope of the claim.
6. "Control Circuit"

Plustek argues for "an electronic circuit that is located outside of the main case and that receives system control signals from the computing device and generates logical control signals for the image sensing module and motion mechanism."

Syscan argues for "a circuit that receives system control signals from the computing device and generates logical control signals for the image sensing module and motion mechanism."

The specification repeatedly and clearly distinguishes the patented scanner from the prior art on the basis of the patented scanner's minimalist approach. More specifically, the specification states that "fundamentally different from the scanners in the market, there is no microcontroller and other electronic components in main module 402 to control the operation of the image sensor and the illumination source." See Dang Decl., P 2, Ex. A ('124 Patent), 7:3-7, emphasis added. The patent's express exclusion dictates that the image sensor (or image sensing module) and the motion mechanism must be controlled by electronic components located outside of the patented scanner. SciMed Life Systems, Inc., 242 F.3d at 1341 ("where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question"); see also CCS Fitness, 288 F.3d at 1366-67 ("a claim term will not receive its ordinary meaning if the intrinsic evidence shows that the patentee distinguished the term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention.").

The interface engine and the control circuit are electronic components that control the operation of the image sensor and the illumination source as well as the motion mechanism. See e.g., Dang Decl., P 2, Ex. A ('124 Patent), Fig. 3, 6:32-34, 11:9-13 (claim 5), Fig. 5. Therefore, the interface engine and the control circuit must be located outside of the main case. SciMed Life Systems, Inc., 242 F.3d at 1341; see also CCS Fitness, 288 F.3d at 1367.

The Court construes this claim as "an electronic circuit that is located outside of the main case and that receives system control signals from the computing device and generates logical control signals for the image sensing module and motion mechanism."
structure only indicated what function the recited "means" element performed rather than its structure).

Here, Claim 1 appears to recite sufficient structure to avoid application of section 112, paragraph 6. As in Greenburg, the "control circuit" element is not drafted in means-plus-function form. Additionally, Imperial has cited nothing in the prosecution history or elsewhere which indicates that the inventors of the '402 patent intended to invoke section 112, paragraph 6. Furthermore, the "control circuit" element is supported by structure. Claim 1 specifies that the "control circuit" comprises a first port, second port, a first control line, and a second control line and defines their structural relationship. See Col. 67:1-8. The term "circuit" alone indicates sufficient structure to avoid application of section 112, paragraph 6. Accordingly, the "wherein" clauses merely provide functional limitations to the structure specified in the claims. The control circuit also has two ports. The first port is coupled to volatile memory and the second port to the hard disk drive.

14. "control circuit which controls duty cycle of the primary winding circuit" ('021 patent)

While there was an initial dispute as to whether this term is a means-plus-function limitation or not, SynQor has stated that Defendants are apparently not contending that it is a means-plus-function limitation. Further, Defendants did not provide any arguments in the briefs or during oral arguments for this term. Thus, there is no dispute as to the construction of this term. Nonetheless, the Court finds that, because the claim element "control circuit which controls..." does not use the word "means," there is a rebuttable presumption that § 112, P 6 does not apply. MIT, 462 F.3d at 1353-54. The Court finds that the "control circuit" term recites sufficient structure and has a reasonably well understood meaning. The Court finds that there has been no rebuttal of the presumption. Thus, it is not a means-plus-function limitation governed by 35 U.S.C. § 112 P 6. SynQor argues that no construction of this phrase is required besides the term "primary winding circuit." Defendants have not argued anything to the contrary for this term. Thus, in this instance, the Court finds that "primary winding circuit" means the agreed upon definition for "primary transformer winding circuit."

15. "control circuitry determining when the power MOSFET switches are turned on and off in a switching cycle at a switching frequency" ('083 and '702 patents)

While there was an initial dispute as to whether this term is a means-plus-function limitation or not, SynQor has stated that Defendants are apparently not contending that it is a means-plus-function limitation. Further, Defendants did not provide any arguments in the briefs or during oral arguments for this term. Thus, there is no dispute as to the construction of this term. Nonetheless, the Court finds that, because the claim element "control circuit determining..." does not use the word "means," there is a rebuttable presumption that § 112, P 6 does not apply. MIT, 462 F.3d at 1353-54. The Court finds that the "control circuit" term recites sufficient structure and has a reasonably well understood meaning. The Court finds that there has been no rebuttal of the presumption. Thus, it is not a means-plus-function limitation governed by 35 U.S.C. § 112 P 6. The parties have not provided any terms within the phrase that need to be construed. Thus, the Court finds that this phrase does not need a construction.

7. "control commands"

TiVo argues no construction of "control commands" is needed, or, if construed, should mean "commands that control the DVR system." TiVo's Opening Br. at 12; '389 patent at cols. 12:65-67, 15:47-49. EchoStar argues "control commands" means "commands that are accepted and sent through the system" and "affect the flow of said MPEG stream, including, for example, reverse, fast forward, play-pause, fast/slow reverse play, and fast/slow play." 4 See '389 patent at col. 2:33-37; EchoStar's Response Br. at 14.
4 EchoStar argues that "said MPEG stream" is indefinite and cannot be construed due to a lack of antecedent basis for the term. EchoStar's Opening Br. at 20-21; EchoStar's Slide Presentation at 134-36. EchoStar also argues claim 32 is indefinite because it combines apparatus and process limitations in a single claim. EchoStar Opening Br. at 21-22. As discussed above in footnote 1, definiteness is a validity challenge that should be raised by summary judgment motion.

The court finds "control commands" is defined clearly by claims 1 and 32, with no indication from the specification that any specific meaning should attach. Therefore, for purposes of clarification, the Court defines "control commands" as "commands that control the system."

D. "control data passing"

The term "control data passing" is found in the preamble of claim 25: "wherein the user's rule set contains at least one of a plurality of functions used to control data passing between the user and a public network." The term "control data passing" is not found in the specification. According to Linksmart, the ordinary meaning of this term is self-evident and no construction is necessary. The defendants' proposed construction is "filter and redirect data sent."

The Summary of the Invention describes the purpose of the invention: "The present invention allows for creating and implementing dynamically changing rules, to allow the redirection, blocking, or allowing, of specific data traffic for specific users, as a function of database entries and the user's activity." (118 patent, 2:61-65) (emphasis added). Other text in the specification confirms this functionality: "The redirection server . . . is programed to implement . . . checking data packets and blocking or allowing the packets . . . [and] performing the physical redirection of data packets . . . ." (118 patent, 4:59-65). These passages indicate how the claimed invention enables control of the data passing through the redirection server. As such, the court construes this term to mean "redirect, allow, or block data traffic."

1. at least one control key for initiating the predetermined operations relating to said digital camera memory module

The plaintiff proposes a construction of "not less than one key for initiating predetermined operations relating to said digital camera memory module." However, the main dispute involves the term "control key." Instead of proposing a construction for the entire disputed phrase, the defendants only propose a construction for "control key" to mean "a one-touch key that can be manually depressed by a user and that, in response to a single touch, causes the repository device to copy, or erase or reformat, a flash memory module." To support their proposed construction, the defendants cite to examples of "control keys" in the specification. The claim phrase is broader than the examples of the preferred embodiment cited by the defendants; nevertheless, the terms are readily understandable and the court concludes that this phrase requires no construction.
7. receipt … at a control input

The ordinary meaning of the term "control input" is an I/O port of a computer, where the instruction initiating the control of that computer is input. Thus, the computer located within the switching system receives the first, second and third switch commands at an I/O input. See supra § II.A.4 (describing remote control by switch commands).

2. Claims 12 and 24

The parties disagree whether Section 112, paragraph 6 is applicable to the "control means" element in claims 12 and 24. Goss argues the statute does not apply to either claim because they "explicitly include[] the structure for performing the [recited] function." Pl. Memo. at 28, 32. According to Goss, the "control means" function varies the speed of the motors in the article feeder means and the motor in the conveyor drive means. Id. The claims specify the structures necessary to perform the function: a main controller and a plurality of sheet material feeder controllers which are connected with the main controller. Id. Goss contends these are known structures to persons of ordinary skill in the art. Id. at 28-29. Goss supports its argument by citing to the claim language, specification, and a technical dictionary. Id.

K&M argues Goss has not rebutted the presumption in favor of means-plus-function analysis. As to claim 12, K&M contends that Goss is attempting to improperly "swap out" the restrictive definition of "control means" in claim 1, for a construction that does not contain any means-plus-function elements. Def. Resp. at 11-12. K&M argues that claim 12 is limited by Section 112, paragraph 6, because it is dependant on claim 1, which is governed by means-plus-function analysis. Id. Goss' construction is an attempt to broaden the claim beyond the specification. Id. As for claim 24, K&M contends the "control means" element is described in the "classic 'means for' format." Def. Resp. at 12. K&M asserts the claim does not recite sufficient structure to perform the specified function. Id. at 13. "Main controller" and "a plurality of sheet material feed controller" are functional terms; they provide no indication of their structure to a person of ordinary skill in the art. Id. at 28-29. Goss supports its argument by citing to the claim language, specification, and a technical dictionary. Id.

K&M's argument that Goss' construction of claim 12 is contrary to settled law is similarly unavailing. K&M relies on Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991), to argue that Goss' construction renders dependant claim 12 broader than independent claim 1. Def. Resp. at 10-11. While K&M is generally correct that a dependant claim cannot be construed more broadly than the claim on which it depends, that is not a concern here. Application of Section 112, paragraph 6 to claim 1's "control means" element results in a construction "cover[ing] the structure described in the specification [i.e., a main controller and a plurality of sheet material feed controllers] and equivalents thereof." Laitram, 939
F.2d at 1538 (emphasis in original). Because Section 112, paragraph 6 does not apply to claim 12's "control means," the element is not construed to include equivalents. Thus, claim 12 is "literally" narrower than claim 1. Id. The Laitram case weakens, rather than strengthens, K&M's position.

### 932

b. "Control Means"

The Defendants object to Special Master Harmon's conclusion that the "control means" limitation does not necessarily include an algorithm. In their Objections, the Defendants argue for the fourth time that WMS Gaming Inc. v. Int'l Game Tech., 184 F.3d 1339 (Fed. Cir. 1999), and Aristocrat Techs. Australia Pty Limited v. Int'l Game Tech., 521 F.3d 1328 (Fed. Cir. 2008) compel a construction of "control means" that requires an algorithm. This construction has been rejected by Magistrate Judge Valdez, Judge Manning, and now Special Master Harmon.

The WMS Gaming line of cases holds that a general purpose computer alone cannot provide sufficient structure for a means-plus-function claim. See WMS Gaming, 184 F.3d at 1348. Instead, what must be claimed is a "special purpose computer," which is what a general purpose computer becomes when an appropriate algorithm is used. Id. at 1349. Here, however, a controller is a known structure that is a type of special purpose computer. See, e.g., Comprehensive Dictionary of Electrical Engineering, 139 (Phillip A. Laplante ed., CRC Press 1999) ("Controller — (1) the entity that enforces the desired behavior—as specified by the control objectives—of the controlled process by adjusting the manipulated inputs."). Specifically, as Judge Manning previously noted, these controllers may not even require any algorithms at all if they consist of only circuitry to perform their specific purpose. (R. 320 at 14.) Magistrate Judge Valdez, Judge Manning, and Special Master Harmon have all addressed this issue at length and all three have concluded that no algorithm needs to be included in the structure for the construction of the term "control means." The Defendants' fourth attempt to challenge the construction of "control means" is unpersuasive. Therefore, the Court overrules the Defendants' objection to the construction of this term.

### 933

3. Claim 8(f) -- "pipe path control means"

Limitation (f) of claim 8 states "pipe path control means for determining a pipe path within said piping between a pair selected from among said first and second containers, said filter unit and said first and second coupling attachments". (Dkt. entry no. 1, Ex. A, '511 patent, at col. 12, lines 11-15.) The parties agree that this language is subject to a means-plus-function analysis. (RTI Br., at 28; Defs. Br., at 29.) However, the parties disagree about the structure that corresponds to the recited function of determining a pipe path within the piping. RTI asserts that 'the 'pipe path control means' recited as element (f) of claim 8 encompasses any manual or electrical system that performs the recited function of determining a pipe path within the piping between a pair of structures selected from the first and second containers, the filter unit, and the first and second attachments." (RTI Br., at 28.) In contrast, the Defendants contend that the mental process of determining a pipe path cannot be claimed, and thus, the Court must limit its interpretation of "pipe path control means" to a plurality of electrically operated valves and a microprocessor based controller for sending operating signals to those valves to select a pipe path. (Defs. Br., at 29.)

The function explicitly recited in limitation (f) of claim 8 is determining a pipe path within the piping between a pair selected from the first and second containers, the filter unit, and the first and second coupling attachments. See Versa Corp., 66 Fed.Appx. at 855. The specification contains the following statements, which reference structures corresponding to this recited function:

- Selecting the pipe path selected for an appropriate cycle can be accomplished either by manually opening and closing appropriate valves as is discussed below, or electronically through a controller such as a panel controller that provides signals to the appropriate valves when a particular cycle is selected. Microprocessor controls for controlling the opening and closing solenoid operated valves are well known. (Dkt. entry no. 1, Ex. A, '511 patent, at col. 6 lines 46-53.)
The various operation cycles and manually operated valves may be completely or partially automated, using microprocessor based controls. (Id. at col. 10, lines 46-49.)

See Omega Eng’g, Inc., 334 F.3d at 1322 (explaining that once the function is identified, the Court must determine what structures disclosed in the specification correspond to that function); Epcos Gas Sys., Inc., 279 F.3d at 1032 (explaining same). Accordingly, the specification indicates that manually or electronically operated valves are the structures that correspond to the recited function of determining a pipe path. See Linear Tech. Corp., 379 F.3d at 1322 (noting that Section 112, paragraph 6 permits a claim element to embrace alternative described structures for performing a claimed function).

The Court notes, as previously discussed, that some level of human intervention is permissible in a patent's claims as long as a human is not a claimed structure, but instead merely operates a claimed structure. See Default Proof Credit Card Sys., 412 F.3d at 1300 (stating that a human being cannot constitute a "means", and noting that it must determine what structure the human being operates to perform the recited function). Here, the '511 patent's specification describes a manual system where a human being will operate a structure such as a knob, which in turn opens or closes a valve that determines or selects a pipe path between certain structures. Therefore, construing limitation (f) of claim 8 as encompassing manual as well as electronic systems for performing the recited function does not infer that human intervention is claimed as part of the corresponding structure.

The independent claims at issue in the present case recite as follows:

13. A device comprising a passage; binding means in said device for binding a species substantially specifically, said binding means being in fluid communication with said passage; exposure means in said device for exposing said species to said binding means and for preventing said binding means from leaving said device; closed regeneration means for separating said species from said binding means for reuse of said binding means in said device; valving for selectively connecting said closed regeneration means in fluid communication with said binding means, and control means for automatically operating said valving.

40. A closed regeneration device for separating a molecule bound substantially specifically to a binding species for reuse of said binding species said regeneration device comprising a first reagent, a first valve selectively connecting said first reagent in fluid communication with said molecule bound to the binding species to separate said molecule from said binding species, a second reagent, a second valve selectively connecting said second reagent in fluid communication with said binding species to return said binding species to a regenerated condition, and control means for automatically operating said valves.

'502 patent col.13 ll.25-35, col.16 ll.20-31 (claim terms at issue emphasized). n2 Claims 14-17 are dependent from claim 13.

n2 The parties treat "control means for automatically operating said valving" and "control means for automatically operating said valves" as identical.

The district court began its construction of the term "control means" with the observation that if a claim element contains the term "means" and recites a function, there is a presumption that § 112, P 6 applies. Biomedino, slip op. at 8. Concluding that the inclusion of the word "control" did not identify structure and thus did not overcome the presumption that the claim limitation was a means-plus-function limitation, the district court began a § 112, P 6 analysis.

The only references in the specification to the "control means" are a box labeled "Control" in Figure 6 and a statement that the regeneration process of the invention "may be controlled automatically by known differential pressure, valving and control equipment." '502 patent col.11 ll.55-58. From this, the district court concluded:
The specification says nothing more than that unspecified equipment may be used to control the regeneration process. The fact that one skilled in the art could envision various types of equipment capable of automatically operating valves does not change the fact that no structure capable of performing that function was disclosed by the inventor.

Biomedino, slip op. at 11. As a result, the court held that "[t]he failure to disclose a structure corresponding to the 'control means' function makes claims 13-17 and claim 40 of indefinite scope in violation of § 112, P 2 of the Patent Act." Id.

Biomedino appeals, and we have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1).

II

"A determination that a patent claim is invalid for failure to meet the definiteness requirement of 35 U.S.C § 112, paragraph 2, is 'a legal conclusion that is drawn from the court's performance of its duty as the construer of patent claims[, and i]ndefiniteness, therefore, like claim construction, is a question of law that we review de novo.'" Intellectual Prop. Dev., Inc. v. UA-Columbia Cablevision of Westchester, Inc., 336 F.3d 1308, 1318 (Fed. Cir. 2003) (quoting Atmel, 198 F.3d at 1378).

III

A

As an initial matter, we address Biomedino's assertion that use of the term "control" to describe "means" takes the phrase "control means" outside the realm in which § 112, P 6 applies. This argument is based on the premise that "control means" recites sufficient structure on its own such that it obviates the need for § 112, P 6. Biomedino argues that a "control" is a precise structure well understood by those of skill in the art, and thus, the word "means" in claims 13 and 40 can be ignored. Additionally, Biomedino contends that "control" is analogous to the term "controller" and conveys, to one skilled in the art, structure for controlling the valves and other equipment. We disagree.

When a claim uses the term "means" to describe a limitation, a presumption inheres that the inventor used the term to invoke § 112, P 6. Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1375 (Fed. Cir. 2003). "This presumption can be rebutted when the claim, in addition to the functional language, recites structure sufficient to perform the claimed function in its entirety." Id. Claims 13 and 40 recite no such structure. As the district court noted, the "reference to 'control' is simply an adjective describing 'means:' [sic] it is not a structure or material capable of performing the identified function." Biomedino, slip op. at 12. We agree with the district court and hold that Biomedino has not rebutted the presumption that § 112, P 6 applies to "control means."

B

Once a court concludes that a claim limitation is a means-plus-function limitation, two steps of claim construction remain: 1) the court must first identify the function of the limitation; and 2) the court must then look to the specification and identify the corresponding structure for that function. Med. Instrumentation, 344 F.3d at 1205 at 1210. If there is no structure in the specification corresponding to the means-plus-function limitation in the claims, the claim will be found invalid as indefinite. See Atmel, 198 F.3d at 1378-79 (citing In re Donaldson, 16 F.3d at 1195).

While the specification must contain structure linked to claimed means, this is not a high bar: "[a]ll one needs to do in order to obtain the benefit of [§ 112, P 6] is to recite some structure corresponding to the means in the specification, as the statute states, so that one can readily ascertain what the claim means and comply with the particularity requirement of [§ 112,] P 2." Atmel, 198 F.3d at 1382. Additionally, interpretation of what is disclosed in the specification must be made in light of the knowledge of one skilled in the art. Id. at 1380. Thus, in order for a means-plus-function claim to be valid under § 112, the corresponding structure of the limitation "must be disclosed in the written description in such a manner that one skilled in the art will know and understand what structure corresponds to the means limitation. Otherwise, one does not know what the claim means." Id. at 1382. However, "the testimony of one of ordinary skill in the art cannot supplant the total absence of structure from the specification." Default Proof Credit Card Sys., Inc. v. Home Depot U.S.A., Inc., 412 F.3d 1291, 1302 (Fed. Cir. 2005).

In the present case, there is no dispute that the claimed function is "automatically operating said valving"/"automatically
operating valves." The parties also agree that the only references in the specification to the "control means" are the box labeled "Control" in Figure 6 and a statement that the regeneration process may be "controlled automatically by known differential pressure, valving and control equipment." ’502 patent col.11 ll.55-58. Biomedino argues that the excerpt from the written description demonstrates that "known differential pressure equipment can be used to operate valves, known valving equipment may be used, or known control equipment may be used." Biomedino further argues that the only remaining inquiry is whether one skilled in the art would identify the structure from that description. To demonstrate that one skilled in the art would identify structure from the description in the written description, Biomedino points to two prior art references and the appellees' (collectively "Waters") own expert's testimony. Together, this evidence suggests that there were many known ways to operate valves, including pneumatically, hydraulically, mechanically, and electrically.

In response, Waters argues that there is no specific structure identified in the specification to correspond to the claimed function of automatically operating the valves/valving: "the reference to 'differential pressure, valving and control equipment' is not at all descriptive of specific structure by which the 'control means' will automatically operate the claimed valving." As to the prior art references and expert testimony, citing Medical Instrumentation, 344 F.3d at 1212, Waters contends that the proper inquiry for identifying the structure corresponding to the recited function is "whether one of skill in the art would understand the specification itself to disclose the structure, not simply whether that person would be capable of implementing that structure."

Essentially this case asks the following question: for purposes of § 112, P 6, is sufficient corresponding structure disclosed when the specification simply recites that a claimed function can be performed by known methods or using known equipment where prior art of record and the testimony of experts suggest that known methods and equipment exist? In Medical Instrumentation, 344 F.3d 1205, we came close to answering that question in the negative. In that case the alleged infringer argued that the district court improperly included software for digital-to-digital conversion as corresponding structure for the claimed "converting means." Medical Instrumentation's expert never pointed to any disclosure of structure for digital-to-digital conversion in the specification. When asked about digital-to-digital conversion in the patents, he explained that such conversion was not disclosed or discussed in the specification presumably because it was well-known in the art and required no explanation. We observed that there was no evidence to indicate that a person skilled in the art would actually understand from the specification that software for digital-to-digital conversion was structure that corresponded to the means for converting. Id. at 1217. "Because software [wa]s not clearly linked in the specification or prosecution history to the claimed function" of converting means, we held that the district court's identification of software as a corresponding structure for § 112, P 6 purposes was erroneous. Id. at 1222.

In another similar case, Atmel, we also stated that the specification must disclose some structure but found that such a disclosure had been made. The claim limitation at issue in Atmel was "high voltage generating means disposed on said semiconductor circuit for generating a high voltage from a lower voltage power supply." 198 F.3d at 1376. The portion of the written description that pertained to the structural component of the means plus function limitation was the following: "the present invention may include high-voltage generator circuit 34. Known Circuit [sic] techniques are used to implement high-voltage circuit 34. See On-Chip High Voltage Generation in NMOS Integrated Circuits Using an Improved Voltage Multiplier Technique, IEEE Journal of Solid State Circuits, Vol.] SC-11, No. 3, June 1976." Id. at 1377. Additionally, the figures of the relevant patent depicted the high-voltage generator circuit as a "black box." Id. n3

n3 The first part of our analysis in Atmel involved a determination of whether the district court erred by failing to assess whether sufficient structure was disclosed in the specification to support the means-plus-function limitation based on the understanding of one skilled in the art. 198 F.3d at 1380. We answered this question in the affirmative.

We began our sufficiency of the disclosure analysis in Atmel by explaining that structure supporting a means-plus-function claim under § 112, P 6 must appear in the specification. Further, we noted that "consideration of the understanding of one skilled in the art in no way relieves the patentee of adequately disclosing sufficient structure in the specification." Id. at 1380. We said that a proper indefiniteness analysis "asks first whether structure is described in the specification, and, if so, whether one skilled in the art would identify the structure from the description." Id. at 1381. Thus, we concluded that the district court acted properly in ruling that the cited article could not take the place of structure that does not appear in the
specification.

As noted, however, the written description in Atmel sets forth the article's title, viz., "On-Chip High Voltage Generation in NMOS Integrated Circuits Using an Improved Voltage Multiplier Technique, IEEE Journal of Solid State Circuits." Id. at 1382. Atmel's expert had testified that the article's title alone was sufficient to indicate to one skilled in the art the precise structure of the means recited in the specification. Id. Because this testimony was unrebuted, we concluded that the court improperly granted summary judgment that the patent was invalid for indefiniteness.

There is a significant difference between the facts of Atmel and those in the present case. In Atmel it was not the fact that one skilled in the art was aware of known circuit techniques that resulted in a conclusion that sufficient structure was recited. Rather, it was the inclusion in the written description of the title of the article which itself described the structure for a "known circuit technique." Expert testimony was used to show what the title of the article would convey to one skilled in the art -- in that case it was "the precise structure of the means recited in the specification." Atmel, 198 F.3d at 1382. The expert's testimony did not create or infer the structure.

In the present case, there is nothing to suggest a structure for the claimed control means. As we have previously explained, § 112, ¶ 6 requires some disclosure of structure in the specification corresponding to the claimed means. "[W]hile it is true that the patentee need not disclose details of structures well known in the art, the specification must nonetheless disclose some structure." Default Proof, 412 F.3d at 1302; see also Atmel, 198 F.3d at 1382 ("There must be structure in the specification" and the requirements of § 112, ¶ 6 will not be met when there is "a total omission of structure."); Med. Instrumentation, 344 F.3d at 1211 ("If the specification is not clear as to the structure that the patentee intends to correspond to the claimed function, then the patentee has not paid [the price for use of the convenience of broad claiming afforded by § 112, ¶ 6] but is rather attempting to claim in functional terms unbounded by any reference to structure in the specification. Such is impermissible under the statute."); Donaldson, 16 F.3d at 1195 ("If one employs means-plus-function language in a claim, one must set forth in the specification an adequate disclosure showing what is meant by that language. If an applicant fails to set forth an adequate disclosure, the applicant has in effect failed to particularly point out and distinctly claim the invention as required by the second paragraph of section 112.").

The inquiry is whether one of skill in the art would understand the specification itself to disclose a structure, not simply whether that person would be capable of implementing a structure. Med. Instrumentation, 344 F.3d at 1212 (citing Atmel, 198 F.3d at 1382). Accordingly, a bare statement that known techniques or methods can be used does not disclose structure. To conclude otherwise would vitiate the language of the statute requiring "corresponding structure, material, or acts described in the specification."

IV

For the foregoing reasons, the judgment of the district court holding claims 13-17 and 40 of the '502 patent as invalid for indefiniteness is

AFFIRMED.

GO BACK

935

"control message"

Claim 1 contains the term "control message." Sutton defines the term as "information intended to reconfigure or manage characteristics of the receiving unit." Defendants urge that the definition is "information that is intended to reconfigure or manage characteristics of a receiving unit, and does not include a subchannel identifying byte." Thus, the central dispute is whether the term embodies a negative limitation that excludes information containing a subchannel identifying byte.

The specification expressly defines a control message by noting that such a message does not contain a subchannel identifier. When describing the transmission of particular types of messages the specification provides that "[i]f the data is an information packet and not a control packet a subchannel of 0-225 is assigned." '238 Patent at 5:58-59. Again, in a section specifically describing the different types of messages, the specification provides that "[u]nlike data messages,
control messages use a different frame byte structure and do not include a subchannel indentifying byte." Id. at 9:20-23.

Sutton responds to this persuasive intrinsic evidence by noting that the claims themselves do not expressly impose the negative limitation on a "control message." The argument misses the point. "The purpose of claim construction is to determine the meaning and scope of the patent claims asserted to be infringed." O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1360 (Fed. Cir. 2008) (internal quotation marks omitted). Thus, terms that are expressly defined in the specification will generally be given that meaning. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) ("The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication."). Thus, the fact that the patentee did not specify, in the claim itself, that a "control message" does not contain a subchannel identifer is not dispositive in light of the specification's express definitions.

Furthermore, Sutton's argument runs afool of the maxim that claim language cannot enlarge what is patented beyond what the inventor described as the invention within the specification. See Inpro II Licensing, S.A.R.L. v. T-Mobile USA, Inc., 450 F.3d 1350, 1355 (Fed. Cir. 2006); On Demand, 442 F.3d at 1340. Accordingly, Nokia's definition is correct and "control message" is defined as "information that is intended to reconfigure or manage characteristics of a receiving unit, and does not include a subchannel identifing byte." 936

a. "a control module arranged to control deployment of said occupant restraint device"

The parties agree that the court should construe this claim to include "a control module that issues a command or commands to control whether to deploy or suppress the occupant restraint device and/or how to adjust the manner in which the occupant restraint device is deployed." (Chart at 6.) However, Plaintiff also wants to append to this construction the phrase "or suppressed." (Id.) This language parallels language the parties agreed upon with respect to airbag deployment rather than that of an "occupant restraint device"; however, the agreed-upon language for airbag deployment does not include the appended phrase, "or suppressed," as proposed by Plaintiff.

Neither party offers argument for inclusion or exclusion of this phrase, and the court will not include it in its construction of this phrase. The ordinary meaning of "suppression" can mean either the opposite of "deployment" as "stopping," Dictionary.com Unabridged (v. 1.1), Random House, Inc., available at http://dictionary.reference.com/browse/suppress (last visited Jul. 7, 2009), or "restraining from a usual course or action," Merriam-Webster, available at http://www.merriam-webster.com/dictionary/suppress (last visited Jul. 7, 2009). However, throughout the specification, "suppression" is used as the opposite of "deployment." For example, one embodiment states:

If the occupant restraint device is an airbag, e.g., a frontal airbag or a side airbag, control of the airbag deployment may entail not only suppression of the deployment but also depowered deployment, adjustment of the orientation of the airbag, adjustment of the inflation rate or inflation time and/or adjustment of the deflation rate of time.

945 Patent col. 210 l.23-29. The specification clarifies that "suppression" is used in a sense directly opposed to that of "deployment" because the specification offers "suppression" as an alternative to "deployment" and further distinguishes "suppression" from "depowered deployment." See Bell Communications Research, Inc. v. Vitalink Communications, Corp., 55 F.3d 615, 620 (Fed. Cir. 1995) ("[I]t is equally fundamental that claims are to be construed in light of the specifications and both are to be read with a view to ascertaining the invention." (quoting United States v. Adams, 383 U.S. 39, 49, 86 S. Ct. 708, 15 L. Ed. 2d 572, 174 Ct. Cl. 1293 (1966)).

Nonetheless, the specification also demonstrates that the phrase to be construed, "control . . . deployment," "may entail not only suppression of the deployment but also depowered deployment, adjustment of the orientation of the airbag, adjustment of the inflation rate or inflation time and or adjustment of the deflation rate of time." 945 Patent col. 210 l.25-29. Accordingly, "control . . . deployment" contemplates (1) "suppression," or no deployment, (2) deployment, and (3) if the airbag is deployed, various rates and modes of deployment. See id. However, any adjustment has to do with whether the airbag is suppressed or deployed, and does not mean that there are multiple ways in which to suppress the airbag, even if there are multiple inputs that could result in such an outcome. Moreover, the specification discusses: "In all of these cases, the position of the occupant is used to affect the deployment of the airbag either as to whether or not it should be deployed
at all, the time of deployment and/or the rate of inflation.” '945 Patent col. 210 l.1-4.

As a result, the parties are correct to construe the phrase as "a control module that issues a command or commands to control whether to deploy or suppress the occupant restraint device and/or how to adjust the manner in which the occupant restraint device is deployed," and the court will not construe the phrase to include "or suppressed" at the end. Because the specification shows that an airbag can be suppressed, deployed, and deployed in multiple ways, the court finds that it should not append the phrase "or suppressed" to the phrase to be construed because it would be superfluous to render the phrase "and/or how to adjust the manner in which the occupant restraint device is deployed or suppressed." The specification reveals multiple ways in which the airbag could be deployed but does not show multiple ways in which the airbag could be suppressed, and the rules of claim construction proscribe an interpretation that renders a term superfluous. See Primos, Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 848 (Fed. Cir. 2006) (holding that a court cannot interpret claim terms such that one is rendered superfluous).

Accordingly, the court will construe the phrase "a control module arranged to control deployment of said occupant restraint device" as "a control module that issues a command or commands to control whether to deploy or suppress the occupant restraint device, and if deployed, how to adjust the manner in which the occupant restraint device is deployed."

7. "control object"

TiVo argues no construction of this term beyond a definition for "object" is necessary, or, if construed, the term should mean "the portion of a computer program that (1) 'receives commands from a user, said commands control the flow of the broadcast data through the system'; and (2) 'sends flow command events to said source, transform, and sink objects.'" See TiVo's Op. Br. at 23-24; '389 patent at cols. 7:48-50, 8:39-40, 15:11-16, 18:26-30; TiVo's Markman Slides at 140-49, 163-65.

EchoStar argues "control object" should have the same construction as "control commands."

The Court finds that persons of ordinary skill in the art readily understand the meaning of "control object" upon a reading of the claim language and its context in the specification. See '389 patent at cols. 7:48-50, 8:9-18, 15:10-12, 18:28-29. Therefore, in accordance with its ordinary meaning, the Court construes "control object" as "a collection of data and operations that receives commands from a user that control the flow of broadcast data."

7. Disputed term in AMD's '879 patent: Control panel (asserted claims 11-24)

11. A video graphics processor comprising:

   a processing unit; and

   memory that stores programming instructions that, when read by the processing unit, causes the processing unit to (a) provide a video control icon that is visible on the display, wherein the video control icon relates to live video that is being presented as a background on a display; (b) detect selection of the video control icon; (c) provide a control panel while the live video remains in the background and an application that was in focus remains in focus when the video control icon has been selected, wherein the control panel includes at least one of the following: a volume adjust icon, a mute icon, a pause icon, a rewind icon, and a fast-forward icon.

12. The video graphics processor of claim 11 further comprises, within the memory, programming instructions that, when read by the processing unit, causes the processing unit to provide, as the control panel, at least one of: volume adjust icon, mute icon, channel up icon, channel down icon, numerical channel display, and alpha-numeric channel display.
13. The video graphics processor of claim 11 comprises, within the memory, programming instructions that, when read by the processing unit, causes the processing unit to remove the control panel when another displayed element is selected.

14. A video graphics processor comprising:

a processing unit; and

memory that stores programming instructions that, when read by the processing unit, causes the processing unit to (a) detect selection of a video control icon, wherein the video control icon relates to live video that is being presented as a background on a display; (b) provide a control panel while the live video remain the background and an application that was in focus remains in focus when the video control icon has been selected; and (c) adjust at least one attribute of the live video based on an input received via the control panel, wherein the at least one attribute included: volume, mute, pause, rewind, and fast-forward.

15. The video graphics processor of claim 14 further comprises, within the memory, programming instructions that, when read by the processing unit, causes the processing unit to adjust the at least one attribute by adjusting at least one of: volume, mute, channel up, and channel down.

16. The video graphics processor of claim 14 further comprises, within the memory, programming instructions that, when read by the processing unit, causes the processing unit to remove the control panel when another displayed element is selected.

17. A digital storage device that stores programming instructions that, when read by a processing unit, causes the processing unit to provide control of background video, the digital storage device comprises:

first storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to provide a video control icon that is visible on the display, wherein the video control icon relates to live video that is being presented as a background on a display;

second storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to detect selection of the video control icon; and

third storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to provide a control panel while the live video remains in the background and an application that was in focus remains in focus when the video control icon has been selected.

18. The digital storage device of claim 17 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to provide, as the control panel, at least one of: volume adjust icon, mute icon, pause icon, rewind icon, and fast-forward icon.

19. The digital storage device of claim 17 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to provide, as the control panel, at least one of: volume adjust icon, mute icon, channel up icon, channel down icon, numerical channel display, and alpha-numeric channel display.

20. The digital storage device of claim 17 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to remove the control panel when another displayed element is selected.

21. A digital storage device that stores programming instructions that, when read by a processing unit, causes the processing unit to provide control of background video, the digital storage device comprises:

first storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to detect selection of a video control icon, wherein the video control icon relates to live video that is being presented as a background on a display;
second storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to provide a control panel while the live video remains in the background and an application that was in focus remains in focus when the video control icon has been selected; and

second storage means for storing programming instructions that, when read by the processing unit, causes the processing unit to adjust at least one attribute of the live video based on an input received via the control panel.

22. The digital storage device of claim 21 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to adjust the at least one attribute by adjusting at least one of: volume, mute, pause, rewind, and fast-forward.

23. The digital storage device of claim 21 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to adjust the at least one attribute by adjusting at least one of: volume, mute, channel up, and channel down.

24. The digital storage device of claim 21 further comprises means for storing programming instructions that, when read by the processing unit, causes the processing unit to remove the control panel when another displayed element is selected.

The '879 patent is entitled "Method and Apparatus for Providing Control of Background Video." The disclosed invention allows users to control video that is playing in the background while applications in the foreground remain in focus. See Abstract. The parties agree that the "control panel" disclosed in asserted claims 11-24 teaches a screen that contains control functions. They dispute whether the control panel is limited to the screens of personal computers. AMD argues that the term "control panel" need not be construed. Alternatively, AMD proposes construing this term as: "Area of the screen containing control functions." Samsung's construction limits the control panel to something that appears on the screen of a personal computer: "An area of the personal computer screen containing control functions."

AMD is correct that the claim language does not expressly limit control panels to personal computer screens. The Court must read the claims in light of the specification, however. See Phillips, 415 F.3d at 1321 (specification is "the single best guide to the meaning of a disputed term") (quotation omitted). The specification of the '879 patent unequivocally limits this invention to computers. The abstract begins, "A method and apparatus for controlling background video on a computer display is accomplished by providing a video control icon, which is visible on the display." The specification describes the technical field of the invention as follows: "This invention relates generally to computer displays and more particularly to providing control of background video," 1:7-9. The "background of the invention" section of the specification begins with a description of computers ("Computers are known to include a central processing unit, cache memory, hard drive memory . . .") and describes three means of displaying live video on a "computer monitor." 1:12-15; 1:23-33. The specification summarizes the problem addressed by the invention as follows:

When an attribute of the live video [i.e. the video displayed on the computer monitor] is to be changed, other applications that were in focus (i.e., actively being displayed and/or being worked upon) must go into a background mode (i.e., taken out of focus). As such, the adjusting of attributes of the live video consume[s] the activity of the computer until such attributes have been changed and the live video is returned to the background mode. As one can readily appreciate, this can be someone burdensome to the user and is an ineffective use of the computer system.

Therefore, a need exists for a method and apparatus for providing control of background video while the video remains in the background.

1:41-53. The section headed "detailed description of the drawings" begins, "Generally, the present invention provides a method and apparatus for controlling background video on a computer display." 2:2-4. Figure 1 of the patent illustrates the control panel on a screen. The specification explains that Figure 1 illustrates "a graphical representation of a computer screen." 2:19-20. The specification concludes with the following summary:

The preceding discussion has presented a method and apparatus for controlling background video. By providing a video control icon which, when selected, pops up a control panel, live video can remain in the background while its attributes are changed via the control panel. This allows a user to simply adjust the attributes of the live background video without having to bring it in focus. As such, the overall operation[] of a computer system is improved.
This intrinsic evidence leaves no doubt that the inventor was working in the field of video displayed by a computer; there is no suggestion in the specification that the invention can be implemented without a computer. As the patentee consistently uses "control panel" in the specification to denote a mechanism for controlling video on a computer display, this understanding of the term is incorporated into the claim language. See Bell Atlantic Network Servs., Inc. v. Covad Commun'cns Group, 262 F.3d 1258, 1271 (Fed. Cir. 2001) (citation omitted) ("[W]hen a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term by implication.")

AMD argues that invention taught in the '879 patent also encompasses user interfaces in devices such as digital cameras, camcorders, and cell phones. None of the intrinsic evidence cited by AMD supports this conclusion. First, AMD cites claim 12, which discloses the following options on the control panel: "volume adjust icon, mute icon, channel up icon, channel down icon . . . ." 4:59-60. (Claim 15 teaches control over the same attributes. 5:15-19; see also claims 19 & 23.) AMD points out that "channel up" and "channel down" displays make more on a television than on a computer. The specification explains, however, that the live video controlled by the control panel may be "sourced" from "a live television broadcast, satellite television, or cable television." 2:36-38. In other words, while the video is displayed on a computer screen, 2:21, the computer can be connected to a television, which is the source for the video, 2:37. The specification also provides that the source of the video could be a DVD player or VCR, 2:39-40, in which case the control panel on the computer screen would display "at least one of a volume adjust icon, a mute icon, a pause icon, a re-wind icon, and a fast forward icon," 2:40-41. Contrary to AMD's contention, the reference to channel controls in some claims does not establish that the control panel can be displayed on a television without a computer.

AMD also cites dependent claim 5, which provides: "The method of claim 1 further comprises, within step (a), providing the live video as the background on a computer display, a television, or a monitor." 5:12-14. Claim 5 does not support AMD's construction. This claim describes embodiments in which other devices (such a television) may be connected to a computer and used to display the video. Claim 5 merely lists types of devices that can display the patented application when those devices are connected to a computer.

Finally, AMD objects that the intrinsic evidence does not limit the control panel application to use on a "personal" computer. On this point, the Court agrees: the specification refers repeatedly to a computer, not a personal computer. The Court will modify Samsung's construction by omitting the word "personal." The Court also finds that Samsung's construction could confuse jurors by leading them to believe that a control panel can only be displayed on a computer screen. As the foregoing discussion has established, claim 5 discloses that a television could be used for a computer display. The Court will therefore replace "screen" with "display" in Samsung's proposed construction.

Accordingly, "control panel" shall be construed as follows: "An area of the computer display containing control functions."

iv. Control processing

The next term to be construed is "control processing." Gobeli contends that "control processing" means "execution of a routine or part of a routine that controls the process (device) sending the interrupt." Sun contends that the correct construction of control processing is "advancing the state of an independent process controlled by a state machine to a new state, to a sub-state, or from a sub-state."

Once again, Sun attempts to read a "state machine" limitation into the claims. The Court has rejected this approach and will not unduly limit the claims to the preferred embodiment. Control processing is a broad term and neither the claim language nor the specification limits its construction. Accordingly, "control processing" means "executing program instructions that control a process."
8. "control program"

The term "control program" appears in independent claims 1 and 7 of the 037 Patent. Claim 1 recites a "processor unit" associated with each operating system peer-level facility "capable of executing a control program." 037 Patent, 55:22-30. Similarly, claim 7 claims, in relevant part, "a plurality of processors, each being coupled to a respective control program store." Id. at 56:29-30. As in claim 1, each of the control programs is associated with a separate processor and peer-level facility. Plaintiff again argues that the term "control program" need not be construed, while defendant requests that the court construe the term as "an explicit specification of definitions and sequences of instructions written in a particular programming language to control other system resources."

Here too, plaintiff contends that the words of the claims adequately define the disputed term. For example, plaintiff observes that claim 1 recites "a first control program portion that includes one of said distinct sets of operating system peer-level facility related functions" and "a second control program portion that provides for the implementation of the multi-tasking interface function." Id. at 55:36-43. However, this argument fails here for the same reason that the court rejected it in construing the term "multi-tasking interface": namely, that the quoted claim language describes what the control program does, and not what it is. Regardless, the control program itself is an additional claim limitation that is separate from the other claim limitations that describe its function. Accordingly, the court proceeds to construe the disputed term.

The parties cite dictionary definitions of "control," "program," and "control program" in support of their proposed constructions, or lack thereof. Plaintiff, relying on Texas Digital, argues that the scope of the disputed term should encompass all of these definitions. However, claim construction is not merely an exercise in compiling dictionary definitions for common words like "control" and "program"; rather, "[d]etermining the limits of a patent claim requires understanding its terms in the context in which they were used by the inventor, considered by the examiner, and understood in the field of invention." Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1299 (Fed. Cir. 1999). In the context of the patent in suit, each control program claimed in the 037 Patent performs tasks such as implementing one of the peer-level facilities and its associated multi-tasking interface function. 037 Patent, 55:36-43. Consistent with these functions, the AP Dictionary defines "control program" as "any of a class of programs within the operating system of a computer that controls the execution of other system resources." Id. at 514. The court concludes that this definition best represents the scope of the "control program" term as it is used in the claims of the 037 Patent. Accordingly, the court construes "control program" to mean "a program within the operating system that controls the execution of other system resources."

V. "[C]ontrol section"

Claim 2 of the '563 and '882 Patents utilizes the term "control section." The term is also described in the specification of each patent in suit. E.g., '493 Patent col. 8, ll. 25-47. Having placed the disputed term in context, the Court will summarize the Special Master's proposed construction as well as his rationale.

A. The Special Master's Recommendation

Based on his analysis of the relevant claim language and portions of the specifications of the patents in suit, the Special Master recommended that a "control section" be defined as "a portion of a window module that includes at least one module control." (R&R at 152.) In essence, the Special Master found that the relevant claim language required that a "control section" have at least one module control, and that this interpretation was consistent with the specifications of the patents in suit, which mentioned or described "control sections." Although the Special Master found that: (1) DMODs "act like any other window such as those within a windows based operating system desktop environment"; (2) the patents in suit identify Windows 98 as an example of such a "windows based operating system desktop environment"; and (3) "the windows in Windows 98 could be dragged . . . by placing the cursor of a mouse on the control section of the window, depressing the mouse button, moving the mouse to drag the window to a different location on the screen, and releasing the mouse button," he determined that it would be inappropriate to ascribe this functionality to control sections in the context of the patents in
suit because the relevant claim language was silent regarding the matter. (Id. at 151-52.) Having summarized the Special Master's reasoning and recommended construction of the term "control section," the Court turns to CA's corresponding objection and Simple's counter arguments.

B. CA's Objection and Simple's Counter Arguments

CA objects to the Special Master's recommended construction of "control section" because it obscures the fact that a user may place a cursor, controlled by a mouse, over the "control section" of a window object and then move said window object to a different location on screen by depressing the mouse button and moving said mouse. (See CA's Claim Construction Objections at 20.) For its part, Simple agrees with the Special Master's analysis and recommended construction and argues that it is consistent with the claim language and specifications of the '563 and '882 Patents. (Simple's Resp. to CA's Objections to the Claim Construction R&R (Dkt. No. 586) ("Simple's Reply to CA Objection"), at 16-17.) Simple further argues that CA's proposed construction ignores the relevant claim language of the '563 and '882 Patents which requires that a control section include at least one module control. (Id. at 17.) Having summarized the parties' objections and counter arguments, the Court will conduct its own analysis of the term "control section."

C. Analysis

As the Special Master points out, a "control section" is not expressly defined by the intrinsic evidence found in the '493, '563, and '882 Patents, but claim 2 of the '563 and '882 Patents clearly states that a "control section is . . . a portion of a window object . . . associated with control of the window object." (R&R at 146.) Specifically, claim 2 of the '563 Patent states that a control section includes "a set of at least one control corresponding to a set of attributes which operate to affect manifestation of said at least one window object and at least a portion of said content within said content display section." Id.; see also '882 Patent Cl. 2. Indeed the real dispute between the parties is over "whether the 'control section' itself -- apart from the 'control' and 'attributes' -- may be used to control the 'window object.'" (R&R at 146.)

The Court's analysis of term "control section," will entail the following steps: (1) construing the relevant claim language; (2) analyzing the relevant portions of the specifications of the '563 and '882 Patents; (3) accounting for the knowledge of one skilled in the art; and (4) addressing the deficiencies in the Special Master's proposed construction and the parties arguments.

1. The Patents in Suit Indicate That "control sections" Can Be Used to Move Window Objects

Claims 1 and 2 of the '563 and '882 Patents indicate that window objects can be moved and contain a control section. As shown by the excerpted claim language below, claim 1 of the '563 and '882 Patents indicates that a window object can be moved as a result of a "moving operation" performed on a controllable attribute. Specifically, claim 1 of the '563 Patent claims:

1. A network client . . . comprising:

   a content retrieval module . . . ; and

   a processing engine coupled to said content retrieval module configured to provide a content manifestation environment within the data processing system, to process said content to produce at least one corresponding window object . . . ,

   said at least one corresponding window object is associated with a controllable attribute, said controllable attribute configured to permit said at least one corresponding window object to be controlled as a result of performing at least one of a moving operation, a resizing operation, a minimizing operation, or a maximizing operation within said content manifestation environment.

'563 Patent Cl. 1 (emphasis added). Claim 1 of the '882 Patent claims:

1. A network client . . . comprising:

   a content retrieval module . . . ; and
a processing engine . . . , to process said content to produce at least one window object within said content manifestation environment, said at least one window object is associated with a controllable attribute, said controllable attribute configured to permit at least one window object to be controlled as a result of performing at least one of a moving operation, a resizing operation, a minimizing operation, or a maximizing operation within said content manifestation environment.

'882 Patent Cl. 1 (emphasis added). Claim 2 of the '563 and '882 Patents "depends" from claim 1 of said patents. Accordingly, the window object referenced in claim 2 of the '563 and '882 Patents can be movable. Claim 2 of the '563 and '882 Patents further refines window objects to include a content display section and a control section. As provided below, Claim 2 of the '563 Patent claims:

2. The network client according to claim 1, wherein said processing engine is further configured to process said content to produce a control section and a content display section within said at least one corresponding window object, said content display section configured to manifest at least a portion of said content therein, said control section including a set of at least one control corresponding to a set of attributes which operate to affect manifestation of said at least one window object and at least a portion of said content within said content display section.

'563 Patent Cl. 2 (emphasis added). For its part, claim 2 of the '882 Patent claims:

2. The network client according to claim 1, wherein said processing engine being further configured to process said content to produce a control section and a content display section within said at least one window object, said content display section configured to at least a portion of said content therein, said control section including a set of controls corresponding to a set of attributes which operate to affect manifestation of said at least one window object and at least a portion of said content within said content display section.

'882 Patent Cl. 2 (emphasis added). As shown above, claim 2 of the '563 and '882 Patents refers to a window object, which may be movable and contains a control section, which is distinct from its content display section. Having analyzed the claim language of the '563 and '882 Patents, the Court will turn to their specifications to further inform its construction of the term "control section."

Footnotes

20 The following may be of assistance in deciphering the meaning of the term "depends": 35 U.S.C. § 112 P 2 and 37 C.F.R. § 1.75(a) require that a patent's specification conclude with one or more claims. See Landis on the Mechanics of Patent Claim Drafting § 2:1. There are three types of claims: (1) independent; (2) dependent; and (3) multiple dependent. Id. § 2:10. Since the '493, '563, and '882 Patents only have independent and dependent claims, the Court need not discuss multiple dependent claims.

An independent claim, is one that "stands alone, includes all its necessary limitations, and is not dependent upon and does not include limitations from any other claim to make it complete." Id. Independent claims are usually the broadest claims in a patent. See generally id. In essence, they contain the fewest limitations and claim the most subject matter. See generally id.

Dependent claims depend from a single independent claim and incorporate an additional limitation. See 35 U.S.C. § 112 P 4. For example independent claim 1 Could read as follows:

We Claim:

1. A car with four wheels, four doors, and an engine that runs on gasoline.

Dependent claim 2 would read:

2. The car according to claim 1 wherein said engine also runs on electricity.

In actuality, claim 2 covers: A car with four wheels, four doors, and an engine that runs on gasoline and electricity. As one may already have deduced, a dependent claim includes every limitation found in the independent claim, from which it
According to the specifications of the '493, '563, and '882 Patents, "control sections" allow for the manipulation of modules through the use of "Module Controls." 21 The identical glossaries found in each of the patents in suit state that a module is a layer "having (1) a control section, and (2) a related content display section." E.g., '563 Patent col. 6, ll. 1-4. The "control section" hosts "Module Controls," which "control objects . . . associated with screen icons." E.g., '563 Patent col. 6, ll. 25-30. By reacting "to events, . . . [such as] mouse clicks, mouse-overs, double-clicks, etc," said objects allow a user to control certain attributes of a module, such as "minimization, maximization, closure, resizing, etc." Id. This description correlates with the ability of a "control" to affect the manifestation of a window object as specified in claim 2 of the '563 and '882 Patents. However, if the role of "control sections" were to end there, there would be no way in which a user would be able to move a module type window object such as a DMOD. This deficiency is critical since it is undisputed that certain embodiments of window objects, such as DMODs, are movable. As the following analysis of the relevant extrinsic evidence shows, control sections also allow users to move windows in windows based content manifestation environments.

2. A User Cannot Move a Module Without Utilizing its "control section"

When evaluating disputed claim terms, it is critical to note that: (1) claim interpretation is performed "from the perspective of one of ordinary skill in the pertinent art at the time of filing"; (2) claims do not stand alone and must be read in light of their accompanying specifications; and (3) it is not improper to refine a claim term in light of consistent definitive remarks within a patent specification. See Chamberlain Group, Inc., 516 F.3d at 1335; Computer Docking Station Corp., 519 F.3d at 1374; Markman, 52 F.3d at 979; Phillips, 415 F.3d at 1314. In light of the specifications of the '563 and 882 Patents, one of ordinary skill in the art at the relevant time period would understand that control sections also allow users to move window objects. The patentees and CA agree, in accordance with the relevant intrinsic evidence, that window objects such as DMODs can be dragged and acted upon "like any other window such as those within a windows based operating system desktop environment." See, e.g., '563 Patent col. 7, l. 65 - col. 8, l. 18, col. 8, ll. 4-6; '882 Patent col. 8, ll. 25 - 46, col. 9, ll. 1-6; Decl. of Danny Goodman in Supp. of the Claim Construction Brief of CA (Dkt. No. 326) ("Goodman Claim Construction Declaration"), at Attach. 22 P 28. CA's expert, Mr. Goodman, stated that Microsoft Windows, Apple Macintosh and "almost every windowed operating system environment" allow users to drag a window by placing a cursor over the title bar region, clicking and dragging. (Goodman Claim Construction Declaration P 28.) One of ordinary skill in the art would know this while interpreting the function of a control section within a window object.

Indeed, Figure 2B, supra at 17, in the '493 and '882 Patents as well as Figure 2, supra at 20, in the '563 Patent all display DMODs with titles imbedded into their control sections. '882 Patent fig. 2B, items 203 and 204, col. 8, ll. 25 - 56, col. 10, ll. 13-28; '563 Patent fig. 2, items 204, 206, 208 and 210 col. 9, l. 54 - col. 10, l2. In this context, one of ordinary skill in the art would understand that control sections are analogous to the title bar sections referred to by Mr. Goodman. In light of the undisputed facts that DMODs are movable and intended to act like windows in a "windows based operating system," the intrinsic evidence before the Court leads to the conclusion that control sections can be clicked on and dragged in order to move a window object. Having analyzed the term control section in light of the intrinsic evidence before the Court as well as the knowledge of one skilled in the art, it is clear that a control section not only contains a module control, but must also enables a user to move a movable window object.

3. "[C]ontrol section" Defined

The Court defines a "control section" as a portion of a window object that contains a module control and enables user control. The Court finds that one of ordinary skill would interpret the intrinsic evidence found in the '493, '563, and '882 Patents to mean that control sections allow users to manipulate and control window objects. Necessarily included in this
functionality is the ability to move a window object, which acts like a window in a standard operating system, such as Windows 98. The ability to move a module window object cannot be separated from the definition of a control section. Having defined the term "control section," the Court will discuss the deficiencies in the definitions proposed by the Special Master and CA.

4. The Special Master Incorrectly Narrowed the Meaning of the term "control section"

In the context of defining a "control section," the Court disagrees with the Special Master's overly narrow interpretation of claims 1 and 2 of the '563 and '882 Patents. Although it is irrefutable that the patentees intended for certain embodiments of modules to be movable, the Special Master stated that such a "method of control[, via the control section,] is simply not addressed in the claims or specification." (R&R at 152.) The Special Master rested his finding on the language of claims 1 and 2 of the '563 and '882 Patents. (Id. at 145-46, 151-52.) However, in doing so, the Special Master gave insufficient consideration to statements made consistently throughout the specifications of the patents in suit and ignored the knowledge of one skilled in the art. To that point, the Special Master does not seem to dispute that: (1) window objects are movable; (2) window objects can be and are meant to be moved like windows in the Windows 98 operating system; e.g., '882 Patent col. 9, ll. 1-6, (3) windows in Windows 98 operating system are moved by clicking on their "title bar regions" and dragging; (4) the control sections in the DMODs disclosed in the patents in suit are functionally similar to these title bar regions; (5) one skilled in the art would know of the Windows 98 operating system; and (6) the patents in suit disclose no other way of moving DMODs, apart from the inherently known method of clicking on the control section and dragging. (See generally R&R at 151-52.) Accordingly, any construction of the term "control section" must also account for the user's ability to drag a DMOD type window object and the only way to move a DMOD would be by clicking on its "control section" and dragging.

5. The Court Agrees, in Part, with CA but Declines to Adopt Its Proposed Construction

Although the Court agrees with some of CA's arguments, it declines to adopt their recommended construction in its entirety. CA correctly points out that the Special Master's recommended construction of "control section" obscures the fact that a user may move a window object by placing a mouse over its "control section" and dragging. Indeed there is ample support for this view in the specifications of the patents in suit although it may not be explicitly stated in the language of claim 2 of the '563 and '882 Patents. However, since CA's proposed construction does not explicitly state that a control section contains a module control, the Court will decline to adopt it.

6. Simple's Argument's Parallel the Special Master's Analysis and are Rejected for the Same Reasons

The thrust of Simple's response to CA's objection aligns with the Special Master's recommended construction of the term "control section." Accordingly, the Court rejects Simple's arguments for the same reasons it declines to adopt the Special Master's recommended construction of the term "control section." Having conducted its analysis, the Court will rule on the term "control section."

D. The Court's Ruling on the Term "control section"

CA's objection is granted in part and the Court defines a "control section" as a portion of a window object that contains a module control and enables user control.

III. Interpretation of the Term "Control Signal Generator"

The parties dispute the meaning of the term "control signal generator" in claims 1, 71, 83, and 97 of the 855 Patent and claims 1, 17, 22, 27, 31, 35, and 42 of the 480 Patent. The relevant claim language references "a control signal generator for generating a control signal."

The language of the disputed claims does not use the phrase "means for." Therefore, 35 U.S.C. § 112, P 6 presumptively does not apply. Harmonic Design has not pointed to a dictionary definition of "control signal generator." It does appear, however, that the term refers to a component of an electronic circuit that produces a control signal, which is defined as "any signal
that purposely affects the recording, processing, transmission or interpretation of data by a system element." IEEE Standard Dictionary, p. 218.

A review of both intrinsic and extrinsic evidence supports this conclusion. First, the language of the disputed claims specifies that the control signal generator is electrically connected to the electronic circuit, which is in turn electrically connected to the battery. See, e.g., 855 Patent, claim 1. Such language suggests that the patentee intended to recite a structural element as opposed to functional language that would invoke 35 U.S.C. § 112, P 6. See Cole, 102 F.3d at 531. Second, Figure 7 of the 480 Patent identifies a control signal generator as a component of the electronic circuitry. And third, extrinsic evidence indicates that the term "control signal generator" connotes sufficiently definite structure to one of ordinary skill in the art. See Kamm Decl., P 9 (noting that those skilled in the art would recognize that a control signal generator may refer to an electronic circuit or component, a photodiode, a phototransistor, or other devices).

Because the term "electronic circuit" connotes sufficiently definite structure to avoid application of 35 U.S.C. § 112, P 6, it follows that the term "control signal generator" also connotes sufficiently definite structure. That the term may not connote a specific structure is not dispositive. See Personalized Media Communications., 161 F.3d at 705. Accordingly, the Court finds that the term "control signal generator" connotes sufficiently definite structure to avoid application of 35 U.S.C. § 112, P 6. The Court also finds that the term "control signal generator" refers to a component of an electronic circuit that produces a control signal.

The Court also finds that the term "control signal generator" refers to a component of an electronic circuit that produces a control signal.

After holding a Markman hearing, the Court issued its Memorandum Opinion and Order on Claim Construction in which it construed six terms integral to the determination of this case and the instant motions. (doc. 270) The claims were construed as follows:

(1) "connected and connectable" -- These terms mean "directly joined to one another within the same unitary piece of equipment without any intervening equipment."

(2) "unified structure" -- Although not a claim term, the Court defines the term "unified structure" to mean "a consolidated structure with all components directly connected to one another."

(3) "bypass" -- "Bypass" means "a structure and path by which data channels completely go around and in no respect go through the TST switch."

(4) "control store" -- "A 'control store' is included within a single unified DRTST switching unit that includes a memory, processor, and operating software that determines (1) which data circulating on the network loop is to be selected and diverted to the TST switch of a given switching node; (2) how that data passes through the TST switch; (3) which data is output from the TST switch back onto the network loop; and (4) which data is to bypass the TST switch of that node."

(5) "means for measuring" -- The Court finds that this term is not capable of construction.

(6) "direction of the timing adjustment interval" -- This term means "[t]he timing adjustment control command signal is fed in a reverse direction from the data signal; that is, from a downstream digital switching unit to an upstream digital switching unit, in a direction opposite the data flow."

(Mem. Op. and Order on Claim Constr. at 30-31)
The plaintiffs say that "control trading" or "control subsequent trading" means "to have the option to trade additional volume of an item to the exclusion of other participants desiring to participate in the trade." (D.I. 463 at 6; D.I. 464 at 26.) The defendants' proposed construction is that to "control trading" means "to exercise authority to hold up a trade for as long as a participant continues to respond to its contra-party's size offerings, substantially as described in the '580 patent." (D.I. 463 at 6; D.I. 482 at 14.)

Claim 20 provides an example of the use of the term "control trading" in the patent, as it recites that "[a] period of exclusivity is provided during which the aggressor participant and a designated passive participant may control trading by transacting additional volume of the item with each other at the defined price to the exclusion of other participants desiring to participate in trading." (580 patent, col. 20, II. 19-24 (emphasis added).) Further, both the plaintiffs and the defendants cite the following language from the specification in support of their respective claim constructions (see D.I. 463 at 6; D.I. 464 at 27-28; D.I. 482 at 14-15):

The initial participants in the Workup State (i.e., the Aggressor 10 and the first customer on the passive side) are known as "current workers" and are vested with the authority under system control to hold up a trade for a predetermined duration of time.

(580 patent, col. 8, II.46-51.)

Current workers control the trade and can submit additional transaction volume to their contra-traders; this to the exclusion of outside customers.

(Id., col. 12, II. 48-50.)

10 An Aggressor is defined in the '580 patent as "a customer who initializes a trade". A "trade" is defined as "a string of transactions at one price initiated by a hit or lift and continuing until timed out or done". A "hit" is "accepting a pending bid (the dollar amount offered to buy a security - issue)" and a "lift" is "accepting a pending offer (the dollar amount offered to sell a security - issue)". (See '580 patent, col. 6, II.30-45.)

The defendants argue that the claim language of claim 20 supports their proposed construction of "control trading" because it "expressly notes that traders 'control' trading 'by transacting additional volume'" and that "the adverb 'by' indicates that the mechanism by which traders exercise control is by continuing to trade." (D.I. 482 at 15 (emphasis in original).) In response, the plaintiffs say that "even if 'transacting additional volume' is the 'mechanism' by which participants control trading" it does mean that a participant may control trading indefinitely by continuing to transact additional volume. (D.I. 490 at 10.) The plaintiffs also say that claim 20 clearly states that the ability to control trading only exists for a period that is "'provided' whether or not the participants exercise the option to transact additional volume." (Id.) Finally, the plaintiffs say that there is "no suggestion" in the language of claim 20 "that transacting additional volume could mean that the 'period' never ends." (Id. at 11.)

The defendants also say that the plaintiffs' proposed claim construction is too broad, as it "conflates 'control' with any period of exclusivity," and is inconsistent with the intrinsic record of the '580 patent. (D.I. 492 at 24.) They rely on the following language from claim 29, reciting

…a system trading state which (a) executes a trade transaction in accordance with the hit or lift at a defined price set by the hit or lift, (b) provides a period of exclusivity enabling the aggressor participant and a designated passive participant to control subsequent trading by executing transactions between the aggressor and designated passive participant of additional volume of the item at the defined price to the exclusion of other participants desiring to participate in the trading…

(580 patent, col. 22, II. 21-28.) The defendants also cite this language from the specification in support of their proposed claim construction:
The status of current worker dissipates upon entry of "done", or the lapsing of the trading inactivity interval. Again, this interval is a pre-set system parameter triggered via system logic. Absent such termination, current workers can trade almost indefinitely, as long as they continue to respond to their contra-party's size offerings.

(Id., col. 12, II. 58-62.) Finally, the defendants cite the prosecution history of the '580 patent, namely, declarations submitted by two of the inventors (Mr. Paul and Mr. Fraser) during prosecution wherein the defendants claim they used "the term 'control' as a synonym for the right to continue trading until 'done'…." (D.I. 482 at 15.) This, say the defendants, "demonstrates that the concept of ‘controlling’ trading encompasses more than a limited option to trade additional volume (such as for a pre-set time interval), as plaintiffs' definition implies." (Id. at 15-16) The plaintiffs say that the defendants have "distorted the content of these declarations" and that Mr. Paul's declaration emphasizes that control over a trade is temporally limited to a certain period. 11 (Id. (citing D.I. 459 at Tab 50, P 11).)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

11 The plaintiffs also say that the defendants' construction of "control trading" contradicts the use of the term "control" in the defendants' "own internal development documents and sales literature." (D.I. 464 at 30.) However, extrinsic evidence is relevant only when the intrinsic record leaves some ambiguity as to a term's scope. Vitronics, 90 F.3d at 1584. The intrinsic record here does not leave any ambiguity as to the scope of the term "control trading", and therefore I need not consider this extrinsic evidence. See id.; see also Interactive Gift, 256 F.3d at 1332.

2. The Court's Construction

Simply stated, the parties' dispute over the construction of "control trading" hinges on whether the term is construed as a period in which participants trade to the exclusion of others for as long as they continue to respond to each other's offers and counteroffers, or if it is construed as trading to the exclusion of others for a predetermined period of time. At the claim construction hearing, counsel for the defendants said that "the [580] patent doesn't say that the rule is you only get three seconds, and then whether you've done your full volume or not, or whether you're finished or not, you're out. That was an idea that BrokerTec came up with, not these plaintiffs." (D.I. 514 at 92:12-17.) When I restated the defendants' position that the plaintiffs' "invention is limited to a system that allows the first seller and first buyer to keep trading without a time limitation, except some non-trading intervention time that might kick in. But as long as one person - that one person is selling one share, they could theoretically keep going for as long as they want," (id. at 94:11-19), plaintiffs' counsel said only that "it must be preferred embodiment" (id. at 95:3-4). In support of that assertion, the plaintiffs directed my attention to language from the specification stating that "current workers…are vested with the authority under system control to hold up a trade for a predetermined duration of time." (Id. at 95:20-96:10.)

However, that portion of the specification, together with the other intrinsic evidence cited by the plaintiffs, is not enough to overcome the plain language of the claims themselves. I agree with the defendants' argument that the claim term "control trading", as it is used in the claims, indicates that the manner in which the aggressor and the passive participant trade to the exclusion of other participants, is "by transacting additional volume of the item with each other". (See '580 patent, col. 20, II. 19-24, 46-49; col. 22, II. 19-27.) The plaintiffs say that the defendants' proposed claim construction means that the period of exclusivity never ends. (D.I. 490 at 11.) This, I think, overstates the defendants' position. The defendants do not dispute that the period of exclusivity (as in, an interval of time) eventually ends. Their position is that the period of exclusivity ends when a participant no longer responds to its contra-party's size offerings (D.I. 482 at 14-16) and not, as the plaintiffs would have it, that the period of exclusivity times out regardless of the trading activity of the participants.

The plaintiffs have not pointed out any intrinsic evidence that contradicts the defendants' proposed construction of "control trading". For that reason, and because the defendants' proposed construction is supported by the claim language and the specification of the '580 patent, I will construe "control trading" or "control subsequent trading" to mean "to exercise authority to hold up a trade for as long as a participant continues to respond to its contra-party's size offerings."
The parties also dispute the trial court's construction of several claim terms in the '509 patent. Claim 35, from which asserted claims 45 and 51 depend, contains the limitation of "a control unit for controlling the communication unit, wherein the control unit comprises a central processing unit ("CPU") and a partitioned memory system." LGÈ contends that the trial court erroneously construed the term "control unit" as a means-plus-function limitation.

"[A] claim term that does not use 'means' will trigger the rebuttable presumption that § 112 AP 6 does not apply.'" Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (quoting CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002)). This presumption can be rebutted by showing that the claim element recite[s] a function without reciting sufficient structure for performing that function." Watts v. XL Sys., 232 F.3d 877, 880 (Fed. Cir. 2000) (citing Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999)). However, the presumption "is a strong one that is not readily overcome." Lighting World, Inc., 382 F.3d at 1358.

Here, the claim limitation at issue does not use the term "means," and the presumption against means-plus-function treatment is not overcome. The claim itself provides sufficient structure, namely "a CPU and a partitioned memory system," for performing the stated function, "controlling the communication unit." See id. at 1359-60. Thus, the proper construction of "control unit" is "a combination comprising a CPU and a partitioned memory system capable of controlling the communication unit."

Lutron contends that Term 3 means "A controllably conductive device for adjusting the status of the electrical device (which may include the on/off state, the intensity level, or both, of the electrical device)." Control4 contends the term means "A controllably conductive device for adjusting the status of the electrical device (which may include but is not limited to the on/off state, the intensity level, or both, of the electrical device)."

Lutron did not limit its patent to lighting control only. Instead, it specified its control device could be used in security systems, HVAC systems, computer systems, and audio/visual systems. Due to these inclusions, Control4 argues that status feedback may include more information than just a device's on/off state or intensity level. For example, it may include the status of a damper on a heating or cooling system.

Neither claim 1 nor the specification limits status feedback solely to the intensity level of a light or its on/off state. The construction therefore should not contain this limitation. Additionally, because "[c]laim construction is for the purpose of explaining and defining terms in the claims," it "usually requires use of words other than the words that are being defined." Based on these factors, the Court concludes the term means "A controllably conductive device for altering the condition of the electrical device (such as, the on/off state or intensity level of the electrical device)."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Independent claims 1 and 21 include the term "controller." The parties propose the following meanings to this term:
Braun's Proposed Construction
An electronic device that actuates and/or directs the operation of other components, including being operable to selectively delay execution of the door operation commands.

VMI's Proposed Construction
A device capable of making decisions with respect to the operation or actuation of a physical system such that the physical system behaves in a desired way.

Because the specification describes a function of the controller as "intercept[ing] communications with an OEM control module . . . [and] coordinat[ing] ramp deployment and stowing operations with the OEM control module," Braun argues that "controller" is a device that actuates and directs the operation of other components within the system. Braun insists that "controller" is not a "relay based control system." (Braun Constr. Br. at 14.)

VMI, on the other hand, maintains that nothing in the specification excludes a relay logic controller as a type of "controller." VMI submits that "[i]f a device detects, intercepts, or relays signals to control and synchronize the operation of the ramp, door or kneeling motors with the rest of the vehicle to prevent accidental or operational interference between the vehicle components it would be understood by one skilled in the art reading the '628 patent to be a 'controller.'" (VMI Resp. at 8.)

The specification gives examples of "controller": "controller can be a programmable logic control system (PLC), a microprocessor, or other type of electronic controller as known by those skilled in the art. Controller can be composed of one or more components of a digital and/or analog type. Controller can be programable by software and/or firmware, a hardwired state-machine or a combination of these. In one form, controller is based on a Motorola 68C705P6 microprocessor that includes four A/D (analog-to-digital) converter channels." ('658 Patent col. 5:44-50.) These examples do not exclude a relay based control system. To the contrary, insofar as PLC closely relates to a relay logic controller (see DE 87-3 Ladder Logic), the specification contemplates a relay. And again, since the Court does not construe "communication pathway" to mean a medium able to carry only coded data, Braun's argument that relays are not part of the invention as they cannot be connected to "communication pathway" carrying only coded data is unconvincing. In summary, the Court construes "controller" as a device that actuates and/or directs the operation of other components, or is capable of making decisions with respect to the operation or actuation of those components, including being operable to selectively delay execution of the door operation commands.

### "Controller" and "controlling"

Several method claims of the shock delivery patents require "controlling" the duration of a waveform phase, while several apparatus claims require a "controller" that operates a connecting mechanism between the energy source and the electrodes. Philips offers straightforward definitions: "controlling" means "regulating," and a "controller" is a circuit or component that controls. Defibtech, on the other hand, believes that "controlling" means "operating switches or other connecting mechanism to adjust the shape of the waveform delivered to a patient in response to a patient-dependent electrical parameter measured during the delivery of the waveform."

The court adopts Philips' definition. Defibtech correctly notes that in many instances, the inventors described their "invention" (as opposed to an embodiment) as "provid[ing] a defibrillator method and apparatus for adjusting the characteristics of the defibrillator waveform in response to a real-time measurement of a patient-dependent electrical parameter." 927 Patent at 5:56-58. Defibtech does not, however, point to a single instance in which the term "controlling" or "controller" is employed inconsistently with this description of the invention. In the claims, the language surrounding the term "controller" or "controlling" is uniformly consistent with this object of the invention. E.g., 927 Patent Claim 1 ("controlling duration of the truncated exponential biphasic waveform"), Claim 6 ("a controller operating the connecting
mechanism to deliver electrical energy . . . "); 454 Patent Claim 3 ("controlling the duration of a waveform phase based on a value of the electrical parameter"). Thus, Defibtech's proposed definition is surplusage. The claim language places limitations on "controlling" or the "controller" that are consistent with the purpose of the invention. There is no need for the definitions of "controller" and "controlling" to contain those limitations.

B. Construction

i. "controller" in the '638 patent

Lexar's proposed construction: A device that interfaces between a host and flash memory

Toshiba's proposed construction: -- none --

Pretec's proposed construction: A device that interfaces between a host and nonvolatile memory

The parties' disagreement over the meaning of the term "controller" in the '638 patent is less about the meaning of the actual claim term and more about the scope of the device with which the controller interfaces. While Pretec suggests that the "controller" interfaces between the host and any kind of nonvolatile memory, Lexar proposes a narrower construction, that the controller interfaces with a specific type of nonvolatile memory -- "flash memory (or any other semiconductor having the same characteristics as flash memory)." Toshiba offers no proposed construction.

Lexar suggests that the claim language in the '997 and the specification of the '051 patent supports its construction. However, the '997 and '051 patents, wholly unrelated to the '638 patent, are irrelevant to the claim construction analysis of the term "controller" in the '638 patent for the reasons explained above.

Pretec argues that claims 31 and 34 support construing "controller" as interfacing with a broader range of semiconductors: all nonvolatile memory. The Court agrees. In Claim 31 (dependent from Claim 18 in which a "controller" is first claimed), "flash memory" is expressly claimed as one form of nonvolatile memory with which the controller may interface. Dependent Claim 31 alone, according to the doctrine of claim differentiation, creates the presumption that the claim from which Claim 31 is dependent (independent Claim 18) is broader than flash memory; otherwise, it is assumed, the inventor need not state the additional limitation in the dependent claim. However, the Court need not rely solely on the claim differentiation presumption here because another dependent claim, Claim 34, claims that the controller may alternatively interface with E<2>PROM cells. That another dependent claim offers an alternative type of nonvolatile memory with which the controller may interface means that the independent claim from which claims 31 and 34 are dependent claims a broader range of nonvolatile memory. Therefore, the language of the claims themselves supports Pretec's proposed construction.

The '638 specification does nothing to limit the claims further. It might be argued that the nonvolatile memory is really limited to flash memory because the preferred embodiment uses flash memory for memory storage. ('638 patent, 3:46-47.) But in construing disputed claim terms, a limitation cannot be imported from the preferred embodiment into the claims themselves. Markman, 52 F.3d at 980. In any case, we need not even address that line of argument because the description of the preferred embodiment actually expressly embraces E<2>PROM as a form of nonvolatile memory with which the controller may interface: "In the preferred embodiment, all of the memory storage is flash EEPROM. It is possible to substitute E<2>PROM for some or all of the data bits shown." ('638 patent, 3:46-49 (emphasis added).) The specification does not limit "controller" to flash memory and in fact, serves to support Pretec's proposed broader construction.

Lexar suggests that the title of the '638 patent, "Flash Memory Mass Storage Architecture Incorporation Wear Leveling Technique," supports limiting the construction of "controller" to a device that interfaces with flash memory, rather than all non-volatile memory. But it is well-settled that the title of a patent is largely "irrelevant to claim construction." Robert L. Harmon, Patents and the Federal Circuit § 6.3(c) (6th ed. 2003). "[I]f courts do not read limitations into the claims from the specification that are not found in the claims themselves, then they certainly will not read limitations into the claims from the patent title." Id. Here, although the title of the patent suggests that the inventor intended to focus on flash memory, the Court will not allow implications from the title of the patent to override what the patent, having considered the claims
themselves and the specification, actually claims.

The Court therefore declines to adopt Lexar's proposed construction of "controller" in the '638 patent as it is unsupportably narrow and instead finds Pretec's proposed construction is the correct one. In the '638 patent, the "controller" is a device that interfaces between a host and nonvolatile memory.

ii. "controller" in the '997 patent

Lexar's proposed construction: A device that interfaces between a host and flash memory

Toshiba's proposed construction: 1. The internal controller of the flash array and control signaling from the external controller

Lexar proposes that "controller" in the '997 patent should be construed as a device that interfaces between a host and flash memory (or another semiconductor with the same characteristics). Lexar suggests three ways in which its proposed construction is supported. First, Lexar argues that the specification of the '051 patent supports its construction. Again, the '051 patent, wholly unrelated to the '997 patent, is irrelevant to the claim construction analysis of the term "controller" in the '997 patent as explained above. The '051 specification will not be considered in this discussion. Second, Lexar argues that the title of the '997 patent, "Flash Memory Leveling Architecture Having No External Latch," supports its proposed construction of "controller." As explained above, the title of a patent is largely "irrelevant to claim construction." Harmon, Patents and the Federal Circuit § 6.3(c). The Court will not ignore the title as entirely insignificant but it will not find the title dispositive either. Third, and most convincingly, Lexar suggests that the claim language in the '997 supports its construction because independent claim 1 and its corresponding dependent claims (2, 5, 7, 8, 9, 11, and 12) all expressly claim "a flash memory system comprising flash memory." (Lexar's Opening Brief at 9.) Because the '997 patent claims are expressly limited to flash memory (unlike, for example, the '638 patent discussed above), Lexar is correct. Indeed, Toshiba concurs that the controller interfaces between a host and flash memory.

But there is more to the dispute over this term than the type of nonvolatile memory with which the controller interfaces. Toshiba's disagreement with Lexar's construction of "controller" in the '997 patent is not centered on the type of memory with which the device interfaces so much as with clarifying the controller's role with respect to the internal flash controller and the control signals from the external controller. Toshiba argues that because the controller, as recited in claims 1 and 12 of the '997 patent, encompasses both the internal controller (that directly transfers data to the destination) and the control signals from the external controller (that allows the internal controller to transfer data), "controller" should be construed to include those functions. The Court finds that to do so, however, would render the portions of the claims specifying the functions of internal controller function control signals from the external controller redundant. Loading the single term "controller" with additional limitations already captured by the rest of the claims themselves is unnecessary. The Court therefore construes "controller" in the '997 patent as a device that interfaces between a host and flash memory.

iii. "controller" in the '051 patent

Lexar's proposed construction: A device that interfaces between a host and flash memory

Toshiba's proposed construction: Interfaces with nonvolatile memory

Pretec's proposed construction: A device that interfaces between a host and nonvolatile memory

Again, the dispute here is over the type of nonvolatile memory with which the controller interfaces. Lexar proposes that...
"controller" in the '051 patent be construed as a device that interfaces between a host and flash memory (or another semiconductor with the same characteristics) while Toshiba and Pretec propose that the controller interfaces with a broader range of semiconductors: all nonvolatile memory.

Lexar suggests that the claim language of the '997 patent supports its construction. The '997 and '051 patents do not share a common specification. Therefore the Court finds that the '997 patent is not particularly relevant to the construction of the term "controller" in the '051 patent. Lexar also argues that two aspects of the '051 patent itself evidence its position that the controller interfaces with flash memory only. First, Lexar argues that the title of the '051 patent, "Moving Sectors Within a Block of Information in a Flash Memory Mass Storage Architecture," supports its proposed construction of "controller." As explained above (in the context of construing "controller" in the '638 patent), limitations will not be read into the claims based solely on the patent's title. Lexar's second and more compelling argument is that the language of the claims in the '051 patent dictates that the controller interface between a host and flash memory (not, as Defendants propose, between a host and all nonvolatile memory).

For example, Claim 1, wherein a "controller" is first claimed, describes a "memory controller for use with a host requiring access to a nonvolatile memory" and then claims that "nonvolatile memory includ[es] a plurality of selectively erasable block locations." Lexar claims that nonvolatile memory other than flash memory (e.g., Electronically Erasable Programmable Read Only Memory ("EEPROM")) cannot have a plurality of selectively erasable block locations and that therefore, the controller, as claimed in the '051 patent, cannot be construed to interface with anything other than flash memory (or another semiconductor with like characteristics). To the contrary, Pretec claimed, both in its brief and at oral argument, that EEPROM can indeed be erased in blocks. (Claim Construction Hearing Transcript at 184-85; Pretec Brief, Ex. D.) Either way, the language of the preferred embodiment, absent more explicit language in the claims limiting nonvolatile memory to flash, suggests that an alternative embodiment of the invention could interface with EEPROM. (051 patent 8:34-36.) A claim construction that does not read on a preferred embodiment is "rarely, if ever, correct." Vitronics, 90 F.3d at 1583-84. Therefore, the Court cannot construe "controller" here to be limited to flash memory because the preferred embodiment allows the controller to interface with EEPROM. The appropriate construction for the '051 term "controller" is a device that interfaces between a host and nonvolatile memory.

iv. "controller" in the '314/138 patents

Lexar's proposed construction: A device that interfaces between a host and flash memory
Toshiba's proposed construction: interfaces with nonvolatile memory

- Footnotes -

2 Pretec offers no proposed construction here. Pretec only proposes constructions for disputed terms in the '638 and '051 patents.

- End Footnotes-

The dispute here is the same. Lexar again proposes that "controller" interfaces with flash memory only while Toshiba contends the controller interfaces with all nonvolatile memory.

The Court looks first to the language of the claims. Toshiba argues that the language of the claims themselves supports a finding that "controller" in the '314/138 patent interfaces with all nonvolatile memory. Indeed, nothing in the language of the claims themselves suggests that the "controller" interfaces with just flash. Specifically, Claim 1 of the '314 and Claims 1, 13, and 46 of the '138 recite a controller connected to a nonvolatile memory unit, and say nothing about flash memory. Toshiba additionally argues that the doctrine of claim differentiation supports its construction but that argument is without merit. According to Toshiba, Claim 11 and Claim 29 in the '138 patent, which claim that the nonvolatile memory unit is a "flash memory chip," suggests that the doctrine of claim differentiation applies here. Had the patentee intended to teach a controller that interfaces only with flash memory, the argument goes, the patentee would not have specified flash in the dependent claims only. However, as Lexar correctly pointed out at oral argument, a flash memory chip is one method of using flash memory. That a flash chip is claimed in a dependent claim does not necessarily indicate, through the doctrine of claim differentiation, that the independent claim is intended to claim all nonvolatile memory. Indeed, the dependent claim's
mention of a flash memory chip alone could very well mean that the broader, independent claim claims all forms of flash memory. Toshiba's claim differentiation argument fails. This does not mean, however, that Toshiba's construction of "controller" is wrong.

Lexar argues that the Court must look at the larger context of the patents. Flash memory, according to Lexar, is the only type of nonvolatile memory that can be erased in blocks and the patents claim only the type of nonvolatile memory that is erasable in blocks. However, even if, arguendo, being selectively erasable is what distinguishes flash memory from other types of nonvolatile memory, the '314/'138 patents do not expressly limit the claimed "controller" to interface only with selectively erasable nonvolatile memory in the same way that the '051 does. Lexar contended at oral argument that the '138 patent teaches a "block-oriented memory structure." But Lexar's characterization is a leap from claim language that expressly claims a device that interfaces with nonvolatile memory generally and neither claims that it is limited to flash memory devices nor that it is limited to nonvolatile memory that is selectively erasable. Based on the language of the claims, Toshiba has the better of the argument here.

Having determined that the claim language suggests that the broader construction of "controller" is the proper one, the Court next examines the specification to determine whether the patentee acted as his own lexicographer and assigned a construction other than the ordinary meaning as understood by a person skilled in the relevant art. In keeping with its contextual argument, Lexar contends that it is clear from the disclosures in the '138/'314 patent that the inventor intended that "nonvolatile memory" be limited to flash. Specifically, Lexar suggests that the title of the '314/'138 patent, "Increasing the Memory Performance of Flash Memory Devices By Writing Sectors Simultaneously to Multiple Flash Memory Devices," is suggestive of its limitation to flash memory. But again, while the title of the patent may be considered, it is not dispositive of the construction of a disputed claim term. Second, Lexar proposes that the block-oriented nature of the patents, as gleaned from the Abstract and the Field of the Invention sections, supports limiting the construction to flash. However, it is a strict rule of claim construction that limitations from the specification cannot be imported into the claims. Markman, 52 F.3d at 980. Moreover, nothing in the specification suggests any narrower a construction than exists in the language of the claims themselves. While the Court does not pretend that context is insignificant, the Court finds that here, the language of the claims indicates the broader construction is the right one and the specification does not compel a different result. 3

--- Footnotes ---

3 Lexar again attempts to use other patents (the '997 and '051 patents) to support its construction of "controller." The '997 patent is wholly unrelated to the '314/'138 patent and does not help Lexar. While the '051 is related (in part) to the '314P138, common claim terms need not be construed consistently across patents. MSM, 259 F.3d 1335. The Court therefore declines to look to other patents to construe "controller" in the '314/'138.

--- End Footnotes ---

Not only is there no support in the specification for a narrower construction, there is, as Toshiba points out, support in the specification for the broader construction of "controller" consistent with a plain reading of the claim language. The Summary of the Invention in the '314/'138 patent states as follows:

It is an object of the present invention to increase the performance of a digital system having a controller coupled to a host for operating a nonvolatile memory bank including one or more nonvolatile memory devices, such as flash and/or EEPROM chips, by reducing the time associated with reading and writing information to the nonvolatile memory bank.

('314 patent, 3:61-65; '138 patent, 3:54-60 (emphasis added).) That EEPROM is mentioned as a type of nonvolatile memory device in the context of a description of the invention supports construing "controller" broadly, consistent with the claim language, which claims a controller that interfaces with nonvolatile memory devices generally, not just flash. Toshiba also directs the Court to the '138's specification, column 1, lines 38-40, in which EEPROM is mentioned, and argues that this suggests that the patentee considered types of nonvolatile memory, other than flash, to be encompassed by the claims. (Toshiba's Opposition at 10.) However, this portion of the specification, as well as column 1, lines 43-47 of the '314 patent, describes the prior art, not the invention itself. The claims cannot be construed solely on the basis of a prior art description. These portions of the specification merely provide the context for the problem that the inventor sought to resolve, not what is actually claimed in the patent. The misguidedness of that particular argument notwithstanding, Toshiba is right that the
The plaintiff proposes "an electronic device that can be programmed to selectively provide electric power to the devices to which it is connected." Defendants propose "a device or circuit which controls the operation of another device or circuit."

The principal dispute is whether the "controller" needs to be "programmable." The plaintiff argues that the "controller" must be a device that can be used to generate a wide variety of light signals. The plaintiff, therefore, argues that Defendants' proposed construction is too broad because it would include a simple on/off switch which would not be able to generate a wide variety of signals. The plaintiff also argues that the "controller" needs to be programmable because the dependent claims recite "a programmable external controller for programming said controller." '269 patent, claim 14. According to the plaintiff, if the controller was not programmable, then dependent claim 14 would not make sense. The plaintiff also argues that its construction is supported by the IEEE definition of controller - "a device or group of devices that serves to govern, in some predetermined manner, the electric power delivered to the apparatus to which it is connected." IEEE Standard Dictionary of Electric and Electronics Terms (6th ed. 1996).

Defendants contend that the IEEE definition actually supports its construction because the definition does not require programmability. Defendants also argue that the programmability of the controller is only one embodiment and should not be read into the claims. In terms of claim structure, Defendants point to the fact that, in some cases, dependent claims regarding "a programmable external controller" are also dependent on claims requiring the controller to be a "microprocessor." Defendants argue that microprocessors are inherently programmable, and, therefore, there is no need to place a programmability limitation on "controller." n3

--- Footnotes ---

n3 In reply, the plaintiff notes that there other types of circuits, other than microprocessors, that are programmable, e.g., field-programmable gate arrays (FPGAs).

--- End Footnotes ---

The Court concludes that one of ordinary skill in the art would understand a "controller" to be a circuit or device that is either programmable or has a pre-determined function. In the context of the patents-in-suit, the controller is used to selectively activate LEDs. '269 patent, 4:37-38. A programmable controller is an aspect of a preferred embodiment that should not be read into the claims. Accordingly, "controller" means "a device or circuit capable of selectively activating LEDs."

As is pertinent here, in its January 24, 2005 Claims Construction Order, the Court construed certain terms of Claim 1 as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;controller&quot;</td>
<td>a device that interfaces between a host and nonvolatile memory.</td>
</tr>
<tr>
<td>&quot;host&quot;</td>
<td>interfaces, through the controller, with nonvolatile memory.</td>
</tr>
</tbody>
</table>
M. Tomar's Claim Construction Arguments

Tomar did not join in the other defendants' claim construction briefing, but separately filed its own arguments focusing on the interpretation of "controller" as represented in claim 1 of the '615 patent. n4 In summary, Tomar argues that the Court should interpret "controller" as a means-plus-function claim under 35 U.S.C. § 112, P 6 even though the claim itself does not use the term "means." The basis for Tomar's argument is that the "controller" limitation does not "particularly point out and distinctly claim" the invention as required under 35 U.S.C. § 112, P 2 because the patent fails to disclose a circuit capable of creating complex light patterns as discussed in the specification. See '743 patent, 11:59-62. Tomar contends that this renders the claim indefinite under Halliburton Oil Well Cementing Co. v. Walker, 329 U. S. 1, 67 S. Ct. 6, 91 L. Ed. 3, 1946 Dec. Comm'r Pat. 628 (1946) (superseded by the 1952 Patent Act) because "controller" is the "most crucial element" of a claimed combination described "in terms of what it will do rather than in terms of its own physical characteristics."

--- Footnotes ---
n4 The use of "controller" in claim 1 of the '615 patent is the same as the use of "controller" in claim 1 of the '269 patent and as discussed above in Section H.

--- End Footnotes ---

Tomar contends that in order to save the claim from invalidity, the Court needs to interpret "controller" as a means-plus-function limitation. To support this contention, Tomar cites to the specification's preferred embodiment stating that a controller "provides a means for activating LED's 30 individually . . . ." '743 patent, 11:59-61, 23:16-18 (emphasis added), and argues that the use of "means" in the specification is an express disclaimer of claim scope. n5

--- Footnotes ---
n5 In its response, the plaintiff points out that Tomar has not complied with the Court's docket control order requiring identification by March 16, 2006 of claim elements that should be governed by 35 U.S.C. § 112, P 6 nor the deadline of April 5, 2006 for complying with P.R. 4-2 requiring preliminary claim constructions for each element governed by 35 U.S.C. § 112, P 6. Nevertheless, the Court has considered Tomar's arguments as part of the claim construction process.

--- End Footnotes ---

The plaintiff argues that Tomar has not met its burden of rebutting the presumption that 35 U.S.C. § 112, P 6 does not apply in absence of the word "means." See Phillips v. AWH, Corp., 415 F.3d 1303, 1311 (Fed. Cir.2005). In addition, the plaintiff contends that the term "controller" would be understood by one of ordinary skill in the art to have a structural meaning, and, therefore, is not subject to 35 U.S.C. § 112, P 6. See Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1360 (Fed. Cir. 2004).

Claim language not containing the term "means" is presumptively not subject to means-plus-function construction under section 112 P 6. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002). The presumption may be overcome if the claim term fails to recite sufficiently definite structure or recites function without reciting sufficient structure to perform that function. Id. (quoting Watts, 232 F.3d at 880). Tomar, however, fails to overcome this presumption. Here, one of ordinary skill in the art would understand "controller" to refer to a specific type of circuitry, and "circuitry" has been found in other cases to connote structure. See The Massachusetts Institute of Technology and Electronics for Imaging, Inc. v. Abacus Software, 462 F.3d 1344, 1355-56 (Fed. Cir. 2006) (stating that "circuit" combined with a description of the function of the circuit connotes sufficient structure). The claim language does not merely describe a controller, but adds further structure by describing the operation of the controller. See '578 patent, 9:14-18 (claiming that the controller is used to activate light emitting diodes and produce warning light signals). Accordingly, the description of the operation of a controller is sufficient to avoid section 112 P 6, and Tomar's indefiniteness argument is rejected.
The term "controller" is disputed by the parties. Microfil asserts that the term "controller" should be limited to a single device that controls the entire automated pill dispensing system. AutoMed, on the other hand, asserts that the modifier "single" does not appear in the claims, the specifications, or the prosecution histories and that the term should be construed to mean a device or system that regulates a process or another device. AutoMed's construction, however, is inconsistent with the written specification. In the written specification, the patentee clearly states that a control system regulates all aspects of the automated pill dispensing device. For example, the written specification states that "the control system places a refill request with the vibratory dispenser," that the "control system assigns at least one accumulation receptacle," and that the control system controls the various processes employed by the system. (927 Patent Col. 9 L 48-51, Col. 10 L. 12-14, Col. 11 L. 43-46; '671 Patent Col. 9 L. 61-63, Col. 10 L. 14-16, and Col. 11 L. 44-47).

Accordingly, while the patentee did not modify the term controller with the word single, the specification indicates that a single control system regulates the entire process.

**1. "Controller"**

We agree with the district court's initial construction, with the clarification that the "controller" need not be limited to a single device, as applied by the district court and asserted by Microfil. We see no basis in the intrinsic record to warrant reading the term "controller" to be limited to a single device or to any particular hardware or software. The specifications of the '671 and '927 patents support a broad interpretation of "controller." While the specifications differ in some respects, these differences are not material to our analysis here; we rely on text common to both specifications. Moreover, "the same term or phrase should be interpreted consistently where it appears in claims of common ancestry." Epcon Gas Sys. v. Bauer Compressors, Inc., 279 F.3d 1022, 1030 (Fed. Cir. 2002). The specifications disclose at least two structures that perform control functions: a "controller 180," which apparently controls only the rate of vibration; and a "control system 80," which seems to control many aspects of the entire process. Compare, e.g., '927 patent col.8 ll.51-59, with id. col.11 ll.43-46.

Unfortunately, the specifications fall short of clarity in outlining the exact functions and details of the control system software and hardware. Even though the relationship between these structures is not entirely clear from the written description, what is unmistakable is that no single device is disclosed which performs or is capable of performing all of the functions recited in claim 1 of the '927 patent, namely, to receive a patient's prescription information and to control the entire apparatus, including the vibratory dispenser, the container transport assembly, and the vial transport assembly. See '927 patent claim 1. To the contrary, the patents describe only in general terms the control of several distinct systems and processes. E.g., '927 patent col.8 ll.1-2 (drive unit vibration); id. col.10, ll.58-62 (vial transport); id. col.11, ll.47-63 (patient...
entry process). With all due respect to the view expressed in the dissent, a construction of the term "controller" to be "a single module or specific device which operates automatically to regulate a controlled variable or system," as argued by Microfil, would fly in the face of the specification and would engraft onto the claims an unwarranted limitation. See Phillips v. AWH Corp., 415 F.3d 1303, 1322-23 (Fed. Cir. 2005) (en banc) (cautioning that dictionary definitions cannot be used to "contradict any definition found in or ascertained by a reading of the patent documents" (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 n.6 (Fed. Cir. 1996))). Without a clear indication from the patentee that a single device must control these varied functions, it is improper to limit the term "controller" to a single device rather than a single system. Accordingly, while we affirm the district court's initial construction of "controller" to mean a "single control system that regulates the entire process," we clarify that the controller need not be limited to a single device, nor to any particular hardware or software.

1. CLAIM CONSTRUCTION

Citrix argues that the term "controller," contained in each of the independent patent claims that Mr. Orenshteyn says are infringed by Citrix products, refers to a replacement for a general purpose CPU. Because each of Citrix's accused products uses a general purpose CPU, it contends that the products do not infringe as a matter of law.

When construing a patent claim, three sources should be considered: (1) the language of the claims themselves; (2) the patents specification; and (3) the prosecution history. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995). A court may also consider extrinsic evidence, such as expert testimony as to how those skilled in the art would interpret the claims. See id. A court, however, is not required to rely on expert testimony if the intrinsic evidence establishes the proper construction of the claims. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) ("It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record . . . Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language.").

Additionally, a patentee is his own lexicographer, and the specification may act as a dictionary, defining terms used in the claim. See id. If the patentee does not offer a unique definition of his own, a court may refer to a dictionary to determine the proper definition of the claim. See, e.g., National Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1195 (Fed. Cir. 1999) (referring to the dictionary definition of "select"); Hazani v. U.S.I.T.C., 126 F.3d 1473, 1480 (Fed. Cir. 1997) (referring to the dictionary definitions of "integral" and "in"). Finally, claim construction is a question of law for the court, and is therefore amenable to resolution on summary judgment. See Johnston v. IVAC Corp., 885 F.2d 1574, 1579-80 (Fed. Cir. 1989).

Where a patentee has clearly defined a claim term, that definition is usually dispositive. See Jack Guttman, Inc. v. Kopykake Enters., Inc., 302 F.3d 1352, 1360 (Fed. Cir. 2002). In this case, Mr. Orenshteyn, in the patent specifications, has defined the term "controller" to mean something other than a general purpose CPU.

The patent specifications indicate that the term "controller," contained in each of the independent claims of the '942 and '569 patents, refers to a less expensive replacement for a general purpose CPU. For instance, the specifications state that "expensive general purpose processing CPUs are preferably replaced with inexpensive but powerful controllers, such as DSP chips." They also go on to define the purpose of the inventions as follows: "General purpose computing on the desktop, i.e., desktops having a standard OS (such as Windows 95(R)) and a microprocessor (such as the Pentium(R) chip), has to be replaced by a system which is less expensive to own and maintain but at the same time does not short-change the user by taking away features we all have come to expect from our PCs . . . ." These statements in the specifications indicate that the term "controller" means something other than a general purpose CPU.

Additionally, the specifications go on to describe two embodiments of the invention, the claimed one that features a "controller," and an unclaimed one that does not. In describing the unclaimed invention, the specification states that a general purpose CPU can be used. "It should be understood that general purpose computers will also work with the present invention (with little or no modifications), such that existing owners of PCs can access any specialized server to spawn a selected application, as desired." When describing the claimed invention that features a controller, however, the specification makes clear that "controller" does not mean a general purpose CPU:
Instead of a conventional general purpose CPU, inexpensive but powerful controller circuits will be utilized for controlling storage devices and other I/O hardware. An example of a controller is a TI TMS320C4x or C3x DSP chip. The controller or a plurality of controllers will control the client file system (file I/O logic) and low-level graphical interface logic (e.g. GUI). For example, each client may have a separate controller chip for the file system/disk controller block, the communication block and the display/human interface block of the client, or one DSP control may control all three blocks.

Motion for Summary Judgment, Exh. D-1, Col. 9, ln. 30-40 (emphasis added). Accordingly, the specification indicates that the term "controller" means something other than a general purpose CPU.

To the extent additional discussion is necessary, this definition and construction of the term "controller" in the patents also comports with the testimony of Dr. Fortes, who provided his opinion of how one of ordinary skill in the art would construe the language. Dr. Fortes' opinion was based on the patent specifications, engineering treatises, and dictionaries. He opined that the term "controller" refers to a replacement for a general purpose CPU. Additionally, although the testimony of an inventor should be given little weight in a court's claim construction, see Markman, 52 F.3d at 985, Mr. Orenshteyn clearly testified that the term "controller," as used in his patents, means a hardware device, and not a general purpose CPU:

Q. What's a controller?
A. A processing element.

Q. What's an example?
A. A processor, a chip, an integrated circuit.

Orenshteyn Deposition at 126-27.

Mr. Orenshteyn's opposition to the motion for summary judgment responds to Citrix's argument that the term "controller" means something other than a general purpose CPU in one sentence: "Indeed, Citrix's construction of the term is in direct contradiction to the patent specification." Opposition at 11. Mr. Orenshteyn, however, neither identifies any contradiction or cites to any part of the specifications which allegedly contradict Citrix's construction. Mr. Orenshteyn, therefore, has offered no viable alternative to the claim construction asserted by Citrix. Citrix's construction of the term "controller" comports with the patent specifications, and is, moreover, supported by expert testimony. Accordingly, the term "controller," contained in each of the independent claims of the '942 and '569 patents is construed as a matter of law to mean something other than a general purpose CPU.

Claim 1 of the '942 patent reads as follows:

1. A secured system for accessing application services from at least one application program, comprising:

   at least one client station having low-level application independent logics stored therein and at least one controller for controlling said low-level application independent logics, said low-level application independent logics including a user interface logic, a device control logic for controlling devices, a file system logic, and a communication interface logic, wherein said file system logic includes a file system capable of storing data corresponding to said at least one application program;

   at least one application server having high-level application logic stored in a server device for running said at least one application program, said server device being coupled to said at least one application server; and

   a low-level interface between said at least one client station and said at least one application server for connecting said at least one client station to said at least one application server,

   wherein upon accessing by said at least one client station, said at least one application server runs said at least one
application program which selectively controls said low-level application independent logics for controlling devices of said at least one client station and for accessing data of said at least one client station, and wherein said at least one application server processes said corresponding data from said at least one client station on said at least one application program without permanently storing said data in a server device coupled to said at least one application server.

(emphasis added).

As indicated above, the district court construed the term "controller" in Claim 1 "to mean something other than a general purpose CPU." Orenshteyn, 265 F. Supp. 2d at 1329-30. The court then found that because the '942 and '569 patents "use a 'controller,' which has been construed as something other than a general purpose CPU," while the accused Citrix products "all use a general purpose CPU to execute application program code," Orenshteyn had failed to show infringement. Id. at 1331

On appeal, Orenshteyn argues that the district court erred in construing the term "controller." Orenshteyn argues that, while the specification of the '942 patent discusses using controllers that are not CPUs in order to lower costs, the specification does not limit his claims to non-CPU controllers. Orenshteyn argues that the district court correctly recognized that the specification discloses an embodiment in which the controller is a CPU, but erred in finding that this embodiment was unclaimed. Orenshteyn argues that claim 2 of the '942 patent and the doctrine of claim differentiation require a construction of "controller" that includes CPUs.

We agree with Orenshteyn that Citrix is not entitled to summary judgment of noninfringement of claim 1. The district court granted Citrix's motion because the MetaFrame product uses a CPU, in contrast to its construction of the '942 patent as referring to something other than a CPU. However, as we shall demonstrate, claim 1 of the '942 patent covers products that employ a CPU, and the district court's grant of summary judgment of noninfringement was therefore erroneous.

Claim 1 of the '942 patent claims a secured system for accessing application services that is made up of a client station connected through an interface with an application server. '942 patent cl. 1. The client station consists of a controller and a number of "low-level application independent logics," such as a user interface logic, a file system logic, and a device control logic. Id. The client station accesses the application server, which runs an application program that in turn controls the application logics of the client station. Id.

Claim 2 of the '942 patent claims the system of claim 1, "wherein said at least one client station lacks a general purpose central processing unit to prevent execution of application program code on said at least one client station, so as to decrease cost and protect said at least one client station." Id. cl. 2. Claim 2 adds to claim 1 only that the "client station lacks a general purpose" CPU. Thus, claim 1, as the parent of dependent claim 2, presumably includes the possibility of a client station that possesses a general purpose CPU; otherwise claim 2 is identical to claim 1 and therefore superfluous. See Xerox Corp v. 3Com Corp., 267 F.3d 1361, 1366 (Fed. Cir. 2001) (stating that reading a limitation into a claim that would render two claims superfluous "will not do").

There can be no doubt, when looking at the specification and comparing claim 2 to claim 1, that a CPU may be included in the client station of claim 1. The district court, in granting summary judgment of noninfringement, found that because Citrix's "products all use a general purpose CPU to execute application program code," those products did not infringe claim 1 of the '942 patent because that claim required the use of a controller, which was construed as "something other than a general purpose CPU." Orenshteyn, 265 F. Supp. 2d at 1329-30. However, as we have demonstrated, because claim 2 claims a client station that "lacks a general purpose [CPU] to prevent execution of application program code," claim 1 impliedly may include just such a CPU.

In support of its decision, the district court noted the portions of the specification that seem to indicate a distinction between a "controller" and a general purpose CPU. See id. at 1329; '942 patent col.6 ll.17-20 ("expensive general purpose processing CPUs are preferably replaced with inexpensive but powerful controllers, such as DSP chips."); id. c.1 ll.65-67 -- col.2 l.1 ("General purpose computing on the desktop, i.e., desktops having a standard OS (such as Windows 95(R)) and a microprocessor (such as the Pentium(R) chip), has to be replaced by a system which is less expensive . . . ."). However, those portions of the specification do not "define" the term controller, as the district court held they do. Rather, they suggest that there are inexpensive controllers that are not CPUs; they do not indicate that all controllers are distinct from all CPUs.
Furthermore, another portion of the specification indicates that the invention can, in fact, employ a CPU. '942 patent col.9 ll.48-52 ("It should be understood that general purpose computers will also work with the present invention (with little or no modifications), such that existing owners of PCs can access any specialized server to spawn a selected application, if desired."). The court explained that portion of the specification, which appears to contradict its claim construction, by describing that portion as an "unclaimed invention." OrenshTyen, 265 F. Supp. 2d at 1329. While it is true that a specification may contain unclaimed inventions, we have shown that the claims in this case indicate that the use of a CPU is, in fact, encompassed within the claims. We therefore find that the district court erred in concluding that Citrix failed to demonstrate that there was no genuine issue of material fact concerning infringement of claim 1 of the '942 patent.

3. "Controller."

The court shall apply the ordinary definition of the word "controller" in the relevant art. Thus, the term "controller" shall be construed to mean "electronic circuitry that generates a control signal."

As to "controller," the parties have agreed to Power-One's proposal of "circuitry that controls the operation of one or more devices." As to the other terms, Power-One argues for the same construction, while Artesyn proposes "part of a distributed power control system that activates and at least partially programs and monitors a regulator and allows the output of the POL regulator to be transmitted to an external load circuit." The Court notes that a "power supply controller" is discussed in the '999 patent as follows:

Traditionally, POL regulators operate in conjunction with at least one power supply controller. The controller (1) activates and partially programs the POL regulator by providing data directly to the POL regulator, (2) monitors the output of the POL regulator by measuring data external to the POL regulator, and (3) allows the output of the POL regulator to be transmitted to an external load circuit. The Court finds that this language supports Artesyn's proposal and therefore, construes "power supply controller" and "system controller" as "part of a distributed power control system that activates and at least partially programs and monitors a regulator and allows the output of the POL regulator to be transmitted to an external load circuit."

The Court construes "primary display controller" to mean "circuitry for interfacing a primary display with a computer" and "secondary display controller" to mean "circuitry for interfacing a secondary display with a computer."

Primary display controller & Secondary display controller

At the hearing, both parties agreed that "display controller" should be construed as "circuitry for interfacing a display with a computer." The only dispute is over the use of the word "first" versus "primary" and "second" versus "secondary" to modify "display." As the Court already construed both "primary display" and "secondary display," it is unnecessary to re-construct the terms here. Therefore, the Court adopts the parties agreed language and construes "primary display controller" as "circuitry for interfacing a primary display with a computer" and "secondary display controller" as "circuitry for interfacing a secondary display with a computer."
I. "controller adapted to provide selectively modulated illumination to the illuminated LEDs/light sources"

This phrase appears in the claims of only the '865 patent. The plaintiff proposes "the controller adapted to provide illumination whose intensity is selectively varied to illuminate LEDs/light sources." Defendants propose "the controller produces incremental variation in brightness of LEDs/light sources during illumination." The main dispute is over "selectively modulated illumination" and whether it means that "intensity" is "selectively varied" or whether it means that there is "incremental variation in brightness."

The plaintiff argues that its construction allows for a full range of modulation while Defendants' construction only allows for "incremental variation." The plaintiff bases its argument on the fact that "modulation" encompasses a variety of waveforms, such as "sinusoidal" and "triangular," which could not be characterized as "incremental variation." In addition, the plaintiff points out that claim 1 of the '743 patent recites "the controller is capable of providing variable illumination intensity . . . ." Because different claim terms are presumed to mean different things, "modulated illumination" cannot mean the same thing as "variable illumination intensity." Finally, the plaintiff points to the prosecution history where the patentee distinguished prior art through the invention's modulated illumination of light sources to create strobe, flashing and/or alternating light signals. '189 application, Sept. 5, 2001 Amendment, at 5-6. According to the plaintiff, these signals are all on/off patterns, which would not be covered by "incremental variation," but would be covered by "selectively varied."

Defendants argue that the specification and prosecution history make it clear that "modulated intensity" does not include "flashing light." According to the defendants, the specification separately lists "modulated or variable intensity light" and "a flashing light." '865 patent, 5:2-5, 30-32, 38-40, etc. Defendants contend that the prosecution history disclaims "flashing light signals" because the patentee, in responding to a rejection, described the controller to be "adapted to provide selectively modulated illumination to the illuminated LEDs." '189 application, Sept. 5, 2001 Amendment, at 12.

The Court agrees with the plaintiff. One of ordinary skill in the art would understand "modulated" to include drastic variations. Therefore, something "modulated" only needs to be "varied," and is not limited to an "incremental variation." Accordingly, "controller adapted to provide selectively modulated illumination to the illuminated LEDs/light sources" means "controller adapted to provide illumination whose intensity is selectively varied to illuminate LEDs/light sources."

III. Claim Term of "controller computer"

The Communication System in the '491 Patent requires a "controller computer." (491 Patent at Claims 1,40). Windy and AOL disagree as to how the term "controller computer" should be construed. (Mem. 13-17). Windy argues that the claim term "controller computer" should be construed to include "multiple computer devices." (Mem. 14-15). Specifically, Windy argues that the claim term "controller computer," as it is used in Claims 1 and 40 of the '491 Patent, should be construed as "one or more interconnected controller computer devices that control operations in the system." (Mem. 13). AOL, on the other hand, argues that the term "controller computer" should not be construed to include the generic term "computer devices." (Mem. 17-19). AOL contends that the '491 Patent specification supports the "existence of a single controller computer." (Mem. 18-20). Accordingly, AOL argues that the term "controller computer" should be construed as "a computer that connects each of the participator computers through the Internet and performs the arbitration and distribution of messages in the system." (Mem. 13)(emphasis added).

By the terms of the '491 Patent, in both Claims 1 and 40, it is entirely clear that the inventor of '491 Patent only required one controller computer in the Communication System. ('491 Patent at Claims 1, 40). For instance, in Claim 1 of the '491 Patent, the language states that the Communication System includes "a controller computer" and "a plurality of participator computers." ('491 Patent at Claim 1)(emphasis added). In addition, in Claim 40 of the '491 Patent, the language states that one of the steps required to operate the Communications System is to program "the controller computer to control communication of the messages between the participator computers." ('491 Patent at Claim 40)(emphasis added). Further,
since there is no language anywhere in the '491 Patent to indicate that the controller computer comprises more than one device, adding the terms "one or more interconnected controller computer devices" to define the term would do nothing to benefit the claim construction and only cause confusion. Therefore, the term "a controller computer" will be construed, according to its ordinary language and use in Claims 1 and 40, as "the computer programmed to perform certain functions in the Communication System."

In the Memorandum, AOL also requests that the court determine whether the controller computer "must perform the functions of 'connecting,' 'arbitrating,' and 'distributing.'" (Mem. 17-18). Windy argues that AOL's request for the court to determine whether the controller must perform such functions is "misplaced" because "the functional language AOL wants to add is not found in the 'controller computer' element." (Mem. 16). We agree with AOL and find that it is not necessary, for purposes of the instant claim construction, to determine what functions the controller computer "must" perform in the Communication System. (Mem. 17-18). Accordingly, we decline to include a determination of whether the controller computer must perform the functions of "connecting," "arbitrating," and "distributing" in the instant claim construction.

8. "A controller, coupled to the visual display, for automatically determining when the terrain information is displayed on the visual display" 60

--- Footnotes ---

60 This construction applies to Claim 1 of the '060 Patent.

Honeywell argues that this claim is not written in means plus function format, and that "controller" and "automatically" should be given their plain and ordinary meaning. Again, Honeywell cites various dictionaries in support of its proposed construction. Further, Honeywell asserts that one skilled in the art would recognize the controller structure, and that contrary to defendants' assertions, "controller" does not lack a specific structure.

Sandel asserts that controller has no recognized meaning or structure in the art, noting that the only definition of controller in the aviation industry is an air-traffic controller. Additionally, Sandel argues that the term is vague and could include any number of things.

Universal asserts that the patent fails to set forth a definitive structure, so it should be limited to the controller described in the specification. The "controller" described in the specification is a computer program that corresponds to a switch.

Because the claim does not contain the term "means" it is presumed that this is not a means-plus-function claim. Therefore, it is the defendants' burden to show that Honeywell failed to show a "sufficient" structure. Once again, it is necessary for the court to evaluate the parties' arguments in light of the context of the patented invention. Honeywell claimed a system which automatically displayed the terrain information, without any action on the part of the pilot. Thus, although Sandel may be technically correct in asserting that a "controller" may be a director of air traffic, it is clear that this is not the case in the
context of the '060 patent. From reading the patent, Honeywell's description of "controller" would be clear to someone skilled in the art, as a device which governs when something else moves, acts or happens. Here, the controller governs when the terrain information will display to the pilot. Honeywell's description is sufficient to describe the structure, and thus, the court adopts its proposed construction.

The court adopts Philips' definition. Defibtech correctly notes that in many instances, the inventors described their "invention" (as opposed to an embodiment) as "provid[ing] a defibrillator method and apparatus for adjusting the characteristics of the defibrillator waveform in response to a real-time measurement of a patient-dependent electrical parameter." 927 Patent at 5:56-58. Defibtech does not, however, point to a single instance in which the term "controlling" or "controller" is employed inconsistently with this description of the invention. In the claims, the language surrounding the term "controller" or "controlling" is uniformly consistent with this object of the invention. E.g., 927 Patent Claim 1 ("controlling duration of the truncated exponential biphasic waveform"), Claim 6 ("a controller operating the connecting mechanism to deliver electrical energy . . ."); 454 Patent Claim 3 ("controlling the duration of a waveform phase based on a value of the electrical parameter"). Thus, Defibtech's proposed definition is surplusage. The claim language places limitations on "controlling" or the "controller" that are consistent with the purpose of the invention. There is no need for the definitions of "controller" and "controlling" to contain those limitations.

controlling a computer

Claims 1-18 contain the term "controlling a computer" in the preamble. Accolade contends that the body of the claim sets out the complete invention, and the preamble does not constitute or explain a claim limitation and therefore should not be construed. Alternatively, Accolade argues that "controlling a computer" means "providing input to a computer." Citrix contends that the term means "taking over the entire functionality of a host computer," and alternatively, "taking over all of the functionality of a host computer that can be controlled by a mouse or keyboard." The parties dispute whether "controlling a computer" is a limitation even though it is found only in the preamble, and if it is a limitation; whether the term limits the claimed invention to taking over all of the functionality of a computer; whether "controlling a computer" is accomplished only by a mouse or keyboard; and whether "a computer" is the "host computer." The Court construes "controlling a computer" as "taking over the functionality of the host computer that is responsive to an input device event received from a client computer."

The parties dispute whether "controlling a computer" in the preamble is a limitation. "Clear reliance on the preamble during prosecution to distinguish the claimed invention from the prior art transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention." Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808-9 (Fed. Cir. 2002) (citations omitted). On several occasions, the applicant relied on "controlling" a computer to distinguish the claimed invention from the prior art. See Defs.' Br., Ex. 11 (8-13-01 Amendment C), 7; Defs.' Br., Ex. 15 (2-25-04 Amendment E), 9; Defs.' Br., Ex. 13 (6-18-02 Amendment D), 6. In each of these amendments, the applicant distinguished the claimed invention from the prior art by referring to the claimed invention's characteristic of controlling a host computer. 2 Accordingly, "controlling a computer" is a limitation.
"Frese teaches a method for remotely controlling an application program over a network. It does not allow for the remote control of a computer system [sic] a network as does Applicant's invention." Defs.' Br., Ex. 11 (8-13-01 Amendment C), 7.

"Frese uses a downloaded client program and a network browser program, but only to control a specific demonstration program running on a host computer. As such, it does not take over the functionality of the host computer, but simply runs a demonstration copy of an application program being offered for sale. Claim 1, as amended, specifies that the client program that is run in conjunction with the browser program encrypts the event data of the client computer and decrypts encrypted image information set by a host computer." Defs.' Br., Ex. 15 (2-25-04 Amendment E), 9.

"It is therefore very clear that Doyle does not teach the [sic] control the basic functionality of a host computer but, rather, specific applications running on remote computers." Defs.' Br., Ex. 13 (6-18-02 Amendment D), 6.

"Furthermore, the invention of Popp is very similar to that of Doyle in that it only allows the access of application programs on remote computers, rather than controlling the basic functionality of the computers." Id.

However, Citrix's construction creates limitations that are not supported by the intrinsic record. Citrix asserts that "controlling a computer" means that the "entire functionality," or in the alternative, "all of the functionality" of a host computer is controlled. Neither the patent nor the prosecution history suggest that the claims cover only situations where all of the functionality of the host computer is controlled. The prosecution history distinguishes the prior art stating only that "[Frese] does not allow for the remote control of a computer system," "[Frese] does not take over the functionality of the host computer," "Doyle does not teach the control the basic functionality of a host computer," and "[Popp] only allows the access of application programs on remote computers, rather than controlling the basic functionality of the computers." Defs.' Br., Ex. 11 (8-13-01 Amendment C), 7; Defs.' Br., Ex. 15 (2-25-04 Amendment E), 9; Defs.' Br., Ex. 13 (6-18-02 Amendment D), 6. The most limiting of these statements, "take over the functionality" and "control the basic functionality," do not require "taking over all of the functionality." Thus, Citrix's construction is too limiting as unsupported by the intrinsic record.

Citrix also proposes that "controlling a computer" is accomplished "by a mouse or keyboard." However, adding "keyboard" to the Court's construction would be repetitive of what is already in the claim. Claim 1 already states, "a client computer coupled to said TCP/IP protocol network, said client computer having a monitor, a keyboard, and a pointing device." Col 13:44-46. In regards to adding "a mouse" to the Court's construction, intrinsic evidence gives a broader meaning to "controlling a computer" than Citrix proposes. The patent uses the language, "a pointing device," in claim 1, Col. 13:46, and references to "a mouse" in the specification are only exemplary. 3 Thus, the intrinsic record does not support limiting the invention to a mouse, and the Court does not include "a mouse" in its construction. 4

3 See, e.g., Col. 3:43-46 ("Alternatively, the client computer can be used to both monitor the screen of the host computer and to provide inputs to the host computer via a keyboard, mouse, or other input device") (emphasis added); see, e.g., Col. 5:34-37 ("Each of the computer systems 14-18 typically include . . . , a keyboard, and a "pointing" device such as a mouse") (emphasis added); see, e.g., Col. 10:38-43 ("a client computer can 'control operations' of the host computer as if the keyboard, mouse, etc. of the client computer were directly coupled to the host computer. Of course, keyboards and mice . . . are just two instances of input devices") (emphasis added).

4 While claim 1 does not require a mouse, it does require a keyboard because "having . . . a keyboard" is expressly stated in the claim, and the Court does not read out this aspect of the invention. However, the "comprising" language of claim 1 permits other input devices to be used with the invention in addition to a keyboard.
The parties also dispute whether "a computer" is the host computer. "A computer" in "controlling a computer" refers to the host computer as described in the intrinsic record. Claim 1 claims a client computer, which includes a monitor and an input device, and a host computer, which is capable of being accessed by the client computer and is in fact initially accessed by the client computer. See Col. 13:44-14:15. Claim 1 states, "said host computer running a host program that is responsive to said keyboard and said pointing device due to the event data in the event queue." Col. 13:64-66. The event data is transmitted by a client computer. See Col. 13:53-55. Also, the specification refers to the host computer as capable of being accessed/controlled. See Abstract; see Col. 6:23-25; see Col. 9:31-33. For instance, the Abstract explains that "[h]aving the host computer posted on a web page creates a 'virtual computer' that can be view [sic] and/or controlled by the client computers." Furthermore, the prosecution history is consistent with the claim language and specification, stating, "Doyle does not teach the control the basic functionality of a host computer but, rather, specific applications running on remote computers." Defs.' Br. (6-18-02 Amendment D), 6; see also n.2. While the applicant did not unequivocally limit "computer" to "a host computer" in distinguishing Doyle, the consistent references in the prosecution history, see n.2 supra, and throughout the patent to controlling a host computer support the limitation. Given the relationship between the host and client computers stated in claim 1 and the intrinsic record, the computer controlled is the host computer. Accordingly, the Court construes "controlling a computer" as "taking over the functionality of the host computer that is responsive to an input device event received from a client computer."

3. "CONTROLLING THE ROUTING OF THE STREAM OF PACKETS"

AOL: "Directing the specific path (selected from multiple paths) taken by a stream of packets. Is not mere transmission of a stream from point A to B."

TWM: "Influencing at least a portion of the routing path, selected from among possible multiple paths, taken by the stream of packets."

The question here is how much control is meant by the word "controlling." TWM argues that "controlling" the routing simply means fixing an intermediate point through which a data stream must pass--hence, "influencing" the routing. (D.E. 69, pg. 11). AOL's position is that using the word "influencing" as a substitute for the word "controlling" would allow TWM to broaden the claim's scope. (D.E. 68, pgs. 3-4).

A layperson probably would associate "control" with "directing" as opposed to "influencing." Influencing is not strong enough to capture the force of "controlling." However, the Court is mandated to act as an ordinary skilled person in the field. With that in mind, a study of the claim language and the specification reveals that TWM's argument is persuasive.

Specifically, the remainder of the claim states, "controlling the routing . . . in response to selection signals received from the users." An ordinary person in the computer networking field would know that a user cannot dictate the route on which packets travel on the Internet. Instead, a user can merely mandate that a packet go through a particular intermediate server. For example, if a user in Texas starts downloading music from a company's main server in New York, he has affected the travel of packets because the New York server will send information to an intermediate server in, for example, Oklahoma--not an intermediate server in, for example, Oregon. All the user has done is require the packet to go through Oklahoma; he has no control of how the packet travels from New York to Oklahoma or from Oklahoma to Texas. The packets may zig-zag up and down the East Coast before heading to Oklahoma--the user cannot control initial zig-zag travel.

Not only does the claim language buttress TWM's argument, but the specification aids as well. Specifically, the preferred embodiment (which is contained in the specification) describes the controlling-the-routing process in the same manner as described above. The specification states that users only affect packet routes by directing them to intermediates--they do not control the entire path the packets take to or from the intermediate servers.

AOL also argues that, because TWM disclaimed the proposal it now espouses at the PTO hearings, it can no longer argue it during litigation. AOL's recitation of law is correct. Essentially, once a party concedes a definition at the prosecution hearing
it can not revive it during litigation. See, e.g., Jonsson v. The Stanley Works, 903 F.2d 812, 817-18 (Fed. Cir. 1990).

However, the statement that AOL identifies does not manifest any contradiction by TWM. TWM's PTO statement--"it is clear that the mere act of transmitting a stream so that it goes from point A to point B does not qualify as 'controlling' the 'routing'"--is not inconsistent with its argument here. TWM's statement is a self-evident; of course the Internet's transmittal of packets from A to B does not qualify as controlling the routing. That statement does not address the issue of whether users' ability to route packets through intermediate servers constitutes control or influence of those servers.

TWM's use of the word "influencing" is not strong enough to express how powerful a user's selection is in shaping the paths' travel. The Court read the following construction of the "controlling the routing of the stream of packets" claim limitation from the bench at the July 19, 2007 hearing:

"directing a portion of the routing path selected from among the possible routing paths [taken by the stream of packets] to one or more intermediate computers located in specific geographic areas."

Having reviewed the parties' summary judgment motions and subsequently re-reviewed the parties' Markman submissions and the Markman hearing transcript, however, the Court has determined that the above construction needs revision. See Pfizer, Inc. v. Teva Pharms.USA, Inc., 429 F.3d 1364, 1377 (Fed. Cir. 2005) ("We . . . recognize that 'district courts may engage in rolling claim construction, in which the court revisits and alters its interpretation of the claim terms as its understanding of the technology evolves.'") (quoting Jack Guttman, Inc. v. Kopykake Enters., Inc., 302 F.3d 1352, 1361 (Fed. Cir. 2002)). Based on its review of the aforementioned materials, as well as additional review of the '187 and '005 Patent specification and claims, the Court proposes the following construction:

"directing a portion of the routing path taken by the stream of packets from one of a group of intermediate computers located in a specific geographic area to the user"

The Court invites both parties to submit objections and/or proposed alterations to this construction no later than Wednesday, August 15, 2007, at 5:00 PM. The objections and/or proposed alterations shall not exceed five pages in length.

5) "the network management system controlling when the video program is forwarded to the display unit for display" (claim 15)

Defendants argue that this term means "the network management system determines the specific time at which the video program is forwarded and displayed at the display unit of each of the receiving sites." In support of their position, Defendants cite to the specification and an exchange in the prosecution history. STV Asia argues that this term needs no further construction beyond that which is required for the term "network management system" and further objects to Defendants' proposed construction to the extent it limits the term to a "specific time." According to STV Asia, this limitation is not supported by the specification and results in an overly narrow construction of the word "when." In particular, STV Asia asserts that requiring that "when" mean a "specific time" is inconsistent with the "wheel" concept that is described in the specification. The Court concludes that Defendants have the stronger position.

Defendants assert that their proposed construction is consistent with both the ordinary meaning of the word "when" and the specification. In particular, Defendants cite the Merriam Webster dictionary, which defines "when" as "a: at or during the time that: WHILE <went fishing he was a boy> b: just at the moment that <stop writing the bell rings>." They also quote the specification, which explains that one of the benefits of the invention is its ability to "more efficiently tailor its commercial messages to particular chains, stores, times of day and geographic regions." '069 patent, col. 3, ll. 36-40.

STV Asia argues that "when" doesn't mean a specific time because that construction is inconsistent with the wheel system described in the specification. Yet it is not clear why use of a wheel system would be inconsistent with Defendants' proposed construction. The specification describes the wheel system as follows:

A "wheel" concept is used to handle the high volume of commercials and other programs which are displayed in the stores. A wheel is a cycle of time that represents the format of what will be shown on the television in the stores. For
example, if the wheel cycle is three hours, then every three hours the display would repeat itself. The network management system provides the cycling needed for this wheel concept. Multiple wheels per day allow the system to establish playlists for the entire day. Additionally, the wheel format simplifies the contract, invoicing and billing required because these can be initially based on the original wheel(s) and later changed based on the actual number of plays. Rates may be sold and set by the wheels.

'069 patent, col. 9, l. 64 - col. 10, l. 9. Given that the network management system itself creates the playlists and determines the length and content of the wheels, nothing in the above description suggests that the network management system's use of the wheel system is inconsistent with Defendants' proposed construction. To the contrary, it is apparent that the network management system does control the specific time at which video programs are forwarded to the display units.

The Court construes this claim term as follows: "the network management system determines the specific time or times at which the video program is forwarded and displayed at the display unit of each of the receiving sites."

E-Watch initially proposed "a sensor which outputs information in a format other than the Internet Protocol." March Networks suggested "a sensor that detects a predetermined event and which outputs data in a protocol other than an IP network protocol."

At the hearing the parties agreed to the following definition which, for the reasons stated on the record, is adopted by the court:

"A conventional security sensor" means: "a sensor that outputs a signal or information in a format other than an Internet Protocol."

1. Convergence criterion based upon a partition size

<table>

<td>Partition size</td>
<td>Number of cells in a partition or the total area of cells in a partition</td>
<td>Number of cells contained in a partition</td>
</tr>
</tbody>
</table>

The phrase "establishing a convergence criterion based upon a partition size" appears in claims 1, 6, and 11 of the '114 patent. For example, claim 1 states:

In the design of integrated circuits, a computer controlled method for placing cells in a placement area, comprising: generating a netlist through a synthesis process; establishing a convergence criterion based upon a partition size; executing a cell separation process according to the netlist; changing the netlist in response to how the cells are placed; modifying the
The example in the specification suggests, nonetheless, that the convergence criterion is intended to be a condition which, in the specific example discussed in the specification, and no party argues for such a limitation.

In the preferred embodiment of the invention, a five-step process occurs during the "rough placement process." (See id. at 3:8-15, 3:47.) The five steps are (1) cell separation, (2) changing the netlist, (3) changing the spacings, (4) partitioning the cells, and (5) determining whether the then-current placement "has successfully converged." (See id. at 3:14-61.) In the fourth step, according to the specification, "[p]artitioning refers to the process of subdividing the cells in order to better 'spread' them apart." (See id. at 3:48-49.) In step four, "the partitions are defined"; then, in step five, "a determination is made as to whether the current placement has successfully converged." (See id. at 3:47, 3:52-54.) In the preferred embodiment, convergence is achieved when each of the partitions reaches a pre-determined size. For example, the user can set the convergence point to occur whenever each of the partitions is comprised of less than twenty gates.

(See id. at 3:54-57.) If convergence has not been reached, the first four steps are repeated. (See id. at 3:57-58.) "Otherwise, once convergence has been achieved, the detailed placement and route process is performed to complete the physical layout." (See id. at 3:59-61.)

Although the description of the preferred embodiment cited above describes the size of the partitions by reference to the number of gates or cells contained therein, nothing in the specification requires partitions to be measured in that manner. See Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331 at *15 ("[A]lthough the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments.") Indeed, the claims demonstrate that measuring the size of the partitions by reference to the number of cells contained therein is only one method of measuring the size of the partitions. In particular, independent claim 1 states that the convergence criterion is "based upon a partition size," without stating any particular method of determining partition size; the only difference between independent claim 1 and dependent claim 5 is that in claim 5, "the partition size is measured by the number of gates contained therein." (Compare '114 Patent at 6:56-7:3 (claim 1) with id. at 7:11-12 (claim 5).) Under the doctrine of claim differentiation, "different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope," and the doctrine "is at its strongest where the limitation sought to be read into an independent claim already appears in a dependent claim." See Seachange Int'l, Inc. v. C-Cor, Inc., 413 F.3d at 1368-69 (internal quotations and citations omitted). Were the Court to adopt Magma's proposed construction, claim 1 and claim 5 would be identical.

Moreover, the specification states that the number of cells in each partition is "approximately the same" and the area of each partition "is proportional to the area of the cells included in it." (See '114 Patent at 4:45-47.) As the '114 patent expressly notes that the sizes of cells may be changed, (see id. at 3:21-22), there can be no assumption that all cells are the same size. Consequently, there is no way to ensure that the area of the partition is "proportional to the area of the cells included in it" without, in fact, measuring the size of the partition by reference to the area of the cells. Consequently, Synopsys's proposed construction of "partition size" as being measured by either the "number of cells in a partition or the total area of cells in a partition" is supported by the specification and the Court will adopt that construction.

With respect to "convergence criterion," the specification states that, in the preferred embodiment, "convergence" is reached once the partitions reach a specified size. (See id. at 3:54-55.) Thus, in that example, the "convergence criterion" is the specified size of the partitions. In the preferred embodiment, the purpose of the "convergence criterion" is to determine when to perform "the detailed placement and route process . . . to complete the physical layout," (see id. at 3:59-61); the specification notes, however, that the invention "can be applied to any one of several phases associated with the physical route and placement of an IC design," (see id. at 3:8-10). Thus, it is clear that "convergence criterion" is not limited to the specific example discussed in the specification, and no party argues for such a limitation.

The example in the specification suggests, nonetheless, that the convergence criterion is intended to be a condition which,
when achieved, triggers the next step in the process. In the example set forth in the specification, once the steps of (1) "cell separation," (2) "tweak[ing]" the netlist, (3) "changing the spacings," and (4) "partitioning" the cells, are completed, "a determination is made as to whether the current placement has successfully converged," i.e., whether the partitions have reached the desired size. (See id. at 3:14-55.) If so, "the detailed placement and route process is performed to complete the physical layout"; if not, the first four steps are repeated until the partitions reach the desired size, i.e., the "convergence criterion." (See id. at 3:57-61.)

Magma argues that the term "convergence criterion" can only apply to an iterative process, i.e., a process that repeats until a desired result is reached. Magma's expert, Majid Sarrafzadeh, Ph.D. ("Dr. Sarrafzadeh"), attests that "the phrase 'convergence criteria' . . . necessarily refers to an iterative process" and not to a "direct process that is designed to solve the problem in one pass (i.e., in a known number of steps)." (See Sarrafzadeh Decl. PP 21-22.) Dr. Sarrafzadeh characterizes "optimization methods," such as the process of "arranging transistors in a computer chip so that the resulting layout occupies the smallest area and uses the smallest number of components," as either "direct" or "iterative." (See id. at PP 17-18.) According to Dr. Sarrafzadeh, "direct" methods are those that "produce an answer in a fixed number of computational steps," while "iterative" methods are those that "produce a sequence of approximate answers, designed to converge ever closer to an optimal solution under the proper conditions." (See id. at P 18.) An "iterative process," Dr. Sarrafzadeh attests, consists of "a sequence of steps that is repeated, or iterated, until some specified result is achieved." (See id. at P 20.) Dr. Sarrafzadeh further attests that the "rate at which an iterative process gets closer to the desired end result is called the 'convergence rate'". (See id. P 20.) Where iterative processes are used to address complex problems, Dr. Sarrafzadeh attests, there is no guarantee that the optimal point will be found in an acceptable amount of time; consequently, a "termination constraint" or "convergence criterion" must be set so that the process "will terminate when it generates an intermediate result that is close enough to the optimal point." (See id.)

According to Dr. Sarrafzadeh, a "direct process," by contrast, "does not make small improvements to the answer gradually with the goal of converging on the desired result." (See id. P 22.) Rather, Dr. Sarrafzadeh attests, a "direct process is designed to run through a known set of steps once and produce the result generated at the end of the entire process" and "[o]nly at the end of execution of the algorithm can the output be realized." (See id. P 22.) Thus, in Dr. Sarrafzadeh's opinion, "there can be no concept of establishing criteria to identify when an intermediate result has come close enough to the desired result so that the process should be terminated" and "there is no concept of convergence criteria for a direct or non-iterative process." (See id. P 23.) Further, according to Dr. Sarrafzadeh, "a person of ordinary skill in the art would have used the term 'convergence' only to refer to an iterative method, and the term 'convergence criteria' to refer to conditions for terminating an iterative process." (See id. P 29.) Dr. Sarrafzadeh notes that the "Summary of the Invention" section of the '114 patent expressly states that "[a] number of iterations of cell separation, synthesis of new netlist, size adjustment (if necessary), spacing, and partitioning are performed until the cells converge." (See '114 Patent at 2:25-28.) The specification, Dr. Sarrafzadeh notes, also describes the act of partitioning as an iterative process:

The cells are partitioned first into two groups, then into four, then into eight, and so on, until there are only a few cells in each group . . . If each of these partitions . . . is small enough to meet a particular criteria set by the user, convergence is declared.

(See id. at 4:41-43, 4:52-53.) Dr. Sarrafzadeh thus concludes that the "convergence criteria" must be defined as referring to "conditions for terminating an iterative process." (See Sarrafzadeh Decl. P 29.)

Synopsys's expert, Dr. Harris, recognizes that the inventors of the '114 patent explained to the PTO that the significance of their invention was that "the overall number of iterations required for the design of integrated circuits is minimized." (See Harris Decl. P 125 and Ex. Y at 6.) Dr. Harris argues, however, that there is no requirement in the '114 patent that the iterative process described in the '114 patent be performed more than once because, ideally, if the convergence criterion is met after the first iteration, there is no need to repeat the process. (See id. PP 126-128.) Although the Court agrees that there is no requirement that the process actually repeat before the convergence criterion is met, the process itself is still iterative in that it is designed to repeat until the convergence criterion is met. (See, e.g., '114 Patent at 3:57-58 ("If convergence has not been reached, steps 103-106 are repeated.").)

For the reasons set forth above, the Court will adopt Synopsys's proposed construction of "partition size" and Magma's proposed construction of "convergence criterion." Accordingly, the Court will construe "convergence criterion based upon a partition size" as "condition for terminating an iterative process based on the number of cells contained in a partition or the
total area of cells in a partition." For clarity, the Court will define "iterative process" as "a sequence of steps that is intended to be repeated until some specified result is achieved." (See Harris Decl. P 104; Sarrafzadeh Decl. P 20.)

1. The Term "Conversation Set"

The "Uniform Control Template Generating System and Method for Process Control Programming" relates to process monitoring and control systems in the automation of industrial processes. The control system provides multiple "views" by which employees at different stations along the process monitoring path, and having different assignments within an industrial plant, may monitor assigned aspects of a particular process. The system also permits employees at the various assigned stations to adjust the industrial process peculiar to their needs through local interaction.

Fisher-Rosemount has submitted a glossary listing proposed construction of various terms. One of the terms that appears in its glossary and that is used in both the dependent claims and the independent claims is the term "conversation-set." Claims 40 and 41 do not contain the "conversation-set" limitation and are not addressed in this discussion. The sole term for which significant dispute remains between the parties then is the term "conversation-set". As observed earlier, CSI does not dispute that other proposed constructions in the '858 patent glossary are based on the usage of the terms consistent with the claims.

Each independent claim describes the role of "conversation-set" as follows:

A 'conversation-set' associated with the process control function information and the attribute information which enables a user to interact with the attribute information in a manner specified by a selected control template view.

The specification describes "conversation-set" as defining the " . . . users interactions . . . [that] include definitions of soft keys, windows, fields, and the like, which enable the user to communicate with the template and insert new attribute values or modify old ones in the function." Fisher-Rosemount argues that the correct construction of "conversation-set" is "a system's interaction with a user" whereby the "conversation-set" defines and structures that interaction in a manner such as a dialog." See [Expert Report, Prof. Thomas Edgar]. Professor Edgar limits "conversation-set" to interactions associated with a process control function that affect all screen display views of the process control function. He goes on to describe "conversation-set" as dynamic and, therefore, customized so that it associates with customized control templates. Hence, the process monitoring and control system operates from a "plurality of conversation-sets."

CSI presents two contentions in rebuttal to Fisher-Rosemount's claim that '858 patent invents something new. First, CSI asserts that a number of disclosures in the prior art disclose "conversations" and "conversation-set" because the prior art discloses both the "dialog box" for user interaction and the structured interaction. CSI cites prior disclosures, such as the X11 and Windows 3.0 as examples of concepts that are well understood by one of ordinary skill in the art and that they were understood as such at the time that Fisher-Rosemount filed the '858 patent.

As its second assertion, CSI argues that the term "conversation-set" is not amenable to a proper construction. Therefore, CSI argues that because the term is not amenable to construction, it is hopelessly indefinite and fails due to the "law of indefiniteness." To demonstrate its indefiniteness claim, CSI questioned several of Fisher-Rosemount's witnesses concerning whether they understood the term "conversation-set." In all instances, CSI contends it was told that the term or related terms have no meaning that is attributed to them.

Professor Ananth Grama, CSI's expert, offered his opinion that "a "conversation-set" was a structured, user interaction with a control system with the objective of manipulating attribute information. Further, he opined that this method of interaction is consistent with the specification associated with the selected control template view." Based on this testimony, Fisher-Rosemount argues that Professor Grama's opinion is consistent with that of Professor Edgar's and represents a proper construction of the term, albeit a more limited construction. The evidence further shows that Professor Grama would limit the field of "persons of ordinary skill in the art" to those who also have a degree in Computer Science because the '858 patent deals with software development.

(2) Conclusion -- "Conversation Set" '858 Patent
The Court is of the opinion that CSI's claim of indefiniteness fails. As a first point, the Court returns to Professor Grama's opinion concerning the meaning of the term "conversation-set." Professor Grama's argument is clear, "conversation-set" is associated with the data type(s) that insure that attribute information (data) is manipulated in particular ways. For example, a real value attribute is never assigned a Boolean value. Nor are pre-specified bounds of a real value exceeded. Hence, the Court concludes that CSI's assertion, that the term "conversation-set" is insolubly ambiguous and not amenable to construction, fails. CSI's indefiniteness argument also fails because the inventor assigned a meaning to the term "conversation-set" that governs. See Phillips, 415 F.3d at 1316. Moreover, that assigned meaning is consistent with its use in the specification. See Ballard Med. Prods., 268 F.3d at 1359.

CSI's assertion that the '858 patent fails to invent, because the term "conversation-set" is disclosed in the prior art also fails. CSI argues that because both the use of the dialog box for user interaction and the structured interaction are disclosed nothing new is invented. In its papers, CSI and Professor Grama reference the disclosure of the X11 and Windows 3.0, as examples. These examples do not advance their argument because XII and Windows 3.0 are associated with software programs for functions unrelated to a "control system" associated with the automation of an industrial process. Without doubt, the invention uses the science of the computerized system that uses control templates or screens so that functions and alterations may be viewed. However, the '858 patent does not seek to invent a computerized system. Instead, it utilizes a computerized system to invent a "process control system."

There is yet another reason that the term "conversation-set" is not disclosed by the prior art. CSI's expert, Professor Grama testified that it is not disclosed. Specifically, he testified that the term "conversation-set" "is not defined in prior art and is not understood by one of ordinary skill." He then goes on, in his testimony, to define the term, with limited exception(s), consistent with the definition adopted by Professor Edgar's.

Finally, the evidence proffered by Fisher-Rosemount reveals that during the prosecution, the patent examiner and the inventor discussed the term "conversation-set." In this interview, the summary documents of the patent prosecution reveal the following comment from the patent examiner:

Inventor discussed the conversation set feature in detail, and Examiner agreed that said feature, along with the automatic generation of control templates, appears novel.

There is no separate evidence proffered by CSI that the claim term is ambiguous or indefinite, therefore, the Court concludes that no factual ambiguity exists. Markman, 52 F.3d at 986. The Court, therefore, adopts the construction proposed by Fisher-Rosemount and defines the term "conversation-set" as a system's interaction with a user which exchange defines and structures that interaction in a manner such as a dialog box.
that the district court ever explicitly construed this limitation. The court did conclude, however, that a MONSTR STR was a type of conversation. See Action Techs., 1997 WL 337577, at *4. The court reasoned that an STR conversation consisted of an exchange of communications regarding a particular software problem and that the course of the STR conversation was governed by a protocol. See id.

In challenging the district court's ruling, Action Tech argues that the term "type," as used in the '603 patent, refers only to the universally-applicable, generic categories of conversation types described in the patent's specification: conversations for action (CFA), and conversations for possibilities (CFP). See '603 patent, col. 7, l. 47 to col. 8, l. 33. According to Action Tech, the invention of the '603 patent requires a system that "structures communications according to generic conversation types regardless of specific subject matter." Action Tech asserts that this limitation is not met in MONSTR because MONSTR does not use either a CFA or a CFP conversation type. Novell responds that the patent does not attach any special meaning to the term "type" and that the ordinary meaning of the term therefore should apply. Thus, Novell contends, MONSTR anticipates claim 1 because it embodies a type of conversation.

The specification does provide support for the argument that the disclosed system uses the two generic conversation types. See '603 patent, col. 3, ll. 59-62 (noting that the invention performs the step of "defining all communications between a set of participants as moves in conversations for declaring specific realizable possibilities or as moves in conversations for producing actions to complete specific possibilities."). However, claim terms are generally given their ordinary meaning unless it appears from the specification or file prosecution history that they were used differently by the inventor. See Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1577, 27 U.S.P.Q.2D (BNA) 1836, 1840 (Fed. Cir. 1993). When an inventor chooses to give terms an uncommon meaning, he must set out his specialized definition in a manner sufficient to give one of ordinary skill in the art notice of the uncommon meaning. See Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387-88, 21 U.S.P.Q.2D (BNA) 1383, 1386 (Fed. Cir. 1992). The specification for the '603 patent does not indicate that the term "type" is limited to only CFA and CFP. Indeed, the specification refutes Action Tech's argument when it states:

The method of this invention contemplates general purpose embodiments which involve standard sets of permitted moves and special purpose embodiments in which customized sets of permitted moves are defined to achieve special purpose conversations within a particular organization.

'603 patent, col. 9, ll. 51-56. Moreover, it is improper to import an extraneous limitation from the specification into the claim. See E.I. DuPont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, 7 U.S.P.Q.2D (BNA) 1129, 1131 (Fed. Cir. 1988). In our view, "type" should be given its ordinary meaning, which is "a kind, class, or group having distinguishing characteristics in common." Webster's New World Dictionary 1446 (3d College ed. 1994). Accordingly, we construe the term "conversation type" in claim 1 to mean an exchange of communications possessing a shared set of distinguishing characteristics.

In view of the above claim construction, no reasonable juror could conclude that an STR in MONSTR was not a "conversation type." Each STR concerns software bugs and each STR is governed by the same protocol. All STR conversations share these same distinguishing characteristics, and therefore, an STR conversation is a conversation type.

GO BACK

6. The '141 Patent

United States Patent No. 5,970,141 is a continuation of the '245 and '704 patents; broadly speaking, the patent discloses a means for converting words into text. The parties' disagreement on this patent concerns claims 4 and 6, which depend from claim 1. The relevant claims read as follows:

1. A transcription network utilized during a testimonial proceeding, the transcription network comprising:

   an attorney terminal;

   a converter assisting in the conversion of spoken words to text;
a remote terminal disposed at a location remote from the attorney terminal and the converter;
the converter delivering the text to the attorney terminal and to the remote terminal for real time display; and
the remote terminal supporting communication of messages regarding the real time display to the attorney terminal.

* * *

4. The transcription network of claim 1 wherein the messages are associated with portions of the text.

* * *

6. The transcription network of claim 1 further comprising an additional terminal communicatively coupled to the converter but not communicatively coupled to attorney terminal.

The parties dispute the meaning of the word "converter." Engate contends that converter can mean anything used by the CAT system to convert digital coded signals representative of verbal communications to alphabetic and numeric text. The defendants, on the other hand, contend that converter means "voice recognition software and/or hardware in the form of an A/D converter board run on a computer and connected to a microphone." Defendants' Brief, p. 15. Construing these claims to read on a network wherein the converter is a stenographic system, the defendants argue, would render claim 8 redundant. Claim 8 reads as follows:

8. A transcription network utilized during a testimonial proceeding, the transcription network comprising:

an attorney terminal;

a stenographic system assisting in the conversion of spoken words to text and in the characterization of at least portions of the text as questions and answers;

a remote terminal disposed at a location remote from the attorney terminal and the stenographic system;

at least one communication link; and

the stenographic system delivering the text for real time display at the attorney terminal and at the remote terminal via the at least one communication link.

U.S. Patent No. 5,970,141, col. 32, lines 6-17.

Even if the Court were to agree that defining "converter" to include a stenographic system renders this claim redundant -- and the additional elements of claim 8 suggest that this may not necessarily be the case -- this argument would not justify limiting "converter" to voice recognition software and hardware; at best, under defendants' theory, the word converter should be construed to mean anything, other than a stenographic system, that converts signals to text.

The defendants argue that because the specification uses "converter" to mean only voice recognition software, we should limit the term to that meaning; at the January 3 hearing they cited Scimed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337 (Fed. Cir. 2001), to support their position. The cases coming out of the Federal Circuit instruct that we must construe claims in light of the specification, but that we must never read limitations from the specification into the claims. See Advanced Cardiovascular Systems, Inc. v. Scimed Life Systems, Inc., 261 F.3d 1329, 1338 (2001). "It is the claims that measure the invention." SRI International, 775 F.2d at 1121 (emphasis in original). In Scimed, the case cited by the defendants, the court limited the claims of the patent-in-suit because the language of the specification expressly disavowed a broader interpretation: the court held that the claims read only on catheters having coaxial -- as opposed to dual -- lumens not only because those were the only lumens mentioned in the specification, but also because the patents
distinguished the prior art on the basis of the lumen type, and the specification expressly stated that the description governed "all embodiments of the present invention contemplated and disclosed herein . . . ." Scimed, 242 F.3d at 1343-44. In other words, the patentee in Scimed "clearly disclaimed subject matter that, absent the disclaimer, could have been considered to fall within the scope of the claim language." Id. at 1344. That is not the case here. It is true that, for the most part, the specification addresses an embodiment where the "converter" is the stenographic system. And the one alternative embodiment discussed is a setup where the "converter" involves voice recognition software. But the patentee did not limit the patented invention to those embodiments; on the contrary, the patentee stated that the voice recognition setup is "an alternate embodiment" -- not the alternate embodiment. U.S. Patent No. 5,970,141, col. 7, line 49. And, in marked contrast to the Scimed patent, the '141 patent wraps up with a statement that additional embodiments are not disclaimed: "Additionally, it is obvious that the embodiments of the present invention described hereinabove are merely illustrative and that other modifications and adaptations may be made without departing from the scope of the appended claims." Id., col. 31, lines 36-40. In short, the '141 patent did not expressly disclaim converters other than voice recognition software, and reading such a limitation into the claim would violate basic claim construction principles. Accordingly, we adopt Engate's construction of the "converter" element as used in claim 1 and dependent claims 4 and 6.

4. "converter for converting"

<table>
<thead>

<td>converter: &quot;a device that accepts data in one form or mode and changes it to another&quot; 35 U.S.C. § 112(6).</td>
<td>This element should be construed in accordance with</td>
</tr>
<tr>
<td>Alternatively, should the Court construe this element pursuant to 35 U.S.C. § 112(6):</td>
<td>Agreed Function: &quot;converting the first stream of data symbols into plural sets of N data symbols each&quot;</td>
</tr>
<tr>
<td>Agreed Function: &quot;converting the first stream of data symbols into plural sets of N data symbols each&quot;</td>
<td>Structure: Fig. 1 (item 10), Fig. 4 (item 10), and col. 4:1-2</td>
</tr>
<tr>
<td>Structure: i) element 10 in Fig. 1 including corresponding descriptions in the specification (col. 4:1-2 and 2:36-40); ii) element 10 in Fig. 4 including corresponding descriptions in the specification (col. 4:1-2 and 2:58-62); and equivalents thereof.</td>
<td></td>
</tr>
</tbody>
</table>

The parties dispute whether the "converter" terms should be construed under 35 U.S.C. § 112 P 6, and if so, further dispute the corresponding structure. The Court finds that, because the claim element "converter for converting..." does not use the word "means," there is a rebuttable presumption that § 112, P 6 does not apply. MIT, 462 F.3d at 1353-54. The Court finds that the Defendants have not met their burden to rebut the presumption. One of ordinary skill in the art would understand the term "converter" to recite sufficient structure and to have a reasonably well understood meaning. The term is not "simply a nonce word or a verbal construct that is not recognized as the name of structure." See Lighting World, 382 F.3d at 1359-60. The specification of the '802 patent describes the capabilities and uses of the converter. See '802 patent, 4:1-2; see also FIG. 1 (item 10). Wi-LAN has presented dictionary definitions for the term "converter" to mean "a device that accepts data in one form and converts it to another" and "a device capable of converter impulses from one mode to another, such as analog to digital, parallel to serial, or from one code to another." Consistent with these dictionary definitions, the Court finds that a person of ordinary skill understands that a "converter" has a generally understood structural meaning that, in general, means a device that accepts data in one form or mode and changes it to another. The claims expressly require that the converter convert a stream of data symbols into plural sets of data symbols. Consistent with the claims, Figure 1 of the '802
patent shows that the converter is a serial-to-parallel converter. The Court notes that the Defendants have not provided an alternative construction, and have not argued against Wi-LAN's proposed construction, if the term is not construed under § 112, P 6. Thus, the Court construes the term "converter" to mean "a device that accepts data symbols in one form or mode and changes the data symbols to another form or mode."

B. Converter Means

Converter means for converting includes any firmware, software, and/or hardware that functions to carry complimentary color control signals.

D. Converting

The term "converting" appears in claims 40 and 42. The use of the term in both claims is similar. Claim 40 reads: "Apparatus for producing a speech message comprising: … means for converting the plurality of pulse amplitude and location codes of said time interval into a signal representative of the excitation of the time interval portion of said speech message." ( '580 patent, Col. 23:25-26, 23:37-24:2) (emphasis added.) Claim 42 reads: "A method for producing a speech message comprising the steps of: … converting the plurality of pulse amplitude and location codes of said time interval into a signal representative of the excitation of the time interval portion of said speech message." ( '580 patent, Col. 24:13-15, 24:25-28) (emphasis added.) Microsoft proposes the definition "changing without the use of other values (such as 'pitch period' signals)," while AT&T argues the definition should read "changing or turning one thing into another." (Joint Letter, Ex. B.) In its Post-Hearing Brief, Microsoft also accepts the definition, "changing one thing into another without the use of other values (such as 'pitch period signals')." (Microsoft PHB at 15; Tr. at 127.)

The parties generally agree on the plain meaning of "converting," (Tr. at 123, 127; AT&T PHB at 14), but differ as to whether the term should include the limiting language "without the use of other values," as further elucidation of the word "changing." (Tr. at 128.) The parties agree that the plain meaning of "converting" to a lay person is "changing or turning one thing into another." (Tr. at 127-128.)

Webster's Dictionary defines "convert" as "to change or turn from one state to another; alter in form, substance, or quality." Webster's Third New Int'l Dictionary of the English Language Unabridged at 499 (G.&C. Merriam Co. 1981). Microsoft also cites to the technical dictionary definition of "convert" --"to transform the representation of data," and "converter" to mean one that "changes numerical formation from one form to another, as from decimal to binary …. " McGraw-Hill Dictionary of Scientific and Technical Terms at 360, 364 (3rd ed. McGraw-Hill, Inc. 1984).

This Court construes "converting" to mean "changing one thing into another." This definition to one skilled in the art is consistent with that term's use in claims 40 and 42, as well as in the specification, and coincides with both the technical and lay dictionary definitions. First, in one embodiment the specification describes that the speech signal from the microphone is "converted into a sequence of pulse samples in filter and sampler circuit 113." ( '580 patent, Col. 3:23-3:25.) See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1340-41 (Fed. Cir. 2001) (claims must be read in light of the specification); ATD Corp. v. Lydall, Inc., 159 F.3d 534, 540 (Fed. Cir. 1990) (same). "Varied use of a disputed term in the written description demonstrates the breadth of the term rather than providing a limited definition." Johnson Worldwide, 175 F.3d at 991 (citing Enercon GmbH v. Int'l Trade Comm'n, 151 F.3d 1376, 1385 (Fed. Cir. 1998)). The specification's use of "converted" relates to converting speech signals into speech samples, which is varied from the use of "converting" in claims 40 and 42. Accordingly, the Court declines to apply a narrow scope to the claim term. Johnson Worldwide, 175 F.3d at 991.

Second, both dictionary definitions are consistent with each other and the plain language of the claims. See Texas Digital Sys., 308 F.3d 1203. The technical and lay definitions both contemplate "converting" as a change from one form into
another, thus the Court's definition incorporates the plain meaning of the word as one skilled in the art would understand it as well.

Third, this Court recognizes the heavy presumption that the ordinary meaning of claim terms must apply. Pourchez, 2003 U.S. Dist. LEXIS 7934, 2003 WL 21220791, at *2 (citing cases); see also Inverness Med. Switzerland, 309 F.3d at 1369 ("It is well settled that dictionaries provide evidence of a claim term's 'ordinary meaning'.") (citations omitted). Microsoft's proposed language appears nowhere in the claims or in the specification, and thus will not be incorporated into the construction of the claim term. See Altiris, 318 F.3d at 1369-71; see also Pourchez, 2003 U.S. Dist. LEXIS 7934, 2003 WL 21220791, at *9 (declining to import party's limiting language that was unsupported by intrinsic evidence). Additionally, there are neither: (1) expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope, in the intrinsic evidence; nor (2) any evidence that the patentees acted as their own lexicographers and used this claim term in a manner other than its ordinary meaning. See Inverness Med. Switzerland, 309 F.3d at 1372.

The Court declines to further limit the construction of the term with Microsoft's proposed parenthetical "such as 'pitch period' signals." Microsoft argues that this limitation is derived from the prosecution history (Pros Hist. at 110-11), which provides a disclaimer of the claim's scope. The cited prosecution history, however, does not address the term "converting" or any converting steps. See Inverness Med. Switzerland, 309 F.3d at 1372 (finding no clear and ambiguous disclaimer of broader definition of claim term). Even assuming arguendo that the prosecution history contains a disavowal by the patentees, the patentee's Office Action response concerning original claims 1-39 cannot rise to the level of a disavowal of claim scope with respect to the term "converting," which only appears in reissue claims 40 and 42. See Laitram, 143 F.3d at 1460 n.3.

8. Converting Data Relating to a Selected Matching Item And An Associated Source To Data Relating To An Item And A Different Source

'683 Patent, Claims 28, 29

According to ePlus, this term does not need construction, but, if construed, should mean: a process of cross-referencing data relating to a selected matching item and an associated source to an item and a different source. Lawson proposes that the term mean: substituting a catalog entry related to a product with a catalog entry describing the product from a different source by using matching codes in a cross-reference table for sourcing and pricing.

a. Words of the Claim

Claim 28 of the '683 Patent claims a method comprising the steps:

    maintaining at least two product catalogs in a database containing data relating to items associated with the respective sources;

    selecting the product catalogs to search;

    searching for matching items among the selected product catalogs;

    building a requisition using data relating to selected matching items and their associated source(s);

    processing the requisition to generate one or more purchase orders for the selected matching items; and

    converting data relating to a selected matching item and an associated source to data relating to an item and a different source.

b. Specification

The most significant disagreement between the parties is whether the term "converting" means "cross-referencing" or "substituting." The specification provides that "an entry in a an inventory-sourced Requisition Management screen may indicate for a requisitioned item a vendor and vendor catalog number that has been changed, from what was obtained from a catalog search, to a corresponding vendor and vendor catalog number for that item from another source." '683 Patent at 14:38-44 (emphasis added). Appendix X provides an example of a part that is replaced by a corresponding part. The specification describes the Appendix message which "indicate[s] that a part number for line 001, identified as part number 53610, was successfully added in substitution for a prior part number…These messages were generated because the originally entered part ($100-06) did not exist in the Fisher catalog, but its corresponding part number…did exist in that other catalog." Id. at 16:19-27 (emphasis added). Thus, the specification provides support for Lawson's assertion that converting means substituting.

c. Prosecution History

The prosecution history states that the applicant clarified the claims that contain the "converting" step and the "amended language properly claims identical matching items from different sources, as well as a suitable replacement for the selected matching item." (Def. Ex. K at 14 (emphasis added).) This too supports Lawson's assertion that converting requires substitution with a suitable replacement.

d. Proper Construction

The specification and prosecution history demonstrate that "converting" means "substituting." Additionally, the word "convert" is defined as (1) to change from one form or function to another, (2) to alter for more effective utilization and (3) to exchange for an equivalent. Merriam-Webster Online Dictionary, http://www.merriam-webster.com/dictionary/convert, last visited April 7, 2010. Cross-referencing simply cannot accomplish conversion, as it is ordinarily defined, and is an inadequate construct of the claim term.

Finally, while Lawson is correct that "converting" requires more than mere "cross-referencing," it offers no support for its contention that conversion is accomplished using "catalog entries," "matching codes," or that the cross-reference table used is "for sourcing and pricing." Thus, this claim term means: "substituting data relating to a selected matching item and an associated source to data relating to an item and a different source."

B. "Converting said set of three dimensional coordinates into a set of two dimensional positions"

Claim 1 of the 406 patent claims:

A method of adding a graphic to a video representation of an environment, said method comprising the steps of:

(a) determining a set of three dimensional coordinates using information identifying a position in said environment and a three dimensional model of at least a portion of said environment, wherein said set of three dimensional coordinates corresponds to said position and includes at least one three dimensional coordinate not listed in said information;

(b) converting said set of three dimensional coordinates into a set of two dimensional positions in said video representation; and

(c) enhancing said video representation with said graphic in an area based on said set of two dimensional positions.

Sportvision contends the phrase should be construed as: "Mathematically converting the set of three data values that together identify a location into a set of two data values that together identify a position." (Sportvision's Memo at 19.)

SportsMEDIA proposes: "Mathematically converting the set of three dimensional real world space coordinates (x, y, z) into
The Court construes this phrase to mean: "Mathematically converting the set of three-dimensional coordinates (x, y, z) into a set of two-dimensional positions. The two-dimensional positions have x and y coordinates."

D. Construction of "converts the access as required for the register set and address assignment of the device."

The term at issue appears in Claim 1 as follows:

a UART emulation which in response to an access by the procedure for accessing the register set of a UART, converts the access as required for the register set and address assignment of the device

PCTEL submits that the term means, "converts the request for data from a hardware UART to a request for data from the register set and address assignment of the device." Agere contends that the term means, "chooses between accessing the registers of a hardware UART or the corresponding registers in the computer's memory."

According to PCTEL, the essence of the 305 patent is the translation of requests for data from the operating system, which is expecting a hardware UART to be present, to that of a non-UART device which is actually present. PCTEL argues that Agere's construction unduly limits the invention to systems which have a component which chooses between accessing the hardware UART registers and registers in the computer's memory. PCTEL points out that the presence of a hardware UART is optional according to the specification, thus undermining Agere's requirement that there be a component which makes such a choice. n9

n9 "Optionally, the system includes a standard device having a UART coupled to an I/O slot corresponding to a second COM port, and the COM driver contains routines for accessing the standard device." 305 Patent at 2:31-34.

PCTEL also cites the preferred embodiment, which, it argues, describes an invention closely aligned with its construction. The preferred embodiment describes a system which accesses storage in the computer's main memory in response to the operating system's request for UART data. n10 The system may have to translate the request for the particular device that is present, since each device might have its own special set of commands. According to PCTEL, the "as required" language refers to this conversion. Additionally, PCTEL argues that Agere's construction impermissibly limits the 305 invention to that which is described in the preferred embodiment section of the specification.

n10 "In one embodiment of the invention, a computer system includes a non-standard device and a COM driver for the non-standard device. The non-standard device connects to an I/O slot corresponding to a first COM port but has a register set which differs from the standard register set for a UART. The COM driver contains: a UART emulation which in response a procedure requesting access to a register of a UART at the first COM port, instead accesses storage locations in main memory of the computer system." 305 Patent, 2:20-8.
patent from the prior art by changing the words "UART emulation which . . . accesses storage locations in main memory" to the current language. Agere argues that reading the claims now to including accessing storage would expand the scope of the claim beyond what was disclaimed during the prosecution process. Finally, Agere argues that the phrase "request for data" in PCTEL's proposed construction involves a broader concept than the word "access" found in the claim terms, and would similarly enlarge the scope of the claim.

From the specification, it is clear that the system claimed by the 305 patent performs translation for non-UART devices for operating systems which are expecting UART hardware. Generally speaking, PCTEL's construction is closer to the plain meaning of the claim terms in light of the specification. However, Agere's objection that the phrase "request for data" is too broad is persuasive. Accordingly, the clearest reading of the disputed term "converts the access as required for the register set and address assignment of the device" is "converts the request for accessing the register set and address assignment of a UART to a request for accessing the register set and address assignment of the device."

GO BACK

978

"lexical co-occurrence" and "co-occurrence of words"

Claim 1 of the '819 Patent contains the term "lexical co-occurrence," and claims 1, 25, 27, 28, and 31 contain the term "co-occurrence of words." The parties disagree as to whether the term "lexical co-occurrence," located in the preamble to claim 1, is a limitation and thus, requires construction. A preamble is limiting if it includes the "essence of the invention," Boehringer Ingelheim Vetmedica, Inc. v. Schering-Plough Corp., 320 F.3d 1339, 1345 (Fed. Cir. 2003), or if it is necessary to "give life, meaning, and vitality" to the claim, Intirtool, Ltd. v. Texar Corp., 369 F.3d 1289, 1295-96 (Fed. Cir. 2004). The preamble specifies that the method of generating a thesaurus of words vectors is "based on lexical co-occurrence of words within documents." '819 Patent, col. 24:39-40. In addition, the specification indicates that "the invention determines the co-occurrence patterns of words in a document to form a thesaurus of word vectors." '819 Patent, col. 1:10-12. Accordingly, the term "lexical co-occurrence" gives life, meaning, and vitality to the body of the claim by describing how the "thesaurus" is generated and thus, is a limitation.

The parties agree that the terms "lexical co-occurrence" and "co-occurrence of words" should be consolidated and construed consistently. IPI contends that the terms mean: "Two or more words or terms which appear in text within some distance of each other. Two terms lexically co-occur if they appear in text within some distance of each other." Google contends that the term means "the appearance of two words within a specified range of each other." Further, the parties' proposed constructions differ only in the phrasing of the "distance" language--IPI contends the words appear "within some distance of each other," while Google contends that the words appear "within a specified range of each other."

Google argues that IPI's proposed construction, although taken from the specification, omits a critical clause which highlights the requirement that the distance between words be a "specified range" or window of predetermined size of words: "Two terms lexically co-occur if they appear in text within some distance of each other, i.e., a window of k words." '819 Patent, col. 4:29-31. IPI argues that "[t]he distance between the two words can, but need not, be a specified range of words." In support of its argument, IPI cites to Dimensions of Meaning, where the inventor stated that "co-occurrence can be defined with respect to window of a given size or on the basis of sentence boundaries." IPI's Opening Brief, Exhibit C, at 787, § 1, col. 2. In addition, IPI argues that Google's proposed construction reads in limitations from a claim 1 limitation, which states "recording a number of times a co-occurring word co-occurs in a same document within a predetermined range of the retrieved word." '819 Patent, col. 24:45-47 (emphasis added). IPI reasons that the "predetermined range" limitation in claim 1 should not be read as a limitation because "[l]ogically, words could co-occur within some distance outside of the predetermined range," even though "[t]he claim governs which co-occurring words are recorded, i.e., those within a predetermined range." IPI's Reply Brief, at 4.

Google's use of the phrase "specified range" is overly limiting with respect to the specification's disclosure of "a window of k words." '819 Patent, col. 4:29-31. Moreover, while IPI's use of the phrase "within some distance of each other" does not adhere to the specification's disclosure of "a window of k words," the second sentence of IPI's proposed construction approximates the boundary of a window of words. However, IPI's proposed construction is unnecessarily verbose. Thus, the Court rejects both parties' proposed constructions and construes the terms "lexical co-occurrence" and "co-occurrence of words" to mean "two words that appear in text within some distance of each other."
1. "Cooperating with said first optical filter element so as to form a band-pass optical filtering system"

Said second optical filter element cooperating with said first optical filter element so as to form a bandpass optical filtering system having a narrow wavelength bandwidth positioned about said predetermined wavelength, and passing laser light reflected off said code symbol and having wavelengths only within said narrow wavelength bandwidth;

'359 Patent, col. 11, l. 1-8. The parties dispute whether either of the two filters of patents '359 and '731 may exist as a bandpass filter by itself before cooperating with the second filter, as plaintiff argues, or whether neither of the two filters may exist separately and apart from each other before the cooperation gives rise to a narrow bandpass filter, as defendant argues. Plaintiff Metrologic argues that the "cooperating . . . so as to form a band pass optical filtering system" term of Limitation 12 should be construed in the following way:

Cooperate here means that the net bandpass optical filtering system should be the combination or cooperation of the light transmission characteristics of the two spatially separated optical filtering elements. Further, this cooperation must result in a narrow bandpass optical filtering system.

Pl.'s '359 & '731 Markman Br. at 18. Thus, plaintiff advances the position that the two filters may consist of band-pass filters which can exist independently prior to cooperation.

Defendant argues that the second filter cannot be a bandpass filter before the cooperation with the first filter. Defendant PSC counters that the term

"Cooperating . . . so as to form a band pass optical filtering system" should be construed to mean that the first and second filters act together to give rise to a narrow bandpass filter. The two filters must cooperate to create a narrow bandpass filter, which does not exist before this cooperation occurs.

Def.'s '359 & '731 Br. Mot. Partial Summ. J. at 25. 7 Thus, defendant urges the Court to construe this limitation to mean that neither of the two components may act as a band-pass optical filter independently of the other, prior to the cooperation in forming the filter system. For the following reasons, the Court finds defendant's construction to be correct.

7 In the context of its summary judgment motion, defendant PSC contends that the Duet and VS800 devices contain an internal bandpass filter that is capable of existing with or without the first optical filter element (the window), and that the presence of the window has no practical effect on the operation of the internal bandpass filter. See Def.'s '359 & '731 Br. Mot. Partial Summ. J. at 36.

Looking at the claim language, the language of claim 1, as it relates to the filters that "cooperate," includes the following limitations which refer to the first and second optical filter elements: 8

[A] first optical filter element installed over said light transmission aperture disposed along a laser light return path extending through said light transmission aperture, and having wavelength-selective filtering characteristics in the visible band, said first optical filter element functioning as a scanning window in said compact housing, and preventing light having wavelengths up to slightly below a predetermined wavelength in said visible band from passing from the outside of said compact housing, through said scanning window, and into said compact housing; . . .

'359 Patent, col. 10, ll. 30-40. The claim additionally describes the second filtering element as:
[A] second optical filter element, spatially separated from said first optical filter element, disposed along said laser light return path between said first optical filter element and said laser light detection means, and having wavelength-selective filtering characteristics in said visible band. . . .

'359 Patent, col. 10, l. 64-col. 11, l. 12. The claim language provides for the first filter to prevent light having wavelengths up to a predetermined wavelength, which indicates that the first filter may be a band-pass filter which blocks out ambient light on only one side of the visible spectrum. That the second filter is spatially separated from the first filter and has wavelength-selective characteristics in the visible band is not determinative of the issue whether the two filters must cooperate together before they can form a narrow band-pass filter.

--- Footnotes ---

8 PSC has disputed neither plaintiff's claim construction of these limitations 2-4 and 10-11, nor that the accused devices meet this limitation.

--- End Footnotes ---

Turning to the claim's specification, and focusing on it within the context of the invention, the Summary of the Present Invention provides for the first optical filter to transmit only light having wavelengths from below a predetermined wavelength and greater, whereas the second element is capable of transmitting light having wavelength from slightly above a predetermined wavelength and below:

The first optical filter element is installed over the light transmission aperture of the scanner housing, and has wavelength selective properties which transmit only light having wavelengths from slightly below a predetermined wavelength in the visible band of the electromagnetic spectrum (e.g., slightly below 670 nanometers and greater). The second optical filter element is installed within the housing, . . . , and transmits only light having wavelengths from slightly above the predetermined wavelength (e.g., slightly above 670 nanometers and greater [sic]). Collectively, the first and second optical filter elements cooperate to form a narrow wavelength band-pass filtering system centered about the predetermined wavelength . . . .

Other parts of the specification language also refer to the ability of the first filter element transmitting wavelengths of only slightly below 670 nanometers and greater, and the ability of the second filter element to transmit only wavelengths only slightly above 670 nanometers and below, to cooperate to form a narrow wavelength band-pass filtering system that rejects wavelengths outside this spectral band of scanned laser beam. Id. col. 3, ll. 25-35; id. col. 6, ll. 50-52; id. col. 8, ll. 49-53, id. col. 9, ll. 23-27.

Defendant relies upon Figure 3 of the patent, see '359 patent, Pl.'s App. Ex. 2, 9 which displays a transmission curve. This transmission curve, according to defendant, shows the cooperation between a high pass and a low pass filter. The graph indicates transmission of wavelengths of a high pass and low pass filter separate and apart from the combination of the two filters. The specification states that the graph is a schematic representation graphically illustrating how the spectral transmission characteristics of these spatially-separated optical filter system elements cooperate to produce a narrow-band optical filter system centered about the characteristic wavelength of the visible laser scanning beam. '359 Patent, col. 4, ll. 9-16. The description provided here, as in the other language of the specification, supports PSC's construction that the two filters are not each a band-pass filter, but that the two filters are comprised of a high pass filter and a low pass filter, centered about a predetermined wavelength near a predetermined wavelength, each filter filtering out light of wavelengths on either side of the spectrum.

9 This graphic was referred to earlier as Pl.'s Markman Hrg. Ex. 1 (attached hereto as Appendix E).

--- End Footnotes ---
Consideration of the prior art supports the conclusion that neither of the two filters is a band-pass filter independently. Defendant PSC argues that the references to the internal one-piece band-pass filter throughout the specification of the patents is clear acknowledgment of the prior art, and that the patent cannot be construed so broadly as to encompass this disclosed prior art, citing to Wang Lab., Inc. v. America Online, Inc., 197 F.3d 1377 at 1382 (1999) (concluding that references to prior art was not considered an enlargement of the patent's invention). Here, the specification repeatedly contrasts the combination of the first and second filter elements, in the present invention, from the system used in prior art devices, emphasizing the "novel laser scanner construction" in which the second filter element is spatially separated from the larger first filter element, which is located at the light transmission aperture and is semi-transparent in order to hide the components from plain view. That the first filter transmits red light, at approximately 640 nanometers, allowing higher wavelength lights to pass through and thereby appearing red itself, supports this conclusion. Markman Hrg. Tr. 8/6/02, at 19. The specification refers to these two filter elements as an improvement upon the problems of prior art, in terms of manufacturability, and in terms of its ability to shield its components from plain view:

A further object of the present invention is to provide such a laser bar code symbol scanner, in which the wavelength selective components of the optical filter system are strategically installed in a spatially-separated manner in order to achieve improved scanner performance, appearance, and manufacturability, in a simple low-cost manner.

A further object of the present invention is to provide such a laser bar code symbol scanner in which the optical filtering system employed therein inherently hides from view, unappealing electro-optical components mounted within the laser scanning housing, while rejecting unwanted spectral noise outside the narrow spectral band of the laser scanning beam.

'359/’731 Patent, col. 2, ll. 45-56. Furthermore, the specification refers to the first filter, transmitting red light and light of higher wavelengths, and the second filter, referred to as "relatively small," as representing a "significant advance in the state of the art in laser scanner design and construction." '359/’731 Patent, col. 3, ll. 45-53. The continuous references to the invention as an improvement upon prior art devices in terms of manufacturability, and the spatial separation of the two filters, one of which is relatively smaller, the other which hides internal components from view due to its transmission of wavelengths of red light, support the construction that neither of the two filters is independently a band-pass filter that encompasses the characteristics of both a high-pass and a low-pass filter.

The prosecution history supports the finding that the limitation of this scope refers to filters with the selective wavelength capability, and that each is not a one-piece internal band-pass filter. The Supplemental Preliminary Amendment refers to the "simple and inexpensive" way of making a laser bar code scanner that resolves some of the problems encountered by prior art devices. See Supp. Prelim. Amendment, Palmer Decl., Pl.'s ’359/’731 Br. Ex. K, at 1, 20. The Response to Office Action and Amendment also refers to an interview with inventors Thomas Amundsen and George Rockstein, who "demonstrated how the laser scanning system of the claimed invention effectively solves such problems in an inexpensive manner." Resp. to Office Action & Amendment, Palmer Decl., Pl.'s ’359/’731 Br. Ex. K, at 1, 4-5. The two amendments thus refer to the improved cost of manufacturability of the patent, compared to the prior art devices which encountered high costs due to the singularity of the internal band-pass filter pieces. It can again be inferred that the purpose of the invention is to combat previous problems with prior art devices, which utilized the more expensive one-piece filter system design.

In conclusion, the specification language throughout the patent indicates that each of the two filters covers only part of the visual spectrum of colors, either just under and greater than 670 nanometers, or just above and less than 670 nanometers. Nowhere in the specification does the language discuss the ability of either filter component to block out ambient light measuring both above and below the 670 nanometer range. The specification readily distinguishes plaintiff's invention from internal band-pass filters of prior art devices in discussing the patent's novelty and in its overcoming the problems of laser scanners with its aesthetic appearance and the invention's use of the first optical filter element which is in the form of a red window.

This case does not resemble one in which the parties dispute the meaning of a term. Rather, this case involves the imputation of a requirement upon the terms of the claim. Much like Bell Atlantic, which construed the term "mode" to refer only to three possible modes as referred to throughout the specification, the patentee has defined the term "by implication, through the term's consistent use throughout the [] patent specification." Bell Atlantic Network Servs., Inc. v. Covad Communications Group, 262 F.3d 1258, 1273 (Fed. Cir. 2001) (citing Vitronics, 90 F.3d at 1582). The consistent use of the two filter elements as pertaining to filters with the capability of transmitting certain wavelengths of light, either above or
below the predetermined wavelength of the laser light, indicates that neither of these two elements constitutes an internal
band-pass filter that is capable of blocking out ambient light with wavelengths both above and below the predetermined
level. Plaintiff's novel invention of spatially-separated filters, which was meant to solve the problems encountered by one-
piece band-pass filters in the prior art, would be turned on its head if it were allowed to disregard the exact distinction it
meant to create by the novel invention presented in its patent. This Court recognizes that "there is sometimes 'a fine line
between reading a claim in light of the specification, and reading a limitation into the claim from the specification.'" Bell
Atlantic, 262 F.3d 1258, 1270 (Fed. Cir. 2001) (quoting Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187
(Fed. Cir. 1998)). However, in light of the consistent language of the claim and the specification, and the prosecution
history, indicating the intent of the patent holder to improve upon the poor manufacturability and transparency of the prior
art, the term "cooperating with said first optical filter element so as to form a band-pass optical filtering system" is
construed to mean the cooperation of the two band-pass filters, neither of which is itself a narrow bandpass filter. The two
filters, one of which transmits light of wavelengths just below and above a predetermined wavelength, the other transmitting
light of wavelengths just above and below the predetermined wavelength, cooperate to form a narrow band-pass optical
filter which does not exist before the cooperation between the two filters. The claim is not entitled to a broader scope.

Claims 1, 7, 11, and 14 refer to the term "coordinates" or "coordinating." The Court adopts NCI's proposed interpretation of
the term "coordinate." To "coordinate" means to harmonize, work together, or bring into a common action, effort or
condition. This interpretation is supported by the ordinary meaning of the claim language, the patent specification, see '124
word "coordinate" does not connote a "dominating influence" as Microsoft proposes, and the specification does not so limit
this term.

Defendants' navigation systems operate by downloading the coordinates for an upcoming maneuver point (sometimes called
a "driving event") and either distance or time values. In the case of the Celcico and Networks in Motion ("Celcico") system,
the server sends various information to a cell phone, including a "max-instruction distance," the coordinates of the
maneuver point, and the speed of travel. The cell phone uses some of this information to calculate a warning distance, which
is then compared to the max-instruction distance to determine when the user should receive the next instruction. Both the
warning distance and the max-instruction distance are scalars; in other words, they are what the district court called
"numeric values." Similarly, the GM OnStar(R) ("GM") system downloads driving event coordinates and up to three
distance or time offsets, each of which is also a scalar. In part because it found that numeric values like those downloaded
by Defendants' systems cannot be coordinates, the district court held that Defendants did not infringe the '743 patent.

VIP argues that the patentees did not limit the term "coordinate" in the '743 patent, and therefore the term must be "broadly
defined." And while VIP agrees that the term should be construed according to its ordinary meaning, VIP does not believe
the court's construction reflects that meaning. Instead, VIP argues that the ordinary meaning of a coordinate is "any one of a
set of numbers used in specifying the location of a point on a line, in space, or on a given plane or other surface." VIP
presses us to find that this construction allows for a numeric distance offset "so long as that offset specifies the location of a
point."

Regardless of whether the district court correctly identified the term's ordinary meaning, however, we agree with the district
The term "coordinate" appears twice in the language of independent claims 1, 23, 35, and 56. Although the first mention of the term is as a plurality ("notification coordinates"), the second time, the term is used in the singular: a direction "segment" is presented when "the location of the mobile unit substantially corresponds to a notification coordinate defining the notification region." In the '743 patent, the mobile unit's location is identified using a GPS device. '743 patent col.2 ll.64-col.3 l.1. To compare a notification coordinate to the mobile unit's location, as required by the claims, the notification coordinate necessarily must be of the same kind or type as the mobile unit location coordinates. The location of the mobile unit is expressed in terms of latitude and longitude, and cannot "substantially correspond" to a scalar value, such as 500 meters. No meaningful comparison between the two is possible. The plain language of the claims precludes the possibility that a coordinate can be a scalar.

The prosecution history lends further support to the conclusion that a scalar cannot serve as a "coordinate" as that term is used in the '743 patent. On March 14, 2001, the Examiner rejected claims 23 and 35 as being anticipated by U.S. Patent No. 5,126,941 (the "Gurmu patent"). In traversing the rejection based on the Gurmu patent, the applicants stated:

The present invention differs fundamentally from Gurmu. The present invention teaches and claims that the location of the vehicle is compared . . . to the notification coordinate. It is apparent that the location is determined independently of the notification coordinate to be able to compare the vehicle location to the notification coordinate. This fundamental difference is not taught, shown, or suggested by Gurmu.

J.A. 2191. If the location of the mobile unit must be determined independently of the notification coordinate, then the notification coordinate necessarily must provide an absolute location (as opposed to a location by reference to the mobile unit's position). VIP's argument to the effect that this is not a clear disclaimer is to no avail. See 800 Adept, Inc. v. Murex Sec., Ltd., 539 F.3d 1354, 1364-65 (Fed. Cir. 2008) (recognizing that prosecution disclaimer is "typically invoked to limit the meaning of a claim term that would otherwise be read broadly," but consulting the prosecution history in that case "as support for the construction already discerned from the claim language and confirmed by the written description").

VIP maintains that while a distance offset standing alone might not be a coordinate, "the distance offset identifies a specific location in advance of a driving event." In other words, a distance offset of 500 meters should be read as "500 meters from the maneuver point." Once armed with the maneuver point's latitude and longitude, the argument goes, the system could calculate the latitude and longitude of the distance offset—in effect, transforming a scalar value into coordinates properly comparable to those at the maneuver point. But again, this interpretation is precluded by the plain language of the claims, which require comparison between the current location and a single notification coordinate. Further, a scalar and a maneuver point taken together do not define a second point at the distance offset, but instead define a circle centered at the maneuver point with a radius equal to the scalar value. To pinpoint precisely where on that circumference the distance offset lies requires something more. For these reasons, we agree with the district court and hold that a distance offset of the type used in Defendants' systems is not a "coordinate" as the term is used in the '743 patent.
comparison. Any point described by one coordinate system may be easily converted to another coordinate system for direct comparison. Appellees contend that the plain language of the claims precludes any conversion for comparison purposes because the claim recites using only a single notification coordinate. I am not convinced because a coordinate in this usage appears to be a single unique point in space among many points that collectively define a notification region, not just part of the description of a point. Further support is found in the claims because a notification region is defined by a plurality of notification coordinates. A plurality of points is required to define a region in space. It is consistent to use coordinate in the singular to describe a single point within such a region. Also, the specification often uses coordinate in the singular in the term "geographical coordinate," which is clearly a point in space.

I therefore agree with VIP that a coordinate can be anything that describes a particular point on a line, on a plane or surface, or in space. This includes a numeric value (a scalar) describing an offset to a fixed point along a known curve.

The parties disagree as to the proper construction of the terms "x,y coordinate" and "x,y coordinate location" in claims 1 and 8 of the '110 patent and the terms "x, y coordinate location" and "x and y coordinate" in claims 1 and 7 of the '267 patent. The parties do agree, however, that whatever construction the Court adopts for any one of these terms should also be adopted for all of these "x, y terms." (See D.I. 351 at 30; D.I. 359; D.I. 384 at 16-17.) I agree. Therefore, the following analysis applies to all of the disputed "x, y" terms.

Claim 1 of the '267 patent shows how the claims use the terms "x, y coordinate location" and "x and y coordinate":

1. A system for selecting and delivering medicine package from a holding means to fill orders comprising:

   a) holding means comprised of a frame having a plurality of support rods each support rod sized for holding a plurality of medicine packages, each rod associated with a given medicine and holding medicine packages with only the same medicine each support rod having a distinct x, y coordinate location; . . .

   . . .

   c) a computer having a database containing an x, y coordinate location for all packages in the holding means, the computer able to receive orders for packages and able to direct the means for picking packages; and

   d) a supply structure having a plurality of supply support rods which extend from said structure to form an x, y coordinate system, with each supply support rod and medicine package thereon having a unique x and y coordinate, said picking means disposed to have access to said structure such that a given medicine package on an associated supply support rod can be picked by the picking means to fill a patient's prescription, or a given medicine package in the supply structure can be picked by the picking means to restock an associated rod from the holding means.

'267 patent, col. 13 lines 1-9, 16-32 (emphasis added).

McKesson proposes that the "x, y" terms be construed as "one or more points that designates the position of a package where the picking means selects, grabs and replaces packages." Swisslog, by contrast, proposes that these terms be given their plain and ordinary meaning and construed as "a location identifier 'X,Y,' in which X designates a position of the location along an X-Axis and Y designates a position of the location along a Y-Axis."

While the parties have devoted many pages to briefing this issue, their dispute essentially comes down to a single question: does the x, y plane being referred to in the claims exist only where the picking means can access packages, or may it also exist in places where the picking means cannot access packages? McKesson advocates the former position and Swisslog the latter. After careful review of the claim language, the specification, and the prosecution history, I conclude that the claims require that the x, y plane exist in an area where the picking means can access a package. Therefore, I recommend that the Court adopt McKesson's proposed construction of the x, y terms.
5 As McKesson puts it, "[b]oth parties . . . agree that these claim terms should be given ordinary and customary meaning. . . . The parties disagree, however, regarding the identification of the area, or place in space, that defines the boundaries in which the 'x, y coordinate location' may exist." (D.I. 364 at 2)

Looking first at the claim language, it is clear that the claims require a relationship between the "x, y" plane and the locations where packages are accessible to (i.e., may be picked by) the picking means. As McKesson states, "the claims consistently refer to x, y coordinates in relation to packages held in a storage area location that are accessible to the picking means." (D.I. 364 at 4; see also id. at 3-8.) For instance, element d) of claim 1 of the ’267 patent recites "a supply structure having a plurality of support rods which extend from such structure to form an x, y coordinate system, with each supply support rod and medicine package thereon having a unique x and y coordinate, said picking means disposed to have access to said structure such that a given medicine package on an associated supply support rod can be picked by the picking means." ’267 patent, col. 13 lines 22-29 (emphasis added). Similarly, element a) of claim 1 of the ’110 patent recites "a storage area comprised of a plurality of storage area locations each location having a package: . . . the packages being held in a manner so that each location can be placed into and removed from the storage area locations and . . . each location having a distinct x, y coordinate." ’110 patent, col. 12 line 66 to col. 13 line 11 (emphasis added).

Consistent with the claims, the specification also demonstrates a relationship between known "x, y" coordinates in a plane and the automated picking means. As McKesson notes, the Applicants made this relationship evident by referencing the picking means as part of the specification's explanation of the x, y coordinate system. (D.I. 351 at 15-16) The specification discloses:

The frame 28 with rod supports 32 form an X, Y coordinate system with each rod 30 and medicine packages 14 therein having a unique x, y coordinate. Packages are placed in the storage rack so that each product is located at a known X, Y coordinate. Since every product is a known X, Y location, it is possible to direct an automated picking means to any product location to select a desired item . . . .

The racks of FIGS. 3, 4, and 5 have two important features. First, the packages are held in areas having known X, Y coordinates. Those coordinates could be single X, Y values as may correspond to the position of the package holes 15 or a group of X, Y values defining an entire package. Second, there is sufficient clearance between packages to allow automated picking means to select, grab and replace individual packages.

’267 patent, col. 5 lines 18-51 (emphasis added). Additionally, while describing the actual operation of the automated system, the Applicants described the "x, y coordinate" with reference to selection of packages from the storage rack:

The system is now ready to pick the drugs 188. First, the column-type vehicle 44 goes to the rack where the drug to be selected is stored and stops at the X coordinate of that drug package. The picking means 38 then moves along the column 44 to the Y coordinate of the medicine package to be picked. It is also turned to the proper storage rack 12 which has the desired package 14. These actions may be performed simultaneously by the system 189.

’267 patent, col. 9 line 64 to col. 10 line 4 (emphasis added). As a result, one of ordinary skill in the art would comprehend that the x, y coordinate is determined relative to both the storage area locations and the action of the picking means - which acts to grab, select, and place packages. (D.I. 351 at 16) 6

6 While McKesson purports to find support for its construction in the prosecution history, see D.I. 351 at 16-17 (citing D.I. 360 Ex. E at MA000194, MA000209-10), I do not find the prosecution history to be either supportive or detrimental to either side's proposed construction of the x, y terms.
Swisslog insists that "the inventors used the terms 'X, Y coordinate,' 'X, Y coordinate location,' and 'X and Y coordinate' in accordance with their notoriously well-known, plain, and ordinary meanings as location identifiers for designating the position of various locations within the automated system of the patents-in-suit." (D.I. 349 at 18) Swisslog adds: "This customary definition, which has existed for almost four centuries, is applied routinely in the scientific arts." (D.I. 361 at 1) I do not disagree. However, as McKesson explains, Swisslog's proposal to construe the x, y terms as a sterile, dictionary definition fails to account for the context in which the terms appear in the claims of the patents-in-suit and would, if adopted, result in an incorrect elucidation of the patentees' rights. In the context of the patent claims at issue in this lawsuit, the "well-known, plain, and ordinary" x, y plane exists at locations where the picking means can pick packages. It does not, within the context of the patent claims asserted here, exist elsewhere. That is the extent of the patent right claimed by the Applicants and granted by the PTO. It will assist the jury to have this fact made clear, and McKesson's proposed construction does so.

Another Swisslog criticism of McKesson's proposed construction is that it is limited to the location of packages. (D.I. 361 at 11-12) The claim language uses the x, y terms also to refer to the location of storage area locations and support rods. '110 patent, col. 13 lines 10-11 ("each [storage area] location [has] a distinct x, y coordinate"); '267 patent, col. 13 lines 7-9 ("each support rod having a distinct X, Y coordinate location"); id. col. 14 lines 19-21 (same). While McKesson is correct that all points in the x, y plane claimed in the patent claims are locations accessible to the picking means, it is also true that this plane is identified in some portions of the claims by reference to the location of the storage rods or the storage area locations. For the reasons already given (as well as those given below with respect to the construction of "storage area location"), I agree with McKesson that the claims' references to "support rods" and "storage area locations" must also relate to locations that render the packages accessible to the picking means. Hence, Swisslog's argument does not detract from my conclusion that the x, y terms define a plane in which the packages are accessible to the picking means. Whether it is necessary to further refine the construction of the x, y terms (e.g., to sometimes refer to storage rods and not always just to packages) is a matter on which I will confer with the parties at a later date.

Thus, I recommend that the Court construe the x, y terms to mean "one or more points that designates the position of a package where the picking means selects, grabs and replaces packages."

1. "[X],y coordinate" 12

12 This disputed limitation appears in a variety of forms; however, the parties and the court agree that one construction should apply to all instances. Claims 1 and 7 of the '267 patent describes this limitation as "x, y coordinate location" and "x and y coordinate." Claims 1 and 8 of the '110 patent refer to "x,y coordinate" and "x,y coordinate location." The court refers to each of these instances through the use of "x,y coordinate."

Judge Stark construed "x,y coordinate," to mean "one or more points that designates the position of a package where the picking means selects, grabs and replaces packages." In recommending this construction of "x,y coordinate," Judge Stark agreed with McKesson's position that the x,y plane referred to in the claims must exist only where the picking means can access packages. Swisslog objects to this construction and argues that the court should construe "x,y coordinate" in accordance with its ubiquitous mathematical meaning, to wit, "a location identifier 'X,Y;' in which X designates a position of the location along an X-Axis and Y designates a position of the location along a Y-Axis."

While construing "x,y coordinate" in terms of where the picking means can access packages has intuitive appeal based on the claim language and the specification (which demonstrate a relationship between x,y coordinates and the automated picking means), Judge Stark's proposed construction goes one step further and associates the "x,y coordinate" with the
location of the packages themselves. The court declines to adopt this construction for several reasons. First, the claims themselves are replete with language requiring the accessibility of packages to the picking means. (‘267 patent at col. 13:10-14, col. 13:26-32, col. 14:23-29; ‘110 patent at col. 13:5-11, col. 13:12-23) Therefore, the construction of the "x,y coordinate" limitation need not contain a duplicate requirement. Second, and most importantly, designating a nonpermanent, movable object (i.e., package) as a location identifier runs the inherent risk of defining a transient coordinate system which varies according to the position of a given package. Neither does Swisslog's proposed construction comport with the claims or specifications of either of the patents-in-suit. Construing "x,y coordinate" according to its ubiquitous meaning fully divorces this claim limitation from the context of the patents-in-suit, which makes clear that the x, y plane exists in certain locations and not others.

In light of the above, the court concludes that the patents-in-suit contemplate a coordinate system anchored by the various means for holding the packages. With respect to the ’110 patent, designating the "package holding means" 13 as the anchor of the coordinate system resolves the permanency issues associated with the recommended construction, while simultaneously preserving the context of the invention. This understanding of "x,y coordinate" comports with the claims and specifications. Limitation a) of claim 1 of the ’110 patent recites "a storage area comprised of a plurality of storage area locations each location having a package holding means . . . each location having a distinct x, y coordinate." Dependent claim 8 of the ’110 patent further requires a "supply station . . . having a plurality of locations each location having package holding means . . . each location having a distinct x, y coordinate." (Emphasis added) In both claims, the package holding means are "sized and configured" to hold one or more medicine packages. The ’267 patent uses slightly different terminology, claiming a "holding means" and a "supply structure." Consequently, the "holding means" and "supply structure" anchor the coordinate system of the ’267 patent.

13 Judge Stark has construed "package holding means" in accordance with 35 U.S.C. § 112, P6 to have the function of holding packages and corresponding structure of the "rods, brackets, shelves and dividers as disclosed at positions 30, 25, 29 and 31 of, e.g., FIG. 3-6, and col. 5, lines 10-19 and 25-40.

In sum, the package holding means of the ’110 patent, as well as the holding means and supply structure of the ’267 patent, relate to discrete and permanent locations that render the packages accessible to the picking means. Accordingly, with respect to the ’110 patent, the court construes "x,y coordinate" to mean "one or more points that designates a position in the package holding means." With respect to the ’267 patent, the court construes "x,y coordinate" to mean "one or more points that designates a position in the holding means or supply structure."

"viewpoint coordinate data"

Claims 1 and 52 of the ’785 Patent contain the term "viewpoint coordinate data." IPI contends the term means "information representing the position of the viewpoint in a three dimensional workspace." Google contends the term means "the position on the x-axis, the y-axis, and the z-axis in a three-dimensional workspace from which the workspace is viewed." The parties disagree as to what "coordinate" means.

IPI contends that the term refers to "information representing" a position and argues that the specification supports such a construction. Specifically, IPI cites to two specific portions of the specification. First, the specification provides:

In order to present a three-dimensional workspace, a system may store data indicating "coordinates" of the position of an object, a viewpoint, or other display feature in the workspace. Data indicating coordinates of a display feature can then be used in presenting the display feature so that it is perceptible as positioned at the indicated coordinates.

that IPI's proposed construction is overly broad in that not all position information is "coordinate data." For example, Google argues that "to the left" or "above the table" is "information representing the position of the viewpoint," but they are not coordinates. Google's Responsive Brief, at 24. At the hearing, the Court indicated that "information representing" was too broad and IPI agreed to an alternate construction of "data representing the position of the viewpoint in a three-dimensional workspace."

Google's proposed construction includes a reference to Cartesian coordinates (e.g., x-axis, y-axis, and z-axis), which Google argues is supported by the specification's use of Cartesian coordinates to compute the coordinates of the viewpoint. IPI argues that Google's proposed construction seeks to limit the claims "to a preferred embodiment of an 'x,y, and z' coordinate system despite the fact that such a limitation is not called for by the claims." IPI's Reply Brief, at 7. A preferred embodiment disclosed in the specification is not a claim limitation, and the Court refuses to import the Cartesian coordinates limitation from the preferred embodiment into the claims. See Phillips, 415 F.3d at 1323. In addition, as indicated by IPI's cited portions of the specification, the specification does not limit "viewpoint coordinate data" to Cartesian coordinates. Instead, the specification simply describes the invention in terms of coordinates in a three-dimensional workspace. See '785 Patent, col. 14:9-15 and col. 6:56-62.

Google's proposed construction is too narrow in light of the specification. Thus, in order to give the term the greatest amount of breadth consistent with the specification, the Court construes the term "viewpoint coordinate data" to mean "data representing the position of the viewpoint in a three dimensional workspace."

E. Coordinates in the Terrain

The Plaintiff construes the phrase "coordinates in the terrain" to mean "any of a group of one or more numbers used to determine a position in the terrain, such as x, y, longitude, latitude, height, and/or resolution level." The Defendants counter that "coordinates in the terrain" must refer to "a pair of numerical coordinates, such as latitude and longitude or x and y coordinates, of a particular location in the terrain." Before turning to the heart of the dispute, I note that resolution level is not within the meaning of the "coordinates in the terrain". Claim 1 and various parts of the specification refer to the "coordinates in the terrain" and the "resolution level" as separate variables.

The debate with respect to the term coordinates is a consequence of the fact that the term connotes two different meanings, as understood by a person of skill in the art that may be readily apparent even to lay judges, and that the term appears to be used in the two different ways within the patent specification. Thus, my task requires choosing the most appropriate meaning as used in the claims in light of the two uses in the specification.

A coordinate typically refers to an individual value, such as an x-coordinate, which along with another coordinate on a
different axis (y), would locate a point in a two-dimensional plane. Thus, a longitude coordinate and a latitude coordinate would together locate a point on the Earth's surface. By adding a third coordinate (z), the three values together would specify a point in a three-dimensional space. Consequently, with respect to storing a proposed flight plan, the specification speaks of inputting "three-coordinate points which describe the route. The three coordinates preferably represent longitudinal, latitudinal, and height coordinates of the points along the course[.]" (col. 10, 11. 39-41) Similarly, "each block is referenced using longitudinal and latitudinal (x, y) coordinates of one of the points in the block, such as the top right corner pixel, together with the resolution level of the block." (col. 9, 11. 35-38) However, the term coordinates' can also be used to refer to a set of two or more values used to determine the position of a point on a plane or in space. In this sense, the statement that "each object is preferably accompanied by coordinates which state the position of the object within sub-block" can be thought of as referring to a set of at least two coordinate elements that together identify the object's location. (col. 8, 11. 43-44) From this perspective, the plural form of coordinates' simply contemplates that more than one data block may be requested at a time and that to identify each block one needs a set of coordinates. Consequently, coordinates' may refer to the plural of coordinate' or to the set made up of at least a pair of coordinate points.

The question, then, becomes whether "one or more coordinates in the terrain" refers to one coordinate, such as x, or more than one coordinate, such as x and y, or rather to one set of coordinates, such as x/y, or more than one set of coordinates, such as x/y and x1/y1. I find that adopting the latter understanding reconciles the claim language ("one or more") with the Defendants' concerns and the specification. This meaning also makes sense when contrasted to the reference in other claims to a "plurality of coordinates", that is to more than one set of coordinates requiring more than one data block to represent the terrain to be viewed.

If "one or more coordinates" meant that only one numerical value ('coordinate') would be sufficient, the processor could not provide the renderer with the data block(s) corresponding to the coordinates of the terrain specified. The preferred way of structuring the data blocks is to have "a header record comprising an index to the blocks", (col. 9, 11. 25-26), and to reference each block "using longitudinal and latitudinal (x, y) coordinates of one of the points in the block, such as the top right corner pixel, together with the resolution level of the block." (col. 9, 11. 35-38). Then the "renderer determines the exact blocks needed and calls for them using their (x, y) coordinates and their resolution level. Alternatively or additionally, renderer specifies, for each resolution level, the coordinates of the boundaries of the necessary areas, and cache manager determines the identities of the required blocks." (col. 14, 11.10-15) Consequently, even in the alternative scenario, the system requires multiple sets of numerical values ('coordinates') that define the boundaries of the particular area of the terrain.

Construction: (coordinates in the terrain) a set of numerical values that identifies a particular location in the terrain

3. a copy key for initiating the copying of the contents of a memory of a digital camera containing picture image data previously captured by said digital camera from said memory of said digital camera to said mass storage device

The plaintiff contends that no construction is needed. The defendants propose "a user interface key that is an exclusive copy button, which is only used for transferring images from the camera card to the system/collector etc." The defendants cite to the prosecution history and an interview summary by the examiner stating that the examiner "[d]iscussed an amendment to the claims to include the feature of having an exclusive, copy button only used for transferring images from the camera card to the system/collector etc." "927 Prosecution History, August 2, 2005 Interview Summary. The plaintiff argues that the statement does not refer to an agreement between the patentee and the examiner. The plaintiff also argues that the statement does not show conclusively that the discussion occurred prior to the patentee's amendment on July 15, 2005 because the examiner summarized interviews that occurred on July 14, 2005 (prior to amendment) and July 19, 2005 (after amendment). After careful examination of the prosecution history, the court agrees with the defendants that the patentee limited its claims during prosecution of the patent as stated in the examiner's summary. Accordingly, the court construes the phrase as "an exclusive copy button used only for copying the contents of a memory of a digital camera containing picture image data previously captured by the digital camera to the mass storage device."
12. "[C]ore:”15 “A longitudinally-extending element that separates the transmission media.” This construction is consistent with the specification. (see col. 1:8–9; col. 2:67–3:2; col. 3:11,13; col. 4:62–64) The parties' respective proposed constructions differ only by inclusion of "the." Defendants argue that this article is necessary to indicate that the core separates each twisted pair from one another, as opposed to separating some, but not all, twisted pairs. The court agrees. None of the described embodiments contain transmission media which are not individually separated by the core.

--- Footnotes ---

15 '503 patent.

--- End Footnotes ---

"corpus of documents"

Claims 1, 25, 27, 28, and 31 of the '819 Patent contain the term "corpus of documents." IPI contends that "corpus of documents" means "a collection of documents which are available to an information retrieval system." Google contends that the term means "a collection of documents on a particular subject matter or from a particular source." The parties' main dispute centers around whether "corpus of documents" should be limited to a collection of documents "on a particular subject matter or from a particular source."

IPI contends that neither the claims nor the specification of the '819 Patent support limiting the term as Google proposes. IPI further argues that Google's proposed construction seeks to limit the claimed "corpus of documents" to preferred embodiments in the specification which are directed to documents on a particular subject matter (e.g., computer science) and from a particular source (e.g., New York Times). See '819 Patent, col. 1:39-41, col. 13:35-37 and col. 16:44-46. In support of its proposed construction, Google asserts that it is not seeking to limit the claimed "corpus of documents" to a collection of documents on any particular subject or from any particular source described in the specification. Instead, Google contends it "only seeks to limit the definition to the well-known concept in the field"—that a "corpus" is a collection of documents on a particular subject matter or from a particular source. Google's Responsive Brief, at 16.

Google further argues that its proposed construction is consistent with the patent's teaching that the "thesaurus must be tuned to the corpus of documents--a concept that makes no sense if the 'collection' consists of documents unrelated to each other by source or subject matter." Id. (emphasis added). Google's argument is misplaced. The specification states that the "thesaurus must be tuned to the corpus of interest," not to the "corpus of documents." ’819 Patent, col. 1:46-47. The claim term "corpus of documents" is broader in scope than the "corpus of interest." In other words, simply because the specification states a thesaurus must be tuned to the "corpus of interest," does not mean it must be tuned to the entire "corpus of documents." The logic of Google's argument does not follow from the correct language of the specification.

Moreover, the specification identifies two problems in the prior art: an ambiguity problem and a synonymy problem. ’819 Patent, col. 1:18-26. The synonymy problem refers to the situation where a query may miss relevant documents that use words synonymous to words in the query. The ambiguity problem refers to the situation where a query may share the same ambiguous word with a document, but the words are used in a different sense. This results in a false similarity match. Google argues that the '819 Patent teaches the ambiguity problem is solved by tuning the thesauri to the "corpus of interest." However, when the specification identifies two different problems in the prior art, it is not necessary for every claim in the patent to address both problems. See Honeywell v. Victor, 298 F.3d 1317, 1325-26 (Fed. Cir. 2002); Resonate v. Alteon, 338 F.3d 1360, 1367 (Fed. Cir. 2003); Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 908 (Fed. Cir. 2004) ("The fact that a patent asserts that an invention achieves several objectives does not require that each of the claims be construed as limited to structures that are capable of achieving all of the objectives."). Thus, claim 1 of the '819 is not limited to solving both the ambiguity problem and the synonymy problem.
The specification does not support the narrow focus of Google's proposed construction limiting "corpus of documents" to a collection of documents on a particular subject matter or from a particular source. Furthermore, IPI's use of the word "available" in its proposed construction is vague as it does not clarify what it means for documents to be "available" to an information retrieval system. However, in view of the claim language and the specification, it is clear that IPI's use of the term "available to" is used in the sense of "accessed by." Accordingly, the Court construes the term "corpus of documents" to mean "a collection of documents which can be accessed by an information retrieval system."

12. "correct level required to turn on a selected memory cell access transistor"

Claims 1 and 13 of the '620 patent contain the "correct level" claim limitation. Claim 1 of the '620 patent is representative and states in relevant part: "a feedback loop . . . to regulate the boosted voltage to a substantially static value . . . of a correct level required to turn on a selected memory cell access transistor." '620 patent, claim 1.

Defendants contend that "correct level" should be construed to mean the lowest voltage necessary to turn on a memory cell access transistor. MOSAID, on the other hand, contends that "correct level" is any voltage level greater than or equal to the lowest voltage necessary to turn on the access transistor so long as that voltage level will not cause damage to the access transistor. Thus, the dispute as framed by the parties is whether the "correct level" is limited to the lowest voltage necessary to turn on an access transistor, or includes higher voltages that are less than transistor damaging voltages.

Defendants assert that the ordinary meaning of the word "required" supports their claim construction. The word "require" is defined as "to have as a requisite; need," 25 "to demand as necessary or essential: have a compelling need for," 26 and "to have need of; need." 27 Recognizing that the word "necessary" is common to all of those dictionary definitions, Defendants conclude that "the voltage level that is 'required to turn on' the access transistor is the minimum voltage that is necessary." (Infineon Br. at 59).

Defendants' conclusion is wrong. None of the Defendants' dictionary definitions include the word "minimum." The ordinary meaning of "required" is "necessary," not "the minimum necessary." And if the ordinary meaning of "required" is used, the voltage level that is "required to turn on an access transistor is a voltage level that is "necessary" to turn on the access transistor. A voltage level that is necessary to turn on the access transistor can be the lowest voltage necessary, but it can also be a higher voltage that does not damage the transistor.

The claim language supports the broader construction of "correct level." When the claim term is viewed in the context of the claim, as this Court is required to do, it is clear that the "correct level" voltage is a boosted voltage of a "substantially static value." '620 patent, claim 1. A "substantially static value" is obviously not a static value and, thus, the plain language of the claims indicate that the voltage level may have some amount of variation. Regardless of the amount of variation, the fact that the claims indicate that there may be some amount undermines Defendants' contention that "correct level" must be limited to "the lowest voltage necessary," i.e., only one voltage.

Further, the claims require the voltage to be of "a" correct level. The use of the word "a" indicates that the "correct level" may be one or more voltages, not just a single voltage. KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000). Accordingly, the ordinary and plain meaning of the "correct level" claim term is "a voltage level sufficient to fully
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

turn on a memory cell access transistor but not so high that it will damage the transistor." 28

28 Defendants argued at the Markman hearing that if MOSAID's construction is adopted, the term is indefinite because one of ordinary skill in the art would not know what a transistor damaging voltage is. Defendants' argument is not well received because it agreed with MOSAID that the definition of "transistor damaging voltage" is "a voltage that instantaneously causes the gate oxide to rupture." (1/27/04 Chart entitled "Agreed and Partially Agreed Claim Terms" at p. 5). Thus, one of skill in the art would understand what range of voltages the "correct level" falls between and accordingly Defendants' indefiniteness argument must fail.

Defendants also contend that the patentees acted as their own lexicographers and defined the "correct level" by limiting it to the lowest voltage necessary to turn on the access transistor. After reviewing the written description, the Court disagrees. Although the patentees did describe an embodiment where the word line voltage is brought to the "exact word line supply voltage, neither too low nor too high," 29 that was a description of a specific, preferred embodiment, not all embodiments. '620 patent, col. 2, 11. 25-51. The '620 claims buttress that conclusion because that specific embodiment is not required by all of the claims. Compare '620 claim 1 with dependent claim 10. Accordingly, the patentees did not limit the meaning of "correct level" in the Foss specifications and, thus, the ordinary and plain meaning governs.

"Correlated" and "correlated noise" appear in claims 2 and 5 of the '839 Patent and claim 1 of the '180 Patent. Those claims read as follows:

2. The method of claim 1 further comprising the step of receiving said signal samples, said signal samples having signal-dependent noise, correlated noise, or both signal-dependent and correlated noise associated therewith.

5. The method of claim 4 further comprising the step of receiving said signal samples, said signal samples having signal-dependent noise, correlated noise, or both signal-dependent noise and correlated noise associated therewith.

1. A method of determining branch metric values in a detector, comprising:

   receiving a plurality of time variant signal samples, the signal samples having one of signal-dependent noise, correlated noise, and both signal dependent and correlated noise associated therewith;

   selecting a branch metric function at a certain time index;

   and

   applying the selected function to the signal samples to determine the metric values.

- 1450 -

CMU's proposed construction of "correlated" and "correlated noise" are:

Two items are "correlated" when they have a tendency to vary together.

"Correlated Noise" means 'noise with 'correlation' among 'signal samples,' such as that caused by coloring by front-end equalizers, media noise, media nonlinearities, and magnetoresistive (MR) head nonlinearities."

RDCTC at 5.

Marvell's proposed construction of "correlated noise" is:

"Correlated noise" means "noise having nonzero 'covariance' (see construction of 'covariance' below)."

"Covariance" means "the expected (mean) value of the product of (ri-mi) and (rj-mj), where ri and rj are observed signal samples (at time i and j, respectively) and mi and mj are the expected (mean) values of the samples (at time i and j, respectively)(i.e., E[(ri-mi)( rj-mj)])]."

RDCTC at 5, 9.

CMU's sources for its construction of "correlated" are the same dictionaries used to interpret "correlation" as discussed above. See supra at 9-10. CMU's source for "correlated noise" is from both its construction of "correlated" and language found in the specifications of the '839 and '180 Patents. Marvell, on the other hand, cites to Dr. Proakis's textbook as the source of its construction for "correlated noise" and "variance." The textbook citation reads as follows:

Two random variables are said to be uncorrelated if \( E(X_i X_j) = E(X_i)E(X_j) = \mu_{ij} \). In that case, the covariance \( \mu_{ij} = 0 \). We note that when \( X_i \) and \( X_j \) are statistically independent, they are also uncorrelated. However, if \( X_i \) and \( X_j \) are uncorrelated, they are not necessarily statistically independent.

In first looking at the claims, it would be apparent to the PHOSITA that the claim terms distinguish "correlated noise" from signal-dependent noise, but do not otherwise define the term. The term "correlated" appears only twice in the '839 Patent's specification. First, in the summary of the invention section it is stated that "noise samples corresponding to adjacent signal samples are heavily correlated as a result of front-end equalizers, media noise, and signal nonlinearities combined with nonlinear filters to cancel them." '839 Patent col. 2 ln. 3-7. Second, in the detailed description section of the '839 Patent it states that for the correlation-sensitive branch metric "[t]he noise is now considered to be both correlated and signal-dependent." '839 Patent col. 6 ln. 38-39.

CMU points out, and the Court agrees, that the language "heavily correlated" would not make sense if Marvell's construction were adopted as such language could only be understood as meaning that the noise had a heavier or greater nonzero covariance. Such a construction would not be how the PHOSITA would read "heavily correlated." CMU's construction, however, that "two items are 'correlated' when they have a tendency to vary together" would be consistent with the notion that the noise could have a greater or heavier tendency to vary together.

Furthermore, based in part on the construction adopted for "correlation," CMU points out that Marvell's construction is consistent in scope with CMU's, except that it relies on mathematical terminology. The parties agree that if variables are not related then their covariance is zero. 7 (Docket No. 81 at 7). To say that two random variables have a non-zero covariance is then to say that they have some relation between them or in the words of CMU the "variables will vary together." As a result, stripped of its mathematical terminology, Marvell's construction becomes "correlated noise" means noise that varies together with other noise samples.
It should be noted that if two random variables have a zero covariance, this does not necessarily mean they are independent variables. "If non-Gaussian random variables: it is possible for X and Y to be uncorrelated but not independent." Leon-Garcia, Probability and Random Processes for Electrical Engineering, at 234 (2d ed. 1994)(Docket No. 82-18 at 6). "The correlation of random variables X1 and X2 indicates the degree of linear dependence between the variables. If \( \rho(X_1, X_2) = 0 \), then there is no linear relation between the random variables, but there may well be some different relation between them." Polyanin and Manzhirov, Handbook of Mathematics for Engineers and Scientists, at 1061 (2007 ed.) (Docket No. 83-15 at 5).

Marvell argues that the use of the term "tendency" is too vague. CMU correctly points out, however, that terms of degree, such as "tendency" can be used in claim construction. Power-One, Inc. v. Artesyn Techs., Inc., 599 F.3d 1343, 1348 (Fed. Cir. 2010). Additionally, Marvell's construction is equally as broad, as any non-zero value of the covariance would be construed to be correlated. Therefore, the Court finds no issue with CMU's use of "tendency" in the proposed construction.

Marvell also finds fault with CMU's use of examples of sources of correlated noise as an attempt by CMU to erroneously import limitations into the claims. CMU's construction, however, only uses the sources as examples and does not purport to give a complete list of sources of correlated noise due to use of the words "such as." (See Docket No. 119 at 150:18-151:2) Furthermore, the examples are taken directly from the specification and would provide context for the jury to learn what correlated noise is with respect to the Patents.

As a result, the construction for "correlated" and "correlated noise" that is consistent with the intrinsic evidence and would be understood by the PHOSITA is as follows:

Correlated means two items that have a tendency to vary together.

Correlated noise means "noise with 'correlation' among 'signal samples,' such as that caused by coloring by front-end equalizers, media noise, media nonlinearities, and magnetoresistive (MR) head nonlinearities."

Avago submits that the above claim language means "comparing an arrangement of pixel values from the first image with an arrangement of pixel values from the second image. The comparison mathematically detects changes in location of common features of the environment in the successive images." Elan proposes the following construction: "Comparing the first set of pixel values with one or more subsequent sets of pixel values to recognize calculated changes in location of features viewed by the array within the three-dimensional environment in the first set of pixel values with relation to features in one or more subsequent sets of pixel values." Given the Court's determination that Claim 14 discloses a device
capable of tracking changes in a three-dimensional environment, further construction of this term is unnecessary.

F. "Correlating The Electrooxidized Electroactive Reaction Product To The Concentration Of Glucose In The Blood Sample"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiffs' Construction</th>
<th>Defendants' Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;correlating the electrooxidized electroactive reaction product to the concentration of glucose in the blood sample&quot;</td>
<td>Using a relationship between the electrooxidized reaction product and the concentration of glucose in blood.</td>
<td>Accurately determining the concentration of glucose in the blood sample.</td>
</tr>
</tbody>
</table>

Defendants contend that this claim term should be limited to the "accurate" determination of glucose concentration in the blood sample. However, the independent claims already specifically include the step of "determining . . . the glucose concentration in the blood sample." The Court sees no basis for introducing the vague and extraneous limitation that this process be done "accurately," whatever that might mean. Indeed, as Plaintiffs note, the term "accurately" has "no interpretive frame of reference in the specification, is too vague for consideration, and would create new problems," including the possibility of a party attempting to introduce some statistical or commercial standard of "accuracy." (See, D.I. 380 at 26-27.) In these circumstances, Defendants' proposed limitation is not appropriate. See, Allen Eng'g Corp. v. Bartell Indus., 299 F.3d 1336, 1346-47 (Fed. Cir. 2002) (declining to interpret the preamble term "fast steering" as a claim limitation because it was a "relative term, and no interpretive frame of reference [was] provided in any of the claims or in the specification").

To the extent Defendants criticize Plaintiffs' construction for "cover[ing] only the 'relationship' between current and the result, but omit the 'result,'" (D.I. 379 at 21), the Court notes again that the claims specifically recite "determining . . . the glucose concentration in the blood sample." Thus, it is not necessary to, as Defendants request, construe this term to require "determining the concentration of glucose in the blood sample."

Accordingly, the Court will construe the claim term "correlating the electrooxidized electroactive reaction product to the concentration of glucose in the blood sample" to mean, as Plaintiffs contend, "using a relationship between the electrooxidized reaction product and the concentration of glucose in blood.

A. Correlation; Correlation-sensitive branch metrics; Correlation-sensitive metric computation update circuit

The principal dispute between the parties for the "correlation" terms is whether "correlation" refers to a general English meaning of relatedness or if it refers to a specific statistical usage and calculation as found in technical dictionaries.

The term "correlation" as well as the terms "correlation-sensitive branch metrics" and "correlation-sensitive metric computation update circuit" appear in claims 11, 16, 19, and 23 of the '839 Patent and claim 6 of the '180 Patent. Claim 11 of the '839 Patent is illustrative of how the terms are used and it reads as follows:

11. A method for detecting a sequence that exploits the correlation between adjacent signal samples for adaptively detecting a sequence of symbols stored on a high density magnetic recording device, comprising the steps of:
(a) performing a Viterbi-like sequence detection on a plurality of signal samples using a plurality of correlation sensitive branch metrics;
(b) outputting a delayed decision on the recorded symbol;
(c) outputting a delayed signal sample;
(d) adaptively updating a plurality of noise covariance matrices in response to said delayed signal samples and delayed decisions;
(e) recalculating said plurality of correlation-sensitive branch metrics from said noise covariance matrices using subsequent signal samples; and
(f) repeating steps (a)-(e) for every new signal sample.

'839 Patent col. 15 ln. 2-17.

CMU and Marvell agree on the construction of "correlation-sensitive metric computation update circuit" except for the underlying definition of "correlation" and "correlation sensitive branch metrics." The parties' agreed construction is:

"A correlation sensitive metric computation update circuit" means "a circuit that recalculates 'correlation*-sensitive branch metrics' using statistics from the 'noise statistics tracker circuit.'"

RDCTC at 8.

CMU’s constructions of "correlation" and "correlation-sensitive branch metrics" are:

"Correlation" means "the degree to which two or more items (here, noise in signal samples) show a tendency to vary together."

"Correlation sensitive branch metrics" means "branch metrics' that use 'correlation' in signal samples in their calculation by including at least one term that involves multiplying signal samples from different time instances."

RDCTC at 6-7.

Marvell's construction of "correlation" and "correlation-sensitive branch metrics" are:

"Correlation" means "the expected (mean) value of the product of two random variables (e.g. E[rirj], where ri and rj are signal samples at time i and j, respectively)."

"Correlation sensitive branch metrics" means "branch metrics' that use 'correlation' in signal samples in their calculation."

RDCTC at 6-7.

As an initial matter, Marvell argues that its definition of "correlation" ought to be adopted because it reflects how the person having ordinary skill in the art ("PHOSITA") would understand the use of the term based in part on the fact that its definition comes from a technical dictionary and thus is closest to the term's ordinary meaning in engineering and statistics. Although CMU cited several general English dictionaries in support of its construction, CMU also cited to three statistics dictionaries. The definitions from the statistics dictionaries cited by CMU are as follows:

Correlation: A general term for interdependence between pairs of variables.

Correlation A general term used to describe the fact that two (or more) variables are related . . . Although the word 'correlation' is used loosely to describe the existence of some general relationship, it has a more specific meaning in the context of linear relations between variables. See correlation coefficient.

Correlation- A general term denoting association or relationship between two or more variables. More generally, it is the extent or degree to which two or more quantities are associated or related. It is measured by an index called correlation coefficient.
In electrical engineering, it is customary to call the $j=1$ $k=1$ moment, $E[XY]$, the correlation of $X$ and $Y$.

The second-order moment $m_{11} = E[XY]$ is called the correlation of $X$ and $Y$. It is so important to later work that we give it the symbol $R_{xy}$.

The probabilistic autocorrelation of the random process $X$, at the times $t_1$ and $t_2$, is simply the correlation of the two random variables $X(t_1)$ and $X(t_2)$, and is denoted by

$$E[X(t_1)X(t_2)] = R_{x(t_1,t_2)}.$$ 

Correlation describes a random process in a way that is impossible for the mean and the variance to do. Both the mean and variance depend on a pdf, which included time at only one instant. Correlation, on the other hand, is a bivariate parameter, and uses a bivariate pdf $[\ ]$ which included two different times: $t_1$ and $t_2$. We therefore define an autocorrelation function:

$$R_{x(t_1,t_2)} = E[X(t_1)X(t_2)]$$

CMU and Marvell agree that the PHOSITA in this case would be a person with at least a Master's degree in electrical engineering who had specialized in data detection and signal processing and had at least two years work experience in the industry. See (Docket No. 79-1, Dr. McLaughlin Declaration at ¶8); (Docket No. 84, Dr. Proakis Declaration at ¶29). Based upon the above definitions and the agreed upon qualifications of the PHOSITA, the Court concludes that the PHOSITA would be knowledgeable about both the general definition of "correlation" used by CMU as well as the more technical definition and formula used by Marvell. The question then is not which definition would the PHOSITA understand and use in the daily practice of his or her art. Rather, the issue is which definition would the PHOSITA conclude to be the most consistent with the claims, specification and prosecution history (the intrinsic evidence) of the '839 and '180 Patents. The above cited extrinsic evidence is thus only relied on to the extent that it informs the Court as to what the PHOSITA's general understanding is; however, the following treatment of the claim terms is based on only the intrinsic record.

As stated in the preamble of claim 11 of the '839 Patent, the method "exploits the correlation between adjacent signal samples." '839 Patent col. 15 In. 2-3. The purpose for exploiting the correlation is explained in the background and summary of the invention section of the '839 Patent. In the background of the invention section of the specification, it is stated that the "[prior art] methods do not take in consideration the correlation between noise samples in the readback signal. These correlations arise due to noise coloring by front-end equalizers, media noise, media nonlinearities, and magnetoresistive (MR) head nonlinearities." '839 Patent col 1 In. 57-61. In the summary of the invention section of the '839 Patent, it states:
In high density magnetic recording, noise samples corresponding to adjacent signal samples are heavily correlated as a result of front-end equalizers, media noise, and signal nonlinearities combined with nonlinear filters to cancel them. This correlation deteriorates significantly the performance of detectors at high densities.

The trellis/tree branch metric computation of the present invention is correlation-sensitive, being both signal dependent and sensitive to correlations between noise samples.

'839 Patent col. 2 ln. 2-11.

From this, a PHOSITA would conclude that there is a correlation between noise samples, that the correlation exists due to certain structures that exist in the recording circuit, and that the failure to account for the correlation between the noise samples in the prior art detracts from the performance of the prior art detectors. How the correlation between the noise samples is taken into account and "exploited" is what is discussed in the remainder of the specification.

The detailed description of the invention section of the '839 Patent discusses the prior art branch metrics before explaining how the "Correlation-sensitive branch metric" works. For the prior art Euclidian branch metric, it is stated, that "the noise samples are realizations of independent identically distributed Gaussian random variables with zero mean and variance σ2... This implies that the correlation distance is L = 0 and that the noise pdfs have the same form for all noise samples." '839 Patent col. 5 ln. 60-64 (emphasis added). L is stated to be the correlation length of the noise, that is, the number of signal samples with which the noise is considered to be correlated. (See Docket No. 79-1, McLaughlin Declaration at ¶11). As a result, the Euclidian branch metric does not consider any of the samples to be correlated with each other, therefore, they are independent and the correlation length or distance is set at zero.

For the prior art variance dependent branch metric, it is stated that "the noise samples are samples of independent Gaussian variables, but that their variance depends on the written sequence of symbols. The noise correlation length is still L = 0, but the variance of the noise samples is no longer constant for all samples." 839 Patent col. 6 ln. 16-20 (emphasis added). Since the variance dependent branch metric accounts for noise that depends on the written sequence of symbols, this branch metric is said to be signal-dependent. The variance dependent branch metric, however, still has its correlation length set to zero, thus it does not take into account noise from other signal samples.

The correlation-sensitive branch metric is first distinguished from the prior art Euclidian and variance-dependent branch metrics by indicating that the correlation length is now set at some number greater than zero. '839 Patent col. 6 ln. 36-37. As a result, the correlation-sensitive branch metric uses more than one signal sample from different time instances so as to take into account the noise at a given time that is attributable to noise from other time instances. (See Docket No. 79-1, McLaughlin Declaration at ¶11). The specification goes on to explain how the correlation-sensitive branch metric can be calculated and it is provided that the general correlation-sensitive branch metric is equation (13). '839 Patent col 6 ln. 66 - col. 7 ln. 5.

As CMU points out, in one of the embodiments, the general correlation sensitive branch metric (13) is calculated, but the correlation equation cited by Marvell is not used. According to CMU, the variance (σ 2), which is used in the 2 first logarithmic term of equation (13), is shown to be able to be calculated without using the equation cited by Marvell for correlation. See (Docket No. 90-3, McLaughlin 2nd Declaration at ¶9). CMU points to equation (23) to show that the variance used in logarithmic circuit 50 may be calculated without a correlation value or the use of a covariance matrix. '839 Patent col. 7 ln. 14-15; col. 10 ln. 12-13. Marvell does not dispute this, but rather argues that a claim need not cover every embodiment. (Docket No. 93 at 6-7) (citing Intamin, 483 F.3d at 1337). However, it is the Court's conclusion that the PHOSITA would not read the general correlation-sensitive branch metric equation (13) to become correlation insensitive if equation (23) were utilized in calculating the branch metric. Equation (13) would still account for the noise at a given time that is attributable to noise at other time instances with the utilization of equation (23). As a result, since Marvell's construction would require the use of calculating the expected (mean) value of the product of two random variables in the correlation-sensitive branch metric, it is not supported by the specification.

Support for CMU's general English construction can also be found in the detailed description. For example, a PHOSITA would read the following language to refer to the general meaning of correlation and not the formula provided by Marvell:
Although recently very popular, such a method [of employing a nonlinear filter] introduces further correlation between noise samples due to the nonlinear character of the filter.

Note that both filters add correlation to the noise.

The PR4(C2) detector performs better because it partially removes the effects of noise correlation introduced by the PR4 shaping filter.

The EPR4 shaping filter does not introduce unnecessary noise correlation.

PR4(C2) still outperforms the two other algorithms, showing the value of exploiting the correlation across signal samples.

The prosecution history adds further clarification as to what makes the branch metric in the patent correlation-sensitive. In the prosecution history, the examiner initially rejected claims as being anticipated by U.S. Patent No. 5,862,192 to Huszar et al. (Docket No. 83-1 at 9). The patentee stated that Huszar did not have a correlation-sensitive branch metric because, although the branch metric did contain signal samples from different time instances, the branch metric did not have a term that "corresponds to the correlation between ri(0) and ri(1), i.e. there is no term that involves multiplying ri(0) with ri(1)." (Docket No. 83-1 at 10). As a result, the patentee distinguished its branch metric as being correlation-sensitive from Huszar by stating that the signal samples were multiplied together in the branch metric. Id.

Marvell takes this statement to mean that the patentee required the calculating of the expected (mean) value of the product of two random variables in its correlation-sensitive branch metric. CMU points out, however, that there is nothing said in regards to the calculating of the expected value, and that it would be inappropriate to read in the requirement of calculating the expected value of the product of the signal samples. The Court agrees that adding such a limitation would be inconsistent with the specification and how the applicants sought to distinguish the correlation-sensitive branch metric from the branch metric in Huszar. Marvell cites to other sections of the specification of the '839 Patent where the term "expected value" is used; however, those sections do not refer to the expected values of the product of random variables.

In considering all of the intrinsic evidence and extrinsic sources provided by the parties, the PHOSITA would find that "correlation," as used throughout the patent refers to the general English meaning. Marvell argues that CMU's construction comes from an amalgam of sources. The Court, however, is satisfied that CMU's construction both reflects how the PHOSITA would understand the term and is construed in a way to aid a jury in understanding the claims.

While CMU's construction for "correlation sensitive branch metrics" does contain the requirement that multiple signal samples are multiplied together, further clarification should be added to the construction to make the requirement of using more than one signal sample explicit. This requirement would be understood by the PHOSITA as the result of setting the correlation length to a number greater than zero (L > 0). To that end, the Court's construction of "correlation sensitive branch metrics" amends CMU's construction to reflect this requirement.

As a result, the Court concludes that the construction of the terms "correlation," "correlation sensitive branch metrics," and "correlation sensitive metric computation update circuit" are as follows:

Correlation means the "degree to which two or more items (here, noise in signal samples) show a tendency to vary together."

Correlation sensitive branch metrics means "'branch metrics' that account for 'correlation' in the signal samples by using multiple signal samples from different time instances and including at least one term in the branch metric calculation that involves multiplying signal samples from different time instances together."
A correlation sensitive metric computation update circuit means "a circuit that recalculates 'correlation-sensitive branch metrics' using statistics from the 'noise statistics tracker circuit.'"

"correlation coefficient"

Claims 25, 27, 28, and 31 of the '819 Patent contain the term "correlation coefficient." IPI contends the term means "a value representing or corresponding to the degree to which two variables are similar, e.g., the degree of difference or similarity between a query context vector and a context vector for a given document." Google contends the term means "a calculated number using a cosine function comparing the context vector of the words in a query and the context vector of the words in a document in the corpus of documents." The parties disagree as to whether "correlation coefficient" should be limited to a "cosine function."

IPI contends that the "correlation coefficient" is "simply a determination of the relative similarity and difference between the query or document context vectors" that is used to rank the documents. IPI's Opening Brief, at 15. IPI argues that although the "value" used to rank the documents can be a number, there are other ways to represent the similarity and differences, such as "a Boolean condition, a logic statement, or a log." Id. Thus, IPI opposes limiting "correlation coefficient" to a number, and particularly to a "number using a cosine function."

Google argues that "[w]here as here, the specification makes clear that a claim term necessarily involves a certain feature, Phillips requires the claim construction to include that feature." Google's Responsive Brief, at 19. Google contends that the specification consistently shows that a "correlation coefficient" is computed using a cosine function, '819 Patent, col. 18:26-33, and further cites to extrinsic evidence confirming the use of a cosine function. However, a preferred embodiment disclosed in the specification is not a claim limitation, and the Court refuses to import the cosine function limitation from the preferred embodiment into the claims. See Phillips, 415 F.3d at 1323.

Further, IPI asserts that the doctrine of claim differentiation precludes limiting the "correlation coefficient" as Google suggests. Although claim 25 does not specifically require that the "correlation coefficient" be calculated using a cosine function, dependent claim 26 does require computation using a cosine function. Thus, IPI contends that the "correlation coefficient" in independent claim 25 should not be limited to the specific embodiment claimed in claim 26. Because courts presume a difference in meaning and scope when a patentee uses different phrases in separate claims, the doctrine of claim differentiation applies in this case and "correlation coefficient" is not limited to calculation by only a cosine function. See Phillips, 415 F.3d at 1314-15.

IPI's proposed construction is consistent with the specification and the claim language, but the attached example is unnecessary because the claim language clearly indicates that the "correlation coefficient" compares the query context vector and the context vector for a given document. Accordingly, the Court construes the term "correlation coefficient" to mean "a value representing or corresponding to the degree to which two variables are similar."

14. "correlator"

Wi-LAN's Proposed Construction

"a device that measures the degree of similarity between the received signal and each code from a set of more than one and up to M codes, where M is the number of chips per code"

Defendants' Proposed Construction

Invalid for failure to meet 35 U.S.C. § 112, if M does not equal N

Alternatively, "a correlator for correlating each modulated data"
symbol from the received sequence of modulated data symbols with a code from a set of more than one and up to M codes, where M is the number of chips per code and where M equals N"

Claim 12 requires a correlator for correlating, where M is the number of chips per code. The specification provides that "[t]he dot product in FIG. 2 can be implemented as a correlator." '802 patent, 4:15-16. The specification further states: "The computing means 24 shown in FIG. 2 includes a correlator 26 for correlating each I modulated data symbol from the received sequence of modulated data symbols with the I code symbol from the set of N code symbols and a detector 28 for detecting an estimate of the data symbols from output of the correlator 26." '802 patent, 4:22-28. Similar to the "first computing means" term of claim 33, Defendants argue that the "correlator" term in claim 12 is indefinite, and thus renders claim 12 invalid, if M does not equal N. Defendants argue that, like independent claim 33, dependent claim 12 is invalid because the specification does not provide structure corresponding to the "M" chips per code function. Similar to its previous findings, the Court finds that changing N to M for certain terms is not an impermissible broadening of the claims during reissue. The Court finds that M need not equal N, and conversely, the Court is not convinced that M cannot be a different number than N. Thus, the Court rejects Defendants' arguments that claims 2, 4, 12, and 33 reciting the term "M" is invalid if M does not equal N. The Court further rejects Defendants' argument that this dependent claim is broader than claim 1 by eliminating the fixed numerical relationship between the number of data symbols and chips per code. The Court finds that the ordinary meaning of the term "correlate" is to put or bring into mutual, complementary, parallel, or reciprocal relation; related by a correlation; having corresponding characteristics. Wi-LAN proposes a definition for the term "correlator" that is consistent with the ordinary meaning of that term, while Defendants do not provide a definition and only argue that M must equal N. The parties have not disputed the meaning of other claims that use the terms "correlator" or "correlating." Claim 12 specifically requires a detector for detecting an estimate of the data symbols from output of the correlator, implying that the correlator correlates for the purpose of "detecting an estimate of the data symbols." Thus, the Court construes the term "correlator" to mean "a device that measures the degree of similarity between the modulated data symbols and a code."

GO BACK

999

c. "Displaying Pixels Which Correspond To"

The district court construed the words "correspond to" in context to mean that the pixels illuminated on the display screen must pictorially represent the threat object or the part thereof that caused the radiation response. The district court explained that it was applying the ordinary meaning of "correspond to":

Although the lit pixels may not form a complete image of the object that is x-rayed, they correspond to characteristics of that object. The pixels display information about the point at which the interaction occurred between the radiation and the object scanned. They indicate whether or not the strength of the signal from the interaction exceeds the designated level and, by shading, give some information about how far the strength of the signal exceeds the designated level. Described in another way, the pattern made by the pixels of different colors develops an image of the threat object.

Vivid Techs., 997 F. Supp. at 99. AS&E argues that the claims do not contain the limitation "image," and that "displaying pixels which correspond to" a level of radiation does not require displaying an image of the object. Vivid responds that the specification does not permit this interpretation.

The specification defines a pixel as "an elementary portion of an image that will be formed and displayed." In discussing the pixel display resulting from the radiation response, the specification states that "the intensity of the pixel can be used to represent the attenuation presented to the illumination beam by the portion of the object 40 which was illuminated when the pixel was generated," and that "the intensity of the pixel generated by the backscatter detector can be mapped to that region of the object 40 whose illumination by the penetrating pencil beam 30 produced the backscattered x-rays which generated the pixel." These and similar statements relate the pixels to the object or region thereof that produced the radiation response,
whereby the pixels display an image of that object or part thereof. In view of the statements in the specification we conclude, as did the district court, that "correspond to" means that an illuminated image of the object or part thereof is displayed.

DISCUSSION

Beasley's application pertains to a system and method for generating an image on a screen display by using a light pen. Generally speaking, when the raster beam of the display hits the light pen, the light pen stores (i.e., writes) the intensity of this event in a memory chip within the system. When the memory is read, the stored data is used to generate an appropriate image on the screen corresponding to the location of the interaction of the light pen and the display. As disclosed, each memory location corresponds to a discrete point on the display. This correspondence is effected, in the words of the claims, by "sequentially addressing the memory locations in synchronization with the position of the beam so that the memory locations correspond to different points on the screen," 1 hereinafter referred to as the "means for sequentially addressing" limitation.

1 Claim 1 reads as follows:

1. In a system for forming an image on a display screen scanned in frames by a beam:

a light pen movable relative to the screen and having a light sensing element for providing a signal when the position of the light pen coincides with the position of the beam,

a memory having a plurality of addressable storage locations,

means for sequentially addressing the memory locations in synchronization with the position of the beam so that the memory locations correspond to different points on the screen,

means responsive to the signal from the light pen for writing data into the memory at locations corresponding to the position of the light pen on the screen during successive frames,

means for reading the data out of the memory locations as they are addressed, and

means responsive to the data read out of the memory for producing an image corresponding to the points where the light pen is positioned during successive frames.

(paragraphing added). The only other independent claim is claim 4, which claims a "method of forming an image," but which is otherwise similar to claim 1 in all material respects. Beasley does not make separate arguments with regard to the patentability of claim 4, or for that matter with regard to dependent claims 3 and 6. Claims 1, 3, 4, and 6 accordingly stand or fall together. See In re Kaslow, 707 F.2d 1366, 1376, 217 U.S.P.Q. (BNA) 1089, 1096 (Fed. Cir. 1983).

* * *

Beasley argues that his invention requires mapping the entire display screen into the memory on a point-by-point basis by sequentially addressing the memory locations in synchronization with the position of the raster beam. Beasley argues that Pieters does not disclose this feature because the memory locations in Pieters do not correspond with any particular point on the screen, but rather correspond with successive interactions between the light pen and the beam, regardless of the point on the screen at which these successive interactions occur. The Patent and Trademark Office responds that the claim does not require a memory location for every point in the display.
The issue before us is one of claim construction—viz., whether the claims require a one-to-one correspondence between particular memory locations and particular points on the display. We conclude that they do not. In drawing this conclusion we rely on the premise that the PTO is required to give claims their broadest reasonable interpretation during prosecution. See, e.g., In re Morris, 127 F.3d 1048, 1054, 44 U.S.P.Q.2D (BNA) 1023, 1027 (Fed. Cir. 1997). As asserted by Beasley, the claims do require a "correspondence" between sequentially-addressed memory locations and different points on the screen, but this claim language is not sufficiently narrow to require a one-to-one correspondence in which a particular memory location corresponds to a pre-determined point on the screen display. Accordingly, the claims can be read such that Pieters anticipates. While we recognize that the system disclosed in Beasley's specification does disclose one-to-one correspondence, we cannot read this attribute of the disclosed system into the claims as a limitation. See, e.g., Paulsen, 30 F.3d at 1480, 31 U.S.P.Q.2D (BNA) at 1674.

4 We note that the "means for sequentially addressing" limitation is drafted in means-plus-function form. See 35 U.S.C. § 112, P 6 (1994). This limitation is therefore to be construed as covering structures that (1) are identical or equivalent to those disclosed in the specification for performing the claimed function, and that (2) perform a function identical to the claimed function. See Pennwalt Corp. v. Durand-Wayland, Inc., 833 F.2d 931, 934, 4 U.S.P.Q.2D (BNA) 1737, 1739 (Fed. Cir. 1987) (en banc). The parties do not dispute whether Pieters discloses a structure equivalent to that disclosed in Beasley; instead they only dispute whether Pieters discloses performing the function of "sequentially addressing the memory locations in synchronization with the position of the beam so that the memory locations correspond to different points on the screen." We accordingly need not identify or consider the structures in Beasley that correspond to this function.

H. "corresponding"

1. The Parties' Proposed Constructions

Ampex asserts that "corresponding" should be construed to mean "having a working relationship." (D.I. 305 at 11.) Of the claims asserted by Ampex in this case, claim 7 recites a "corresponding reduced size version," claim 12 recites a "corresponding one of said reduced size image data sets," and claims 13 and 15 recite a "corresponding plurality of reduced size reproduction images." n6 ('121 patent at 6:29-30, 8:26-27, 8:53-54, 10:15-16.) Ampex states that, in the context of these claims, "corresponding" requires that "a relationship be maintained between each full size image and the reduced size image generated from that full size image," (D.I. 305 at 11-12.) Ampex bases its proposed construction on a dictionary definition, the specification, the purpose of the invention, the prior art cited in the '121 patent, and expert testimony. (D.I. 300 at 26-28.) Defendants, however, argue that a "corresponding" reduced size image is "one that relates to a full sized image in that it is a smaller (lower resolution) version of the full sized image." (D.I. 305 at 11.) To support their position, Defendants rely on the language of the claims and the specification. (D.I. 299 at 28-29.)

n6 Claim 10 also includes the term "corresponding," but does not use it to describe the relationship between a full size image and its reduced size version. ('121 patent at 7:36-41.)

2. The Court's Construction

Although Defendants argue otherwise, the specification of the '121 patent does establish that a "relationship" is maintained between each full size image and the reduced size image generated from that full size image. The specification explains that the full and reduced size images are stored together. ('121 patent, Abstract.) More specifically, when a "frame of video data
is transferred from [the] frame store ... to [the] disk store ... for more permanent storage, both the full resolution and the quarter resolution copy are transferred." (Id. at 4:16-19.) In order for the still store system to transfer a full size image and its reduced size copy between memory components, the two images must have a relationship that can be detected by the system. Otherwise, it would be impossible for the system to determine which two images were being transferred.

Ampex argues that the browse function of the still store system supports the existence of a working relationship. (D.I. 300 at 26.) According to Ampex, the browse function permits a user to select one of the reduced size images in a multi-image display, and the still store system will retrieve its full size version. (Id.) Although not described in much detail, the specification does support this capability. The specification states that the still store system allows "an editor ... to view and compare several images at the same time for the purpose of selecting those images which will be used in a television broadcast." ('121 patent at 1:27-34.) This statement can be understood to mean that an editor can view several reduced size images at once and then "select" which full size versions to use in the broadcast. This ability to retrieve a full size image based on its reduced size copy clearly requires that a relationship be maintained between the two versions of each image.

There is another feature of the still store system disclosed in the specification which supports Ampex's proposed construction. The specification states that "[w]hen video data received from [the] disk store ... does not contain a corresponding quarter spatial resolution copy, [the] size reducer ... may be employed to generate a quarter spatial resolution copy for subsequent transfer to either [the] frame store ... or [the] disk store ..." (Id. at 4:7-12.) Unless a relationship exists between the full and reduced size versions of an image, the still store system would not be able to determine whether a full size image already has a reduced size copy. While Ampex admits that this feature is optional and is not recited in any of the claims at issue (D.I. 300 at 28, n.12), the still store system must be able to support this function. Therefore, based on the portions the specification discussed, I will construe "corresponding" to mean that "a relationship is maintained between each full size image and the reduced size image generated from that full size image."

4. corresponding time signal (Claims 28, 29, 32, 34 and 65)

Since this term is related to the preceding means plus function term, defendants propose that this should be the output of the means defined for the previous term. As discussed earlier, the Court rejects this approach.

Plaintiff's proposed construction is reasonable. The specification indicates this is the time that corresponds to receipt of the "sense signal" that is recorded by the device. Although it is true that recordings are made only when signal changes, the claim language does not include this limitation for the term, "corresponding time signal." See, e.g., '276 Patent, Cl. 65. Therefore, the Court construes this term as: "A signal indicating the time when the sense signal is received."

B. Information "corresponding to an alignment state" (claims 1, 9)

One of the steps of the method disclosed in claim 1 is: "extracting a correction condition by extracting information corresponding to an alignment state of said process[.]" The parties dispute the scope of the limitation "corresponding to an alignment state." Samsung contends that information "corresponding to an alignment state" could include many different types of information, including identifying the equipment or tools that were used to process a particular layer of a semiconductor wafer. Samsung's proposed construction is, "relating to the alignment of a lower layer or a reference layer formed during the manufacturing process of a semiconductor device." AMD contends that the extracted information consists of a comparison of the alignments of wafers in two layers. AMD proposes construing this limitation as follows: "relating to the relative position of one layer on a semiconductor wafer as compared to another layer on the same wafer in a photolithography application."

The specification supports AMD's construction. In the preferred embodiment, the "alignment parameter … indicates the correlation between the reference layer and the layer expected to be currently performed." 4:8-12. 11 In contrast, Samsung's
broad construction of information that corresponds to an alignment state is not supported by the intrinsic evidence. Samsung argues that information "corresponding to an alignment state" could include "reflectivity of the individual wafers," Samsung Br. at 9, but offers no citation to support this construction. Samsung also contends that information "corresponding to an alignment state" could include "the identification of the particular equipment that was used to process the lower layer in the current lot." Id. Samsung cites the following language from the specification in support of this reading: "When the parameters are added for processing using the same equipment, it is possible to set more precise optimal parameters. Thereby, it is also possible to minimize errors generated in the alignment & exposure process." 5:54-57. The Court finds that nothing in this language indicates that "information corresponding to an alignment state" includes information that identifies the processing equipment. This portion of the specification follows an explanation of how the preferred embodiment derives parameters, i.e. data that will be used to reset manufacturing processes. The concluding paragraph at 5:54-57, which Samsung relies on, simply explains that accuracy is increased if the same equipment is used to control the manufacturing process and to derive the information that will be used to correct that process.

--- Footnotes ---

11 Samsung agrees with AMD that the "alignment state" limitation refers to the photolithography process. Samsung Reply at 7.

--- End Footnotes ---

Samsung also argues that "information," as it is used in claim 1, must be broader than the term "resultant value" in claim 8. Samsung's comparison of the claim language in claim 8 is inapt. Claim 1 explicitly limits the type of "information" that is extracted: this step in the method concerns only information "corresponding to an alignment state." The reference to resultant values in claim 8 is not pertinent.

Accordingly, the Court adopts AMD's construction.
In the JACCC, Joyner construes "countdown timer" as "a timer which: (1) is started 'immediately upon' initiation of the video; (2) runs for the predetermined time; and (3) triggers the signal to release the ball." JACCC (docket no. 174), at 20. ProBatter does not offer a construction in the JACCC, because it believes the plain meaning of the clause is clear.

Accordingly, in light of the court's ruling in Part V.C.1, the court shall adopt ProBatter's construction of "countdown timer."

"Coup Message"

Cisco's proposed construction for "coup message" is "communication sent from one router to another that can cause the sending router to take over as the active router." Alcatel's proposed construction is "a message that is unicast by any router only to the active router to notify such active router that the router sending the message wishes to become the active router."

The major difference between the two proposals is that Alcatel seeks to limit the coup message as used in this patent as only being unicast from the sending router to the active router, while Cisco claims that the coup message can be broadcast to more than one router at a time. Since "coup message" is not explicitly defined in the patent, nor is it a term commonly known to one of ordinary skill in the art, the Court must look to the term's use in the patent, and the overall purpose of the patent, in order to glean its proper meaning as used in the claims. See Apple Computer v. Articulate Sys., 234 F.3d at 25 ("[T]he claim must be interpreted in light of the teachings of the written description and purpose of the invention described therein."); Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 956 (Fed. Cir. 2000) (looking to the written description of the patent in order to determine the meaning of a claim term).

The specification provides support for both proposed constructions. At one point in the specification, the patent describes the "coup message" as being "broadcast . . . to the active router." Li, at 12:56-57 (emphasis added). However, elsewhere the specification states that "a coup message may only be received by the active router." Li, at 14:67-15:1 (emphasis added). Nevertheless, as used in the claim language, "coup message" is not described as being either broadcast or unicast. It is only described as being intended to "notify a current active router that the router [sending the coup message] will attempt to become the active router." Li, at 17:14-16; see also Li, at 18:4-6; 19:2-4; 20:20-23. Therefore, the Court will not limit the term "coup message" to only a unicast message, because it is not so limited in the claim language, and the preferred embodiment is not clear on whether the reference to the "coup message" being received only by the active router was meant to limit a "coup message" to a unicast transmission in all instances. See Rhine, 183 F.3d at 1346 (particular embodiments in the specification should not be read into the claims when the claim language is broader than such embodiments).

Thus, the Court construes the term "coup message" as "communication sent from one router to notify the active router that the router sending the message wishes to become the active router."

Zebco's second interpretive argument is that the term "coupled" in the phrase "[a] heading lock coupled to a trolling motor" found in the preamble of claim 1 is limited to a mechanical or physical coupling. We are unpersuaded. Even assuming—as did the district court and Zebco—that the language of the preamble of claim 1 constitutes limitations on the claim rather than mere description, see Bell Communications, 55 F.3d at 620, 34 U.S.P.Q.2D (BNA) at 1820 (Fed. Cir. 1995) ("When the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects."), Zebco cannot demonstrate that a limitation to the broad and general term "coupled" must be read into the claim.
As with "heading signal," Zebco (a) recognizes that the unmodified term "coupled" generically describes a connection, and does not require a mechanical or physical coupling; and (b) does not suggest that "coupled," as used in the preamble, lacks clarity. Instead, Zebco points to passages of the written description implying the relationship between elements of the preferred embodiment, and argues that such language constitutes a special (and limited) definition of "coupled." For example, Zebco argues that the phrase "feedback means for providing a feedback signal to the control means, wherein the feedback signal is indicative of the direction of thrust," '825 patent, col. 2, lines 32-34, defines "coupled" to mean "mechanically coupled." However, just as the preferred embodiment itself does not limit claim terms, see Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120, mere inferences drawn from the description of an embodiment of the invention cannot serve to limit claim terms, e.g., Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571, 7 U.S.P.Q.2D (BNA) 1057, 1064 (Fed. Cir. 1988), as they are insufficient to require a narrower definition of a disputed term.

Zebco also identifies statements in the prosecution history which purport to indicate the true (and limited) meaning of "coupled." Specifically, Zebco points to the aforementioned June 17, 1992 amendment of the '586 application, where the applicant argued that "it is not obvious to affix a compass to a propulsion device in a matter recited by [the] claims." However, as we noted above, that statement lends no support to Zebco's position, as it was made in reference to original claims 4 and 14, each of which expressly required that the compass be fixed to the trolling motor.

Because Zebco has not shown a sufficient reason to alter the clear meaning of the term "coupled," we agree with the district court that the term is not limited to a mechanical or physical coupling.

## 1008

### A. "Coupled"

#### 1. Proposed Constructions

Plaintiffs assert that "coupled" should be construed as "two things being connected in some way so that information can be transferred from one to the other." Plaintiffs' '736 Br. at 7. Plaintiffs assert that this is the ordinary meaning of the word. Id. Defendants, on the other hand, assert that "coupled" should have a much narrower construction. Defendants' '736 Br. at 8-9. They propose that "coupled" be construed to mean "directly connected via signal lines, busses, and/or multiplexers." Id. at 8. Defendants contend that the types of components that must be used to accomplish the coupling claimed are those which "allow for the flow of digital data without it being subject to an operation or processing step that would cause a state change in that digital data." Id.

#### 2. Claim Language

The word "coupled" appears in the preambles of claims 1 and 7 and in several other places in the bodies of the two claims. In claim 1, "coupled" is used in the following six ways: "a controller coupled with a MPEG decoder" ('736 patent at 10:43-44); "a first signal processor coupled to the read channel subsystem" (id. at 10:50-51); "a second signal processor coupled to the read channel subsystem", (id. at 10:56-57); "a read first-in-first-out buffer coupled to a memory data input register" (id. at 11:4-5); "a write first-in-first-out buffer coupled to a memory data output register", (id. at 11:6-8); and "a single memory cell coupled to the memory data output register and the memory data input register" (id. at 11:8-10). In claim 7, "coupled" is used in the following three ways: "a signal processor coupled to the read channel subsystem" (id. at 13:3-4); "a memory subsystem that includes a single memory cell coupled to the signal processor" (id. at 13:17-18); and "a parallel interface coupled to the MPEG FIFO interface" (id. at 13:24). In claim 5, which is not asserted in this action, "coupled" is used as follows: "a write first-in-first-out (FIFO) buffer, a read first-in-first-out (FIFO) buffer coupled to the error code correction and detection subsystem" (id. at 12:7-10).

To support the construction of the term "coupled" as meaning "two things being connected in some way so that information can be transferred from one to the other," plaintiffs contend that "coupled" is used to describe different types of connections in the claims. They point to the numerous examples of connections designated as "coupled" some involving two items directly coupled, others apparently designating as "coupled" items that are separated by an intervening component. Plaintiffs' '736 Br. at 7. By contrast, defendants argue that the claims clearly refer to two components as "coupled" only if
they are directly connected via signal lines, busses, and/or multiplexers in such a way that no operation or processing step occurs that changes the state of the digital data. Defendants' '736 Br. at 8.

3. Specification

Defendants argue that the specification, like the claims, refers to two components as "coupled" only if they are directly connected via signal lines, busses, and/or multiplexers such that no state change occurs in the digital data. Id.; see '736 patent at Fig. 1 & 1:35-52, Fig. 2 & 5:8-26, Fig. 4 & 6:40-55. Plaintiffs, however, argue that defendants are impossibly imposing limitations from the specification into the claims, particularly with respect to the portion of defendants' proposed construction that requires no state change between two coupled components. '736 Reply at 3. In support of their own proposed construction, plaintiffs argue that "coupled" is merely used in the '736 patent to describe a connection between two different components in the system. Plaintiffs' '736 Br. at 7.

Plaintiffs cite two examples they contend serve to rebut any requirement that components and systems must be directly connected to be coupled. They first note that claim 7 refers to "a memory subsystem that includes a single memory cell coupled to the signal processor. . . ." Second, based on the claim language in claim 7, they argue that the signal processor in Fig. 5 is connected to the single memory cell but only through multiple intervening components, namely elements 98 and 100, the write FIFO 108, and MDRO 112.

The court reads claim 7 as denoting that the memory subsystem is coupled to the signal processor, i.e., "a memory subsystem that includes a single memory cell coupled to the signal processor." The single memory cell is appropriately read as a component included within the memory subsystem of claim 7, not a component to which the signal processor is connected. Read appropriately, the single memory cell is not coupled to the signal processor, rather, the memory subsystem (that includes a single memory cell) is coupled to the signal processor, another subsystem.

However, even with the court's reading of the limitation, Fig. 5 illustrates the memory system 102 is coupled to the signal processors 92 and 94 via additional elements 98 and 100 located between the memory subsystem and the signal processors. 98 and 100 are described in the specification as multiplexors, neither of which is an intervening subsystem. However, they are components between the subsystems. Thus, the subsystems are not directly connected to one another without intervening components -- intervening components exist between the subsystems.

Under defendants' proposed construction, multiplexors are permissible components between "coupled" elements because, so long as no state change occurs in the digital data, multiplexors are merely connective elements. Defendants' proposed construction, however, is too narrow, as it specifies the nature of the connective elements and adds a requirement for "no state change" found nowhere in the claims or specification, thereby introducing limitations not expressly called for in the specification. The court is, however, also concerned that the plaintiffs' proposed construction is overly broad and that under plaintiffs' proposed construction, every pair of subsystems would be considered "coupled", independent of location, function, or relation to each other. Thus, it finds another construction to be appropriate.

The specification and claims designate specific subsystems as being "coupled" when they are directly connected in both prior art and the preferred embodiment, see, e.g., '736 patent at 1:49-50, 2:26, 5:24, 6:49, 6:51, 6:52 & claim 1, 2; they designate specific components as being "coupled" when they are directly connected, id. at 2:32 & claim 1, 2; and they designate specific components connected to subsystems as being "coupled" when they are directly connected, id. at 2:24, 2:38 & claim 5. Thus, the court adopts neither party's construction and construes "coupled" as describing a direct connection, specifically, a connection between subsystems without intervening subsystems, a connection between components without intervening components, and a connection between components and subsystems without any intervening components.

This court has consistently construed the term "coupled" to mean "directly or indirectly connected." Accordingly, the court adopts Lucent's construction of this term.
8. "Coupled"

The court defines the term "coupled" to mean "electrically connected, directly or indirectly."

(2) "Coupled"

EMC contends that the term "coupled" means connected by a communications path. While HP does not dispute that "coupled" means connected, it contends that the requisite connection must be direct, i.e. without the intervention or interposition of any additional system or device. The parties agree that the requisite connection may be physical or logical.

The plain and ordinary meaning of the term "coupled" is "mechanically or electrically connected." Webster's Third International Dictionary, 522 (1981). There is no requirement that such connection be direct rather than indirect. Moreover, there is no indication in the Specification that the term "coupled" is limited only to "direct" connections. The Specification states, in relevant part,

[t]he primary system controller 16 is coupled to the storage device 20 by means of a data signal path 24.

[t]he . . . second disk adaptor 36 is coupled, via a high speed communication link 40 to disk adapter 42 on a secondary data storage system controller . . . .

[u]tilizing network connections, the primary and secondary data storage system controller 16 and 44 may be connected to FDDI networks, T1 or T3 based networks and SONET networks.

'347 Patent, Col. 4, ll. 18-20, 53-56 and 62-65 (emphasis added). Although Figure 1 in the Specification of the '347 Patent depicts the aforementioned "couplings" as direct connections, EMC has not demonstrated, either in the Specification or in the prosecution history, a clear intent to disavow or disclaim the plain and ordinary meaning of the term "coupled." Consequently, the term coupled will be construed to mean connected, directly or indirectly, by a communication path.

3. Element [B] -- "Coupled"

The parties dispute the proper construction of the term "coupled" in element [B] of claim 35. WeddingChannel argues that "coupled" means connected, directly or indirectly, to allow the transfer of signals or information. The Knot interprets "coupled" to mean connected directly via an internal computer bus.

WeddingChannel argues that the term "coupled" has a well-understood meaning in the art: Computer engineers understand that one structure is "coupled" to another if signals or information can pass -- directly through a wire or indirectly through an intervening computer or circuit -- from one to the other. In support of this interpretation, WeddingChannel cites a definition of "coupling" drawn from a technical dictionary:

(3) (software) The manner and degree of interdependence between software modules…

(7) The association of two or more circuits or systems in such a way that power or signal information may be transferred from one system or circuit to another.
The IEEE 100, The Authoritative Dictionary of IEEE Standard Terms at 247 (7th ed. 2000). WeddingChannel argues that its proposed construction of the term "coupled" is also supported by relevant case law holding that the ordinary meaning of "coupled" is "connected, directly or indirectly." Silicon Graphics, Inc. v. nVIDIA Corp., 58 F. Supp. 2d 331, 346 (D. Del. 1999); see also Intel Corp. v. Broadcom Corp., 172 F. Supp. 2d 478, 490 (D. Del. 2001) (stating that "coupled" is "a term of art in patent parlance that means electrically (or otherwise) connected to allow the transfer of signals").

WeddingChannel argues that the patent specification confirms that the term "coupled" should be read broadly (and according to its ordinary meaning) to include indirect coupling. The specification states that "one or more registry databases 120 may actually reside on one or more remote servers 142 that are accessible to system memory 114 through network interface 112." '753 Pat. at col. 11, ll. 34-39. WeddingChannel argues that because such data typically passes through numerous intervening computer systems as they traverse the internet, the specification necessarily contemplates indirect coupling.

The Knot argues that the generic definition of "coupling" -- i.e., the direct or indirect connection of two components so that information or power can be passed between them -- is not applicable to the '753 patent. Rather, the Knot takes the position that the term "coupled" has different meanings depending on the patent that is being construed. See, e.g., Acacia Media Technologies Corp. v. New Destiny Internet Group, No. SA CV 02-1040-JW (MLGx), 2004 U.S. Dist. LEXIS 13415 at *42 (C.D. Cal. July 12, 2004). 4 The Knot argues that any construction of the term "coupled" must take into consideration the following: (1) that in the '753 claims, only the "central processing unit" and the "memory" are recited as being "coupled," and (2) that in the specification, the only connection shown or described between the central processing unit and the memory is computer bus 138, a direct physical connection. ('753 Pat. at col. 4, ll. 25-29; Fig. 1).

The Knot disputes WeddingChannel's contention that the specification provides that remote servers are "coupled" across the internet to system memory 114 through intervening network interface 112. Rather, the Knot argues that the specification merely states that one or more remote servers are "accessible" to system memory 114 through network interface 112.

The Knot argues that this intrinsic evidence must be consulted "to identify which of the different possible dictionary meanings of the claim terms in issue is most consistent with the use of the words by the inventor." Tex. Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002). 5

The Knot's construction of the term "coupled" is based on the incorrect assumption that the '753 patent only recites the CPU and "memory" as being coupled. As discussed above, element [B] provides that the CPU is also coupled to registries from database providers. As demonstrated in the specification, the connection between the CPU and the registries from database providers is necessarily indirect. Therefore, the term "coupled" must encompass both direct and indirect connections. On this basis, WeddingChannel's construction of the term "coupled" is adopted.

--- Footnotes ---

4 The Knot points out that in Acacia, the court found that the ordinary meaning of the phrase "coupled to" was "directly connected or attached to." Acacia, 2004 U.S. Dist. LEXIS 13415 at *42. It should be noted that the Acacia court read the directness requirement into the definition; there is no such directness requirement contained in the dictionary definition cited by the Acacia court. Id. (stating that Webster's Ninth New Collegiate Dictionary (1991) defines "couple" to mean 'to connect for consideration together'").

--- End Footnotes ---

5 The Texas Digital Systems court also stated that "if more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings." Tex. Digital Sys., 308 at 1203. (quoting Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1343 (Fed. Cir. 2001)).

--- End Footnotes ---

--- WeddingChannel's construction of the term "coupled" is adopted. ---
Verizon asserts that the term "coupled" means "separate from but operatively connected for electrical communication." Verizon Brief at 25. According to Katz, no special construction of "coupled" is necessary. Katz, however, also provides a definition: "two things are coupled if they are associated in such a way that power or signal information may be transferred from one to another." Katz Brief at 40.

"Coupled" means associated in such a way that power or signal information may be transferred from one to another. It appears that one of ordinary skill in the art understands the term "coupled" to connote a broad range of associations between two things. The plain meaning of coupled, as understood by someone ordinarily skilled in the art, does not require that the "coupled" components be necessarily physically separate from one another. See Lucanoni 1/15/03 Decl. PP 6-8, & Exs. 2, 3; see also Webster's Ninth New Collegiate Dictionary at 298 ("couple" means "to join together for combined effect"). Verizon points to nothing in the specification or prosecution history of the 734 patent that justifies deviating from the broad meaning of "coupled" as understood by one of ordinary skill in the art. At the Claims Construction Hearing, Verizon alleged that two elements must have an interface between them to be "coupled" within the proper meaning of the term. Verizon's contention, however, begs the question as to whether this interface must be physically defined or defined purely by software.

Fairchild contends that the term "coupled" should be given its plain and ordinary meaning. Specifically, Fairchild contends that "two circuits are coupled when they are configured such that signals pass from one to the other." (D.I. 152 at 10). Fairchild contends that Power Integrations' construction of this term seeks to imply a requirement that the connection be a direct connection, or a connection without any intermediate circuit elements. Fairchild contends that such a construction is inappropriate and is driven by Power Integrations' concern that the claims may be found invalid in light of the prior art.

Power Integrations contends that "two circuits are coupled when they are connected such that voltage, current, or control signals pass from one to another." (D.I. 152 at 10; D.I. 164 at 17-18). According to Power Integrations its construction of the term "coupled" does not require a direct connection as Fairchild contends. Rather, Power Integrations contends that its construction reflects more accurately the nature of the coupling recited in the patent, because the recited coupling is present "for the purposes of control (i.e., 'digital to analog converter coupled to the control input for varying the switching frequency' and 'counter coupled to the . . . digital to analog converter, the counter causing the digital to analog converter to adjust...')" (D.I. 152 at 10).

Construing the term "coupled" in light of the claim language and specification, the Court concludes that "two circuits are coupled when they are connected such that voltage, current or control signals pass from one to another." In reaching this determination, the Court concludes that Fairchild's construction is overly broad and generic and fails to consider the term "coupled" in the context of the invention. In the Court's view, its construction of the term "coupled" is consistent with the claim language and the context of the specification which describes the purpose for which various parts of the claimed invention are coupled. (876 patent, claim 1, col. 8, ll. 48-49, 50-52). However, the Court's construction of the term "coupled" should not be read to imply or necessitate a direct connection, as the Court does not read the patent to require a direct connection or to preclude the use of intermediate circuit elements.

25. Coupled
This term appears in claims 3 and 17 of the '313 patent. The plaintiff argues that this term needs no construction. The defendants contend that the term means "totally coupled," which is a variant of the position that the claims (even the non-means-plus-function claims) are limited a network that provides each processor full access to each storage register in a non-blocking manner. This position is rejected. The term "coupled" means "connected, directly or indirectly."

Intergraph again argues this term carries its ordinary meaning "in connection with." Intel argues "coupled" means electrically connected. The Court construes "coupled" as connected, directly or indirectly.

(2) coupled

The issue here is whether "coupled" describes a direct connection, indirect connection, or both. Dell argues that the patents use the term throughout the specification as meaning a "direct physical connection." Contrary to Dell's assertion, claims 14 and 94 of the '216 patent, read together with the specification, suggest that "coupled" can include an indirect connection. Claims 14 and 94 state the following:

At least a first updatable switchtable in said first station for storing information indicating at least the destination of data;

a microprocessor operating according to a first clock, coupled to said updatable switchtable, said updatable switchtable operating according to a second clock asynchronously with said first clock;

a register coupled to said microprocessor for receiving update data from said microprocessor during a first time period at a data rate corresponding to said first clock and coupled to said first updatable switchtable for outputting said update data to said first updatable switchtable. '216 Patent, cl. 14 (emphasis added).

Looking to the specification, claims 14 and 94 of the '216 patent appear to be shown in Figure 12. As discussed in the specification, "FIG. 12 depicts another configuration which permits the processor 138a to update the receive and transmit switch tables 140, 162 without such inefficiency." '216 Patent, col. 15, ll. 5-7. The processor is not directly connected to the switchtable. The claims, when read in light of the specification, indicate that "coupled" means more than a "direct physical connection."

As such, the court defines "coupled" to mean the following: "connected directly or indirectly."

"Coupled" means "the transfer of energy over a conductive or dielectric medium, such as an optical waveguide or wire."

3. What is the Proper Construction of the Term "Coupled" in Claim 1 of the '481 Patent?

Claim 1 of the '481 patent uses the term "coupled." Silicon Graphics contends the term "coupled" requires that the specified components be coupled or connected, directly or indirectly. This would encompass any electrical connection that allows a
signal to travel from one circuit to another, whether directly or indirectly. nVidia contends the term "coupled" means "directly coupled" or "directly connected." Under nVidia's proposed construction, "coupled" would include, for example, a wire between points A and B with no other components in between.

Neither the claim nor the specification defines the term "coupled." Both parties refer to dictionary definitions to support their proposed constructions. For example, Silicon Graphics cites a technical dictionary of electronics, which defines the term "couple" as "to connect two circuits so signals are transferred from one to the other." Sclater, N. and Markus, J., McGraw-Hill Electronics Dictionary (6th Ed. 1997). nVidia counters with definitions of "couple" that include: (1) "to link together; connect," from The American Heritage College Dictionary, (3d Ed.) at 318; and (2) "a rather vague term, used to indicate that systems which might operate separately are actually being used in some form of cooperative mode. . . ." from the Dictionary of Computing, (4th Ed. 1996)

The Federal Circuit teaches that "a court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms." Johnson Worldwide Associates, Inc. v. Zebco Corp., 1999 WL 243570, *3; see also Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 951 (Fed. Cir. 1993) ("Although a patentee can be his own lexicographer, as we have repeatedly said, the words of a claim 'will be given their ordinary meaning, unless it appears that the inventor used them differently.'"); Intelicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387 (Fed. Cir. 1992). The court notes that the ordinary and accustomed meaning of the term "couple," even when used in an electronics context does not solely mean "directly coupled."

The specification of the '481 patent sheds some light on the meaning of "coupled." For example, Claim 1 recites that the cache is coupled to the input. Figure 2 is a block diagram of a TRAM as an embodiment of the inventions claimed in the patent. In this diagram, the cache is not directly connected to the input line, instead there is a DRAM array and an input buffer between the cache and input line. This arrangement suggests that "coupled" means directly or indirectly connected.

The specification and claims of the '709 patent also support this construction. Claim 1 of the '709 patent recites "an interpolator coupled to said main memory and said cache memory." Figure 2 of the specification is a diagram similar to Figure 2 of the '481 patent that shows the interpolator directly connected to the cache but not to the main memory. The Federal Circuit teaches that the prosecution history of a parent application may be considered by the court in its interpretation. See, e.g., Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1027 (Fed. Cir.) modified, 131 F.3d 1009 (Fed. Cir. 1997) (noting statements in the parent application may be considered but must be confined to their proper context). The Federal Circuit has explained that an inventor is not likely to define the invention in a way that excludes the preferred embodiment. Hoechst Celanese Corp. v. BP Chemicals, Ltd., 78 F.3d at 1581.

The court finds no reason not to apply the ordinary meaning of the term "couple," and determines that the ordinary meaning in this context is "coupled or connected, directly or indirectly."

Claim 1 of the '481 patent states "an output coupled to said interpolator for outputting said output rendered pixel . . . ." Claim 10 of the '481 patent states "outputting said output rendered pixel from said semiconductor chip . . . ." The parties dispute the meaning of the terms "output," and "outputting" and "output rendered pixel."

All of nVidia's arguments concerning the meaning of these terms flow from the underlying premise that the '481 patent does not claim further processing of the pixel on the semiconductor chip after the interpolator has performed its texture mapping functions and rendered a value. To support this position, nVidia contends that outputting from the interpolator and from the semiconductor are one in the same, and that an output rendered pixel is the texture mapped pixel output by the interpolator that has not received further on-chip processing. nVidia bases its argument upon statements made in the '481 patent's specification and the prosecution history.

Silicon Graphics, on the other hand, contends the phrases at issue can be understood according to the ordinary meaning of their terms. Silicon Graphics argues the phrase "an output coupled to said interpolator for outputting said output rendered pixel" in Claim 1 describes an output and outputting from the interpolator, and not necessarily from the semiconductor.
Similarly, Silicon Graphics contends the phrase "outputting said output rendered pixel from said semiconductor chip" in Claim 10 describes outputting from the semiconductor, and not necessarily from the interpolator. Silicon Graphics also argues the claims encompass other on-chip processing in addition to texture mapping.

This claim construction dispute underlies the literal infringement dispute. nVidia's allegedly infringing graphics chips perform processing in addition to mapping texture onto a pixel before outputting the pixel from the chip. For example, additional on-chip processing maps lighting and fogging effects on the pixel. According to Silicon Graphics's claim construction, a graphics chip which performs on-chip processing in addition to mapping texture onto the pixel may literally infringe Claims 1 and 10. According to nVidia's interpretation, a chip which performs on-chip processing of a pixel after the pixel is output by the interpolator does not literally infringe either Claim 1 or Claim 10.

a. What is the meaning of the phrase "an output coupled to said interpolator for outputting said output rendered pixel" in Claim 1 of the '481 patent?

The plain language of Claim 1 does not suggest that outputting or the output from the interpolator must be the same as outputting or the output from the semiconductor chip. Neither does the claim language define "output rendered pixel" as a rendered pixel output from the semiconductor with no processing other than the texture mapping performed by the interpolator.

nVidia argues that the inventors understood the output and outputting from the interpolator to be the same as the output and outputting from the semiconductor, and that they understood an "output rendered pixel" to be a texture mapped pixel that had not been further processed before being output by both the interpolator and the semiconductor. nVidia cites the '481 patent's "Summary of Invention," which states: "also included within the same semiconductor chip is one or more interpolators. These interpolators produce an output texel by interpolating from the textures stored in memory. The interpolated texel value is output by the semiconductor chip for display."

nVidia argues that, based upon this understanding of the invention, the applicants limited the meaning of the term "output rendered pixel" during prosecution. During the prosecution of the '709 patent, the applicants amended pending Claims 1 and 19, replacing the word "texel" with the phrase "output rendered pixel." With respect to this amendment, the applicants stated: "the word 'texel' as used in the claims refers to a pixel element of an object to which the texture pattern has been mapped, the pixel element being available at the chip's output as a 'rendered pixel.'"

These combined statements lead to the conclusion that the applicants understood that the pixel processed by the interpolator would be output from the semiconductor chip. These statements do not lead to the conclusion, however, that the inventors thought the patent did not disclose mapping additional data onto the pixel after the pixel is output from the interpolator but before the pixel is output from the semiconductor.

nVidia argues the patent's specification discloses that the "output rendered pixel" undergoes further processing in addition to texture mapping only after being output from the TRAM. In support, nVidia cites the specification, which reads: "the pixel data is sent to the raster subsystem, whereupon the z-buffering, blending, texturing and anti-aliasing functions [additional processing functions] are performed. The resulting pixel values are stored in frame buffer 109. The display subsystem reads frame buffer and displays the image on display monitor" U.S. Patent No. 5,706,481, col. 4, ll. 16-21.

The language nVidia cites refers to the specific example of a computer system utilizing the invention depicted in Figure 1 of the '481 patent. The Federal Circuit teaches that particular embodiments appearing in a specification should not be read into the claims when the claim language is broader than such embodiments. See, e.g., Electro Medical Systems, S.A. v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994). Accordingly, the court finds that this statement does not disclaim processing on the TRAM in addition to the texture mapping performed by the interpolator.

Because nVidia has not demonstrated that the claim, specification, or prosecution history limits the meaning of the phrase at issue, the court construes it according to the ordinary meaning of its terms. Johnson Worldwide Associates, Inc. v. Zebo Co., 1999 WL 243570, *3. The court finds the phrase "an output coupled to said interpolator for outputting said output rendered pixel" in Claim 1 of the '481 patent means an output coupled to the interpolator for outputting the output rendered pixel. The court finds that outputting the output rendered pixel from the interpolator, as described in Claim 1, does not have to be the same step as outputting the output rendered pixel from the semiconductor. The court also finds that an "output
rendered pixel" may undergo further on-chip processing in addition to texture mapping.

1020

10. Coupled/Coupled To

The terms "coupled" and "coupled to," as used in Claims 1, 8, and 13, are not defined in the claims or specification and therefore must be construed in accordance with their ordinary meaning to a person skilled in the art. Citec's proposed construction is supported in part by reference to the Random House Unabridged Dictionary (2d ed. 1993), which defines the verb "couple" as "to fasten, associate or link together" or "to join or associate by means of a coupler." However, Citec's proposed definition of "functionally, operatively, or communicatively linked" seeks to introduce limitations not suggested by the specifications. Similarly, Romtec's interpretation of the term "coupled to" as used with "user actuated switching means" improperly seeks to read into the term a limitation in the specification. Therefore, the Court construes the terms "coupled" and "coupled to" to mean linked together.

1021

4. "coupled between"

Claims 1, 4, 7, 10, 15, 18 and 21 contain the phrase "coupled between." Toshiba contends that no construction is necessary and the ordinary meaning of the phrase should apply. Jt Cl Const, Ex B at 9. Alternatively, Toshiba proposes that the phrase means "a current path permitting signals to be transferred between two points." Id. Hynix construes "coupled between" as ". . . residing between distinct elements and connecting the distinct elements directly or indirectly." Id. Hynix illuminates the court with the following statement: "The phrase 'coupled between [sic] has two aspects: it must couple two elements and it must be between those two elements." Hynix Br at 17 (emphasis in original). While the court cannot disagree with Hynix's tautological reasoning, Hynix has not provided any reason why its far more cumbersome construction would assist a jury perform its duties better than the simple term "coupled between." Accordingly, the court declines to construe this term.

1022

c. "A control coupled only to said preprogrammed memory for selectively communicating said preprogrammed memory to said electronic control module."

According to Plaintiff, this phrase means "a control coupled to a physical structure containing at least one additional program, for the sole purpose of communicating contents of that preprogrammed memory to the ECM." Defendants advance the following construction: "a control physically connected only to the preprogrammed memory and to nothing else, for the purpose of physically switching a physical memory to a physical computer, not merely transferring the program contents of that memory to another memory." The first point of contention here is whether the word "only," as situated within the phrase at issue, refers to the elements being connected or to the purpose of the connection. Plaintiff argues that the word indicates that the coupling is intended only to communicate the memory. Defendant contends that the claim allows coupling only between the control and the preprogrammed memory. The second disputed issue is whether the memory conveyed consists of the contents of the memory module (i.e., the software) or the physical memory itself (i.e., the hardware). Plaintiff takes the former position, while Defendant advances the latter.

Mr. Lundell recommends that "only" be read to refer to the purpose of the connection and not to the components involved. He suggests that the Court construe "only . . . for" to mean "for the sole purpose of." The Court agrees with Mr. Lundell's construction, which -- unlike Defendants' interpretation -- has the advantage of encompassing the embodiments described in the patent.
Mr. Lundell further recommends that the Court read "selectively communicating said preprogrammed memory" to mean "the transfer of information from the preprogrammed memory to the electronic control module at different times and for different purposes." This construction permits the transfer of either the contents of a memory or the physical memory itself and is consistent with the Court's holding that the device must be permanently affixed to the vehicle. Accordingly, the Court adopts the following construction: "a control coupled to the preprogrammed memory for the sole purpose of permitting the transfer of information from the preprogrammed memory to the electronic control module at different times and for different purposes."

F. "A control coupled only to said preprogrammed memory for selectively communicating said preprogrammed memory to said electronic control module, operation of said vehicle being changed by said control according to said additional program in said selected preprogrammed memory in lieu of said originally provided program."

This term means that the external module includes a control circuit that is connected only to the preprogrammed memories and to nothing else. The control circuit is used to regulate or guide the operation of the vehicle. The control circuit regulates or guides the operation of the vehicle according to the additional program within the preprogrammed memory in lieu of, that is, instead of, the original program within the fixed system's memory.

In Adrain's proposed construction, the word "only" refers to the phrase "selectively communicating." However, such a construction goes against and distorts the plain language of the claim. The language of the claim recites that the "control is coupled only to said preprogrammed memory . . . ." The word "only" directly follows the word "coupled" and is directly followed by the phrase "preprogrammed memory." Adrain's construction would require that the word "only" follow the phrase "selectively communicating," which it does not do. The word "only", then, clearly refers to where the control is coupled, that is, the preprogrammed memory. It does not refer to "selectively communicating."

This same language is found in the Brief Summary of the Invention section of the 948 patent: "A control circuit is coupled only to the plurality of preprogrammed memories and selectively communicates one of the plurality of preprogrammed memories to the electronic control module." (948 Patent, col. 2, ln. 39-42). Again, "only" immediately follows "coupled" and obviously refers to where the control circuit is coupled.

2. Whether or Not the Processor Means Must be "Coupled to" the Memory Key During a Test

Biosite, and to a certain extent Apex/HDI, n8 contend that the "coupled to" limitation of the "processor means" element necessitates that the processor means be connected to the memory key means during a test. Biosite argues that all the experts in the case agree that the "processor means" accesses data on the pluggable memory key means during the test. Moreover, Biosite continues, the experts agree that the "coupled to" limitation in claim 4 also means that the "processor means" is connected to the pluggable memory key means during the test, therefore, the same meaning should apply the to term in claim 1. To further support its position, Biosite points to language in the specification that implies that the "processor means" must be able to access data during a test: "Because the amount of random access memory (RAM) contained within microprocessor 59 is limited, data from ROM key 30 is loaded into RAM by microprocessor 59 only on an as needed basis, after which it is discarded, with new data taking its place." n9 Id. col. 6, ll. 14-18.

n8 Apex/HDI contend that the corresponding algorithm for what they have interpreted as an "accessing" function of the "processor means" requires the microprocessor to access parameter values and procedure routine specifications on a real-time basis during execution of the entire algorithm. In effect, this is the same argument that Biosite makes regarding the "coupled to" limitation.
Roche contends that a continuous connection is not required by the term "coupled to." Roche argues that Biosite takes Dr. Dunsmore's testimony out of context, and that the expert did not opine that the "processor means" has access to the pluggable memory key means during the test. Furthermore, Roche argues that the embodiment of the invention that includes using a cyclic redundancy check ("CRC") indicates that all the necessary data is downloaded to the microprocessor before the test is run. See id. col. 8, ll. 16-29; id. Fig. 8. A definition for "coupled to" that requires the "processor means" to be connected to the pluggable memory key means during the test would obviate this embodiment.

The Court finds that the plain meaning of the term "coupled to" is: joined or connected to during performance of the algorithm. The claim language itself implies that the "processor means" responds to data on the pluggable memory key means during performance of the algorithm that controls the sense means, and calculates an analyte value. Claim 1 states, "processor means coupled to said memory key means and responsive to parameter values and procedure routine specifications accessed from said pluggable memory key means, for controlling operation of said sense means in accordance with said algorithm and for calculating . . . a concentration value. . . ." Id. col. 9, ll. 4-11. The language of claim 4 is equally persuasive. See id. col. 9, ll. 52-68 (describing how the processor means uses data from the pluggable memory key means to execute the test procedure).

The specification supports the conclusion that the invention of the 609 patent, as disclosed to one of ordinary skill in the art at the time of the inventions, would have read the limitation "coupled to" to require some connection between the "processor means" and the "pluggable memory key means" during execution of the algorithm. As pointed out by both Biosite and Apex/HDI, the description of the preferred embodiment indicates that the "processor means" is connected to or communicating with the pluggable memory key means during the test. The specification teaches that information is loaded from the pluggable memory key means by the processor "only on an as needed basis." Id. col. 6, ll. 14-18.

Roche argues that the disclosure of another embodiment that uses a CRC necessitates a different result; the second invention requires all data to be read from the pluggable memory key means at once, the test is run, then the values are read again. The invention described by Figure 8 and the text of the specification that describes the algorithm in Figure 8 suggests that "all data is read from ROM key 30 and a CRC checksum is calculated therefrom . . . [and] the CRC checksum is stored in RAM in microprocessor 59 and the test continues until a glucose value has been calculated. . . ." Id. col. 8, ll. 19-27. Then, "all data is again read from ROM key 30 and a CRC checksum is again calculated. . . ." Id. col. 8, ll. 28-29; id. Fig. 8. Roche's reading of this passage and Figure 8 ignores the subtlety of this disclosure. It is clear from the passage in column 8 that all the data is read, a CRC value is calculated from the data, but only the CRC value is stored. As taught by the other description of the invention found earlier in the patent, the data is only used as needed, then it is discarded. Id. col. 6, ll. 16-18. Therefore, all the values are used to calculate the CRC value, but then they are discarded. The claim, however, requires that "processor means" access the parameter values and procedure routine specifications to run the algorithm. If the microprocessor does not store all the values it needs to run the algorithm, and it must access them to run the algorithm, then the "processor means" must be connected to the pluggable memory key means during the test. Roche tries to broaden the claim language too far to insist otherwise.

For the foregoing reasons, the Court concludes that the "coupled to" limitation means: joined or connected to during performance of the algorithm.
This term raises only one question: to be "coupled to" each other, how close must the connection be between the message transmitting processor and the message receiving processor? I agree with defendant that the two processors do not have to be adjoining; there may be an intermediate link in between them. This is shown in the specification, which states that different items may be "coupled to one another by the backplane bus," '181 pat., col. 2, lns. 66-68 (emphasis added). Figure 1 below provides an example of this in which one processor 20 is "coupled to" another processor 20 by a backplane bus 14:

Any further construction at this point would be both unnecessary and unhelpful. The terms "direct" and "indirect" are themselves ambiguous. Thus, adopting one of the parties' constructions would only invite further debate at summary judgment regarding the meaning of those terms.

NeoMagic argues that the common and ordinary meaning of the term 'coupled to' within claims 7 and 18, which recite "a memory portion coupled to said logic portion," should apply. They argue that the Federal Circuit's construction of the term 'coupling' from the '955 patent should not apply to the term 'coupled to' of the '806 patent because the claim in the '955 patent had an additional limitation within the claim language that required the 'coupling' to be "determined by a voltage of said underlying substrate." 46 They argue that 'coupled' requires that the memory and graphics (logic) portions electrically communicate, which is consistent with the use of the term 'coupled' in the asserted claims, with the common and ordinary meaning of the term 'coupled' and with the specification.

Trident argues that the disputed term 'coupled' should be construed consistently with the Federal Circuit's construction of the term in the '955 patent. They assert that the terms 'coupled' and 'coupling' between these two related patents are essentially identical and that one skilled in the art would understand that the way in which the memory portion is 'coupled to' the logic portion is "determined by the voltage of the underlying substrate." Further they contend that 'coupled to' cannot simply mean 'connected to' because both terms are present in the disputed claims and because in claims 1 and 4 of the '806 patent, 'connected to' is used to describe a simple connection. Lastly, Trident argues that its construction is consistent with the rest of the language of the claim ("negative with respect to") as interpreted by the Federal Circuit.

The Federal Circuit held that the ordinary meaning of 'coupling' refers to "an electrical communication--the transfer of energy--between two circuits … See New IEEE Standard Dictionary of Electrical and Electronics Terms 277 (5th ed. 1993) (defining coupling as 'the association of two or more circuits or systems in such a way that power or signal information may be transferred from one to another')." 47 Furthermore, the Federal Circuit stated that the parties agree that "coupling" refers to electrical communication between the two specified components. Their position is consistent with the technical definition of coupling, which means "[a] mutual relation between two circuits that permits energy transfer from one to another, through a wire, resistor, transformer, capacitor, or other device." McGraw-Hill Dictionary of Scientific and Technical Terms 474 (5th ed. 1994); see also Rudolf F. Graf, Modern Dictionary of Electronics 157 (7th ed. 1999) (defining coupling as "the association or mutual relationship of two or more circuits or systems in such a
way that power may be transferred from one to the other"). 48

47 Id. at 1071.
48 Id. at 1072.
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Neither the District Court in its previous decisions nor the Federal Circuit construed the term 'coupled to' in reference to the '806 patent. Judge McKelvie's and the Federal Circuit's previous constructions started with the plain meaning of the term, just described above, then further limited the meaning of 'coupling' in the '955 patent to the language of its claim which includes the limitation "determined by a voltage of said underlying substrate regions." This limiting language of the '955 patent is not present in the disputed claims of the '806 patent.

The analysis starts with the language of the claims of the '806 patent. Claims 7 and 18 simply recite "a memory portion coupled to said logic portion" without any additional limitation. The technical definition stated above, to which the parties agree, delimitates the term 'coupled' as an electrical communication between the two specified components, here being the memory portion and the logic portion of the integrated circuit. There is a "heavy presumption" that a claim term carries its ordinary and customary meaning. 49 The limitation that Trident would like to read into the claim language is based on the Federal Circuit's interpretation of the term 'coupling' in the '955 patent. Even though both the '955 and the '806 patents share the same specification, they recite two separate inventions, which is supported by the prosecution history outlined in detail in Judge McKelvie's previous decision. 50 The two coupled components of the '955 patent are the logic gates and the substrate, whereas the two coupled components in the '806 patent are the memory portion and the logic portion of the integrated circuit. Furthermore the limitation of the '955 patent requiring that the 'coupling' be "determined by a voltage of said underlying substrate regions" is not within the language of the '806 patent claims. These are two separate inventions. The ordinary meaning of the terms of the claims of the patent at issue are controlling.

Therefore, as already elaborated in detail in previous decisions of this court and the Federal Circuit, the term 'coupled to' means an electrical communication between the two specified components, here being the memory portion and the logic portion of the integrated circuit.

4) "Coupled To"

MKS contends that the phrase "coupled to" in claim 1 and claim 24 means "connected in a fashion that allows for the transfer of power." (D.I. 103 at 28). Advanced Energy contends that the phrase "coupled to" cannot "be construed so as to include the use of an impedance matching network," that is, the term must be construed to mean directly connected to the primary winding, without intervening components. (D.I. 110 at 22).

Again, with regard to the term "coupled to," the parties' dispute centers on the absence or presence of an impedance matching network. As discussed previously, based on the patent specification and prosecution, the Court concludes that the invention was not intended to encompass an impedance matching network. (D.I. 94 N.J.L. 480, 111 A9 col. 2 ln. 22-26, A12 col. 7 ln. 49-60, A13 col. 10 ln. 19-21, A121-22, 124, A169-70). Accordingly, the term "coupled to" means connected.
not through an impedance matching network, but in a fashion that allows for the transfer of power.

1028

c. "coupled to"

The Court construes the phrase "coupled to" to have its plain and ordinary meaning, which is "directly connected to or attached to." See e.g. Webster's Ninth New Collegiate Dictionary 298 (1991) (defining "couple" to mean: to connect for consideration together); see also CCS Fitness, 288 F.3d at 1366 (holding that there is a heavy presumption that a claim term carries its ordinary and customary meaning). The term "coupled to" as used in the claims and specification means two elements are directly attached to one another such that using a diskette to transfer information from one to another would mean that the two computers are not "coupled to" one another. 17

17 Similarly, transferring a diskette from one computer to another would not make the two computers "in data communication with" one another. See '702 patent claims.

I. Limitation 8: Drain electrode

36. The next element of Claim 1 is as follows: "a drain electrode coupled to said drain conductive region." For example, in Figure 8 "further region" 83 is "coupled" to the electrode (the unnumbered cross-hatched structure) at the bottom surface of the wafer and top electrode 85 is "coupled" to N+ region 95 and buried layer 84. Similarly, in the Figure 2 embodiment, electrode 26 is "coupled" to the unnumbered substrate layer. This claim element is properly construed to include any electrode electrically coupled to the "drain conductive region." This "coupling" is properly construed to indicate device current flowing through both the drain conductive region and the electrode.

3. "coupled to a telephone"

Klausner proposes "connected to a telephone so that signals are transferred from one to the other," while Vonage proposes "connected to the called party's telephone line." The primary dispute here is whether the telephone access device ("TAD") is connected to the "called party's telephone line." Vonage argues that the TAD must be connected to the "called party's telephone line" because the specification limits the invention to the answer mode described in Figures 3A and 3B. For the reasons discussed above, the Court rejects this argument. In light of the preamble's description of the method as one of "automatically answering incoming telephone calls and storing and retrieving information from the incoming telephone calls," the Court finds Klausner’s proposal to be deficient as well. The patent specification simply describes the telephone answering device as being connected to the telephone line that receives an incoming call. '576 patent, col. 5:41-44. Accordingly, the Court construes this term as "connected to a telephone receiving an incoming call."

6. "a data bus coupled to the computer system and the unit for transferring unit data information" (Claim 1)
Defendants propose the following construction of the term: "A common communications pathway connecting multiple devices that allows for the transfer of address, control and data information between the devices."

Keystone's proposed construction is "one or more wires or electrical connections between the computer system and the unit for transferring data from the unit." Keystone points out that the central disagreement between the parties is whether the data bus allows for transfer of all three types of information, namely address, control and data information. Defendants argue that this is the understanding of the term "bus" in the art. Moreover, it argues the specification discloses that the data bus and I/O discrete line network includes "address, control and data connections" to connect the I/O processor to a unit. See '123 Patent, 6:43-45.

Keystone responds by arguing that this description simply discloses one embodiment of a data bus structure that can transfer a combination of address, control and data information. It argues the claim scope should not be limited require a combination of all three. It notes that in another part of the specification, the data bus is listed as providing only data to and from the I/O processor. See '123 Patent, 8:59-62. Even though similar claims in the '592 patent use the language "for transferring a combination of address, control and data information," Keystone argues that the inventor intended to include this limitation in the claims of that patent, but not here. Keystone's arguments are not persuasive as to require the Court to exclude the transmission of any address or control information on the data bus, in contrast to what the inventor has disclosed in the specification common to both the patents. The Court construes this term as: "A communications pathway connecting the computer system to one or more units that allows for the transfer of address, control and data information between the computer system and each of the units."

The parties dispute the meaning of the term "a device coupled to the local bus" which appears in Claim 1 of the 305 patent:

A. Construction of "a device coupled to the local bus"

1. A system comprising: a computer having a processing unit, a main memory, and a local bus; a device coupled to the local bus, wherein the device occupies an I/O slot that corresponds to a first communications port on the local bus . . .

PCTEL contends that the term means "[a] device arranged so that electrical signals can pass between the device and the local bus", whereas Agere proposes that the term means "a device directly connected to the local bus." PCTEL argues that the term "coupled" does not necessarily imply a physical connection, asserting that such an interpretation is more suited in the field of mechanical engineering, rather than to the relevant field of art, electrical engineering. PCTEL urges the Court to adopt a definition of coupling which focuses on the passing of signals rather than physical attachment. To support its position, PCTEL points to the following language from Claim 1,

"a software modem adapted to convert digital samples from the device to data values transmitted to the UART emulation and adapted to convert data values from the UART emulation to digital samples for the device."

PCTEL also cites the claim language "the device occupies an I/O slot" to support the conclusion that the device is not directly connected to the bus. According to PCTEL the relevant physical connection is between the bus and the I/O slot and not between the bus and the device. Therefore, PCTEL argues, the device is indirectly connected to the bus through the I/O slot. PCTEL supports it argument with dictionary definitions for the word "couple" which focus on the meaning of the word with respect to the transfer of energy, rather than any physical connection. n1

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n1 PCTEL offers the following dictionary definition for the word "coupling":

"coupling: The association of two or more circuits or systems in such a way that power or signal information may be transferred from one to another. IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS (1988)"
couples: "The association or mutual relationship of two or more circuits or systems in such a way that power may be transferred from one to another."

Agere disputes PCTEL's construction, pointing to the prosecution history of the 305 patent for support. n2 During prosecution, the PTO rejected PCTEL's submission based upon Patent Number 5,408,614 ("Thornton patent") which claimed a similar system, except that the Thornton invention was connected to the computer through a parallel port. Declaration of Jordan N. Malz ("Malz Declaration"), Ex. 6 at 17643. The patent examiner noted that the major difference between the Thornton patent and the 305 patent was that the former was "coupled to the parallel port" and the latter had a "direct connection to the control/address/data bus within the PC." Id. (emphasis added) The patent examiner deemed it obvious to "couple a device to the local bus" in light of Thornton. In response, PCTEL sought to distinguish the 305 patent from the Thornton patent arguing that Thornton, "teaches away from connecting a device to the local bus."

n2 Agere also cites dictionary definitions that support its interpretation of the term "coupling".

PCTEL's construction is problematic. The first place a Court must look to construe the meaning of a patent are the words of the claim itself. Vitronics, 90 F.3d at 1582. Immediately following the phrase "coupled to the local bus" is the phrase "wherein the device occupies an I/O slot." The use of the word "occupies" elaborates upon the phrase "coupled to the local bus" and strongly suggests a direct, physical connection to the local bus through the I/O slot.

This interpretation is supported by language the specification itself, which notes that "[t]his invention relates to a . . . device having a non-standard I/O interface coupled to a local bus . . . common devices connected to a . . . bus include serial I/O devices such as . . . a modem. . . . [t]he non-standard device connects to an I/O slot . . ." (305 Patent, Description, 2). n3 The claims and the specification indicate that the inventor understood the I/O slot to be physical entry-point on the local bus through which the device would be coupled, and therefore directly connected, to the local bus.

n3 Emphasis is added unless otherwise indicated.

The prosecution history also supports this reading. There is evidence that the patent examiner understood "coupled to" to mean "directly connected to." The Court finds the patent examiner's rejection of PCTEL's claims, on the basis of Thornton prior art, particularly instructive. The Thornton patent taught an invention similar to the 305 patent, but which was connected to a parallel port, whereas the 305 patent was connected to the bus through an I/O slot. In rejecting PCTEL's claims, the patent examiner stated, "the Thornton device is coupled to the parallel port . . . [i]t would have been obvious for one of ordinary skill in the art to have [the] device coupled to the local bus because it would have a [a] direct connection to the control/address/data bus within the PC." (Malz Decl., at 17643). This implies that the examiner understood the phrase "coupled to" to mean "directly connected to" since the Thornton device was directly connected to the parallel port, and the patent examiner referred to it as "coupled" to the parallel port; similarly, PCTEL's device was "coupled" to the local bus through the I/O slot and the examiner referred to it as "directly connected . . . to the bus." PCTEL's own papers acknowledge the fungibility of these terms as used during the prosecution, stating that "[o]ne distinction debated in the prosecution history was that the 305 device would not connect externally through a parallel port, but would connect internally with the local bus. "(Reply, 4). PCTEL thereby acknowledged that the issue involved "connecting" devices to the local bus, despite the fact that the examiner used the word "coupling" as well as "connecting."

The intrinsic evidence supports a finding that the inventor had this same understanding of the word "coupled", namely, that
that the multiplexer circuit connects 2:1 TGMs in series. Thus, under the terms of the patent, an N:1 multiplexer connects
connected in series. While claim 47 specifies a 4:1 multiplexer, claim 48 specifies a 5:1 multiplexer. Both claims specify
Representative claim 47, like representative claim 48, clearly claims a multiplexer circuit with a number of 2:1 TGMs
Id. at 1315. (internal quotations omitted). The specification "is the single best guide to the meaning of a disputed term." Id.
the art in question." Id. at 1313. For this reason, "claims must be read in view of the specification, of which they are a part.
construction. According to that decision, the words of a claim "are generally given their ordinary and customary meaning." Id.
proposed constructions of both parties. "A claim should not rise or fall based upon . . . the court's independent decision,
uninformed by the specification, to rely on one dictionary rather than another." Phillips, 415 F.3d at 1322. Accordingly,
given the language of the claims and the inventor's understanding of these terms during the prosecution history, the Court
finds that the clearest reading of "a device coupled to the local bus" is a "device directly connected to the local bus".
The Court gives more weight to the intrinsic evidence of the specification and prosecution history than to PCTEL's extrinsic
dictionary evidence. PCTEL's reliance on dictionaries is problematic as there are dictionary definitions supporting the
proposed constructions of both parties. "A claim should not rise or fall based upon . . . the court's independent decision,
uninformed by the specification, to rely on one dictionary rather than another." Phillips, 415 F.3d at 1322. Accordingly,
given the language of the claims and the inventor's understanding of these terms during the prosecution history, the Court
finds that the clearest reading of "a device coupled to the local bus" is a "device directly connected to the local bus".
Translogic puts forth three major arguments that the Board erred in holding the claims of the '666 patent obvious over Gorai
in view of Weste. First, Translogic contends that the Board incorrectly construed the claim term "coupled to receive." Second,
Translogic contends that the Gorai reference is not relevant prior art with respect to the '666 patent. Third,
Translogic contends that the Gorai reference does not disclose that each input and control input terminal must receive a variable signal from a different source. Thus, according to Translogic, the Weste
reference merely describes TGMs but does not suggest their use in this purported inventive combination.
The Board construed the term "coupled to receive" signals to mean terminals merely "capable of receiving" signals.
Translogic argues that the Board should follow the claim construction in the companion infringement case from the United States District Court for the District of Oregon. The Oregon District Court determined that "signal input terminal 'coupled to receive' an input variable" would mean "connected to receive an input variable, directly or through one or more intervening inverters or buffers." Translogic Tech., Inc. v. Hitachi, Ltd., Civ. No. 99-407-PA, 2005 U.S. Dist. LEXIS 45724 (D. Or. May 12, 2005) (Claim Construction Chart). Under this construction, representative claims 47 and 48 require each input and control input terminal to be connected to receive a variable signal from a different source. Thus, according to Translogic, the Gorai reference does not disclose that each input and control input terminal must receive a variable signal from a different source. Instead, according to Translogic, Gorai teaches logic circuits with input terminals coupled to share signals and receive constants.
In Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005) (en banc), this court set forth the best practices for claim
construction. According to that decision, the words of a claim "are generally given their ordinary and customary meaning." Id. at 1312. The ordinary and customary meaning "is the meaning that the term would have to a person of ordinary skill in the art in question." Id. at 1313. For this reason, "claims must be read in view of the specification, of which they are a part." Id. at 1315. (internal quotations omitted). The specification "is the single best guide to the meaning of a disputed term." Id.
Representative claim 47, like representative claim 48, clearly claims a multiplexer circuit with a number of 2:1 TGMs
connected in series. While claim 47 specifies a 4:1 multiplexer, claim 48 specifies a 5:1 multiplexer. Both claims specify
that the multiplexer circuit connects 2:1 TGMs in series. Thus, under the terms of the patent, an N:1 multiplexer connects
(N-1) TGMs in series with each TGM controlled by a corresponding (N-1) control input signal. ’666 Patent col.3 ll.63-66. Fig. 3 from the ’666 patent shows the claimed circuit for the 4:1 multiplexer.

The words of the claim coupled with the specification define the term "input terminals 'coupled to receive' first and second input variables." First, the claim terms do not specify any structural connection for the input terminals. Furthermore, Fig. 3 of the ’666 patent and the other figures show no structural connection for the input terminals (i.e., I0, I1, I(N-1)) or the control input terminals (i.e., S1, S2, S3). In fact, Translogic admits, as is proper for a structural circuit, that the input variables (i.e., signals) are not part of the claimed invention.

A claim language comparison also shows the proper construction for the term at issue for the ’666 patent. Claim 47 has two similar, but significantly different phrases, "coupled to receive" and "coupled to." The term "coupled to" in the phrase "second stage input terminal 'coupled to' the first stage output terminal" defines a connection between the TGMs. In other words, "coupled to" in the context of this claim phrase defines the connection between two of the TGMs essential for a series multiplexer.

On the other hand, the term "coupled to receive" in the phrase "input terminals 'coupled to receive' first and second input variables" does not specify a particular connection. In other words, the claimed circuit does not require any specific input or connection. Instead, like any logic circuit, this part of the circuit only accepts inputs from an external source. As such, "coupled to" and "coupled to receive" are clearly different in the claimed ’666 patent multiplexer circuit. As shown in Fig. 3 of the ’666 patent, the input terminals (i.e., I0, I1, I(N-1)) only need to be "capable of receiving" an input variable for the multiplexer circuit as claimed in the ’666 patent. Even if the input terminals are not connected, the circuit claimed in the ’666 patent defines a series multiplexer. Therefore, this court agrees with the Board's construction that "coupled to receive" means "capable of receiving." With the disputed term limitation decided, this court now turns to obviousness.

"coupling" or "coupled"

The term "coupling" or "coupled" refers to the direct connection of two or more circuits or systems in such a way that power or signal information may be transferred from one to the other.

Lucent proposes that "coupling" or "coupled" requires a direct connection. 149 Plaintiff argues that this construction is contrary to a recent Federal Circuit case in which "coupled" was not limited to a mechanical or physical coupling. 150 Rather, plaintiff argues that coupling merely requires an association such that information may be exchanged. 151 Plaintiff further argues that if Lucent's definition were accepted, the remote user could never "couple" to the VPS because of the numerous intermediate hops within the PSTN.

149 Docket no. 76 at 10. Weiss testified that "coupling . . .[is] even stronger than connected. Coupling [means] literally cabled together" (Tr. 1494).

150 Johnson v. Worldwide Assocs., Inc., 175 F.3d at 992.151 Docket no. 104 at 18-19; docket no. 114 at 3.

Although the ’639 patent discusses "coupling through a communication mechanism or channel" 152 which, arguably, suggests intermediate connections or "hops," the patent also discusses the VPS having "connections" that are adapted for "coupling" to a transmission media, the telephony server and the LAN and the patent refers to the user communications device as being adapted for "coupling" to the transmission media. 153 These "couplings" imply direct connections between the elements, without unnecessary intervening connections between the elements, as illustrated by figure 2 of the patent, 154 but do not exclude intermediate "hops" within an element, for example, within the PSTN. The direct connections also
do not exclude the logical connections proposed by plaintiff. 155 This construction is not inconsistent with the teaching of Johnson Worldwide Associates, Inc.

152 '639 patent, col. 4, lines 35-37.

153 See '639 patent, col. 4, lines 40-58.

154 Autogiro Co. v. United States, 384 F.2d at 398 ("in those instances where a visual representation can flesh out words, drawings may be used in the same manner and with the same limitations as the specification").

155 Docket no. 108 at 8.

4. "coupling"

Coupling refers to the "plurality of signal lines" and the nature of the connection between the claimed multiplexed "address data buses" and the "host platform." The parties dispute whether "coupling" refers to a direct connection between the host platform and signal lines or whether the connection must be done electronically.

There is nothing in the specification requiring an electrical connection. The terms "electrical," "electric," and "electronic" never even appear in the specification. The figures and the specification repeatedly show the host platform directly connected to peripheral devices by a plurality of signal lines. See Figs. 1 and 8; '807, 4:53-5:12, 7:14-17, 12:13-24, 13:23-27; '141, 4:57-5:16, 7:17-21, 12:20-30, 13:29-33. Defendants argue that the patentee explicitly used "directly" when necessary and used "coupling" when an indirect connection is permissible. 11 Defendants' example, however, does not pertain to multiplexing which in the context of the claims, is the purpose of "coupling" a plurality of signal lines to the host platform. '807, 4:56-67; '141 4:60-5:4. Further, an indirect connection would not allow multiplexing to occur. Multiplexing requires streams of data to "take turns" using a common signal line. An indirect connection would interrupt this process. It is precisely the direct connection of the signal lines to the host platform that drives the number of pins whose reduction is a principal goal of the patent. Accordingly, the court construes the term "coupling" to mean "directly connecting."

11 "Connecting speaker 895 directly to line 805 would cause the line to begin a transition when it was tri-stated. Therefore, speaker 895 should be further coupled with a high impedance input 892..." '807, 13:21-24.

B. "coupling"

The term "coupling" appears in one of the asserted claims of the '955 patent. Claim 1 of the '955 patent requires "logic gates with a voltage supply having a coupling to said underlying substrate regions determined by a voltage of said underlying substrate regions." NeoMagic contends that "coupling" means coupled or connected, directly or indirectly. Trident, on the other hand, argues that the term "coupling" requires a voltage potential in the substrate that is different than the voltage potential in the logic gates.
In the specification of the '955 and '806 patents, the inventors describe their method for reverse biasing the substrate to solve the noise problem. According to the specification, the logic circuits are redesigned to decouple the V[SS] line connected to the source terminals of the N-channel pulldown transistors from the P-substrate tap. The specification further provides that the logic circuit is connected to a V[SS] line at 0 volts, while the substrate is tapped by a V[BB] line at -1.5 volts. By reverse biasing the substrate in this manner, excess charge carriers flow away from the logic and memory portions of the graphics controller.

NeoMagic's proposed construction of "coupling" to mean "connection," is inconsistent with this explanation in the specification. Moreover, NeoMagic's proposed construction of the term is also inconsistent with the claim language. Claim 1 of the '955 patent states that the logic gates have "a voltage supply having a coupling . . . determined by a voltage of said underlying substrate." In accordance with the specification, this language requires that the reference potential, V[SS], for the logic gates must be different from the voltage potential, V[BB], that is applied to the substrate. Otherwise, the phrase "determined by a voltage of said underlying substrate" would be superfluous and meaningless.

Therefore, as advocated by Trident, the court finds that "coupling" requires a voltage potential in the substrate that is different than the voltage potential in the logic gates.

1037

We begin, as always, with the language of the claim. The patent claims logic gates "having a coupling to said underlying substrate regions. . . ." As noted above, the parties agree that "coupling" refers to electrical communication between the two specified components. Their position is consistent with the technical definition of coupling, which means "[a] mutual relation between two circuits that permits energy transfer from one to another, through a wire, resistor, transformer, capacitor, or other device." McGraw-Hill Dictionary of Scientific and Technical Terms 474 (5th ed. 1994); see also Rudolf F. Graf, Modern Dictionary of Electronics 157 (7th ed. 1999) (defining coupling as "the association or mutual relationship of two or more circuits or systems in such a way that power may be transferred from one to the other"). The claim further states that the coupling is "determined by a voltage of said underlying substrate." This indicates, of course, that the voltage applied to the substrate will affect the degree--and possibly the existence of--the claimed coupling between the substrate and the gate. However, this language does not help differentiate between the proposed definitions of NeoMagic and Trident because in both definitions the coupling depends upon the voltage applied to the substrate. In the case of junction capacitance, proffered as the proper definition by NeoMagic, assuming a constant voltage applied to the logic gate circuit, variations in the voltage at the substrate will affect the junction capacitance, thereby altering the capacitive coupling between the two components. In Trident's formulation, the degree of coupling depends upon the potential difference between the two components, and--again, assuming constant voltage to the logic gate--altering the voltage applied to the substrate obviously changes the potential difference between it and the logic gate. Because the language of the claim does not speak with clarity, we turn to the specification to improve our understanding of the meaning of "coupling." Robotic Vision Sys., Inc. v. View Eng'g, Inc., 189 F.3d 1370, 1375, 51 USPQ2d 1948, 1952-53 (Fed. Cir. 1999).

The specification describes the redesigned logic gate by reference to the figure shown below.

GET DRAWING SHEET 3 OF 6

The specification explains that "the logic circuits of the integrated circuit are redesigned to decouple the VSS line connected to the source terminals of the N-channel, pulldown transistors from the P-substrate tap." '955 Patent, col. 4, lines 34-37. In other words, the supply line for the N-channel transistor of the logic circuit is different from that for the substrate. By itself, this explanation would be consistent with either party's explanation of the term "coupling." However, the specification then expressly teaches a design in which the voltage supply lines for the two components are at different voltages: "As shown in FIG. 4, the source of the N-channel, pulldown transistor 35 of a representational logic circuit is connected to a VSS line 45 (at 0 volts), while the substrate is tapped by a VBB line 47 (at -1.5 volts)." '955 Patent, col. 4, lines 38-42. While it would be improper to limit the claims to the particular voltages used in the preferred embodiment (zero and -1.5 volts), it is perfectly clear that the specification contemplates that the two voltages be different from each other, regardless of their absolute value. Notably, this is the only place in which the specification describes the interaction of the logic circuitry and the substrate, and it specifically requires that different voltages be applied to the substrate and the logic circuit. As Trident notes, this description is fully consistent with its proposed definition of the term "coupling" because, under Trident's definition,
coupling is attenuated if the two circuits are at different potentials, thereby achieving the object of the invention: permitting substantial amounts of memory and logic to operate on the same integrated circuit without interfering with one another. We agree, and hold that, consistent with the specification, the term coupling requires that the voltage applied to the substrate be different from that applied to the logic circuit. Thus, the coupling is "determined by a voltage of said underlying substrate regions" because the extent of electrical coupling is dependent upon the voltage difference applied between the substrate and the logic circuit.

Under this construction of "coupling," the accused devices do not infringe the '955 patent as a matter of law. This is so because Trident's devices tap both the substrate and the logic circuit at the same voltage: VSS--zero volts. Therefore, we affirm the district court's judgment that Trident's devices do not have the claimed coupling limitation and do not infringe the '955 patent.

1038

C. Noise Covariance Matrices

The dispute between the parties for "noise covariance matrices" centers around whether the patentee acted as a lexicographer 8 and gave a definition of "noise covariance matrices" in the specification.

-- Footnotes --

8 "An applicant is entitled to be his or her own lexicographer and may rebut the presumption that claim terms are to be given their ordinary and customary meaning by clearly setting forth a definition of the term that is different from its ordinary and customary meaning(s)." Manual for Patent Examining Procedure § 2111.01 IV. (8th ed., rev. July 2010).

-- End Footnotes --

The term "noise covariance matrices" is used in claims 11, 16, 19, and 23 of the '839 Patent and claim 6 of the '180 Patent. Claim 19 of the '839 Patent is illustrative of how the term is used and it reads as follows:

19. A detector circuit for detecting a plurality of data from a plurality of signal samples read from a recording medium comprising:

   a Viterbi-like detector circuit, said Viterbi-like detector circuit for producing a plurality of delayed decisions and a plurality of delayed signal samples from a plurality of signal samples;
   a noise statistics tracker circuit responsive to said Viterbi-like detector circuit for updating a plurality of noise covariance matrices in response to said delayed decisions and said delayed signal samples; and
   a correlation-sensitive metric computation update circuit responsive to said noise statistics tracker circuit for recalculating a plurality of correlation-sensitive branch metrics from said noise covariance matrices, said branch metrics output to said Viterbi-like detector circuit.

'839 Patent col. 15 ln. 50-66.

CMU's construction for "noise covariance matrices" is:

"Noise covariance matrices" means "noise statistics used to calculate the 'correlation-sensitive branch metrics.'"

RDCTC at 11.

Marvell separately provides constructions of "covariance" and "covariance matrices" in addition to its construction of "noise covariance matrices" all of which are as follows:

"Covariance" means "the expected (mean) value of the product of (ri-mi) and (rj-mj), where ri and rj are observed signal samples (at time i and j, respectively) and mi and mj are the expected (mean) values of the samples (at time i and j,
respectively)(i.e., E[(ri-mi)( rj-mj)])."

"Covariance matrices" means "arrays of covariance of pairs of signal samples, e.g.:

[SEE ILLUSTRATION IN ORIGINAL]

"Noise covariance matrices" means "covariance matrices of signal samples (where the signal samples include noise)."

RDCTC at 9-11.

CMU's source for its construction is from the specification, which CMU argues is an explicit definition for "noise covariance matrices," that reads:

A noise statistics tracker circuit 34 uses the delayed samples and detector decisions to update the noise statistics, i.e., to update the noise covariance matrices.

'839 Patent col. 3 ln. 36-38. CMU then argues that the use of "i.e." equates "noise covariance matrices" to noise statistics and cites Abbott Labs v. Novopharm Ltd., 323 F.3d 1324 (Fed. Cir. 2003), in support.

Marvell states that its construction is the plain meaning of the term "noise covariance matrices," and Marvell's sources for its construction are technical dictionaries and textbooks. Marvell cites the following as an example of the ordinary meaning for "covariance matrix":

covariance matrix - A square array that represents all the pairs of covariances of a set of random variables. A covariance matrix is a square matrix in which main diagonal elements represent variances of the variables and off-diagonal elements are the covariance. Moreover, like the correlation matrix, a covariance matrix is also symmetrical about the diagonal. Pocket Dictionary of Statistics at 66 (2002)(Docket No. 82-16 at 4-5).

As stated above, "the specification is 'the single best guide to the meaning of a disputed term,'" and consistent with that general principle "the specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs." Phillips, 415 F.3d 1303, 1321 (quoting Vitronics, 90 F.3d at 1582; citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed.Cir.2002)). The Court of Appeals for the Federal Circuit has recognized that a patentee can act as a lexicographer with the use of "i.e. 9" followed by a definition of the term. Pfizer, Inc. v. Teva Pharmaceuticals USA, Inc., 429 F.3d 1364, 1373 (Fed. Cir. 2005). The Court of Appeals cautioned, however, that a person of ordinary skill in the art is always considered to have read the claims in light of the full specification. Id. (citing SanDisk Corp v. Memorex Prods., Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005); Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1379-80 (Fed. Cir. 2001)). As a result, support for an alternative construction found elsewhere in the specification may indicate that the patentee did not use "i.e." in a lexicographical manner and thus, the proper construction will be found elsewhere in the patent. Pfizer, 429 F.3d at 1373-74.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 "i.e. is an abbreviation for the Latin id est and means 'that is.'" Webster's Dictionary of English Usage (1989)(Docket No. 94-1 at 4).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

In Pfizer, the Court of Appeals found that "saccharides (i.e. sugars)" did not constitute an explicit definition of saccharides because elsewhere in the specification the patentee explained what saccharides meant. Id. at 1373-75. In the specification, there was a section entitled "SACCHARIDES" that gave context to the term that was inconsistent with equating saccharides with sugars only. Id. The Court of Appeals stated, however, "[p]roperly understood, then, these sections do not define the exact meaning of 'saccharides' and 'excipients.'" Id. at 1374. Rather, since the section left an open ended meaning that was inconsistent with equating saccharides to sugars, the Court of Appeals was left to conclude that the "i.e." was not definitional. As a result, if a person of ordinary skill in the art would find the purported "i.e." definition inconsistent with the
rest of the patent, the court will not find the "i.e." to be used to define the term that precedes it. This is consistent with the cases that have found "i.e." to be used to create a definition, because in those cases, either the specification added further support to the definition, or the only use of the term in the specification was in conjunction with the "i.e." See Abbott, 323 F.3d at 1330 ("Moreover, the inclusion of the word 'intimate' in the definition, together with the fact that fenofibrate and SLS are the only ingredients present in every co-micronized mixture described in the '726 patent's specification, makes it abundantly clear that [what followed the i.e. is definitional]"); Tidel Engineering L.P. v. Fire Kind International, Inc., 613 F. Supp. 2d 823, 829 (E.D. Texas Jan. 6, 2009)("Indeed, the term 'economy safe' is not used but one time in the specification. Following that only instance is the parenthetical (i.e., comprised of just a safe and a unit 16, without a PC board and printer."); Caritas Technologies, Inc. v. Comcast Corp., No. 2:05-CV-339-DF, 2006 U.S. Dist. LEXIS 98006, 2006 WL 6112191 at *16 (E.D. Texas Oct. 18, 2006)("Therefore, the specification does not teach any other meaning of 'connection status information' besides that taught after 'i.e.' introduces a definition."); ESN, LLC v. Cisco Sys., Inc., 685 F. Supp. 2d 631, 2009 WL 2849742 ("[T]he specification does not identify "SIP User Agent" other than in connection with an endpoint, so the use of "i.e." cited above is especially probative of the meaning of "SIP User Agent."")

In the '839 Patent, the term "noise covariance matrices" appears elsewhere in the patent, not only with the purported "i.e" definition, and it is used as follows:

Because the noise statistics are non-stationary, the noise sensitive branch metrics are adaptively computed by estimating the noise covariance matrices from the read-back data.

A noise statistics tracker circuit 34 uses the delayed samples and detector decisions to update the noise statistics, i.e., to update the noise covariance matrices.

The focus is shifted to tracking the noise covariance matrices needed in the computation of the branch metrics (13).

'839 Patent col. 2 ln. 15-18; col. 3 ln. 36-38; col. 9 ln. 21-23.

The term "noise statistics" which CMU argues is equated with "noise covariances matrices" is used elsewhere in the specification, as follows:

Specific expressions for the branch metrics that result under different assumptions on the noise statistics are next considered.

Also, the signal and noise statistics will be different if a head is flying slightly off-track or if it is flying directly over the track.

The past samples and detector decisions are used to update the noise statistics at step 44.

'839 Patent col. 5 ln. 56-58; col. 8 ln. 31-33; col. 11 ln. 16-18

In reading the entire patent, the PHOSITA would not read the "i.e." cited by CMU to define "noise covariance matrices" as meaning "noise statistics" because the term's usage elsewhere in the specification indicates they are separate concepts with separate definitions. For instance, the phrase "[t]he focus is shifted to tracking the noise covariance matrices needed in the computation of the branch metrics (13)" would indicate that the noise covariance matrices can be found in equation (13). '839 Patent col. 9 ln. 21-23. The general correlation-sensitive metric equation (13) reads:

[SEE ILLUSTRATION IN ORIGINAL]

'839 Patent col. 7 ln. 1-5. Prior to equation (13), it is stated that "[t]he (L+1)x(L+1) matrix Ci is the covariance matrix of the data samples ri, ri+1, . . . , ri+L, when a sequence of symbols ai-Kl, . . . ai+L+Kt is written." '839 Patent col. 6 ln. 53-55.

The PHOSITA would take this to mean that the covariance matrix of the data samples Ci used in equation (13) is the "noise covariance matrices" being referred to by the language "the noise covariance matrices needed in the computation of the branch metrics (13)". '839 Patent col. 9 ln. 21-23. Furthermore, the covariance matrices and the "noise covariance matrices" are equated in the summary of the invention section. It states that "[b]ecause the noise statistics are non-stationary, the noise sensitive branch metrics are adaptively computed by estimating the noise covariance matrices from the read-back data.
These covariance matrices are different for each branch of the tree/trellis due to the signal-dependent structure of the media noise. '839 Patent col. 2 ln. 15-20.

"Noise statistics" can be shown not to have the same meaning as "noise covariances matrices" in the wording "specific expressions for the branch metrics that result under different assumptions on the noise statistics are next considered." '839 Patent col. 5 ln. 56-58. In this instance, the assumptions on the "noise statistics" are the prior art assumptions of white Gaussian noise and variance dependent noise as well as the novel assumption that the noise is correlated and signal-dependent for the correlation-sensitive branch metric. Because the term "noise statistics" has a broad enough meaning, as used by the patentee, to encompass both the prior art noise assumptions as well as the correlated and signal-dependent noise assumptions, the intrinsic evidence does not support equating "noise statistics" with "noise covariance matrices" and the PHOSITA would not define "noise covariance matrices" as "noise statistics." To do so would allow the prior art noise assumptions to be used in the correlation-sensitive branch metric which the PHOSITA would understand to be inapposite to the purpose of the invention.

CMU argues that the language "[t]he past samples and detector decisions are used to update the noise statistics at step 44" provides a second intrinsic example of where the patentee explicitly defines "noise covariance matrices" as "noise statistics." '839 Patent col. 11 ln. 16-18. Step 44 of Fig. 6 shows:

[SSEE FIG. 6 IN ORIGINAL]

'839 Patent Fig. 6. CMU argues that updating the "noise statistics" at step 44 means that "noise statistics" and "noise covariance matrices" are the same thing. The text "[t]he past samples and detector decisions are used to update the noise statistics at step 44" and Fig. 6 are consistent with the language "[a] noise statistics tracker circuit 34 uses the delayed samples and detector decisions to update the noise statistics, i.e., to update the noise covariance matrices." '839 Patent col. 11 ln. 16-18; col. 3 ln. 36-38. However, the PHOSITA would not read either section of the Patent to be providing a definition of "noise covariance matrices." Rather, both statements would be read as meaning when the "noise statistics" are updated, this has the effect of updating the "noise covariance matrices." This understanding is consistent with the notion that the "noise covariance matrices" are derived from the data samples that contain noise. See '839 Patent col. 6 ln. 53-55.

CMU also points out that alternative embodiments contained in the specification do not require the use of a covariance matrix in order to calculate the correlation-sensitive branch metric. (See Docket No. 90-3, McLaughlin's 2 Declaration nd at ¶¶ 9-12). It is true that "[a] claim construction that excludes a preferred embodiment . . . is 'rarely, if ever correct.'" Pfizer, 429 F.3d at 1374 (citing SanDisk Corp., 415 F.3d at 1285; Vitronics, 90 F.3d at 1583). However, at the hearing, Marvell stated that the alternative embodiment mentioned by CMU would be covered by another set of claims, citing specifically claim 20, to which CMU agreed that all embodiments would be covered by at least one claim under Marvell's construction. (Docket No. 118 at 180:7-12, 204:15-17). "A patentee may draft different claims to cover different embodiments." Intamin, 483 F.3d at 1337. Since the alternative embodiment that calculates the correlation-sensitive branch metric is covered by another claim, the PHOSITA would not have reason to read "noise covariance matrices" as meaning "noise statistics."

Turning to Marvell's construction, when the Court asked CMU if separate definitions were adopted for "covariance" and "covariance matrices," what would its constructions be, CMU responded that Marvell's constructions were appropriate. (Docket No. 118 at 178:19-179:12). As stated above, the specification says that "Ci is the covariance matrix of the data samples" and Ci is the noise covariance matrix used in equation (13). '839 Patent col. 6 ln. 53-55. This language from the specification is directly reflected in Marvell's construction.

As a result, the construction of the terms "covariance," "covariance matrices and "noise covariance matrices" is as follows:

Covariance means "the expected (mean) value of the product of (ri-mi) and (rj-mj), where ri and rj are observed signal samples (at time i and j, respectively) and mi and mj are the expected (mean) values of the samples (at time i and j, respectively)(i.e., E[(ri-mi)(rj-mj)])."

Covariance matrices means "arrays of covariance of pairs of signal samples, e.g.:

[SEE ILLUSTRATION IN ORIGINAL]
Noise covariance matrices mean "covariance matrices of signal samples (where the signal samples include noise.)."

A. Creating.

The plaintiff contends that "creating" should be defined as "selecting, forming, or making." The defendants contend that the term should be defined as "making or bringing into existence, in real time, something new." The court defines the term "creating" as "forming or making."

A. "Creating a Circle"

The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiff's Proposal</th>
<th>Defendants' Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>creating a circle: calculating values that define the set of all points in a plane equidistant from a center point</td>
<td>circle: A closed curve of all points within the same plane that are equidistant from a fixed center point. An arc is not a circle unless all its points are equidistant from a center point and the arc spans a full 360 degrees. A point and a distance by themselves are not a circle. In the context of a computer program, an object need not have been physically plotted in order to constitute a circle, but the program must at least have designated the object as an object with the attributes and behavior of a circle.</td>
</tr>
</tbody>
</table>

The underlying dispute over this heavily contested term was central to the motion for a preliminary injunction: whether or not the creation of an arc is equivalent to the creation of a circle. In light of the parties' briefs and their arguments at the Markman hearing, the Court adopts the following construction:

creating a circle -- Calculating values that define the set of all points in a plane equidistant from a center point, and specifying that the values represent all such points. Merely calculating a center point and a distance (or "radius") would not create or comprise a circle. Points equidistant from a center point that would constitute an "arc" if reduced to tangible form would not become a circle until and unless the points extended a full 360 degrees and all of the points were equidistant from the center point.

The reasons for adopting this construction are discussed below. Both sides relied primarily on extrinsic evidence in support of their constructions, and the Court consequently bases its conclusion largely on those sources.

1. Dictionary definitions of "circle" 2

2 I begin with the dictionary definition of "circle" because it is logical to pin down a definition of "circle" before looking to
the intrinsic evidence to understand what it means to "create" a circle by means of a computer program, which is the crux of the parties' dispute. See Phillips, 415 F.3d at 1324 ("[A] judge who encounters a claim term while reading a patent might consult a general purpose or specialized dictionary to begin to understand the meaning of the term, before reviewing the remainder of the patent to determine how the patentee has used the term. The sequence of steps used by the judge in consulting various sources is not important; what matters is for the court to attach the appropriate weight to be assigned to those sources in light of the statutes and policies that inform patent law.")

Both sides draw on dictionaries to define the term "circle." The only difference in their approach is that Defendants rely on general purpose dictionaries, while Plaintiff draws from mathematical dictionaries. Defendants' preferred definition is "a closed plane curve every point of which is equidistant from a fixed point within the curve." Merriam-Webster's Collegiate Dictionary (10th ed. 1996). Plaintiff's preferred definition is "the set of all points in a plane equidistant from a center point." Potel Decl. I P 10; Potel Decl. II P 7. Plaintiff's sources are more authoritative because the parties agree that the patent describes a mathematical process. The Court thus adopts this definition of "circle."

2. The specification

"The inquiry into how a person of ordinary skill in the art understands a claim term provides an objective baseline from which to begin claim interpretation." Phillips, 415 F.3d at 1313. "Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim . . . but in the context of the entire patent, including the specification . . . ." Id. The Federal Circuit has urged district courts to look to the patent specification to illuminate the meaning of terms used in the claims. See id. at 1315 ("the specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive . . . .") (citation omitted).

Defendants rely on the patent's specification to argue that (1) the patent makes clear distinctions between arcs (or semicircles) and circles; and (2) the patentee intended "circle" to entail a "closed plane curve." Plaintiff objects to this reliance on the specifications, but its vague and general analysis is not helpful. I conclude that Defendants' reliance on the specifications is acceptable because they have not "imported" limitations from the specifications into the claims. Rather, they have identified repeated uses of the disputed language in the specification that illuminate the term's meaning.

As to Defendants' first argument concerning distinctions made in the patent between circles and arcs, the patent's Definitions section, the descriptions of the preferred embodiments, and language in other claims are revealing. For example, the patent's "Definitions" section, which is under the "Detailed Description of the Invention," defines a "circular arc" as "the set of all points equidistant from a fixed point called the center, i.e. a portion of a circle." (013 patent 4:55) (emphasis added). In the description of the Sixth Preferred Embodiment, the patent defines arcs as "pieces of the original circles." Id. at 20:33-34 (emphasis added). Defendants cite several other spots in the specifications and the claims themselves containing or reflecting distinctions between circles and arcs, and circles and radii or center points. See Ds' Brief at 8:28-9:17; 11:12-25. Some are more probative than others, but together these distinctions show that the specification cannot be reconciled with a definition that would encompass the creation of a circular arc. Nowhere does the specification confute the creation of an "arc" and the creation of a "circle." See Intamin, 483 F.3d at 1336 (finding support for court's construction in fact that patent specification used term consistent with the construction).

However, as to Defendants' second argument, concerning whether a circle entails a closed curve, the specifications do not support the conclusion that the patentee intended "circle" to entail a "closed plane curve." Although figures in the specification show closed curves, those figures are obviously for illustrative purposes. I also agree with Plaintiffs that "closed" suggests a visual representation of a circle, which is not appropriate in the context of computer software creation (discussed below).

3. The ordinary and customary meaning of "creating circles" in the field of software development

Although claim 14 refers only to a method for creating a tool path, claim 35 claims a software program that is to perform the claimed methods. Furthermore, the opening paragraph of the "Field of the Invention" section of the '013 patent states, "[t]his invention relates to computer aided manufacturing and more specifically to a method and apparatus for generating a computer numerical control program for controlling a numerical control machine." (013 patent 1:15-18.) The parties thus
agree that the terms should be construed in the context of creating software.

Both sides enlisted competing experts to educate the Court on the ordinary and customary meaning of "creating circles" in the field of software design. Plaintiff's expert, Michael J. Potel, Ph.D. has significant experience in software development and "computer graphics." Defendants' expert, Professor Gerald Farin, has a great deal of experience in the field of computer aided design: he has designed CAD software; authored 100 papers and authored/edited over 20 books in the field of geometric modeling, including leading textbooks on Computer Aided Design; is the editor-in-chief of the journal Computer Aided Geometric Design; received an award for achievements in computer aided geometric design; teaches courses in computer aided geometric design; and has many other relevant credentials. See Farin Decl. PP 4-8. Defendants also rely on expert declarations from Defendant Evan Sherbrooke, who created the allegedly infringing software and previously participated in developing Plaintiff's embodiment of the '013 patent.

Farin's declaration for Defendants explains that when a software program "creates" a circle, it requires two things: (a) a center point and a radius that define the set of all points in a plane equidistant from a center point; and (b) some indication that those values are meant to create a circle, such as an associated method or algorithm. Without such an indication, a center point and a radius could be used to define many different shapes, including an equilateral triangle, a regular pentagon, or any other regular polygon. They could also be used to define three-dimensional objects, such as spheres and cubes. Farin Decl. PP 13-20.

Based on the above considerations, I conclude that the evidence of the ordinary and customary meaning of "creating a circle" in the field of software development requires a construction that specifies that creating a circle involves not just "calculating values that define" a circle, but specifying that those values comprise a circle, as opposed to some other figure.

4. Prosecution history

Defendants contend that during the application process the patentee argued to the United States Patent and Trade Office that its invention was not obvious because previous patents that involved the use of "medial axis transforms" did not entail the creation of families of concentric indexed circles. Therefore, they assert, Plaintiff cannot now argue that merely specifying a radius and center is equivalent to "creating a circle." Plaintiff contests this conclusion, but even if Plaintiff is correct on this issue, its analysis would show only that the prosecution history does not support either side's preferred construction. Thus, because the factors above compel the conclusion that specifying a radius and center per se is not equivalent to "creating a circle," the Court need not reach this issue.

For these reasons, the Court adopts the above construction, which incorporates elements of Plaintiff's and Defendants' proposals.

C. The Dispute Over the Creation of Concentric Indexed Circles

Independent claims 14 and 35 of the '013 patent describe the same first step:

creating a family of concentric indexed circles at each of two or more separate and distinct selected points within the
Defendants argue that VoluMill's process does not create any circle at all, much less "a family of concentric indexed circles." The Court finds that Plaintiff has not established that it is likely that it can prove that VoluMill's process does create the claimed circles.

5 This limitation is referred to herein as "the concentric circle limitation."

1. Claim construction

Defendants use a dictionary definition to define a "circle" as "a closed plane curve every point of which is equidistant from a fixed point within the curve." Merriam Webster's Collegiate Dictionary (10th ed. 1996); see also Oxford English Dictionary (2d ed. 1989) ("a plane figure bounded by a single curved line, called the circumference, which is everywhere equally distant from a point within, called the centre. But often applied to the circumference alone, without the included space."). 6 Defendants assert that a circle "family" "consists of multiple circles that have the same center but where the closed loops that define the circles are located at different distances from the center." Taken as a whole, Defendants contend that "this limitation means practicing the step of selecting two or more centers, constructing concentric circle families around those centers, and assigning each circle within a family a number, or index."

6 At the hearing on this motion, Plaintiff suggested for the first time that a "circle" should be defined as "the set of points equidistant from a center point." If the Court used that definition instead of the dictionary definition suggested in Defendants' papers, the analysis in this Order would be the same because Plaintiff has not shown that VoluMill creates the set of points equidistant from a center point, or that it creates families of concentric sets of points equidistant from a center point.

Plaintiff did not offer a construction of any of the terms in this concentric circle limitation in its opening motion. It is curious that even in its Reply, Plaintiff did not challenge Defendants' construction of the term "circle" nor offer any construction of the term "creating," even though, as discussed below, Plaintiff's theory of infringement turns on the contention that VoluMill is "creating" circles. The dictionary definition of the term "create" is "to bring into existence." Merriam Webster's Collegiate Dictionary (10th ed. 1996). Plaintiff points to nothing in the patent or prosecution history that would suggest a different construction of that term, and that is the construction the Court adopts for the purposes of this motion only.

The Court finds that Defendants' constructions of the other terms in the limitation are consistent with well-recognized principles of claim construction and adopts them for the purpose of this motion only. See Vitronics, supra. In short, the concentric circle limitation means the following: "practicing the step of selecting two or more centers, bringing into existence multiple circles that have the same center but where the circles are located at different distances from the center, and assigning each circle a number, or index." 7

7 This construction adopts and assumes the dictionary definition of "circle" stated above.
E. "Creating an Error Detection Code (EDC1) by Coding"

The patent defines error detection coding as coding "in such a manner as to permit detection of changes." (‘148 patent, col. 5, ll. 41-43) Thus, the term "creating an error detection code (EDC1) by coding" shall be construed to mean "creating an error detection code (EDC1) by applying an algorithm to information in such a manner as to permit detection of changes but without complete recovery of the original information."

Claim 8 recites, in relevant part:

8. A method of producing an instrument face having functional indicia thereon, utilizing a computer and printer, comprising the steps of:

(a) creating the instrument face with functional indicia thereon in the computer in electronic format . . . .

Col. 8, ll. 1-5 (emphases added). While claim 3 has the broader language "creating or providing," claim 8 recites only "creating." Nonetheless, the district court interpreted both claims to require "creating or providing in a computer a multicolor logo and hour markings to comprise the face of an instrument." (Emphasis added.) The district court found that the Sweda catalogue inherently anticipated "creating or providing" as required by its claim construction. Because claim 8 requires "creating" rather than "creating or providing," the district court erred in its construction of that claim and in its corresponding determination of inherent anticipation.

The ‘717 patent does not define expressly "creating" or "providing." The two terms, however, have distinct meanings. Each term appears in claim language. Each therefore imparts a different scope to the claim in which it appears. See, e.g., Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1562, 19 U.S.P.Q.2D (BNA) 1500, 1503 (Fed. Cir. 1991) ("The fact that mitered linear border pieces meet to form a right angle corner does not make them right angle corner pieces, when the claim separately recites both linear border pieces and right angle corner border pieces."").

In its teachings, the specification treats the two terms differently. For example, with respect to preparing an instrument face for printing, the specification describes a two step process: "The artwork . . . is created in electronic format in the computer. Information may initially be inputted into the computer for this purpose from a conventional scanner or a CD ROM." Col. 4, ll. 7-11 (emphasis added). In sum, the patent recognizes that information may be provided (input) into the computer after creation elsewhere or, alternatively, may be created in the computer from scratch. Regarding the creating step, the specification further teaches that "commercially available software programs" may be used to "produce almost any design desired on an instrument face." Col. 4, ll. 11-14, 18. In view of these teachings, this court construes "creating" to require more than simply using the computer as a conduit to convey information to the printer from a scanner or a CD ROM. Creating requires, rather, a substantive addition or modification of the artwork in the computer, such as when graphics software adds a design to an instrument face.

I. "Credential"

Defendants attempt to import limitations from examples in the specification. Defendants' construction would require a physical credential and thus, the physical presence of the parties. The specification, however, recites that "until the present invention, it has not been possible to verify the identity and to secure the interests of . . . absent parties to a transaction." (‘148 patent, col. 2, ll. 2-5) Importing defendants' limitation would be improper. Thus, the term "credential" shall be construed to mean "a document or information obtained from a trusted source that is transferred or presented to establish the
H. "credential"

This term appears in claims 7, 47, and 53 of the '302 patent. The parties primarily dispute whether a credential must conclusively establish the identity of a party and whether it must be non-secret. Defendants offer the Delaware court's construction of this term.

Plaintiff argues that a credential need not conclusively establish the identity of a party. A credential is only used to establish a party's identity. Pl. Brief at 26. "[A] credential is presented as evidence or proof of identity, and the receiving party or system uses the credential for that purpose." Id. Plaintiff also argues that the credential must be non-secret because it must be "publicly presented for purposes of identifying a party." A credential, according to Plaintiff, cannot be a password.

In addition to making collateral estoppel arguments, Defendants argue that a credential is not merely used to authenticate a party but does authenticate a party. Def. Brief at 31. Defendants point to the specification, which states, "As part of the credential authentication process, the identity of the user is authenticated." '302 patent, 12:27-40. Defendants also argue that Plaintiff's proposal would make a credential overbroad and would read on a business card. Def. Brief at 32. If the credential were only required to be presented for purposes of determining the identity of a party, according to Defendant a business card would serve as a credential.

Both parties agree that part of the definition of credential includes a requirement that it come from a "trusted source." A mere business card, without more, would not serve as a credential under either proposal. Also, as used in the patent, a credential is intended to be a document or information presented to another for review. As such, it would make sense that the credential cannot be secret. Nonetheless, in the '302 patent, Claim 7, the inventor specifies that the credential has non-secret information. If the Court construes credential to be a non-secret document, this limitation would be meaningless. The Court is therefore of the opinion that "non-secret" should not be part of the definition of credential.

The Court now turns to the issue of whether a credential "establishes" identity. Although a driver's license or a passport is often used to establish identity, social security cards and birth certificates cannot by themselves establish the identity of the bearer. Yet the patent refers to a social security card as a credential. See '302 patent, 8:54-58. This is one of those instances in which the interests of comity yield to this Court's view of its independent obligation to give the correct meaning to claim terms. The Court construes the term to mean, "a document or information obtained from a trusted source that is transferred or presented for purposes of determining the identity of a party."
2. "credit"

The parties dispute the meaning of the term "credit" in the phrase "storing a credit at the subscriber location" of claim 1. Echostar argues that "credit" is limited to prepaid credit, whereas IPPV argues that "credit" also includes an amount of value placed by the system operator at the disposal of a subscriber to purchase television programming.

In support of its proposed construction, Echostar points to the prosecution history and in particular, to the April 4, 1984 amendment in which the inventors explained in response to a rejection based on prior art, that the references cited by the examiner were "not . . . pre-paid and stored credit system[s] as in the present invention." Echostar argues that the inventors should have disclosed the advance credit method in their amendment distinguishing the prior art, and because they did not, the doctrine of prosecution history estoppel limits the meaning of "credit" to prepaid credit.

IPPV argues in response that the plain and ordinary meaning of "credit" includes different forms of credit. It also cites portions of the specification as evidence of the broad meaning of "credit." One passage states that "with the illustrated system, the station operator has the option of allowing the subscriber to continue to purchase . . . programs until the credit is completely used up, an option which may be desirable if the credit is prepaid by the subscriber. On the other hand, if the . . . credit is an advance credit given to the subscriber without prepayment, the operator has other options." Another passage states that "the credit initially may represent an amount actually prepaid by the subscriber or an advance credit provided by the pay television operator against future use by the subscriber."

With regard to Echostar's prosecution history estoppel argument, IPPV argues that the inventors' statement must be read in the context of the entire prosecution history, including the application, the references cited by the examiner and the applicants' whole remarks. Furthermore, it urges the court to not only consider the statement, but why the statement was made.

IPPV explains that the two references cited by the examiner against claim 1, Loew and Mountjoy, disclose systems for controlling the distribution of programming, where prepayment in advance of viewing is required. The examiner rejected claim 1 because it covers an embodiment in which the credit represents an amount of value that is prepaid by the subscriber. IPPV further explains that in order to overcome the rejection, the applicants distinguished the prepaid credit embodiment covered by claim 1 from the payment systems described in the cited references on the basis that they did not store credit. Instead, the cited references were real time payment systems. Thus, IPPV argues that the examiner's rejection was limited to prepaid systems, and as such the advance credit system was not relevant to the rejection. It therefore contends that the inventors had no reason to include the advance credit system in their response, and as a result, to amendment should not serve to limit the meaning of "credit" to prepaid credit under the doctrine of prosecution history estoppel.

Having reviewed the specification and the prosecution history, the court finds that "credit" includes advanced credit as well as prepaid credit. The court further finds that the advance credit system was not relevant to the examiner's rejection based on Loew and Mountjoy. As such, the doctrine of prosecution history estoppel does not apply in this instance. The court therefore concludes that "credit," as used in claim 1, includes prepaid credit and an amount of value placed by the system operator at the disposal of a subscriber to purchase television programming.

3. "credit"

The parties disagree about the meaning of the term "credit" in the phrase "storing, at the subscriber location a credit indicating an amount for future payment of charges for access to information in the transmission" of claim 13. Echostar again argues that "credit" should be limited to prepaid credit, while IPPV argues that "credit" should not be limited to any specific type of credit.

In support of its position, Echostar contends that the plain and ordinary meaning of the term "charges" limits the meaning of credit. It explains that a "charge" is a debt or an entity in an account recording a debt. Applying this plain meaning, Echostar argues that "credit" cannot include advanced credit because one cannot pay a debt using credit advanced by the same party. It analogizes an advanced credit system to paying a credit card bill with the same credit card, and therefore contends that the
advanced credit system does not make sense. Finally, Echostar points to one of the embodiments of the specification that, it argues, illustrates the prepaid credit method as a limitation on the meaning of "credit."

In response, IPPV argues that the words "future payment of charges" mean payment for charges that occur in the future. Based on this meaning, IPPV contends that there is no reason to limit "credit" to prepaid credit, and that "credit" should therefore be construed to mean credit available for future use, whether prepaid or advanced.

After reviewing the parties' proposed constructions and the specification, the court finds that there is no reason to limit the meaning of "credit" to prepaid credit. The credit card analogy is inaccurate because it does not take into account the fact that in this instance, the credit card bank is providing the service. That is, it is true that a credit card holder would not pay a credit card bill with the same credit card, but a better question is whether the holder would pay for services or goods rendered by the credit card bank with the same credit card. This happens all the time, and the best example is a cash advance.

The bank issues the cash advance and charges the amount against the holder's available credit. In essence, the holder initially satisfies the cash advance charge with credit from the same bank. At a later date, the holder pays the bill reflecting the accumulated charges.

The specification makes clear that the invention contemplates the same system. A program charge is initially satisfied with advanced credit from the program provider, and the subscriber later pays a bill reflecting the charges. Thus, the court construes "credit" in accordance with its plain meaning and does not limit the term to any particular type of credit.

6. "Credit Account"

Walker proposes that the claim term "credit account" be construed to mean "[a]n account that allows a customer to buy goods or services from a merchant without cash and pay the issuer of the account at a later date." Capital One disagrees with Walker's proposed construction and offers the alternative construction of "[a]n account wherein a lender (such as a bank) advances an amount of money in accordance with certain terms." The crux of the argument as it relates to this claim term is whether or not the term, as used in the Walker Patents, should be construed broadly enough to include credit accounts other than those used to purchase goods or services. Thus, under Capital One's proposed construction, a "credit account" would include a mortgage account, a home-equity line of credit, and a personal loan. The court finds that a person of ordinary skill in the art at the time of the invention would not read this claim term so broadly in the context of the entire patent, including the specification.

The Walker Patents speak in terms of credit accounts that are "used throughout the world for non-cash payments of goods and services." (478 patent, Col. 1:10-11). In addition, although the independent claims refer only to "credit accounts," the specification describes these accounts as those that are used to purchase goods and services with payment to be made at a later date. It is important to note that the independent claims are not limited to credit cards. Rather they are defined in such a way that non-credit card credit accounts, such as a line of credit at a store, are also included. Every example in the Walker Patents related to the meaning of a "credit account" refers to those used to purchase goods and services. For these reasons, the court construes the term "credit account" to mean "an account that allows a customer to buy goods or services without cash and pay the issuer of the account at a later date." 2

2 Capital One argues that the inclusion of "merchant" in Walker's proposed construction is improper because merchants do not sell services. In response Walker believes this is "harmless" but has suggested including "or service provider" in its proposed definition. The court finds that neither merchant nor service provider should be included in the definition to be presented to the jury.

GO BACK
I. "credit authorization provider"

CAT proposes that the term "credit authorization provider" means "a service provider that maintains the intrinsic value of the debit styled card in a central database identified by the card." CAT contends this term requires construction because otherwise it might be misinterpreted by a jury to mean only a Visa/MasterCard credit card processor. (D.I. 44 at 33-34) SVS, on the other hand, proposes that the term "credit authorization provider" be accorded its plain meaning. (D.I. 47 at 32) I conclude that neither proposal is satisfactory.

Adopting CAT's construction would have the result of importing the constructions it proposes for other disputed claim terms into this term. For instance, the portion of CAT's proposed construction that reads "the intrinsic value of the debit styled card" incorporates CAT's proposed construction of the terms "debit styled card" and "debit purchase transaction," which I have recommended that the Court reject.

Although I reject CAT's proposed construction, I agree that the term "credit authorization provider" may be confusing to the jury. Accordingly, I recommend that the Court construe the term "credit authorization provider" according to its plain meaning, which is "a service provider that maintains the value associated with a debit styled card.”

1. "Merchant-Specific Credit Value," "Merchant-Specific Credit Rate," "Merchant-Selected Credit Rate," "Credit Rate," and "Credit Value"

Independent claim 14 requires "determining a merchant-specific credit value for the transactions from a merchant-specific credit rate and the purchase amount." Claim 15, which depends from claim 14, requires that the credit value be "determined by multiplying a merchant-selected credit rate by the purchase amount of the transaction." The parties' principal dispute concerns the meaning of these terms.

The defendant proposes that "merchant-selected credit rate" means "a rate selected by a merchant, irrespective of any other merchant and independent of a central authority." The defendant further argues that "merchant-specific credit rate" should have the same construction as "merchant-selected credit rate." If, however, the court determines that "merchant-specific credit rate" means something different, then the defendant proposes "a credit rate selected or otherwise indicated by a merchant, irrespective of any other merchant and independent of a central authority." With respect to the term "merchant-specific credit value," the defendant proposes that it means "a credit value selected or otherwise indicated by a merchant, irrespective of any other merchant and independent of a central authority." The defendant also contends that the terms "credit rate" and "credit value" refer to the antecedent terms "merchant-selected credit rate" and "merchant-specific credit value," respectively. Therefore, according to the defendant, "credit rate" and "credit value" must have the same meaning as "merchant-selected credit rate" and "merchant-specific credit value," respectively. If the court determines otherwise, however, the defendant proposes that "credit value" means "a portion of a purchase amount that is to be credited to a consumer's account, regardless of how the transaction is paid for. The credit value is determined at the point of sale by applying a credit rate selected by that merchant irrespective of any other merchant and independent of a central authority, to the purchase amount of the transaction and is then transmitted to a central system." The defendant appears to agree with the plaintiff that "credit rate" means "a rate used along with a purchase amount to determine a credit value."
The plaintiff, on the other hand, proposes that "merchant-selected credit rate" means "a credit rate selected by a particular merchant," "merchant-specific credit rate" means "a credit rate determined for a particular merchant," and "merchant-specific credit value" means "a credit value determined using either a merchant-specific credit rate or a merchant-selected credit rate." According to the plaintiff, "credit rate" means "a rate used along with a purchase amount to determine a credit value," and "credit value" means "a value determined in connection with point-of-sale transactions." The principal disputes are 1) whether a third party may set the credit value and/or credit rate, and 2) whether there are any limitations on how the credit value is determined.

a. Third Party Determination

In support of its proposed constructions that a third party may not set the credit value and/or credit rate, the defendant argues that the patentee defined "merchant-specific credit value" in the prosecution history by stating that "the salient point [is] that the merchant may select or otherwise indicate the desired credit value (in some claims, by reference to a 'credit rate')." Combined Reissue Declaration and Power of Attorney, February 15, 1996, at 2. In addition, the defendant argues that the patentee distinguished his invention over prior art by stating that the prior art "fails to disclose or suggest . . . the concept of permitting each of several merchants to select a merchant-specific rate . . . ." Response to Office Action, February 26, 1997, at 10. The defendant points to this statement and also contends that the Examiner used the terms "merchant-selected credit rate" and "merchant-specific credit rate" interchangeably when it issued an Interview Summary referring to "the limitation of 'merchant-specific credit rate' from Claim 15, . . . ." even though Claim 15 actually used the phrase "merchant-selected credit rate." Interview Summary, March 12, 1998 (emphasis added). Finally, the defendant argues that the Examiner, in his Notice of Allowance, stated that "the prior art of record, neither singularly nor in combination, discloses a rebate system whereby a consumer receives a cash rebate, based on the amount of purchases made and a credit rate that is determined by the merchant." Notice of Allowability, May 22, 1998, at 2. Because the patentee did not respond to this notice, the defendant argues that the patentee acquiesced in the examiner's statement.

The plaintiff argues that, under the doctrine of claim differentiation, "merchant-specific credit rate" and "merchant-selected credit rate" cannot mean the same thing. The plaintiff also argues that the specification does not require that the merchant actually assign the rate in all circumstances. The plaintiff points to passages in the specification which state that the rate "may be selected" by the merchant and "the credit rate for one merchant is preferably selected by a third merchant and not by any other merchant or the central system." '116 patent, 1:39-42, 3:38-40 (emphasis added). In addition, the plaintiff points to the prosecution history and urges that the applicant distinguished between "merchant-specific" and "merchant-selected." See Response to Office Action, February 26, 1997, at 10-11. Finally, the plaintiff argues the failure to respond to the notice of allowability does not represent a clear disavowal of claim scope. See 37 C.F.R. § 1.104(e) (1998); Salazar v. Proctor & Gamble Co., 414 F.3d 1342, 1345 (Fed. Cir. 2005).

Although it is a close issue, application of the rules governing claim construction supports the plaintiff's proposed constructions. It is a general principle of claim construction that different words in a claim have different meanings. Innova/Pure Water, Inc., 381 F.3d at 1119 ("[W]hen an applicant uses different terms in a claim it is permissible to infer that he intended his choice of different terms to reflect a differentiation in the meaning of those terms."). Without question, the two phrases "merchant-selected" and "merchant-specific" are different. The former connotes that it is the merchant who selects the applicable rates; the latter implies that, although the applicable rate is keyed to a particular merchant, a third party (or the merchant) may specify the rate. Under Phillips, the language of the claims supports the plaintiff's argument.

The court has also considered the claims in light of the specification. As the plaintiff correctly notes, the written description does not equate the term "merchant-selected" with the term "merchant-specific." Moreover, the specification explicitly states that the merchant "may" select the applicable rate. The cited passages in the specification, although not conclusive, further support the plaintiff's proposed construction.

Finally, the court has examined the prosecution history. There is no clear statement in the prosecution history in which the applicant explicitly defined "merchant-specific" to mean "merchant-selected." To the contrary, the applicant stated that "[i]ndependent claim 14 includes the slightly different limitation of 'determining a merchant-specific credit value for the transaction' . . . ." Response to Office Action, February 26, 1997, at 11 (emphasis added). It does not appear that the applicant made a clear disavowal of claim scope and, therefore, the credit rate of claim 14 may be assigned by a third party.
b. Credit Value

Next, the court examines the term "credit value." The defendant contends that the credit value must be 1) determined at the merchant location, 2) determined by multiplying the credit rate by the purchase amount, and 3) can be determined regardless of how the consumer pays for it.

i. Merchant Location

The defendant contends that the patentee disclaimed any system and method for determining credit value other than at the merchant's location in his appeal brief. In that brief, the patentee stated that claims 1, 14, 22, and 35 "clearly recite electronic capture of . . . credit value at the merchant location and its electronic transmission to the central system . . . ." Appeal Brief, June 12, 2006, at 13.

In reply, the plaintiff points out that the appeal brief also states that "[t]he prior art fails to disclose the electronic delivery of credit values and/or account numbers to a central system . . . ." Appeal Brief, June 12, 2006, at 18 (emphasis added). According to the plaintiff, this does not require that the credit value be determined at the merchant location.

There is no clear disclaimer of claim scope. The patentee chose to include this limitation in some claims, but not others. For example, claims 1, 8, and 35 specifically require the credit value to be calculated at the merchant location while claims 22 and 31 do not require the credit value to be calculated at the merchant location. Accordingly, this limitation should not be included in the construction of these terms because imposing this limitation would be redundant in some claims and, without a clear disclaimer, would be improper in the other claims.

ii. Multiplying Credit Rate by Purchase Amount

Next, the defendant contends that the only method for determining a credit value in the '090 specification is multiplying the credit rate by the purchase amount. The defendant attempts to limit the intrinsic evidence to the specification of a different patent and to import a limitation from a preferred embodiment into the construction of a claim term. Furthermore, dependent claim 15 states that "the credit value is determined by multiplying a merchant-selected credit rate by the purchase amount of the transaction." Therefore, the court concludes that the term "credit value" is broader, standing alone, than the limitation in the dependent claim. The proposed limitation is rejected.

iii. Determination Regardless of How a Product is Paid For

Finally, the defendant contends that the inventor's notes disclaimed any system which is dependent on the form of payment. Defendant's Responsive Claim Construction Brief, Ex. B., at PS 11339. The defendant also cites to the specification which states "consumers build up cash value by buying products from participating merchants independent of how that product is paid for . . . ." '116 patent, 2:22-24. Again, the defendant attempts to import a limitation from a preferred embodiment. The court rejects this limitation.

c. Constructions

Based on the foregoing discussion, the court issues the following constructions:

"Merchant-selected credit rate" means "a credit rate selected by a particular merchant."

"Merchant-specific credit rate" means "a credit rate associated with a particular merchant."

"Merchant-specific credit value" means "a credit value associated with a particular merchant."

"Credit rate" means "a rate used along with a purchase amount to determine a credit value."

The term "credit value" has been defined in the prosecution history as proposed by the plaintiff. See Response to Office Action, February 26, 1997, at 3. "Credit value" means "a value determined in connection with point-of-sale transactions."
6. Cross-Reference Table

516 Patent, Claims 21, 22, 29

ePlus asserts that the Court need not construe this term, but if it does, it should mean: a reference from one part of an index to another for additional information. Lawson proposes that the term mean: a table including reference or identification codes used to link vendor items by catalog number between two or more different vendors determined by a Distributor to be equivalent.

a. Words of the Claims

Claims 21 and 22 of the '516 Patent claim an electronic sourcing system comprising:

- a requisition module including data fields, user-generated criteria entered into at least one of said data fields to generate at least partial criteria corresponding to a desired item;

- a catalog collection searching module, said searching module including a collection of catalogs of items stored in an electronic format, a catalog selection criteria used to select less than said entire collection, said searching module being used to generate additional search-module criteria for said data fields of said requisition module;

- a multiple purchase order generation module, said purchase order generation module creating multiple purchase orders from a single requisition created with said user-generated criteria and said search-module criteria;

- wherein each of at least two catalogs include a generally equivalent item from a different source, said requisition module working in combination with said catalog searching module to determine multiple sources for said item;

- wherein said multiple sources is limited by said catalog searching module providing a match according to said user-generated criteria, said search-module criteria and a determination system that located items are generally equivalent; and

- wherein said determination system includes a cross-reference table matching an identification code from a first located item and a second identification code from a second located item.

516 Patent at 25:56-26:18 (emphasis added). Claims 21 and 22 make clear that the cross-reference table operates within a determination system that locates generally equivalent items. Claim 29 provides for an electronic sourcing system comprising:

- a collection of catalogs of items stored in an electronic format;

- a first set of pre-determined criteria associated with said collection of catalogs;

- a second set of pre-determined criteria associated with items each of said catalogs;

- a catalog selection protocol, said catalog selection protocol relying on first set of pre-determined criteria to select less then said entire collection of catalogs, and including a matching vendor identification code with a subset of said collection of catalogs, wherein said subset of catalogs includes both a vendor catalog from a predetermined vendor and a second catalog from a predetermined third party;

- a search program, said search program relying on said second set of criteria to select specific items from said catalogs determined from said catalog selection protocol; and

- a cross-reference table linking a vendor item catalog number from said vendor catalog with an item catalog number from said predetermined third party.

b. Specification

ePlus asserts that Lawson's proposed construction imports an improper limitation by requiring a distributor to determine equivalency. According to Lawson, this requirement come from U.S. Patent No. 5,712,989 (the "'989 Patent"), which is incorporated by reference into the Patents-in-Suit. A patent incorporated by reference "becomes effectively part of the host document as if it were explicitly contained therein." Telemac Cellular Corp. v. Topp Telecom, Inc., 247 F.3d 1316, 1329 (Fed. Cir. 2001). The '989 Patent provides:

The Host Cross-Reference Table includes, for each item regularly stocked or supplied by the Distributor…a list of the corresponding part numbers of Distributor's vendor and other distributors… for items which have been determined to be equivalent. This relational database is created by the Distributor by, for example, reviewing the catalogs of other distributors and determining which items are equivalent to items in the Distributor catalog.

'989 Patent at 32:14-24. And says, Lawson, it is essential that "determined to be equivalent" be included in the construction of the term, because without it, what is cross-referenced has no meaning or context. (Def. Reply at 27.)

c. Proper Construction

Lawson's proposed construction improperly imports unnecessary limitations. Specifically, the claims at issue demonstrate that it is not necessary that items be linked by catalog number because the '516 Patent links items by identification code. And, while the Patents-in-Suit do not require that a distributor determine equivalency, Claims 21 and 22 do state that the cross-reference table operates within a determination system that locates equivalent items. As Lawson correctly observes, the '989 Patent, incorporated by reference, provides that it is the Distributor that determines equivalency. However, as the claim terms and specification make clear, and as the parties have agreed, a "Distributor" is but one kind of vendor. To define the term "cross-reference table" solely with reference to the incorporated '989 Patent would inappropriately limit the term. Considering the Patents-in-Suit as a whole, the incorporated limitation from the '989 Patent is the concept of determined equivalency, not the limitation that a Distributor determines the equivalency. It would truly distort the plain meaning of the patent and the specification to impose the limitation that the Distributor is the sole determiner of equivalency. Thus, the term "cross-reference table" means a table that links vendors items determined to be equivalent between two or more different vendors.

GO BACK

1051

Maintaining a consistent position, Intergraph argues "crossbar" or "crossbar switch" carries its ordinary meaning to one skilled in the art. Intel claims the terms "crossbar, associative crossbar, and associative crossbar switch" are all synonymous and mean a switch located within the scalar cache, that has a set of connectors in electrical contact with the storage, is controlled solely by pipeline identifiers embedded by the compiler within each of the software-scheduled instructions being routed through the switch, and has another set of connectors in electrical contact with the processing pipelines. Intel arrives at this definition by, again, placing specific requirements from one or more claims into the definition of the term itself. The Court cannot embrace this method of defining terms, as the claim requirements vary from claim to claim. Accordingly, the Court construed "crossbar" and "crossbar switch" as a switch that selectively couples a group of instructions from the very long instruction word storage to the processing pipelines. '028 patent at 3:11-18; 9:66-10:9.

GO BACK

1052

D. "Crossbar"
Intel also challenges the district court's construction of the "crossbar" limitation in the '003 patent, arguing that the recited crossbar must be implemented within the cache. Intel asserts that the claim language, the specification, and the prosecution history all require that the crossbar be physically located within the cache. Intel further argues that there can be no infringement under its proposed definition of the term "crossbar" because the accused devices have significant decoding and processing circuitry located between the cache and the crossbar.

Intergraph responds that nothing in the claim language, the specification, or the prosecution history specifies the location or the position of the crossbar in the claimed invention. Intergraph further maintains that the district court's finding that the accused microprocessors satisfy the "crossbar" limitations should be affirmed because there was no claim construction error.

We agree with Intergraph that the district court did not err in construing the asserted claims of the '003 patent as not requiring the crossbar to be located within the cache. Claims 1 and 22 recite a "super-scaler cache comprising . . . an associative crossbar," while claim 6 refers to "an associative crossbar switch in a super-scaler cache." Intel argues that the plain meaning of the words "in" and "comprising" mandates that the crossbar be located within the cache. We disagree, as neither "comprising" nor "in" necessarily conveys information about the location or position of the crossbar relative to the cache. The word "comprising" in claims 1 and 22 is a term of art that simply means that the crossbar is an essential, but not necessarily the only, element of the cache. See Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997). The word "in" may similarly be used to indicate that the crossbar is a constituent of the cache; or it may be used to indicate that the crossbar is within the bounds or area of the cache. See Webster's New World Dictionary 680 (3d college ed. 1988). Nothing in the claim language, however, clearly points to one particular meaning over another for that ordinary word. We therefore conclude that the claim language does not compel Intel's proposed claim construction.

The specification of the '003 patent likewise does not require the crossbar to be located within the cache. Indeed, Figures 2, 4, and 5 depict the instruction cache and the crossbar as two distinct entities; they certainly do not show the crossbar as being located within the cache. And the specification, at most, suggests that the preferred embodiment places the crossbar in the cache, stating only that the placement of the crossbar switch earlier in the instruction pipeline "allows the crossbar to be a part of the cache itself." '003 patent, col. 1, ll. 46-47 (emphasis added), and that "in a preferred embodiment of this invention the associative crossbar is implemented in the instruction cache," id., col. 2, ll. 22-23. Without more, however, we will not read that purported aspect of the preferred embodiment into the broader claim language. See RF Del., Inc. v. Pac. Keystone Techs., Inc., 326 F.3d 1255, 1263 (Fed. Cir. 2003).

The prosecution history of the '003 patent also fails to convince us that the recited crossbar must be located within the cache. Intel asserts that Intergraph distinguished the prior art during prosecution on the basis that the claimed invention places the associative crossbar within the cache. However, the prosecution history shows that Intergraph distinguished the Blaner and Hiller references by arguing that neither disclosed using an associative crossbar switch, let alone a cache that includes an associative crossbar switch. The prosecution history also shows that Intergraph distinguished the Rustad reference by pointing out that it did not disclose the recited means and steps for forming and storing groups of software-scheduled instructions. 8 Intergraph's other prosecution history remarks regarding the recited associative crossbar switch largely repeat the language found in the specification of the '003 patent, which we have already found to be unconvincing. We therefore do not read Intergraph's prosecution history statements as clearly disclaiming crossbars that are not physically located within the cache.

8 During prosecution Intergraph did state: "Figure 1 is the only figure in Rustad et al. that illustrates a crossbar switch in conjunction with a cache. Furthermore, the crossbar switch is not within a cache." That Figure 1 was of a prior art reference cited in Rustad and depicted an instruction cache and a crossbar in nearly the same way as do the block diagrams in the '003 patent. Intergraph did not meaningfully explain what distinction, if any, existed between its claimed invention and Rustad's Figure 1 and, in any event, did not rely on any such distinction to overcome the examiner's § 103 rejection, which was based on Rustad itself. Intergraph's one vague statement regarding Figure 1 therefore does not amount to a clear disavowal of claim scope.

Having affirmed the district court's claim construction, we discern no clear error in the court's factual finding that the
accused devices satisfy the "crossbar" limitations. Intel essentially concedes as much. We therefore affirm the court's finding that the accused devices have "crossbars" as claimed in the '003 patent.

1053

"enabling a secure communication mode of communication at the [a] first computer without a user entering any cryptographic information for establishing the secure communication mode of communication"

The '759 patent, claims 1 and 16 contain the phrase "enabling a secure communication mode of communication at the [a] first computer without a user entering any cryptographic information for establishing the secure communication mode of communication." VirnetX contends that this phrase means "providing to the first computer at least one resource necessary for a virtual private network communication, based on a domain name service (DNS) that provides the resource according to user identity, without user input of encoding or decoding information." Microsoft contends that the phrase does not require construction. Alternatively, Microsoft contends that only "cryptographic information" requires construction and means "information used for encryption." The parties dispute whether construction is necessary, and if construction is necessary, what limitations to apply.

The only term that requires construction in "enabling a secure communication mode of communication at the [a] first computer without a user entering any cryptographic information for establishing the secure communication mode of communication" is "cryptographic information" as a jury may not understand the meaning of "cryptographic." VirnetX argues that "cryptographic information" is encoding or decoding information. Microsoft argues that "cryptographic information" is information used for encryption. Microsoft contends that "encoding or decoding" is too broad because all information stored on a computer or transmitted over the Internet is encoded or decoded. VirnetX contests that "encryption" is too narrow because "encryption" does not account for the "decryption" aspect of "cryptographic information."

The Court construes "cryptographic information" as "information that is encoded/decoded or encrypted to ensure secrecy." This construction addresses both VirnetX's request to use "encoding or decoding" and Microsoft's request to use "encryption" to construe "cryptographic information." Also, Microsoft's concern that "encoding or decoding" is too broad because all information is encoded and decoded is addressed by the Court's construction language "to ensure secrecy," which modifies both "encoded/decoded" and "encrypted." Additionally, extrinsic evidence is consistent with the Court's construction. "Cryptographic" is defined as "in an encrypted form; using a code or cipher." ACADEMIC PRESS DICTIONARY OF SCIENCE AND TECHNOLOGY 556 (1992) (second definition). This supports the most limiting portion of the Court's construction that states "cryptographic information" is information that is "encrypted."

VirnetX contends that the additional terms--"enabling," "establishing," and "secure communication mode of communication"--require construction. VirnetX argues that these terms require constructions because they do not by themselves explain how the claimed invention is carried out. However, the claims do not need to state how to perform the claimed invention. See SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1121 n.14 (Fed. Cir. 1985) ("Specifications teach. Claims claim."). Limitations from the specification do not have to be imported just because the claims do not state how to perform the invention. Furthermore, VirnetX's citations describe only particular aspects and embodiments. See Pl.'s Br. (Docket No. 194) at 34; see Col. 6:37, 44. "Although the specification may aid the court in interpreting the meaning of disputed claim language, particular embodiments and examples appearing in the specification will not generally be read into the claims." Comark, 156 F.3d 1182, 1187. Accordingly, the Court does not adopt VirnetX's proposed limitations and construes only "cryptographic information" as "information that is encoded/decoded or encrypted to ensure secrecy."

1054

1. "cryptographic processing; cryptographic operation"

The parties dispute over the meaning of the phrase "cryptographic operation," which appears in various claims throughout the asserted patents. The dispute also encompasses the related terms "cryptographic processing operation," "cryptographic
processing," and "cryptographically processed."

One aspect of the dispute is whether the phrase "cryptographic operation" should be limited to encryption and decryption.

The specification refers to "cryptographic operations" as including more than simply encryption and decryption. For example, in the '442 patent: "Such keys are used in connection with various cryptographic operations including, without limitation, symmetric encryption using DES, triple DES, IDEA, SEAL, and RC4; public key (asymmetric) encryption and decryption using, RSA and ElGamal; digital signatures using, DES, ElGamal, and RSA; and Diffie-Hellman key agreement protocols." Col. 1, ll. 27-33.

The language of certain dependent claims also supports a broader definition. In the '699 patent, for example, Claim 9 provides "The cryptographic token of claim 7, wherein said cryptographic operations include DSA signing operations." Col. 22, ll. 7-8. Similarly, Claim 20 of the '658 patent provides: "The method of claim 19 where said asymmetric cryptographic operation includes a digital signing operation." Col. 24, ll. 30-31. Thus, "cryptographic operation" includes digital signing and cryptographic hashing.

The Court construes the phrase "cryptographic operation" to mean: "an operation within a class of techniques or algorithms used to secure data and avoid digital identity misrepresentations."

C. "Cue" and "Select Code"

Beery contends that the word "cue" refers to a list or grouping of one or more channel tuning designations located within a memory. Beery's proposed definition must be rejected because it fails to reflect the definition of the word "cue" in the specification, which states:

'Cue' is the listing in memory of the various programmed entries made by the viewer, wherein each select code is stored along with its corresponding channel code and display code.

(Doc. # 1, Exh. A at col. 6).

Beery's proposed definition is broader than the definition set forth in the specification because Beery's definition does not require a viewer to program the list of entries in the memory. By choosing to be his own lexicographer in the specification, Beery set the definition of the term "cue" by which he must live. See Zebco Corp., 175 F.3d at 990. He is bound to his written word, and he may not broaden its meaning beyond the one he wrote in the specification.

Beery contends that the term "cue" is not limited in the claim language by the requirement that a viewer must enter the select code or the display code. This is seen, Beery maintains, in the memory means of claims 8, 9, 20, and 29, which contain no requirement that a viewer must enter information into the cue. This leads Beery to conclude that a cue may contain information entered not only by a viewer but also by a third party such as a cable service provider. This contention lacks merit upon review of the memory means in claims 8, 9, 20, 29, even though the memory means in each of these claims does not specifically use the word viewer as the person who must enter information into the cue. Having specifically defined the term "cue" in the specification, the '952 patent claim language must be understood in light of that definition in each of its claims. Indeed, one reason for permitting an inventor to act as his or her own lexicographer is to make claim language more concise, and hence more easily understood. Such definitions accomplish concision by allowing the inventor to write claim language using the term or phrase without repeating its definition in each claim. However, once an inventor chooses a particular definition, and explicitly and clearly writes it into the specification, a claim term or phrase thus defined may not be expanded unless other claim language presents a basis for doing so. As a result, because the specification's explicit and clear definition of the word "cue" requires a viewer to make programmed entries, the absence of a reference to a "viewer" in claims 8, 9, 20, 29 does not provide a basis for altering the specification's definition.

Turning to the phrase "select code," Thomson contends that the specification's definition of the phrase "select code" applies. As with the term "cue," Beery acted as his own lexicographer by specifically defining the phrase "select code." He is
therefore limited to the specific definition of this phrase as it appears in the specification. See Zebco Corp., 175 F.3d at 990.

Accordingly, the word "cue" in the '952 patent is "the listing in memory of the various programmed entries made by the viewer, wherein each select code is stored along with its corresponding channel code and display code." (Doc. # 1, Exh. A at col. 6). The phrase "select code" in the '952 patent refers to "the channel designation chosen by the viewer for subsequent use in selecting a particular channel." Id.

8. "cumulative index of revisions"

Disputed Term "The system of claim 8 wherein the technical database further comprises a cumulative index of revisions to publications….

Plaintiff's Construction no construction needed due to plain meaning

Defendant's Construction the list of all changes made since the first change, but excluding merely updated information

Plaintiff contends that "cumulative index of revisions" has a "plain meaning" and thus requires no construction. (Jt. Stmt. at 25.) In contrast, Defendant argues that this claim term means "the list of all changes made since the first change, but excluding merely updated information." (Id.) The Court disagrees with Plaintiff's unsupported assertion that the meaning of "cumulative index of revisions" is sufficiently clear to obviate the need for construction. See United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir.1997) (claim construction appropriate "when the meaning or scope of technical terms and words of art is unclear and in dispute and requires resolution to determine"). Therefore, the question remains whether Defendant's proposed construction is appropriate.

Defendant cites the preferred embodiment, which notes that "[t]he revision letter index is cumulative in that it includes all changes, not just the changes since the last CD-ROM release." (‘806 Patent at 61:32-34.) This supports Defendant's contention that the "cumulative index of revisions" necessarily includes "the list of all changes made since the first change…." (Jt. Stmt. at 25.) However, it does not support the second aspect of Defendant's proposed construction, as it makes no mention of "excluding merely updated information." To the contrary, the preferred embodiment specifies that the cumulative list includes "all" changes, and not only the most recent changes. 4 As such, the Court construes the claim limitation "cumulative index of revisions" to mean "the list of all changes made to publications since the first change."

4 Equally unhelpful is Defendant's citation to Mr. Sandifer's expert report which, as noted, was submitted during the reexamination process of the '806 Patent. (Jt. Stmt. at 26; Lavorga Decl. Ex. 17.) Defendant cites generally to twenty pages of the report without identifying specifically what and where in the report Defendant's proposed construction of "cumulative index of revisions" is supported. (Lavorga Decl. Ex. 17 at 69-89.) Nevertheless, the Court has independently reviewed the cited pages of the Sandifer report and has found no support for Defendant's position.

D. Current Bandwidth Metric (claims 10, 14, 28 and 29 of the '700 patent)

Plaintiff's Construction: The present measurement of a moving average of transmission capacity

Defendant's Construction: The moving average over a preselected number of measuring time periods of the bandwidth achieved by a particular queue. The measuring time period is some preselected number of packets transmitted by all queues
from the port

At the claim construction hearing, defendant withdrew its proposed limitation "achieved by a particular queue," Cl. Const. Tr., dkt. # 48, at 39, so I need not consider plaintiff's arguments that the limitation is improper. In addition, plaintiff said that it had "removed" the term "capacity" from its construction (without explaining why). Id. at 27. This still leaves several disputes.

The precise nature of the parties' remaining disputes is somewhat elusive with respect to this term because each party characterizes the disputes differently. For example, plaintiff says that defendant's construction omits any reference to "metric," which plaintiff addresses in its construction with the word "measurement." Plaintiff stated repeatedly at the claim construction hearing that it was adopting the ordinary meaning of "metric" even while acknowledging that the ordinary meaning of "metric" is not a "measurement" but a standard of measurement. (Neither side proposed a construction that reflected that understanding of "metric." Plaintiff came closest when it explained at the hearing that "you have to take a measurement of that . . . moving average" in order to "compare that moving average to the minimum bandwidth as the claim contemplates." Cl. Constr. Tr., dkt. # 48, at 30.) In any event, it is nonsensical to speak of a "measurement" of an average; an average is not "measured" but calculated.

Although defendant recognized that the average is calculated, the construction it proposed does not simply replace "present measurement" with "present calculation" of the average. Apparently (defendant did not make the argument explicitly), defendant believes that "current" does not mean simply "present." Rather, defendant's construction assumes the relevant time is a "preselected number of measuring time periods." Defendant says it is taking this part of its construction from a portion of the specification that states "[t]he current bandwidth should not be mistaken for a bandwidth at an instant in time, rather the current bandwidth is a moving average that is updated periodically upon the expiration of a predetermined time period." '700 pat., col. 10, lns. 3-7.

There are number of problems with defendant's reliance on this passage. First, as plaintiff points out, this is a description of "current bandwidth," not "current bandwidth metric." Defendant never distinguishes these two terms but treats them as interchangeable. Second, the passage refers to a "predetermined time period" (singular) not a "preselected number of measuring time periods" (plural). Third, the passage addresses only how often the moving average is updated; it says nothing about the time interval for calculating the moving average.

Nevertheless, as plaintiff acknowledges in its brief, by its nature, an "average" must take into account some notion of time because it is the result of multiple figures. Even if the calculation is the "present" one, any construction must include the time period over which the average is calculated. Accordingly, I will adopt the following construction: "the present calculation of a moving average of bandwidth over a predetermined time period."

1058

1. "Current metering circuitry [for monitoring the positive and negative ion output current]"

ITW proposes that the court define this element of the claim as: "circuitry used to measure a value corresponding to the amount of current." Pl.'s Revised Proposed Order Regarding Claim Construction at 3. Ion argues that it means: "circuitry used to produce a binary number corresponding to the amount of current." Def.'s Proposed Order re Claim Construction for the '756 patent at 2.

The parties' chief disagreement is over whether the circuitry "measures" or "produces" the value that corresponds to the amount of current. 6 Neither side discusses why one word is superior to the other, nor why either of these words should replace the language of the claim itself: monitoring. The word "monitor" is consistent with the specification. See '756 patent, col. 7:42-42. The word "measure" is not. The specification says that the current metering circuitry can "amplify" the voltage that draws a current through a resistor and "pass" this signal to the A/D converter. '756 patent, col. 8:5-8. The words "amplify" and "pass" could resemble the verb "to produce." On the other hand, "to measure" implies a degree of computation or calculation. 7 There is no intrinsic evidence that supports the inference of measurement or calculation. The word that appears consistently throughout the patent's language is "monitor" and, therefore, "monitor" will be used in the construction. Insofar as there is evidence for Ion's preferred verb as well, I will also include "produce" in the claim.
6 Ion, foreshadowing the parties' debate over how to construe "ion output current reference value," asserts that the word "value" should be defined as a "binary number." Because the word "value" is not part of the term "current metering circuitry," it would be premature to construe it now. I will discuss the proper construction of the word "value" in § 2 directly below.

7 Dictionary definitions for the verb "to measure" include: "to ascertain the dimensions, quantity, or capacity of" and "to estimate by evaluation or comparison." American Heritage Dictionary of the English Language (4th 2000). Acts of ascertaining or estimating require analysis, whereas "passing" and "amplifying" do not.

The term "current metering circuitry," for purposes of the '756 patent shall mean: "circuitry used to monitor or produce a value corresponding to the amount of current." The meaning of the word "value" in this construction shall be consistent with the definition given to the word in § 2 directly below.

1059
e. "current patient condition parameter"

MiniMed argues that the term "current patient condition parameter" means "a recent patient condition parameter, such as a patient's recently measured glucose level using a test strip in a glucose meter." (D.I. 214 at 29.) Smiths argues that during the prosecution of the '065 patent, the patentee made clear that the "current patient condition parameter" was a real time glucose reading because the patentee used such language to distinguish prior art. (D.I. 190 at 25-26.) The office action that Smiths cites to support this argument, however, does not require that conclusion.

In that office action, the patentee wrote that the reference "does not contemplate automatic or substantially continuous blood glucose readings, for example, by means of an implanted sensor. Instead … the blood glucose readings are taken manually by enzyme test strips or the like." (D.I. 192, Ex. 24 at 6.) A further examination of that paragraph reveals, however, that the patentee was distinguishing the reference because the reference contemplated "a recommendation with regard to timing for taking the next blood glucose reading," not with respect to recommending a modified dispensing protocol. (Id. at 6-7.) Thus the reference to "manually" taking a blood glucose reading was to highlight the fact that the prior art reference alerted the user to take such a reading. It was not to highlight that the invention used real time glucose monitoring. Read in context, the office action cited by Smiths provides no reason to limit "current patient condition parameter" to a real time reading. Consequently, I hold that the meaning of the term is "a recent patient condition parameter."

1060

2. "Current-status information"

The parties ask the court to construe the phrase "current-status information," which appears multiple times in Claim 1 of the patent, including in the transmitting, calculating, and displaying steps. See '877 Patent col.32 ll.36, 39-40, 42-43.

Papyrus alleges that it acted as lexicographer by providing the following definition in the specification:

As used herein, "status" refers to the stage of the transaction, that is, whether a quotation has been received in response to a quotation request and whether an order has been completely filled. If the quotation has yet to be received, or an order remains unfilled, or only partially filled, the status is "pending."
Based on this language, Papyrus suggests that "current-status information" means "information indicating whether an instruction is pending." Pl. PCCO 2; Pl. Br. 14.

According to Papyrus, the written description provides that several types of information may qualify as current status information: (1) volley codes indicating the order's stage; (2) a leaves quantity indicating the pending status of an order, and (3) volley codes indicating the request's stage. See '877 Patent col.9 ll.33-38, col.10 ll.17-21, col.18 ll.16-53, col.23 l.16-col.25 l.49. Further, Figure 1 in the '877 Patent illustrates several types of current-status information for quotation requests (symbols "Q," "A," "R," "S," and "U"), for orders (symbols "*" and ",r"), and for leaves quantities (numeric values). '877 Patent Fig. 1.

Papyrus contends that a leaves quantity exemplifies current-status information in that a zero quantity indicates a completely filled order and a non-zero quantity denotes an unfilled or partially filled order.

Although NYSE also relies on the language of the specification, NYSE concludes that "current-status information" means "characters or digital means conveying the stage of a transaction." Def. PCCO 4; Def. MHSP 99. Specifically, NYSE relies on language stating that "status' refers to the stage of the transaction" and that the "system utilizes volley codes to define the present stage of the transaction or instruction." 8 '877 Patent col.9 ll.33-34, col.18 ll.17-18 (emphasis added).

Although NYSE cites the '002 Patent col. 10 ll.3-6 and col.18 ll.40-41, identical language appears in the '877 Patent at col. 9 ll.33-34 and col. 18 ll.17-18.

When construing terms, the court generally "begin[s] with the presumption that the same terms appearing in different portions of the claims should be given the same meaning unless it is clear from the specification and prosecution history that the terms have different meanings at different portions of the claims." Fin Control Sys. Pty, Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001). Furthermore, "a claim term should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent." Rextord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). Where "a patentee defines a claim term, the patentee's definition governs, even if it is contrary to the conventional meaning of the term." Honeywell Int'l., Inc. v. Universal Avionics Sys. Corp., 493 F.3d 1358, 1361 (Fed. Cir. 2007). Indeed, "the specification is the single best guide to the meaning of a disputed term, and . . . acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Phillips, 415 F.3d at 1321 (quotations & citation omitted).

In light of the case law and language in the specification, there are several issues that the court must balance in construing the term "current-status information." First, the court must adopt a construction consistent with the definition in the specification because Papyrus demonstrated an intent to act as lexicographer by defining the term "status." Second, the court is reluctant to adopt a construction, like that suggested by NYSE, which does not reflect the definition in its entirety. Crucially, the specification explains that "status" is more than just the "stage of the transaction." The specification clearly states that instructions are either pending or not pending, i.e., either a broker has not received a quotation or not completely filled an order, or the broker has carried out the instruction in its entirety. See '877 Patent col. 9 ll.33-38. Third, because multiple types of information may denote the "status" of an instruction, e.g., volley codes and leaves, the court must avoid a construction that overlaps the respective meanings of several terms or which uses terms to define each other. 9 Fourth, because the specification uses "stage" to explain the meanings of the terms "status" and "volley codes," confusion may arise from a construction that employs the term "stage." '877 Patent col.9 ll.33-34, col.18 ll.17-18. Any construction of "status" must therefore make clear the subtle but important difference between "stage of the transaction" and the "stage" of an instruction as denoted by volley codes, such as whether an instruction has been sent, received, or cancelled. 10 '877 Patent
col.18 ll.16-53, col.23 ll.16-col.25 l.49. Thus, the court finds that "current-status information" means "information indicating whether an instruction is pending or not pending."

9 The court notes that NYSE's suggested construction for "current-status information" is markedly similar to its proposed definition for "volley codes." Def. PCCO 3-4. In addition, during oral argument NYSE argued that the "volley code defines the stage of the transaction." Def. MHSP 100. NYSE's proposed construction would in effect use the term "volley code" to define "status," thereby indicating that it is used for that function only.10 For the full discussion and construction of the term "volley codes," see discussion infra part III(C)(4).

GO BACK

1061

7. Current Web site (First appearing in claim 1 at col. 12, l. 56, and as used thereafter in claims 1-31)

Websidestory contends that the term "current website" does not require construction, while Netratings construes the term to mean "the website providing the page requested by the network browser." See Joint Claims Construction Chart at 3-4. Netratings contends that the use of this term in claim 1 of the '479 Patent requires the adoption of its construction. Websidestory contends that the meaning of "current website" would be clear to an ordinary person skilled in the art in 1999, and does not need to be construed by the Court. If the Court requires construction of "current website," Websidestory proposes that "current" should be construed to mean "belonging to the present," and "website" should be construed to mean "a collection of thematically related, hyperlinked World Wide Web services, mainly HTML documents, usually located on a specific Web server and reachable through a URL assigned to the site." Joint Claims Construction Chart at 3-4.

The term "current website" is neither defined nor mentioned in the specification, and appears for the first time in the second element of claim 1 of the '479 Patent as follows:

receiving a request from a network browser for a page at a website, the page having at least one graphical element having an image source attribute that specifies a website traffic path analysis data location;

detecting if the website page request includes a website cookie having website traffic path analysis data from the network browser for the current website;

producing a website cookie in response . . ., wherein the website cookie contains data . . . for the current website.

Patent at col. 12, ll. 50-61 (Emphasis added.). The term appears in a similar context in other claims. After considering the language of the claims, and particularly the context within which the terms "current website" and "current website visit" are used in the claims, the Court concludes that it would be readily apparent to a person of ordinary skill in the art in question at the time of the invention that the term "current website" is used to refer to the web page which is requested by a visitor's network browser. The Court adopts Netratings' proposed construction for "current website," and concludes that the acquired meaning of "current website" is: "the website providing the page requested by the network browser."

GO BACK

1062

11. Current website visit (First Appearing in claim 1 at col. 12, l. 1, and as used thereafter in claims 1-31)

The invention embodied in the '479 Patent utilizes website cookies to track a website's usage in real-time, thereby providing a website operator with, among other things, information regarding visitor traffic patterns. While the use of website cookies in this manner has many advantages, one, in particular, is that a cookie can be programmed to expire, allowing the invention to differentiate between multiple visits to a website by the same browser. Claim 1 describes this aspect of the invention as
determining if the cookie for the current website has expired, if a website cookie for the current website was detected; setting the traffic path analysis data of the website cookie to initial values if the website cookie has expired, and otherwise updating traffic path analysis data for a current website visit by the network browser by adding the current requested website page.

Patent at col. 12, l. 63 - col. 13, l. 5 (Emphasis added.) As noted in the specification, allowing for the expiration of cookies "keeps the traffic path data analysis more valid, so that separate visits are not calculated as one." Patent at col. 8, ll. 58-64.

The chief dispute regarding the term "current website visit," centers on the related idea of a cookie "expiring." See Joint Claims Construction Chart at 5. Netratings contends that a determination as to whether a visit is "current" is solely based on the time between visits to a website by a web browser. Accordingly, Netratings contends that "current website visit" should be construed as, "a visit to a website containing multiple web pages during which no more than a preselected time limit elapses between requests for a page at the particular website." In support, Netratings cites to numerous references in the specification. Joint Claims Construction Chart at 5. Websidestory contends that the term "current website visit" does not need construction, and notes that Netratings' construction improperly limits the scope of the '479 Patent. Joint Claims Construction Chart at 5. Specifically, Websidestory argued at oral argument and in their briefs that a cookie could expire in ways unrelated to the passage of time.

The specification states that, "[i]n the preferred embodiment, a current visit is defined as a visit during which no more than 15 minutes elapses between requests for a page at a particular website. Other time limits may be selected, as desired." Patent at col. 9, ll. 46-50. Netratings argues that this language amounts to a specific and binding definition of "current website visit." In addition, Netratings points to the following language in the specification:

In the preferred embodiment, the time between visits to the website is tracked by checking the timestamp data that is placed in request header information . . . . If a cookie has a timestamp value that indicates a sufficiently large amount of time has elapsed since the previous visit to the website, then that cookie is deemed expired. . . . A typical expiration time for a cookie will be approximately 15 minutes.

Patent at col. 8, ll. 53-63. Netratings contends that this language specifically defines the way a cookie expires in the '479 Patent. Netratings correctly notes that the specification is "the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315-16.

Websidestory contends that Netratings' proposed construction with reference to the specification improperly limits the scope of the '479 Patent. Websidestory contends that other methods of expiration are possible and within the scope of the invention, and notes that adopting Netratings' proposed construction would improperly read limitations from the specification into the claim. Websidestory's Rebuttal Brief at 9; see also Callicrate, 427 F.3d at 1368; Phillips, 415 F.3d at 1312. Websidestory contends that no construction is necessary, but proposes dictionary definitions of the words "current," "website," and "visit," in the alternative, and urges the Court to adopt those meanings as the acquired meaning of "current website visit" if the Court determines that construction is necessary. Websidestory also cites the '479 Patent's notice of allowability, and notes that it does not indicate a particular methodology for expiring patents. Swinton Decl. at Ex 4.

As noted in InnovalPure Water, it is often difficult to apply two of claims constructions' most important axioms, "that (a) a claim must be read in view of the specification and (b) a court may not read a limitation into a claim from the specification." 381 F.3d at 1117; see also Leibel-Flarsheim, 358 F.3d at 904-05. Here, the '479 Patent specification could be read to shed light on the term "current website visit," or limit the term. In determining the proper construction for "current website visit," however, the Court finds instructive White v. Dunbar, 119 U.S. 47 (1886), where Justice Bradley stated that:

Some persons seem to suppose that a claim in a patent is like a nose of wax which may be turned and twisted in any direction, by merely referring to the specification, so as to make it include something more than, or something different from, what its words express. The context may, undoubtedly, be resorted to, and often is resorted to, for the purpose of

- 1510 -
better understanding the meaning of the claim; but not for the purpose of changing it, and making it different from what it is. The claim is a statutory requirement, prescribed for the very purpose of making the patentee define precisely what his invention is; and it is unjust to the public, as well as an evasion of the law, to construe it in a manner different from the plain import of its terms.

119 U.S. at 51-52. Evident from this language is the import of construing the claims as they are written, and the idea that the claims themselves are what defines the invention. "[P] articular embodiments appearing in the written description will not be used to limit claim language that has broader effect . . . even where a patent describes only a single embodiment." Innova/Pure Water, 381 F.3d at 1117; see also Electro Scientific Industries, Inc. v. Dynamic Details, 307 F.3d 1343, 1349 (Fed. Cir. 2002).

After reviewing the use of the phrase "current website visit" in the claims of the '479 Patent, the Patent specification, as well as the prosecution history, the Court concludes that Netratings' proposed construction of "current website visit" improperly limits the scope of the '479 Patent by reference to the specification. See Lucent Technologies v. Extreme Networks, 367 F. Supp. 2d 649, 657-59 (D. Del. 2005). In addition, the doctrine of claim differentiation, with particular respect here to claims 2 and 3, supports this conclusion. See Liebel-Flarsheim Co., 358 F.3d at 910.

Though the meaning of "current website visit" is not tied to the passage of time, it would be readily apparent to a person of ordinary skill in the art at the time of the invention that the claim language limits the phrase to a cookie which has not expired. Accordingly, the Court concludes that the acquired meaning of "current website visit" is: "a visit to a website in which the website cookie is not expired."

Claim One of the '399 Patent recites:

wherein the first command interpreter is configured in such a way that the command interpreter, when receiving an inquiry from the host device as to a type of a device attached to the multi-purpose interface of the host device, sends a signal, regardless of the type of the data transmit/receive device attached to the second connecting device of the interface device, to the host device which signals to the host device that it is an input/output device customary in a host device, whereupon the host device communicates with the interface device by means of the driver for the input/output device customary in a host device . . .

For purposes of construing the contested meaning here, the differences between the '399 Patent and the '449 Patent are not relevant. The '449 Patent states:

wherein the interface device is configured by the processor and the memory in such a way that the interface device, when receiving an inquiry from the host device as to the type of a device attached to the multi-purpose interface of the host device, sends a signal, regardless of the type of the data transmit/receive device attached to the second connecting device of the interface device, to the host device which signals to the host device that it is a storage device customary in a host device, whereupon the host device communicates with the interface device by means of the driver for the storage device customary in a host device . . .

'449 Patent, col. 11:59-67 & col. 12:1-3 (emphases added to identify words not present in the '399 Patent). For clarity, the Court omits reference to the "storage device" in the '449 Patent in the remainder of this discussion.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - -
Claim One first states that the interface device sends a signal to the computer that it is "an input/output device customary in a host device" and then that the computer communicates by means of the "driver for the input/output device customary in a host device." Id. The parties agree that the "input/output device" must be "customary in a host device." But they disagree about what "customary in a host device" means and about whether the adjectival phrase "customary in a host device" modifies "driver." The Camera Manufacturers contend that the phrase modifies both -- "an input/output device customary in a host device" means a "data input/output [ ] that was normally present within the chassis of most commercially available computers at the time of the invention," Tr. 2:85 (CMs), and "the driver for the input/output device customary in a host device" means "the driver normally present in most commercially available computers at the time of the invention." CMs' Markman Br. at 26.

According to Papst, the phrase "customary in a host device" modifies "input/output device" and not "driver." Papst's Reply at 24-25; Papst's Slides at 105. Papst asserts that the phrase "an input/output device customary in a host device" means "a hardware device that inputs or outputs data with respect to a host computer, and is a device that is sufficiently common such that software drivers for communicating with the input/output device are typically provided with the host computer as it is purchased. Input/output devices customary in a host device include, for example, hard disk drives, floppy disk drives, CD-ROM drives, tape drives or printers." Papst's App. at 4. Papst proposes that "the driver for the input/output device customary in a host device" should be construed in context to mean "upon receiving the 'signal,' the host device automatically uses one or more software driver for use with the input/output devices to communicate with the interface device." Id.

The phrase "customary in a host device" raises three questions: (1) what does "customary" mean?; (2) "customary" as of when?; and (3) what does "in" a host device mean? Tr.2:85 (CMs). First, the specification expressly defines "customary" as "normally present in most commercially available host devices" as follows:

The present invention is based on the finding that both a high data transfer rate and host device-independent use can be achieved if a driver for an input/output device customary in a host device, normally present in most commercially available host devices, is utilized. Drivers for input/output devices customary in a host device which are found in practically all host devices are, for example, drivers for hard disks, for graphics devices or for printer devices.

'399 Patent, col. 4:23-27; '449 Patent, col. 3:27-31. When a specification expressly defines a term, as it does here, it acts as a dictionary. See Vitronics, 90 F.3d at 1582. Accordingly, "customary" means "normally present in most commercially available host devices."

The next question -- customary as of when? -- must be answered: as of 1998 when Mr. Tasler applied for the '399 Patent. A court must interpret the words of a contested claim from the perspective of one skilled in the art at the time of invention. See Phillips, 415 F.3d at 1313. The word "customary" is time-dependent, like the word "conventional" construed by the court in Muniauction, Inc. v. Thomson Corp., 532 F.3d 1318, 1326 (Fed. Cir. 2008). There, the court determined that "conventional" when modifying the term "internet browser" meant web browsers in existence at the time of the invention. See id.; accord PC Connector Solutions LLC v. SmartDisk Corp., 406 F.3d 1359, 1363-64 (Fed. Cir. 2005) (input/output port "normally" connectible to a computer port meant technology existing at the time of the invention). A claim cannot be interpreted to have different meanings at different times. See PC Connector, 406 F.3d at 1363. The word "customary" means customary in a host computer at the time of the invention. 18

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

18 The Camera Manufacturers argue that Papst conceded that customary is a time-dependent term. Tr. 2:86 (CMs) ("Mr. Kuwala said this very morning that customary is a time dependent term and therefore, it has to be customary at the time of the invention."). Papst did not concede this issue, however. It merely noted that you "might argue" that the word "customary" imposes a time limitation. Tr. 2:41 (Papst).

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

With regard to the third question -- what does "in" a host device mean? -- the answer is straightforward in the context of the phrase "the driver for the input/output device customary in a host device." The Camera Manufacturers assert that "in" means "in," that is, within the chassis of the host computer. Tr. 2:86 (CMs). The specification makes it clear that certain "drivers"
are "normally present in most commercially available host devices," i.e., are normally inside most computers:

The present invention is based on the finding that both a high data transfer rate and host device-independent use can be achieved if a driver for an input/output device customary in a host device, normally present in most commercially available host devices, is utilized. Drivers for input/output devices customary in a host device which are found in practically all host devices are, for example, drivers for hard disks, for graphics devices or for printer devices . . . . [T]he hard disk driver is utilized in the preferred embodiment of the interface device of the present invention. Drivers for other storage devices such as floppy disk drives, CD-ROM drives or tape drives could also be utilized in order to implement the interface device according to the present invention.

'399 Patent, col. 4:23-39 (emphases added); '449 Patent, col. 3:26-43 (same). As the specification further explains, the interface device sends a signal to the computer that the computer is communicating with an input/output device, and the interface device then communicates with the computer using either a driver present in the computer's BIOS system or a specific driver for the multi-purpose interface. See '399 Patent, col. 5:5-20; '449 Patent, col. 4:9-24.

The interface device according to the present invention therefore simulates, both in terms of hardware and software, the way in which a conventional input/output device functions, preferably that of a hard disk drive. As support for hard disks is implemented as standard in all commercially available host systems, the simulation of a hard disk, for example, can provide host device-independent use. The interface device according to the present invention therefore no longer communicates with the host device or computer by means of a specially designed driver but by means of a program which is present in the BIOS system (Basic Input/Output System) and is normally precisely matched to the specific computer system on which it is installed, or by means of a specific program for the multi-purpose interface.

'399 Patent, col. 5:5-20; '449 Patent, col. 4:9-24 (same). Thus, what is "in" the computer are the drivers for internal computer components (such as the multi-purpose interface or an internal hard disk drive) and for various peripherals, some of which are always outside the computer such as printers.

The Patent requires "drivers" to be "customary." Again, the parties agree that the "input/output device" must be "customary in a host device." Since every input/output device has its own driver, for every input/output device that is "customary" there must also be a driver that is "customary." This explains the statement in the specification that "[d]rivers for I/O devices customary in a host device which are found in practically all host devices are, for example, drivers for hard disks, for graphics devices or for printer devices." '399 Patent, col. 4:27-30; '449 Patent, col. 3:31-34. Because all input/output devices must have individual drivers to function, and because Mr. Tasler referenced "customary input/output devices," the Court concludes that when he also referenced "drivers for the input/output device customary in a host device," he meant that such drivers themselves must be customary in a host device.

The question -- what does "in" a host device mean? -- is more difficult in the context of the phrase "an input/output device customary in a host device." The Camera Manufacturers again assert that "in" means "within the chassis of the host computer." CMs' Markman Br. 29. Papst suggests that an input/output device "in" a computer should be construed more broadly to mean "with respect to," as in "a hardware device that inputs or outputs data with respect to a host computer." Papst's App. at 4. "We don't read in as requiring it to be inside. It means part of the system." Tr. 2:80 (Papst).

The parties' conflicting interpretations arise from the garbled language of the Claims. The specification clarifies that drivers must be internal to the host device: "[d]rivers for I/O devices customary in a host device which are found in practically all host devices." 399 Patent, col. 4:27-30; 449 Patent, col. 3:31-34. But in describing such drivers, the specification refers to drivers for printers. The parties agree that printers are not inside a computer. Tr. 2:80 (Papst); Tr. 2:87 (CMs).

The specification expressly defines "drivers customary in a host device" in relation to the devices that such drivers direct. Those devices described are both inside and outside a computer. However, the interface device "signals to the host device that it is an input/output device customary in a host device." The phrase "customary in a host device" refers to the immediately antecedent noun "device;" there is no other antecedent word that the phrase reasonably could modify. Thus, the input/output must be "customary in a computer." And the word "in" should be construed in accordance with its ordinary meaning to mean "within," not "with respect to" as Papst proposes. Papst's construction ignores the word "in," rendering it superfluous, and such a construction is disfavored. See Merck, 395 F.3d at 1372 (a construction that gives meaning to all the terms of the claim is preferred over one that does not). Papst's assertion -- that the Patent must mean input/output devices
customary in a computer system because the specification refers to drivers for devices both inside and outside the chassis of the computer -- might be what the inventor meant to say when he wrote his Patent. But the Patent does not say that the interface device "signals to the host device that it is an input/output device for which the host device has drivers that are customary in a host device." The Court must construe the claims of the Patent as they are written.

Accordingly, the Court finds that "an input/output device customary in a host device" must be construed similarly to the phrase "the driver for the input/output device customary in a host device." "An input/output device customary in a host device" in the '399 Patent means a "data input/output device that was normally present within the chassis of most commercially available computers at the time of the invention," and "the driver for the input/output device customary in a host device" means "the customary driver(s) in a host device used to communicate with customary internal and external input/output device(s), which driver(s) were normally present within the chassis of most commercially available computers at the time of the invention." Thus, "a storage device customary in a host device" in the '449 Patent means a "storage device that was normally present within the chassis of most commercially available computers at the time of the invention," and "the driver for the storage device customary in a host device" means "the customary driver(s) in a host device used to communicate with customary internal and external storage device(s), which driver(s) were normally present within the chassis of most commercially available computers at the time of the invention."

--- Footnotes ---

n2 The Court also notes that in their proposed construction of "plurality of customer answers," Defendants do not contend that "plurality" modifies "customer," instead they argue plurality modifies "answers."

--- End Footnotes ---

Customer

Defendants urge the Court to construe the term to mean: "The potential purchaser of a product for whom the proposal is customized. The customer is not the person using the computer to customize the proposal for the customer." Thus, Defendants argue that the customer and user cannot be the same person.

The claims do distinguish between the roles of customer and user: "presenting to a user of the computer a plurality of questions . . . inputting into the computer a plurality of customer answers to the questions. . . ." Col. 39:56-60; see also col. 41:65-42:2. Thus, according to the claim language, the user is the person using the computer and the customer is the person who answers the plurality of questions relating to the product's features and uses. But the claims do not require that different people fulfill the roles of customer and user.

Defendants argue that the claim language does require that the user and customer be different people because claim 1 is drawn to a method "for selling products to particular customers" by "presenting to a user" a plurality of questions. Defendants contend the claim is directed to a situation where one user operates a computer in an effort to sell products to multiple customers. The claim language belies Defendants' argument. Claim 1 goes on to describe "inputting . . . a plurality of customer answers n2 . . ., the answers specifying a customer's desired product features and uses." Col. 40:57-60 (emphasis added). Thus, the steps of the claim do not require multiple customers.

--- Footnotes ---

n2 The Court also notes that in their proposed construction of "plurality of customer answers," Defendants do not contend that "plurality" modifies "customer," instead they argue plurality modifies "answers."

--- End Footnotes ---

Defendants also contend the specification describes the user and customer as different individuals. See e.g., col. 8:46-53 ("When a user begins to deal with a customer, the user will typically want to gather specific customer and product information. . . ."). Although in the preferred embodiment, the user and customer may be different individuals, Defendants have not shown that this limitation of different individuals as opposed to different roles should be imported into the claim language. Accordingly, the Court does not adopt it. "Customer" is not used in the claims in any manner different from that of its ordinary meaning in the art, which is no different than its ordinary lay meaning. "Customer" does not require construction.
Third, Lockwood argues that the word "customer" should be construed to mean "someone with whom you do business" and therefore that American's "customers" are the travel agents that use SABREvision. American counters that the patent itself explicitly excludes travel agents from the definition of "customer." We agree. The specification states that the purpose of the invention is to replace travel agents so that the customer can purchase travel-related goods and services directly. It is "a new device capable of performing the promotion and sales of services such as those commonly dispensed by travel agencies, in a fully automated fashion and from easily accessible locations." Given the patent specification's use of the term "customer," it is clear that the accused device lacks this essential limitation. SABREvision is not used by, nor is it designed to be used by, the customers who are purchasing the goods and services. Lockwood does not genuinely dispute American's contention that SABREvision uses a command structure that requires experience to operate, nor does he argue that SABREvision is suitable for self-service operation by the consumers of the travel related goods and services.

The defendants argue that their orders come only from resellers, not from individual purchasers, and that printing is at a remote factory, not at the customer's site. They point out that the Ross specification describes the customer as a consumer who, upon choosing a book, sets in motion the "high speed manufacture of a single copy of a selected book on the immediate premises while the customer waits for a very short time." Col. 3, lines 7-15. The defendants argue that the district court, in refusing to include this limitation of "customer" in its Markman definition and jury instruction, placed too much weight on a dictionary definition of "customer" that is out of context.

ODMC argues that the patentee did not disavow the standard dictionary meaning of "customer," and that the Ross invention is not limited to any specific kind of customer. However, when the scope of the invention is clearly stated in the specification, and is described as the advantage and distinction of the invention, it is not necessary to disavow explicitly a different scope. See AstraZeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1339-40 (Fed. Cir. 2004) ("Where the general summary or description of the invention describes a feature of the invention (here, micelles formed by the solubilizer) and criticizes other products (here, other solubilizers, including co-solvents) that lack that same feature, this operates as a clear disavowal of those other products"); Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1268-69, 1271 (Fed. Cir. 2001) ("the written description 'can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format.'" (quoting SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1344 (Fed. Cir. 2001)).

The Ross specification repeatedly reinforces its usage of the term "customer" as the retail consumer. See col. 7, lines 24-25 ("All customer actions are conducted within customer console 103"); col. 15, lines 59-60 ("the customer seats himself or herself in front of computer screen 157" as depicted in Fig. 2); col. 2, lines 8-12 ("if the consumer wishes to purchase a book, he may either pay for the book through a store clerk . . . or the consumer may enter his credit card into the system"). The specification distinguishes "general purpose machines . . . not specifically designed to be consumer operated for the on demand, automatic manufacturing of a single book at the point of sale." Col. 10, lines 37-43.

In Phillips, 415 F.3d at 1321, the en banc court explained that the role of the specification is to describe and enable the
invention. In turn, the claims cannot be of broader scope than the invention that is set forth in the specification. Although we agree with the district court that the Ross invention does not concern itself with whether the "customer" reads the book or obtains it for resale, the focus of the Ross patent is immediate single-copy printing and binding initiated by the customer and conducted at the customer's site. The district court's definition of "customer" cannot eliminate these constraints in order to embrace the remote large-scale production of books for publishers and retailers.

E. "entering a customer authorization code for authorizing access to a customer data base of a host data processor"

SVS asks that the term "entering a customer authorization code for authorizing access to a customer data base of a host data processor" be construed to mean "the customer enters via the keypad a personal identification number for authorizing access to a customer data base of a host data processor." (D.I. 43 at 15) CAT proposes instead "a series of numbers and/or letters, or a combination thereof, on the card for authorizing access to a customer data base of a host data processor." (D.I. 44 at 21-22) CAT contends that SVS's construction would improperly import four limitations not found in the plain language of the claims, namely limitations that: 1) the customer know the code, 2) the customer physically enter the code, 3) the customer enter the code through the keypad, and 4) the code be a PIN (i.e., personal identification number). (D.I. 44 at 22) SVS responds by challenging CAT's insistence that the code is found "on the card" as this would exclude a preferred embodiment. (D.I. 47 at 19) I conclude that both parties, to some extent, are correct.

First, I find that the customer authorization code is not limited to a PIN. SVS argues that the "customer authorization code" is a PIN based on the following disclosure:

The customer selects a product, takes it to the sales counter for checkout, then as illustrated with reference to FIG. 2 provides input, by way of example, by swiping 101 the ATM/debit card through the card reader 20 of the terminal unit 12 described earlier with reference to FIG. 1. The display 14 of the terminal unit 12 will prompt 102 the user to enter their PIN. The PIN is entered by the customer.

('859 patent, col. 3 lines 28-34) CAT responds that it would be improper to import the limitation of a PIN into the claims on the basis of its usage in one embodiment when other embodiments do not detail entry of a PIN. (D.I. 44 at 24) CAT is correct. The Federal Circuit has warned against confining the claims to specific embodiments described in the specification. See Phillips, 415 F.3d at 1312-13. While the ATM card embodiment requires the customer to enter a PIN, the phone card and prepaid card embodiments do not.

I turn next to how the customer authorization code is entered. In contrast to SVS's proposal that the customer enters the code via the keypad, CAT's proposal that the customer authorization code is located "on the card" implies that any party, through a swipe of the debit styled card, may enter the code. CAT finds support for its construction in the specification's "Gold Card Program," an example of a prepaid debit card embodiment. (D.I. 46 at 9) The patent states:

6. After the card purchase, customer goes to cash register to place order. Clerk rings up order and customer presents his Gold Card for payment.

7. Clerk swipes card through register terminal. Register terminal calls host. Host checks the card value against the original card purchase amount. Host then deducts current purchase and sends back balance remaining which is printed out on customer receipt.

('859 patent, col. 6 lines 38-44) In CAT's view, this passage indicates that the customer authorization code is located on the card and is entered by the clerk who swipes the card through the terminal. (D.I. 60 at 157-58) However, as SVS points out, requiring the customer authorization code to be on the card would improperly exclude the ATM card preferred embodiment. (D.I. 47 at 19)

SVS instead proposes that a customer authorization code must be entered by a customer through the keypad of the terminal unit, reasoning that since the claim language states the purpose of the keypad is "for data entry," a customer would necessarily enter her authorization code through it. (D.I. 43 at 16) This, SVS contends, is in keeping with portions of the
specification that describe "a keypad 18 for entry of Personal Identification Numbers (PIN)." (’859 patent, col. 2 lines 59-60 & Abstract) However, the patent contemplates data other than just the authorization codes being entered through the keypad. For example, claim 1 recites the step of "entering transaction data to the computer through the keypad data entry." (’859 patent, col. 7 lines 54-55)

SVS also argues that prosecution history estoppel limits entry of the customer authorization code to "via the keypad." (D.I. 47 at 22-26) I do not agree. The file history shows that original independent claims 30 and 40 recited the element "entering an authorization code through the keypad for having the computer initiate communication with a host data processor." (D.I. 43 Ex. E (Sept. 8, 1999 Amendment) at SVS000201-02) Original claims 30 and 40 were rejected as anticipated by the Gutman patent, which taught entry of an authorization code through a keypad for having the computer initiate communication with a host data processor. (D.I. 43 Ex. D (March 8, 1999 Office Action) at SVS000190) In the same office action, the examiner indicated that dependent claims 31 and 43, which depended from claims 30 and 40 and recited the steps of "entering a customer authorization code for authorizing access to a customer data base of a host data processor" and "entering a clerk authorization code for initiating a debit purchase transaction," would be allowable if rewritten in independent form to include all the limitations of the rejected base claims. (Id. at SVS000193) Instead, the applicants cancelled claims 31 and 43 and rewrote independent claims 30 and 40, substituting the steps of "entering a customer authorization code for authorizing access to a customer data base of a host data processor" and "entering a clerk authorization code for initiating a debit purchase transaction" for the rejected element "entering an authorization code through the keypad for having the computer initiate communication with a host data processor." (D.I. 43 Ex. E (Sept. 8, 1999 Amendment) at SVS000201-02)

This prosecution history does not support an estoppel argument. The examiner's indication of allowability regarding the customer and clerk code elements shows that the examiner viewed the customer, clerk, and authorization codes as distinct elements with distinct functions. Neither the customer nor clerk code elements ever recited the "via the keypad" limitation. The applicants did not accept the examiner's invitation to rewrite the rejected dependent claims, and were thus not required to import the limitations of the rejected base claim into them. Instead, the applicants permissibly rewrote the rejected independent claims by deleting the anticipated subject matter in favor of subject matter identified by the examiner as allowable. See Festo v. Shoketsu, 344 F.3d 1359, 1382 n.2 (Fed. Cir. 2003) (concurring opinion) ("It is customary to present broad and successively narrow claims, to rewrite or cancel claims, and to move elements between dependent and independent claims.").

Accordingly, the intrinsic evidence indicates that the customer authorization code is neither limited to being on the card nor to being entered via the keypad. I thus recommend that the Court construe the term "entering a customer authorization code for authorizing access to a customer data base of a host data processor" to mean "a series of numbers and/or letters, or a combination thereof, which may be entered via the keypad by the customer or may be on the card itself, for authorizing access to a customer data base of a host data processor."

1068

Customer Identifier

Plaintiff proposes the construction, "any information submitted to a merchant or its designee for payment of goods or services." Defendant advances a construction of "unique identifying account number." However, Plaintiff argues that while an account number may serve as a customer identifier, one of ordinary skill in the art would clearly understand from reading the claims and the specification of the ’281 patent that an account number is only one kind of identifying information that can be submitted to a merchant as payment for goods and services as recited in claims 1 and 10. Plaintiff discounts any attempts by Defendant to limit this term to a single specific embodiment disclosed in the ’281 specification.

Defendant counters that the ’281 specification consistently explains that the invention is concerned with the use of unique identifying account numbers. Defendant points to Column 1, lines 31-32, in the ’281 specification which provides several examples of "unique identifying account numbers" as "e.g., credit, debit, charge, payment, smart, etc. card numbers."

Indeed, the ’281 specification notes that the payment information that is forwarded to the merchant processor "relates to a customer identifier" and "that identifier can be the account number associated with, for example, a debit card, a smart card,
a credit card (e.g., a Visa or MasterCard card), a charge card (e.g., an American Express card), etc." Col. 1, lines 55-61. The '281 patent identifies card transactions as the basic starting point of the invention. The summary of the invention also emphasizes that the invention is based on transactions involving unique identifying account numbers, particularly card account numbers. See Col. 1, lines 17-25 and lines 29-33.

Because the '281 specification consistently refers to the use of account numbers, rather than just "any information," when explaining the loan repayment process, see Col. 2, lines 44-48, the Court finds Defendants to be correct that Plaintiff's construction is overly broad and is incompatible with the environment within which the invention operates. Thus, the Court adopts Defendant's construction and construes the term customer identifier as "unique identifying account number."

1069

2. "Customer Information"

Walker proposes that this term should be construed to mean "[i]nformation which identifies the account of the customer," Capital One has since withdrawn its objection to Walker's proposed construction. The court has reviewed this claim term as used in claims 9, 17 and 19 of the '478 patent and the specification and finds that Walker's proposed construction is supported by the intrinsic evidence presented to the court and is consistent with what a person of ordinary skill in the art would have ascertained from the intrinsic evidence. For that reason, the court construes "customer information" to mean "facts about a customer or a customer's credit account."

1070

The parties also dispute the meaning of "customer interface," as this term appears in claims 1 and 15. Plaintiffs do not appear to dispute defendant's definition regarding the purpose of the customer interface as "communicating information about the status of the vending machine to the customer." (Def.'s Rebuttal Claim Construction Br. 21). The parties' disagreement instead rises from plaintiffs' definition of interface as "the place where two different systems meet and interact with each other," for example, "a GUI (graphic user interface, the display on a computer screen," with the vending machine as one system and the user as a second system. (Pls.' Mem. On Claim Construction 14). Defendant disputes this definition to the extent that it would allow a vending machine's customer interface to be located elsewhere than in the machine. Plaintiffs argue that support for the remote location of an interface comes from specification language providing that "[a]lternatively, the user interface can be present inside or uploaded to the user's laptop or other device thereby obviating the need for an interface within the vending machine unit." ('400 Patent 6:20-23). Defendant's expert correctly clarifies, however, that this provision "describes an arrangement where the vending machine does not have a customer interface." Cooley Aff. P 43. Indeed, the specification clarifies that presence of the interface on a user's computer "obviat[es] the need for an interface within the vending machine unit." ('400 Patent 6:22).

I construe the disputed claim language as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Customer interface</td>
<td>A part of the vending machine for communicating information about the status of the vending machine to the customer</td>
</tr>
</tbody>
</table>

1071

D. "payment instructions"

The differences between the parties' proposed claim interpretations are as follows:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Emergis's Construction</th>
<th>Cable One's Construction</th>
</tr>
</thead>
</table>
"payment instructions" data entered by the customer that may include information such as a selected method or source of payment, a payment account number or other identifier, payment amount, comments or initiation date data relating to a customer's authorized payment to an invoicer, which includes at least an invoice number and a customer payment account

The parties agree that this phrase should be construed as data relating to the customer's authorized payment. However, the parties dispute the content of these instructions. Cable One contends that the "customer payment instructions" must include two pieces of information—the invoice account number and the customer payment account, while Emergis contends that the data can include any combination related to the customer's payment. Emergis states that the customer may, but is not required, to include the invoice account number or customer payment account.

Claim 1 reads: "transmit the customer payment instructions from the customer directly to said invoicer, said payment instructions including at least a customer invoice account number and an associated customer payment account." n86 Claim 36 similarly states that the remote electronic customer authorization interface is a "means for transmitting the customer payment instructions from the customer directly to said invoicer, said payment instructions including at least a customer invoice account number and an associated customer payment account." n87 According to the claim language, the construction should include at least both of these pieces of information.

The specification shows that the customer payment instructions may, but need not always, include this information. However, in the preferred embodiment, both the customer invoice number and customer payment account are included in the customer payment instructions. The specification states that "[t]he information included in this electronic authorization could include the customer invoice number and an associated customer payment account. In the preferred embodiment, both these items of information are submitted simultaneously with the authorization." n88 Therefore, based on the plain meaning of the claim language and the preferred embodiment of the specification, the Court finds that "customer payment instructions" includes at least these two pieces of information. The Court will construe "customer payment instructions" as "data relating to a customer's authorized payment to an invoicer, which includes at least an invoice number and a customer payment account."

The parties proffer differing constructions of Step 1, which provides "creating at least one customer profile for each eligible recipient of said data, said customer profile indicating the customer's preferences for data having predetermined
characteristics." Amazon narrowly construes "customer profile indicating the customer's preferences for data having predetermined characteristics" as "a list of mathematical values indicating the customer's preferences for predetermined characteristics that describe the content of data." Def. Mem. at 16. Amazon relies on a general purpose dictionary, its expert witness, and the patent specification. Amazon generally defines "profile" as "a formal summary of analysis of data, often in the form of a graph or table, representing distinctive features or characteristics." Def. Mem. at 16 (quoting The American Heritage Dictionary of the English Language (4th ed. 2000)). Amazon then submits its expert witness' declaration that "in the specific field of these patents, information filtering, customer profile is understood to mean the user profile in an information filtering system that indicates a user's preferences for characteristics of the content of the items being filtered . . . as a numerical value for a corresponding characteristic in the user and item profiles." Def. Mem. at 16 (citing Resnick Decl. at P. 59). Amazon contends the patent specification confirms this construction: "The content profiles and the customer profiles are thus described as a collection of mathematical values representing the weighted significance of several predetermined characteristics of the video programming." Def. Mem. at 16, Ex. 1, Col. 10.

Unlike Amazon, Pinpoint proffers separate constructions for each key term in the phrase "customer profile indicating the customer's preferences for data having predetermined characteristics." According to Pinpoint, "customer profile" means "a set of information related to a specific customer that describes significant characteristics of the customer;" "indicating the customer's preferences for data having predetermined characteristics" means "the customer profile points out or shows indirectly the customer's preferences for certain kinds of information or items of interest;" and "predetermined" means "the characteristics are established before the system practices the method claimed." Pinpoint relies on the IBM Dictionary of Computing and the Merriam-Webster Dictionary, which provide respective definitions of "profile" as "data that describes the significant characteristics of a user, a group of users, or one or more computer resources" and "indicate" as "to point out" or "to show indirectly."

The parties' disputed claim construction primarily focuses on whether customer profiles use mathematical values to express customer preferences. Amazon asserts that "[mathematical] constructs are core to what is described as the invention," while Pinpoint counters that Amazon is "just limiting the claim terms to the preferred embodiment." Neither the plain language of the asserted claims nor the patent specification supports Amazon's proposed construction of "customer profile" as a "mathematical construct." Unlike other '257 patent claims, the plain language of Pinpoint's asserted claims do not reveal a narrow "mathematical construct." Compare Def. Mem. at Ex. 1, Col 52, Claim 1 ("relating said selected customer profile with the content profiles for the data available from each data source to the customer at a particular time by determining a distance between a customer profile and a content profile in a characteristic space by calculating an agreement scalar for common characteristics, ac, between said selected customer profile, cv, and said content profiles, cp, in accordance with the relationship . . . ") with Claim 43 ("relating said at least one customer profile with the content profiles for the data available from each data source to the customer"). The existence of narrower claims requiring application of specific mathematical equations is suggestive of a broader construction of the term "customer profile" in the asserted claims of the '257 and '722 patents. Arlington Industries, Inc., 345 F.3d at 1327.

Nor is the court persuaded by Amazon's insistence that "customer and content profiles are sets of numbers associated with the same set of characteristics." Def. Reply at 3. See also Def. Mem. at 18 ("The patent claims a specific method that requires particular constructs, e.g., 'content profiles' and 'customer profiles' that are themselves made up of particular information, i.e., degrees of, or relative preferences for, predetermined characteristics") (emphasis added). This cannot be right. As Pinpoint correctly argues, not all the asserted claims refer to "predetermined characteristics." Compare Def. Mem., Ex. 1 at Col. 55, Claim 17 ("creating at least one customer profile for each eligible recipient of said data, said customer profile indicating the customer's preferences for data having predetermined characteristics") with Claim 43 ("creating at least one customer profile for each eligible recipient of said data, said customer profile including a profile of data previously accessed by said customer"). This suggests a broader construction of customer profiles, not all solely made up of "predetermined characteristics." Vitrionics, 90 F.3d at 1582 ("first, we look to the words of the claims themselves, both asserted and nonasserted, to define the scope").

The specification also refutes Amazon's narrow construction. Contrary to Amazon's contention, the specification contemplates instances where a customer profile using mathematical values to indicate range is not required. Instead, the customer profile may simply indicate whether a characteristic is "liked" or "disliked." See Def. Mem. Ex. 1 at Col. 11 ("On the other hand, as in the Strubbe system, the weights could simply indicate a 'like' or 'dislike' value for each characteristic"). Accordingly, Pinpoint's broader construction, which is based on the plain and ordinary meaning of the disputed language, will be adopted. Superguide Corp. v. DirecTV Enterprises, Inc. et al., 358 F.3d 870, 875 (Fed. Cir. 2004) ("dictionaries are
often helpful in ascertaining the plain and ordinary meaning of claim language). The court construes customer profile as "a set of information related to a specific customer that describes significant characteristics of the customer"; indicating the customer's preferences for data having predetermined characteristics as "the customer profile points out or shows indirectly the customer's preferences for certain kinds of information or items of interest"; and predetermined as "the characteristics are established before the system practices the method claimed."

1. "Customer Specified Credit Parameter" and "Customer-Selected Account Parameter"

Walker proposes that the court construe these claim terms to mean: "[a] term of a credit account that is chosen by a customer." Capital One originally proposed that these claim terms be construed to mean "[a] term of a desired credit account that is chosen by a customer." However, in its opposition to Walker's Markman motion, Capital One states that it is willing to stipulate to Walker's proposed construction of these two claim terms. The court has reviewed these claim terms as used in claims 8, 16 and 18 of the '478 patent and claim 12 of the '230 patent and the specification and finds that Walker's proposed construction is supported by the intrinsic evidence presented to the court and is consistent with what a person of ordinary skill in the art would have ascertained from the intrinsic evidence. As such, the court construes "customer specified credit parameter" and "customer-selected account parameter" to mean "a term of a credit account that is chosen by a customer."

Customer Terminal Means

Furnace Brook contends that "customer terminal means" should be construed in the same way as "telephone terminal," which they assert means "a customer's terminal, whether hard wired or portable." Overstock contends that "customer terminal means" is a "standard customer telephone unit which may be hardwired or portable and has a standard commercial handset, a touchtone pad, a display unit and an audio unit, such that it is not a computer system or personal computer, or alternatively is an interactive hookup with a touchtone telephone and a cable TV system to selectively display the requested catalog data and menu on a particular TV channel."

"Customer Terminal Means" first appears in Claim Five, which recites, in part:

An improved interactive computerized catalog system comprising: central data processing means for storing and selectively addressing digitized graphic catalog data, a plurality of customer terminal means for displaying alphanumeric data during interactive communications between the terminal and central data processor means, switchable communication means activated by individual ones of said plurality of customer terminal means for selectively interconnecting ones of said plurality of customer terminal means with said central data processing means, ...

'832 Patent at 11: 32-44. Claim Seven recites:

The improved interactive computer catalog system of claim 5 wherein said customer terminal means comprise display means for displaying alphanumeric and graphic data and further including data entry means including a key pad for entering alphanumeric data for transmission to said central data processor means.

'832 Patent at 12: 4-9. "Customer terminal means" also appears several other times in Claim Eight.

Overstock contends, and the Court agrees, that the claim does not provide the structure for performing the function "for displaying alphanumeric data," or "for displaying alphanumeric and graphic data," and that this term is therefore a "means-plus-function" element, and that the claim scope is therefore limited to the structures disclosed in the specification, and their equivalents.

An element in a claim for a combination may be expressed as a means or step for performing a specified function without
the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112. See also Intel Corp. v. VIA Techs., 319 F.3d 1357, 1367 (Fed. Cir. 2003) (means-plus-function claims are allowed, but their scope is limited to the specific structures disclosed in the specification and their equivalents). "Means-plus-function claiming applies only to purely functional limitations that do not provide the structure that performs the recited function." Phillips v. AWH Corp., 415 F.3d 1303, 1311 (Fed. Cir. 2005)(citation omitted). The specification provides:

The user terminal may be the type described in conjunction with FIG. 1 or alternatively may be an interactive hookup with a touch tone telephone and a cable TV system to selectively display the requested catalog data and menu etc. on a particular TV channel."

The only structures disclosed for the user terminal, which the Court reads to be the same as the customer terminal means, are the "telephone terminal" in figure 1 and the "interactive hookup with a touch tone telephone and a cable TV system." The patent includes references to dialing toll-free 800 numbers, and connecting via a telephone exchange. Because this term is subject to Paragraph 6 of Section 112 of the Patent Law, the Court accordingly limits the term to corresponding structures disclosed in the specification and their equivalents.

The Court concludes that a "customer terminal means" is "either a standard landline telephone unit, which has a standard commercial handset, a touchtone pad, a display unit and an audio unit, and which may have a cordless handset, or is an interactive hookup with a touchtone telephone and a cable TV system to selectively display the requested catalog data and menu on a particular TV channel."

2. With respect to claim 5, the critical limitation recites a "customer terminal means" that activates a communication means to connect with a central data processing means. '832 patent, col. 11, ll. 39-43. Because the customer terminal means limitation uses the term "means" and because the phrase "customer terminal" identifies no significant structure, the district court correctly interpreted the limitation as a means-plus-function limitation in accordance with 35 U.S.C. § 112, P 6. The district court identified two means disclosed in the specification for performing the claimed function: a "standard landline telephone unit" and a "touchtone telephone" connected to a television for displaying catalog data. Furnace Brook asserts that the district court ignored as a disclosed means a device communicating over an "online interactive communications network" (shown in figure 4 of the patent), which Furnace Brook defines as a device in "connection to, or communication with, a computer." The label "online interactive communications network," however, identifies no specific structure for performing the claimed function; it describes only a generic class of structures and was thus properly ignored. See Fonar Corp. v. GE, 107 F.3d 1543, 1551-52 (Fed. Cir. 1997) (holding that the disclosed wave forms for performing a claimed function included a wave form specifically identified in the specification but did not include the nonspecific set of "other wave forms" mentioned only generically in the specification as suitable for performing the claimed function).

Furnace Brook also faults the district court for not stating that the literal scope of the critical limitation includes equivalents of the disclosed means. According to Furnace Brook, those equivalents include Internet-enabled cellular telephones and personal computers. The district court, however, stated in its claim construction order that the scope of a means-plus-function limitation "is . . . limited to the structures disclosed in the specification, and their equivalents," which indicates that the court understood the requirements of section 112, paragraph 6. The district court then addressed the issue of equivalent means at the summary judgment stage, holding that "no reasonable juror could find an insubstantial difference between the [c]ustomer [t]erminal [m]eans' disclosed in the '832 patent and an Internet-enabled cellular telephone or personal computer. As explained above in connection with claim 1, that ruling is correct. Dr. Stevenson's declaration and Dr. Nemes's deposition testimony do not address the equivalence of communication with a server over the Internet and communication with a server by dialing the server over telephone networks. Furnace Brook offered no other evidence of equivalence. Furthermore, Furnace Brook proffered no evidence that the Internet is an after-arising technology that could be within the reach of the doctrine of equivalents as applied to the disputed means-plus-function limitation. See Chiuminatta Concrete
Concepts, Inc. v. Cardinal Indus., Inc., 145 F.3d 1303, 1310-11 (Fed. Cir. 1998). Because Furnace Brook's evidence of equivalence was insufficient to survive summary judgment, we uphold the judgment of noninfringement as to claim 5.

1076

Customized Proposal

The Staples parties agreed that "customized proposal" did not require additional construction. Since the Court had already construed "proposal" as "information intended for conveyance to a potential customer," the Court agreed that "customized proposal" was not a term with special meaning in the art or in this patent. The Court reasoned that it is an everyday term that the jury will be sufficiently familiar with.

Hyundai argues that "customized proposal" was given a special meaning in the specification and during prosecution and should now be construed as "the utilization of a customer's answers to questions to select product pictures, product environment pictures, and text segments and compile this information for conveyance to a potential customer."

Hyundai's proposed construction is unnecessary as it merely restates what is elsewhere in the claim. Accordingly, for the reasons given in its Staples opinion, the Court construes "proposal" as "information intended for conveyance to a potential customer," and "customized proposal" does not require further construction.

1077

E. Customized Software

Claim 1 provides that the device interface, network interface, and memory perform operations for "sending customized software to the client machine over the network." Digi contends that this term should be construed as "executable software, delivered to and running on the client machine, which provides device-appropriate user interface and control operations." Lantronix, on the other hand, asserts that this term should be defined as "software specific to the device that allows for the generation of device control signals and reception of device status information. By way of example only, Java applets or HTML-based control software."

The parties have clarified their positions, and it appears that the main dispute is whether the software provides "device-specific" user interface and controls, or "device-appropriate" user interface and controls. Digi argues that the term "device-appropriate" is more suitable here, as this broader term encompasses an interface that could potentially be tailored to work on more than one device. The Court agrees with Digi's construction. The claim language and specification do not limit the user interface to merely one specific device. For instance, a single interface may be suitable for use with more than one brand of copier or with more than one brand of digital camera. For this reason, the Court construes "customized software" to mean "executable software, delivered to and running on the client machine, which provides device-appropriate user interface and control operations."

1078

G. Customized to Characteristics of the Device

Claim 4 is a dependent claim related to the module of Claim 1. Claim 4 describes software in the module that is comprised of bytecode instructions that are "customized to characteristics of the device."

Digi maintains that "customized to characteristics of the device" should be defined as "the [bytecode] instructions are customized to characteristics of the device: the applet or similar program is designed to display on the client machine a virtual interface that has the appropriate appearance and offers the proper control options for the device." Lantronix contends that this term should be given its plain meaning, which Lantronix contends is "instructions that are specifically
customized to the characteristics of the device. By way of example only, a Java applet or HTML page."

The Court agrees with Lantronix that this term needs little construction, as its plain meaning is clear. However, the Court also sees no support for including the specific examples that Lantronix describes--a Java applet or HTML page--into the claim construction of this term. Thus, the Court construes "customized to characteristics of the device" to mean that "the bytecode instructions are specifically customized or tailored to the characteristics of the device."

B. Effect of Prior Litigation

As stated above, SunTiger prevailed in a prior patent infringement suit against Scientific Research Funding Group (SRFG) on the same patents now in question. Both SunTiger and Sunglass Products have stipulated that the claim construction in the prior suit will control here:

The patents-in-suit have already been construed by the U.S. District Court for the Eastern District of Virginia [and that] construction . . . is binding on the parties in this case. To the extent that the terms in the asserted claims were not construed in the said prior litigation, the parties are asking the Court to make a claim construction based on the arguments submitted in the summary judgment motions.

Stipulation at 1-2. "In a patent litigation action, where the parties do not dispute any relevant facts regarding the accused product but disagree over possible claim interpretations, the question of literal infringement collapses into claim construction and is amenable to summary judgment." Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1324 (Fed. Cir. 2002).

The relevant terms and their stipulated construction are as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Stipulated Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;cut-on filter&quot;</td>
<td>&quot;... an optical filter that substantially blocks all wavelengths shorter than the cut-on wavelength and substantially transmits all wavelengths that are longer than the cut-on wavelength. The cut-on wavelength is that wavelength in the transition zone at which the transmission is 1%.&quot;</td>
</tr>
<tr>
<td>&quot;portion&quot;</td>
<td>&quot;... part or share of something&quot;</td>
</tr>
</tbody>
</table>

Plaintiff SunTiger contends that this Court cannot apply the stipulated construction in a way that would contradict the finding of the Eastern District of Virginia that YE-82 infringed SunTiger's patents. Pl.'s Mot. at 1 ("[T]he YE-82 lens material must literally infringe whatever claim construction the Court adopts in this case."). In essence, SunTiger argues the following: (1) the parties have stipulated to the prior construction, (2) the decision in the prior suit does not bind this Court, but (3) any ruling that this Court issues must not be inconsistent with the fact that YE-82 was found to infringe its patents.

I disagree with this assessment. My decision is not foreordained by the result in SunTiger, Inc. v. Scientific Research Funding Group. SunTiger attempts to elevate the prior claim construction to the level of a decision. Despite the parties' agreement that the prior claim construction would be binding, that prior court's decision applying its own construction is only persuasive. Although the parties have agreed to be bound to the use of the prior construction, they have not agreed that this Court's application of that construction must be consistent with prior decisions involving a different defendant and different lenses. Indeed, were consistency with prior results necessary, that would be tantamount to an improper form of collateral estoppel against a current party, i.e., Sunglass Products, which was not a party (nor a party in privity) to SunTiger v. Scientific Research Funding Group. Cf. MCA Records, Inc. v. Charly Records, Ltd., 865 F.Supp. 649, 654 (C.D. Cal.
1994) ("[D]ue process requires that the party to be estopped must have had an identity or community of interest with, and adequate representation by, the losing party in the first action as well as that the circumstances must have been such that the party to be estopped should reasonably have expected to be bound by the prior adjudication.").

C

The final claim interpretation issue in this case concerns the claimed term "cyclic redundancy checker." On appeal, Oak contends that the term simply refers to "any circuitry that performs a cyclic redundancy check." Intervenors align themselves with the Commission's interpretation: "The cyclic redundancy checker is hardware, commonly available in June 1994, that performs the division of a CRC generator binary polynomial into a 16,000-bit EDC code word to produce a CRC remainder."

The '715 patent document does not provide much guidance on the meaning of "cyclic redundancy checker," and only states that "these ECC and EDC-CRC circuits are commonly available as hardware used in many other applications." '715 patent, col. 6, ll. 41-43. However, based on the correct interpretation of "said assembled data" and "after," we know that only those "cyclic redundancy checkers" which operate on an entire Sector of data once the Sector of data has been processed by the "error correction circuitry" are included within the scope of the asserted claims.

Our review of the record indicates that several relevant facts are undisputed. First, there is no dispute that the common hardware implementation of a "cyclic redundancy checker" as of 1994 was a structure called a "linear feedback shift register," which was well known to ordinarily skilled artisans. Also, it is undisputed that as of 1994, certain "special case" variations of cyclic redundancy check operations were known in the art, which did not use the common linear feedback shift register. However, there is no evidence in the record that any of these alternative cyclic redundancy check operations were ever implemented in hardware. Moreover, as the Commission correctly pointed out, even the references relied upon by Oak to demonstrate the existence of these alternative embodiments explicitly admit that the "normal" way of performing a cyclic redundancy check operation is by using a linear feedback shift register. 5

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Most importantly, the definition of "cyclic redundancy checker" in this case is actually undisputed. The parties agree that the correct definition is set forth in the 1976 edition of the Encyclopedia of Computer Science:

> [In cyclic redundancy checking], all the characters in a message block are treated as a serial string of bits representing a binary number. This number is then divided modulo 2 by a predetermined binary number and the remainder of this division is appended to the block of characters as a cyclic redundancy check (CRC) character.

Oak attacks this reference on the basis that it illustrates a linear feedback shift register structure as the preferred embodiment of performing a cyclic redundancy check operation. However, Oak explicitly agrees with the Encyclopedia's mathematical definition. The Commission's claim interpretation of "cyclic redundancy checker" is consistent with this definition, and we therefore affirm it.

We also note once again that--in this case--not every structure that literally fits the definition of "cyclic redundancy checker" set forth in the Encyclopedia is covered by the claim. Only those cyclic redundancy checkers which meet the additional interactive limitations explicitly imposed by the claim language are within the properly construed scope of the claim. Specifically, the only cyclic redundancy checkers covered by the claim are those which operate on "said assembled data"
(i.e., on a Sector's worth of data) "after" all such data has been processed by the "error correction circuitry," according to the manner in which we construe those terms herein.

Oak's broad interpretation that a cyclic redundancy checker is any circuitry that performs a cyclic redundancy check must be rejected. As we have already discussed, the claim language itself imposes significant restrictions on the "cyclic redundancy checker." Specifically, due to the "said assembled data" and "after" limitations in the claim which we have already resolved in favor of Intervenors and the Commission, the only cyclic redundancy checkers which can possibly be covered by the claim language—as a matter of simple logic—are those which operate on an entire Sector of data after the Sector of data has already been processed by error correction circuitry.

A. 2D documentation package (Claims 1 and 11)

HP contends that the term means "software that can produce 2D representations of 3D objects." Intergraph states that the term means "a software package that enables a user to add annotations and/or dimensions to a 2D drawing, thereby quantifying the 2D representations."

HP bases its proposed construction on the text of the claims and specification of the patent. Specifically, HP directs the Court to language in the specification that states that a 2D documentation package "provides two dimensional (2D) representations of objects which are projections of object features onto a viewing plane." '241 patent, col. 3:65-67. It is this definition that HP primarily relies upon for its proposed construction.

Intergraph argues that there is nothing in the '241 patent or in the prosecution history that gives the term "2D documentation package" a precise meaning. Intergraph further argues that the plain language of claims 1 and 11 make clear that the 2D documentation package is a separate package distinct from the solid modeler. In order to defend its proposed construction, Intergraph directs the Court to language in the specification that states as follows: "The 2D documentation package typically contains a group of tools to both annotate a 2D drawing and to quantify different aspects of the planar projections used to depict an object . . ." '241 patent, col. 2:4-8.

HP counters that the specification provides that the 2D documentation package may "typically" provide such functions as annotation, but such functions are not required in every instance.

In essence, the parties' fundamental disagreement revolves around whether the 2D documentation package is a separate "package" from the 3D objects being modeled. HP's proposed definition clearly attempts to blur the line between the 3D object (solid model) and the 2D documentation package, and could easily lead a person to believe that the 2D documentation package is the actual software that produces the 2D representation of 3D objects. But the patent claims (1, 11) make clear that it is the "automated re-layout process," not the "2D documentation package," that produces the 2D representation of 3D objects. 1 Hence, HP's proposed construction is overly broad.

1 "The process of passing the 3D model features into the 2D documentation package will be referred to herein as 'laying out' the solid model or the 'layout process.'" '241 patent, col. 2:1-3.

Intergraph's proposed construction is also significantly flawed. The specification states that "[t]he 2D documentation package typically contains a group of tools to both annotate a 2D drawing and to quantify different aspects of the planar projections used to depict an object . . ." '241 patent, col. 2:4-8 (emphasis added). The use of the word "typically" is important, and leads to Court to conclude that the 2D documentation package does not necessarily have to include dimensioning or annotation features. Furthermore, it is important to note that first four claims of the patent do not mention dimensions or annotations. Accordingly, Intergraph has not persuaded the Court that the 2D documentation package must be a separate software program distinct from the solid modeler and the re-layout process.
Given these considerations, the clearest reading of "2D documentation package" is software that operates on a two-dimensional representation of a 3D object, and may support dimensioning, text, and other annotation features.

D. 2D representation (Claims 1, 2, 4, 5, 11, 12, 14, 15)

HP contends that the term means "a projection of one or more features of a 3D model onto a viewing plane." Intergraph states that the term means "the 2D geometric data which consists of 2D coordinates that are projections of features of a 3D model onto a viewing plane."

To support its proposed construction, HP relies upon the definition of "2D representation" provided in claim 1 of the patent - "projections of features of said objects onto a viewing plane." A similar definition is found in the patent specification. See '241 patent, col. 1:25-27 ("Two dimensional (2D) representations of objects are projections of object features onto a viewing plane, typically embodied in 2D drawings.").

Intergraph's proposed construction also relies heavily upon language in the specification. Specifically, Intergraph notes that the specification states that "[i]n addition to geometric elements, the 2D drawings may also contain text, dimensions and other supporting information[]." '241 Patent, col. 1:27-29. Intergraph relies upon this language to support its conclusion that the inventors of the '241 patent explicitly defined two-dimensional representations as including geometric data, and hence the inclusion in its proposed construction of the term "2D coordinates." Interestingly, HP reads this identical language to mean only that 2D drawings may contain a number of items including "geometric elements," "text," and "dimensions."

In essence, the disagreement between the parties becomes an issue of parsing the relevant sentence. See '241 patent, col. 1-27:29. After evaluating each parties interpretation of the sentence, the Court concludes Intergraph's interpretation is more reasonable and is more consistent with specification language generally. Accordingly, "geometric elements" must be included in the Court's construction of 2D representation. However, Intergraph has failed to persuade the Court that the 2D geometric data must be expressed using 2D coordinates. The specification does not support such a limiting definition. Therefore, the Court construes "2D representation" as the 2D geometric data that are projections of one or more features of a 3D model onto a viewing plane.

9. "DC voltage supply"

Defendants contend that "DC voltage supply" is the "external supply voltage V[dd]." MOSAID counters by arguing that Defendants' construction is far too limited because nothing in the '620 patent requires that it be limited to an external supply voltage or to the voltage V[dd].

The plain language of the claim term must be considered in the context of the claim that it arises. Claim 1 of the '620 patent is representative of the use of that term and states:

A random access memory comprising:

DC voltage supply providing plural voltage levels;

a boosting capacitor having first and second terminals;

switching circuit including a first switch between one level of the voltage supply and the first terminal of the boosting capacitor and a second switch between the first terminal of the boosting capacitor and a capacitive load, the first and second switches being driven by clock signals, the switching circuit alternately connecting the first terminal of the boosting

- 1527 -
a feedback loop responsive to the boosted voltage level to control the switching circuit to regulate the boosted voltage to a substantially static value greater in magnitude than the voltage levels of the DC voltage supply and of a correct level required to turn on a selected memory cell access transistor; and

a decoder circuit supplying the regulated boosted voltage to a word line and the gate of the memory cell access transistor to store a voltage on a storage capacitor of the memory. '620 patent, claim 1.

Defendants do not dispute that this plain language is not limited to an external voltage or to a voltage \( V_{dd} \). Instead, they assert that the ordinary meaning of "DC voltage supply" supports their construction.

Defendants provide dictionary definitions for the phrase "supply voltage." MOSAID contends that these definitions are inapt because "voltage supply" and "supply voltage" are two separate and distinct concepts in the art of DRAM chips. However, as Defendants point out, the '620 specification uses the terms interchangeably, see '620 patent, col. 1, 11. 27-31; col. 1, 1. 63 - col. 2, 1. 2; col. 3, 11. 49-53; col. 5, 11. 23-25; col. 5, 11. 62-64, and thus the Court will consider these definitions as informative of the ordinary meaning of the phrase "DC voltage supply."

The first definition of "supply voltage" is "the voltage, usually direct, applied by an external source to the circuit of an electrode." IEEE Standard Dict. of Electrical and Electronics Terms 968 (4th ed. 1988). The dictionary definition for "direct current (dc) supply voltage" is "the mean value of the direct voltage between the input terminals, taken over one period of the ripple voltage appearing between the input terminals." Id. at 270. In order to further understand that definition, Defendants assert that one of skill would look to the definition of the word "terminal" set forth in that dictionary, which is defined as "an externally available point of connection to one or more electrodes or elements within the device." Id. at 997. Thus, argue Defendants, the ordinary meaning of "direct current (dc) supply voltage" would inform one that it is referring to the direct voltage applied to the externally available points of connection.

Defendants then seize on the word external in the "supply voltage" and "direct current (dc) supply voltage" definitions, and argue that it means "external to the DRAM chip." However, those definitions are not that restrictive. "External" in those definitions could mean external to a circuit, e.g., pass transistor 14A, not necessarily external to the entire DRAM chip. Nothing in those definitions requires a supply voltage to be external to the DRAM chip. Thus, the Court gives the ordinary meaning of "DC voltage supply" its full range and finds that it includes both internal and external voltages.

Defendants argue that the patentees considered "DC voltage supply" to be synonymous with \( V_{dd} \). As proof, Defendants cite to the prosecution history of the '620 patent where the patentees used the phrases "the main DC supply \( V_{dd} \)" and "the DC voltage supply \( (V_{dd}) \)." Appl. No. 09/483,626, 10/31/00 Response to PTO Action at p. 4. However, those phrases are not indicative of a clear disavowal of scope for "DC voltage supply." Instead, they were used when discussing the embodiment set forth in Figure 3 of the Foss patents. Id. at 3-4. As a result, they simply show that in Figure 3 of the patent, the "DC voltage supply" is equal to \( V_{dd} \).

Further, nothing in the ordinary meaning or intrinsic evidence requires that "DC voltage supply" be limited to \( V_{dd} \) voltage levels. The plain meaning of the claims suggests that the "DC voltage supply" may provide "plural voltage levels." '620 patent, claim 1. Although this may include \( V_{dd} \) voltage levels, the plain meaning does not require that it be limited to \( V_{dd} \). Indeed, if the patentees wanted to limit "DC voltage supply" to \( V_{dd} \), they could have simply used the term \( V_{dd} \). But the patentees purposefully used the term "DC voltage supply," and absent some clear indication that it was meant to be limited to \( V_{dd} \), the Court will not find it so limited.

Accordingly, the plain and ordinary meaning of the term "DC voltage supply" is "a supply that provides two or more substantially constant output voltages." 21

--- Footnotes ---

21 The parties agree that the term "voltage supply" (‘620 patent) is related to "DC voltage supply" and thus should be resolved in an identical manner. Accordingly, "voltage supply" means "a supply that provides two or more substantially..."
constant output voltages.

7. "DNIS" and "called number identification data"

The next terms the Court must construe are "DNIS" and "called number identification data." These terms appear in many of the Analysis Control System claims, including Claim 104 of the '707 patent which reads "a system according to claim 96 for use with a communication facility having a capability (DNIS) to provide called number identification data to identify a called number from a plurality of different numbers for calling," 21 Claim 192 of the '707 patent which reads "an analysis control system according to claim 183, wherein said communication facility automatically provides called number identification data (DNIS) to identify a select called number from a plurality of called numbers," and Claim 65 of the '863 patent which reads "an interface structure . . . including means to automatically receive call number identification signals (DNIS) to identify a select format from a plurality of formats." 22

21 This language is found in Claim 103 of the '707 patent, upon which Claim 104 depends.

22 The terms "DNIS" and "called number identification data" appear in claims other than the Analysis Control System claims; the parties agree and the Court concludes that the terms have a uniform meaning across all of the claims at issue.

The parties agree that the terms "DNIS" and "called number identification data" have the same meaning and are used interchangeably in the patents. The plaintiffs contend that the terms mean "a signal representative of the number called." The defendants argue that DNIS or called number identification data must represent the full dialed number, which is seven or ten digits. The defendants also contend that DNIS or called number identification data cannot be internal routing numbers or vector directory numbers; because the claims indicate that the communication facility provides DNIS or called number identification data to the interface and the interface receives DNIS or called number identification data from the communication facility, the defendants argue that DNIS or called number identification data cannot be any signal sent internally in the communication facility.

The Court concludes that the terms "DNIS," "called number identification data," and like terms have the same meaning and are used interchangeably in the patents. The plain import of these phrases is a signal or data that identifies the number that has been called. Thus, the language of the claims does not support the defendants' argument that "DNIS" or "called number identification data" must be the full seven or ten digit dialed number. The claim language does not support the defendants' argument that "DNIS" or "called number identification data" cannot include internal routing numbers within the telephone network; indeed, such numbers are neither mentioned in nor relevant to the Court's construction of the claims at all.

The passages of the specifications to which the defendants point do not support the limited construction proposed by the defendants either. In Column 12, lines 2 through 6 of the '707 patent, Katz describes one of the structural elements that have reoccurring significance in his inventions as "utilizing the called number to select a specific operating format." The defendants emphasize that Katz lists a ten or seven digit number as an example of the called number in the specifications; in Column 6, lines 41-45 of the '707 patent, Katz explains that "receiving the call signal, the automatic call distributor AC1 associates the called number ((213) 627-3333, rendered available using standard telephone DNIS techniques) through the interface 20 and the switch 21 to attain connection with the specific processor . . . ." However, the mere reference to "called number" does not restrict "called number identification data" to a certain number of digits, nor is there reason to restrict the terms "DNIS" and "called number identification data" to the examples provided by Katz in the specifications.
Further, in Column 4, lines 62 through 64 of the '707 patent, Katz stated that "generally, DNIS capability is a function of the communication facility C (composite telephone system) to provide called terminal digital data indicating the called number." "Data indicating the called number" undermines the defendants' contention that the data must be the full dialed number. Similarly, in Column 10, lines 39 through 42 of the '707 patent, Katz stated that "note that the communication facility C provides the dialed number ((213) 627-4444) to the processing system P1 through well known telephonic equipment DNIS." These passages confirm that DNIS or called number identification data must only be a signal that identifies the called number and need not be only the seven or ten digit number.

The prosecution history cited by the defendants does not alter the meaning of the terms conveyed by the claim language and specifications. The first set of statements by Katz in the prosecution history, the defendants argue, indicates that DNIS or called number identification data must be the full dialed number. In an Information Disclosure Statement dated September 20, 1994 submitted during the prosecution of the '285 patent, Katz attempted to distinguish his claims from a group of patents and other references. (Ex. 50). Katz described the '012 patent to Matthews et al. as a "system identified as Direct Inward Dialing or 'DID,' which involves the capability of utilizing the last three or four digits of a called number for routing to a desired recipient's telephone" and distinguished the system as "quite different from the combinations set forth in the claims in that, neither DNIS signals were utilized nor were formats selected. Additionally the system was void of either qualification or operator control. . . . " 23

Similarly, in a Supplemental Amendment dated March 14, 1995 during the prosecution of the '734 application, Katz also distinguished the '906 patent to Matthews on the basis that the Matthews system "utilizes so called 'DID' signals for accessing an individual program . . . . However, again, the structure and operation is distinct from Applicant's techniques utilizing DNIS for format selection and further involving testing." (Ex. 61).

It is unclear from these two statements however, whether Katz was basing his distinction on the difference between the number of digits or content of a DID signal versus a DNIS or caller number identification data signal, or if he was basing his distinction on the different functions that those signals performed. What is clear is that Katz did not explicitly state that DNIS or called number identification must include all of the digits of the number dialed.

The second set of statements by Katz in the prosecution history, the defendants argue, indicate that DNIS or called number identification data cannot be internal routing numbers in the telephone network. In the September 20, 1994 Information Disclosure Statement, Katz described the '682 patent to Vij et al. as "another utilization of 'DID' operation to route calls. Again, the operation is quite distinct from DNIS operation and is further distinguished from the claims herein on the basis of testing, computer interface and so on." 24 (Ex. 50). In the same Information Disclosure Statement, Katz described the '500 patent to Binkerd et al. as "another alternative for routing calls utilizing inputs by a caller. Again the system is quite distinct from the utilization of DNIS capability." (Ex. 50). During the prosecution history of the '075 patent in the Preliminary Amendment dated July 17, 1990, Katz stated that "recognizing that the Riskin patent discloses the utilization of ANI and DNIS signals to accomplish telephone routing, it is respectfully submitted that applicant's system involves entirely different philosophical considerations and structure. The provision of an interface system utilizing these signals, not only to select an operating format but further to accomplish associative data, is submitted to involve a patentable distinction." (Ex. 40). In an Amendment dated August 31, 1995 during the prosecution of the '707 patent, Katz attempted to distinguish the '336 patent to DeBruyn for an international lottery system on the basis that the system indicated direction or routing to different processors for individual language operation in response to different dialed numbers, but "no suggestion of DNIS appears nor is the system otherwise pertinent." (Ex. 51).

24 Katz made an almost identical statement regarding the Vij patent to the PTO in the prosecution of the '734 patent. (Ex. 61).
These statements indicate that Katz distinguished his inventions from other patents on the basis of the comparative functions of the systems; the systems in the other patents use signals to route telephone calls, not select a format from a group of formats or to store data associated with those signals. However, Katz never informed the PTO that the same numbers that other systems used to route calls could not be used to identify the called number and select a format. In short, it is not clear from Katz's statements, contrary to the defendants' contention, that "internal routing numbers," to the extent they can identify the called number, could not be included in the meaning of called number identification data or DNIS, as used in the Katz patents.

Based on the foregoing, the Court concludes that the terms "DNIS" and "called number identification data" are synonymous and mean: a signal or data that identifies the number called.

A.1.c. "digital signals including DNIS"

Verizon alleges that "digital signals including DNIS" should be interpreted to mean "signals or data that indicates the number called." Verizon Brief at 17. Katz disagrees with the term "indicate" in Verizon's interpretation, preferring use of "identify."

The term "digital signals including DNIS" means digital signals or data that identify the number called. 4 DNIS appears to be a commonly understood acronym in the art for Dialed Number Identification Service, a service that identifies a dialed number. See Hopenfeld 1/31/03 Decl. Ex. B. The passages in the specification cited by Verizon do not compel adoption of its asserted interpretation. Moreover, the description in the 734 patent of both DNIS and ANI 5 technologies as "indicating" a dialed and calling number, respectively, suggests that Katz used the term "indicate" in a manner synonymously with "identify." See 734 patent, Col. 57-62 ("For example, the so-called "ANI" telephone equipment provides digital signals indicating a caller's telephone number. Equipment designated "DNIS" is similarly available to indicate the called number. Thus, digital signals may be provided telephonically to a system associated with individual calling terminals as for identification or other use.") (emphasis added).

4 Although the parties appeared to agree at the Claims Construction Hearing that "indicate" and "identify" have essentially the same meaning, the Court adopts Katz's asserted interpretation for purposes of ensuring clarity to potential jurors. 5 The parties do not dispute that ANI signals identify calling numbers.
the '301 Family specification's reference to the grouping of individual DS0s into an "Nx64 call", with the "N" apparently referring to the number of individual DS0s and the "64" referring to the bit rate for each DS0. ('301 Family at 8:54-58.) The problem with Big River's argument, however, is that the cited references may define "DS0" as a 64-kilobit-per-second signal, but they do not define a "DS0 connection." The ordinary meaning of "DS0 connection" would be a channel using DS0 signals, as the Court instructed the jury in Vonage. Big River has not provided evidence that a "DS0 connection," as the term is used in the patent claims, must relate to the use of a single DS0 signal, so that the bit rate for the entire connection is 64 kilobits per second. The Court therefore rejects Big River's proposed construction.

Big River has not challenged the Court's prior construction in any other way. Accordingly, the Court again construes "DS0 connection" to mean a channel over which DS0 communication signals (a term of art meaning Digital Signal Level 0) are transmitted or received.

F.

The final area of discussion focuses on the acronym "DVD." The dispute centers on whether the acronym should read "digital versatile disc" or "digital video disk." Mediamatics' argument relies on the association of "digital video disk" and the acronym in the specification that explains the invention. It also refers to the use of DVD in the claims. The embodiment as well as the prior art, refer to DVD as "[A] digital video disk (DVD) which has more than two data layers …." Thus, Mediamatics argues that based on the specification and manner of use in the claims, DVD should be defined as, "[A] digital video disk conforming to the standardized DVD format."

LaserDynamics refutes this definition as a limitation that it asserts is not originated in the claims of the '743 Patent. Relying on the Modern Dictionary of Electronics, 7th Ed., LaserDynamics contends that "DVD" means '[A] high capacity optical storage medium with improved capacity and bandwidth over compact disks."

Mediamatics is correct that in columns one, two and three of the specification references to DVD are limited to a digital video disk. However, this limitation does not dictate a limitation in the invention. See Tate Access Floors, Inc. v. Maxcess Tech., Inc., 222 F.3d 958, 966 (Fed. Cir. 2000). The specification in the patent-in-suite describes how the invention may be used on a digital video disk. The Court notes that in reviewing the claims, only the dependent claims 2, 4, 6, 8, 10 and 12 refer to DVD as meaning digital video disk. However, the invention also includes independent claims 1, 3, 5, 7, 9 and 11 and they refer to the invention as a "method usable with a multilayered optical disk, comprising …." Thus, the invention does not adopt the technology [invention] stated in the independent claims and chooses the digital video disk as the medium through which it is expressed. Thus, while it may be argued that the dependent claims are limited to digital video disk, it is not so with the independent claims. In fact, the Abstract describes the invention as "[A] data recording and reproducing method for an optical disk data storage system to record data compressed at different data compression rate. …" Thus, the invention is not limited to an expression on a digital video disk, but includes the digital video disk as an "optical storage medium" to express the invention in the dependent claims. The ordinary use and meaning of the acronym is "digital versatile disc" and the Court adopts this use and meaning.

Preamble to '257 and '722 Asserted Claims

The parties dispute the construction of the preamble to '257 patent claims 17, 41, 43 and '722 patent claims 1, 3, 4, 6, and 7. The first asserted claim in which this preamble language appears is Claim 17, providing "a method of scheduling customer access to data from a plurality of data sources, comprising the steps of]." Def. Mem. Ex. 1, Col. 55. The key phrases in dispute are "scheduling customer access" and "data from a plurality of data sources."

Amazon asserts "scheduling customer access" is a claim limitation that means "assigning the days and time slots when a customer will be given access." Amazon directs the court to a broadcasting definition and the patent specification.
According to Amazon, "scheduling" means "to assign a start time and duration to a broadcast program or data element." Def. Mem. at 11-12 (citing ATSC Standard: Delivery of IP Multicast Sessions over ATSC Data Broadcast (Advanced Television Systems Committee, Doc. A/92, 1/31/2002)). Amazon contends the patent specification confirms the applicability of this definition: "The introduction of time dimensions makes possible the scheduling of video programs, i.e., the assignment of programs to days and to time slots in accordance with each customer profile." Def. Mem. at Ex. 1, Col. 22:10-13. Pinpoint disagrees and argues this term is not a claim limitation subject to claim construction. Alternatively, Pinpoint advances a broader definition: "selecting and/or ordering . . . the information that will be provided to the customer." Pinpoint's alternative construction relies on the IBM Dictionary of Computing and the Merriam-Webster Dictionary, which provide respective definitions of "scheduling" as "to select jobs or tasks that are to be dispatched," and "to appoint, assign, or designate for a fixed time." Pl. Opp. Mem. at 10.

The Federal Circuit instructs that the claim preamble is deemed part of the claim that may be interpreted if it "recites limitations of the claim" or is "necessary to give life, meaning, and vitality" to the claim. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1309 (Fed. Cir. 1999). Contrary to Pinpoint's position, the preamble should not be ignored; it is vital to the meaning of the claim. At a minimum, the phrase "scheduling customer access" instructs what is to be done with the "data from a plurality of data sources," i.e., that data is scheduled for a customer's access. In the absence of the preamble, this is unclear. Instead, the claim language describes the customer profiles, the content profiles, and the method by which customer profiles are updated to better reflect the content profiles of the monitored data sources without reference to the requisite scheduling.

However, Amazon's proposed construction of "assigning the days and time slots when a customer will be given access to the data" must be rejected. Neither the claim language nor the specification are this restrictive. While Amazon is correct that the specification discusses "scheduling" as "the assignment of programs to days and to time slots in accordance with each customer profile," this discussion solely refers to the preferred embodiment of the patented invention. Amazon cannot use a preferred embodiment to limit the claim language to the field of broadcasting. Arlington Industries, Inc. v. Bridgeport Fittings, Inc., 345 F.3d 1318, 1327 (Fed. Cir. 2003). Neither '257 patent claims 17, 41, 43 nor '722 patent claims 1, 3, 4, 6, and 7 appear limited to broadcast scheduling embodiments. These claims use broad terms such as "data," "data source," and "data objects." Compare Def. Mem. Ex. 1 at Col. 55, Claim 17 ("a method for scheduling customer access to data from a plurality of data sources") with Col. 55, Claim 18 ("a method of scheduling customer access to video programs"), and Col. 61, Claim 48 ("a system as in claim 45, further comprising means for transmitting said content profiles to each customer along with electronic program guide data for upcoming television viewing periods"). In this regard, the patent specification's discussion of non-broadcasting embodiments is instructive. See, e.g., Def. Mem. Ex. 1 at Col. 1 ("The present invention relates to a system and method for controlling . . . customer access to data") (emphasis added); Col. 4 ("In accordance with the invention, a method of scheduling customer access to data from a plurality of data sources is provided. . . . The technique of the invention may be applied to match customer profiles for such disparate uses as computerized text retrieval, music and music video selection, home shopping selections, infomercials, and the like") (emphasis added); Col. 50 ("a music or book kiosk to aid in the selection of music or books"). Each of these non-broadcasting embodiments suggest "scheduling" includes broad "ordering" of customer access to data, not just narrow "assigning" of "days and time slots." Accordingly, the court construes "scheduling customer access" to mean "selecting and/or ordering . . . the information that will be provided to the customer."

--- Footnotes ---

3 In its reply, Amazon summarily argues that another patent, U.S. Pat. No. 6,020,883 (‘883), covered the kiosk embodiment, and that neither ‘257 nor ‘722 patents should be construed as covering the kiosk. This argument must be rejected. Amazon's motion for claim construction fails to include a complete copy of the '883 patent for the court's consideration. See Def. Reply. at 1 (no attachment included).

--- End Footnotes ---
In contrast, Pinpoint broadly defines "data" as "information" and "data source" as "a source of data." Pl. Opp. Mem. at 11 (quoting IBM Dictionary of Computing at 164 as defining "data" as a "representation of facts or instructions in a form suitable for communication, interpretation, or processing by human or automatic means. Data includes constants, variables, arrays, and character strings" or "information"). As Pinpoint suggests, a broad definition of "data" and "data source," with the latter including examples such as Six Feet Under or Star Trek, finds support in the claim language and patent specification. None of the asserted claims of the '257 patent [claims 17, 41, and 43] discuss "equipment" or "a cable or satellite channel." Rather, the claim language instructs that specific content profiles will be created for each data source and/or that specific data sources will be monitored to determine what was accessed by the customer. See Def. Mem. at Ex. 1, Col. 55, Claim 17 ("creating content profiles for each data source"); Claim 41 ("monitoring which data sources are actually accessed by each customer"); Claim 43 ("creating content profiles for each data source"). Amazon's contention is untenable that a program, such as Star Trek, is the "data" for which a content profile is created based on its time slot position on a "data source," such as Sci-Fi Channel. The plain language requires "creating content profiles for each data source of said data," not creating content profiles for the data on each data source." See Def. Mem. at Ex. 1, Col. 55, Claim 17. Nor does Claim 43 doom Pinpoint's proposed construction; this particular claim must contemplate multiple programs. Otherwise, neither Amazon's nor Pinpoint's proposed construction is correct. Compare Def. Reply at 2 ("data" is a "program") with Def. Mem. Ex. 1, Col. 55, Claim 17 ("presenting said subset of data to said customer for selection") (emphasis added).

Moreover, the patent specification supports a broader construction. For example, the specification details the creation of a content profile for a program such as Star Trek - a "data source" - in which its characteristics with respect to romance, high-tech, and violence are represented. Def. Mem. at Ex. 1, Col. 21. Other examples, such as references to real estate, similarly support a broader construction of "data source." Amazon's proposed construction cannot be reconciled with the claim language or the specification. Vitronics, 90 F.3d at 1583. Accordingly, the court construes "data" to mean "information" and "data source" to mean "a source of data."

1. "data acquisition unit"

The district court construed "data acquisition unit" to mean "one structure that includes the electronic positioning device and the physiological monitor." Claim Construction Op. at 5. Paragon disagrees, having argued to the district court that "data acquisition unit" meant "an assemblage of inter-related components that unify the function of acquiring data from an electronic positioning device and a physiological monitor." Id. at 2. On appeal, Paragon offers a slightly modified proposed construction: "an assemblage of inter-related components that perform the function of acquiring data from an electronic positioning device and a physiological monitor." Reply Br. of Plaintiff-Appellant Paragon Solutions, LLC at 29. Timex argues that the district court's construction was correct. The dispute between the parties thus reduces to the question of whether the data acquisition unit must be a single structure, or whether it can be made up of physically separate structures.

a. Claim Language

Each party argues that the claim language supports its construction. Timex argues that the claims "are written in structural terms," specifying a data acquisition unit that is "separate from" the display unit. Br. of Appellee Timex Corp. at 31. Paragon argues that claim 7, which depends from claim 6 and, in turn, claim 1, shows that the data acquisition unit may be made up of separate structures. Claim 6 recites "[t]he system of claim 1, wherein said electronic positioning device comprises a GPS device, and further wherein said data acquisition unit further comprises a support member, and said GPS device and said physiological monitor are provided on said support member." '759 patent col.28 ll.30-34. Thus, in claim 6, the "data acquisition unit" comprises a support member for both a GPS device (the electronic positioning device) and a physiological monitor. Claim 7 recites "[t]he system of claim 6, wherein said GPS device and said physiological monitor are removable.
secured to said support member." Id. col.28 ll.35-37 (emphasis added). Because the GPS device and the physiological monitor are each "removably secured" to the support member, it stands to reason that they may be separate structures that are separately removable from the support member. Thus, claim 7's recitation of a "removably secured" electronic positioning device and the physiological monitor suggests that the data acquisition unit may be made up of separate physical structures.

Timex next argues that the recitation in claim 29 that "said electronic positioning device is provided as part of a data acquisition unit" suggests that the data acquisition unit must be a single structure that encompasses the electronic positioning device. '759 patent col.30 ll.15-17 (emphasis added). Paragon counters by pointing out that, although claim 29 recites that the electronic positioning system is part of the data acquisition unit, by reciting "a physiological monitor" in a separate limitation, with no mention of the "data acquisition unit," it is apparent that the data acquisition unit may be separate from and need not include the physiological monitor. Contrary to Timex's argument, it is our view that the recitation of a "data acquisition unit" in claim 29 casts doubt on--rather than supports--the district court's construction of data acquisition unit as "one structure that includes the electronic positioning device and the physiological monitor." Claim Construction Op. at 5 (emphasis added).

From the foregoing, it can be appreciated that while the claim term "unit" might suggest that the data acquisition unit is a single structure, the separate recitation of a physiological monitor in claim 29 and the recitation of "removably secured" elements in claim 7 can be read to suggest persuasively that the data acquisition unit may be multiple structures. We turn next to the specification. See Phillips, 415 F.3d at 1315 ("The claims, of course, do not stand alone. Rather, they are part of a fully integrated written instrument, consisting principally of a specification that concludes with the claims. For that reason, claims must be read in view of the specification, of which they are a part.") (citations and internal quotation marks omitted).

b. Specification

In the specification, Paragon's proposed construction finds strong support in one key sentence:

"The data acquisition component of a monitoring system according to the present invention may even comprise multiple structures which are physically separate from each other."

'759 patent col.8 ll.36-39. As discussed above, the '759 patent refers interchangeably to the "data acquisition component" and the "data acquisition unit." See id. col.3 ll.15-16.

The drawings of the '759 patent--in particular figure 1 and its associated text--are also instructive. Figure 1, reproduced supra, depicts one embodiment of the exercise monitoring system. Id. col.7 ll.30-32. In that figure, only three structures are shown and described: an electronic positioning device, a physiological monitor, and a display unit. Id. fig.1. Each structure is shown separate from each of the other structures. Id. Figure 1 is consistent with and supports the conclusion that the electronic positioning device and the physiological monitor may be separate structures. Timex seeks to avoid the implications of figure 1 by arguing that the specification discloses two separate embodiments, only one of which is claimed. Specifically, Timex concedes that, in the configuration depicted in figures 1 and 2, "the electronic positioning device is separate from the physiological monitor." Br. of Appellee Timex Corp. at 32. However, according to Timex, figures 3, 4, and 5 introduce a single-structure data acquisition unit, and it is only this second embodiment--with a data acquisition unit--that is claimed. Id. But in the section that appears between the discussion of figures 2 and 3, the specification makes clear that the invention is not so limited. See '759 patent col.8 ll.6-8 ("An exercise monitoring system according to the present invention may comprise a single structure, or may be subdivided into one or more component structures."); id. col.8 ll.36-40 ("[T]he data acquisition component of a monitoring system according to the present invention may even comprise multiple structures which are physically separate from each other."). In light of this language, we disagree with Timex that the structural configuration depicted in figure 1 is nothing more than an unclaimed embodiment.

c. Prosecution History

The district court did not suggest that either the claim language or the specification compelled a construction of "data acquisition unit" that was limited to a single structure. Rather, the district court reasoned that the applicants' statements during prosecution in response to the Patent Office's "notification of problems due to the preexisting Root patent" resulted in a clear and unmistakable disavowal of "the concept of an assemblage of inter-related parts and embrace[d] a single structure
unit concept." Claim Construction Op. at 5. Specifically, the district court relied on the applicants' amendment of claim 1 "to require that the electronic positioning device and physiological monitor are provided as a 'data acquisition unit,'" and on the applicants' argument that the amendment overcame Root "by separating the data acquisition unit from the display unit which in Root are apparently provided in a single unit." Id. at 4.

We cannot agree with the district court's interpretation of the prosecution history. The examiner rejected claim 1 as anticipated by Root because Root disclosed an electronic positioning device, a physiological monitor, and a display unit. Doc. 21, Ex. 2-N (J.A. 295). Root disclosed all three elements in a single structure. See, e.g., Root fig.6. To overcome Root, the applicants amended the claims to separate out the display unit from the remaining structure. The way that the applicants chose to express this separation was to characterize the electronic positioning device and the physiological monitor collectively as a "data acquisition unit," then to add the limitation requiring that the display unit be separate from the data acquisition unit. See '759 patent col.27 ll.66-67, col.28 ll.5-6; Doc. 21, Ex. 2-P (J.A. 308) ("[C]laim 1 has been amended to require that the electronic positioning device and physiological monitor are provided as a data acquisition unit . . . . Claim 1 has also been amended to require that the display unit is separate from the data acquisition unit . . . ."). The applicants argued that this amendment overcame Root, because "the monitor described in Root is a unitary structure in which the data acquisition unit and the display screen are provided as a single unit." Doc. 21, Ex. 2-P (J.A. 308).

"[A] patentee may limit the meaning of a claim term by making a clear and unmistakable disavowal of scope during prosecution." Cohesive Techs., Inc. v. Waters Corp., 543 F.3d 1351, 1361 (Fed. Cir. 2008) (quoting Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1374 (Fed. Cir. 2008)). By amending the claims to require a separate data acquisition unit and display unit, and by remarking that this distinguished the "unitary structure" of Root, the applicants clearly and unmistakably disavowed a single structure that encompassed an electronic positioning device, a physiological monitor, and a display unit. The claimed exercise monitoring system must be at least two structures. However, there is nothing in the amendment or the applicants' comments that clearly and unmistakably disavows a monitoring system with more than two structures. Thus, there was no clear and unmistakable disavowal of a "data acquisition unit" made up of physically separate structures.

We conclude that, read in light of the specification, the claim term "data acquisition unit" is not limited to a single structure but may comprise multiple physically separate structures, and that the applicants did not make a clear and unmistakable disavowal of multiple physically separate structures during prosecution. We therefore construe "data acquisition unit" as used in the '759 patent as "a structure or set of structures that includes at least the electronic positioning device and the physiological monitor."
whether he or she would win or lose prior to playing the amusement game.

n6 The '603 patent uses the term "games," while the '082 patent uses the term "game." ('082 patent at 11:3-6; id. at 12:7-10; '603 patent at 16:2-5.)

The specification confirms this reading of the claim language. Although GameLogic is correct in pointing out that many of the embodiments of the patent talk about "decrypting and decoding" the data, (see, e.g., '082 patent at 3:20-21), the patent also offers other ways of obscuring the data to make it unrecognizable to a player. For example, in addition to describing the codes as encrypted and encoded, the specification talks about "comparing the Destiny Code to a lookup table to determine if the number is a loser or a winner and the size of the prize, if any." ('082 patent at 9:64-66.) Furthermore, contrary to GameLogic's argument that, to be unrecognizable, the code must be encrypted, the specification also states that "[i]f the player knew the procedure to decode the Destiny Code, the player would be able to determine if the Destiny Code contained a winning chance or a losing chance." (Id. at 2:64-67.) Thus, there are references in the patent to various ways of making the code unrecognizable, and there is nothing in the specification or prosecution history that indicates the patentee intended to give up any of the scope of the word "unrecognizable." I will therefore construe the phrase "data being unrecognizable to the player" to mean "the player is not able to recognize from the data whether the player wins or loses the lottery game and amusement game."
To construe the term "data block," we look first to the claim language, the written description, and the prosecution history. See Zelinski v. Brunswick Corp., 185 F.3d 1311, 1315, 51 U.S.P.Q.2D (BNA) 1590, 1592-93 (Fed. Cir. 1999). The ordinary and customary meaning of "data block" in the context of programmable machine tools is a computer data structure containing the information needed by a machine tool to perform a single machining operation. Haas contends that the ordinary meaning does not apply because the patentee gave the term "data block" a special meaning by describing the preferred embodiment in the patent as follows: "The sequence of inquiries on the CRT screen for a data block follows the sequence: data block number, machine mode, control mode, X dimension, Y dimension, Z dimension, feed rate, pack rate and tool number." 754 patent, col. 6, ll. 4-7. We find nothing in the written description, however, that indicates this is the patentee's specialized definition of "data block." Rather, the written description merely describes the preferred embodiment, and to limit "data block" to the sequence of variables disclosed would be to impermissibly read a particular embodiment into the claim. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186-87, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998).

Haas also argues that the following statement, made by the applicant during prosecution of the '754 patent, limits the meaning of the term "data block" to the specific variables and display sequence set forth in the written description: "particular attention should be paid to the term 'data block' as used in the specification and claims when considering the scope of these claims." Joint App. at 319. This statement alone cannot narrow the scope of the claims. Haas contends further that a brochure submitted to the Examiner by the applicant limits the term "data block" to the specific variables and display sequence disclosed in the written description. This argument is also without merit, for it is clear from the prosecution history that the brochure was intended only to assist the Examiner in understanding the preferred embodiment. In sum, we hold that nothing in the written description or prosecution history is sufficient to overcome the ordinary meaning and to require that the meaning of "data block" be limited to the specific variables and display sequence disclosed in the written description as the preferred embodiment.

Another issue raised by Haas is whether other statements made during the prosecution and reexamination of the '754 patent limit a "data block" to a format that in no way relies on G- and M-codes. In distinguishing over a prior art reference, the applicant stated that the claims were "intended to focus upon a novel interactive system in which the operator was sequentially asked questions and via the display the operator in response simply answered the question rather than have to worry about how to program the device." Joint App. at 319. The applicant made two more similar statements in responding to later office actions. IMS argues that these statements were intended to convey the interactive nature of creating a parts program using the claimed invention and do not disclaim the use of prior art programming languages such as G- and M-codes so long as a program is created interactively according to the claims.

During reexamination, the patentee distinguished several other prior art references by emphasizing the interactive programming technique of the invention, including the use of nested inquiries to prompt the user to enter additional information based on the user's response to a previous inquiry. No statements regarding the prior art clearly disclaim the use of G- and M-codes as Haas contends. In the last response to the PTO during reexamination, the patentee contrasted the invention with the cumbersome prior art programming process:

    The present invention utilizes an interactive display which operates in a question and answer format without resorting to the M and G codes of the machine tool. . . . The interactive processing of the data blocks enables the machine tool operator to perform the tasks of both the programmer and machinist on the shop floor.

Joint App. at 932.

We agree with IMS that this statement, taken in context, as well as the other statements made during prosecution and reexamination, do not disclaim the use of G- and M-codes in the claimed invention. The purpose of the statements was to emphasize the interactive nature of the invention as an improvement over the prior art programming method in which a user had to create a program line-by-line using only G- and M-codes. Thus, the claimed invention does not require the creation of a G- and M-code program; at the same time, however, the invention does not preclude the creation of a G- and M-code program so long as it is created using the claimed interactive inquiry process.
Haas further argues, in support of its contention that a data block cannot be stored in G- and M-code format, that the written description never mentions the use of G- and M-codes. While it is true that the embodiment disclosed in the written description does not purport to store data blocks in G- and M-code format, the use of data blocks in the invention as claimed is independent of the storage format. The claimed invention is an apparatus and method for interactively creating a program for controlling the machine tool. That program contains data blocks, each of which, according to the customary meaning of the term, includes the information needed by a machine tool to perform one machining operation. It is irrelevant to the claimed invention whether a data block is stored as a line of G- and M-code, in a binary format, or in any other format.

In sum, we conclude that the proper construction of the term "data block" is a computer data structure containing the information needed by a machine tool to perform a single machining operation. As properly construed, a "data block" is not limited to the specific set of variables and display sequence disclosed in the written description and does not preclude the use of G- and M-codes. (Transcript, pp. 12-13) Given the principles in Phillips, I find that the most accurate construction will be one that includes the insights provided by the specification and the claims themselves.

Initially, Skyline suggested that the court construe "data block" broadly to mean "a quantity, set or amount of information or data representing a portion of the terrain." The Defendants offered instead the following narrower construction, on the premise that the patentee acted as his own lexicographer with respect to this term: "an image of a terrain area that is composed of pixels, where each data block optionally also contains data associated with the image of the terrain area, such as data describing other objects that overlay the terrain; each block has one particular resolution." At the Markman hearing, however, the Defendants did not protest Skyline's critique of equating data with image, and both parties were open to the idea of data blocks meaning something like information necessary to render graphically an image of all or part of the terrain, including any additional features overlaid thereto, at a particular resolution level. The method for preparing the database in accordance with the preferred embodiment of the present invention requires a processor, referred to as a Terra Builder, to cut up images it receives into blocks. (col. 9, 1. 55) The end result is that the user's "processor renders three-dimensional terrain images responsive to the data blocks" corresponding to the requested coordinates and viewpoints on a display. (col. 6, 11. 56-57)

These excerpts from the specification demonstrate -- despite the seemingly anomalous statement that "blocks are preferably real-life images of terrain areas received from airborne or satellite cameras" (col. 8, 11. 36-37) -- that the term does not refer to the actual images of the terrain area, but to the data or information that represents sections of the terrain in the preferred embodiment. In the preferred embodiment, the blocks may "include altitude data of the terrain" and "optional objects to be overlaid on the terrain." (col. 5, 11. 38, 40-41) These objects may "include, but are not limited to, labels, annotations, lines and 3D objects." (col. 8, 11. 38-42)

Having said that, the patent specifically disclaims the idea that the data streaming methods only describe the display of images of terrain. Rather, the patent specifies that "the data streaming methods of the present invention may be used to convey large databases of data which are to be displayed graphically, such as in graphic displays of stock values." (col. 16, 11. 20-24) Consequently, I must technically construe the term "data block" broadly as a block or collection of data or digital information, but I do so only with the understanding that the terms "data block describing three-dimensional terrain" and "image block", refer to a block or collection of data or digital information that represents or describes a section of three-dimensional terrain at a particular resolution level and that includes any additional data overlaid on the digital image of the terrain, such as altitude, labels or optional objects. I construe the subsequent references to "data blocks" in Claims 1 and 12 as referring in shorthand to "data blocks describing three-dimensional terrain", as opposed to any kind of data block,
because the scope of the claimed invention is a method and apparatus for providing data blocks describing three-dimensional terrain to a renderer.

**Construction:** (data block) A block or collection of data or digital information.

### A. Data Blocks

I begin with a term found throughout the patent -- "data blocks", often referred to simply as "blocks" in the specification.

Initially, Skyline suggested that the court construe "data block" broadly to mean "a quantity, set or amount of information or data representing a portion of the terrain." The Defendants offered instead the following narrower construction, on the premise that the patentee acted as his own lexicographer with respect to this term: "an image of a terrain area that is composed of pixels, where each data block optionally also contains data associated with the image of the terrain area, such as describing other objects that overlay the terrain; each block has one particular resolution." At the Markman hearing, however, the Defendants did not protest Skyline's critique of equating data with image, and both parties were open to the idea of data blocks meaning something like information necessary to render graphically an image of all or part of the terrain, including any additional features overlaid thereto, at a particular resolution level. (Transcript, pp. 12-13) Given the principles in Phillips, I find that the most accurate construction will be one that includes the insights provided by the specification and the claims themselves.

The specification teaches that "image blocks . . . contain data representing the terrain" (col. 8, 11. 18-20) and the claims speak of "data blocks describing three-dimensional terrain" (Claim 1, col. 16, 11. 28-29; col. 4, 1. 12), such that "each terrain area is described in a plurality of blocks at different resolution levels." (col. 3, 11. 5-6) The method for preparing the database in accordance with the preferred embodiment of the present invention requires a processor, referred to as a Terra Builder, to cut up images it receives into blocks. (col. 9, 1. 55) The end result is that the user's "processor renders three-dimensional terrain images responsive to the data blocks" corresponding to the requested coordinates and viewpoints on a display. (col. 6, 11. 56-57)

These excerpts from the specification demonstrate -- despite the seemingly anomalous statement that "blocks are preferably real-life images of terrain areas received from airborne or satellite cameras" (col. 8, 11. 36-37) -- that the term does not refer to the actual images of the terrain area, but to the data or information that represents sections of the terrain in the preferred embodiment. In the preferred embodiment, the blocks may "include altitude data of the terrain" and "optional objects to be overlaid on the terrain." (col. 5, 11. 38, 40-41) These objects may "include, but are not limited to, labels, annotations, lines and 3D objects." (col. 8, 11. 38-42)

Having said that, the patent specifically disclaims the idea that the data streaming methods only describe the display of images of terrain. Rather, the patent specifies that "the data streaming methods of the present invention may be used to convey large databases of data which are to be displayed graphically, such as in graphic displays of stock values." (col. 16, 11. 20-24) Consequently, I must technically construe the term "data block" broadly as a block or collection of data or digital information, but I do so only with the understanding that the terms "data block describing three-dimensional terrain" and "image block", refer to a block or collection of data or digital information that represents or describes a section of three-dimensional terrain at a particular resolution level and that includes any additional data overlaid on the digital image of the terrain, such as altitude, labels or optional objects. I construe the subsequent references to "data blocks" in Claims 1 and 12 as referring in shorthand to "data blocks describing three-dimensional terrain", as opposed to any kind of data block, because the scope of the claimed invention is a method and apparatus for providing data blocks describing three-dimensional terrain to a renderer.

**Construction:** (data block) A block or collection of data or digital information.

**Construction:** (data block describing three-dimensional terrain) A block or collection of data or digital information that represents or describes a section of three-dimensional terrain at a particular resolution level and that includes any additional data overlaid on the digital image of the terrain, such as altitude, labels or optional objects.
B. Data Blocks Belonging to a Hierarchical Structure

The parties agree that this phrase, as used in the patent, would be understood by one of ordinary skill in the art to mean data blocks that are organized into multiple levels of resolution. Skyline, however, takes issue with the two additional limitations proposed by the Defendants: data blocks that are organized into multiple levels of resolution, whereby (1) each level contains data blocks at the same resolution, and (2) each successive level contains data blocks of a higher resolution than those in the preceding level.

First, in its submissions and at the Markman hearing, Skyline questioned whether or not the concept of hierarchy, as used in the patent, includes the idea of "directionality," that is whether each successive level contains data blocks of a higher resolution than those in the preceding level. Second, at the Markman hearing Skyline also questioned whether each level of the hierarchy must contain data blocks at the same resolution, contending that this construction could be interpreted as meaning that each data block must contain the same amount of data. Instead, Skyline prefers the less specific construction that the "data blocks are arranged into multiple levels of resolution, wherein each level of the structure contains blocks of a different resolution." For support, Skyline cites to col. 6, 11. 3-6 of the '583 patent.

The portion of the specification cited by Skyline describes how U.S. patent application Ser. No. 08/939,948 (now United States Patent No. 6,111,583 (the '583 Patent)), which is incorporated by reference, "uses a hierarchical database in which substantially each terrain area is described in a plurality of blocks at different resolution levels." The '583 Patent is relevant because "in some preferred embodiments of the present invention, the data is stored at the remote server in accordance with the hierarchical structure described in the 948 application." (col. 3, 11. 13-15) The '583 Patent describes arranging the units of data into an ordered hierarchy according to successive resolution levels.

FIGS. 3A and 3B . . ., taken together, are simplified pictorial illustrations of a data structure useful in storing a terrain image constructed and operative in accordance with a preferred embodiment of the present invention. A terrain image is typically stored as a hierarchy of one or more two-dimensional grids of one or more tiles, with each grid 24 representing the image at a given resolution. . . . Each grid has four times more detail then the grid preceding it in the hierarchy.

('583 Patent, col. 7, 11. 36-49)

The '189 Patent provides even more detail in describing its Fig. 2, "a schematic block diagram illustrating the data structure of images stored in a database . . . in accordance with a preferred embodiment of the present invention." (col. 7, 11. 27-31)

Blocks 42 are preferably stored in database 40. . . . Blocks 42 are classified in successive resolution levels 44 labeled 44A, 44B, etc., according to the height from which they view the terrain and, therefore, the level of detail which they include. A plurality of blocks 42A which belong to the lowest resolution level 44A, labeled "level 1," cover the largest area per block and therefore have the least detail per area unit. It is noted that the size of the geographical area covered by blocks 42A of "level 1" is dependent on the specific application of database 40 and may be very diverse. For example, in some flight applications, a single block 42A includes an image of the entire Planet Earth, while in an atom-simulation application, which shows the terrain of an atom, block 42A shows the entire atom. Blocks 42B of the next level 44B, labeled "level 2," preferably cover a quarter of the area of blocks 42A of "level 1". Thus, for substantially each block 42A, there exist four blocks 42B which cover the same area. In a similar manner, each successive level 44 comprises blocks 42 which cover a quarter of the area of the blocks 42 of the lower resolution level.

Four blocks 55 of a certain level 44C, which cover the same area as a block 57 of the preceding level 44B, are referred to as descendants of block 57. Conversely, block 57 is referred to herein as the parent of blocks 55. The parent block 59 of block 57 is referred to herein as an "ancestor" of blocks 55, and is said to be of a lower resolution level than its descendants. It is noted that in FIG. 2, the lower resolution levels appear higher on the page.

(col. 8, 11. 59-67; col. 9, 11. 1-21) (emphasis supplied)
From these descriptions, it is clear that the patent claims a database with a hierarchical structure in which each successive level contains data blocks of a higher resolution than those in the preceding level. While I recognize that Fig. 2 is only a schematic and level 1, level 2, level 3 etc. are just labels, it is important to include the successively ordered nature of the database in the construction of the term "hierarchical structure", even if a database might be arranged conceptually from the top down rather than from the bottom up.

As for Skyline's concern over describing the hierarchical structure with the limitation that each level contains data blocks at the same resolution, I disagree that the limitation erroneously suggests that each level has the same amount of data. As Skyline contends, the amount of data in a given resolution level depends on the image being depicted. Or as the specification explains, the "size of the geographical area covered by blocks of level 1' is dependent on the specific application of database and may be very diverse. For example, in some flight applications, a single block includes an image of the entire Planet Earth, while in an atom-simulation application, which shows the terrain of an atom, block shows the entire atom." (col. 8, 1. 67; col. 9, 11. 1-7)

Construction: (data blocks belonging to a hierarchical structure) data blocks that are organized into multiple levels of resolution, whereby each level contains data blocks at the same resolution, and each successive level contains data blocks of a higher resolution than those in the preceding level.

Plaintiff's Construction
One or more operably connected data structures and computers used for processing or transmitting data.

Defendant's Construction
This claim term is indefinite.

"If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, [the Federal Circuit has] held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." Exxon Res. & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). "A claim will be found indefinite only if it 'is insolubly ambiguous, and no narrowing construction can properly be adopted . . . ." Praxair, Inc. v. ATMI, Inc., 543 F.3d 1306, 1319 (Fed. Cir. 2008) (quoting Exxon, 265 F.3d at 1375). Thus, Defendant faces a difficult task in establishing by clear and convincing evidence that a claim term is indefinite.

The specification provides an example of a "data center," explaining that "the data center 2 preferably comprises database servers 10, web servers 12, a load balancing router 14 and a firewall 16 connected to the Internet 8." ('809 patent at 2:40-42.) The specification goes on to describe the functions of each of these components. In particular, the specification explains that (1) the firewall performs functions related to the safeguarding of data, (2) the load balancing router distributes data and tasks, (3) the web server accesses and retrieves information from the database server, and (4) the database server store information regarding venues, events, tickets, ticket status, bidders, etc. (Id.) In the Court's view, Plaintiff's proposed construction comports with this description. Accordingly, the Court will construe the term "data center" to mean, as Plaintiff contends, "[o]ne or more operably connected data structures and computers used for processing or transmitting data."

"Data changes" appears in both independent claims of the '910 patent. CashEdge asserts that the inventors have acted as their own lexicographer, and expressly defined "data changes" as meaning "data from an Internet site not matching data last accessed from an Internet site," while Yodlee contends that the term "data changes" needs no construction. The Court agrees with Yodlee; CashEdge's proposed construction does not appreciably differ from the plain and ordinary meaning of "data
"data collection application"

Claims 1, 7, and 12-15 of the '057 patent and claims 1, 4, and 10-13 of the '362 patent contain the term "data collection application." The parties agree that the term does not have a plain meaning. Typhoon defines the term as "a software application for receiving and storing data that utilizes libraries." To arrive at this definition, Typhoon relies on several phrases describing the operation of a data collection application within the specification and then reduces those descriptions to their most general form. For example, Typhoon cherry-picks general references to a data collection application's ability to collect and record data and converting them into the limitation's defining characteristic. See '057 Patent at 2:64-67 ("For data collecting and recording, the memory of the portable computer stores a data collection application . . . . ").

In fact, the patents do explain that data collection applications assist in collecting data. See id. However the description also explains that "data collection is facilitated by using displayed help fields for each question or subject, sequential and consequential libraries, and cross referencing of entered responses." '362 Patent at 3:7-10. As will be more thoroughly explained, "libraries" are generally groups "of possible responses" to questions. See id. at 3:12-17. Along these same lines, the description of the preferred embodiment details how a data collection application is formatted for "question and answer" data collection. See, e.g., id. at 12:10-14 ("The loop procedure's main function is to go to each question on the data collection screen one by one, interact with the user to get the information, validate the information, and return to the beginning of the loop or exit.").

Because the specification exclusively refers to the data collection application's ability to collect data by question and answer, Defendants urge that the term be defined as "a computer program that collects responses to a predetermined series of questions." Thus, the parties' principal dispute is whether a "data collection application" broadly "collects and stores data" or is limited by the disclosed question and answer format.

The specification provides several indications that a data collection application is limited to its disclosed "question and answer" format. First and foremost, in a paragraph entitled "[w]hat is an application?" located in an illustrative appendix to the specification, the patent recites that "[t]he basics of designing applications can be summarized in the following single sentence: 'The application is a series of multiple-choice questions.'" '057 Patent at 18:27-31. Additionally, several dependent claims contain references to "changing the flow of said data collection applications." See, e.g., '362 Patent at 17:21-21, 18:44-45. Defendants assert that "flow" has no antecedent basis in the claims, unless "flow" refers to a characteristic of a "data collection application." Defendants are correct that use of the term "flow" in reference to applications is consistent with a data collection application having a flow of questions described in the specification. See '057 patent at 3:32-36 (explaining that consequential libraries contain "actions or executable instructions . . . which change the flow of the application") (emphasis added).

Typhoon responds by arguing that a construction requiring a "question and answer" format would violate the canon of claim differentiation because claims 11 and 12 of the '057 patent contain a limitation requiring "an application generator for generating said data collection applications and . . . said application generator further comprising means for cross referencing responses to said inquiries with possible responses from one of said libraries." See '057 Patent at 32:18-22, 37-40. Typhoon asserts that this reference to "inquiries" and "responses," only found in claims 11 and 12, precludes limiting a "data collection application" to collecting the responses to predetermined questions.

However, while a data collection application may collect responses to questions, the limitation in claims 11 and 12 specifically call for a "means for cross referencing responses" to questions. The doctrine of claim differentiation does not apply. See Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380-81 (Fed. Cir. 2006) (discussing the doctrine of claim differentiation as applied to independent claims). Further, the language in claims 11 and 12 further suggest that data collection applications collect responses to predetermined questions because (as claims 11 and 12 explain) the application generator provides a means to cross reference provided responses with the stored responses contained within the libraries. Thus, the language in claims 11 and 12 assume that there are responses that have been collected by a data collection application and stored predetermined questions.
Typhoon's suggestion that the patent very generally describes a data collection application as "receiving and storing data" is incorrect. As discussed, the specification and the claims of the patent refer to a data collection application as a specific sort of data collection tool that gathers answers to a series of questions. Accordingly, "data collection application" is defined as "a computer program that collects responses to a predetermined series of questions."

"data collection unit"

Claim 14 of the '057 patent contains the term "data collection unit." The parties agree that the term has no established meaning within the art. Despite this, Typhoon advocates that the term means "a device for collecting data." Thus, Typhoon's argument is essentially that "unit" should be construed as "device" and that the patentee did not attach any specialized or restricted meaning to the term as a whole. Conversely, Defendants argue that the term means "a device that is designed to collect data for transfer to a central location." Typhoon responds by arguing that Defendants' definition is overly restrictive in requiring a "data collection unit" to "transfer to a central location."

The patentee essentially coined a phrase in using "data collection unit." The meaning given to it by the patentee is gleaned from the attributes of data collection described in the specification. The patent describes that a data collection unit "can continuously and repetitively collect data." '057 Patent at 7:56-57. Then, "the collected data is stored locally on the satellite computer." Id. at 7:59-60. "[T]he data provided from the computer . . . is uploaded to the host computer." Id. at 7:62-63. The patent also refers to the uploaded data as "transferred data." Id. at 7:67. However, the fact that the data is transferred to a "host computer" in the specification is merely illustrative and has nothing to do with the operation of a "data collection unit." By way of analogy, the patent describes that data being transferred to a host computer can be accomplished in a variety of ways, including by floppy disk, cable or satellite connection. Id. at 8:1-5. That recital, nor the recital that transferred data flows to a host computer, restricts a "data collection unit" to transferring data solely by those described methods or solely to the described recipient. Thus, the attributes essential to the patentee's use of the term "data collection unit" are collection of data and transfer of data. Accordingly, "data collection unit" is defined as "a device to collect data for transfer."

"data combiner"

The parties dispute whether "data combiner" is governed by 35 U.S.C. § 112(6). Verimatrix proposes that "data combiner" should be construed as "software on a computing device that combines different portions of input data into a single output," arguing that the specification implicitly supports its proposed construction. Verimatrix argues that "data combiner" does not connote any particular structure and the surrounding claim language does not provide the needed structure. According to Verimatrix, "data combiner" is a coined term commonly used in the art that refers to a category of structures that combine data. In Verimatrix's view, sufficient context is necessary to identify which structure of the category is intended. Verimatrix also argues that the prosecution history shows that the claim limitations were initially drafted using means-plus-function language.

The Court finds that the surrounding claim language provides the necessary structure. The parties agreed that both parser and encrypter are "software on a computing device" and, as both are elements of the apparatus of Claims 1, 58, and 70, so too is "data combiner." In that context, "data combiner" is "software on a computing device that combines different portions of input data into a single output."

(1) data communication system

This term appears in only the preambles of claims 15 and 97 of the '216 patent. N-Data argues that this term should be given
its plain and ordinary meaning. Both Dell and National assert that the specification expressly defines the term. The particular section relied on by Dell and National states, "[t]he present invention relates to communications between stations in a data communication system, such as a local area network or wide area network, and in particular to a network for transferring isochronous data via an asynchronous processor to a local switch table." '216 Patent, col. 1, ll. 13-17. The court agrees with N-Data. Given the logical reading of the above sentence, it is clear that "a network for transferring isochronous data via an asynchronous processor to a local switch table" refers back to the invention, not the data communications system. Furthermore, "a local area network or wide area network" is preceded by "such as." As discussed above, the court is not willing to limit a term to an exemplary embodiment absent clear language indicative of the patentee's intent to the contrary.

As such, the court defines the term as a "system for communicating data."

4. In data communication with

The Court lets stand its previous definition of "in data communication with" to mean two or more devices connected such that data is being transferred between the devices in real time. During the September hearing, questions arose as to the meaning of "in real time" after the previous order was issued. The Court defines "in real time" to mean that the receiving system receives the data in the same electronic time frame as the transmission system sends the data.

20. Data communication with one or more of the plurality of data storages that may be different than the one or more of the plurality of data storages in communication with the other session modules

The court concludes that this phrase requires no additional construction other than those previously provided for "data storage" and "session module."

I. "obtaining data concerning the fluid catalytic cracking unit in order to establish . . ." '236 patent, col. 15, ll. 50-51.

Plaintiff asserts that this phrase means "obtaining factual or other experimental information of any kind (such as by trial and error) concerning the FCC unit in order to arrive at. . . ." 9 Defendants contend that it means "gathering data from the FCC unit for which catalyst addition is sought to be controlled for the purpose of determining or setting the four parameters recited thereafter." 10 The Court will examine each of the disputed terms in turn.

9 (Pl.'s Claim Construction Br. at 15.)

10 (Defs.' Opening Claim Construction Br. at 17.)

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

A. "obtaining"

The first disputed word is "obtaining." Plaintiff contends that "obtaining" needs no construction, but it alternatively defines "obtain" as "to gain or attain possession," "to arrive at," or "attain." 11 Defendants define "obtain" as "gain or attain usu[ally] by planned action or effort." 12 However, relying upon the specification, they also define "obtaining" as
"gathering." 13

11 (Pl.'s Claim Construction Br. at 15, Ex. E at I-31101 (Webster's Third New International Dictionary (1993))).

12 (Defs.' Opening Claim Construction Br. at 16, Ex. 5 at WRG-51159 (Merriam Webster's Collegiate Dictionary (10th ed. 1995))).

13 (Id. at 17 (citing '236 patent, col. 8, ll. 1-4).)

The Court finds that "obtaining" requires no construction. The Court could substitute "gaining" or "attaining" for "obtaining," as both dictionaries cited by the parties define "obtain" in those ways, or the Court could substitute "gathering" for "obtaining," as the specification states that "employment of the methods . . . of this patent disclosure will normally begin with a gathering of certain hereinafter described operating data." '236 patent, col. 8, ll. 1-4 (emphasis added). But none is an improvement over "obtaining." In fact, in a circularity common among similar words, each word is defined by the others. For example, Webster's Third New International Dictionary (1986) defines "gain" as "to get or attain" and "obtain"; it defines "attain" as "gain" and "obtain"; and it defines "gather" as "to gain gradually." Id. at 140, 928, 940. Given this circularity, the Court presumes that "obtaining" speaks for itself and carries its ordinary meaning. See Texas Digital, 308 F.3d at 1202 ("The terms used in the claims bear a 'heavy presumption' that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." (citations omitted)). Nothing in the specification or the prosecution history rebuts this presumption. See Brookhill-Wilk 1, 334 F.3d at 1298-99; Texas Digital, 308 F.3d at 1204.

B. "data"

The second disputed word is "data." Plaintiff defines "data" as "factual or other experiential information of any kind." 14 Defendants define "data" in their brief as "numerical or qualitative values derived from scientific experiments," but their proposed construction leaves "data" undefined. 15

14 (Pl.'s Claim Construction Br. at 15, 16, Ex. E I-31087 (Webster's Third New International Dictionary (1993))).

15 (Defs.' Opening Claim Construction Br. at 16, Ex. 6 at WRG-51962-63 (McGraw-Hill Dictionary of Scientific and Technical Terms (2d ed. 1978))).

The Court finds that "data" requires no construction. The word is unambiguous and there is a "'heavy presumption'" that "data" means what it says 'and [has] the ordinary meaning that would be attributed to [it] by persons skilled in the relevant art." Texas Digital, 308 F.3d at 1202. Nothing in the specification or the prosecution history rebuts this presumption of ordinary meaning. See Brookhill-Wilk 1, 334 F.3d at 1298-99; Texas Digital, 308 F.3d at 1204.

C. "in order to"

The third disputed phrase is "in order to." Plaintiff contends that "in order to" needs no construction, but it alternatively defines this phrase as "in regard or reference to" and "for the purpose of." 16 Defendants define "in order to" as "for the purpose of." 17 The Court finds that "in order to" means "for the purpose of." Both dictionaries cited by the parties define "in order to" in this way. This ordinary meaning is presumed and nothing in the specification or prosecution history rebuts this presumption. See Brookhill-Wilk 1, 334 F.3d at 1298-99; Texas Digital, 308 F.3d at 1204.

16 (Pl.'s Claim Construction Br. at 15, Ex. E I-31097 (Webster's Third New International Dictionary (1993))).

17 (Defs.' Opening Claim Construction Br. at 16, Ex. 6 at WRG-51962-63 (McGraw-Hill Dictionary of Scientific and Technical Terms (2d ed. 1978))).
16 (Pl.'s Claim Construction Br. at 19, Ex. E at 1-31093 (Webster's Third New International Dictionary (1993))).

17 (Defs.' Opening Claim Construction Br. at 17, Ex. 5 at WRG-51177 (Merriam Webster's Collegiate Dictionary (10th ed. 1995))).

D. "establish"

The fourth disputed word is "establish." Plaintiff defines "establish" as, among other things, "to arrive at (as a result)." 18 It also argues that one may "establish" the four values listed thereafter by "trial and error." 19 Defendants define "establish" in various ways, 20 but at oral argument they settled on "to determine." 21

18 (Pl.'s Claim Construction Br. at 16, Ex. E at I-31088 (Webster's Third New International Dictionary (1993))).

19 (Id. at 18.)

20 (Defs.' Opening Claim Construction Br. at 17, Ex. 5 at WRG-51922 (Merriam Webster's Collegiate Dictionary (10th ed. 1995))).

21 (Markman Hr'g Tr. at 75; Defs.' Hr'g Presentation at 34-37.)

The Court finds that "establish" requires no construction. There is a "'heavy presumption'" that "establish" means what it says "and [has] the ordinary meaning that would be attributed to [it] by persons skilled in the relevant art." Texas Digital, 308 F.3d at 1202. The parties' proposals, while acceptable, provide no more clarity than "establish."

The Court also finds that one may "establish" the four values listed thereafter by "trial and error." "Trial and error" is defined as "a finding out of the best way to reach a desired result or a correct solution by trying out one or more ways or means and by noting and eliminating errors or causes of failure." Webster's Third New International Dictionary 2439 (1986). The specification's teachings and prosecution history are consistent with the "trial and error" approach. For example, the specification teaches that the evaluation of "operating data" will "commence with a taking of a series of successive (e.g., every 1/2 hour) samples from the FCC unit's total bulk catalyst." '236 patent, col. 8, ll. 3, 8-10. The specification also teaches that desired "maximum and minimum levels" of a particular catalyst "can be determined by overdosing or withholding catalyst from the FCC unit under otherwise controlled conditions of operation." '236 patent, col. 8, ll. 46-49. Both the evaluation of data "with a taking of a series of successive . . . samples" and the ebb and flow of "overdosing or withholding catalyst" to reach desired maximum and minimum levels are in line with a "trial and error" view. Finally, the prosecution history refers to the "establishment' step as "empirical in nature." (Pl.'s Claim Construction Br. Ex. G at I-3151.) Although not defined in the intrinsic record, "empirical" is defined in Webster's Third New International Dictionary (1986) as "proceeding strictly experimentally or by the trial and error method." Id. at 743.

E. "concerning"

Perhaps overshadowing the previous disputes, however, is the dispute over "concerning." Claim 1 reads: "obtaining data concerning the fluid catalytic cracking unit in order to establish . . .". '236 patent, col. 15, ll. 50-51 (emphasis added). Defendants contend that data must be obtained "from the FCC unit for which catalyst addition is sought to be controlled." 22 They argue that use of the definite article "the" in "the fluid catalytic cracking unit" indicates that the denoted FCC unit was previously introduced in the preamble to the claim. 23 The preamble states, in pertinent part: "A method for controlling addition of a catalyst into a fluid catalytic cracking unit . . ." '236 patent, col. 15, ll. 45-46 (emphasis added). Thus, according to Defendants, 'the data' is obtained from the particular FCC unit into which the catalyst will be added." 24

22 (Pl.'s Claim Construction Br. at 16, Ex. E at 1-31088 (Webster's Third New International Dictionary (1993))).

23 (Id. at 18.)

24 (Defs.' Opening Claim Construction Br. at 17, Ex. 5 at WRG-51922 (Merriam Webster's Collegiate Dictionary (10th ed. 1995))).

25 (Markman Hr'g Tr. at 75; Defs.' Hr'g Presentation at 34-37.)
Plaintiff contends that data need only be obtained "concerning" the FCC unit, not "from" it. 25 It argues that had the patentee intended to limit the claim by requiring that the data must come "from" the particular FCC unit to which catalyst is to be added, he would have said so and would not have said "concerning" the FCC unit. 26 It further argues that "concerning" needs no construction, but it alternatively defines "concerning" as "relating to: regarding, respecting, about." 27

Defendants are correct in asserting that "the fluid catalytic cracking unit" refers back to "a fluid catalytic cracking unit" introduced in the preamble. A patent treatise describes how a patentee refers back to elements previously named in a claim:

The first time an element or part is mentioned, it should not be preceded by a definite article ("the") or by "said." Instead the indefinite article ("a" or "an") should be used, as in . . . "a container," "a base," etc. . . . When each previously identified element or part is referred to again, the definite article should be used, as "the container," "the base" . . . .

Robert C. Faber, Landis on Mechanics of Patent Claim Drafting § 23 (2002) (footnote omitted); see Zenith Elecs. Corp. v. ExZec, Inc., 1995 U.S. Dist. LEXIS 6177, at *12, No. 93 C 5041 (N.D. Ill. May 5, 1995) ("An indefinite article ('a' or 'an') is used to introduce an element. A definite article ('the' or 'said') is used when a term has already been introduced, thereby making mention of the earlier recitation of the element." (citation omitted)).

But Defendants are incorrect in asserting that data must be obtained "from" the particular FCC unit for which catalyst addition is sought to be controlled. "From" is not used in the claim language. And "from" is not a synonym for "concerning." While "concerning" means 'relating to: regarding, respecting, about," "from" is a function word indicating "a starting point," "the act, fact, or condition of removal, withdrawal," and "the source or original or moving force of something." Webster's Third New International Dictionary 470, 913 (1986). It is presumed that "concerning" carries its ordinary meaning of "relating to" and does not mean "from" as Defendants contend. See Brookhill-Wilk-1, 334 F.3d at 1298; Texas Digital, 308 F.3d at 1202. Had the patentee intended the data to be obtained "from" the particular FCC unit, he could have explicitly said so. See Superguide Corp v. DirecTV Enters., Inc., 358 F.3d 870, 880 (Fed. Cir. 2004) ("Had the patentees intended to limit the disputed claim terms to 'analog' technology, they could have easily done so by explicitly modifying the disputed claim language with the term 'analog.'"). Nothing in the specification or prosecution history rebuts the presumption that "concerning" carries its ordinary meaning of "relating to." See Brookhill-Wilk 1, 334 F.3d at 1298-99; Texas Digital, 308 F.3d at 1204.

F. Summary

Accordingly, the Court concludes that the phrase "obtaining data concerning the fluid catalytic cracking unit in order to establish . . ." means "obtaining data relating to the fluid catalytic cracking unit for the purpose of establishing (such as by trial and error). . . ."
5. Data corresponding to one or more thoroughfares

The fourth subpart of claim 1 reads:

```
wherein said processor retrieves from said memory, data corresponding to one or more thoroughfares and determines a desired orientation for display of said cartographic data based upon a current location of said vehicle, a direction of travel of said vehicle, and a direction of at least one of said one or more thoroughfares corresponding to said current vehicle location, wherein said direction of said at least one of said one or more thoroughfares is determined from said retrieved cartographic data.
```

The first phrase in dispute is: "wherein said processor retrieves from said memory, data corresponding to one or more thoroughfares." Plaintiff seeks to limit the definition of "data corresponding to one or more thoroughfares" to simply "thoroughfares." Defendant has proposed the better definition, which incorporates the concept of X and Y coordinates. As discussed in section E.3 above, the specification makes it clear that this invention works by detecting thoroughfares through their corresponding coordinates. There is no question that "data corresponding to one or more thoroughfares" includes not only the thoroughfares themselves but also their corresponding coordinates. I construe "data corresponding to one or more thoroughfares" to mean "the X and Y coordinates corresponding to one or more thoroughfares."

6. "First and second data couplers, each coupled to a respective one of said first and second ports, and each having a data signal port operative to pass only a data signal"

This phrase appears in claim 18 of the '280 patent. SercoNet argues that this term should be construed as: "Two data couplers, each coupled to a different port, where each such port transmits a data signal, but not a power signal." NetGear's proposed construction is: "The device has two data couplers, each coupled to a different port (the first and second port). Each data coupler is capable of separating the data from the power received at that port, and passing along the data signal."

Turning to the claim language, the claim describes: "A device for configuring a local area network in a building for the transport of power and data signals across a wiring, wherein the wiring includes at least first and second wiring segments, the device comprising: . . .

[1] first and second ports each connected to a respective one of said first and second wiring segments;

[2] first and second data couplers each coupled to a respective one of said first and second ports, and each having a data signal port operative to pass only a data signal;

[3] first and second modems each coupled to said data signal port of a respective one of said first and second data couplers, for full duplex data signal communication with a respective one of said first and second wiring segments; . . .

[5] first and second power couplers each coupled to a respective one of said first and second ports, and each having a respective one of first and second power signal ports, each signal port being operative to pass only the first power signal;

[6] a power supply coupled to the first power signal port and to at least one of said modems to be powered by the power signal and for powering said modem."

The term at issue notes that the port is "operative to pass only a data signal." The language therefore focuses on the port's ability to pass and transmit a data signal. This term does not state anything about separating data, nor does it discuss separating data from power. In fact, other portions of the claim separately deal with the passing of power signals. NetGear's
definition suggests that the port must separate data from power, and may not simply just allow data to pass without performing this separation. NetGear is apparently importing an extraneous limitation that is not suggested by the language of the claim.

NetGear, however, argues that because claim 18 as a whole describes a device that transports both power and data across the same wires, and because the data coupler passes only a data signal, this necessarily means that the coupler separates data from the power signal. While this is certainly one logical reading of the invention, it is unclear from the plain claim language that separating the signal is the only mechanism by which the coupler passes the data signal, but not the power signal.

Turning to the specification for further clarification, NetGear notes that the couplers in this claim are the power/data splitter/combiners in the specification, which decouple the data signal from the power. See '280 patent at 5:63-66 & Figure 5. However, the specification specifically states that "in some cases . . . the power/data splitter/combiner is not required, and the power lines are directly connected to the SIC power-supply while the data connects directly to the modems." Id. at 6:16-23. The specification, therefore, seems to indicate that this separating function is not a necessary part of the invention in all circumstances. And, while this portion of the specification indicates that the couplers that are at issue here might not be a part of the invention in these alternative embodiments because they are not "required," there is nothing in the specification that precludes the couplers from being part of these alternative embodiments.

As with the previous claim term, while SercoNet's definition may not be perfect, it does not import an extraneous limitation into the term, and therefore does not suffer from the same difficulties as does NetGear's proposed construction.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "First and second data couplers, each coupled to a respective one of said first and second ports, and each having a data signal port operative to pass only a data signal" and construes the term as: "Two data couplers, each coupled to a different port, where each such port transmits a data signal, but not a power signal."

1106

Instruction does not have any data dependencies with preceding issued instructions which have not yet been completed (claims 8 and 17)

Defendant argues that claims 8 and 17 are limited to "data dependencies" which include both essential and false dependencies. Defendant relies on the facts that claim 8 depends from claim 7, and claim 7 specifies both essential and false dependencies. Therefore, claim 8 must include both as well. The same argument applies to claim 17, which depends from claim 16.

Plaintiff's position on this issue is not clear. In its proposed Findings of Fact and Conclusions of Law plaintiff proposes that "data dependencies" in claims 8 and 17 be construed as meaning "an instruction that depends for its issuance on a value in another instruction." In this regard, plaintiff argues that defendant improperly imports into claims 8 and 17 the requirement of both essential and false dependencies. Plaintiff's argument is supported by application of the doctrine of claim differentiation to claims 8 and 17 and the claims which depend from them (claims 9, 10, 18 and 19). Plaintiff's proposed construction of dispatch stack for claims 8 and 17, however, includes both essential and false dependencies.

The Court is aware that claim differentiation is not a rigid rule, see Comark, 156 F.3d at 1187, and, in light of the fact that claims 8 and 17 depend from claims which recite both essential and false dependencies, the Court adopts defendant's construction. Accordingly, the Court construes the phrase "instruction does not have any data dependencies with preceding issued instructions which have not yet been completed" in claims 8 and 17 as meaning "an instruction that is free of [alpha] and [beta] dependencies."

1107
2. "data download circuit"

3Com proposes "a circuit that retrieves data from memory." Doc # 81 (05-0098) at 31. Realtek proposes "the circuitry that downloads data corresponding to the frame segment descriptor." Id. The court looks to intrinsic evidence to ascertain the meaning.

The specification discloses that the "data download circuit [is] coupled to the segmentation circuit to receive the frame segment descriptors." '446 patent at 2:31-33. The specification also discloses that the "data download circuit uses the frame segment descriptor to retrieve the data from memory." '446 patent at 10:60-61. Given this evidence, a person of ordinary skill in the art would interpret the coined term "data download circuit" to refer to a structure that downloads data corresponding to the frame segment descriptor.

3Com objects to Realtek's narrow proposed construction because "sometimes the data download circuit downloads data that corresponds to descriptors that are not frame segment descriptors. Doc # 340 at 19. But claim 26 requires the data download circuit to download data corresponding to a descriptor signal. '446 patent at 14:13-22. If the data download circuit downloads other data, it would not be within the method described by claim 26. Accordingly, the court adopts Realtek's proposed construction "the circuitry that downloads data corresponding to the frame segment descriptor."

A. "Data Error Detection and Correction Circuitry"

1. Proposed Constructions

Plaintiffs argue that "data error detection and correction circuitry" should be construed to mean "any error detection and correction circuitry." Defendants, on the other hand, assert that the term should be construed as "circuitry that first performs Reed-Solomon error correction, followed by error detection with a cyclic redundancy checker." There are three fundamental construction disputes between the parties: (1) whether the term implies any temporal requirements, (2) whether the error correction must be done using only Reed-Solomon error correction codes, and (3) whether error detection must be done with a cyclic redundancy checker. Plaintiffs contend that there is no sequence implied by the claim term; defendants argue that the vagueness of the term mandates reference to the specification, which clearly sets forth the sequence of operations performed by the "error detection and correction circuitry" and further requires error correction to be done according to the Reed-Solomon error correction codes and error detection to be done by a cyclic redundancy checker.

2. Claim Language and Prior Construction of Similar Terms

The term "data error detection and correction circuitry" appears in claims 1 and 2 of the 527 patent. The Federal Circuit construed "data error detection and correction means" as claimed in the 715 patent to require both Reed-Solomon error correction codes and error detection using a cyclic redundancy checker. Plaintiffs contend that, contrary to defendants' assertions otherwise, this construction is not warranted with regard to the "data error detection and correction circuitry" in claims 1 and 2 of the 527 patent. Plaintiffs illustrate the limitations set forth in the 715 patent claim term that are inappropriate to the 527 by setting the claims side-by-side and underlining the limitations they contend that defendants seek to impermissibly import:

<table>
<thead>
<tr>
<th>'527 patent term</th>
<th>'715 patent term</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;data error detection and correction means for correcting said assembled data, said detection and correction means including error correction for performing error correction on said assembled data, and a cyclic redundancy checker for detecting errors in said assembled&quot;</td>
<td>&quot;data error detection and correction circuitry, said detection and correction circuitry including: error correction on data received from said interface and detecting errors in data prior to&quot;</td>
</tr>
</tbody>
</table>
The court agrees that these limitations require different constructions. First, the Federal Circuit noted in affirming the ITC's construction requiring error correction before error detection, Reed-Solomon error correction codes, and the cyclic redundancy checker "that the plain language of the disputed limitation of claim 1 explicitly requires certain interactions between the error correction circuitry, the cyclic redundancy checker and said assembled data." Oak v. ITC, 248 F.3d 1316, 1325 (Fed. Cir. 2001). In limiting the claim to a particular sequence of error correction and detection, the Federal Circuit appropriately relied upon the language in the 715 claim providing for the use of a cyclic redundancy checker to detect errors in the assembled data after the correction circuitry had provided corrected data. However, the Federal Circuit also recognized that "[t]he sequential limitation is imposed by the claim language itself, and the written description simply confirms this understanding." Id. at 1328-29. By contrast, the language at issue in the 527 patent utilizes no language requiring interactions between the components indicating sequential operation of the error correction and detection circuitry, except that errors must be detected prior to transmission to host computer.

n6 Notably, the Federal Circuit did not construe the "data error detection and correction means" as a means-plus-function claim under 35 U.S.C. § 112 P 6. The parties stated at oral argument that Oak and UMC had stipulated that this claim limitation was not to be construed as means-plus-function.

Defendants rely upon the Federal Circuit's statement that the intrinsic record of embodiments in the shared specification provides no discussion of "error detection and correction means' which do not operate in a straightforward sequential manner" and that "if such a disclosure existed, these embodiments would not be covered by the language selected by the claim drafter." Id. at 1329. However, there is little question claim drafter for the 527 patent chose different language. It is that language, not the claim language of the 715 patent, that this court must construe.

3. Specification

The specification discusses the "error detection and correction circuitry" in several places. The abstract of the 527 patent states that "an error correction code (ECC) data corrector, an error detection and correction (EDC) device employing cyclical redundancy checking techniques (EDC/CRC) . . . are described." 527 patent, Abstract. The Summary of the Invention of the 527 patent specification discloses that

'[t]he digital signal processor interface of the CDDC [compact disk drive controller] further comprises an error correction circuit to perform error correction on said digital information. That error correction circuit could employ Reed-Solomon codes. The digital signal processor interface of the CDDC further comprises a cyclic redundancy checker for detecting errors in the digital information after correction of the digital information by the error code correction circuit. 527 patent 3:20-28. The patent specification describes the error correction and detection circuitry referring to Fig. 2:

The error correction circuitry would first perform Reed-Solomon error correction on each block of data. Reed-Solomon codes are random single-or multiple-symbol error correcting codes operation on symbols which are elements of a finite field. All encoding, decoding, and correction computations are performed in the field. Then, a cyclic redundancy check of the corrected data would be performed. Since each codeword contains two parity bytes the drive controller of this invention can correct one error in each codeword. These ECC and EDC/CRC circuits are commonly available as hardware used in many other applications. The host control allows the corrected data to be transferred from the RAM to the host.

Id. at 6:26-41. The parties do not dispute that the specification only expressly discloses one method of error correction and detection in the preferred embodiment. In this method, the error correction is implemented using the Reed-Solomon error codes and is performed prior to error detection (which is implemented by way of a cyclic redundancy checker). The court agrees with the Federal Circuit that there is no specific discussion of error code detection and correction that operates in a
different sequence than that suggested by the defendants. However, "although the specification often describes very specific embodiments of the invention, [the Federal Circuit has] repeatedly warned against confining the claims to those embodiments." Phillips, 415 F.3d at 1323 (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906-08 (Fed. Cir. 2004); also citing Nazomi Communications, Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1369 (Fed. Cir. 2005) for the proposition that claims may embrace "different subject matter than is illustrated in the specific embodiments in the specification").

In addition, the specification, by stating that "error correction circuit could employ Reed-Solomon codes," id. at 3:22-23 (emphasis added), makes it reasonably clear that the Reed-Solomon is one option for error correction, but not the only one. Furthermore, as pointed out by plaintiffs at the claim construction hearing and in their response to defendants' sur-reply, the specification cites a text, Practical Error Correction Design for Engineers, which describes various error correction codes and techniques. Plaintiffs attach excerpts of this text, published in 1991, to their declaration in support of their response to defendants' sur-reply. Reed-Solomon is one of the techniques, indeed, the preferred technique, disclosed for error correction and detection for optical drives but there are others. See Neil Glover & Trent Dudley, Practical Error Correction Design for Engineers (2d ed. Cirrus Logic 1991), Decl. of William Goldman Supp. Resp. Sur-reply, Ex. A. at pp. 158, 272, 276-77.

Similarly, the discussion of a "cyclic redundancy checker" in the patent specification indicates that a cyclic redundancy checker may not always be required in an error code detection and correction system. As with Reed-Solomon codes, the specification indicates that a cyclic redundancy checker in an alternate embodiment. The specification states that the "digital processor interface of the CDDC further comprises a cyclic redundancy checker for checking errors in the digital information after correction of the digital information by the error correction code circuit." 527 patent at 3:23. This indicates that the cyclic redundancy checker need not necessarily be present nor need error detection be performed in a particular sequence with respect to error correction. The "further comprises" language also demonstrates that the specification is disclosing an embodiment rather than establishing the outer boundary of claim scope.

4. Prosecution History

The prosecution history of the 527 patent includes exchanges regarding the "error detection and correction circuitry." Applicants filed original claim 25, which issued as claim 1, as a preliminary amendment to a continuation application under 37 C.F.R. 1.62. The relevant portion of original claim 25 read:

    data error detection and correction circuitry, said detection and correction circuitry including error correction circuitry for performing error correction on said data received from said interface and generating corrected data therefrom, and a cyclic redundancy checker for detecting errors in said data or in said corrected data

'527 Prosecution History ("'527 PH"), Schwartz Decl., Ex. C at ZC12000. The preliminary amendment also included claim 30, dependent upon original claim 25 which read, "[t]he drive controller of claim 25, wherein said error correction circuitry performs Reed-Solomon error correction on said data received from said interface." Id. at ZC001201.

On June 13, 2000, the applicants amended claim 25 in response to a January 13, 2000 office action. n7 The amendment to claim 25 removed the cyclic redundancy checker limitation, replacing the words "a cyclic redundancy checker" with "error detection circuitry." The amendment also removed "or in said corrected data", replacing it with "prior to transmission to said computer." Id. at ZC001502. n8 The accompanying comments read

    Applicant has also amended claim 25 to further clarify that with regard to the timing of error detection operations, it is only required that data errors be detected before the data is transferred to the host computer. Moreover, any kind of error detection circuitry may be employed, regardless of whether or not it uses a cyclical redundancy code or error detection codes other than a cyclical redundancy check code.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

n7 The January 13, 2000 office action is found at ZC001229.

n8 These amendments to original claim 25 modified the language to that with which it ultimately issued as claim 1 to the 527 patent:
data error detection and correction circuitry, said detection and correction circuitry including: error correction circuitry for performing error correction on said data received from said interface and generating corrected data, and error detection circuitry for detecting errors in data prior to transmission to said host computer.

--- End Footnotes ---

A notice of allowability was issued on the 327 application on December 4, 2000. Id. at ZC001510. In the reasons for allowance issued with that notice, the examiner took official notice that

the claimed invention requires that the data errors must be detected and corrected before the data is transferred to the host computer and the error correction must occur before the data error detection. The Official position is that the scope of all the independent claims . . . are interpreted in view of the embodiment disclosed in the specification. In particular, see Specification, page 8, lines 3-9 . . . and page 9 after line 8 . . .

Id. at ZC001511. He also noted with regard to error detection circuitry that

Applicant stated in the Remarks that "any kind of error detection circuitry may be employed, regardless of whether or not it uses a cyclical redundancy code or error detection codes other than a cyclical redundancy check code." Official notice is taken that the only kind of error detection circuitry disclosed in the Specification is a cyclical redundancy check (CRC) circuitry. . . Official notice is taken that, at the time of the invention, the only one specific type of EDC-CRC commonly available as hardware used in many other applications was a linear feedback shift register.

Id. at ZC001512. Thereafter, applicants filed a continued prosecution application that included "comments on statements of reasons for allowance." In those comments, the applicants disagreed with the examiner's December 2000 statement for reasons of allowance, stating

The "Statement of Reasons for Allowance" relies upon a decision of the ITC . . . that Applicant is currently appealing . . . . For the same reasons asserted by the Applicant in this appeal, the Applicant respectfully disagrees with the "Statement of Reasons for Allowance."

Id. at ZC001621. On August 7, 2001, the applicants filed original claim 35, which issued as claim 2 to the 527 patent. Along with that claim the applicants again addressed the December 4, 2000 notice of allowability, referring to the Federal Circuit's opinion in ITC II:

The claim language relied upon by the Federal Circuit is not present in the now pending claims and there is no basis for restricting these claims in this manner. . . . Applicant traverses paragraph 3 of the "Statement of Reasons for Allowance" because it inappropriately takes Official notice that "the claimed invention requires that the data errors must be detected and corrected before the data is transferred to the host computer and that the error correction must occur before the data error detection." . . . Similarly, Applicant traverses paragraph 4 of the "Statement of Reasons for Allowance" because it also reads limitations of the specification into claim 25. In this regard, the Federal Circuit decision clearly based its decision on the language in the claims of U.S. Patent 5,581,715, which language clearly is not present in the now pending claims of this application. As such, Applicant respectfully requests withdrawal of the "Statement of Reasons for Allowance" and reconsideration of the new pending claims.

Id. at ZC001741-43.

The examiner rejected claims 25 and 35 in an office action dated July 8, 2002. He based the rejection in part on obviousness under 35 U.S.C. § 103(a) in light of the Yellow Book specification, stating "Based on Yellow Book' specification, one of ordinary skill in the art would recognize that the error correction process is performed before the error detection process." Id. at ZC001827. Applicants responded by stating, "With regard to claims 25 and 35, there is no limitation that the error correction process is performed before the error detection process' . . ." Id. at ZC001938. Plaintiffs argue that these broadening statements clarify the knowledge of one of skill in the art and demonstrate that they did not acquiesce to the examiner's statement regarding Reed-Solomon and cyclic redundancy checker being the only techniques known to one of skill in the art. Plaintiffs' 527 Reply Br. at 5. They argue that the inventors' traverse prevented any disavowal of claim scope.
Cf. Salazar, 414 F.3d at 1347.

a. "Cyclic Redundancy Checker" Removed During Prosecution

When construing claims, courts may rely on unissued claims to determine the scope of a claim term. Cf. Lemelson v. TRW, Inc., 760 F.2d 1254, 1262 (Fed. Cir. 1985). As evidence that defendants' attempt to require the "error detection and correction circuitry" use a cyclic redundancy checker is improper, plaintiffs point out that the limitation "cyclic redundancy checker" was removed during prosecution and replaced with "error detection circuitry." Hence, they contend that defendants' attempt to narrow their claim by substituting "cyclic redundancy checker" back into the claim for "error detection circuitry" impermissibly narrows a claim broadened during prosecution. U.S. v. Telectronics, Inc., 857 F.2d 778, 783 (Fed. Cir. 1988) ("courts are not permitted to read back into the claims limitations which were originally there and were removed during prosecution of the application through the Patent Office.").

b. Claim Differentiation

Plaintiffs also argue that the claim cannot be construed to require Reed-Solomon error correction because the prosecution history demonstrates that pending claim 25 (now claim 1) was accompanied by pending dependent claim 30, which provided that error correction would be done via Reed-Solomon codes. According to plaintiffs, this indicates that claim 25 did not require Reed-Solomon correction, and likewise did not include a requirement that error correction precede error detection before the corrected data was transferred to the MPEG decoder. Long-established principles of claim differentiation support plaintiffs' contention. Cf. Wright Medical Technology, Inc. v. Osteonics Corp., 122 F.3d 1440, 1445 (Fed. Cir. 1997) ("we must not interpret an independent claim in a way that is inconsistent with a claim which depends from it.").

c. Understanding of One of Skill in the Art

Defendants contend that the only method of error correction known to one of skill in the art as of the effective filing date of the patent application was Reed-Solomon correction. See Phillips, 415 F.3d at 1313 ("We have made clear, moreover, that the ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention, i.e., as of the effective filing date of the patent application."). They contend that this level of understanding at the time of filing was confirmed by the Federal Circuit in Oak v. ITC, and again by the examiner when he took official notice that Reed-Solomon and the cyclic redundancy checker were the only methods at the time of filing that were known to one of skill in the art for error correction and detection respectively. Thus, according to defendants, the only possible way to construe "error detection and correction circuitry" would require error correction by Reed-Solomon error code prior to error detection using a cyclic redundancy checker.

5. Jepson Claim Format

Their sur-reply, defendants contend, based loosely on Phillips, that the Jepson form of claim 3 of the 527 patent demonstrates that the error detection and correction circuitry requires the Reed-Solomon, cyclic redundancy checker, and temporal limitations. Notably, the "error detection and correction circuitry" limitation appears nowhere in claim 3. Instead, defendants contend that the term "optical drive controller," which appears in the preamble, requires error detection and correction circuitry according to the specification. Because the preamble of a Jepson claim defines structural limitations that are conventional or known, Rowe v. Dror, 112 F.3d 473, 479 (Fed. Cir. 1997), defendants contend that the optical drive controller includes error detection and correction circuitry as would have been known in the art at the time the parent application was filed. Because they contend that the only such circuitry known in the art would have used Reed-Solomon and a cyclic redundancy checker, they assert that the form of claim 3 supports their construction of the "error detection and correction circuitry" limitation.

The court finds defendants' argument to be without merit. First, nothing in Phillips justifies the late assertion of defendants' Jepson argument. The argument is a relatively transparent attempt to advance a new claim construction theory on the eve of the claim construction hearing. Second, defendants' attempt to fix the knowledge of one of skill in the art with respect to a term that does not appear in the claim (error detection and correction circuitry) though a prior art term (optical drive controller) by asserting that the structure of the optical drive controller requires error detection and correction circuitry is an unwarranted stretch. Construing "error detection and correction circuitry" through the "optical drive controller" cited in the
preamble of a Jepson claim by reference to the required element of a prior art optical drive controller is attenuated at best, particularly given that the term explicitly appears in claims 1 and 2 of the 527 patent. Third, as set forth above, plaintiffs have presented evidence that techniques other that Reed-Solomon where known by one of skill in the art at least as of 1991 when the second edition of Practical Error Correction Design for Engineers was published.

6. Conclusion

The court declines to narrowly construe the term based on the understanding of one of skill in the art as set forth by the Federal Circuit in Oak v. ITC and by the examiner of the 527 patent in the examiner's notice. As set forth above, the claim language does not limit error detection and correction circuitry to using Reed-Solomon or a cyclic redundancy checker. The specification leaves open the possibility that Reed-Solomon is but one possible error correction method and that cyclic redundancy checker is one error detection method. Likewise, the indication in the specification that the error correction circuitry "further comprises" a cyclic redundancy checker indicates that error detection need be accomplished by a cyclic redundancy checker nor need it occur in any particular sequence in the error detection and correction subsystem. Further, during prosecution, the applicants clearly asserted that error correction and detection could be done either in the sequence disclosed or another sequence. The applicants stated that error detection and correction could be accomplished by any means, specifically challenging the PTO's "Statement for Reasons of Allowance" on the grounds that neither a cyclic redundancy checker nor error detection after correction were required. None of these assertions is at all ambiguous. Finally, plaintiffs have presented extrinsic evidence cited in the specification itself that corroborates that techniques for performing error correction with techniques other than Reed-Solomon may have been known (although potentially not employed) at the time the parent application was filed. Thus, the court finds "data error detection and correction circuitry" means, as plaintiffs contend, "any error detection and correction circuitry."

n9 The court's decision on this matter does not necessarily mean the claim is valid. For example, claims having this limitation may suffer from enablement problems, but that is a separate inquiry. See Phillips, 415 F.3d at 1335 ("While we have acknowledged the maxim that claims should be construed to preserve their validity, we have not applied that principle broadly, and we have certainly not endorsed a regime in which validity analysis is a regular component of claim construction.") (citing Nazomi, 403 F.3d at 1368-69); see also, Nat'l Recovery Techs., Inc. v. Magnetic Separation Sys., Inc., 166 F.3d 1190, 1196 (Fed. Cir. 1999) (separating the claim construction and enablement inquiry).

A. Data Flow Diagram.

The parties' single biggest dispute is over the meaning of the term "data flow diagram." The parties now agree that the term "data flow diagram" means more than simply a graphical construct that displays a procedure. The parties also agree that the term "data flow diagram" incorporates certain semantic principles. The claim language does not specifically contain the semantic principles but the specifications are replete with references to these concepts.

4 The parties agree that "data flow diagram" is used interchangeably throughout the four patents-in-suit with "block diagram," "diagram," "diagram display . . . graphically displays data flow," "user defined data flow diagram," and "diagram display which displays . . . graphical representation and . . . data flow structure representation." Although National initially asserted that "data flow diagram" meant "a block diagram that displays lines that connect function blocks and indicates that data produced by one block is used by another block," in its reply brief and at the claim construction hearing, National abandoned that construction in favor of one that contained certain semantic limitations. Mathworks, as the briefing evolved, settled on a definition similar to the one National proposed in its reply brief. There are two aspects to any computer programming language: syntax and semantics. The syntax defines how the program is expressed and the semantics define what those expressions mean.
The parties' proposed definitions vary slightly. National proposes that the court's construction of data flow diagram should incorporate four semantic principles:

1. Nodes are connected by lines indicating data dependency;
2. Nodes execute after data is available; and
3. The complete order of execution is not necessarily specified by the user; and
4. Nodes which do not depend on each other for data could be executed in any order, or in parallel on parallel-processing hardware.

Mathworks urges the court to construe data flow diagram as incorporating the following four semantic principles:

1. The order of operations is not specifically specified by the user;
2. The order of operations is implied by data interdependencies;
3. A node may only execute once it has received all necessary inputs; and
4. All outputs are generated after a node executes.

The question is how one skilled in the art would construe "data flow diagram" in the context of these patents in light of the intrinsic evidence. In this case, the inventors used the terms "data flow" and "data flow diagram," throughout the specifications, the claims, and in the descriptions of the inventions in a manner that incorporates very specific characteristics. The court adopts these characteristics and concludes that "data flow diagram" as used in the patents in suit, incorporates the following four semantic limitations:

1. the order of operations is not completely specified by the user;
2. the order of operations is implied by data interdependencies;
3. a node may only execute after all necessary inputs have become available; and
4. outputs are generated after a node completes execution.

The intrinsic record supports this approach. First, the court is mindful that it is not addressing data flow diagramming in the abstract. The inventors made it plain that their inventions sought to make data flow programming friendlier while recognizing that conventional data flow diagramming had certain shortcomings. Meanwhile, these inventors sought to preserve certain advantages -- namely speed -- that resulted from data flow programming's parallel data processing method. In the Background of the Invention portion of the patents, the inventors state that "[a] general type of program design technique involves data flow diagramming." (221 Patent, Col. 3, 11. 18-19)(emphasis added). The inventors noted advantages of data flow programming -- namely speed -- but recognized that data flow diagramming had difficulty representing certain functions and was difficult to implement. Id. at Col. 3, 11. 22-37. The inventors recognized a need for a system which employed data flow techniques and overcame the difficulties in representing conditional and iterative functions. They urged that "the present invention meets these needs." Id. at Col. 3, 11. 41-47 (emphasis added). In these passages, the inventors are not referring to the preferred or sole embodiment of the invention but to the invention itself.

The written description of the invention sets forth the appropriate semantic principles. To be sure, the written description provides no explicit definition of the terms "data flow" and "data flow diagram;" however, these terms are used throughout the description in a consistent way and they have but one meaning in the context of these patents. The inventors taught that "data flow programming typically involves an ordering of operations which is not specifically specified by a user but which
is implied by data interdependencies." Id. at Col. 3, 11. 19-22. Moreover, the inventors made repeated statements to the effect that the concept of "data flow" means that a node may only execute after all necessary inputs have become available and outputs are generated after a node completes execution. See, e.g., 221 Patent, Col. 10, 11. 13-18 ("in accordance with data-flow principles, used in the preferred embodiments of the present invention, the sequence structure does not begin execution until all incoming signal paths have data available, and none of the outgoing signal paths produce data until all diagrams have completed execution.")(emphasis added). The description goes on to illustrate that "in accordance with data flow principles, all inputs must be available to start execution of an iteration loop. Furthermore, all outputs are generated after execution completes." 221 Patent, Col. 11, 11. 15-18 (emphasis added). At least three other portions of the specifications provide like limitations. E.g., 221 Patent, Col. 11, 11. 43-46; Col. 12, 11. 18-22; Col. 13, 11. 17-30. The specifications demonstrate that the inventors used the term data flow diagram to include the various semantic principles included in the court's construction. A review of the claim language together with the intrinsic evidence discloses no ambiguity; accordingly, the court need not consult any extrinsic definitions.

1110

The technology of the patents in suit concerns the creation of model systems (generally known as "data flow diagrams") through building diagrams on a computer screen by pointing and clicking with a mouse, rather than writing traditional lines of code. Relying upon the intrinsic evidence of record, the trial court interpreted the disputed claim term "data flow diagrams" as a graphical computer program whose execution follows a set of semantic or operational rules as follows:

1. the order of operations is not completely specified by the user;

2. the order of operations is implied by data interdependencies;

3. a node may only execute after all necessary inputs have become available, and;

4. outputs are generated after a node completes execution.

Nat'l Instruments Corp. v. Mathworks, Inc., 2002 U.S. Dist. LEXIS 27577, No. 2:01-CV-11 (E.D. Tex. May 24, 2002) ("Claim Construction Opinion and Order") (emphasis added). The trial court determined that the written description did not provide an explicit definition of the terms "data flow" and "data flow diagram," but the disclosure did use the terms according to the semantic principles in a consistent way. MathWorks contends only that the word "necessary" was erroneously added to the court's interpretation and that the proper construction should require "all inputs" to be available before a given block may start and complete execution.

The trial court did not adopt the proposed definition offered by either party but instead drafted its own based upon the intrinsic evidence. We agree with the court's interpretation. MathWorks proffered the word "necessary" as a qualifier for "inputs" throughout its claim construction briefing. MathWorks proposed that "a node may only execute once it has received all necessary inputs," and "an operation may only execute once it has all necessary inputs available." As to part three of the semantic principles, the trial court essentially adopted MathWorks' proposed definition, which MathWorks now attempts to disavow or modify. See Metabolite Labs., Inc. v. Lab. Corp. of Am. Holdings, 370 F.3d 1354, 1364 (Fed. Cir. 2004) (a party will be judicially estopped from asserting a claim construction inconsistent with a position it advocated at trial and persuaded the trial court to adopt). We agree with the trial court that the inclusion of "necessary" was proper given that the ordinary meaning of "data flow" and "data flow diagram" does not limit the scope of the terms to await inputs that may be unnecessary for execution, and, likewise, the specification does not limit semantic limitation three to require "all inputs" to be available before execution.

The portions of the specification relied upon by MathWorks concerned embodiments that describe the operation of certain nodes as "in accordance with data flow principles." See, e.g., 221 patent, col. 11, ll. 43-44. This language, directed to certain embodiments, is insufficient to limit "data flow" or "data flow diagrams" because the patents do not manifest an intent to impart a special meaning to the terms and the broader language of the claims only require that nodes wait for inputs that are then needed, not "all inputs." See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001) ("unless compelled to do otherwise, a court will give a claim term the full range of its ordinary meaning as understood by an artisan of ordinary skill").
d. “data for servicing and/or programming”

Plaintiffs contend that the term “data for servicing and/or programming of said at least one multimedia box” should be given its plain and ordinary meaning: “data used to service and/or program one or more multimedia boxes.” Opening Brief at 28. Defendants' proposed construction is “data exclusively transferred over the third data link to service and program the multimedia box.” Resp. Brief at 29.

Defendants base their proposed construction on the same arguments used to support their proposed construction of the phrase “third data link.” As described above, see Section 7(c) supra, the Court has rejected defendants' proposed construction of that term. The claim cannot be limited to allowing servicing and programming data to travel only over the third communication link when a preferred embodiment of the third link is composed of the first and second link in series.

In addition, defendants' proposed construction would unnecessarily import limitations that do not appear in the claim. The claim says that the third data link “can” carry data for servicing and programming. Opening Brief, Ex. 7 at 6:65. It does not define the data as being carried only over the third link. Finally, as described above, plaintiffs did not adopt this limitation during prosecution. See Section 7(c) supra. The Court construes the term as meaning “data used to service and/or program one or more multimedia boxes.”

H. "Data Gathering System" ('042 Patent)

The '042 patent discloses a system and method for generating reports based on data gathered from multiple Internet sites. "Data gathering system" appears in both independent claims (claims 1 and 8) of the '042 patent. CashEdge asserts in the joint claim construction statement that "data gathering system operating on the portal system, gathering data from multiple Internet sites specifically associated to, and storing secured information person to the requesting user" should be construed as being written in means-plus-function format, although its brief contains no argument on this. Yodlee asserts that it is not written in means-plus-function form, and proposes that "data gathering system" be construed to mean "a gatherer or software gathering agents, which is a software component and/or related data that once processed can be employed to locate and retrieve information from Internet destinations based on user or enterprise request." The presumption against means-plus-function analysis applies given that the language above is not written in means-plus-function language. In light of this presumption, the Court believes that there is sufficient structure in claim 1 of the '010 patent to establish that the "data gathering system" is software. Accordingly, the Court does not construe this claim in means-plus-function terms.

Yodlee's construction is similar to its construction for "gatherer" from the '077 patent. The Court agrees that the term "data
E) "data communication facility"

Citrix asserts that this is a mean-plus-function pursuant to 35 U.S.C. Section 112, paragraph 6.

Use of the term "means" creates a presumption that the element is to be construed in accordance with Section 112, paragraph 6. This presumption may be rebutted, however, when claim element recites sufficiently definite structure or material to perform the claimed function. Absence of the term 'means' creates a presumption that the element is not to be construed in accordance with Section 112, paragraph 6. However, this presumption may be rebutted when the claim element does not recite sufficiently definite structure or material to perform the claimed function. In determining whether these presumptions have been rebutted by a preponderance of the evidence, the court may examine the intrinsic evidence and any relevant extrinsic evidence.

Schwartz, supra, § 5.III.C.

There are four permutations of "communication facility" at issue here, and Citrix asserts that all of them are subject to Section 112, paragraph 6. The court disagrees. The four permutations are as follows: 1) "Data Communication Facility"; 2) "Location Facility"; 3) Communication Facility"; 4) "Data Generating Facilities."

None of these four permutations use the word "means" and Citrix fails to rebut the presumption that this is not a means-plus function by a preponderance of the evidence. The court agrees that the specification provides a clear description of the "facilities" and particularly the "data communication facility" as a computer software product. Indeed, the specification provides that "a number of computer program facilities are described in this invention as separate facilities for the sake of describing the invention." '479 Patent, col. 10, lines 11-13. Therefore, the court concludes that 01 Communique's proposed construction is correct, which is "Computer software associated with the personal computer."

T) "data generating facilities"

As detailed in section E), the court agrees with 01 Communique that the appropriate proposed construction is "Computer software that generates data, such as voice message reception, fax reception, e-mail retrieval, alarm monitoring facilities, child monitoring facilities and the like."

The defendants support a narrow definition of "data in digital form," limiting it according to the specification to "measurement data," or numbers taken from measurements of the lip positions of the foreign face and the actor/translator's face. 4 This argument encompasses two purported limitations: first, that the data is derived from manual measurements, and second, that the "control points" which define the standard curves are not included in the definition. Bloomstein argues that limitations of the preferred embodiment should not be imported into the claims so the data need not have been developed from manual measurements, and that data in digital form includes control points.

--- Footnotes ---

4 The defendants rely on the following language from the specification:

The actor with the new language records the new language on a recording medium 4 . . . and at the same time the lip movements and configurations of that actor are video-taped, displayed and measured. This information is converted into
digital form. Similarly, the head and lip movements of the actor in the film are measured together with head movements. This information is converted into digital form. The two groups of data are compared in a programmed computer to provide a measure of the amount of correction that must be made to the lip movements of the foreign film actor to bring those lip movements, along with facial movements, into positions which correspond to the new language sound to the new actor.

Joint Memorandum, Ex. A at column 4:24-37. Bloomstein's identification of the lip movement measurements as "data" after conversion to "digital form" does not compel the conclusion that data in digital form can be comprised only of the measurement data. This excerpt is equally consistent with measurement data being merely a type of data in digital form.

The Federal Circuit has held that "particular embodiments in a specification will not be read into the claims when the language is broader than such embodiments." Electro Medical Sys. v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994). Absent ambiguous language in the claims that lends itself to the defendants' narrow construction, the court declines to limit "data in digital form" to data developed from manual measurements (or automated measurements, for that matter). The defendants argue, and Bloomstein does not dispute, that the only preferred embodiment disclosed uses manual measurements to record the lip movements of both the face in the unaltered cinematic work and the face of the translator/actor. However, the claim language is unambiguously broader than the embodiment described in the specification, so the court declines to read the limitations of the specification into the claim. "Data in digital form" should not be limited to data derived from measurements of the foreign face or the actor/translator's face. The question remains, however, whether "control points" are included in the definition of data in digital form.

The language of the claim itself is ambiguous as to whether control point data is included in the definition. Claim 1 begins by describing a method for altering a motion picture to conform to a new facial display with "lip movements" significantly different from the original. The specification consistently uses the term "lip movements" to refer to the lip positions, not the control points of the standard or working curves. However, the subsequent language refers more broadly to the "configuration" of the facial displays. The ordinary meaning of "configuration" is "a relative arrangement of parts." Webster's New Collegiate Dictionary 237. This definition could easily include both the lip movements and the standard curves of the foreign face's lips, which are represented by control points.

The defendant's primary contextual argument is that "data in digital form" must mean the same thing when it modifies the "second facial display" as it does when it modifies the "first facial display." In other words, they argue that because "data in digital form representing the configuration of the second facial display" refers only to the measurements of the actor/translator's lip positions, "data in digital form representing the configuration of the first facial display" must be similarly limited to measurements of the foreign face's lip positions and cannot possibly include control point data. Defendant reaches this result only by conveniently truncating the phrases before they diverge and refer to the different facial displays. By identifying the different uses of the two facial displays, the specification contradicts defendant's construction. While the second facial display is used only to calculate the lip position data corresponding to the new language, the first facial display is used to develop both lip position data and control point data for the standard curves. 5 The court construes "data in digital form representing the configuration of the first display" to include both lip position data and control point data. "Data in digital form representing the configuration of the second display" is construed to include only lip position data.

5 It has been found that only a limited number of measurements need be taken on the new language lip movements, as shown in FIG. 3. Generally speaking the measurements taken are upper height 26, lower height 28, inner width 30 and outer width 32.

The existing or "foreign" head and lip movements on the film are measured by the operator viewing the frames from the film or from the screen projection of a video tape. . . . Like the lip movements of the new language referred to previously, the existing lip movements are measured to include the same measurements as in FIG. 3.
Before introducing the data relative to the lip movement measurements shown in FIGS. 3 and 4, the operator identifies and defines control points for standard curves to characterize the actor in the section of the film being processed. While the new and original lip movement measurements will be used to control the amount of alteration of each frame the standard facial curves will control the location of the alterations. Only a small number of control points need be defined to characterize the actors [sic] face in the film for resynchronization to the new sound.

The standard curves are defined by measuring and transcribing the X, Y coordinates of operator-selected control points shown for example in FIG. 8 with respect to the open upper lip curve 94. The same procedure is followed with respect to the other [standard] curves. Normally, control points for the lip curves include a blend point at the cheeks 1a, 7a, the corners 2a, 6a, the center 4a and one or two points on either side of the center end corner 3a, 5a.

The operator can measure the X, Y coordinates of the standard curve control points in a manner similar to measuring the head and lip movements earlier described.

6 Contrary to defendants' argument, the court's construction does not attribute two different meanings to the same language. "Data in digital form" is given the same, ordinary meaning in each clause. In other words, that phrase alone could include both control point data and lip position data for both facial displays. However, the specification clarifies that only the first facial display need be characterized by control point data to define its standard curves. No standard curves are required for the second facial display. The claim clearly allows such a divergence in construction by providing separate "generating" steps for the first and second facial displays.

GO BACK

1115
e. data in packetized format from any of said sources is written into any available empty payload field of any of said frames

In disputing the meaning of this phrase, Bellcore contends that this phrase means that packetized data can be placed into the payload field of any frame interval whenever a complete data packet becomes available. To this effect, Bellcore contends that the circuit does not wait for a particular frame or predetermined time to output the packet. Bellcore relies on Figures 4 and 12 of the '306 Patent in support of its argument. (D.I. 142 at 29).

In response to Bellcore's interpretation, FORE contends that this language means that packets are only put in frames that have zero data in their payload. FORE directs the Court to the "Summary of the Invention" section of the specification, which provides:

Illustratively, a DTDM multiplexer may be used to merge traffic from three different communications sources or tributaries into a single DTDM bit stream. The available frames are shared by the three tributaries by giving higher priority to the circuit tributary, and allowing the voice and graphics tributaries to contend on a first-come, first-served basis. The circuit tributary seizes one out of every three empty frames passing by... In this case the voice tributary will on average seize one out of every 2,160 frames. Similarly, at a rate of 1 Megabit per second, the graphics tributary will fill one frame out of 150. In this way, three diverse data streams are multiplexed into a single bit stream.

( '306 Patent, col. 5, lines 13-38 (emphasis added)). According to FORE, this description of the invention makes it clear that each source detects and then "seizes" empty frames. FORE contends that once a packet is inserted into a frame, it is no longer empty so other sources will not seize the filled frame. Rather, if another source has a packet to send, it will insert its packet into the next "available empty frame."

The Court agrees with FORE's proposed construction. Indeed, this construction is consistent with the Court's conclusion that an empty payload field has zero data in it. In addition, the Court believes this interpretation is consistent with the description of the invention contained in the "Summary of the Invention" section of the specification of the '306 Patent. In the Court's
view accepting Bellcore's proposed construction of this phrase would read the word "empty" out of the claim language. In Bellcore's own words its construction would allow "any packet to be written into any frame." (D.I. 142 at 29). This construction is at odds with the claim's express language which requires the data to be written into "any available empty payload field of any of said frames." Accordingly, the Court concludes that the phrase "data in packetized format from any of said sources is written into any available empty payload field of any of said frames" means that packets are only put in frames which are empty, i.e. which have zero data in their payloads.

I. "said advertisement data includes at least one time for said at least one advertisement to be run"

The dispute regarding this term centers on the definition of the words "at least one time." Touchtunes proposes that term be construed as "at least one predetermined time," whereas Arachnid proposes that it be construed as "data which permits a determination of a time within which, or event in relation to which, said advertisement will be run." Touchtunes notes that the patents describe the object of "the present invention" as having the jukebox run downloaded advertisements "at specified times." '398 Patent 2:43-48; '834 Patent 2:52-57. In discussing the only embodiment relating to the "at least one time" (or "when") the advertisement is to be run, the patents teach that the management system tells the jukebox "at what times" the advertisement should be run and that "[t]he advertisements can then be displayed at the predetermined times on the visual display 125." '398 Patent 9:4-8. While "at least one time" (or "when") could refer to a specific time of day, nothing in the language cited by Touchtunes requires such a limitation: it is clear that "at least one time" can refer to a time related to an event, not merely a time of day. The specification even contemplates the possibility that an advertisement may not be run at all. See '398 Patent 9:17-21. This suggests that "at least one time" must include an event in relation to which the advertisement should be run, such that if the event does not occur, the advertisement does not run.

Furthermore, it is improper to import the limitations from the preferred embodiment cited by Touchtunes into the claim term. See Phillips, 415 F.3d at 1320.

For these reasons, the Court agrees with Arachnid and construes the term as "data which permits a determination of a time within which, or event in relation to which, the advertisement will be run."

4. "Data loading mechanism for loading at least fact data from the relational data store"

For the same reasons as for the previous terms, the court concludes that the term "data loading mechanism" as used in claims 4, 5, 17 and 18 would connote sufficient structure to one skilled in the art to build that component. Accordingly, the court rejects Hyperion's proposed means-plus-function construction and declines to construe this term.

6. "data mart"

The term "data mart" appears in several claims of the '374 patent (claims 1-5, 7-12). Informatica proposes the construction "Software that extracts, transforms and loads data into one or more databases, where the database(s) contain a subset of corporate data useful for decision support for an aspect of a business." BODI proposes the construction "An analytical database containing a subset of corporate information useful for decision support for an aspect of a business."

The crux of the parties' dispute is whether a data mart in the context of the '374 patent is limited to a passive database or incorporates both the end product target database and the associated metadata and applications used to build and maintain a
data mart database, i.e. a data mart environment. Informatica posits that the term data mart and the term data mart application should be construed similarly. The Court finds that there is no support in the patent for this proposition and declines to adopt Informatica's proposal. In addition, while the Court is mindful that the patent as a whole teaches a "method and system for accessing and sharing metadata amongst a number of data marts through the use of object referencing," neither the specification nor the claims describe data marts as having software functionality.

--- Footnotes ---

2 The parties previously reached an agreement regarding the construction of data mart application. They agree that a data mart application is software that extracts, transforms and loads data into one or more databases, where the database(s) contain a subset of corporate data useful for decision support of an aspect of a business.

--- End Footnotes ---

The specification states that a "data warehouse is comprised of an analytical database containing information useful for decision support." "Data marts are similar to data warehouses, except that data marts usually contain only a subset of corporate data which is directed towards a singles aspect of that business (e.g., a separate finance data mart, sales data mart, human resources data mart, etc.)." BODI's proposed construction combines these two concepts and moreover, comports with the ordinary meaning as understood by one skilled in the art.

The Court adopts BODI's construction and construes the phrase "data mart" to mean: An analytical database containing a subset of corporate information useful for decision support for an aspect of a business.

1119

TERM # 8: "data messages" - Again, this is not a complex technical term, and is assigned no special meaning by the intrinsic record. Defendants' citation to intrinsic evidence does not support their proposed construction to limit the content of the messages to the bid itself. In the context of the patent, this phrase means: "information associated with an electronic auction in a form suitable for processing by a computer."

1120

A. Data Objects (Claims 8, 10, 11)

HP contends that the term means "data records and their associated manipulative programs." Intergraph states that the term means "a data record containing at least one other data record and a link to the other data record's manipulative programs."

HP's proposed construction relies heavily on the definitions of "data objects" found in the '208 specification. The specification states that "[a] data-object is a data record that has a link to its manipulative programs." '208 Patent, col. 4:65-67. The specification also states that "each data record and its manipulative programs . . . still function as a data-object." '208 Patent, col. 5:11-12. HP contends that the '208 Patent inventors clearly intended to act as a lexicographer and give express definition to the term "data objects."

Intergraph's proposed construction relies heavily upon the language in Claim 8 of the '208 Patent. Claim 8 states that a computer graphics program for designing a system includes "a plurality of data objects, each having data records representing primitive elements in said system and a plurality of manipulative programs linked to each data record . . ." Based on this language, Intergraph concludes that a data object must contain multiple data records and that a "link" must exist between a data record and its corresponding manipulative program.

The Court disagrees with Intergraph's interpretation that a data object must contain more than one data record. Contrary to Intergraph's argument, this interpretation is not supported by the claim or specification language. The specification often refers to a data object as manipulative programs that are linked to a single, as opposed to multiple, data records. See '208
With regard to Claim 1 of the '002 Patent, the parties request that the court begin by construing the term "data packet," which appears throughout the text of the claim. 18 Papyrus contends that the term "data packet" means "a unit of data sent across or over a network," a definition consistent with the varied use of the term in the written description of the patent. Pl. PCCO 3; Pl. Br. 22, 24; Markman Hr'g Tr. vol. 2 at 23. According to Papyrus, because the written description employs the term "data packet" in various contexts, the term denotes different units of data at different points in the communication process. Pl. Br. 24. For example, Papyrus argues that "data packet" refers to (a) an execution report, '002 Patent col. 17 ll.47-51; (b) a unit of data containing a broker identification number, id. at Fig. 14 step 720; (c) a transmission packet, id. at Fig. 15 step 740; and (d) a network packet, id. at Fig. 16 step 782. In addition, Papyrus also argues that a data packet may not necessarily be ready for transmission. Markman Hr'g Tr. vol. 2 at 31. As Figure 14 shows, it is only when the data packet is ready for transmission that the device adds a broker identification number to the packet so that it can be addressed to the broker. See '002 Patent Fig. 14 step 720. That step 738 of Figure 15 also shows the addition of address information to an outbound packet also indicates that the packet does not necessarily contain address information at all times. See '002 Patent Fig. 15 step 738.

18 Although they propose different constructions, the parties agree that "data packet" and "packet" are synonymous. Pl. MHSP vol. 2 at 4.

NYSE proposes a definition in which "data packet" is construed as "a group of binary digits, including data and control elements." Def. PCCO 3. During oral argument, NYSE maintained that the minimum unit of data that can be transmitted necessarily includes address information. Def. MHSP 135. To illustrate this point, NYSE analogized data to the contents of a letter and "data packet" to the envelope and letter together, where the letter cannot be delivered if the envelope has no address. Id. at 136; Markman Hr'g Tr. vol. 2 at 39.

Because neither party cites a portion of the patent specification or the prosecution history to support its arguments, the court is left with the task of construing an ambiguous term. Where ambiguity surrounds a term in the patent, the court may employ extrinsic evidence, such as dictionary definitions to guide its analysis. See Vitronics Corp., 90 F.3d at 1583. In this case, Papyrus relies on several dictionary definitions of "packet" to support its position. See Comprehensive Dictionary of Electrical Engineering (1st ed. 1999) ("EE Dictionary"), Pl. App. Ex. 53 at 521 ("a unit of data which is sent over a network"); Free On-Line Dictionary of Computing (1993), Pl. App. Ex. 54 at 520 ("[t]he unit of data sent across a network"); Newton's Telecom Dictionary (8th ed. 1994), Pl. App. Ex. 52 at 516 ("[a] bundle of data, usually in binary form, organized in a specific way for transmission"); Internet User's Glossary 37 (1993), Pl. App. Ex. 55 at 522 ("a unit of data sent across a network"); Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1308 (Fed. Cir. 2003) (holding that "varied use of a disputed term in the written description attests to the breadth of a term rather than providing a limiting definition.").

NYSE, in contrast, cites only to The New IEEE Standard Dictionary of Electrical and Electronic Terms (5th ed. 1993) ("5th IEEE Dictionary"), which defines "packet" as "[a] group of binary digits including data and control elements which is switched and transmitted as a composite whole." 19 Pl. App. Ex. 56 at 530.
Papyrus challenges NYSE's choice of dictionaries, arguing that the court should instead consider The IEEE Standard Dictionary of Electrical and Electronics Terms (6th ed. 1997) ("6th IEEE Dictionary"), which defines "packet" as "a group of binary digits including data and control elements which is switched and transmitted as a composite whole" where "[t]he data and control elements and possibly error control information are arranged in a specified format." Pl. App. Ex. 57 at 541. Papyrus claims that NYSE's definition from the fifth edition is "narrow" and "context-dependent" on the facsimile field, based on its reference to standard # 168-1956, which was limited to the facsimile field and later withdrawn. 20 Pl. Br. 23.

While the origins of the definition arguably do not apply to the field at hand, the court may still consider the IEEE definition during its claim construction. The court need only consider those dictionary definitions that were "publicly available at the time the patent is issued," as they will be "reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art." Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002). That the definition specifically includes the parenthetical "data communication," also suggests that the definition applies in all data communication contexts, not just those related to facsimiles. See Pl. App. Ex. 56 at 530.

Even if the IEEE definition did not apply in this context because of its origins, Papyrus's other dictionary sources also indicate that a data packet contains address and control elements. For example, in its entirety, Newton's Telecom Dictionary defines "packet" as

[a] bundle of data, usually in binary form, organized in a specific way for transmission. Three principal elements are included in the packet: 1. Control information -- destination, origin, length of packet, etc., 2. the data to be transmitted and 3. Error detection and correction bits.

Pl. App. Ex. 52 at 516 (emphasis added). Similarly, the complete definition in the EE Dictionary states that a "packet" is "a unit of data which is sent over a network. A packet comprises a payload containing some data, and either a header or a trailer containing control information." Pl. App. Ex. 53 at 521 (emphasis added).

"[B]ecause words often have multiple dictionary definitions . . . the intrinsic record must always be consulted to identify which of the different possible dictionary meanings of the claim terms in issue is most consistent with the use of the words by the inventor." Texas Digital Sys., Inc., 308 F.3d at 1203. Should "more than one dictionary definition [be] consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings." Id. Taking into consideration the patent specification and the multiple definitions cited, the court construes the phrase as "data in binary form, including address and control elements."
The parties request construction of three different types of "paths," as well as resolution of a global issue pertaining to all "paths" in the asserted claims. The three disputed uses of the term "path" appear in Claim 1 of the '654 patent:

1. A teleconferencing system for conducting a teleconference among a plurality of participants, comprising:
   (a) a plurality of workstations, each workstation having first and second monitors and in communication with audio and video (AV) capture capabilities;
   (b) a data path in communication with the plurality of workstations, over which data can be shared among the plurality of participants; and
   (c) an AV path in communication with the plurality of workstations, along which AV signals, representing video images and spoken audio of the participants, can be carried;

   wherein, the system is configured to reproduce images, based on data signals shared along the data path, on at least two first monitors so as to permit participants associated with the workstations having the two first monitors to interactively share the reproduced images and reproduce participant video images, based on AV signals carried along the second path, on at least two second monitors.

'654 patent at 41:36-55.

A. "path"

Tandberg argues that each type of claimed path must be "defined" or specified before data or AV signals are transmitted. Tandberg argues that the claim language compels this finding. For example, claim 15 states that the data conferencing control establishes "communications with the central control manager to set up requested data paths along a second network over which the data conference can be conducted." '654 patent at 44:3-9. According to Tandberg, once the central control manager has "set up" the path (which occurs before transmission takes place), the path has been defined.

This argument depends on the meaning of "set up." For Tandberg's argument to be valid, "set up" must mean "define." The phrase "set up," however, encompasses other meanings, such as "establish" or "make ready." See, e.g., Webster's Third New International Dictionary of the English Language Unabridged 2079 (1993) ("to put (a machine) in readiness or adjustment"); Random House Unabridged Dictionary 1751 (2d ed. 1993) ("to be assembled or made ready for use") (emphasis added). Moreover, as discussed below, Tandberg's narrow construction would exclude all of the embodiments disclosed in the specification, which unquestionably make use of opportunistic routing and do not require predefined paths.

Tandberg next points to Figure 4 of the patent, which depicts different routes that an AV signal may take through the Wide Area Network ("WAN"). The portion of the Specification corresponding to Figure 4 states that "[t]he system also provides optimal routes for audio/video signals through the WAN. For example, in Figure 4, location A can take either a direct route to location D via path 47, or a two hop route through location C via paths 48 and 49." Spec. at 10:55-59. The fact that data can take one of two routes, however, says nothing about whether the choice of route is predetermined. Indeed, Tandberg observed at argument that in packet-switched networks such as those described in the Specification, the route through the WAN could change during the middle of a transmission, depending on network load and other factors. The routing of each packet through a packet-switched network is individually determined and can change to adapt to changing network conditions. See Spec. at 10:63-66 ("In a more complex network, several multi-hop routes are typically available, in which case the routing system handles the decision making, which for example can be based on network loading considerations.").

Tandberg's remaining arguments in support of its contention that all paths must be predefined relate to a different question—whether the AV and data paths must lie on physically separate wires. The court considers these arguments below. The fact that signals may travel on different wires, however, is not determinative of whether the path for each signal individually is pre-defined. The court will therefore not limit the claim terms as Tandberg requests, and construes "path" to mean "a route or course."

B. "AV path"
CPI argues that the "AV path" should be construed to mean "a route or course over which audio and/or video (commonly abbreviated 'AV') information travels for real-time delivery." Tandberg does not expressly offer a construction of "AV path," but suggests in its papers that the AV path must be physically separate from the data path.

In an earlier litigation involving the '654 and '547 patents, Judge Chesney of this district has already construed the terms "AV path" and "data path" and rejected the very argument which Tandberg advances in this case. Collaboration Props., Inc. v. Polycom, Inc., No. C 02-04591, slip op. at 27 (N.D. Cal. Mar. 23, 2004). The Polycom court reviewed the intrinsic record and concluded that the claimed inventions cover both the preferred embodiment, in which AV and data signals travel over two separate physical paths, and alternate embodiments in which the AV and data signals travel on the same wire through the use of multiplexing. Id. at 26. With respect to arguments already presented to the Polycom court, this court has not been given a compelling reason to revisit them. See, e.g., id. at 25 (noting that "claim 29 of the '547 patent requires the data path and AV path to be on a single set of wires."). This court further notes that the AV and data paths may pass through a common "switch"; a physically separate AV switch is not required. The Specification makes clear that in an all-digital implementation, "a common switching vehicle (e.g. ATM) could be used." Spec. at 7:16-18. The court therefore adopts the Polycom court's finding, as augmented above, that the AV and data signals may travel on logically separate "paths," via multiplexing, while traveling over the same physical wires and while being routed through the same switching mechanism.

Tandberg offers several additional arguments not discussed by the Polycom court. First, Tandberg argues that CPI conceded during prosecution that AV and data signals are transmitted along two different network paths. The examiner rejected certain claims for indefiniteness because "applicant should clarify the nature of the associations as claimed in respective claims where the word 'associated' is used This is especially true where there are two different network paths and two monitors in the system." Day Dec., Exh. F P 20. According to Tandberg, CPI did not dispute the examiner's characterization, and cannot now allege that AV and data signals may travel along the same path. This argument is unavailing because, among other reasons, the examiner's observation that there are two "paths" says nothing about whether the two paths must travel on two separate physical wires. As the Polycom court noted, claim 29 of the '547 patent expressly covers two logical "paths" on the same physical wire: "A method for conducting a teleconference . . . over at least one unshielded twisted pair of wires defining both a UTP data path and a UTP AV path." '547 patent at 45:1-4 (emphasis added).

Second, Tandberg argues that CPI conceded that physical separation is required in response to another rejection by the PTO, in which the examiner challenged claims in which data and video were displayed on two separate monitors. In response to the rejection, CPI identified Figure 18B of the patent, which shows separate physical connections from the AV and data networks. As CPI points out, however, the examiner was concerned with the narrow question of how the display could be split between two monitors, and not the broader question of whether AV and data signals could travel along the same physical wire at some point. See Supplemental Frahn Dec., Exh. 1(a) at 4-5.

Third, Tandberg argues that CPI limited the scope of the invention in the '654 patent in response to a restriction requirement which compelled CPI to choose between inventions with two physical paths and inventions with one physical path. The restriction which the examiner imposed divides the claims into two groups: a group "drawn to a teleconferencing system having two networks and two monitors" and a group "drawn to a teleconferencing apparatus having a unitary housing." Id. at 2. The '654 patent issued from the first group.

Tandberg's reliance on this portion of the prosecution history is misplaced. As an initial matter, it is not clear from this restriction what the salient difference between the two groups is. The description of the second group suggests that the important distinction is the number of monitors-requiring a "unitary housing" as opposed to "two monitors." The second group is not limited to a single network. Also, as CPI points out, the applicants submitted amended claims in response to the examiner's rejection in which they eliminated the requirement of a first and second network. Id., Exh. 1(b) at 2. The final claims on the '654 patent issued in substantially the same form. Finally, to the extent the restriction requires two separate "networks," it does not require that the networks make use of separate physical wires.

Fourth, Tandberg argues that the multiplexing embodiment, in which data and AV signals travel over the same wire, is not enabled, and therefore should not be included within the claims. As CPI points out, however, it is now clearly established law that claims should not be construed to preserve validity unless they are truly ambiguous in all other respects. See Phillips, 415 F.3d at 1327 ("we have limited the maxim [that claims should be construed to preserve their validity] to cases in which 'the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous.'"). Here, in particular, claim 29 of the '547 clearly requires that both paths travel along the same physical wire.
LizardTech, Inc. v. Earth Resource Mapping, Inc., 424 F.3d 1336 (Fed. Cir. 2005), reh'g en banc denied, 433 F.3d 1373 (Fed. Cir. 2006), cited by Tandberg, is not to the contrary. The LizardTech court invalidated a patent for lack of enablement rather than revise the claim construction to exclude the non-enabled subject matter. Id. at 1346-47 ("Therefore, we affirm the district court's judgment that claims 21-25 and 27-28 are invalid for failure to satisfy the requirements of section 112."). Tandberg has the burden of proving lack of enablement at a later date, by clear and convincing evidence.

Finally, Tandberg argues that the Polycom claim construction is inconsistent in that it provides both for paths that are physically separate and paths that are not. The Polycom court only noted, however, that certain claims expressly require varying degrees of physical separation while others do not. Nothing about this holding is inconsistent.

The court therefore adopts the Polycom construction; "AV path" means "a route or course over which audio and/or video (commonly abbreviated 'AV') information travels for real-time delivery."

C. "data path"

Tandberg offers the same arguments with respect to "data path." Having rejected them, the court adopts the Polycom construction: "a route or course over which information represented in a form suitable for processing by computer can travel, but such information does not include AV signals."

28. Data path

The term "data path" is construed to mean "the buses and circuit elements that convey data."

5. Disputed term in AMD's '200 patent: Data pattern (claims 1-3, 5-8, 11-13, 15-17, 19)

1. A configuration register for controlling a logic testing circuit, said logic testing circuit being coupled to a logic module for testing the integrity of said logic module, said logic testing circuit having a normal state and a low power state, said configuration register comprising:

   a key input disposed to receive a key signal;

   a reset input disposed to receive a reset signal;

   an output coupled to said logic testing circuit;

   a key logic circuit coupled to said key input, said reset input, and said output, said key logic circuit generating to said logic testing circuit, through said output, a control signal responsive to said key signal and said reset signal;

   wherein said control signal drives said logic testing circuit to said low power state when said reset input is triggered by said reset signal; and

   wherein said control signal drives said logic testing circuit to said normal state when said key signal matches a predetermined data pattern.

2. The configuration register of claim 1 wherein said control signal is a clock signal when said key signal matches said predetermined pattern, and wherein said output is coupled to a clock port of said logic testing circuit.
3. The configuration register of claim 2 further comprising a clock input coupled to a clock signal source, said clock signal being generated responsive to a signal generated by said clock signal source.

5. The configuration register of claim 3 further comprising a NOR gate, wherein said key logic circuit and said clock input are coupled to said output through said NOR gate.

6. A circuit arrangement comprising:

a logic component having a logic module and a built-in logic testing circuit, said logic testing circuit being coupled to said logic module for testing the integrity of said logic module and having a normal state and a low power state, wherein said logic testing circuit may be disabled to save power when testing operations are not being performed;

a configuration register for controlling said logic testing circuit, said configuration register comprising

- a key input disposed to receive a key signal,
- a reset input disposed to receive a reset signal,
- an output coupled to said logic testing circuit, and
- a key logic circuit coupled to said key input, said reset input, and said output, said key logic circuit generating to said logic testing circuit, through said output, a control signal responsive to said key signal and said reset signal;

wherein said control signal drives said logic testing circuit to said low power state when said reset input is triggered by said reset signal; and

wherein said control signal drives said logic testing circuit to said normal state when said key signal matches a predetermined data pattern.

7. The arrangement of claim 6 wherein said control signal is a clock signal when said key signal matches said predetermined data pattern, and wherein said output is coupled to a clock port of said logic testing circuit.

8. The arrangement of claim 7 further comprising a clock signal source, wherein said configuration register further comprises a clock input disposed to receive said clock signal from said clock signal source.

11. The arrangement of claim 6 wherein said logic testing circuit has a clock port and wherein the state of said logic testing circuit is responsive to a signal at said clock port.

12. The arrangement of claim 11 wherein said output is coupled to said clock port, said logic testing circuit is driven to said low power state when a LOW is applied to a clock port, and wherein said control signal is LOW when said reset input is triggered by said reset signal.

13. The arrangement of claim 11 wherein said output is coupled to said clock port, said logic testing circuit is driven to said normal state when a clock signal is applied to a clock port, and wherein said control signal is a clock signal when said key signal matches said predetermined data pattern.

15. A circuit arrangement comprising:

a logic component having a logic module and a built-in logic testing circuit for testing the integrity of said logic module, said logic testing circuit being coupled to said logic module and having a normal state and a low power state, said logic testing circuit further having a clock port, wherein the state of said logic testing circuit is responsive to a control signal applied at said clock port, wherein said logic testing circuit may be disabled to save power when testing operations are not being performed;

a configuration register for controlling said logic testing circuit, said configuration register comprising
a key input disposed to receive a key signal,

a reset input disposed to receive a reset signal,

a clock input disposed to receive a clock signal,

a signal output coupled to the clock port of said logic testing circuit,

a key logic circuit coupled to said key input and said reset input, wherein said key logic circuit generates a mode signal responsive to said key signal and said reset signal,

wherein said mode signal is a disable signal when said reset input is triggered by said reset signal, and wherein said mode signal is an enable signal when said key signal matches a predetermined data pattern, and

a logic gate having inputs coupled to said clock input and said key logic circuit and an output coupled to said signal output, said logic gate generating at said signal output said control signal responsive to said clock signal and said mode signal; and

wherein said control signal drives said logic testing circuit to a low power state when said mode signal is said disable signal, and wherein said control signal drives said logic testing circuit to said normal state when said mode signal is said enable signal.

17. The arrangement of claim 15 further comprising a clock signal source coupled to said clock input, said clock signal source generating said clock signal.

19. The arrangement of claim 15 wherein said key input is a multi-bit digital input and wherein said predetermined data pattern is determined by the configuration of the components of said key logic circuit.

AMD's '200 patent is entitled "Power Saving Feature for Components Having Built-In Testing Logic." The '200 patent relates to the field of "built-in testing logic" on electronic devices. 1:6-8. Built-in self testing ("BIST") logic provides a way to test whether the components of computer systems are working properly. 1:13-20. A problem with the prior art was that BIST consumed power whether or not it was being used to run a test. 1:37:45. As a result, BIST-equipped components were less efficient. Id.

The claimed invention of the '200 patent is a "configuration register" that controls a component's BIST. 1:55-57. The configuration register includes a "key logic." 1:61-63. The key logic generates a signal that puts the BIST in a low power state when it is not being used. The key logic also generates a signal that puts the BIST in a "normal" state "when the key signal matches a predetermined data pattern." 1:66-2:2. The parties dispute the meaning of "data pattern."

Both parties agree that the data pattern functions like a key and turns on a component's internal testing system. They also agree that a data pattern consists of a pattern of bits, which represent information. The dispute concerns whether (1) it is accurate to characterize the pattern as a "sequence" and (2) whether "data" can include addresses and instructions. AMD contends that data pattern should be construed as "bit sequence." Samsung's proposal is: "A pattern of bits representing information and not representing an address or an instruction."

The Court agrees with Samsung on the first disputed point. The ordinary meaning of "sequence" is "the following of one thing after another." The use of this word could suggest to the jury that the information in a data pattern arrives successively, rather than all at once. AMD does not contest that this interpretation would be incorrect because it would exclude the preferred embodiment. See 3:40-44. It is undisputed that in the context of the '200 patent, a data pattern consists of an ordered, predetermined set of data. The word "pattern" captures this ordered relationship and needs no construction.

On the second point, the Court agrees with AMD. Samsung points to no intrinsic evidence in support of the negative limitation it seeks to impose on the word "data." Instead, Samsung cites three dictionary definitions that purportedly establish that in the computer arts, the word data excludes addresses and instructions. See Haskett Decl., exs. 20-22. This
extrinsic evidence does not persuade the Court that the word "data" is includes this negative limitation. One of the dictionaries cited by Samsung defines data as: "a general term for information; also used to distinguish input and output information from instructions." See id., ex. 22 at 35. As AMD points out, this definition supports AMD's view that "data" can have a general meaning. The claims and specification place no limitations on the word data, and the Court declines to do so.

Accordingly, the Court construes "data pattern" as "a pattern of bits representing information."

4. Data Processing Device

a. The Parties' Constructions

LPL also argues that "data processing device" should be accorded its ordinary and customary meaning. Defendants urge limiting "data processing device" to a portable computer.

b. The Special Master's Constructions

Having already concluded that the invention is not restricted to a portable computer, and, additionally, the term "data processing device" not being specifically defined in either the claim language itself or the common specification of the patents, the Special Master concludes that "data processing device" should be given its ordinary and customary meaning. Vitronics, 90 F.3d at 1582.

The term "data processing device" is well known in the art. The IEEE Standard Computer Dictionary (1991) defines "data processing" as "the systematic performance of operations on data" n18 and "device" as "a mechanism or piece of equipment designed to serve a purpose or perform a function."

\[\text{Footnotes}\]

At the same time, the Special Master is of the view that the Defendants raise the meritorious argument that LPL’s construction is improper because one of ordinary skill in the art would conclude that it is not physically possible to mount a flat-panel display device to a component that is contained within the flat-panel display device -- if so, the "housing of the data processing device" would in reality be the housing of the flat-panel display device. The Special Master concludes therefore that the plain claim language "flat panel display device capable of being mounted to a data processing device ... the flat display panel ... being fixed to a housing of the data processing device" ('641 patent, claim 35) mandates that the flat-panel display device be separate from the "data processing device" so as to be able to be fixed to the housing of the "data processing device."

Accordingly, the Special Master's construction is as follows:

<table>
<thead>
<tr>
<th>CLAIM TERM</th>
<th>SPECIAL MASTER CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>data processing device</td>
<td>A mechanism or piece of equipment separate from the flat-panel display device that systematically performs operations upon data</td>
</tr>
</tbody>
</table>
A "data reference," is a term of art in the patents which the inventor defines and explains in the ’321 patent specification at column 8, ln. 30-39:

DR column 30 includes a list of DRs. A DR is a unique phrase or word which may be used in a record to refer to another record or record segment. In the context of a medical facility an exemplary DR may be as simple as "medication given", "ECG report", or "Admission NMR heartbeat". As explained in more detail below, when a processor linking feature is selected, processor 14 searches for DRs in a specified record and, when a DR is identified, links the DR to a record or record segment associated with the DR via a hyperlink or other mechanism.

It is apparent that this definition is intended to generally define "data reference" as the term is used throughout the patents in suit.

The unmistakable meaning of these terms is that there be a reference to a single, specific record which the created link retrieves. In each case the claim element includes the singular form -- "a second data record" -- clearly implying only one such record. The phrase retrieving "said record" suggests that there is a particular record to be retrieved. ’321 patent claim 1, subpart (ii)(c) requires "identifying the referenced record," further confirming that the intent to claim a reference to one particular second record.

The patent specifications unequivocally confirm the inventor's intent to limit the claims in this manner. Every example in the preferred embodiments involves the use of data references (or a data reference in conjunction with modifying references) to identify a single medical record (or record segment) for a particular patient. For example, at col. 16, ln. 28-54, describes the referencing and retrieving of the particular patient's "Admission ECG," clearly a single specific record. Column 8, ln. 34 of the ’321 patent, refers to exemplary DRs "medication given", "ECG report", or "Admission NMR heartbeat" which, in the context of a medical record with patient identification numbers and dates, point to one particular record. Column 10, ln. 32-34 explains how the invention "constructs an address identifying the referenced record and links the address to the identified DR," leaving no doubt of the requirement that one and only one record is retrievable by use of the DR.

A. Claim Construction

We here only review the district court's construction of the term "data reference." The parties do not raise on appeal any other claim construction issue, including regarding the term "address format." Upon review, we conclude that the district court erred by unduly narrowing the scope of the term "data reference" and improperly importing from the specification the limitation that the data reference only refer to one and only one possible data record.

We begin with the parties' agreement, and district court's holding, that the terms "data reference," "record reference," "specifying reference," and "reference," as used throughout the Patents-In-Suit, are interchangeable and have the same meaning. We agree. The claims and specifications of the Patents-In-Suit all indicate to a person of ordinary skill in the art that these terms are interchangeable.

As a result, we are led, as the district court was, to the explicit definition of "data reference" set forth in the ’321 patent: "A [data reference] is a unique phrase or word which may be used in a record to refer to another record or record segment." ’321 patent col.8 ll.30-32. It is well settled that a patentee may choose to be his own lexicographer and that definitions so provided will govern. See, e.g., CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) ("A claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history.") Thus we adopt this definition as the correct construction of "data reference."

The district court's error, however, was in going beyond this explicit definition to hold that a data reference may only refer to one and only one possible record. We first reject the district court's reading of the language of the asserted claims, which the court held supported its narrow construction. See Summary Judgment Order at 18. For example, claim 1 of the ’889
between records, it is a "modifier reference" and not a "data reference" according to the patent. While the word "admission" is being "used in the process" of creating a link, a "ECG" can be coupled with a modifier reference such as "admission" to specify a particular ECG record, i.e., the ‘321 patent discloses a "modifier reference" element separate and distinct from "data references" that is generally "used in the process" in the ‘321 patent requires that the reference itself refer to a record. See ‘321 patent col.8 ll.30-32. Further, the ‘321 patent simply being generally "used in the process" of creating a link between records is insufficient because the stated definition of a "modifier reference" is "one and only one," typically encompasses both singular and plural possibilities. E.g., Scanner Techs. Corp. v. ICOS Vision Sys. Corp., 365 F.3d 1299, 1304 (Fed. Cir. 2004); Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999). Claim language such as "references to the first record," ‘298 patent cl.1 (emphasis added), and "the referenced record," ‘321 patent cl.1 (emphasis added), similarly do not support the district court's narrow claim construction.

An intent to claim more narrowly and limit singular elements to one and only one such element can of course also be expressed in the specification and/or prosecution history. But the patentee did not do so here. The district court relies heavily on its observation that "[e]very example in the preferred embodiments involves the use of data references . . . to identify a single medical record (or record segment) for a particular patient." Summary Judgment Order at 18 (emphasis added). But this observation is not entirely accurate. For example, Figures 14C-E in the '889 patent depict an embodiment of the invention that shows the use of a data reference referring to multiple records. Figure 14C depicts a "conventional text document," which in this embodiment is a medical record. ‘889 patent fig.14C; id. col.10 ll.60-63. Figure 14D illustrates how the text "Catheterization Reports" in Figure 14C is replaced by hyperlinks to two other medical records, a "Radiology Catheterization Report" and a "Hemodynamic Catheterization Report." Id. fig.14D. It becomes clear from the context of the specification that the original text "Catheterization Reports" is a data reference. The specification discloses that Figures 14C-E demonstrate how "hypertext links 744 may be inserted based upon the recognition of phrases or special character sequences, such as 'Catheterization Reports' 728," and that a user can then use those hyperlinks to access either of the two referenced records. Id. col.10 l.67-col.11 l.5. Clearly, the text "Catheterization Reports" is a "unique phrase . . . used in a record to refer to another record or record segment." See ‘321 patent col.8 ll.30-32 (defining "data reference"). Equally clear is that this data reference does not refer to one and only one record but rather refers to multiple records, two in this example. In fact, not only does "Catheterization Reports" contemplate and refer to multiple possible records, but that data reference is then actually linked to multiple records in this embodiment.

Although the specifications of the Patents-In-Suit disclose embodiments in which data references refer to multiple records, the district court's claim construction would exclude those embodiments from the scope of the patents. A claim construction that excludes an embodiment of the relevant claim(s) is typically incorrect. See Vitronics Corp. v. Conception Inc., 90 F.3d 1576, 1583-84 (Fed. Cir. 1996); see also SanDisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005). And while many of the embodiments do indeed illustrate data references referring to single records, the district court's adoption of that limitation here constituted an improper importation of that limitation from the specification into the claims, especially given that other embodiments refute that limitation. See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1117 (Fed. Cir. 2004) ("[P]articular embodiments appearing in the written description will not be used to limit claim language that has broader effect.").

In sum, we hold that the district court erred in its claim construction of the term "data reference." We hold that the correct construction is "a unique phrase or word which may be used in a record to refer to another record or record segment," and that a data reference may refer to one or more than one record.

5 While we agree with Hyperphrase that the district court's claim construction was erroneous in this one respect, we do not adopt Hyperphrase's proposed claim construction: "Hypertext links, multi-media requests, key words or phrases which may be parsed from a record, temporarily stored, and used during the process of creating a link to another contextually related record." See Pet. Br. at 14. This definition is overbroad and is not supported by the claim language or the specification. Simply being generally "used in the process" of creating a link between records is insufficient because the stated definition in the '321 patent requires that the reference itself refer to a record. See ‘321 patent col.8 ll.30-32. Further, the ‘321 patent discloses a "modifier reference" element separate and distinct from "data references" that is generally "used in the process" of creating links but does not itself refer to a record. See, e.g., id. cl.1. For example, the patent teaches that the data reference "ECG" can be coupled with a modifier reference such as "admission" to specify a particular ECG record, i.e., the patient's admission ECG. Id. col.12 ll.1-8. While the word "admission" is being "used in the process" of creating a link between records, it is a "modifier reference" and not a "data reference" according to the patent.
2. Construction of the phrase "Reflecting/Concerning a Particular Selection of Dialysate"

The parties agree that the validity of most of the asserted claims of the '027 Patent hinges on the construction of the claim term "data reflecting/concerning a particular selection of dialysate to be circulated," which appears in claims 1 and 7. As such, the Court must construe this disputed claim term.

Claim 1 recites:

A kidney dialysis machine comprising:

(a) means for circulating dialysate at a dialysate conductivity through a dialysate circuit including a dialysate compartment for a dialyzer;

(b) means for circulating blood from a dialysis patient through an extracorporeal blood circuit including a blood compartment of the dialyzer; and

(c) control means operable to receive chemical-composition data reflecting a particular selection of dialysate to be circulated and to calculate from the data an expected conductivity reading of the dialysate and to automatically set conductivity alarm limits around the expected conductivity reading.

027.1 (emphasis added).

Claim 7 recites:

7. A kidney dialysis machine, comprising:

(a) a dialysate pump for circulating dialysate at a dialysate conductivity through a dialysate circuit including a dialysate compartment for a dialyzer; and

(b) a controller operable to receive non-conductivity data concerning a particular selection of dialysate to be circulated and to calculate from the data an expected conductivity reading of the dialysate.

027.7 (emphasis added).

Fresenius contends that the phrase "data reflecting/concerning a particular selection of dialysate to be circulated" should be given its plain and ordinary meaning. Baxter contends, however, that the phrase "particular selection of dialysate" means: "brand of dialysate concentrate." The Court hereby rejects Baxter's narrow construction and finds that the phrase shall be given its plain and ordinary meaning.

Baxter first argues that its construction is correct because "the specification and prosecution history of the '027 Patent establish that the microprocessor of Claims 1 and 7 receives data reflecting the particular selection of brand of dialysate concentrate in order to calculate the expected conductivity." Baxter is correct that the specification refers to the dialysate "brand." For example, the specification provides:

The software controlling the operation of the machine's microprocessor includes a routine for predicting correct dialysate conductivity. Such predictions automatically reflect the particular brand of concentrate being used, since different groups of concentrate brands require different proportioning to yield a dialysate having a correct ionic strength and electrolytic profile.

See 027:26:66-27:5 (emphasis added). However, although the Court may examine a specification when construing claims, a court is not allowed to read limitations from the specification into the claims. See Burke, Inc., 183 F.3d at 1340. In fact, it is well established that limitations unintended by the patentee cannot be imported from examples, figures, or preferred
embodiments. Phillips v. A WH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005) (en banc). Thus, even where a patent describes only a single embodiment, claims will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope. Innova/Pure Water, Inc., 381 F.3d at 1117 (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed Cir. 2004)). Importantly, as Fresenius points out, Baxter has not shown that the specification ascribes any special meaning to the phrase "data reflecting/concerning a particular selection of dialysate to be circulated." In fact, the term "a particular selection of dialysate to be circulated" does not appear anywhere in the specification.

Baxter's argument that the prosecution history supports its claim construction is also unavailing. For instance, Baxter claims that the prosecution history supports its narrow construction because the examiner requested that the language "reflecting a particular selection of dialysate to be circulated" be added to the pending claims and cited this amendment in his "Reasons for Allowance." Abernathy Decl. at Ex. 3. However, there is no indication in the record that the applicants expressly adopted the examiner's reasons for allowance or agreed that the amendments made by the examiner were made to overcome prior art. "Although prosecution history can be a useful tool for interpreting claim terms, it cannot be used to limit the scope of a claim unless the applicant took a position before the PTO that would lead a competitor to believe that the applicant had disavowed coverage of the relevant subject matter." Schwing GmbH v. Putzmeister Aktiengesellschaft, 305 F.3d 1318, 1324 (Fed. Cir.2002). Here, Baxter has simply not shown that the inventors made a clear disavowal of claim scope during prosecution.

It is also significant that Baxter's current claim construction conflicts with the construction offered by Baxter's expert, Dr. Ferraro, on the issue of infringement. For example, in his expert report, Dr. Ferraro opined that "a particular selection of dialysate" could refer to "concentration parameters of the dialysate." See McLenahan Decl. at Ex. 32. The law is clear that Baxter cannot assert that one meaning should be ascribed to a claim for the purposes of an infringement analysis and then later contend that another meaning should apply for the purposes of the validity analysis. See Amazon.com, Inc. v. BarnesandNoble.com, 239 F.3d 1343, 1351 (Fed. Cir. 2001).

Accordingly, Fresenius' argument that the disputed phrase should be given its plain and ordinary meaning is persuasive. This construction is in accord with the Federal Circuit's mandate that a court is to indulge a "heavy presumption" that claim terms carry their full ordinary and customary meaning unless the patentee unequivocally imparted a novel meaning to those terms or expressly relinquished claim scope during prosecution. Omega Engineering, Inc, v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003).

Data Regarding an Order Transaction

Furnace Brook's proposed construction for this term is "information relating to a customer's order." Overstock's proposed construction for this term is "customer name, address and order placed."

Furnace Brook argues, and the Court agrees, the language of the specification indicates that a customer may first authorize the addition of his name and address to a customer data file, and secondly, may authorize an update of the customer profile data to include any order then placed. Specifically, the specification provides:

"Preferably as part of the initial menu displayed at the customer's telephone terminal, a request for the customer's approval to include the customer's name and address in a customer data file is made. If the customer signals his approval, e.g., by depressing an appropriate key at the customer terminal, the customer's name and address will be automatically added to the customer data file. In addition, if authorized by the customer, the customer's profile data would be updated to include any order placed at that time."

'832 Patent at 8:10-19.

The specification teaches that a customer who has agreed to have his name and address recorded by the retailer, may additionally agree to have a profile updated to record the order placed. Accordingly, "data regarding an order transaction" is "the order placed by the customer."
1130

4. "data representation(s) of a lifetime(s) of the telephone call"

NICE's Construction  
Data (e.g., voice information and/or metadata) representing an entire telephone call.

Witness's Construction  
Call-centric data record of the telephone call that includes a detailed cumulative start-to-finish history of a telephone call, including all telephony events and participants. The data representation represents only the telephone call, is not event-centric, and is not construed on a 1-to-1 basis for the events during the total lifetime of a call.

The parties dispute the meaning of "data representation(s)" and "data representation(s) of a lifetime(s) of the telephone call," as used in the '570 patent (claim 6) and '345 patent (claim 14). NICE contends that Witness impermissibly seeks to import the preferred embodiment's management of recording in a "call-centric" fashion into the claim. Witness contends that the specification shows that the invention's sine qua non is its creation of a "single call record . . . [where] the call's entire history is contained in the call record," citing '570 Pat., col. 7:12-16. Further, Witness contends that NICE emphasized the event-centric versus call-centric distinction as the distinguishing feature between NICE's invention and the prior art, citing '570 Pat., col. 20:34-64 ("Previous recording systems . . . mimicked the event-oriented interfaces . . . constructed on a 1-to-1 basis for the events occurring during the total lifetime of a phone call.").

After considering the claim language and the specifications, the Court construes (1) "data representation(s)" to mean "digital representation of data," and (2) "data representation(s) of a lifetime(s) of the telephone call" to mean "Call-centric data record of the telephone call that includes a detailed cumulative start-to-finish history of a telephone call, including all telephony events and participants." Though not explicit in the abstract or summary of the '570 patent, the Court concludes that the specification reveals a call-centric compilation of data to be an indispensable element of the invention, and not merely an element of the preferred embodiment. See, e.g., ('570 Pat., col. 7:12-16; col. 26:10-20 ("The Call Record Generator (CRG) in accordance with the present invention . . . is responsible for collecting data from different sources with respect to portions of a call on various recording input channels, and merging them together into a unified call record. . . .")) (emphasis added); col. 20:34-64.) In the Court's view, the additional language proposed by Witness beyond that adopted in the Court's construction is unnecessary.

GO BACK

1131

3. "data representing a complete copy of at least one item of . . . information"

Claim 14 provides:

transmitting compressed, digitized data representing a complete copy of at least one item of audio/video information at a non-real time rate from a central processing location.

The parties dispute the proper construction of the phrase "data representing a complete copy of at least one item of information" as that phrase is used in Claim 14 of the '863 patent. The Court has already defined the phrases, "items containing information" and "information from items" in its December 14 Order. (See December 14 Order at Section 1A7-8.)
In the '863 Patent, the written description, at times, equates "items of information" with "items having information."
However, in the context of Claim 14, the Court construes "items of … information" to mean "information derived from items." With respect to the remaining words of the phrase, the Court finds that skilled artisans, reading the patent claim and written description, would give those words their ordinary and customary meanings.

The Court construes the phrase "data representing a complete copy of at least one item of information" as follows: a complete copy of information from items.

5. "data representing text, a universal resource locator, an image, and a user-selected category"

The plaintiff argues that this term means that "the information submitted to the database by the user communicating over a computer network includes text, a universal resource locator, an image, and a user-selected category." The defendant argues that the term means "data representing (I) text, (ii) the Web address of a document or other resource, (iii) an image, and (iv) a category capable of being selected and defined without limitation by the user. The parties' disagreement with respect to this term concerns the universal resource locator ("URL"). Defendant argues that the URL should be limited to a Web address. Plaintiff proposes that a universal resource locator is a unique address for a file that is accessible on the internet.

This dispute focuses on the breadth of the computer network. Defendant argues that URL should be limited to a Web address. This limitation would necessarily limit the computer network to the World Wide Web, which requires importing a limitation from the preferred embodiment to the claims. The written description, however, states that the term "computer network" is broader than the World Wide Web. See 3:65-67. Consequently, the court construes the term to mean "data representing text, a universal resource locator, an image, and a user-selected category."

a. "data representing the identity ..."

Plaintiffs contend that the term "data representing the identity of each of said advertisements" is clear and describes data that identifies an advertisement. Defendants point to language in the specification that states, "[t]he downloading and storing of advertisements is completed by the same apparatus and method as described above in connection with FIGS. 1 through 5." Id. at 9:34-36. Figures 1 through 5 refer to the downloading, storing, and use of digitized songs. They argue that "data representing the identity of each of said advertisements" is analogous to "data representing the identity of each of said songs," which appears in claim 1 of the 302 patent, and must be construed the same way. They contend that the proper construction of "data representing the identity of each of said advertisements" requires data from each of the seven fields in figure 2 of the 398 patent.

The Court rejects defendants' proposed construction. First, as explained earlier, Section 1(b) supra, song data does not need to include information in each of the fields in figure 2. Rather, it need only include data in one or more of the fields. Second, figure 2 quite clearly relates only to
song record; it says as much on the diagram. If the inventors had intended figure 2 to apply to other data such as advertisements, they would have labeled the diagram differently.

For these reasons, plaintiffs' proposed construction is not inconsistent with the specification. The language in the specification stating that advertisements are downloaded and stored using the same method “described above in connection with FIGS. 1 through 5” appears to be nothing more than a general statement that teaches how advertising data fits into the overall scheme of the computer jukebox and computer jukebox network. In any event, the limitations proposed by defendants are not part of the claim language. Even if the specification included such limitations (which it does not), it would be impermissible to import them into the claim. The Court construes “data representing the identity of each of said advertisements” as “data that identifies each advertisement.” The term has the same meaning in the 834 patent.

b. “data representing when and number of times”

Plaintiffs contend that the term “data representing when and number of times each of said advertisements is to be run” means “data associated with an advertisement that provides ... a period of time within which, or event in relation to which, the advertisement will be run; and permits a calculation of the frequency an advertisement is run within a given period.” Opening Brief at 22. Defendants contend that the proper construction is “data representing the time of day and how many times each of said advertisements is to be run.” Resp. Brief, Ex. E at 3. They argue that “when” means “the time of day” and “the number of times” means “how many times a day” based on language in the specification which states, “the header [which is downloaded with the advertisement] contains information about the advertisement including how many times a day the advertisement should be run and at what times.” Opening Brief, Ex. 5 at 9:4-8. The Court sees no proper basis to read into the claim the limitations proposed by defendants. One meaning of the word “when” is “at or during the time that.” Opening Brief, Ex. 15. This common definition plainly makes sense in the context of the claim. Defendants' attempt to define “when” as “time of day” fails; they are again trying to import
limitations from a preferred embodiment into the claim. Moreover, the specification teaches that “when” can refer to a time related to an event, not merely a time of day. Opening Brief, Ex. 5 at 2:48-51, 9:38-42. Similarly, “the number of times” is not limited to “how many times a day.” Defendants correctly point out, however, that the claim language is forward-looking. It limits the data to that which shows when, in the future, an advertisement is to run. See id. at 9:51-54 (“data representing when ... each of said advertisements is to be run”) (emphasis added). Plaintiffs' proposed construction is backward-looking, and would allow the data to include information regarding when advertisements were run (“the central management system can track the total number of times each advertisement was actually run ....”). Id. at 23 (emphasis added). Claim terms must be construed as they are used in the context of the claim itself. Phillips, 415 F.3d at 1313. The claim language is not broad enough to allow the backward-looking data proposed by plaintiffs. The Court, therefore, construes “data representing when and number of times ...” as “data associated with an advertisement that provides a period of time within which, or event in relation to which, the advertisement will be run and permits a calculation of the frequency an advertisement will be run within a given period.” The term has the same meaning in the 834 patent.

The term "data representing when and the number of times each of said advertisements is to be run" Touchtunes' proposed construction for this claim term, "data that tells the jukebox at what predetermined time each advertisement is to be run and the total amount of times the jukebox is to run each advertisement," renders the "number of times" language superfluous. If the specific time for each advertisement were included in the data, there would be no need to include data regarding the "number of times" the advertisement should be run. A construction that renders claim language superfluous is contrary to basic claim construction principles. See, e.g., British Telecomms. PLC v. Prodigy Commc'ns Corp., 189 F. Supp. 2d 101, 113 (S.D.N.Y. 2002) ("[N]o claim language may be interpreted as mere surplusage.").

The term "when" in this claim is used in a similar way as the term "at least one time" in the previous claim term and is therefore construed as "a time within which, or event in relation to which" the advertisement is to be run, as Arachnid proposes. While this may include a predetermined time of day, it may also include information describing the time to run the advertisement by reference to an event, such as before, during, or after the event.

Touchtunes proposes that "number of times" be construed as "the total amount of times the jukebox is to run each advertisement," again seeking to import limitations from preferred embodiments into the claim. Arachnid proposes instead that it be construed as "the frequency an advertisement will be run within a given period." Touchtunes correctly points out that a frequency is determined by the number of occurrences over a given period of time, and that Arachnid's construction therefore contains a redundancy. However, the jukebox's ability to track the number of times an advertisement has actually run, see '398 Patent 9:17-29, supports Arachnid's proposition that "number of times" refers to the frequency with which the advertisement will be run. If "number of times" were construed as how many times a day, as Touchtunes proposes, there
would be no reason to track the number of times an advertisement has actually run.

This term is therefore construed as "data which permits a determination of a time within which, or event in relation to
which, the advertisement will be run and the frequency an advertisement will be run." This construction eliminates the
redundant "within a given period" in Arachnid's proposed construction.

1136

B

Although this case concerns whether defendants' accused products infringe independent claims 1 and 5 and dependent
claims 3, 4 and 7 of the '273 patent, defendants' summary judgment motions only address independent claims 1 and 5. They
claim as follows:

1. A system for providing a built-in function in an ISA-compatible computer in response to activation of a selected
combination of user activated keys, comprising:

   a keyboard having a set of conventional alphanumeric and function keys and further having at least one additional
function key;

   a keyboard controller connected to said keyboard to monitor said conventional keys and said additional function key to
detect when at least one of said keys is activated, said keyboard controller having first and second interrupt signal lines
connected to said ISA-compatible computer, said keyboard controller responsive to an activation of at least one of said
conventional keys to activate a first interrupt signal to said ISA-compatible computer on said first interrupt signal line, said
keyboard controller responsive to an activation of said additional function key in combination with at least one of said
conventional alphanumeric keys to generate a second interrupt signal to said ISA-compatible computer on said second
interrupt signal line;

   a first conventional interrupt handling routine within said ISA-compatible computer responsive to said first interrupt
signal from said keyboard controller to input data scan codes from said keyboard; and

   a second non-conventional interrupt handling routine within said ISA-compatible computer responsive to said second
interrupt signal from said keyboard controller to input an identification of said activated alphanumeric key and to perform a
predetermined function selected by said identified alphanumeric key.

5. A system for servicing keyboard interrupts in an ISA-compatible computer, comprising:

   a keyboard having a plurality of keys including conventional alphanumeric keys, conventional symbol keys,
conventional function keys and conventional cursor control keys, said keyboard further including at least one non-
conventional function key, said keyboard generating a scan code in response to an activation of at least one of said keys,
said scan code varying depending upon which of said keys is activated; and

   a keyboard controller coupled to said keyboard, said keyboard controller further coupled to said ISA-compatible
computer by first and second interrupt signal lines, said keyboard controller generating a first interrupt signal on said first
interrupt signal line upon receipt of a scan code corresponding to one of said conventional keys, said ISA-compatible
computer programmed to execute a program to input said scan code in response to said first interrupt signal, said keyboard
controller generating a second interrupt signal on said second interrupt signal line upon receipt of a scan code corresponding
to said non-conventional function key, said ISA-compatible computer programmed to execute at least one special routine
upon receipt of said second interrupt signal.

Defendants first argue that their notebook computers do not infringe the claims because they do not meet the "keyboard"
and "keyboard controller" limitations required by independent claims 1 and 5. Doc # 359 at 11; Doc # 341 at 6. Prior to the
court's claim construction order, the parties agreed upon the construction of "keyboard" to mean:

- 1581 -
An input apparatus containing internal circuitry to output or generate data scan codes." Doc # 227 at 16.

The parties also agreed that these scan codes are sent to a "keyboard controller" for processing, which then transmits interrupts to the computer. Id. Hence, the court construed the term "keyboard controller" to mean:

A component, electronically or functionally distinct from the keyboard, that activates interrupt signals in response to receipt of data scan codes from the keyboard, and, upon request, transmits data scan codes to the computer.

Both of these definitions incorporate the phrase "data scan codes"--a term the parties hotly disputed in the Markman hearing. Id at 11-16. In short, at that hearing, Samsung argued that row and column signals--i.e., the electrical signals generated from the grid of wires that underlays the keys of the keyboard--can constitute a scan code; defendants argued that they cannot. Id at 11. Ultimately, the court sided with defendants, defining the term as:

A code number that the keyboard generates whenever a key is depressed or released, said code number created by converting a pairing of a row signal and a column signal in the keyboard matrix. Id at 16.

As the court noted, this construction order makes clear that "row and column signals [produced by keyboards] are not scan codes." Doc # 227 at 15.

6. "address set," "command set," "data set"

The dispute with regard to these terms is whether a "set" can contain a single bit, as Power-One proposes, or, as Artesyn suggests, whether it must contain two or more bits. Power-One concedes that the examples of sets given in the specification are multi-bit sets. See, e.g., '916 patent, col. 4:19-25. However, the '916 specification provides that "communication cycles containing more or less information and/or bits is within the spirit and scope of the present invention." Id. at col. 4:30-33. Although the '916 specification provides examples of multi-bit sets, this does not mean that a "set" referred to in the claims must contain more than one bit. See, e.g., Varco, L.P. v. Pason Systems USA, Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006) ("In examining the specification for proper context . . . this court will not at any time import limitations from the specification into the claims."). Accordingly, the Court declines to narrow the definition of set and construes these terms as follows:

Address set: A set of one or more bits in a message specifying the address of one or more devices connected to a bus.

Command set: A set of one or more bits in a message specifying a given command operation.

Data set: A set of one or more bits in a message reflecting data that is read from or written to a device.

2. "data set"

The term "data set" is used in four of the six steps enumerated in Claim 1. 311 patent, col. 10, ln. 59 - col. 11, ln. 3. They are:

Step 1: "transferring a data set from each of the plurality of data sources to the multi-function card;"

Step 2: "storing said transferred data set from each of the plurality of data sources in the multi-function card;"

Step 5: "selecting with said activated multi-function card a select one of said data sets;" and
Step 6: "displaying on the multi-function card in at least one predetermined display area the data of said selected data set."

Id. While the claim language itself suggests that a "data set" is information derived from a single-purpose card, the parties offer differing constructions as to the content of the information needed to create a "data set." Plaintiff construes "data set" to mean a collection of information representing a particular single-purpose card, document, key or the like. Joint Stmt. at App. A, p. 2. Defendants, on the other hand, state that "[a] data set is any collection of information transferred from a data source." Id.

Plaintiff explains in the Joint Statement that

the collection of information is unique to that particular single purpose card, document, key or the like. The collection of information includes the logo of the issuer of that particular single purpose card, document, key or the like and other information to enable the electronic multi-function card to be converted to and operate as that particular single purpose card, document, key or the like.

Pl. Op. at 11. Defendants' construction differs, including "any collection of information transferred from a data source." Joint Stmt. at App. A, p. 2; see infra construction of "plurality of data sources," at 25-31. Defendants dispute plaintiff's inclusion of items, such as a logo, as being a necessary part of a data set. Def. Resp. at 20-21. The correct construction of "data set" lies somewhere in between the parties' proposed constructions.

The specification itself provides guidance, stating that the electronic multi-function card

...can be converted without any problem to different single-purpose cards by calling up other data sets, the card reproducing in each case the special information or logo of the issuing company or bank, the card number and the date of expiry, any stored photos or, if desired, other machine-readable data and the user's signature.

311 patent, col. 3, lns. 26-32 (emphasis added). This description of what it means to pull up a data set clearly suggests that the composition of a data set will differ, depending on what information the single-purpose card contains. The specification recognizes that single-purpose cards contain "special information" that may differ from card to card. Id. Examples are provided, such as a logo, card number, date of expiry, photos, and the user's signature. Id.

The phrase "or, if desired" is critical to the construction of this term. Id. This phrase demonstrates that the list of components for a data set may contain some of the examples set forth, all of the examples, or others not listed. This view is confirmed by the extrinsic evidence. See Ex. 25, Hennige Dep. Tr., p. 389, ln. 16 - p. 390, ln. 21 (in response to an inquiry regarding what constitutes a data set, Hennige answers that it would depend). In other words, the list provides neither a floor nor ceiling for the extent of information necessary to make up a data set.

The above quoted passage, taken in its entirety, suggests that in answering the question: what is a "data set?," the focus should be on the single-purpose card. That information which is necessary to effectuate a transaction using the single-purpose card is the "data set" that needs to be transferred to the electronic multi-function card in order for the multi-function card to be able to convert itself, in form and function, as a substitute for the single-purpose card. Any attempts to be more specific will result in either an under or over-inclusion of components.

Accordingly, the Court construes "data set" to mean "Any collection of information representing a particular single-purpose card which is necessary to allow the electronic multi-function card to act as a substitute, in both form and function, for that particular single-purpose card."

5. Data slots

The term "data slots" is recited in all of the asserted claims of the 096 patent. The plaintiff submits that "data slots" are "times during which data may be transferred to or from the SDRAM." The defendants propose that "data slots" are
"SDRAM clock cycles for transferring data." The plaintiff contends that the defendants propose "a highly specific construction of data slot related to the SDRAM clock cycle" that is not supported by or disclosed in the specification. However, the defendants argue that the '096 patent makes clear that the "data slots correspond to SDRAM clock cycles in Figs. 4(a-c) and does not disclose any other time period from which a data slot may be defined." Defendants' Sur-reply Brief at 20. After considering the submissions of counsel, the court construes the term "data slots" to mean "SDRAM clock cycles available for transferring data."

1140

B. "Data Source"

The term "data source" appears in all claims for all five patents. In general, the term is used in the claims to describe the source from which data or information is accessed. For example, claim 1 of the '511 patent describes a method of accessing "data" stored in "data sources," while claim 2 describes using a driver to store "information" from a "data source."

Timeline's proposed construction of "data source" is "a collection of computer readable information such as a data file," including "a flat file, a hierarchal database, a relational database, a spreadsheet, and the like." ProClarity's proposed construction is virtually identical. The key difference is that Timeline's proposed construction is "collection of computer readable information," while ProClarity proposes a "collection of computer readable data."

Timeline supports its proposed construction by arguing that the patent specification defines "data source" to include "information." For example, the '511 patent specification states:

'Timeline's proposed construction of "data source" is "a collection of computer readable information such as a data file," including "a flat file, a hierarchal database, a relational database, a spreadsheet, and the like." ProClarity's proposed construction is virtually identical. The key difference is that Timeline's proposed construction is "collection of computer readable information," while ProClarity proposes a "collection of computer readable data."

Timeline supports its proposed construction by arguing that the patent specification defines "data source" to include "information." For example, the '511 patent specification states:

The source data 806A through 806d depicted in FIG. 8 may, in general, be any computer readable information source. Examples include flat file source data, hierarchal databases, relational databases, spreadsheets, and the like.

'511 patent, Col. 9:49-51 (emphasis added); see also '694 Patent, Col. 9:56-59 (same). Timeline also notes that the patent specifications frequently use the words "data" and "information" interchangeably, pointing to multiple examples of such usage. For example, Figure 8 in the '511 patent includes a drawing in which items 806a through 806d are labeled as "information sources." However, the specification refers to the "information sources" in the drawing as "data sources." '511 patent, Col. 9:53-58. Considering this example and the numerous other examples noted by Timeline, it is apparent that the inventor did not draw a sharp distinction between the terms "data" and "information" in the patents.

Because the patents often use the terms "information" and "data" interchangeably, the meaning of the term "data source" is likely to be the same regardless of whether it is construed as a collection of computer readable "information" or "data." However, the court regards Timeline's proposed construction as more consistent with the implied definition of the term in the '511 patent specification. See '511 patent, Col. 9:49-51 (indicating that "source data" may, in general, be any computer readable information source).

Therefore, the court construes "data source" to mean "a collection of computer readable information such as a data file." A data source may be a flat file, a hierarchal database, a relational database, a spreadsheet, and the like.

1141

(4) sources and sinks, data source, data sink

National asserts that the above terms need no construction. N-Data proposes a construction for "sources and sinks," but seeks to give "data source" and "data sink" their plain and ordinary meaning. Dell asserts that the term "sources and sinks" does not require construction in light of the other construed terms. The issue regarding "data source" and "data sink" is whether these terms should be limited to a "physical device" as Dell argues.

The court agrees with Dell regarding "sources and sinks." As to the other terms, the court agrees with N-Data's alternative
constructions; the term "physical" does not provide clear and unambiguous guidance as to its meaning.

The term "data source" is defined as "circuitry that generates data."

The term "data sink" is defined as "circuitry that consumes data."

3. "plurality of data sources"

The preamble to Claim 1 states:

A method for enabling a user of an electronic multi-function card to select data from a plurality of data sources such as credit cards, check cards, customer cards, identity cards, documents, keys, access information and master keys . . .

311 patent, col. 10, ins. 54-58 (emphasis added). Plaintiff argues that "plurality of data sources" means "two or more different single purpose cards, documents, keys or the like." Joint Stmt. at App. A, p. 3; Pl. Op. at 14. Defendants, on the other hand, construe the term to mean "at least two different types of single-purpose cards from the group of the following types: credit cards, check cards, customer cards, identity cards, keys, access information, and master keys." Joint Stmt. at App. A, p. 3 (emphasis added); Def. Resp. at 17.

There are a couple of differences in the parties' formulations. First, defendants' construction calls for two different "types" (or categories) of single-purpose cards, whereas plaintiff construes data sources to mean any two single purpose-cards (e.g. check card, gas card, etc.), regardless of whether they are the same type (or category) of card. Second, defendants seek to limit the category of cards that may qualify as a data source. In particular, defendants argue that plaintiff's inclusion of "documents" and "or the like" as data sources broaden the scope of this term beyond what was allowed when the patent was granted. Each of these issues will be addressed in turn.

a. Whether plurality of data sources means at least two different "types" of data sources.

Defendants contend that "a plurality of data sources" must include at least two different "types" of data sources. Def. Resp. at 17. Defendants make clear that under this view, two credit cards, for instance, would not qualify as different types of data sources, but a credit card and an identification card would. See id. Plaintiff's proposed construction is closer to the mark.

Interestingly, the term "data source" is only found in the claims, not in the specification. As already cited, the preamble to Claim 1 sets forth examples of sources "such as credit cards, check cards, customer cards, identity cards, documents, keys, access information and master keys . . . ." 311 patent, col. 10, ins. 56-58. From this passage alone, one cannot discern with certainty whether a "plurality of data sources" means that the data sets must derive from at least two different categories of cards, or whether the unique data sets can come from the same category of cards (e.g., Visa and Master Card). However, nothing in the claim or specification limits "plurality of data sources" in a way that is consistent with defendant's proposed construction. Thus, it appears that one could transfer data sets from two different single-purpose cards, regardless of whether the data sets derive from the same category of cards.

This interpretation is also consistent with the Court's construction of "multi-function card," which the Court construes in significant agreement with defendants' proposed construction. Defendants proposed that a "multi-function card" will convert the card "to the form and function of at least two different single-purpose cards." Joint Stmt. at App. A, p. 1. That proposed construction says nothing that would require the single-purpose cards to derive from at least two different categories of cards. To be consistent with the Court's construction of multi-purpose card, plurality of data sources must be construed as two or more different single-purpose cards even if derived from the same category of cards.

Furthermore, the Court's previous construction of "data set" is also consistent with a construction of "data sources" that does not differentiate between categories of cards. Claim 1 sets forth the transferring and storing of data sets from each of a plurality of data sources. 311 patent, col. 10, ins. 59-62. Since a data set derives from a data source, and a data set is information from one single-purpose card, it follows that a data source must be a single-purpose card containing...
information that will be transferred as a data set.

Defendants, however, argue that the prosecution history mandates that "plurality of data sources" mean different categories of cards. Def. Resp. at 17. As a general rule, the prosecution history cannot be used to broaden the ordinary meaning of the terms used in the claims and specification. See Multiform Desiccants, Inc. v. Medzam Ltd., 133 F.3d 1473, 1478 (Fed. Cir. 1998). In addition, the prosecution history is more consistent with plaintiff's construction. The Patent Examiner appears to have initially rejected the claim as obvious in light of prior art (the Yoshida patent in particular) that disclosed the claimed invention using a plurality of financial transaction cards (i.e., all of the same category cards) as its data source. See Prosecution History of 311 patent, Office Action of Jan. 29, 1991, p.2; Ex. 33. In response, Hennige distinguished the 311 patent claims from the Yoshida patent, stating:

Yoshida does not disclose or suggest transferring data to the IC card from a plurality of different types of sources such as credit cards, check cards, customer cards, documents and so forth having different associated data sets for storing the data on the IC card itself.

Id. (emphasis added). Based on Hennige's response, defendants define "plurality of sources" to mean "at least two types of single-purpose cards from the group of the following types . . . ." Joint Stmt. at App. A, p. 3. The Court rejects this interpretation, instead interpreting Hennige's response to mean that the multi-function card need only be capable of transferring data sets from at least two different categories of cards. Thus, the patented device need only be capable of transferring data sets from a plurality of data sources. So for example, where the first step in Claim 1 calls for "transferring a data set from each of the plurality of data sources to the multi-function card," this step is satisfied where the device is capable of transferring data sets from more than one category of cards. This interpretation is consistent with the prior discussion on the relationship between "plurality of sources" and "multi-function card."

b. Whether "documents" can constitute a "data source"

The word "documents" is used in the preamble of Claim 1 as an example of a type of data source. 311 patent, col. 10, ln. 57. Defendants correctly note that "documents" is not used anywhere in the specification and that the term may be broad and vague. Def. Resp. at 19. Nevertheless, the Court will not "read out" this term from the claim. Neither of the parties identified, in the Joint Statement, "documents" as a contested term requiring construction. Defendants are now attempting to bootstrap a construction of this term under the guise of the "plurality of data sources" construction. The claim language is clear: "documents" is a type of data source. 311 patent, col. 10, ln. 57.

c. Whether "or the like" is included within the definition of "plurality of data sources"

Plaintiff construes a "plurality of data sources" to mean "two or more different single purpose cards, documents, keys or the like." Joint Stmt. at App. A, p. 3 (emphasis added). As previously mentioned, Claim 1 describes a method for enabling a user of an electronic multi-function card to select data from a plurality of data sources such as credit cards, check cards, customer cards, identity cards, documents, keys, access information and master keys . . .

311 patent, col. 10, Ins. 54-58 (emphasis added). The "such as" language above indicates that the examples that follow represent a non-exhaustive list. The term "or the like" is not included, nor is it found anywhere else in Claim 1.

Furthermore, plaintiff's response brief fails to respond to defendant's argument that use of "or the like" is an invalid expansion of what it means to be a "data source." Since "or the like" is not in the claim itself, and the term "such as" already implies a non-exhaustive list, "or the like" will not be used in the claim construction.

Accordingly, the Court construes "plurality of data sources" to mean "Two or more different single-purpose cards, such as credit cards, check cards, customer cards, identity cards, documents, keys, access information and master keys, regardless of whether the single-purpose cards are from the same category or from different categories."
4. Data storage

The court construes this term to mean "a device that holds data."

GO BACK

2. Data Storage Device

The first element of claim 10 also provides:

… for controlling one of a seek time of the data storage device and an acoustic noise level of the data storage device;

(emphasis added)

The term "data storage device" is used several times in claim 10. The interpretation of this term is linked with the interpretation of "outputting," below. Plaintiffs assert that the data storage device comprises the electromechanical components of the disk drive that perform commands specified by a controller. Defendants assert that "data storage device" should be understood to mean a hard disk drive, including controller electronics. Defendants' construction would exclude from the scope of the claim those devices where shaped commands were generated within the drive itself.

The meaning adduced by both parties to "data storage device" is that it is a disk drive. Plaintiff states that those skilled in the art of control systems typically use a term to refer to that which is controlled, and that therefore what a layperson considers a disk drive would be characterized by a control engineer as a disk drive and a controller. (Pls.' Claim Construction Br. For U.S. Patent No.'s '635, '267, and '473 at 26). The specification supports such a construction. The patent in Col 10:1-21 describes a preferred embodiment of the control of a disk drive. Included in this description is the possibility that the processor controlling the disk drive is located in the PC, or, "alternatively, a separate controller dedicated to the disk drive which receives commands from [that] processor." '473 patent Col 10:6-8. Defendants claim that the specification discloses only two possible structures which can control the disk drive: the first is a processor within the PC, and the second is a controller which receives "commands" from that processor. (Defs.' Responsive. Claim Construction Br. for '473 Patent at 5).

Since the third element of claim 10 uses the term "command" to refer to shaped inputs, defendant infers that the commands must be shaped by the processor located within the PC. Defendant combines a context-specific use within one claim with a more general use in the specification. The term "command" as it is used in the specification refers to signals communicated from a keyboard or mouse (Col. 6:19), to a signal which will be shaped (Col. 8:12), and to signals in a disk drive generally (Col. 2:22-28). Claim 10 refers to a specific kind of "command," one that has been shaped by a processor. The command referred to in Col. 10:6-8 could therefore be a signal which has been shaped by a disk drive engine running on a processor in the PC, or an unshaped signal from the PC which will be shaped by a processor dedicated to the disk drive and not located in the PC. Defendants argue that since "disk drives," as lay people use the term, commonly include on-board electronics dedicated to controlling the drive, a construction that permits on-board electronics to send "commands" is not supported. Such a configuration is within the scope of the claim. Accordingly, the term "data storage device," as used in claim 10, is interpreted to mean:

"a computer disk drive, including all electronic and mechanical components, which receives shaped commands from a processor which may be integrated into the drive."

GO BACK

5. data storage means (Claim 1)

Plaintiff argues that even though this limitation includes the word "means," this need not be construed as a means plus function limitation. "If, in addition to the word 'means' and the functional language, the claim recites sufficient structure for performing the described functions in their entirety, the presumption of § 112 P 6 is overcome--the limitation is not a means-plus-function limitation." TriMed, Inc. v. Stryker Corp., 514 F.3d 1256, 1259 (Fed. Cir. 2008) (citing Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1360 (Fed. Cir. 2004)). The Federal Circuit has also held that if a term, as the
name for a structure, has a reasonably well understood meaning in the art, there may be sufficient structure recited by such a term. Watts v. XL Sys., Inc., 232 F.3d 877, 880-81 (Fed. Cir. 2000). Arbitron argues that term "data storage means" is reasonably well understood in the art and should be construed to mean "a memory." In support of its argument, it points to the fact that the Federal Circuit has previously held that the term "storage" has a reasonably well understood meaning in the art as "[a] device capable of receiving data, retaining them for an indefinite period of time, and supplying them upon command." Gemstar-TV Guide Int'l, Inc. v. Int'l Trade Comm'n, 383 F.3d 1352, 1372 (Fed. Cir. 2004). It argues that the term "data storage" here should also fall within the definition provided by Gemstar.

Defendants note that the Federal Circuit did not decide a dispute over a § 112 (6) term in Gemstar and therefore argue that this Court is required to presume a means plus function limitation here. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002) ("A claim limitation that actually uses the word 'means' will invoke a rebuttable presumption that § 112 P 6 applies."). It insists that the claim language alone needs to disclose sufficient structure to perform the entirety of the described function before a court can find that § 112 (6) does not apply. See Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1375 (Fed. Cir. 2003) ("This [means plus function] presumption can be rebutted where the claim, in addition to the functional language, recites structure sufficient to perform the claimed function in its entirety"). The defendants' proposed construction for the means supporting the function is "A physical memory device 116."

The Court agrees with the defendants. In Gemstar, the Federal Circuit construed the term "storage means in a data processor" to mean "a device capable of retaining data located within a data processing device or system." Gemstar-TV, 383 F.3d at 1372. First, as defendants point out, neither party in that case had argued that there could be § 112 P 6 presumption, or how such a presumption could be overcome. Second, the Federal Circuit noted that there was abundant prosecution history to indicate that the inventor of that patent had intended to define "storage means" as an electronic memory. See id. at 1371 (noting that the inventor had unsuccessfully proposed several reexamination amendments attempting to define "storage means" as an electronic memory). There is no such support for Arbitron's argument here. Finally, the Federal Circuit in Gemstar had included in its analysis the fact that ITC had failed to consider whether the specific expression, "data processor" had an ordinary meaning to one skilled in the art that would have provided insight and context for the claim language "storage means in a data processor." Id. at 1372. In this case, the term is used in conjunction with the "device for storing the sense signal and the corresponding time signal." '276 Patent, Claim 1. Here, the Court has considered the ordinary meaning of "device" to one skilled in the art and concludes that there is not sufficient structure defined by the term "data storage means" to overcome the presumption that it is a means plus function limitation. TriMed, Inc. v. Stryker Corp., 514 F.3d 1256, 1259-60 (Fed. Cir 2008) ("Sufficient structure exists when the claim language specifies the exact structure that performs the functions in question without need to resort to other portions of the specification or extrinsic evidence for an adequate understanding of the structure."). Hence, construing "data storage means" simply as "a memory" would be contrary to Federal Circuit law.

Lastly, the parties dispute the possible locations of the corresponding means for this term. Plaintiff proposes that the means include the physical memory in the docking station as well as that in the device. However, both the claims as well as the specification recite that the storage means is included with the device. Arbitron argues that "with the device," is not the same as "in the device," and that the docking station, as a part of the system, is provided "with" the device. However, this is a stretched construction of the word "with" as used in this context. The defendants' proposed construction is hereby adopted for his term: "A physical memory device 116, or equivalents thereof"

Plaintiff's Proposed Construction

The maximum sustained rate at which data

Defendants' Proposed Construction

The maximum rate at which data
can be written to the data storage device, including, in the case of hard drives, seek time and rotational latency can be stored on the data storage device 9

--- Footnotes ---

9 In the alternative, Blue Coat proposed the construction: "For hard disk drives, the maximum sustained rate at which data can be written to the data storage device means the internal transfer rates set forth in the manufacturer's specification sheets."

--- End Footnotes ---

The parties' primary dispute lies in whether the construction of "data storage rate" should include performance factors such as seek time and rotational latency in addition to the time associated with the internal transfer rate. As indicated in the initial Claim Construction Order, the asserted claims of the '104 and '158 are informed by what the patentee, at the time of the invention, called a "fundamental problem" of limited data storage rates. CLAIM CONSTRUCTION ORDER at 14; '104 patent at 2:33-34. Importantly, the specification of the patent reads: "magnetic disk mass storage devices . . . suffer from significant seek-time access delays along with profound read/write data rate limitations." '104 patent at 2:14-28 (emphasis added). This language persuades the Court that one of ordinary skill in the art, reading the claim term "data storage rate" in the context of the '104 patent, would conclude that the rate is determined by the entire write operation following receipt of a write request, which includes seek access time and rotational latency.

Blue Coat asks that the Court narrowly understand the term "write" to include only the limited transfer of information from the drive head to the disk. In light of the '104 patent's specification, however, the Court construes "data storage rate" to include the parameters impacting the overall data storage process set forth in the claimed invention. One of ordinary skill in the art would read column 2 of the specification to necessarily include practical limitations affecting a data storage process that goes beyond just the transfer of data from the drive head to the disk. REALTIME SUPP. BRIEF at 4. Further, a person of ordinary skill in the art would understand that in order to minimize the bottleneck problem of hard disk drives discussed in the '104 patent, a construction of "data storage rate" must encompass the entire write operation (address lookup, seek operation, rotation of disk platter, data transfer). See also REALTIME SUPP. RESPONSE at 2. Accordingly, the Court reads the specification to disclose a series of steps that are directed toward removing bottleneck(s) and that ultimately affects the performance of the data storage process.

Thus, the Court rejects Blue Coat's interpretation of "write" as being the internal transfer rate listed in the hard disk drive manufacturer's data sheet because it is not consistent with the '104 patent's specification. The initial Claim Construction Order previously recognized that seek time is involved in the write operation, CLAIM CONSTRUCTION ORDER at 14, and the language of the patent is dealing with real world practical considerations. See also '104 patent at 2:23-37 (using "data rate" and "data transfer rate" to inform an understanding of "write" that means a write operation process that includes seek time and rotational latency). A supplemental construction for "data storage rate," therefore, should acknowledge that a number of seek operations may have to be performed when a disk is functioning in a fragmented state, which causes a reduction in the data storage rate of a hard disk drive.

As explained by Realtime, (1) disk fragmentation occurs over time; and (2) the number of seek operations will increase as the disk becomes fragmented. REALTIME SUPP. BRIEF at 8. This effect will necessarily impact the data storage rate. Blue Coat discredits the effect of fragmentation by arguing that data sheet specifications provide definitive information in determining the "data storage rate," BLUE COAT SUPP. RESPONSE at 5, but again, the Court disagrees. The Court finds that the data storage rate of a hard disk drive is determined through "actual real-world performance" as it would vary according to "real world operating conditions." REALTIME SUPP. RESPONSE at 3 (internal citations omitted). Therefore, when considering the effect of fragmentation, the Court adopts a construction that allows for the "data storage rate" of a device to be determined by testing it as deployed at steady state fragmentation, an objectively testable parameter. 10

--- Footnotes ---

10 The Court rejects Realtime's proposed construction of "maximum sustained rate . . . as measured at maximum fragmentation of the hard disk drive when deployed for its intended use" as incomprehensible. See Doc. Nos. 682, 683.
One of ordinary skill in the art would understand "significant seek access delays along with profound read/write limitations" to refer to disk fragmentation, and moreover, one skilled in the art would further understand that the slowest speed at which the (maximum sustained) data storage rate would occur is with the hard disk drive at steady state fragmentation. 11 See '104 patent at 2:20-23. Specifically, the Court finds that the maximum sustained storage rate will be determined in a manner that is inclusive of seek time and fragmentation, and will objectively base "data storage rate" on measurements that are taken once a storage device reaches steady state fragmentation. 12 Accordingly, the supplemental construction accounts for performance factors affecting the claimed invention as it would function in the real world where one of ordinary skill in the art could test the hard drive and calculate the "data storage rate" once it has achieved steady state fragmentation. Moreover, determining the data storage rate, as construed, of an accused device at a condition of steady state fragmentation on the hard disk drive provides an objective standard by which one skilled in the art can determine infringement or non-infringement. Blue Coat contends that the condition of fragmentation of a hard disk drive will vary depending upon each particular installation and manner of using the accused devices. See BLUE COAT SUPP. RESPONSE at 5. Nevertheless, a condition that can expectedly be achieved in the ordinary use of the accused devices is steady state fragmentation, as shown by Blue Coat's own testing. In this regard, the Court also gives due recognition to the principle that an accused product that sometimes, but not always, embodies a claimed method nonetheless infringes. See, e.g., Bell Commc'ns Research, Inc. v. Vitalink Commc'ns Corp., 55 F.3d 615, 623 (Fed. Cir. 1995).

11 "Steady state," an established engineering principle, is a concept that has a plain and ordinary meaning to a person of ordinary skill in the art.

12 Steady state fragmentation in the accused ProxySG devices occurs after approximately 18 hours. REALTIME SUPP. RESPONSE at 4 (citing TOAST testing performed by Blue Coat performance engineer, Mr. Gary McAlpine).

Thus, in order to solve the problem of limited data storage rates of data storage devices by providing an effective increase in the data storage rate, this term must refer to the maximum sustained rate at which the device can operate to store data and must include the practical limitations disclosed in the specification of the '104 patent. For the foregoing reasons, the Court finds that the proper construction for "data storage rate" is "maximum sustained rate at which data can be written to the data storage device, including, in the case of hard disk drives, seek time, rotational latency, and data transfer in a condition of steady state fragmentation of the disk drive."

EMC contends that a "data storage system" is a set of associated components housed in one or more enclosures and working together to store data and a "data storage system controller," is a device that controls one or more data storage operations. HP claims, on the other hand, that (1) the term "data storage system" is so broad that it requires review of the specification for further definition and (2) in the relevant specifications, a data storage system is described as including a controller which contains cache memory. The primary dispute between the parties, therefore, is whether a data storage system or, more specifically, a data storage system controller is required to contain, as a component, cache memory. 3

As a threshold matter, it is undisputed that the plain and ordinary meaning of the terms "data storage system" and "data storage system controller," do not require cache memory. 4 Indeed, a "system" is defined as "a complex unity formed of many often diverse parts subject to a common plan or serving a common purpose." Webster's Third International Dictionary, 2322 (1981). In this case, that common purpose is data storage. In a more technical context, a "controller" is defined as

[t]he control logic in a storage subsystem that performs command transformation and routing, aggregation (RAID,
mirroring, striping, or other), high-level error recovery, and performance optimization for multiple storage devices.

Dictionary of Storage Networking Technology, http://www/snia.org/education/dictionary/c/. In this case, the controller performs its various functions within the data storage system. Therefore, the plain meanings of neither the term "data storage system" nor the term "controller" require, as a component, cache memory.

3 Although it was once in dispute, at the Markman hearing the parties agreed that the components of a "data storage system" are not required to be housed together in the same enclosure.

As a threshold matter, it is undisputed that the plain and ordinary meaning of the terms "data storage system" and "data storage system controller," do not require cache memory. Indeed, a "system" is defined as "a complex unity formed of many often diverse parts subject to a common plan or serving a common purpose." Webster's Third International Dictionary, 2322 (1981). In this case, that common purpose is data storage. In a more technical context, a "controller" is defined as [the control logic in a storage subsystem that performs command transformation and routing, aggregation (RAID, mirroring, striping, or other), high-level error recovery, and performance optimization for multiple storage devices.

Dictionary of Storage Networking Technology, http://www/snia.org/education/dictionary/c/. In this case, the controller performs its various functions within the data storage system. Therefore, the plain meanings of neither the term "data storage system" nor the term "controller" require, as a component, cache memory.

4 Even if, as HP contends, the phrase "data storage system," as a whole, is so broad as to lack a common meaning, this court is not inclined to "abandon its quest" for such and "disregard the meanings of the individual words." Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1372 (Fed. Cir. 2003)(holding that district court erred in disregarding the common meaning of the terms "boot" and "selection" after concluding that the disputed phrase "boot selection flag" was, as a whole, unclear on its face).

The only remaining question is whether EMC has acted as its own "lexicographer" by defining the terms "data storage system" and "data storage system controller" to require, as a component, cache memory. Before turning to the patent specifications, there is evidence in other claim language that EMC has not demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term . . . [by] using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope.

Sunrace, 336 F.3d at 1304. (internal quotation marks omitted). Claim 10 of the '792 Patent, an independent method claim, contains the term "data storage system" with no reference to cache memory. Claim 12 of the '792 Patent (a dependent claim), however, discloses the method as claimed in Claim 10 wherein said data storage system contains a cache memory and a disk data storage device . . . .

'792 Patent, Col. 62, ll. 52-54. Because, by virtue of the doctrine of claim differentiation, limitations from one claim cannot generally be read into another, there is a rebuttable presumption that, with respect to the '347 and '792 Patents, the term "data storage system" does not require cache memory.

As HP aptly contends, Claim 10 is also distinguishable from Claim 12 in that it discloses a data storage system including a "disk data storage device." That additional limitation does not, however, negate the presumption that the term "data storage
system" as used in Claim 10 is not limited in scope to a system which requires cache. See Sunrace, 336 F.3d at 1302-03. Common sense, moreover, reinforces that presumption because if cache were a required component of a "data storage system" or a "data storage system controller", its inclusion in dependent Claim 12 would be wholly redundant.

That evidence notwithstanding, the Specifications of the ’347 and ’792 Patents provide significant support for HP’s contention that a "data storage system" requires cache memory. In the “Detailed Description of the Invention,” the Specification of the ’347 Patent states, in relevant part,

The present invention is shown generally at 10, FIG 1, and includes at site A . . . .

The primary data storage system controller 16 includes at least 1 channel adaptor (C.A.) 26 which is well known to those skilled in the art and interfaces with host processing system 12. Data received from the host is typically stored in cache 28 before being transferred through disk adaptor(D.A.) 30 over data signal path 24 to the primary storage device 20. The primary data storage controller 16 also includes . . . cache memory . . . .

The secondary data storage system controller 44 also includes cache memory . . . .

’347 Patent, Col. 4, ll. 6-7, 21-30, Col. 5, ll. 64-65. (emphasis added). Furthermore, in Figure 1 of the Specification of the ’347 Patent, described as a block diagram illustrating "the system with remote data mirroring according to the present invention," the controller is depicted as including cache memory. Those references, in addition to similar references in the Specification of the ’792 Patent, HP contends, demonstrate that EMC has acted as its own lexicographer and specifically defined a data storage system to include cache memory.

5 Because similar claim terms must be construed uniformly in the ’347 and ’792 Patents, for purposes of efficiency this Court will cite only to the Specification of the ’347 Patent in construing such terms.

First, a simple comparison of other "definitions" in the Specification of the ’347 Patent confirms that EMC has not explicitly redefined data storage system to include cache memory, i.e. by using definitional language. In "defining" the term "geographically removed site," for example, the Specification states, in relevant part,

[for this Patent Application, geographically removed site means not within the same building as the primary data storage system.

’347 Patent, Col. 4, ll. 6-7 - Col. 5, ln. 2. Nowhere in the Specification of the ’347 Patent does EMC so explicitly define the term "data storage system" or "data storage system controller."

A patentee, however, can implicitly supply new meanings for claim terms. Here, HP contends, EMC has implicitly redefined the term "data storage system" by consistently describing the "present invention" as including cache memory. Although "clear language characterizing the present invention may limit the ordinary meaning of claim terms," such language must be read in context of the entire specification and the prosecution history to determine whether the patentee clearly limited the plain meaning of a claim. Rambus, 318 F.3d at 1095.

In Brookhill-Wilk, for example, the patentee disclosed only one embodiment in the patent specification which was referred to therein as "the present invention". See U.S. Patent 5,217,003. In fact, the only figure in that specification was described as "a diagram . . . in accordance with the present invention" and the "Detailed Description" section specifically described the illustration in that figure. Id. Nonetheless, the Federal Circuit Court of Appeals reversed the district court's decision to limit the claim scope on the basis of the sole embodiment disclosed in the specification holding that

[t]he statements from the description of the preferred embodiment are simply that--descriptions of a preferred embodiment . . . . Those statements do not indicate that the invention can only be used in such a manner. Absent a clear disclaimer of particular subject matter, the fact that the inventor anticipated that the invention may be used in a particular
manner does not limit the scope to that narrow context.

Brookhill-Wilk, 326 F.3d at 1223 (emphasis added). Notwithstanding the Federal Circuit's obvious and continuous reference to the patentee's "preferred embodiment", where that term is not used in the patent specification, the Court makes clear that a patentee must clearly disclaim a particular subject matter before the plain meaning of the claim terms are so limited.

Similarly, in Rambus, the district court found that the patentees had acted as their own lexicographers by redefining the claim term "bus" to be a "multiplexed bus". Rambus, 318 F.3d at 1094. Although the patentees had described the "present invention" at various times throughout the specification as including a multiplexed bus, the Federal Circuit reversed the district court's decision and held that while "clear language characterizing the present invention may limit the ordinary meaning of claim terms," the remainder of the specification and the prosecution history did not evince a clear intent to disclaim or disavow the plain and ordinary meaning of the term "bus." Id. at 1094-95. See also Sunrace, 336 F.3d at 1304-05 (patentee did not clearly redefine the term "shift actuator" to include "cam" where, in patent specification, he stated that each shift actuator "contains a . . . cam member" and that "[a] rotary cam member . . . is the heart of the rear handgrip shift actuator").

HP contends that this case is, however, distinguishable from Brookhill-Wilk and Rambus because, in those cases, the Federal Circuit found that parts of the specification and the prosecution history supported a broader construction of the disputed claim terms. Here, HP claims, the subject specifications implicitly define a "data storage system" as including cache memory. There are at least three problems with that contention:

1. Although the relevant specifications do, in various places, refer to a data storage system as including cache, in each instance the patentee is clearly describing "the present invention . . . shown generally at 10, FIG. 1." See '347 Patent, Col. 4, ln. 6. As the Federal Circuit impliedly found in Brookhill-Wilk, EMC's use of the term "present invention" can be considered synonymous with "preferred embodiment" and the fact that the patent discloses only one embodiment does not necessarily limit the claim terms to a description thereof. Moreover, it is well-established that limits from the preferred embodiment are not to be read into the claim terms. See RF Delaware, 326 F.3d at 1263.

2. The Specification of the '347 Patent is not without its ambiguities with respect to whether the terms "data storage system" and "data storage system controller" must be defined to include cache memory. As both parties note, the Specification states, at one point, that

[...]

3. The prosecution history reveals that the PTO considered, as prior art, numerous patents disclosing controllers that did not include cache memory. The PTO did not, however, distinguish EMC's invention on those grounds. Although not dispositive, such evidence indicates that EMC did not clearly disclaim or disavow data storage systems without cache memory during the prosecution of the subject patents.

For each of those reasons and because of the presumption that different patent claims are to be accorded a different scope, EMC has not, either implicitly or explicitly, demonstrated "an intent to deviate from the ordinary and accustomed meaning" of the term "data storage system" or "data storage system controller" by "using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." See Sunrace, 336 F.3d at 1304. In accordance with its plain and ordinary meaning, therefore, a "data storage system" is a set of associated components working together to store data and a "data storage system controller" is a device that controls data storage operations. Neither is required to include cache memory.
2. "Data structure"

The parties also request that the court construe the meaning of the data structure limitation as it appears in Claims 1 and 8. 21 See '002 Patent col.33 ll.30-34, col.34 ll.19-24. The limitation states: "a data structure . . . including: a plurality of data packets stored in said local computer-readable memory . . . ." Id. col.33 ll.30-34. Papyrus argues that the court should construe the phrases to mean "a data structure accommodating a plurality of data packets, which the local computer-readable memory may store sequentially or simultaneously." Pl. PCCO 3.

21 Because Claim 8 addresses the communication between the computer-readable memory in the HHD and the booth clerk's programmed computer, the text of the limitation is modified to reflect the storage of data in the data structures of each device. See '002 Patent col.30 ll.60-63; Pl. TD 79. The limitation in Claim 8 states: "a data structure . . . including a plurality of data packets stored in said computer-readable memories . . . ." '002 Patent, col.34 ll.19-24. As the two devices appear to employ data structures similarly, the court's construction will apply to the phrases in both claims.

According to Papyrus, the data structure acts as a template to arrange data for later use, and is an organizational element that exits regardless of whether data is present or absent from the structure. Pl. Reply Br. 15. In general, the invention provides that the booth clerk's local computer-readable memory ("LCRM") stores, processes, and then sends data packets to a separate storage device. Pl. TD at 64-85. Specifically, the patent provides that "each data packet that is formulated or constructed is stored in a computer-readable memory, and may be transmitted across a two-way [sic] wireless network, as a data structure." 22 '002 Patent col.22 ll.53-56. Thus, the LCRM stores data packets in the data structure of the local memory, using appropriate routines to process each packet. Pl. TD at 81; see '002 Patent col.21 ll.56-59. Papyrus also argues that because the computer program executes different steps for different transaction types, the invention permits sequential storage of data packets and processes the packets on a packet-by-packet basis. Pl. MHSP vol. 2 at 27-28. The specification teaches that in processing newly received information data packets are removed from the local memory and sent to storage. Pl. MHSP vol. 2 at 29. At that point, a "many-to-one relationship" exists between the order and execution data packets even though they are not stored in the LCRM at the same time, but rather, in the separate storage device. Pl. TD at 82; Markman Hr'g Tr. vol. 2 at 53; see '002 Patent col.30 ll.58-63.

22 The data structure includes a header with each of the data packets that contains the badge number of the floor broker, the sequence number of the transaction, the transaction type and subtype, the stock symbol, date, and the time, regardless of whether the communication originates at the programmed computer or the HHD. '002 Patent col.21 ll.34-42.

In addition, Papyrus emphasizes not only that the patent language evinces no intent to limit the claim with a simultaneous storage requirement, i.e., that a particular data packet be stored in both the local memory and the separate storage computer, but that the simultaneous storage in the local memory is not the mechanism for establishing the many-to-one relationship. Markman Hr'g Tr. vol. 2 at 53. Rather, it is "[t]hrough the use of hierarchical volley codes and sequence codes, the claimed data structure enables an electronic matching of multiple, small executions against a single, larger order." Amendment in Application Serial No. 08/478,286 (Apr. 25, 1997), Pl. App. 16 at 231. Papyrus also contends that had the inventors intended to limit the claim, then they would have included the word "simultaneously" in the specification, as in Claim 1 of the '877 Patent. Pl. Reply Br. 16. As written, the computer must process each packet separately because it cannot hold order data packets and execution data packets simultaneously. See '002 Patent col.20 ll.46-col.21 l.33. Moreover, the specification discloses serial storage by expressly stating that the data packet is "sent to storage" rather than "copied to storage" to indicate removal from the data structure in the local memory. Id. col.30 ll.60, 62-63; Pl. Reply Br. 17.

Papyrus also relies on extrinsic evidence from dictionaries to help define the limitation with its ordinary meaning of "a particular way of organizing a group of data." Pl. Br. 25; Pl. MHSP vol.2 at 23. First, Papyrus cites the EE Dictionary, which defines data structure as "a particular way of organizing a group of data, usually optimized for efficient storage, fast search,
fast retrieval, and/or fast modification." Pl. App. Ex. 53 at 520. Second, the Merriam-Webster's Collegiate Dictionary, defines "data structure" as "any of various methods of organizing data items (as records) in a computer." Pl. App. Ex. 49 at 483. Third, Papyrus referenced the 5th IEEE Dictionary during prosecution to explain that "data structure" is a "physical or logical relationship among data elements, designed to support specific data manipulation functions." Pl. App. Ex. 56 at 529; Pl. App. Ex. 16 at 231-32.

NYSE proposes an alternative construction of "a data structure having the plurality of data packets present in the local computer readable memory at the same time." Def. PCCO 3. NYSE argues that the plain meaning of the claim language at issue is that the plurality of data packets are present in the memory at the same time. Def. Br. 29; see '002 Patent col.34 ll.19-24. Because the patent says nothing about removal to a remote storage device -- only that it is stored or sent to storage -- the invention could store the data packets in the local memory. Markman Hr'g vol. 2 at 60; see '002 Patent col.28 l.23, col.29 l.16, col.30 l.63 & col.31 l.23. NYSE also argues that the many-to-one relationship between an order data packet and several execution data packets can exist only if all are simultaneously present in the local computer-readable memory. Def. Br. 29; see Markman Hr'g Tr. vol. 2 at 64.

With regard to extrinsic evidence, NYSE points to the deposition of Dr. Lee A. Hollaar, who answered negatively when asked whether the limitation could mean storage at different points in time, and affirmatively when asked whether it was necessary "to have at one time a plurality of data packets stored." Excerpts from Hollaar Dep., Gaspar Decl. Ex. 4 at 228; Def. Reply Br. 15-16. 23 Based on this testimony, NYSE contends that Dr. Hollaar admitted that multiple packets had to be in the memory at the same time. Def. MHSP 150-51.

23 Following a request for Dr. Hollaar to interpret the phrase "a plurality of data packets stored in said local computer-readable memory," the testimony was as follows:

A: [It] [means] that it stores more than one data packet in the memory.

Q: [Could this phrase mean storage at] different points in time, so if it first stores one data packet and then later stores another data packet, that satisfies having a plurality of data packets stored in memory?

A. Well, certainly not.

Q: Okay. So you have to have at one time a plurality of data packet stored; right?

A. Right.

Gaspar Decl. Ex. 4 at 228.

Papyrus counters, noting that Dr. Hollaar amended his testimony because the questions were allegedly ambiguous. Indeed, Dr. Hollaar changed his responses from "certainly not" and "Right" to "Maybe." Pl. MHSP vol. 2 at 38. Further, Dr. Hollaar testified that "[the patent] says that there has to be a plurality of data packers stored in the local computer memory. That means more than one is stored. It doesn't necessarily say simultaneously." Pl. MHSP vol. 2 at 36.

The Federal Circuit has held that "when the specification describes the invention in broad terms, accompanied by specific examples or embodiments, the claims are generally not restricted to the specific examples or the preferred embodiments unless that scope was limited during prosecution." Kinik Co. v. ITC, 362 F.3d 1359, 1364-1365 (Fed. Cir. 2004). The court therefore need not restrict the meaning of the limitation to the preferred embodiment. Nonetheless, "while it is of course improper to limit the claims to the particular preferred embodiments described in the specification, the patentee's choice of preferred embodiments can shed light on the intended scope of the claims." Astrazeneca AB, Aktiebolaget Hassle, KBI-E, Inc. v. Mut. Pharm. Co., Inc., 384 F.3d 1333, 1340 (Fed. Cir. 2004).

In this case, the only mention in the specification of external storage appears in the explanation of the programmed
computer's functions. During a receive routine, if the transaction sequence number is known, then the file record for that instruction is received at step 792 from a storage area 794 (illustrated as a magnetic storage device, but the storage area could equally be a computer readable memory containing the data that corresponds to that transaction sequence number in the data structure) . . . .

'002 Patent col.29 ll.57-62 (emphasis added). That Figures 14-18 all have illustrations similar to that appearing in Fig. 16 step 794 implies that steps 724, 760, 810, 844, 894 and 906 may also be either separate magnetic storage devices or local computer-readable memories. As the specification seems to specifically allow for either type of device, the court is reluctant to limit the claim by requiring a specific type of storage device. Nevertheless, the court is persuaded by Figures 1 and 7 of the patent, which illustrate the simultaneous display of numerous data packets. See '002 Patent Fig. 1 steps 324, 328 & 342; id. Fig. 7 steps 424, 430, 432. Presumably, to display numerous data packets on the display of either the HHD or the programmed computer, the local computer-readable memories of each device must store the data packets simultaneously for display and access by the user. Additionally, the court notes that Claims 1 and 8 of the patent references "said local computer-readable memory," "a computer-readable memory," and "said computer-readable memories" and not separate storage devices. See '002 Patent col.33 ll.33-34, col.34 ll.14-15, 18-20. Thus, the court agrees with NYSE and finds that the term "data structure" means "a data structure having the plurality of data packets present in the local computer-readable memory at the same time."

GO BACK

E. "Data Structure"

The term "data structure" appears in all claims of the '511, '382, and '617 patents and in claims 10-15 and 19-25 of the '392 patent. In these claims, the term is generally used to describe a driver obtaining information about the "data structure" of a data source.

The parties agree that the term "data structure" refers to the way data is organized. However, Timeline argues that the term refers to the "logical organization of data such as tables, columns, or rows" while ProClarity asserts that the term means "organizational scheme between content of information."

The term "data structure" is not expressly defined in the specifications. However, Timeline notes that the specifications refer several times to the "logical structure" and "logical organization" of data. For example, the '511 patent refers to "[t]he data organized in the logical structure of depicted in FIG. 1." '511 patent, Col. 6:12-13; see also id. Col. 5:64-65 (noting that "FIG 1. is intended to depict the logical structure of the data organized into a plurality of files"). As a result, there is some support in the intrinsic evidence for construing data structure as a "logical organization" of data.

By contrast, ProClarity's proposed construction is somewhat vague and is not well-supported by the intrinsic evidence. Although ProClarity suggests that Timeline's proposed construction is deficient because it would not encompass the physical layout of data, Timeline's proposed construction specifies that the term includes tables, columns, or rows.

Therefore, the court construes the term "data structure" to mean "the logical organization of data such as table, columns, or rows."

GO BACK

5. Data Successfully Received

The Court's Construction: Data from the data file transferred from the server computer to the client computer. Markman Tr. 30:13-15.

RealNetworks did not raise an objection to the Court's construction of this term. n6 Ethos argued "data is successfully
received when it is available for storage." Id. 31:14-15. This construction was not supported by the specifications.

n6 At the Markman hearing the Court construed this term as part of its construction of the entire phrase "storing said data successfully received." Markman Tr. 31:22. RealNetworks objected to the Court's construction of "storing" but not the Court's construction of "data successfully received." Id. 32:16-23.

The specifications use this language in the following manner:

Data received from the server computer as a stream of data in response to the request for the data file is monitored to detect termination of the download of the data file and to track an amount of data from the data file successfully received by the client. The amount of data successfully received by the client is stored when an error is detected that terminates the download.

'892 patent col.3 11.43-51; '709 patent col.3 11.51-58.

In one embodiment, the download is monitored by tracking an amount of data from the data file successfully received by the client. The amount of data successfully received is stored when an error is detected that terminates the download.

'892 patent col.4 11.19-23; '709 patent col.4 11.26-30.

The patent specifications indicate that successful receipt of data is equivalent to the successful transfer of data, whether or not it is available for storage. According to the embodiments described, data successfully received is stored only after an error is detected, indicating that data is still considered successfully received even if it is not available for storage because an error had not occurred. Ethos' construction is therefore inconsistent with the specifications' description of the embodiments of the invention and must be rejected.

4. "Data Terminal." Used in '114 patent, Claims 1-7; '768 patent, Claims 1, 3, and 5.

TGIP states that this claim does not need to be construed. If it is construed, TGIP proposes "a device capable of receiving data and transmitting data." Defendants suggest "a device for on-site point-of-sale activation and recharging of prepaid calling cards."

As the parties agreed at the hearing, the data terminals described in these patents are connected to the host computer and transmit information, specifically charging and recharging information, between the terminal and the host computer. Tr. p. 79-80; see '114 patent, col. 2, 11. 60-61; '114 patent, col. 4,11. 13-15. The only dispute between the parties is whether a data terminal must always be used for activation and for recharging of a card.

The specification states: "The data terminals allow for point-of-sale variable authorization and recharging of calling cards." '114 patent, col. 4, 11. 44-45. This implies that the devices have the capability to do both. Both sides agreed to this. Tr. pp. 81-83, 87. But "allows for" is permissive, not mandatory.

Just because the device "allows for" charging and recharging does not mean that it has to be used for both. A data terminal at a kiosk in a mall which was always available for recharging by those who already had a card might be used for activation only when an employee was available to manually hand out the cards themselves. How the data terminal is actually used will depend on the language of the claim under consideration. The court will define this term as follows:

"Data terminal" means "a device that can transmit and receive data to a host computer to allow for charging and recharging a calling card or calling card account."
6. Data terminal equipment; remote devices

The term "data terminal equipment" appears in claims 11 and 24 of the '774 patent. The term "remote devices" appears in claims 16 and 26 of the '727 patent. The plaintiff asks the court to construe the terms to mean "equipment that processes upper layer protocols including network and transport layer protocols" or, in the alternative, "computer." The defendants ask the court to construe the terms to mean "end-user equipment that receives high speed data addressed to a remote link adapter for routing to data terminal equipment in contrast to using the media access layer." The written description of each patent fails to shed much light on the meaning of each of the terms at hand, as the terms appear primarily within the claims. The court construes each of the above terms to mean "end-user computer equipment."

"data traffic" is construed to mean "transmitted data packets."

Lucent contends that this term should be construed to mean "packets of data traffic." (D.I. 396 at 26.) Extreme contends that this term means "packets of data whose content is not necessarily organized into blocks of droppable bits." In support of its contention, Extreme cites various points in the written description and drawings. (D.I. 395 at 21, citing the '650 patent at 2:66-3:2, 4:30-32, 5:8-11, Fig. 1.)

The Court finds that Lucent has not redefined the term "data traffic" in any of the places Extreme cites. Thus, the Court concludes that Lucent has not made a clear disavowal of claim scope. Further, the Court finds that the parties agree that the ordinary meaning of the term "traffic" is "the information or signals transmitted over a communications system: MESSAGES." (D.I. 379 at 29; D.I. 399 at 21.) The Court finds that the parties also agree that data traffic is generally comprised of "packets of data" or "data packets." (D.I. at 379 at 29; D.I. 399 at 20.) Further, the Court finds that the specification references the transmission of data packets several times in the Summary of the Invention ('650 patent at 3:4-16.) Thus, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

10. data transfer circuitry for controlling the transfer of data stored in said digital camera flash memory module inserted into said memory input port to said hard disk drive n6

The corresponding phrases are "circuitry [contained within said hand-held housing] for controlling the transfer of data stored in said digital [camera flash] memory module [inserted into said memory input port] to said hard disk drive;" and "circuitry embodied in said housing for controlling the transfer of data to and from said mass storage device."

The plaintiff contends that this phrase does not need construction. To the extent that it needs to be construed, the plaintiff proposes "circuitry for controlling the transfer of data stored in said digital camera flash memory modules inserted into said memory input port to said hard disk drive." The defendants propose "circuitry that can copy files from a digital camera's memory and delete them from the digital camera's memory." The claim phrase is broader than the limitations from the preferred embodiment cited by the defendants. Therefore, the court rejects the defendants' proposed limitations. The court incorporates by reference its construction of "port," and concludes that the balance of the phrase requires no construction.
6. data transfer system (Claim 17)

Defendants contend that the inventors have provided a specific definition of this term in the specification and Court should adopt this definition. Defendants propose that the inventors have defined a "data transfer system" as "a docking station and hub including a power source, battery charger, battery status detector, backup battery, communications interface to the device, clock processor, memory, bus switch, sound generator, LCD, LED and communication interface to the PSTN."

Arbitron argues that the specification discloses many ways of transferring data, including cellular telephony as well as physically delivering the devices to the centralized data processing facility. '276 Patent, 4:49-50. Further, they argue that the customary meaning of "data transfer system" is well known in the art and the Court should adopt that meaning. The court agrees. See Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (stating that it is "an evasion of the law to construe [a claim] in a manner different from the plain import of its terms."). Given the clear disclosure in the specification, defendants' argument that inventors defined data transfer means as a narrow collection of communication components is not persuasive. The Court construes this term as "a system or mechanism that transfers data."

1156

Data transformation rule sets

JuxtaComm proposes that the Court construe "data transformation rule sets" as "a collection of rules for transforming data." Defendants propose "a collection of rules used to transform a data bag in one format into another data bag of a different format."

To support their additional limitations, Defendants rely on the specification, which they contend defines the term: "Rule sets 54 (Fig. 5) are collections of rules within the present invention. Rule sets are used to transform a data bag in one format into another data bag of a different format." Col. 5:20-22. Defendants also rely other parts of the specification, which they contend describe the data transformation rule set as operating on the data bags. See col. 7:7-9, 8:29-32, 8:54-55. Finally, Defendants contend that the claims require that the "rule set processor" is "for manipulating a data bag for storing imported data and a data bag for storing exported data." See claim 1.

Similar to "rule," the definition in the specification only specifies that the term means "a collection of rules." The additional statements express what the rules are used to do but do not further define what the rules are and are therefore not properly part of the definition. As the specification does not expressly limit the claim language, the claim language is controlling. The claim language does not require that these rule sets operate on the data bags, but on the data. Had the patentees intended to claim otherwise, they could have claimed "data bag transformation rule sets." That the rule set processor, a separate claim element, is "responsive to said script processor for manipulating a data bag for storing imported data and a data bag for storing exported data" does not affect the meaning of "data transformation rule sets."

Accordingly, the Court construes "data transformation rules sets" as "a collection of rules for transforming data."

1157

1. Data Transmission Device of the Portable Unit

PHT, Invivodata, and CRF's proposed constructions for this phrase are similar to their proposed constructions for the phrase "data transmission device capable of connecting directly" in claim 22. eTrials proposes that the court construe the phrase to mean "a device that transmits data and is included within the portable unit."

--- Footnotes ---
8 eTrials' proposed construction does not include a direct connection between the data transmission device and the network for two reasons: (a) claim 34 does not explicitly cite the "direct connection" requirement; and (b) when the patent applicants compared claim 34 to claim 1 (which contains similar language to claim 22), they told the patent examiner that the data transmission devices of the two claims are different. (D.I. 40, at 27 n.11.) eTrials, however, states that "to the extent the court is inclined to construe claims 22 and 34 to require a direct connection, Etrials believes that the construction urged by invivodata and CRF should be adopted." (Id.)

The court has already construed the phrase "data transmission device" and the phrase "part of a single, unified portable unit." As previously stated, the court should construe claim terms consistently. See Southwall Techs., 54 F.3d at 1579. The court, therefore, will construe the term "data transmission device" consistent with its construction of that term in claim 22 to mean "a device that transmits data." The court will not construe the term "data transmission device" as used in claim 34 to include a direct connection, as claim 34 does not include the "direct connection" requirement. In addition, the court will construe the term "of the portable unit" consistent with the phrase "part of a single, unified portable unit" in claim 22 to mean "part of a coherent group or whole that is capable of being carried." Thus, the court will construe "data transmission device of the portable unit" to mean "a device that transmits data and is part of a coherent group or whole that is capable of being carried."
Claim One of the '399 Patent uses the words "to" or "from" when discussing one-way communication. See, e.g., '399 Patent, col. 13:8-13 ("wherein the second command interpreter is configured to interpret a data request command from the host device to the type of input/output device signaled by the first command interpreter as a data transfer command for initiating a transfer of the digital data to the host device.") (emphases added).

Figures 1 and 2 that accompany both Patents show bidirectional arrows connecting the invention to the data transmit/receive device. 12 Figure 1 "shows a general block diagram of the interface device according to the present invention" and Figure 2 shows a "detailed block diagram of an interface device according to a preferred embodiment of the present invention." '399 Patent, col. 5:38-42; '449 Patent, col. 4:41-44 (emphases added); see '399 col. 9:29-30 ("In the preferred embodiment of the interface device 10 shown in FIG. 2 . . . ."); '449, col. 8:29-30 (same); but see '399 col. 9:15-16 ("Figure 2 shows a detailed block diagram of an interface device, according to the present invention") (emphasis added); '449, col. 8:15-16 (same). Again, the description of features of "the present invention" limits the scope of the invention. Verizon, 503 F.3d at 1308. In explaining the invention, Mr. Tasler specified that "[t]he digital signal processor 13 and the memory means 14 are also attached to a second connecting device 15 by means of bidirectional communication lines (shown for all lines by means of two directional arrows)." '399 Patent, col.5:49-56; '449 Patent, col. 4:51-55 (same except "bidirectional" is spelled "bi-directional"). In other words, communication goes in both directions.

12 While Figure 2 shows bidirectional arrows between the interface device and the transmit/receive device, the other portions of Figure 2 reveal unidirectional interaction, with single direction arrows flowing from the sample and hold circuit (which receives data from the transmit/receive device) toward the other components of the interface device, including the analog to digital converter and the digital signal processor. See '399 Patent, Sheet 2; '449 Patent, Sheet 2.

Additionally, in providing background to the invention, the specification states that "[t]he devices from which data is to be acquired cover the entire electrical engineering spectrum" and constitute "very different electrical or electronic systems." '399 Patent, col. 1:34-35, 56-59; '449 Patent, col. 1:36-37, 57-60; see also '399 Patent, col. 12:37-40 (the specification concludes, "[t]he interface device thus provides a universal solution which can cover the entire spectrum of possible data transmit/receive devices."); '449 Patent, col. 11:41-44 (same).

Even more pointed language in the specification describes Figure 1 as showing:

The second connecting device can be attached by means of an output line 16 to a data transmit/receive device which is to receive data from the host device or from which data is to be read, i.e. acquired, and transferred to the host device. The data transmit/receive device itself can also communicate actively with the host device via the first and second connecting device . . . .

'399 Patent, col. 5:56-62; '449 Patent, col. 4:55-61. This language supports the conclusion that, as its name implies, the data transmit/receive device is to "receive data from the host device," or it is the site "from which data is to be read" and it "can also communicate actively with the host device." Id. The specification also notes an "important advantage of the interface device of the present invention" is the "extremely high data transfer rates by using, for data interchange, the host device own [sic] BIOS routines." '399 Patent, col: 8:43-46; '449 Patent, col. 7:43-47 (emphasis added).

In every instance, the Claims, Figures, and specification refer to data transmit/receive devices and not to "data transmit devices" or "data transmit or receive devices." In fact, the name of the interface device itself emphasizes that both data transfer and receipt are important attributes of the data transfer/receive device: the invention is a "flexible interface for communication between a host and an analog I/O device," i.e., the data transmit/receive device is an input and output device. '399 Patent, Title; '449 Patent, Title. While the data transmit/receive device does not engage in two-way communication at all times, the Claims and specification require it to have the capability of two-way communication. The Court thus construes the term "data transmit/receive device" to mean "a device that is capable of transmitting data to and
receiving data from the host device when connected to the host device by the interface device."

C. "data type"

<table>
<thead>
<tr>
<th>Term</th>
<th>Widevine Construction</th>
<th>Verimatrix Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>Data that corresponds to a particular type or format of data.</td>
<td>format by which the content in the payload portion is organized.</td>
</tr>
</tbody>
</table>

There is very little intrinsic evidence to guide the Court's construction of "data type." The specification uses "data type" in only a few places, but each time equating "data type" with a multimedia or streaming format, like Windows Media format. 1 The abstract does not use "data type," but uses the word "media format" in a manner that is consistent with the claims' use of "data type." 2

--- Footnotes ---

1 "[I]f the encryption unit does not see a data type that it specifically recognizes, then it ignores it, but if the encryption unit sees a data type that it does recognize (e.g. Multimedia content), then it selectively encrypts only the recognized portion of the data stream." '175 patent, 5:27-32. "[T]he EB system provides parsing and encryption for a variety of data types and streams including but not limited to Windows Media format and RTP/RTSP using TCP, TCP/UDP or http delivery." '175 patent, 7:17-20.

2 "The apparatus is platform independent in terms of media format and data protocol. The encryption unit encrypts data transparently to the client based on the media format." '175, Abstract. The claim language describes this selective encryption based on "data type" rather than "media format."

--- End Footnotes ---

Widevine urges the Court to reject a definition of data type that means "format" or its equivalent. Widevine points to the prosecution history, in which the applicant thrice amended the language immediately surrounding "data type." The language in '175 patent, claim 1 changed from the following text in June 2004:

an encrypter configured to determine if the first portion of the data is to be encrypted based on a format of the first portion of the data, and if it is to be encrypted, to encrypt the first portion of the data

to this in March 2005:

an encrypter configured to determine if the first portion of the data is to be encrypted [O] based on a format of <O] by inspecting the first portion of the data, the inspection being independent of a packet header, and if it is to be encrypted, to encrypt the first portion of the data

and finally, in July 2005, became:

an encrypter configured to determine if the [O] first <O] payload portion of the data is to be encrypted by [O] inspecting <O] examining the [O] first <O] payload portion of the data to recognize a predefined data type, [O] the
inspection being independent of a packet header, and if it is to be encrypted, to encrypt the payload portion of the data.

According to Widevine, these amendments are inconsistent with defining "data type" to be "format." The Court disagrees that the prosecution history indicates such a rejection of "format." The amendments increase the specificity in the claim language regarding how the invention performs selective encryption. The language in the July 2005 amendment, "encrypted by examining the payload portion of the data to recognize a predefined data type," is a more explicit way of saying that which appears in the June 2004 amendment, "encrypted based on a format of the first portion of the data."

Furthermore, Widevine's proposal incorrectly equates "data type" with data. A "data type" is not data. Rather, it is the manner in which data is stored. The Court construes "data type" to be "format by which the content in the payload portion is organized."

GO BACK

1160

2. "Database"

Defendants assert "database" should be construed to mean "a collection of information organized in such a way that a computer program can quickly access desired pieces of data." Defendants' construction is drawn directly from the definition of "database" provided in the Background of the Invention of the specification. Col. 1, lines 48-51 ("A database (DB) is a collection of information organized in such a way that a computer program can quickly access desired pieces of data."). Plaintiff asserts the term is entitled to its ordinary meaning, but if the Court deems construction necessary, "database" should be construed to mean "a SQL-compatible or other relational database."

The Court agrees with Defendants that Plaintiff acted as his own lexicographer by defining "database" in the specification. Where a patentee explicitly defines a claim term in the specification, he acts as his own lexicographer and that definition trumps others. Sinorgchem Co., Shandong v. Int'l Trade Comm'n, 511 F.3d 1132, 1136 (Fed. Cir. 2007) ("the patentee must be bound by the express definition.") (citations omitted). "The patentee's lexicography must, of course, appear 'with reasonable clarity, deliberateness, and precision' before it can affect the claim." Renishaw PLC v. Marposs Societa per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998). Here, Plaintiff's definition of "database" was deliberate and clear. In addition, there is nothing in the claims or specification that limits "database" to "a SQL-compatible or other relational database."

"Absent a special and particular definition created by the patent applicant, terms in a claim are to be given their ordinary and accustomed meaning." Id. at 1249-50. Thus, when a claim term is expressed in general descriptive words, the Court may not "add a narrowing modifier before an otherwise general term that stands unmodified in a claim." Id. Moreover, Plaintiff's construction does not actually define "database," but rather specifies a particular type of database.

Therefore, the Court construes "database" to mean "a collection of information organized in such a way that a computer program can quickly access desired pieces of data."

GO BACK

1161

M. "database"

Claim 1 contains the term "database": "a database with entries correlating each of a plurality of user IDs with an individualized rule set." The term "database" appears throughout the specification. The plaintiff asserts that no construction of "database" is necessary. If a construction is required, the plaintiff proposes "a structured set of data held in a computer." In contrast, BWI contends that this term means a "relational database that stores data in a collection of records wherein each record has at least one field common to other records."

BWI argues that "database" must be construed as a relational database. In support of its proposed construction, BWI quotes the following language from the specification: "The database 206 is a relational database which stores the system data." ('118 patent, 4:33-34) (emphasis added). BWI contends that this language does not state that the database could be or may be
a relational database; instead, it says that the database is a relational database. But the quoted sentence is located within the "Detailed Description of the Invention"; this section begins with "[i]n the following embodiments of the invention." ('118 patent, 3:45). Figure 2 and the "database 206," discussed in the Detailed Description, illustrate embodiments of the claimed invention. Although relational databases are a preferred embodiment, nothing in the claims or specification exclude other forms of data storage, such as a flat file. Therefore, the court construes "database" to mean "a structured set of data held in a computer."

9. "database"

This word appears within the phrase "communicating over a network the monitored patient data elements to a remote command center, the remote command center comprising a database and a work station."

Plaintiff requests the construction, "an organized collection of electronic information." Defendants propose, "a device for storing an organized collection of all patient data elements." In short, the dispute is over whether the construction should be a collection of organized information or a device.

Plaintiff submitted the un-rebutted declaration of Dr. Jeff C. Goldsmith, which states that a person of ordinary skill in the art at the time of the inventions would understand a database to be a collection of digital information, not a physical device. In their brief, defendants argue that a database is a physical device and the specification refers to a database server, which is also a physical device. However, defendants point to no intrinsic or extrinsic evidence which would justify using the word "device." Thus, relying in part on the Goldsmith Declaration, we adopt plaintiff's construction. The term is construed as: "an organized collection of electronic information."

G. "Database"

With the exception of claims 1-2 and 4-7 of the '617 patent, the term "database" appears in all claims of every patent. The term is primarily used in the patent claims to describe a database that is created by the invention. For example, claim 1 of the '511 patent describes using information to define a structure for a "first database" that did not previously exist, while claim 2 of the '511 patent describes using a driver to store at least some information from a data source into the "first database." In a different context, the '382 patent also uses the term "database" to describe a type of "data source" from which information may be retrieved. See '382 patent, claim 24.

Timeline's proposed construction of "database" is "a collection of organized information accessible through computer software. A database is not to be confused with a data repository which is a file or other data storage structure in which the database is stored." ProClarity's proposed construction is "a recorded reference to a database repository which serves as the location where the information loaded from the data source or sources will be saved into data tables."

As Timeline notes, its proposed construction finds support in contemporaneous dictionary definitions of the term. See, e.g., American Heritage Dictionary (2d ed. 1985) (defining "database" as "a comprehensive collection of related data organized for convenient access, generally in a computer"); The Computer Glossary (1995) (defining database as ":(1) a set of interrelated files that is created and managed by a DBMS [database management system]. (2) Any electronically-stored collection of data"). However, Timeline's proposed construction is also extremely broad. Conceivably, it could encompass virtually any collection of information stored on a computer-including information collected in "flat file" forms such as a spreadsheet. As ProClarity notes, the specification for the '511 patent explicitly observes that information "may be stored in forms that are not, strictly speaking, database forms such as storing data in a 'flat file' form, as a spreadsheet, and the like." '511 patent, Col. 2:20-23. In addition, the '511 patent specification acknowledges that "at least according to some usage, 'flat file' information storage is not a true database system." '511 patent, Col. 5:52-54.
ProClarity also argues that a "database" as used in the claims is essentially a container in which data is stored (i.e., a repository), rather than the actual collection of information itself. In a similar vein, ProClarity contends that Timeline's proposed construction is deficient because it would fail to account for an "empty database." In response, Timeline argues that the patent claims distinguish a "database" from a "repository." For example, Timeline points to claim 17 of the '382 patent, which claims "'[a] method . . . further comprising creating a database repository without first forming said new database." '382 patent, Col. 24:41-43. Timeline also argues that a database must contain data, noting that claim 24 of the '382 patent uses the term "database" to describe a particular type of data source.

The court declines to adopt either parties' proposed construction in full. The court agrees with Timeline that the term "database" cannot be construed as a "recorded reference to a database repository where information from a data source will be stored." This proposed construction finds little support in the intrinsic evidence and such a cramped construction would not fairly encompass the term as it is used in the patents. By contrast, Timeline's proposal that a database is a "collection of organized information" is consistent with the ordinary meaning of the term. Although ProClarity suggests that the term should be construed to allow for an "empty database," a logical reading of the term would dictate that a database includes data. The patents plainly describe the creation of databases that contain data from various sources. For example, the '511 specification notes that the invention "may create one or more new databases 808, containing data from one or more of the various data sources. . . ." '511 patent, Col. 10:16-18.

However, the court also agrees with ProClarity's argument that a database, as the term is used in the patents, does not include a collection of information stored in a "flat file" form such as a spreadsheet. As discussed above, the specification for the '511 patent expressly noted that "information may be stored in forms that are not, strictly speaking, database forms such as storing data in a 'flat file' form, as a spreadsheet, and the like." The '511 patent specification includes other examples contrasting "flat file" systems to database systems. See, e.g., '511 patent, Col. 8:23-42 (comparing scientific or technical information stored in a flat file system to information stored in a relational database system). In light of such language in the specification, a person of ordinary skill in the art who reviewed the '511 patent would likely conclude that the patentee did not intend the term "database" to encompass a collection of information stored in a "flat file" form.

Therefore, the court construes the term "database" to mean "a collection of organized information accessible through computer software, distinguishable from a collection of information stored in a flat file form such as a spreadsheet."

The Court construes "database" to mean "a collection of logically related data stored together in one or more computerized files." See IEEE Standard Dictionary of Elec. & Elecs. Terms, at 251 (6th ed. 1996) (defining "database"). The parties dispute the relevance of "stored together" in the IEEE Dictionary definition. Sovereign's proposed construction would not limit a database to data stored together. This is too broad to reflect the ordinary and accustomed meaning to one of ordinary skill in the art. Amazon's proposed construction limits a database to data records maintained in a single file. This is too narrow.

The court agrees with 01 Communique that no construction of this phrase is required.
Judge Hubel construed the term "database field" to mean "the space reserved in a database for storage of a particular type of data." Construction Order 1 at 46. Defendant has presented evidence that the XAP System does not reserve space for all of the data to be stored.

Defendant previously requested Judge Hubel and this Court to construe this limitation to mean "each record capable of storing information corresponding to each of the database fields." If so construed, "every record has space reserved for storage for all of the application information fields stored in the database." This Court, like Judge Hubel, rejected Defendant's construction and indicated the issue should "be developed on summary judgment."

(a) Function: retrieve and store data in a relational database system. 
(c) A unit having inputs Structure: the Database Interface Unit with input interface(s) and output interface(s) as illustrated in Figs. 4, 5, 6, 7, 8, and 9 of various embodiments.

(b) Function: retrieve and store data, including metadata, in a relational database system Structure: the Database Interface Unit with input interface(s) and output interface(s) as illustrated in Figs. 4, 5, 6, 7, 8, and 9 of the various embodiments disclosed in the patent, and their equivalents.

(c) Function: retrieve and store data in a relational database system, and to apply statements to the database. Structure: the Database Interface Unit with input interface(s) and output interface(s) as illustrated in Figs. 4, 5, 6, 7, 8, and 9 of various embodiments.

"[A] claim term that does not use 'means' will trigger the rebuttable presumption that § 112 P 6 does not apply." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002). "This presumption can be rebutted 'by showing that the claim element recite[s] a function without reciting sufficient structure for performing that function.'" DePuy Spine, Inc. v. Medtronic Sofamor Danek, Inc., 469 F.3d 1005, 1023 (Fed. Cir. 2006) (quoting Watts v. XL Sys., Inc., 232 F.3d 877, 880-81 (Fed. Cir. 2000)). 

Defendant attempts to rebut the law's strong presumption by arguing "[t]he phrase 'database interface unit . . . for' is a means-plus-function limitation under § 112 P 6 because it recites function without 'sufficiently definite' structure." DEF.'S RESP. at 19. Defendant further argues "unit" is a nonce word and that "database interface unit" does not have a generally understood, non-generic meaning to a skilled artisan. DEF.'S RESP. at 19-20; DEF.'S REPLY at 7-8. Plaintiff responds, arguing the "database interface unit" terms connote sufficient structure such that the presumption that § 112 P 6 does not apply cannot be overcome. PL.'S BR. at 27-28.

Although the "database interface unit" terms connote some function, they more prominently connote structure and are stated
as structure. Indeed, a skilled artisan would understand their implementation as a well-known and definite structure within a software architecture. The written description of the invention describes a software architecture for accomplishing the claimed invention. See generally '776 Patent 4:39-20:67. Particular figures and their accompanying text detail the software components that makeup this overall architecture. See, e.g., id. at 9:66-10:27 (describing the functions performed by and the connections to Database Exchange Unit 210). These components consist of smaller modules or routines which operate in a specifically claimed concert with other modules or routines to perform the described functions. See, e.g., id. at 10:28-44 (describing the modular makeup of Database Exchange Unit 210). The "database interface unit" terms describe a particular module utilized by the Database Exchange Unit, the Schema Generator, and the Schema Reverse Engineering Unit. See id. at Figures 5-9, 10:28-14:34. Throughout the written description and the claim language, the terms are used to signify a software structure or module, connected to other software structures and possessing a specific place in the overall software architecture. See, e.g., id. at 21:29-32 (claiming "a database interface unit having inputs and outputs . . coupled to the relational system and the mapping unit"). In each instance, a "database interface unit" is simply the module or component that interacts with the relational database. E.g., id. Accordingly, the terms recite sufficient structure and the presumption that § 112 P 6 does not apply is not rebutted. One of ordinary skill in the art would understand the database interface unit connotes structure and would further understand the nature of that structure in the overall claimed architecture. See Alcatel USA Res., Inc. v. Microsoft Corp., No. 6:06-cv-500, 2008 U.S. Dist. LEXIS 49615, 2008 WL 2625852, at *17-18 (E.D. Tex. June 27, 2008).

Therefore, the Court finds these terms are not means-plus-function claims subject to interpretation under § 112 P 6. Having resolved the parties' dispute, the Court finds the terms do not require construction because their meanings are clear in the context of the claim and will be readily understandable to the jury. O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1362 (Fed. Cir. 2008); Fenner Inv. Ltd. v. Microsoft Corp., No. 6:07-cv-8, 2008 U.S. Dist. LEXIS 65686, 2008 WL 3981838 at *3 (E.D. Tex. Aug. 22, 2008) (finding that a court need not construe a disputed term as long as it has resolved the claim scope dispute between the parties). The Court recognizes the terms, standing alone, would be difficult for a lay jury to understand. Read in context, however, the claim language explains what a database interface unit is and what it does. 2 Although the Court does not construe these terms, the parties may not interpret them in a manner that is inconsistent with this opinion.

2 The Court's conclusion is further supported by the parties' alternative proposals, which essentially restate the claim language. The Court finds a restatement of the claim language unnecessary.
The Court agrees that this definition, with some adaptation based on the plain language of the claim, more accurately defines the "database server" depicted in Plaintiff's invention. The Court finds that a person skilled in the art would understand "database server" to mean "network device dedicated to storing and providing access to a shared database, including data and forms."

The plain language of claim 1 and the specification support this construction. Browser-based subscribers gain access to the database server, labeled "32" in Figure 1 of the '229 patent, through the home page of a website via an internet service provider ("ISP"). ('229 patent, col. 5, ll. 55-58). Data entered on forms is entered into the database server, which utilizes software to produce billing invoices and statements to clients and customers of subscribers. (Id., col. 5, l. 65-col. 6, l. 4).

The specification explains that the subscriber enters data into the forms which are then entered into the database server:

"Forms are completed and transferred from the corresponding subscriber area for forwarding into a database server which is of the open database compliant type (ODBC)." (Id., col. 3, ll. 58-60). "Data entered via forms processing is transferred into the database server which utilizes appropriate application software therein to produce billing invoices and statements to clients and customers of each corresponding browser-based subscriber." (Id., col. 2, ll. 59-63).

The specification also indicates that subscribers can access information stored in the database server:

"These query forms provide each subscriber with access to the database server which, in combination with drop-down lists, select the desired account for access to the database of the data server 32 to retrieve the requested information to the screen of the remote PC." (Id., col. 4, ll. 9-13).

Subscribers can also access forms from the database server. The specification provides that forms are transferred into the database server from Billingnetwork PCs:

"Input and query forms are developed within the system 11 by billing network PC work stations 38 which are connected at hub 36, all forms and information input being subject to business rules and logic at 34 before entered into the database server 32." (Id., col 4, ll. 13-18).

Next, the specification provides that "once into the particular browser-based subscriber area 80 within the system 71, each browser-based subscriber 72 will have access to one of several customized forms that they will complete electronically at their work station and transfer to the database server 90. Form development and customization will be done within the system at internal work stations 106 by employees of the system." (Id., col. 5, ll. 12-18). Figure 1 shows that the forms must pass through the database server to reach the subscriber areas. As Plaintiff and Defendants suggest by their proposed constructions, the database server stores information and provides access to the database and to the forms.

Plaintiff describes the server as a "computer system on a network," based on the cited dictionary definition. However, the '229 patent specification refers to the "browser-based subscriber system" as encompassing the subscriber PC, homepage, subscriber areas, database server and Billingnetwork PCs, among other components. (Id. at Fig. 1)(emphasis added). Accordingly, the Court finds that the term "system" is inconsistent with the patent specification, as the database server is not a "system."

Defendants' use of the word "device" stems from their cited definition of a database server as "[a] network node, or station, dedicated to storing and providing access to a shared database." (See Dkt. 68 at Ex. B)(emphasis added). As the database server is but one component of the described "system," the Court finds that the term "device" is consistent with the patent specification, utilizing the definitions in the Microsoft Computer Dictionary (Dkt. 68, Ex. B). n2 Further, in accordance with both parties' suggested constructions and the specification descriptions, the purpose of this device is to store a database and provide access to the database and to forms. Accordingly, the Court construes the term "database server" to mean "network device dedicated to storing and providing access to a shared database, including data and forms."

--- Footnotes ---

n2 That dictionary defines a "database server" as a "network node." "Node" is defined as a "device."
2. "database server"

The parties dispute the meaning of the term "database server" as that term is used in claim 1. Manheim argues that "database server" should mean "a computer or program that responds to commands from a client that contains data." This definition is too broad, and would plainly encompass much more than the "database server" claimed. Moreover, it appears in conflict with the declaration of Manheim's expert, who stated that "database server" is a term well known to those of ordinary skill in the art, and means "[a] network node, or station, dedicated to storing and providing access to a shared database." (Bailey Decl. P 21 (quoting Computer Dictionary (3d ed. 1997) at 129).)

AMS and BidSoft contend that the term should be construed to mean "relational database software implemented on a computer," and offer two bases in the intrinsic record to support their construction. First, they note that the claim language itself supports this reading because the ability to "select," "locate" and "organize" data as claimed implies a functionality inherent to relational database systems. (See Alexander Decl. P 67; '873 patent, col. 11, ll 15-21.)

Second, they contend that this reading is supported by the specification, which states in the Summary of the Invention that the "system of the present invention" includes a "[a]n SQL server attached to the host network contain[ing] a relational database of auction information." ('873 patent, col. 2, ll. 8-10.)

Manheim counters that the definition proposed by AMS and BidSoft improperly reads a limitation into the claim from the preferred embodiment, and argues that their interpretation of the claim language as requiring a relational database is nothing more than an unsupported assertion. (See Manheim Resp. Br. [381-1] at 19-20.) Additionally, Manheim argues that there is nothing in the specification which indicates a clear disavowal or disclaimer of database servers other than relational database servers. (See id. at 17-19.)

Contrary to Manheim's position that the interpretation of the claim language offered by AMS and Bidsoft is nothing more than a "bald assertion," Dr. Alexander stated in his declaration:

claim 1, clause (d) provides:

command options selectable by the user to generate the user commands, whereby the selected portions of the auction data stored on the host computer network are located, organized, and transmitted over the communications network to a workstation in response to one or more particular user commands

See '873 patent at col. 11, ll. 15-21 (emphasis added).

The use of terminology relating to "selected portions of the auction data" being "located and organized" indicates that a software program running on a computer on the host network is capable of record selection and the manipulation of data contained within files. It implies functionality such as that found in a relational database, and rules out more trivial database forms such as simple file servers, which are incapable of this form of such behavior in their native form.

(Alexander Decl. P 67.) However, to say that something implies a functionality found in relational databases, is not to say that this functionality is limited to relational databases. To be sure, a relational database may be ideally suited for the task. Indeed, this would explain why the preferred embodiment discloses a relational database. But, simply because the patentee chose to disclose the ideal means for practicing the invention does not mean that the scope of the patent is so limited.

Because the Court can neither conclude that the patentee chose to define "database" as a relational database, nor that the claim language requires the use of a relational database, the court declines to adopt AMS and BidSoft's proposed definition of "database server." Therefore the Court cannot accept AMS's proposed construction. Similarly, because the definition proffered by Manheim is far too broad, and would plainly encompass much more than the "database server" claimed, the Court cannot accept Manheim's proposed definition. Instead, the Court adopts a plain meaning definition, wherein the term

-PUBPAT-
"database server" in claim 1 shall mean a "network device dedicated to storing and providing access to a shared database."

2. "database synchronization process" Used in independent Claims 1, 9, 16, 24 and 27.

The importance of this term is indicated by the prosecution history. The original application for the '600 patent contained Claims 1-29. The applicant filed an amendment, which cancelled these claims and added new Claims 30-49. The PTO Examiner rejected these claims for obviousness. The applicant responded by amending Claims 30, 37, and 43 (now Claims 1, 9, and 16 respectively) to include the language "to initiate a database synchronization process for configuration information of the network element in response to the received trap being out-of-sequence." The applicant also included the new phrase, "for initiating a database synchronization process" in Claims 53 and 58 of the amendment (now Claims 24 and 27 respectively). The Examiner indicated in the Statement of Reasons for Allowance that this distinguished the invention from prior art. Notice of Allowance, July 17, 2001, p. 2, Bates stamped 00000259, Exhibit D part 3 of Cisco's Opening Claim Construction Brief, [Doc. # 49, Attachment # 2, p. 18 of 25].

To define the term "database synchronization process" Cisco proposes:

"updating configuration information stored at a location other than at a network element with configuration information obtained from the network element."

Telcordia suggests:

"a process that reconciles configuration information of a network element with the configuration information for that network element stored in the network manager database."

The parties have agreed that the "network manager" is hardware and/or software that manages and coordinates the operation of network elements in a communication network.

The parties also agree that "configuration information" is any information maintained in a Management Information Base (MIB) of a network element, and any communications from network elements using a management network. The specification states that the network manager (or server) maintains at least portions of configuration information stored in the MIB of each network element in a memory. This memory may be in the form of one or more caches and/or one or more databases. '600 patent, col. 3, ll. 59-64. Maintaining selected configuration information in one or more caches, as well as maintaining full configuration information in a database, improves access to the information. '600 patent, col. 2, ll. 13-17.

--- Footnotes ---

6 One of ordinary skill in the art would know that cache memory or cache refers to a memory from which data can be accessed more quickly than from a database, and is usually of a more temporary nature. See '600 patent col. 4, ll. 6-8. See IEEE Standard Dictionary of Electrical and Electronics Terms 124 (6th ed. 1990); Steven M. Kaplan, Wiley Electrical and Electronics and Engineering Dictionary 89 (1st ed. 2004).

--- End Footnotes ---

The specification states that configuration information in a network element can change for a number of reasons. '600 patent, col. 4, ll. 29-33. The network manager keeps track of these changes "to maintain a consistent and accurate view of the managed network element." '600 patent, col. 2, ll. 20-21. In the claims, this process is called the "database synchronization process." '600 patent, col. 13, ll. 19-22.

Telcordia's proposed construction, as written, implies that changes could be made at the MIB of the network element. This is probably not what Telcordia intended, because its brief states: "the specification is clear, and Cisco's brief repeatedly admits, that the copy of the configuration information being updated is stored at the network manager." Telcordia's Responsive Claim Construction Brief, [Doc. # 57, Attachment # 1, p. 14 of 29].
On the other hand, Cisco's suggestion that information being updated is stored "at a location other than at a network element" seems unnecessarily coy. The configuration information is not being stored in a closet - it is stored in one or more databases. As described repeatedly in the patent it is the network manager or server that maintains the configuration information. See the Abstract; '600 patent, col. 1, ll. 64-67; '600 patent, col. 2, ll. 1-4.

The server "may receive configuration information" in the form of traps, by polling the network elements, or from another network management device or system. '600 patent, col. 2, ll. 18-30. "The present invention manages all of this information to achieve a consistent and accurate view of the network element in both a cache of information immediately available to clients and a database." '600 patent, col. 2, ll. 30-34. Nothing in the claim language, the specification, or the prosecution history, even hints that configuration information from a network element is stored anywhere else.

At the hearing, the court discussed with the parties the possibility that this disputed term referred to updating configuration information being stored in a cache memory. However, the inventors chose the term "database synchronization process." Neither the claim language nor the specification indicates that the inventors chose to specially define "database," as including "cache." To the contrary, the specification consistently distinguishes between the two by describing them separately. "[T]he server maintains one or more caches of selected configuration information readily available to clients, as well as a persistent storage of full configuration information in a database." '600 patent, col. 2, ll. 13-17 (emphasis added). See also '600 Patent, col. 2, ll. 30-34.

The specification notes that configuration information stored in an MIB for a network element is maintained "in a memory, which may include one or more selected caches 30 (referred to generally as cache 30) and one or more databases 32 (referred to generally as database 32)." '600 patent, col. 3, ll. 59-64. (emphasis added) The "cache" includes selected information that is readily accessible, whereas database 32 includes a complete and persistent copy of configuration information stored in MIB 24. '600 patent, col. 3, l. 67 - col. 4, l. 1.

While "database" and "cache" are both used in their normal sense as part of the memory of the system, the inventors did not claim a "memory synchronization process" or a "cache synchronization process." Nothing in the claim language, the specification, or the prosecution history indicates an intent to define "database," as used in this disputed term, as including cache memory. The court will define this term as follows:

"Database synchronization process" means "updating configuration information that is stored by the network manager in one or more databases, based upon the values stored in the MIB of the network elements."

As such, the court defines "receive datapath" as "path of received data." The court defines "transmit datapath" as "path of transmitted data."

EMC asks the Court to construe this term as: "Arranging the computer system such that the faulted component is functionally removed from the system." HP proposes (in its opposition brief): "Functionally removing a non-redundant
faulted component from the computer system such that the function performed by the faulted component is not replaced. De-configuring the computer system does not include the step of replacing the faulted component or the functionality performed by the faulted component with a redundant component or with equivalent functionality."

Nothing in the claim language indicates that only a "non-redundant" component or functionality is removed, and HP's attempt to limit this term on the basis of the prosecution history is unsupported by the record. The inventors did not state that only "non-redundant" components are removed. Rather, in the cited portion of the prosecution history, they stated that in the claimed invention "a faulted component is not replaced by another redundant component nor is the system re-configured." Derringer Decl., Separate Appendix, vol. IX, p. 2611 (file history to U.S. Pat. No. 6,122,756).

The claim language indicates that one result of "de-configuring the computer system" is the removal of the identified faulted component from the computer system. Nothing in the claim language indicates that the component or its functionality is not replaced, although it is true that such replacement is not expressly claimed. Assuming for the sake of argument that the inventor disclaimed a "re-configuration" limitation in the course of prosecution, such an event would lead the Court only to omit such a limitation from protection by the claim at issue. It would not result in defining the "de-configuration" step by reference to a lack of "re-configuration." The claim simply does not refer in any way to replacement of functionality or components.

Accordingly, the Court construes this term as "functionally removing a faulted component from the computer system."

1173

11. "Selectively deactivating" ('771, Claim 1)

The parties agree that "selectively" means "by choice," but they disagree as to the meaning of "deactivate," which Agere defines as "turn off" and Broadcom defines as "make inactive." Broadcom provides two dictionary definitions of "deactivate" that directly support its construction. (Broadcom Reply at 29 (citing Webster's definition, "to make inactive," and OED definition, "to render inactive or less reactive").) By contrast, Agere begins its convoluted dictionary interpretation with a definition of "activate," adds to this the definition of the prefix "de-," and then asserts, purely as an ipse dixit, that the resulting 'definition'--"to stop an operation"--means "to turn off." Agere provides no explanation of why, even if its methodology were proper, the definition "to stop an operation" would support Agere's construction rather than Broadcom's. Thus, the Court finds that Agere's dictionary citations do not support its construction, and therefore the Court credits the testimony of Dr. Acampora and Broadcom's dictionary citations that the customary meaning of "deactivate" to a person of skill in the art is "to make inactive."

The specifications provide no reason to abandon the customary meaning. There is no dispute that the patent uses a variety of different phrases to refer to the transceiver when it is deactivated, including "sleep state" ('771 patent, Abstract), "dormant" (id., col. 52, ll. 54-56), "powered down" (id., col. 34, ll. 34-35), and "turned off" (id., col. 56, ll. 9-10). Agere argues that all of these terms are synonyms meaning "turned off," while Broadcom contends that they describe various points on a spectrum of "inactive" modes. The Court finds that, at the very least, the use of these various terms leads to ambiguity, which falls far short of the "express disclaimer" that would be required to overcome the presumption in favor of the term's customary meaning. Furthermore, even if the Court were to resolve this ambiguity, it would almost certainly be resolved in Broadcom's favor. The patent Abstract, which appears to contain the only explicitly definitional reference to the term "deactivate," states that "the terminal may deactivate the transceiver, i.e., place it in a sleep state." The use of the term "sleep" to describe the transceiver's deactivation strongly suggests a mode that lies between "on" and "off," rather than the complete shut-down suggested by Agere. 45 Thus, the Court finds that the specifications are consistent with the customary meaning of the term, and Broadcom's proposed construction is therefore adopted.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

45 The Court notes the common use of the term "sleep" to refer to the inactive, but not off, state used by laptop computers to preserve battery life. However, because the Court is uncertain regarding whether this usage is applicable to the time of the '771 patent, it is not a basis for the Court's holding.
There are two terms in Claim 1(d) that require construction: "deactivating" and "reset signal."

With respect to the "deactivating" term, Agrizap argues that it should be construed as:

any manner of deactivating the generator at the end of the predetermined time period or in response to a reset signal, the end of the predetermined time frame being determined in any manner and the reset signal being produced and sensed in any manner including hardware, software/ firmware or any combination thereof. (Agrizap's Reply Br., at 14).

Woodstream argues that "deactivating means stopping the activated generator" and that "the generator can be deactivated only upon the two enumerated conditions and not any other conditions, i.e., deactivating can occur only upon expiration of the predetermined time period or in response to a reset signal" and "the generator must be capable of being deactivated under both [of these] recited conditions." (Woodstream's Reply Br., at 10-11). In response, Agrizap argues that requiring the deactivation to be performed only by these two conditions and requiring that the generator must be capable of performing both of these conditions are unsupported and unrelated limitations to this claim construction.

This Court will construe "deactivating" as:

the stopping of the activated generator either upon the expiration of the predetermined time period or in response to a reset signal. The activated generator can be deactivated only upon either of these two conditions (expiration of predetermined time period or in response to a reset signal) and the generator must be capable of being deactivated by both of these conditions.

First, the ordinary and customary meaning of "deactivating" means making the activated generator inactive, or more simply, stopping the activated generator. See Webster's 3d. New Int'l Dictionary 579 (3d ed. 1993) (defining "deactivate" as "to make inactive or ineffective"). The essential disagreement between the parties, however, is not about what "deactivating" means, but rather about how "deactivating" of the activated generator occurs. The words of Claim 1(d) themselves clearly state that deactivation occurs "only" upon (1) the expiration of the predetermined time period or (2) in response to a reset signal. See Phillips, 415 F.3d at 1314 ("[T]he claims themselves provide substantial guidance as to the meaning of particular claim terms."). Therefore, deactivation can occur only upon these two conditions and the generator must be capable of being deactivated by both of these conditions.

Dealer interface

The Court agrees with Autobytel's construction and construes the term as "a hardware/software module used by a dealer to access the Data Center system." Dealix argues that the term should be construed as a "mechanism through which a dealer accesses his exclusive database region of the system database." During the Markman hearing, Dealix agreed to "hardware/software module" in place of "mechanism." However, Dealix still argues that the specification and claim language indicate that the module gives the dealer access specifically to his exclusive database region as opposed to the Data Center system in general. In support of its argument, Dealix points to language in the specification that states, "The dealer access module 612 provides a dealer an interface into the Data Center system. . . . More particularly, a dealer may directly access its exclusive database region, and the information contained therein, by logging into the Data Center system through the dealer access module 612." Col. 17:37-44. Autobytel argues that this same language from the specification supports its construction. Specifically, Autobytel points to the first sentence of the section cited by Dealix, which states, "The dealer access module 612 provides a dealer an interface into the Data Center system. . . ." The second sentence, which Dealix relies on, does not express a limitation of the dealer's access, but clarifies how the dealer gains access to its exclusive database region. Autobytel contends that this first sentence cited by Dealix sufficiently describes the "dealer interface" and that inclusion of the term

- 1614 -
"exclusive database region" only adds unnecessary confusion because the Court is separately construing that term. The Court is persuaded by Autobytel's arguments and construes the term in accordance with Autobytel's proposed construction.

A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>n2&quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface&quot;</td>
</tr>
<tr>
<td>&quot;ID information [stored&quot;</td>
<td>&quot;data stored on the terminal in&quot;</td>
</tr>
</tbody>
</table>
on the terminal"

"Stored thereon prior to the transaction"

"Relates . . . in a predetermined manner"

"Matching" and "Matched"

"Retrieving via the terminal"

"Computer" and "Computer means"

"Transmitting to a computer"

"Validation" and "Valid"

"Computer means disposed remotely"

"Card reader means"

"Communication means" function

"Communication means" structure

"Selected from a group of ID information" (Claim 2)

--- Footnotes ---

n2 "ID," as used throughout this opinion, in whatever context, is shorthand for "identification."
C. "debit purchase transaction"

The parties' dispute with respect to the proper construction "debit purchase transaction" is identical to their dispute over "debit styled card." Essentially, the parties again dispute whether this term includes ATM card transactions. SVS proposes that "debit purchase transaction" means "a transaction made using a debit styled card," with "debit styled card" having the meaning SVS has proposed, which includes ATM cards. (D.I. 47 at 9) CAT proposes that "debit purchase transaction" instead be construed as "a purchase transaction using funds that have been, or are being, assigned to the intrinsic value of a card/account." (D.I. 44 at 10)

For the reasons discussed in connection with the dispute over the "debit styled card" term, I agree that a "debit purchase transaction" includes a purchase transaction made using an ATM card. Accordingly, I recommend that the term "debit purchase transaction" be construed to mean "a purchase transaction made using a debit styled card," with debit styled card construed as I have previously recommended. 6

6 The parties agree that "debit purchase transaction" does not include a credit card transaction. (D.I. 60 at 95, 98)

B. "debit styled card"

SVS proposes that the term "debit styled card," as used in each of the four independent claims of the '859 patent, means "a card having a value in an associated account or a value stored on the card itself." (D.I. 43 at 11) CAT, by contrast, construes the term to mean "a prepaid card having an intrinsic value." (D.I. 44 at 19) The parties' competing constructions reflect their disagreement as to whether the term "debit styled card" includes ATM cards. 3 I agree with SVS that a "debit styled card" includes ATM cards and, therefore, recommend that the Court adopt SVS's proposed construction.

3 The parties agree that the term does not include credit cards. (D.I. 47 at 8; D.I. 46 at 8)

In CAT's view, the '859 patent discloses three distinct inventions: 1) an apparatus; 2) a method for activation of debit cards, cellular phones, and cellular accounts; and 3) a method relating to prepaid debit systems. (D.I. 60 at 26-27) CAT asserts that while the apparatus disclosed may be capable of processing purchase transactions using ATM cards, the method of processing of such cards is not claimed by the patent. (D.I. 46 at 8; D.I. 60 at 29) This is because while the patent was initially filed with apparatus claims, the applicant withdrew those claims during prosecution, and the patent subsequently issued with only method claims. (D.I. 43 Ex. C (Sept. 15, 1997 Preliminary Amendment)) Nothing in the record indicates that the specification was ever amended to reflect that the apparatus claims were withdrawn. (D.I. 60 at 32)

Relying on its expert, CAT contends that while the '859 patent generally discloses three types of point-of-sale transactions utilizing a card -- termed "pay before" (e.g., a prepaid gift card), "pay now" (ATM card), and "pay later" (credit card) -- the patent only claims transactions utilizing pay before (i.e., prepaid) cards. (D.I. 44 at 19-20 Ex. 5 (Grimes Decl.) P 44) CAT submits that references to ATM cards in the patent refer to either the subject matter of the abandoned apparatus claims 4 or
the different payment forms that may be used to purchase a prepaid card. (D.I. 60 at 33; D.I. 44 at 20-21)

4 The abandoned apparatus claims included original dependent claim 10, which generally claimed a counter top terminal system useful in processing debit purchase transactions, the system comprising, among other things, "a phone card, a debit card, and an ATM card." (D.I. 43 Ex. C (Sept. 15, 1997 Preliminary Amendment) at SVS000175-176)

According to SVS, CAT's construction improperly excludes the preferred embodiment relating to ATM cards. (D.I. 47 at 2; D.I. 60 at 53) The portion of the specification that SVS contends details the ATM card embodiment reads:

By way of example, and as illustrated with reference to FIG. 2, ATM/Debit transactions 100 are performed in a manner that is familiar to the customer using their ATM or debit card. The customer selects a product, takes it to the sales counter for checkout, then as illustrated with reference to FIG. 2 provides input, by way of example, by swiping 101 the ATM/Debit card through the card reader 20 of the terminal unit 12 described earlier with reference to FIG. 1.

('859 patent, col. 3 lines 25-33) CAT's response -- that this portion of the specification is limited to the abandoned apparatus claims -- is unpersuasive. The "Detailed Description of the Preferred Embodiments" section is divided into two subparts: "The System" and "In Operation." ('859 patent, col. 2 line 53 & col. 3 line 24) The description of the system (i.e., apparatus) for processing debit purchase transactions immediately follows the subheader "The System," whereas the preferred embodiments of the different methods of processing debit purchase transactions, including the quoted language above, follow the subheader "In Operation." Hence, the quoted language is not limited to a description of the apparatus; rather, it also relates to the issued method claims.

CAT also argues that processing ATM cards is shown not to be part of the claimed invention because the specification describes the system as "capable of performing ATM transactions" ('859 patent, col. 2 lines 2-3), instead of saying processing ATM cards is "another feature of the system" or "yet another application," the language with which the "Summary of Invention" describes activation of prepaid debit cards (id. col. 2 lines 3-6). (D.I. 60 at 26, 29) However, the specification does not use these terms uniformly in the manner CAT's argument requires. Sometimes a "capability" (e.g., the "capability of receiving cash back from the store") is described as "[a]n additional feature" of the invention. ('859 patent, col. 3 lines 47-48) Other times part of the invention (e.g., the "Summary of the Invention's" introduction of the phone card embodiment) is described as merely being "useful." ('859 patent, col. 1 lines 64-66) Thus, the applicants did not use the words "feature" and "application" solely to introduce preferred embodiments of the invention; moreover, their use of word "capability" does not exclude ATM cards from the claimed embodiments.

Moreover, the independent claims of the '859 patent are facially broad enough to encompass the processing of ATM cards and there is nothing in the prosecution history from which one could find that the applicants disclaimed the processing of ATM cards when they disclaimed the apparatus. (D.I. 60 at 92-93, 99)

Furthermore, the problem the inventor was trying to solve supports that a debit styled card includes an ATM card. The "Background of the Invention" indicates that the inventor was trying to develop an inexpensive way of providing purchasing options to customers without the need for high capital investment by retailers, to allow smaller retail stores to capture the business of the 224 million ATM cardholders in the United States. ('859 patent, col. 1 lines 20 to 51) The specification goes on to detail the advantages to the merchant of point-of-sale debit transactions, which include guaranteed payment and a flat low fee for ATM transactions. ('859 patent, col. 2 lines 13-18) These goals indicate that the inventor envisioned that the debit styled card essential to the processing of debit purchase transactions includes ATM cards.

CAT faults SVS's construction for requiring the debit styled card to be associated with an account. (D.I. 44 at 21) However, the specification plainly envisions that the phone card and prepaid card embodiments are associated with an account. ('859 patent, col. 3 lines 53-60 ("For phone card transactions ... the present invention provides for a method whereby card stock in a store has no real value and only upon sale of the debit card 22 will an account be created and activated . . . .") (emphasis added); id. col. 5 lines 10-25 ("[F]or prepaid debit transactions . . . [t]he host keeps a record of the account balances . . . . Alternatively, in applications using smart cards (chip cards), the balance is kept on the card . . . .") (emphasis added))
Likewise, it is undisputed that an ATM card is associated with an account. (D.I. 44 at 21; D.I. 43 at 14)

Finally, CAT's expert, Mr. Grimes, somewhat undermines CAT's contention that debit styled cards do not include ATM cards. In related litigation, CAT submitted a declaration by Grimes that is best read as stating that "debit styled card," as that term is used in the '859 patent, includes "ATM/debit cards." Grimes' 2008 declaration in the related case states, in pertinent part:

44. . . . The specification clearly limits the term "debit styled card" to debit cards, or cards having a value identified in a central database or stored on the card.

45. The interpretation of the phrase "debit styled card" is consistent with the proper interpretation of the phrase "purchasing value of a card." A debit styled card is a card that maintains a purchasing value either in a central database or on the card itself and the value is debited at the time of the purchase.

46. The examples given in the specification, as to which [CAT] agrees, are an ATM/debit card, a gift card and a phone card. The term "debit card" simply does not include credit cards.

(D.I. 47 Ex. H (Feb. 1, 2008 Grimes Decl.) PP 44-46) The subsequent declaration Grimes filed in the instant action in 2010 (D.I. 44 Ex. 5 (Jan. 20, 2010 Grimes Decl.) P 44), which contends that ATM/debit cards are excluded from "debit styled cards," is inconsistent with his prior declaration. 5

5 I recognize that in his 2008 declaration, Grimes was primarily opining that "debit styled card" did not include credit cards, a point not in dispute in the present action. Nonetheless, Grimes did also state in his 2008 declaration that examples of debit styled cards in the '859 patent's specification include ATM/debit cards. I do not agree with CAT's attorney's contention that in this portion of the 2008 declaration Grimes was stating only that ATM cards are a subset of "debit card," and not also a subset of "debit styled cards." (D.I. 60 at 76, 80)

Accordingly, I recommend that the Court construe the term "debit styled card" in the manner proposed by SVS, which is "a card having a value in an associated account or a value stored on the card itself."

1. debit/medical services card (Claim 32)

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>Alexsam's Proposed Construction</th>
<th>Humana's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>debit/medical services card</td>
<td>a card that can function as both a debit card and a medical services card</td>
<td>a card that can be used as both a debit card and as a medical card</td>
</tr>
</tbody>
</table>

The dispute between the parties concerning the construction of this term centers around the meaning of "medical services." Alexsam argues that Humana seeks to limit it to the use of the card only to obtain medical information. Alexsam contends that the patent discloses other examples of medical services that can be provided by the card. See, e.g. '608 patent, 10:40-47 ("In order to allow a cardholder to keep track of medical savings accounts or various other means for paying for medical services (e.g., Medicare), the system 108 also allows access to a database which maintains the medical funds for the cardholder."). Alexsam also makes a claim differentiation argument, pointing to other claims where the patentee repeatedly used "medical information card" rather than a "medical services card." See id., Cl. 14-15, 56, 58-59.

Humana points out that the specification discloses a need for a medical information card that allows medical providers, such as those in an emergency room, to access medical history information of a cardholder by swiping the card through a POS.
Humana argues that "medical card" function of Claim 32 must be "medical information" because it is the only type of "non-debit" medical services/card disclosed in the '608 patent. The Court disagrees. Contrary to Humana's argument, the specification of the '608 patent does not "repeatedly reinforce" the usage of the term "medical services" to mean "medical information" that would relate only to a patient's medical history. Cf. On Demand Mach. Corp. v. Ingram Indus., Inc., 442 F.3d 1331, 1340 (Fed. Cir. 2006). The Court finds sufficient support in the specification to adopt plaintiff's proposed construction.

The Court further finds Humana's proposed phrase "can be used" is less appropriate for the construction of this term. The Court notes that the patent consistently describes the cards as capable of performing "functions."

A "debit/medical services card" is, therefore, construed as "a card that can function as both a debit card and a medical services card."

Claim 13 of the 298 Patent describes a method of "debiting the entered payment amount from the account associated with the entered payment number[.]" (Plf. App., Exh. 1 at 17) (emphasis added). Claim 1 of the 298 Patent and Claims 1 and 6 of the 456 Patent refer to "charging the entered payment amount against the account associated with the entered payment number[.]" (Id., Exh. 1 at 16 & Exh. 3 at 42-43) (emphasis added). The dictionary definition of "debit" is "to charge with a debt". THE SHORTER OXFORD ENGLISH DICTIONARY at 461 (3d ed. 1968). The definition of "charge" is "to impose or record as a financial obligation." MERRIAM WEBSTER COLLEGIATE DICTIONARY at 192. Paymentech argues that these terms should be construed to mean "to charge with a debt during the connection." (Def. Op. Br. at 16) (emphasis added).

It is clear from the express language of the claims and the patent specifications that the act of recording a payment as a debt must be performed during the call. Claim 1 of the 298 Patent specifically describes a method comprising the steps of, inter alia:

- responsive to a determination that a payment amount has been entered and further responsive to a determination that the entered account number and payment number are valid, and during the call:
  - -- accessing a remote payment network associated with the entered payment number, the accessed remote payment network determining, during the call, whether sufficient available credit or funds exist in an account associated with the entered payment number to complete the payment transaction;
  - -- responsive to a determination that sufficient available credit or funds exist in the associated account, charging the entered payment amount against the account associated with the entered payment number, adding the entered payment amount to an account associated with the entered account number, informing the caller that the payment transaction has been authorized, and storing the account number, payment number and payment amount in a transaction log file of the system during the call[.]

(Plf.App., Exh. 1 at 16) (emphasis added). The 456 Patent uses the term "during the session" in lieu of "during the call." (See id., Exh. 3 at 42). Thus, the limitation suggested by Paymentech would be superfluous. See Power Mosfet Technologies, 378 F.3d at 1410.
Moreover, the intrinsic evidence indicates that the actual transfer of funds does not necessarily occur during the call. Rather, as the preferred embodiment illustrates, the remote debit card network moves the funds electronically after the close of the business day. (Plf. App., Exh. 1 at 15). The court therefore determines that terms "debiting" and "charging [ ] against" should be construed to mean "recording as a debt or financial obligation against the accessed account and not the actual transfer of funds from the account."

3. Decoded Data Which Has Not Been Displayed (Claims 1 and 8)

Matsushita argues "decoded data which has not been displayed" should be construed as "data that has been decoded, corresponding to pictures that have not been displayed." Mediatek argues "decoded data which has not been displayed" should be construed as "a decoded forward predictive picture (P picture frame) that has not been displayed." 5

The Court finds, for the reasons stated by Matsushita, that "decoded data which has not been displayed" is properly construed as "data that has been decoded, corresponding to pictures that have not been displayed."

C. "Decoder"

Claims 1 and 5 of the '364 Patent also contain a "decoder" element. Lynx maintains that as properly construed, "decoder" means a stand-alone device that takes a signal encoded in quaternary format and decodes that signal into binary format. Chamberlain disputes this construction, asserting that "decoder" means a "subsystem which can receive the output of the radio receiver and convert it into a form wherein the data contained in the received transmissions can be interpreted by the microprocessor." The disputed construction of "decoder" raises two issues: (1) is the term as properly construed a stand-alone device; and (2) is it a device that decodes quaternary format into binary format.

1. Is the "decoder" a stand-alone device?

In Figure 2 of the '364 Patent, the patented invention is depicted in block form. As depicted in this drawing, the decoder device is a stand-alone or separate device from both the microprocessor and the receiver. In addition, the decoder device is identified in Figure 2 with the number 43. In referring to the decoder device in the written description of the patented invention, the decoder device is regularly referred to as "decoder 43" in reference to the decoder device as depicted in Figure 2. According to Lynx, Chamberlain has only referred to the decoder device in relation to Figure 2 as "decoder 43" and thus Chamberlain has defined the term by implication to be a stand-alone device. For example, in one instance, the specifications state, "as illustrated in FIG. 2 the garage door operator includes a receiver 41 which has a suitable antenna 42 for receiving radio frequency transmission from the transmitters 26 and 28 and supplies an input to a decoder 43 which provides an output to a microprocessor unit 44."

The court notes that the words "stand-alone device" are not used in the written description or claim language to define the
The decoder. On the contrary, the Summary of the Invention section of the '364 Patent states "in the present invention the decoder module in the receiver will be capable of learning several different transmitter codes . . ." (The '364 Patent, col. 1, lines 54-55) (emphasis added). This statement contradicts Lynx's proposed claim construction that the decoder is a stand-alone device. Thus, the term decoder has been used in more than one manner and has not been defined by implication. Bell Atlantic Network Services, 262 F.3d at 1270 (a patentee will be found to have defined a term by implication if the "patentee uses a claim term throughout the entire specification, in a manner consistent with only a single meaning.") In addition, the court notes that although claims are to be "read in light of the specifications . . . limitations from the specifications are not be read into the claims." Id. The court concludes that the decoder is not required to be a stand-alone device.

2. Is the "decoder" limited to a device that decodes quaternary format into binary format?

According to Lynx, in the '364 Patent, the inventors described a particular encoding/decoding scheme to be utilized by the invention. Specifically, Lynx claims that the decoder in the patented invention "takes a signal encoded in quaternary format and decodes that signal into binary format." (Lynx Memo, at 24.) Lynx cites a number of sources in support of this claim construction, but does not address how the Federal Circuit's decision in Overhead Door Corp. relates to this claim construction. Because the court finds the Federal Circuit's decision dispositive, the court does not need to address the parties' arguments at great length.

In Overhead Door Corp. the Federal Circuit stated:

"The claims, however, do not require that the memory store the exact sequence of coded bits transmitted from the transmitter as its identifying signal. This reading of the claim language finds support in the written description, which explains that a code is associated with a transmitter. [The '364 Patent] does not describe any particular format, encryption, or alteration in transmitted and stored codes." 194 F.3d at 1274-75. The Federal Circuit's observation that the '364 Patent does not describe any particular format militates against imposition of the additional claim limitations proposed by Lynx.

The court will, instead, adopt what it believes is the ordinary meaning of the term "decoder." Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1332 n.1 (Fed. Cir. 2001). In determining this ordinary meaning, the court notes that both parties have claimed that their construction comports with the Institute of Electrical and Electronics Engineers (IEEE) definition of "decode" which is "to recover the original message from a coded form of the message." (IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS, at 231.) The court will rely on this agreed definition in construing this claim. Interactive Gift Express Inc., 256 F.3d at 1332 n.1 ("dictionaries, which are a form of extrinsic evidence, hold a special place and may sometimes be considered along with the intrinsic evidence"). Because the court finds that Chamberlain's proposed claim construction most closely conforms with the ordinary meaning, the court adopts its proposed construction: "a subsystem which can receive the output of the radio receiver and convert it into a form wherein the data contained in the received transmissions can be interpreted by the microprocessor."

6. "decoding" ( '181 patent, claim 1; '664 patent, claims 1 and 3, '768 patent, claim 1 and 19)

Defendants seek to limit the term "decoding" to the extraction of URLs that were previously encoded in a television or video programming signal. But as already discussed with reference to "programming," supra, such a limitation is not only at variance with the ordinary meaning of the term but also would render certain claims of the patents nonsensical. For example, claim 1 of the '664 patent expressly encompasses both a means for receiving programming containing a video and audio signal and a second means for receiving one or more uniform resource locators. The third paragraph of the same claims a "means for decoding, connected to the second receiving means" (emphasis added). Based on this language alone, "decoding" must include the extraction of some URLs not encoded in video or television signals.

Furthermore, defendants' definition of decoding would limit the patent claims to the first preferred embodiment. Only in the first preferred embodiment are the URLs encoded in video or television programming upon receipt by the user. In all of the other embodiments in all three patents, the URLs have either been extracted from the video or television programming prior
to receipt by the user or never encoded into the video or television programming at all. Since the "means for decoding" is, in all three patents, linked to the "means for receiving," "receiving means," or "receiver," the term "decoding" must refer broadly to extraction or retrieval of data from any data stream -- not necessarily a video or audio signal -- based on a predetermined format or encoding scheme.

1185

2. "decoding NFS requests"/"encoding NFS reply messages"

The terms "decoding NFS requests" and "encoding NFS reply messages" appear in claims 1, 5, and 8 of the 366 Patent, as well as in claims 1 and 4 of the 918 Patent. Claim 1 of the 366 Patent recites a second processing unit that performs the functions of "decoding NFS requests from a [data] network" and "encoding NFS reply messages for return transmission on said network." 366 Patent, 51:42-47. The remaining claims recite a "means for decoding NFS [or file server] requests" and a "means for encoding NFS [or file server] reply messages for return transmission" on a data network. See, e.g., id., 52:47, 52:51-52. Again, plaintiff takes the position that no construction is required because the phrases "decoding NFS requests" and "encoding NFS reply messages" are unambiguous. In contrast, defendant contends that the terms should be construed to limit the scope of the claims to a processing unit or a means for "processing all protocol layers of NFS requests from the network to extract the NFS messages" and "processing all protocol layers for converting data into NFS messages for network transmission."

In support of its view that the disputed terms need not be construed, plaintiff cites general-purpose dictionary definitions of the words "encode" and "decode." See Joint Claim Construction Statement at A-2 (citing Merriam's Webster's Collegiate Dictionary 299, 380 (10th ed. 1997)). However, the Federal Circuit has repeatedly cautioned against indiscriminate reliance on non-technical dictionaries for defining technical words, observing that "dictionary definitions of ordinary words are rarely dispositive of their meanings in a technical context. A word describing patented technology takes its definition from the context in which it was used by the inventor." Anderson v. Int'l Eng'g & Mfg., Inc., 160 F.3d 1345, 1348-49 (Fed. Cir. 1998). Plaintiff's proposed construction (or lack thereof) improperly attempts to purge the technological context of the invention from the meaning of the words "decoding" and "encoding."

To provide context for the disputed claim terms, the court turns to the claims and specifications of the 366 and 918 Patents. Texas Digital, 308 F.3d at 1204. In the patented inventions, "encoding" and "decoding" are necessary steps for responding to file requests from a data network. See, e.g., 366 Patent, 51:42-48. To perform these steps, the preferred embodiments of the inventions employ a "network controller" that determines whether an incoming data packet is an NFS packet, and if so, identifies the nature of the request. Id. at 9:34-42; see also id. at 6:31-32 (identifying an "XDR/RPC layer" that "provides the decoding necessary to permit a client machine to execute a procedure on the server"). The network controller then determines what procedures must be performed to process the NFS request and dispatches procedure calls accordingly. Id. at 6:33-37. When processing of the request is complete, the network controller generates a "reply message" that is sent over the network to the client computer. Id. at 6:37-40.

Generalizing from the disclosures in the preferred embodiments, the "decoding" and "encoding" functions of the patented inventions are best described as a process of translation. The court finds further support for this view in the AP Dictionary, a technical reference cited and relied on by both parties. The AP Dictionary defines "encode" as "to convert data into code according to a specified coding scheme;" conversely, "decode" is defined as "to convert data by reversing the effect of some previous encoding." Id. at 596, 743. Like the specifications, the dictionary definitions of "encode" and "decode" imply a process of translating or converting data from one format to another. Applying these definitions in the context of the disputed language, the court construes "decoding NFS requests" to mean "converting NFS requests from the format received from the network to another, decoded data format." Similarly, "encoding NFS reply messages" should be construed to mean "converting NFS reply messages from a decoded data format to the format used for transmission on the network."

Although this choice of words is generally consistent with the spirit, if not the letter, of defendant's proposed construction, defendant urges the court to adopt the phrase "processing all protocol layers" as an additional limitation in the "decoding" and "encoding" terms. Defendant relies on a statement in the specifications explaining that the network controller performs "full protocol processing" on "NFS-destined packets." See, e.g., 366 Patent, 9:36-38. However, in describing what full protocol processing entails, the specifications identify one of the protocols as "XDR decoding" -- i.e., a process that
"provides the decoding necessary to permit a client machine to execute a procedure on the server." Id. at 6:31-32, 9:41. Defendant's definition therefore implies that "decoding" refers to both processing a single protocol layer and to "full protocol processing." The court declines to adopt such a strained interpretation of the term. In any event, the limitation "all protocol layers" appears in neither the claim language nor in the specifications of the patents in suit. Accordingly, the court declines to read this limitation into the claim. Thus, for the reasons stated above, the court construes "decoding NFS requests" as "converting NFS requests from the format received from the network to another, decoded format." In addition, the court construes "encoding NFS reply messages" to mean "converting NFS reply messages from a decoded data format to the format used for transmission on the network."

1186

g. "decoding said at least one instruction to determine said predetermined position"

The plaintiffs contend that the term means "interpreting an instruction, in particular the portion thereof that signifies the operation to be performed, in order to identify a position relative to the beginning or end of the instruction group that includes the operand or instruction being accessed, without reference to the operand or address bits in the instruction being interpreted." The defendants propose "interpreting an instruction, in particular the portion thereof that signifies the operation to be performed, in order to identify a position relative to the beginning or end of the current instruction group."

The Court construes the term to mean "interpreting an instruction, in particular the portion thereof that signifies the operation to be performed, in order to identify a position relative to the beginning or end of the instruction group that includes the operand or instruction being accessed."

1187

D. "Decoding Said Data Establishing A Limit"

The parties' dispute over this term follows from their dispute over the "data stream" claim terms. Briefly Defendant contends that because the limiting data and "video product" are transmitted together in a single, continuous "data stream," the "decoding" limitation must, at the very least, refer to the "extraction" or "separation" of the limiting data from the "data stream." (See D.I. 69 at 54:23-55:19.) In further support of this construction, Defendant notes that the specification states that "[r]eferring now to FIG. 3 in addition to FIG. 2, in operation, the limit data is decoded from the down-loaded data stream . . . ." ('402 patent at 4:30-32 (emphasis added).)

Plaintiff responds that Defendant's construction would improperly exclude embodiments in which the limiting data and video product are not transmitted together in a single continuous "data stream." (D.I. 66 at 23.) Plaintiff further remarks that it is not aware of any definition for "decoding" that includes "separating" and any suggestion in the specification that the limiting data needs to be "decoded from" the "data stream" is merely a description of a specific embodiment.

The Court agrees with Plaintiff that language in the specification referring to data being "decoded from" the "data stream" is a description of a specific embodiment. (See '402 patent at 4:30-32.) However, in view of the patentee's unambiguous
statements in the prosecution history confirming that the limiting data and "video product" are transmitted together, the Court finds that this language does in fact refer to the claimed embodiments. Likewise, in view of the prosecution history, other disclosed embodiments, including those in which limiting data is "permanently stored at the customer site" so that the "down-loaded data need not include such user limitation data," do not correspond to claimed embodiments. (‘402 patent at 3:65-68.) Thus, the Court agrees with the Defendant that the "decoding," as used in the claims, must include some "extraction" of the limiting data from the "data stream." Accordingly, the Court construes the claim term "decoding said data establishing a limit" to mean, as Defendant contends, "at the user site, extracting the data establishing a limit for authorized viewing of the video product from the downloaded digital data stream in order to separate the data establishing the authorized viewing limit from the video product."  

2 This construction is not intended to exclude the presence of additional steps that may be related to the decoding process.

Claims 1, 4 and 14 are the independent claims of the ’927 patent, and read as follows:

1. A method for emulating the instruction set of a target computer on a RISC architecture computer, comprising the steps of:

   1) fetching a target instruction of a format compatible with the instruction set of the target computer;

   2) parsing and decoding said instruction into fields designating an opcode and operands;

   3) converting said opcode into an address pointing to a sequence of one or more microcoded instructions;

   4) decoding said microcoded instruction into a LHS instruction having fields essentially compatible with a RISC architecture and a RHS instruction having fields to select a plurality of indirect registers pointing to emulated registers;

   5) processing said emulated registers with an arithmetic logic unit;

   6) calculating a condition code as a function of the operation of said arithmetic logic unit and a selection field within said microcoded instruction;

   7) storing a result of said processing by said arithmetic logic unit;

   8) storing a result of said condition code calculation; and

   9) repeating steps 4-8 with a next microcoded instruction until an end of said microcoded sequence is encountered and then continuing at step 1 with a next target instruction.

’927 patent, col. 52, l. 64 to col. 53, l. 23.

4. A RISC architecture computer having a native instruction width of N bits configured for emulating target instructions from the instruction set of a target computer, comprising:

   a plurality of emulation registers capable of corresponding to registers in the target computer and having data widths greater than or equal to the data widths of the registers in the target computer;

   a plurality of indirect registers for selection of said emulation registers; parsing means to extract a plurality of data fields from a target instruction, at least one said fields including an opcode;
dispatching means using said opcode to direct the RISC architecture computer to select at least one M+N bit expanded RISC instruction from a microcode memory;

an expanded instruction decoder for using said M bits from each said expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer, wherein said M bits define fields, said fields comprising a width field for designating the data width of said emulation registers and the data width of an arithmetic function, an indirect register field for designating said indirect registers, and a condition code field for designating a condition code emulation mode; and

condition code calculation means for determining the condition code for an arithmetic function according to said condition code field.

'927 patent, col. 53, ll. 33-61.

14. A RISC architecture computer having a native instruction width of N bits configured for emulating target instructions from the instruction set of a target computer, comprising:

a plurality of emulation registers capable of corresponding to registers in the target computer and having data widths greater than or equal to the data widths of the registers in the target computer;

a plurality of indirect registers for selection of said emulation registers; parsing means to extract a plurality of data fields from a target instruction, at least one said field including an opcode;

dispatching means using said opcode to direct the RISC architecture computer to select at least one M+N bit expanded RISC instruction from a microcode memory;

an expanded instruction decoder for using said M bits from each said expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer; and condition code calculation means for determining the

condition code for an arithmetic function in accordance with the target computer.

'927 patent, col. 54, ll. 19-43.

As claimed, the invention includes a system or method for using a RISC architecture computer having a native instruction set including, inter alia, instructions of a width of N bits configured for emulating instructions from the instruction set of a target computer; a plurality of emulation registers for simulating registers of the target computer; a plurality of indirect registers for selecting the emulation registers; structure for extracting the data fields of a target instruction, including an opcode field; structure for using the opcode to direct the RISC architecture computer to select at least one M+N bit expanded RISC instruction from memory; an expanded instruction decoder for using M bits from the expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer; a condition code field for designating a condition code emulation mode; and structure for determining the condition code for an arithmetic function according to a condition code field.

Intel's x86 CISC microprocessors share instructions, adding new instructions to those which comprise the instruction set of the previously issued microprocessor. In other words, with the introduction of each new member of the Intel x86 family of microprocessors, new instructions are added to the CISC x86 instruction set of the previous version of the microprocessors. Thus, the P6 instruction set includes instructions unique to that version of the processors, as well as those used by the P5 microprocessor. Like the P6, the P5 instruction set includes all of the instructions found in the instruction set of the 486 microprocessor, as well as each additional instruction unique to the P5. Thus, each new processor executes all of the instructions of its predecessor, without modification, as well as the new instructions unique to that device.

After working on several versions of the 3250, IMS's attempts to produce the microprocessor commercially failed. TechSearch purchased the '927 patent as an asset in the IMS bankruptcy proceeding. Subsequently, TechSearch filed a complaint against Intel in September 1998 alleging that Intel's P6 line of microprocessors infringed the claims of the '927 patent.
The district court held a Markman hearing in August 1999 and issued a Memorandum Decision and Order on November 1, 1999. Recognizing that one skilled in the art would typically identify a computer as RISC- or CISC-based upon its published instructions rather than the microinstructions, the court concluded that, in the context of the patented invention, the classification of the microprocessor was properly assessed from the microcode level. The court concluded that the claims themselves confirm that it is the microcode, not the machine code (or "macro" level), that is relevant to whether a microprocessor is a CISC or RISC microprocessor, and is therefore covered by the patent's claims.

With regard to the term "emulation," the district court referenced the written description that defines the term as "a process in which one computer X behave identically to another computer Y, as X executes the instructions of Y, where the internal architectures of computers X and Y are different." '927 patent, col. 2, ll. 30-33. Concerning the "LHS" (left-hand side) and "RHS" (right-hand side) of the coded instruction recited in claim 1, the court determined that those terms refer to the native instruction of a RISC microprocessor configured for emulation of a target computer's microprocessor. Thus, the court concluded that the LHS and RHS are two subdivisions of a single RISC microinstruction.

Independent claims 4 and 14 refer to the coded instruction as an M+N bit expanded RISC instruction. The court concluded that the M+N bit expanded RISC instruction is composed of N bits corresponding to the native instruction, or the instruction of the host microprocessor's instruction set used when the microprocessor is not in emulation mode, and M bits "which redefines the N bits" in the expanded RISC instruction, thereby enabling the host microprocessor to emulate a target computer.

The district court defined the term "condition code" as a summary of the effects of recently emulated target instructions. Although worded differently, the district court noted that the parties agreed that each independent claim requires a selection field within the microinstruction identifying the particular target computer being emulated so that the condition code matches the operation that would have been performed had the same calculation been performed within the target computer. Finally, the district court interpreted the "expanded instruction decoder" as simply a decoder used in the execution of an M+N bit RISC instruction.

Subsequently, the parties filed cross-motions for summary judgment. On January 31, 2000, the district court issued a Memorandum Decision and Order granting Intel's motion for summary judgment of noninfringement. The district court concluded that to prove infringement of claim 1, TechSearch must show that the P6 microprocessors have "a plurality of indirect registers pointing to emulated registers," and that the accused products process the emulated registers with an arithmetic logic unit. TechSearch had maintained that the macro alias register file ("MAR") found in the P6 corresponds to the claimed indirect registers. The court determined that, even assuming that to be true, there is no dispute that the MAR does not point to emulated registers as required and that there are no registers in the P6 that are both pointed to by the indirect registers and processed with an arithmetic logic unit ("ALU"). Specifically, the court noted that the MAR does not point to any registers or to anything processed by the ALU and that the MAR are logical registers, which are not actual registers but merely references. Nor was the court persuaded that TechSearch had established that there are any emulated registers in the accused device. Therefore, the court determined that claim 1 is not infringed literally or under the doctrine of equivalents.

The court further concluded that the P6 microprocessors are not "configured to emulate the instruction set of a target computer" in accordance with claims 1, 4 and 14. The district court found that "it is beyond dispute that the P6 microprocessors are not configured to emulate in the manner claimed," TechSearch-Judgment, slip op. at 9, and therefore do no infringe. The court noted that "the patent specification makes clear that its emulation scheme entails modifying preexisting native instructions of a RISC architecture computer" such that when the computer is emulating, "the native instructions are redefined by M bits in order to form an M+N bit expanded instruction that enables the host system to emulate the target system." Id. at 9-10. Accordingly, the court determined that to infringe claims 4 and 14, TechSearch must prove that the P6 microprocessor has both a native instruction of N bits and an expanded RISC instruction comprised of M+N bits to be used when the computer is emulating, or their equivalents.

The court determined that no reasonable jury could find that the P6 microprocessors have microinstructions comprised only of N bit instructions when operating in the native mode of the host processor, i.e., when not emulating, and microinstructions comprised of an M+N bit RISC instruction when emulating. The court noted that the format of the instructions that the P6 microprocessors use when executing an instruction from an "earlier version" of Intel's x86 instruction set are indistinguishable from the format of the instructions originating with the "current version." The court
concluded that even were the testimony of TechSearch's expert to be accepted, asserting that the P6 microprocessors emulate, TechSearch has not shown infringement because it is "beyond question" that the P6 runs only one instruction set. Therefore, the court concluded that the P6 microprocessor does not emulate in the manner required by claims 4 and 14.

The district court further determined, in the alternative, that the P6 products do not have an "expanded instruction decoder" using M bits from each expanded RISC instruction to "redefine" the RISC architecture computer in terms of the target computer during emulation. Thus, the court concluded that it is "beyond cavil" that the P6 microprocessor does not infringe.

The court stated that to prove infringement of claims 4 and 14 TechSearch must prove that: (1) the P6 microprocessor has an expanded instruction decoder; and (2) that the expanded instruction decoder uses M bits from each expanded RISC instruction to "redefine" the RISC architecture computer in terms of the target computer during emulation. The district court concluded that the P6 microprocessor does not have a decoder that can decode expanded instructions.

The court concluded that the P6 "alias multiplexer," alleged by TechSearch to correspond to the claimed decoder, differs materially from the decoder contemplated by the patent. Specifically, the court noted that the claimed invention translates the instructions into a form for processing by the ALU in a manner involving considerable interaction between the various elements of the microinstruction. Contrarily, the inputs of the multiplexer are simply routed to its outputs. The court noted that one of ordinary skill in the art would know that decoders and multiplexers perform substantially different functions and consist of substantially different structure.

The court noted that TechSearch's expert, Dr. Hoevel, did not contend that the multiplexer in the P6 microprocessor operates as a decoder and did not dispute that the function of multiplexing differs from the decoding claimed. While the court concluded that the claimed decoder combines the input signals to produce outputs that cause selection of the direct, indirect or emulation registers, it found that TechSearch did not dispute that the P6 microprocessor's alias multiplexer architecture does not combine input signals, but simply steers each signal to the appropriate output field. The court, therefore, found Dr. Hoevel's testimony, and TechSearch's arguments based thereon, insufficient to avoid a grant of summary judgment of noninfringement.

Similarly, the court determined that TechSearch had failed to create a triable issue of fact by arguing that a multiplexer is capable of acting as a decoder, noting that TechSearch failed to provide evidence to explain how the multiplexer of the P6 functions in the manner describing the claimed decoder. The district court further concluded that Hoevel's conclusory allegations failed to raise a genuine issue of material fact.

Finally, noting that the claimed instruction decoder operates to "redefine" the microprocessor when emulating and that no redefinition of instructions is performed by the "decoder" in the P6 microprocessor, the court concluded that no part of the P6 can be found to infringe the instruction decoder recited in claims 4 and 14. Specifically, the court concluded that the P6 microprocessor does not use an additional M bits to redefine N bits of the instruction when "emulating." Although Hoevel asserted that the microinstructions found in P6 microprocessors, known as "Cuops," contain fields for performing register indirection, the court noted that in the P6 microprocessors those instructions are always the same size and use all of its bits, regardless of the version of microprocessor with which they were first introduced. Thus, the court determined that the Cuops microinstruction, and thus the P6 microprocessor instruction set, does not redefine or expand the microinstructions as claimed. Therefore, the court concluded that no reasonable jury could find that the Cuops are redefined "in any way."

In a Memorandum Decision and Order dated November 9, 1999, issued after the Markman hearing but before the grant of summary judgment, the district court informed the parties that it had decided to appoint its own "technical advisor." The court recognized that such appointments should be reserved for the exceptional case, but deemed it appropriate in this particular case because infringement would be "a highly technical [issue] far beyond the boundaries of the normal questions of fact and law with which judges routinely grapple." The court noted that technical advisors "are not witnesses, and may not contribute evidence." As such, the court concluded that a technical advisor is not subject to the requirements set forth in Rule 706 of the Federal Rules of Evidence regulating the appointment of expert witnesses. The district court further explained that "[a] judge may not appoint a technical advisor to brief him on legal issues, or to find facts outside the record of the case; the advisor's role is to acquaint the judge with the jargon and theory disclosed by the testimony and to help think through certain of the critical technical problems." TechSearch, L.L.C. v. Intel Corp., No. 98-CV-03484, slip op. at 4 (N.D. Cal. November 9, 1999) (memorandum decision and order appointing technical advisor) ("TechSearch-Appointment"). Anticipating the difficulty in evaluating the "extremely complicated" technical evidence submitted by the parties involving
"highly technical electrical engineering and microprocessor design," which the district court had to process to formulate its claim construction, the court retained the technical advisor to assist with evaluation of the technical matters before it when resolving pretrial motions, as well as during trial. Specifically, the court recognized that it would be "faced with expert testimony, scientific articles, and patents" the technology of which the court "urgently required" the assistance of a technical advisor to understand. As an example, the court stated that evaluation of the prior art required consideration of technical concepts beyond normal questions of fact regularly addressed by the court.

The court determined that its technical expert, Dr. Hearn, was a neutral third party, and explained its reasoning for that determination in its memorandum decision. TechSearch-Appointment, slip op. at 5-7. The court reiterated that Dr. Hearn had "agreed that he will not engage in any independent investigation of the underlying litigation, provide evidence to the Court, or contact any party or witness in this action." The court further agreed to identify any material relied upon by Dr. Hearn, other than that submitted by the parties or "those upon which a person versed in the relevant field of knowledge would be reasonably expected to rely." The court stated that Dr. Hearn would execute an affidavit indicating his understanding of that order before beginning his engagement, and would file an affidavit attesting to his compliance with its terms at the conclusion of his employment.

TechSearch appeals the district court's judgment. We have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1).

STANDARD OF REVIEW

This court reviews a district court's grant of summary judgment without deference. Cortland Line Co. v. Orvis Co., 203 F.3d 1351, 1355, 53 USPQ2d 1734, 1746 (Fed. Cir. 2000). The moving party is entitled to summary judgment "if the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits, if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law." Fed. R. Civ. P. 56(c). In reviewing the district court's grant of summary judgment, this court draws all reasonable inferences from the evidence in favor of the non-movant. Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 255, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). Summary judgment is appropriate when it is apparent that only one conclusion as to infringement could be reached by a reasonable jury. ATD Corp. v. Lydall, Inc., 159 F.3d 534, 540, 48 USPQ2d 1321, 1324 (Fed. Cir. 1998). Summary judgment of noninfringement is also appropriate where the patent owner's proof is deficient in meeting an essential part of the legal standard for infringement, because such failure will render all other facts immaterial. London v. Carson Pirie Scott & Co., 946 F.2d 1534, 1537, 20 USPQ2d 1456, 1458 (Fed. Cir. 1991).

A patent infringement analysis involves two steps: 1) claim construction; and 2) application of the properly construed claim to the accused product. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 USPQ2d 1321, 1326 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The first step, claim construction, is a matter of law that this court reviews without deference. Cybor Corp. v. FAS Tech., Inc., 138 F.3d 1448, 1454, 46 USPQ2d 1169, 1172 (Fed. Cir. 1998) (en banc). Whether the accused device contains an element corresponding to each claim limitation or its equivalent is a question of fact, which, on summary judgment, is a question we review to determine whether a material factual issue remains genuinely in dispute. Roton Barrier, Inc. v. Stanley Works, 79 F.3d 1112, 1125, 37 USPQ2d 1816, 1826 (Fed. Cir. 1996).

DISCUSSION

I. Claim Construction

While the parties dispute the court's construction of many of the claim terms at issue before the district court, we address the construction of only those terms essential for disposition of this appeal.

The independent claims of the '927 patent recite a method or computer for "emulating" target instructions of the instruction set of a target computer using, inter alia, "emulation registers" capable of corresponding to registers in the target computer. The written description defines the term "emulation" generally as "a process in which one computer X behaves identically to another computer Y, as X executes the instructions of Y, where the internal architectures of computers X and Y are different." '927 patent, col. 2, ll. 30-33. We adopt this construction and conclude that the district court correctly interpreted this term.
Clams 4 and 14 define the particular manner in which the claimed processor emulates. Specifically, both claims require a "M+N bit expanded RISC instruction" with N bits defining the "native instruction . . . configured for emulating target instructions from the instruction set of a target computer." Consistently, the claims require an expanded instruction decoder that uses "M bits from each said expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer." The written description of the '927 patent defines N bits of an expanded RISC instruction, also referred to as the LHS (left-hand side) of the instruction, as the number of bits of the instruction that the microprocessor uses "in its native mode." '927 patent, col. 5, ll. 1-2. With regard to the M bits of the expanded RISC instruction, also referred to as the RHS (right-hand side) of the instruction, the '927 patent states that "contained within the additional M bits [of the expanded RISC instruction] and used in conjunction with the N bits are directions on the use of resources within the RISC computer, peculiar to each emulated instruction." '927 patent, col. 5, ll. 6-9. The written description of the '927 patent explains that the M bits, or RHS, of the expanded RISC instruction are used "to redefine, during emulation of a target processor operation, the register data paths . . . of the LHS [or N bits of the expanded RISC instruction] to correspond to the target processor instruction being emulated, permitting the host processor to mirror, without physical changes, the target processor architecture being emulated." '927 patent, col. 8, ll. 31-37. Consistently, TechSearch's expert, Dr. Hoevel, recognizes that to emulate, "the host computer has to interpret and execute the target instruction set used in the target computer . . . and claims 1 through 3 of the '927 patent reveal the advantages of the special kind of emulation and backwards compatibility found in the '927 patent."

We conclude, as the district court did, that the M+N bit expanded RISC instruction recited in claims 4 and 14 includes N bits corresponding to an instruction of the host microprocessor's instruction set, and M bits which work with the N bits to "redefine" or "translate" the expanded RISC instruction to "emulate" the instructions of the microprocessor of the target computer. We further conclude that the claimed "expanded instruction decoder" is a decoder that "redefines" or "translates" the native instruction identified as N bits of the expanded RISC instruction, using M bits of the expanded RISC instruction, thereby enabling the instruction set of the microprocessor of the computer to emulate the instructions of a target computer.

As noted, the '927 patent defines the LHS and RHS instructions recited in claim 1, as synonymous with the N bits and M bits of the expanded RISC instruction of claims 4 and 14. The '927 patent states, "the native N bits are referred to as the LHS (left-hand side) of the instruction while the M bits are referred to as the RHS (right-hand side) of the instruction." '927 patent, col. 5, ll. 9-12. Consistent with the M+N bit expanded RISC instruction of claims 4 and 14, method claim 1 includes the step of "decoding said microcoded instruction into a LHS instruction having fields essentially compatible with a RISC architecture and a RHS instruction having fields to select a plurality of indirect registers pointing to emulated registers," and "processing said emulated registers with an arithmetic logic unit." For the reasons provided supra, we conclude that the claimed "decoding" step requires "redefining" or "translating" the native instruction, identified in claim 1 as LHS of the instruction, using the fields of the RHS of the instruction to emulate the instruction of a target computer.

1189

2. "[D]ecomposed into a plurality of levels:" 2 "Broken down into two or more structured set(s) of information." The parties agree that decomposed into levels means "broken down into structured sets of information," but dispute the meaning of "plurality." The term "plurality" is consistent with a construction that requires more than one structured set of information. See Bowers v. Baystate Techs., 320 F.3d 1317, 1332 (Fed. Cir. 2003). This construction is consistent with col. 84:34-37 of the specification.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 '284 patent, claim 1 (and dependent claims).

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
The parties disagree on the meaning of "clock decorrelator" and the construction of "cannot be reliably predicted." The parties dispute whether clock decorrelation is limited to causing the skipping of random clock cycles, or whether clock decorrelation is a broader term.

Dependent Claim 16 claims "the device of claim 15 wherein said clock decorrelator comprises a clock skipping module which selects a subset of the cycle of said external clock signal to use as said internal clock signal based on said unpredictable information." '661 patent, col. 16, ll. 39-43. The inclusion in Claim 16 indicates that the clock decorrelator, as referred to in Claim 15 is not limited to the particular clock skipping module described in Claim 16. See Phillips v. AWH Corp., 415 F.3d 1303, 1324 (Fed. Cir. 2005).

In describing clock skipping, the written description appears to equate clock skipping with clock decorrelation: "[W]hat will be referred to herein as clock skipping (or clock decorrelation)," '661 patent, col 6, l. 17. Cf. Novacor Chems., Inc. v. U.S., 171 F.3d 1376, 1381 (Fed. Cir. 1999) (recognizing that "general principles of construction support the view that a parenthetical is the definition of the term which it follows" in interpreting a United States Customs regulation). See also, '661 patent, col. 5-10 ("Clock skipping involves decorrelating cryptographic operations from the normal [external] clock cycles").

Whether referred to as "clock skipping" or "clock decorrelation," however, the specification describes a technique not limited to literally "caus[ing] random clock cycles to be skipped" as Visa proposes:

Within clock skipping module 240, random output 205 is used to select cycles of clock signal 220 to skip in order to produce clock signal 260. Alternatively, random output 205 can be used to select the closest corresponding cycles of clock signal 220 to be used as clock signal 260, or random output 205 can even be used as clock signal 260 itself. Still other approaches are possible, as will be appreciated by those skilled in the art; the basic point being that clock signal 260 be (partially or wholly) decorrelated from external clock signal 220 via random output.

The Court construes "clock decorrelator" to mean "a device that generates an internal clock signal that varies in a randomized way."
The district court limited its claim construction to observing that claims 21 and 24 involve "producing a modulator drive signal which decreases the time that the signal is above threshold." Optical Disc, slip op. at 9. **Claim 24 is representative of the Time Above Threshold Claims and recites, in pertinent part, the step of:**

producing a shaped modulator drive signal by increasing the peak power of the writing beam responsive to the occurrence of said leading edges, **decreasing the time said shaped modulator drive signal is above threshold** to maintain a prescribed duty cycle in the track of surface effects in the moving recording medium, and producing a symmetrical geometry at the leading and trailing edges of said track of said surface effects.

'129 patent, col. 16, ll. 59-67 (emphasis added). The plain meaning of "decreasing" is "becoming less and less." Webster's Third New International Dictionary 588 (1986). Thus, as the district court recognized, the use of the word "decreasing" indicates that the inventors intended to shorten the time the modulator drive signal is above threshold.

More specifically, referring to the waveform of the modulator drive signal, the "SUMMARY OF THE INVENTION" states that "the amplitude of the steep leading edges of the shaped modulator drive signal represent increased peak recording power, while the selection of the point at which the slope of the trailing edges passes threshold relative to the steep leading edge sets the duty cycle of the recorded indicia (pits)." '129 patent, col. 7, ll. 19-22. The "DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT" states that "the timing of its trailing edge is purposely foreshortened to compensate for the increased length of the pit due to the higher-than-normal power level [of the leading edge boost]." Id. at col. 9, ll. 49-52 (emphasis added). Thus, the time the modulator drive signal is above threshold is decreased by shortening the timing of the trailing edge of the modulator drive signal relative to the leading edge.

**1193**

D. "decryption shim" or "shim"

<table>
<thead>
<tr>
<th>Term</th>
<th>Widevine Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decryption shim</td>
<td>A software component that is downloaded to or pre-installed on the client machine and used to decrypt incoming data stream from the encryption bridge on its way to the media player software.</td>
</tr>
<tr>
<td>shim</td>
<td>Verimatrix Construction</td>
</tr>
<tr>
<td>Decryption shim</td>
<td>transparent software that is downloaded to or pre-installed on the client machine and used to decrypt incoming data stream from the encryption bridge on its way to the media player software.</td>
</tr>
</tbody>
</table>

The parties dispute whether the construction for "decryption shim" should include the word "transparent." The language the parties agree upon comes from the specification, which Verimatrix contends is an express definition:

"The invention further provides a client system, also referred to as a decryption shim or simply a shim, which is a piece of transparent software that is downloaded to or pre-installed on the client machine (e.g. personal computer, network appliance or other network capable device) and used to decrypt incoming data streams from the EB on its way to the media player software."

'175 patent, 9:50-56. The issue is whether "transparent" would be an unnecessary limitation imported from the specification into the claims.

Widevine argues, under the doctrine of claim differentiation, that including "transparent" in the definition of "shim" would make that word meaningless in Claim 57, which recites "the shim being configured so that the negotiating and exchanging of the key thereby and the decrypting of the data thereby is transparent to the user." See '175 patent, Claim 57. Apparatus
Claim 81, on the other hand, only uses the word "shim" in the preamble, but does not use the word "transparent" in the body. According to Widevine, Claim 81 is implicitly transparent and the limitations teach how the shim operates transparently. However, "claim differentiation is not a 'hard and fast rule of construction,' and cannot be relied upon to 'broaden claims beyond their correct scope.'" Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001). The intrinsic evidence convinces the Court that the inventor intended the "shim" to be transparent, notwithstanding the doctrine of claim differentiation. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1370 (Fed.Cir.2007) ("the written description and prosecution history overcome any presumption arising from the doctrine of claim differentiation").

The Court does, however, need to clarify the definition provided by the patentee in the specification. While the definition of "shim" is express, a mere two paragraphs later in the specification, the patentee explains some exceptions to the software's transparency:

The installation of the decryption shim is transparent to the user and does not cause a reboot, restart of the user's browser or require interaction. Some exception such as the Mac OS TM and Windos N TM or Windows 2000 TM in secure environments or Linux or Unix based client machines because transparent installation requires administrative user privileges on the client machine and the ability of the client machine to receive programs via the Active-X TM mechanism.

'175 patent, 10:27-36. The specification recognizes a distinction between installation and operation and indicates that the shim will operate transparently, but may not install transparently. To account for this exception, yet remain consistent with the patentee's express definition, the Court construes "shim" and "decryption shim" to mean "software that is downloaded to or pre-installed on the client machine and used to decrypt transparently incoming data stream from the encryption bridge on its way to the media player software."

10. Dedicated Character Memory in Circuitry Controlling Said Output Device

The "dedicated character memory" must be part of the character-based output device and must be used exclusively for the purpose of storing a set of monochromatic characters.

32. Dedicated memory

The term "dedicated memory" appears in all of the claims of the 321 patent. In its reply brief, the plaintiff proposes that "dedicated memory" should be construed to mean "memory that is within the media processor that is accessible only through memory circuitry associated with the media processor." The defendants contend that under the plaintiff's construction, the memory is not dedicated because it is accessible by circuitry associated with the media processor and associated with another processor. Thus, the defendants insist that "dedicated memory" means "memory that is within the media processor that is accessible only through the media processor." Mindful that the claim language requires a "dedicated" memory, the court adopts the defendants' construction of "dedicated memory" and construes this term accordingly.

3. "[D]educting from the initial prepayment amount the running cost of the call"

Step (h) calls for "deducting from the initial prepayment amount the running cost of the call." The parties differ over when this happens. Telco contends that "[t]he running cost is deducted from the prepayment amount at the end of the call" (Joint Claim Chart, at 22), while Aerotel contends the claim does not speak to when the deduction occurs (see id.). The Court
agrees with Telco.

The most natural reading of steps (f), (g), and (h) is that the cost of a call is deducted from an account's available balance after a call is disconnected. As discussed in the following section, claim 23 uses "initial prepayment amount" and "current initial prepayment amount" to refer to the account's balance. Consistent with this usage: step (f) calls for "monitoring the running cost of the call in accordance with its duration;" step (g) calls for disconnecting the call "when the running cost of the call exceeds the current initial prepayment amount" (account balance); and step (h) calls for "deducting from the initial prepayment amount the running cost of the call." The comparison contemplated by step (g) requires that the "running cost" increase over time until the end of the call, whether that is effectuated by the caller hanging up or by the "running cost" eventually increasing to match the account balance. If the latter described comparison causes the end of the call, the immediately following deduction envisioned by step (h) brings the account balance to zero. If the caller simply hangs up then the running cost is deducted to create the new account balance. In both of those scenarios the deduction occurs at the end of the call. This is consistent with the Court's conclusion, supra, that steps (a) through (h) are to be performed sequentially, which requires that step (h) happens after step (g).

Aerotel's only argument for allowing the amount to be deducted during the call is that the patent's drawings and abstract refer to deducting credit "as the call progresses." ('275 patent, at [57]; see Pl.'s Opening Br. 26). But of course, "the words of the claims define the scope of the patented invention." Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1373 (Fed. Cir. 2008); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Where those words clearly describe the functions claimed, the Court will not expand the claim by reference to the specification and drawings. The Court finds, as the Washington Court did, Washington Court at 27, that "deducting from the initial prepayment amount the running cost of the call" means that the cost of the call is deducted from the initial account balance after the end of the call.

A. The Plain Meaning of the Words in the Claim Support a Construction of "Circumventing a Copy Protection Process to Produce a Watchable Copy"

"The words of the claims themselves define the scope of the patented invention. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996); see also Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998). In this case, the words "the effects" do not specify or exclude any specific types of effects. Instead, the term "the effects" is plural and all inclusive. Thus, it follows that "the effects" means all the effects, and the words of the claim provide no basis for interpreting "the effects" to mean "some or all of the effects."

Macrovision objects to this construction because it requires the addition of the words "to produce a watchable copy." Macrovision's argument is unavailing in light of the additional words in the construction that it asserts. Macrovision urges adding the words "and includes reducing the effects of a video copy process." The plain meaning of the words does not support this construction because it not only adds words, it adds a new concept, that of decreasing negative unintended side effects. Macrovision also asserts that this construction is invalid because it improperly adds a modifier "all" to the term "the effects." This construction, however, does not add a modifier. Instead, it recognizes that the word "the" modifies "effects," to produce a phrase that is all-inclusive. Accordingly, the plain meaning favors the construction "circumventing a copy protection process to produce a watchable copy."

B. The Different Words Used in Claim One and Claim Six Do Not Require Different Constructions

Macrovision argues that a comparison of Claims One and Six shows that the defeating phrase in Claim One should not be construed to mean "to produce a watchable copy." The preamble to Claim One asserts "[a] method of defeating the effects of a video anti-copy process" while Claim Six covers "[a] method of defeating a video copy protection process . . . thereby enabling recording a viewable copy of the video signal." Macrovision asserts that these differences were intentional and intended to make Claim One broader than Claim Six.

1. Claim Differentiation Doctrine Does Not Apply

- 1634 -
The doctrine of Claim Differentiation assumes that different claims have different scopes, and creates a presumption that different words have different meanings. The presumption that different words have different meanings, however, only applies if the absence of the different meanings would render one claim superfluous. Tandon Corp. v. U.S. International Trade Commission, 831 F.2d 1017, 1023 (Fed. Cir. 1987). In this case, the presumption does not apply because construing the preamble of Claim One to have the same meaning as the preamble of Claim Six would not render either claim superfluous as multiple differences exist between the two claims. Moreover, the intrinsic and extrinsic evidence in this case show that "defeating the effects of a video anti-copy process" and "defeating a video copy protection process" have the same meaning and overcomes any presumption that would have been created by the doctrine of claim differentiation.

--- Footnotes ---

1 Claim one states "A method of defeating the effects of a video anti-copy process that adds pulses to blanking intervals of a video signal comprising replacing a back porch portion of the video signal having an amplitude at blanking level with a signal having an amplitude below the blanking level." In contrast, Claim Six states: "A method of defeating a video copy protection process that adds paired negative and positive going pulses to blanking intervals of a video signal, the method thereby enabling recording a viewable copy of the video signal comprising the steps of: determining a particular portion of at least some video lines of the video signal, the added pulses being present in the particular portion; and reducing a level of the particular portion to below a blanking level of the video signal."

--- End Footnotes ---

2. The Different Words In Claims One and Six Do Not Require Different Meanings

Although it is unclear whether Macrovision argues that claim differentiation applies, it is clear that Macrovision attempts to rely upon the logic underlying the claim differentiation doctrine. Macrovision argues that it is invoking the "common sense notion" underlying the claim differentiation doctrine that "different words or phrases used in separate claims are presumed to indicate that the claims have different meaning and scope." (Mot. to Modify at 5: 26-6: 2, quoting Karlin Technology Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971 (Fed. Cir. 1999). The notion that different claims are presumed to have different meanings, however, does not mean that different words must have different meanings. In fact, courts have recognized that different words do not require different interpretations:

That the patentee chose several words in drafting a particular limitation of one claim, but fewer (though similar) words in drafting the corresponding limitation in another, does not mandate different interpretations of the two limitations, since "defining a state of affairs with multiple terms should help, rather than hinder, understanding." Bell & Howell Doc. Management Prods. Co. v. Altek Sys., 132 F.3d 701, 707, 45 U.S.P.Q.2d (BNA) 1033, 1039 (Fed.Cir.1997). Moreover, that the claims are presumed to differ in scope does not mean that every limitation must be distinguished from its counterpart in another claim, but only that at least one limitation must differ. See Mantech Envtl. Corp. v. Hudson Envtl. Servs., 152 F.3d 1368, 1376, 47 U.S.P.Q.2d (BNA) 1732, 1739 (Fed.Cir. 1998)

Kraft Foods, Inc. v. International Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000). Thus, the fact that Claim One uses different words from Claim Six does not require that the difference have meaning. See also Tandon, 831 F.2d at 1023 (construing "relatively fixed," "fixed" and "fixedly coupled" all to mean "fixed in all directions.")

C. The Specification Supports the "Circumventing a Copy Protection Process to Produce a Watchable Copy" Construction

The specification is properly used to define claims terms. Vitronics Corp, 90 F.3d at 1582. In the '927 specification, several passages are directed to circumventing the copy protection process. For example, the specification states that "disclosed herein in accordance with the invention are several methods and apparatuses for removal of or 'defeat' of the above-described video signal modifications, to permit unhampered copying and viewing thereof." ( '927 patent, col 5, lines 26- 29)(emphasis added). Similarly, the specification states that figure 15:

shows a two step circuit and method for removing all the above-described anticopy protection signals. A video signal . . . is first input on terminal 228 into the circuitry. . . to defeat the effects of the AGC pulses and pseudo-sync pulses. Second, the output signal from circuitry 230 is input into the enhancement remover 234 which defeats the checker and vertical pulses, and also defeats sync narrowing and any residual AGC pulse of pseudo-sync pulses in the horizontal blanking
interval. The video and signal at terminal 236 is thus free of all effects of copy protection signals.

( '927 patent, col 23:14-26.) (emphasis added.) See also '927 patent, col 23:14-26 ("the circuit of FIG. 39a reduces or removes the effect of the PPS pulses, rendering the video signal recordable").

Macrovision argues that the specification supports its construction. As support for this position, Macrovision points to column 32, which states:

Method and Apparatus for Reducing Effects of Basic Anticopy Process Signals

The following describes a method and apparatus in which the basic anti-copy process signals consisting of pseudo sync and AGC (i.e. basic anticopy process) added pulses (as described above) are reduced in effectiveness without altering these added pulses. Unlike the above described previous methods for altering the added pulses via amplitude attenuation, level shifting or pulse narrowing to offset the added pulses' effect, the present method reduces the effects of added pulses by further adding other pulses that counteract the gain reduction caused by the AGC and pseudosync pulses.

( '927 patent, col 32, lines 19-31.) Macrovision argues that the use of the words "reducing" and "reduced" mandate the inclusion of a partial elimination in order to improve watchability of the original tape. This construction is not supported by the language of the specification. The gain reduction discussed refers to the technology in U.S. Patent number 4,631,603 ("the '603 patent") which affects the automatic gain control system in a VCR to cause an unacceptable recording of the video signal. ( '603 Patent Col 2:21-29, Exh. 6 to Dwight Cavendish's Response to Opening Claim construction Brief) Thus, when read in context, the cited portion refers to defeating the copy protection process, and not to negative side effects on the original tape. 2 Accordingly, the specification supports the "circumventing a copy protection process to produce a watchable copy" construction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Macrovision also argues that Dwight Cavendish's expert, Bernard Lechner, agreed with Macrovision's construction that reducing the effects is covered by claim one. (Reply at 2:15-28.) However, the expert testified that reducing meant "reducing sufficiently that the resulting signal is acceptable for viewing." Lechner Dep. at 114:25-115:20 Thus, Dwight Cavendish's expert did not contradict the "circumventing a copy protection process to produce a watchable copy" construction. Instead, his testimony is consistent with this construction and provides no assistance to the construction which would include reducing unintended side effects on the original tape.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

D. The "Circumventing a Copy Protection Process to Produce a Watchable Copy" Construction Does Not Improperly Limit Claim One to Examples in the Specification

Macrovision argues that the construction of "Circumventing a Copy Protection Process to Produce a Watchable Copy" improperly limits Claim One to the examples in the specification. While it would be incorrect to limit Claim One to examples in the specification, it is equally true that the specification acts as a dictionary for the claim terms. Vitronics, 90 F.3d at 1582; Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1478 (Fed. Cir. 1998). In this case, the specification of the '927 patent uses the term "defeating the effects" in only one way-to mean circumventing copy protection. In fact, Macrovision conceded at the claim construction hearing that the specification does not support interpreting "defeating the effects" to mean reducing side effects on the original tape. Macrovision stated: "And we will concede, as Dwight Cavendish pointed out, there isn't a portion of the specification that we can say here is a section of the specification that talks about reducing the effects to improve the playability of the original tape. That's not in the specification and we're not contending that it is." (Joint App. Exh. B, Hearing Tr. at 30:23-31:4). Thus, the "Circumventing a Copy Protection Process to Produce a Watchable Copy" construction does not improperly limit Claim One to examples in the specification. Instead, it refuses to expand claim one in a manner inconsistent with the use of the term throughout the entire contents of the specification. 3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
The file history also contains no support for the construing "defeating the effects" to mean defeating or reducing some or all of the effects. The Patent Examiner treated "defeating the effects of a video anti-copy process" as synonymous with "defeating" copy protection. Thus, the court's construction is consistent with both the specification and the file history.

E. The Extrinsic Evidence Supports the "Circumventing a Copy Protection Process to Produce a Watchable Copy" Construction

Extrinsic evidence may be used to ensure that the claim construction based on intrinsic evidence is not inconsistent with how a person skilled in the art would understand the claim terms. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1308-09 (Fed. Cir. 1999). In connection with several other patents, Macrovision has used the term "defeating the effects" to refer to circumventing copy protection. For example, in relation to U.S. Patent No. 5,953,417 ("the '417 patent"), Macrovision told the Patent Office that "defeating the effects" means circumventing copy protection to create a watchable copy. Specifically, the '417 patent states:

'It is to be understood that herein the terms "copiable" and "recordable" both mean that the resulting video signal, when recorded by a VCR and then played back, provides a viewable television picture without substantial hue defects due to the color stripe process [i.e. another form of copy protection]. Thus these terms refer to effective elimination (defeat) of the effect of the color stripe process in terms of viewability of the video signal."

'523 patent, col 10, lines 54-60 (emphasis added). Thus, the extrinsic evidence is consistent with the plain meaning of "defeating the effects of a video anti-copy process" as "circumventing copy protection process to produce a watchable copy."

V. ORDER

For the foregoing reasons, the phrase "defeating the effects of a video anti-copy process" is construed to mean: "circumventing a copy protection process to produce a watchable copy." Accordingly, it is hereby ORDERED that the Motion of Dwight Cavendish to Enter the Report of the Special Master is GRANTED and the Motion of Macrovision to Modify the Report of the Special Master is DENIED.

1198

5. "defective floppy diskette controller"

The Special Master found that this term "needs no construction, for its ordinary meaning is clear." He pointed out that the term "floppy diskette controller" has already been construed and that, in light of the construction, a jury would have no difficulty understanding what is meant by "defective."
He rejected Defendants' argument that the defect in the FDC must relate to an inability or failure to detect an error caused by "a delay in the transfer of the last byte of a sector" for two reasons: First, it would be "an egregious example of improperly reading limitations from the specifications into the claim." 102 Second, it would "violate the doctrine of claim differentiation, which creates a presumption that each claim in a patent has a different scope." 103

In the '002 patent, claim 4 is ultimately dependent upon claim 1, through dependence upon claims 2 and 3. But claim 4 adds this language: "wherein the underrun error comprises a delay in transferring a last byte in the transfer." Consequently, if one were to import into claim 1 the "last byte" limitation, it would be present as well in dependent claims 2 and 3, and dependent claim 4 would have the same scope as claim 3. The same correspondence holds true for claims 1, 3, 4, and 5 of the '222 patent; importation of that limitation into claim 1 would result in claim 5 having the same scope as claim 4. 104

102 Id. at 57.
103 Id.
104 Id.

He reasoned that Defendants' proffered claim construction would be presumptively unreasonable because it would result in one claim having the same scope as another claim. 105

105 Id. (citing Beachcombers v. Wildewood Creative Prods., Inc., 31 F.3d 1154 (Fed. Cir. 1994)).

Defendants now argue that the ordinary meaning does not reflect the proper scope of the patents. They assert that the last byte error is the sole problem the patents purport to identify and solve and, therefore, the presumption of claim differentiation is overcome. They also object that the Special Master has not construed an FDC to require that it be a hardware device--again objecting to a passing footnote reference to Eolas and arguing that Defendant described FDCs in the '002 and '222 patents as hardware.

Plaintiff argues that the last byte error is not the sole problem of the patents and that a close reading of Defendants' cites reveals the inventor did not label FDCs as hardware devices.

Defendants' arguments do not convince the Court that the common meaning of the term does not reflect the scope of the patents. Plaintiff did not label the FDCs as hardware devices, and Defendants have not overcome the presumption of claim differentiation.

The Court adopts the following claim construction: The term "defective floppy diskette controller" needs no construction, for its ordinary meaning is clear.
phrase "define an updated form line" should be construed to mean "computing terrestrial locations of a vehicle while the vehicle is diverted from steering guidance by the operator to accommodate a terrain feature on the field." Defendants, by contrast, contend that the phrase should be construed to mean "recompute a previously computed path across the area to be treated."

Defendants' arguments once more prevail. "Form line" has been construed to mean "path across the area to be treated," and "defining" it has been construed to mean "computing" it. Accordingly, to define an updated form line can only mean to "recompute a previously computed path across the area to be treated." This construction logically results from construing the disputed phrase consistently with other disputed phrases construed by the court herein.

Moreover, Trimble does not truly challenge this construction. Its objection to defendants' proposed construction is not based on the fact that defendant interprets the phrase "define an updated form line" to mean "recompute a previously computed" form line, but rather to defendants' construction of "form line," which is construed to mean "path across the area to be treated." This objection has already been taken into account, and resolved, by the court's construction of the term "form line" as noted at the outset.

Accordingly, the court construes the term "define an updated form line" as: "recompute a previously computed path across the area to be treated."

GO BACK

1200

iii. Defined routines

Gobeli asserts that this phrase should be given its plain and ordinary meaning. Gobeli argues that the term should be construed to mean "one or more program instructions associated with an interrupt cause." Defendants contend that the proper construction is "program instructions that, when executed, remedy a specific interrupt cause." Both sides agree that the defined routines are program instructions, but Defendants assert that the additional limitation "remedy" must be part of the claim term. The Court disagrees.

The Gobeli patent does not require the defined routines to remedy the interrupt cause. Instead, the patent uses the word "service." See, e.g., Gobeli patent, Col. 1, 11. 42-43. This Court refuses to incorporate limitations into the claims that do not appear in the specification or in the claims. The patentee at no time limits the claimed invention to remedying the interrupt cause.

However, the Court's analysis does not end at whether or not remedy must be part of the construction. In subsequent clauses in Claim 11, the patentee references specific portions of the routines that are associated with a process. Thus, the defined routines are not tied to the stimulus or interrupt cause, but are instead tied to the device or device subsystem. Instead, it is the "specific portions" of the defined routines that are tied to the actual interrupt cause or stimulus. Accordingly, the court construes "defined routines" as "program instructions that are associated with a device or device subsystem."

3. "defining a second form line using positioning data derived from GPS data and a swathing offset" (Claim 1)

This phrase appears in claim 1. See Tang Decl., Ex. A at 12:34-49, Ex. D at 2 (amended Claim 1). Trimble contends that the above phrase should be construed to mean "comparing two or more terrestrial locations on the field based upon the computed terrestrial locations of the previous form line and a distance determined by an effective width of a towed implement to provide steering guidance." Defendants contend that the phrase should be construed to mean "computing a second path across the area to be treated using geographical positions computed using GPS satellite data transmissions and a distance determined by the effective width of a towed implement."

The disputed phrase here is focused on what it means to define a "second form line" in accordance with the contour
guidance system claimed by plaintiff. Preliminarily, as defendants point out, much of the phrase has already been construed. For example, the term "form line" has been construed to mean a "path across the area to be treated," and "defining" a form line has been construed to mean "computing" it. As such, and putting those terms together to be read consistently, "defining a second form line" must be construed, as defendants propose, to mean "computing a second path across the area to be treated." Defendants also correctly note that the parties previously agreed that "swathing offset" should be construed as "a distance determined by the effective width of a towed implement." See Joint Claim Construction Statement, Appendix C. All of which leaves only one segment of the phrase at issue here that requires construction -- that portion which states "using positioning data derived from GPS data." Plaintiff's proposal construes this as meaning "based upon the computed terrestrial locations of the previous form line," while defendants opt for the construction, "using geographical positions computed using GPS satellite data transmissions."

In construing this portion of the phrase, the specification of the '383 patent is helpful, and argues in favor of defendants' proposed construction. In referring to the guidance system's method for defining the second form line, the specification refers to the process of defining second and subsequent form lines with reference to GPS satellite data, rather than more generalized "terrestrial locations." See Tang Decl., Ex. A at 7:33-8:19 ("if additional form lines are to be sprayed, a decision made at step 114, GPS receiver 60 (or the separate processor) computes a new form line (or swath), based on the GPS data collected while sprayer rig 30 traversed across the first form line path."); 2:17-21 ("the present invention provides a form line following apparatus which includes a vehicle fitted with a GPS receiver configured to receive GPS data and GPS correction information and to compute position information therefrom").

Furthermore, the specification's description of the drawings also refers to a form line following process that is dependent upon GPS data transmissions. Figure 5, for example, depicts the process of computing form lines subsequent to the first form line, and expressly states at step 116 that these subsequent form lines are computed "based on GPS data." See id. at Ex. A, Fig. 5; 7:57-61 ("in figure 5 ..., at step 118, the operator begins the next form line. In general, the operator follows the guidance information computed by GPS receiver 60 and displayed on moving map display 64 and heading indicator 70 and also on light bar 72"); see also id. at 5:40-43 (describing Figure 4 and stating that "GPS receiver 60 uses the GPS data provided through antenna 44 from the GPS satellites 46 and the differential GPS information received through antenna 48 to compute position information for sprayer rig 30"). Accordingly, based on these references to GPS data in connection with the definition of subsequent form lines, defendants' proposed construction -- that "using positioning data derived from GPS data" should be construed as "using geographical positions computed using GPS satellite data transmissions" -- makes the most sense.

The court therefore construes "defining a second form line using positioning data derived from GPS data and a swathing offset" as: "computing a second path across the area to be treated using geographical positions computed using GPS satellite data transmissions and a distance determined by the effective width of a towed implement."

1. "defining an intensity distribution of the illumination light on the Fourier transform plane in the illumination optical system with respect to a pattern on the mask to have increased intensity portions apart from an optical axis"

Distilled to its essence, the parties' disagreement over this prolix claim term centers on two words: "defining" and "on." ASML reads "on" to modify "defining" such that the phrase "defining an intensity distribution of the illumination light on the Fourier transform plane" necessarily places the act of defining "on" the Fourier transform plane itself; for its part, Nikon argues that the claim language demands no such placement, connoting only the existence of "an intensity distribution of the illumination light on the Fourier transform plane in the illumination optical system."

At least in part, basic principles of grammar 20 contradict Nikon's parsing of the claim text. The claim language's use of a gerund-form verb (viz., "defining") unequivocally implies an act. See Anhydrides & Chemicals, Inc. v. United States, 130 F.3d 1481, 1483 (Fed. Cir. 1997) (applying the basic rules of grammar when evaluating a statute); Gen. Foods Corp. v. Studiengesellschaft Kohle mbH, 972 F.2d 1272, 1274 (Fed. Cir. 1992) ("Each claim is an entity that must be considered as a whole."). When claim 12 uses the word "defining," it denotes the act of assigning a definition to an intensity distribution of an illumination light; Nikon cannot construe the claim such that this act does not occur.
Yet precisely where this act of "defining" occurs presents a substantially more difficult question. In its proposed construction, ASML asks the court to place the act of "defining" directly on the "Fourier transform plane," arguing that the location of a particular prepositional phrase (viz., "on the Fourier . . . .") in the claim text compels the court to place the act on the relative position of the plane between the pattern and the light source. As the court reads claim 12, however, the pivotal prepositional phrase could be read to modify the act of "defining" (as ASML suggests), or it could be read to modify the occurrence of the illumination light, but not necessarily one, the other, or both. See '041 Patent at 19:14-20:3 (". . . defining [] an intensity distribution of the illumination light on the Fourier transform plane"). It is simply not clear that the act must occur where ASML says it does, nor that it ever does.

In fact, intrinsic evidence and the core technology suggest that it does not, i.e., that the prepositional phrase modifies the illumination light, not the act of defining alone. Indeed, much in the intrinsic record suggests that the Fourier transform plane functions as a location at which light may exhibit particular characteristics, not that it is where the "defining" must take place. See, e.g., '041 Patent at 3:30-40 & 4:20-5:11. And to say as much does not exclude the embodiment in figure 2; the disclosed embodiment is sufficiently incorporated through a definition denoting the core act itself. Consistent with the claim text and the lessons of the intrinsic record, the court construes "defining an intensity distribution of the illumination light on the Fourier transform plane in the illumination optical system with respect to a pattern on the mask to have increased intensity portions apart from an optical axis" to mean "quantifying or shaping of increased intensity portions of the illumination light, as those portions appear on the Fourier transform plane, in the illumination optical system."
For the reasons already discussed in connection with the proper construction to be given the term "form line," the disputed term here must also be construed as a computed path across the area to be treated, which is based on the new geographical positions recorded while the operator deviated from the original second form line. In addition, the '383 patent's language and specification support a construction that deviating from the second form line while following it, as referred to in the disputed term here, means a process whereby: (a) the operator deviates from the previously computed second form line path; and (b) GPS data records the new geographical positions of the operator associated with the deviations. This GPS recording of the new geographical positions corresponding with the deviated second form line is what it means to "update" the second form line. Only after updating the second form line with the new GPS data, is the updated second form line "defined," by computing an updated path to extend across the area to be treated, based on the new GPS data that recorded the deviated second form line path taken by the operator. See Tang Decl., Ex. A at Abstract ("The updating generally occurs by following the second form line as defined by the positioning data and the swathing offset and then deviating from the second form line to accommodate one or more terrain features. New GPS data is collected during these steps of following and deviating from the second form line and new positions are computed from the new GPS data. Finally, the updated second form line is defined using the new positions computed from the new GPS data."); 3:20-25 ("GPS data may be collected during the steps of following and deviating from the computed second form line path and one or more positions computed therefrom. An updated second form line may then be defined using the computed positions.").

Given this description of the process by which the second form line is updated and then defined, the ordinary plain meaning of the disputed term here is in line with defendants' proposed construction. Accordingly, the court construes "defining an updated second form line according to one or more deviations from said second form line while following said second form line" should be construed as: "recomputing the previously computed second path across the area to be treated using new geographical positions computed while deviating from the previously computed second path across the area to be treated."

f. Defining at least time and yield characteristics of each process step

According to ITI, the limitation "defining at least time and yield characteristics of each process step" should be construed as determining the duration of a stage of manufacturing and the portion of the parts or lots that successfully complete that stage, where the duration and portion can vary in a random manner. Defendants propose that the correct interpretation is: for each process step, fixing distinctly at least the standard process time, set-up time, and yield, and the probability characteristics of fluctuations in the standard process time, set-up time, and yield. The Court believes that both proposals contain superfluous language.

As already mentioned, "process step" is defined in the specification as the fundamental operation performed on a machine. Defendants seem to assume that all process steps include certain attributes, namely, a process time, a vector of parameters describing conditional setup times, a standard yield, and parameters for random yield distributions. But the relevant part of the specification states, "in this embodiment, the attributes of each process step include a process time, a vector of parameters describing conditional setup times, a standard yield, and parameters for distribution describing random yield and process-time fluctuations." U.S. Patent No. 4,796,194, col. 11, lines 30-34 (emphasis added). Clearly, the patent leaves open the possibility that other embodiments of the invention might contain process steps with different attributes. The limitation at issue should not be defined using attributes that might apply only to certain embodiments of the invention.

It is relatively clear from the specification that "yield," here used as a noun, is used in a way consistent with its common meaning: the result or quantity produced. Taking together the definitions of "process step" and "yield," the Court interprets the limitation to mean determining at least the duration of, and the result or quantity produced by, each fundamental operation performed on a machine.
Macromedia contends that the phrase "defining element" should be construed to mean "an element from which derived elements are generated." (D.I. 470 at 6). Adobe contends that the phrase "defining element" should be construed in accordance with the definition expressly provided in the specification, namely "an element that can be used to calculate the essential information required to construct other elements." (D.I. 479 at 12).

In construing the phrase "defining element," the Court has considered the specification of the '443 Patent. ( '443 Patent, Col. 2, lines 37-39). Because the specification expressly defines the phrase "defining element" as Adobe contends, the Court construes the phrase "defining element" to mean "an element that can be used to calculate the essential information required to construct other elements."

b. Defining lots of parts manufactured in the plant

ITI requests that the Court construe "defining lots of parts manufactured in the plant" to mean determining attributes of groups of like parts. According to defendants, the phrase should be interpreted to mean fixing distinctly the essential qualities of the components, not the finished products, that are manufactured in the plant.

The specification states that "lots are composed of like parts and follow a fabrication-sequence." U.S. Patent No. 4,796,194, col. 10, lines 66-68. The patent discusses lots in terms of their "attributes" at least twice. See id., col. 11, lines 1, 5. Thus, ITI's construction is more in keeping with the use of "lots" in the specification. Similarly, defendants' addition of "essential qualities" is unnecessary. Defendants cite the following definition of "defining": "to determine or identify the essential qualities or meaning of." Webster's Ninth New Collegiate Dictionary 333 (1986). Reliance on a dictionary definition is secondary to defining the term in the context in which it is used within the patent itself. Moreover, "essential qualities" is not indispensable language even within the cited definition, and "attributes" conveys the same sentiment.

To define "parts" would confuse the issue, as "lots" are defined in terms of parts and the word "parts" already appears separately in the limitation. The Court is confident that the jury will have no trouble understanding that a part is not equivalent to a finished product.

In sum, the Court adopts the following construction: determining attributes of groups of like parts manufactured in the plant.
7. Access Time/ Access Time Register/ Delay Time

a. Proposed constructions

To optimize transmissions over the bus, the invention attempts to coordinate individual DRAM outputs by injecting a certain time delay before each device responds to a request. A value representing the amount of time the device is to delay is stored in one or more access time registers on each device.

Rambus and Hynix dispute the construction of three related terms: (1) access time register, (2) access time; and (3) delay time. These terms are conceptually interrelated which requires they be construed jointly. "Access time register" is used in '214 patent, claim 18 and the '918 patent, claim 24. The parties have agreed to the construction of "register" as "a data storage element or group of data storage elements not part of a memory array that can store one or more bits of information." Rambus proposes "access time register" be construed as "[a] data storage element to store a value representative of an access time delay." Hynix proposes it be construed as "[a] register programmable to store information representing a particular access time." JCCS, Ex. A at 24.

"Access time" is used throughout the patents yet never as a separate term in the asserted claims. Hynix argues the term should be separately construed by the court because the parties have agreed to a construction of "register," and because both parties use the term in their proposed constructions of several other terms. Hynix proposes "access time" be construed as "the time between the initiation of a memory access and the availability of data at the outputs." JCCS, Ex. A at 22. Rambus opposes a construction of "access time" because the term is only used within the asserted claims as part of "access time register." Although Rambus's briefing contains several arguments in opposition to Hynix's proposed definition, Rambus does not provide a proposed construction for "access time." JCCS, Ex. A at 22.

"Delay time" is used in the '263, '918, '365, and '195 patents. Hynix proposes the term be construed as "the time between the initiation of a memory access and the availability of data at the outputs." JCCS, Ex. A at 25. Rambus proposes "an amount of time before commencing a subsequent action." Id.

b. Access Time Register

i. Claim Language

Two asserted claims use the term "access time register." Each provides significant context for construing the term. Claim 18 of the '214 patent states:

The method of claim 15 [describing the read and output of data synchronously with respect to a first and second external clock signal] further including storing a code in an access time register, the code being representative of a number of clock cycles of the first and second external clock signals to transpire before data is output onto the bus in response to the first read request, wherein the first amount of data corresponding to the first block size information is output after the number of clock cycles transpire.

Claim 24 of the '918 patent states:

The method of claim 18 [describing the read and output of data synchronously with respect to the external clock signal] further including storing a delay time code in an access time register, the delay time code being representative of a number of clock cycles to transpire before data is output onto the bus after receipt of a read request and wherein the first amount of data corresponding to the first block size information is output after the number of clock cycles transpire.

Throughout the patents-in-suit various phrases are used to describe what the value in the "access time register" is meant to represent. Hynix offers "a particular access time." Rambus offers "an access time delay." For purposes of this subsection, in an effort to avoid confusion, the court will use the term "delay time code."
ii. Ordinary meaning

Hynix argues that the contents of the access time register should be defined as a value representing a time equivalent to the ordinary meaning of "access time." The ordinary meaning of "access time" is "the time interval between the instant at which data are called for from a storage device and the instant delivery is completed, that is, the read time." THE AUTHORITATIVE DICTIONARY OF IEEE STANDARDS TERMS 7 (7th ed. 2001). Hynix's proposed construction of "access time" is substantially similar to its ordinary meaning.

Rambus contends that the claims asserted use the term "access time" as simply a label for that type of register. The label, according to Rambus, does not thereby define the contents of the register. The claims' explicit statement that the access time register stores a delay time code supports Rambus's argument. Delay time, as discussed below, is not necessarily equal to Hynix's construction of "access time." Therefore, the ordinary meaning of the label "access time register" does not control the construction of its contents.

iii. Specification

Hynix seeks to limit the delay time code to "a particular access time." Hynix further seeks to precisely define how such "access time" is measured. JCCS, Ex. A at 22. Rambus argues the claims should not be limited to registers where the delay time (represented by the delay time code) is equal to the access time as measured by Hynix.

Hynix's construction of "access time" appears to describe the physically minimum access time. As Rambus observes, in one sense, "access time" describes a physical characteristic of the memory device. It is the minimum amount of time in which it is physically possible for a device to receive a request and then complete its response, whether that response be to write a block of data or to output a block of data through the output pins. See THE AUTHORITATIVE DICTIONARY OF IEEE STANDARDS TERMS 7 (7th ed. 2001). As noted during the tutorial, the physical access time of a device is typically a fixed constant, predetermined by the access mode, the physics of the chip, and the interaction with external variables such as temperature or voltage.

First, in a preferred embodiment, the specification teaches:

The value stored in a slave access-time register 173 is preferably one-half the number of bus cycles for which the slave device should wait before using the bus in response to a request.
