The securing mechanism refers to a locking mechanism that is applied to the back member and shoulder supporting members such that they are affixed together in a manner that precludes any change in orientation, i.e., they are welded together or otherwise locked.

DEG argues that the district court erred in its claim construction because it failed to define the claim limitation of “changeable or adjustable shoulder supporting members.” Specifically, argues DEG, the court erred in removing the “adjustability” feature of the “shoulder supporting members” and thus broadened the scope of the claim to cover any adjustable drum carrier borne on the shoulders of the drummer. According to DEG, the court erroneously applied the limitation of “adjustability” to the carrier as a whole, rather than to the shoulder pieces specifically. Consequently, under the district court’s claim construction, as long as the adjustability feature can be found somewhere on the harness such that the upper section can be adjusted relative to the lower section, the adjustability limitation of the claim is met.

Since the district court provided no explanation of the reasoning behind its claim construction, and since we review claim construction de novo, we look first to intrinsic evidence in construing the claims, i.e., the language of the claims themselves, the written description portion of the specification, and the prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83 (Fed. Cir. 1996). The critical claim language in claim 17 is "a shoulder supported carrier structure … having changeable or adjustable shoulder supporting members for securing said structure on the shoulders of a user." The language of the claim expressly teaches more than one "shoulder supporting member" and this language most clearly maps onto those portions of the harness that support the harness over the shoulder, viz., the two arched shoulder pieces. These likewise reasonably correspond to the "shoulder straps" described in the specification of the ’886 patent. The chest piece and the back bar can be excluded from this claim limitation because they are singular pieces and do not come into contact the shoulders of the drummer. Furthermore, the back bar is separately defined in the following limitations of the claim. The additional chest pieces and the drum carrier brackets comprise the remainder of the "shoulder supported carrier structure" of claim 17.

Moreover, the claim language teaches that the shoulder supporting members should be "changeable" or "adjustable": these terms immediately precede the term "shoulder supporting members" and the only reasonable construction, therefore, is that these shoulder supporting members themselves, rather than the entire assembly, should be adjustable or changeable. And, in the specification of the ’886 patent, the "shoulder straps" which correspond to the shoulder supporting members of claim 17, are not immovably or irretrievably fixed to the back bar and other portions of the supporting carrier, but rather are adjustable or removable so as to be interchangeable with other shoulder straps. For example, the specification describes one preferred embodiment in which the: "[v]est portion (the remainder of the carrier corresponding to the chest pieces) is removably secured to [the] shoulder straps by screws or bolts and has a pair of J-rod receptacles secured by screws or bolts." Likewise, a second embodiment is described in which the:

[back support or back member as shown in this figure is removably secured to shoulder straps by screws bolts or threaded fasteners and has padding. Bolts extend out from the removable back member, and extend into elongated slots located in the shoulder straps to allow for width adjustment on one or both shoulder straps. Alternately slots may be
incorporated into the back member, and a square neck carriage bolt may be used in prevent rotation of the bolt when tightening the nut. The back member may be secured to removable shoulder straps. Removable shoulder straps of various sizes can be used to accommodate different size users. Vest portion is adjustably and removably secured to shoulder straps by screws or bolts which extend through elongated slots which permits adjustment of the straps relative to the anterior vest portion of the harness.

And in every other embodiment described in the specification, the shoulder straps are described and depicted as being changeable or adjustable (or both). Even in those embodiments wherein the shoulder straps are spot welded to the back bar, they are still adjustable or removable with respect to the anterior vest portion of the harness.

We hold, therefore, that the district court erred in its construction of claim 17 (and, consequently, in its construction of dependent claim 19 as well). The district court's elision of the claim limitation (supported by the specification) that the shoulder supporting members are either changeable or adjustable is legal error because all the limitations in a claim must be considered meaningful. Cablestrand Corp. v. Wallshein, 29 F.3d 644 (Fed. Cir. 1994). We therefore amend the district court's language in the portion of its construction of Claim 17 which reads:

The piece of the device that connects on the user's back to the back member and which then sits on the user's shoulders and performs the function of supporting the balance of the device while allowing the user to adjust the upper section of the device relative to the lower section and to replace, remove or substitute the shoulder supporting members with other shoulder supporting members of different sizes

to read:

The adjustable or changeable pieces of the device that rest on the user's shoulders and perform the function of supporting the balance of the device and which connect the back member, situated against the user's back, with the upper portion of the device that rests on the user's chest.

B. "Changing a Blood Parameter"

In addition to the mixing limitation, Claim 1 also contains the following limitation: "changing a selected blood parameter in blood flowing in said circulating system to produce a distinguishable blood characteristic in blood which is delivered to the arterio-venous shunt." During oral argument the parties mainly agreed, as does the Court, that the terms "blood parameter" and "distinguishable blood characteristic" both refer to a "measurable physical characteristic of the blood." Therefore, the terms shall be construed accordingly.

While the parties agreed on this point, the parties disagree as to how "changing" occurs under this limitation. Plaintiff reads the limitation to anticipate any method by which a blood parameter may be changed. Defendant reads the limitation to require the addition of an indicator to the blood to achieve the recited "changing."

Like the term "mixing," however, the term "changing" is an ordinary term meaning to make different, modify, or alter. See e.g., WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY (1993). While defendant points to language in the prosecution history and specification in support of a more narrow construction of the term, nothing in the intrinsic evidence suggests that the plaintiff or PTO effectively re-defined the term "changing" for the purposes of patent '989. Moreover, there is nothing ambiguous about the term "changing." Therefore, as plaintiff suggests, the term "changing" "means to make different, modify, or alter. There is no restriction in [the] limitation as to how the 'changing' is caused." (Pl.'s Reply Brief Append. 1).

Defendant points to two pieces of intrinsic evidence to overcome this interpretation of the changing limitation. First, defendant points to a prosecution history notation in which the PTO states, "the step of changing a selected blood parameter occurs in the venous line where a volume of indicator is injected into the venous line." (Wong Decl. Exh. B, FH 989 0157). However, this statement merely recites an explanation of the preferred embodiment of the claim. It does not suggest that the inventor was claiming only changes brought about through the addition of an indicator. In fact, if anything, the isolated remark would suggest an intent to limit the patent to changes brought about by injection only -- not any means of adding an
indicator as proposed by defendant. 3

3 Defendant suggests that Southwall Technologies, Inc. v. Cardinal IG Co., governs this case and mandates the adoption of defendant's construction of this limitation. 54 F.3d 1570, 1576 (Fed. Cir. 1995). However, unlike in Southwall, it does not appear "from the patent and file history that the [term changing was] used differently by the applicant." Id. at 1578.

Similarly, the specification language relied on by defendant does not necessitate that the Court look beyond the plain meaning of the term "changing." Defendant accurately points out that the specification contains the following language: "measurement of blood flow in the shunt is obtained, in accordance with the invention, by injecting into venous line 32, as by way of an injection port 40, an indicator material. . . . In the preferred embodiment, this material . . . is saline solution." However, when read in context, it is clear that this passage in its entirety refers to the preferred embodiment of the device -- which has an injection port for an injectable indicator such as saline. Thus, because "particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments," the Court cannot limit Claim 1 to changes brought about through the addition of an indicator as requested by defendant. Rhine v. Casio, 183 F.3d 1342, 1346 (Fed. Cir. 1999).

NMT's appeal of the district court's grant of Transonic's motion for a preliminary injunction is based on the court's claim construction. Claim construction is a question of law that we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). NMT argues that the court misconstrued the "mixing," "changing," and "calculating" and "determining" limitations of the asserted claims.

With regard to the "mixing" limitations, NMT raises the same arguments that it raised before the district court, asserting that the statement in the prosecution history regarding "complete mixing" limits the scope of the claims. NMT also cites external evidence, including correspondence between the inventors and their patent attorney and articles authored by the inventors, as demonstrating that "complete mixing" is a required aspect of the invention. Finally, NMT argues that the district court's construction of "mixing" renders the term meaningless because mixing will always occur as a result of the "delivering" steps.

NMT argues that the "changing" limitations are drafted in step-plus-function form and, therefore, must be construed in accordance with 35 U.S.C. § 112, P6. When so construed, NMT argues, "changing" requires the addition of an indicator because that is the only corresponding act disclosed in the specification. NMT argues that even if the "changing" limitations are not construed under § 112, P6, statements in the prosecution history made by the applicant and by the examiner limit the "changing" step to the addition of an indicator. NMT also argues that the district court erred when it determined that the "blood parameter" that is changed to produce a "distinguishable blood characteristic" includes chemical and biological characteristics of the blood, in addition to the physical characteristics disclosed in the specification.

After careful consideration, we reject NMT's arguments. We discern no error in the district court's construction of the "mixing and "changing" limitations or in its findings that those limitations are met by NMT's Delta H method. However, as far as the "calculating" and "determining" limitations are concerned, we believe that the district court's construction was too broad.

3. Channel

Plaintiff's proposed construction: A region of a connector configured to engage a vertical member.
Defendant's proposed construction: A space in the connector for receiving one of the substantially vertical members.

In their pre-hearing briefs, the parties disputed whether a channel is a region engaging a vertical member (plaintiff's construction) or a space receiving a substantially vertical member (defendant's construction). At the hearing it became clear that plaintiff was most concerned with the way the channel functions, arguing that there is a significant difference between receiving and engaging because the channel could merely receive a member without engaging it. Although defendant maintains that "receiving" should be used instead of "engaging," its main concern is that the members be described as "substantially vertical," which plaintiff agreed to at the hearing.

The term "channel" is mentioned only briefly in claim 14 and the specification. The claim states that the channel is for engaging the vertical member. The specification teaches that the face guard connector has at least two parallel channels, each which receives a portion of the face guard. '151 patent, col. 8, lns. 1-4. Because the claim language makes clear that the channel engages the members and I agree that there is a meaningful difference between receiving and engaging something, I will use "engage" in defining the term. The parties agreed that "portion" is an acceptable alternative to "region" and "space."

I conclude that the term "channel" as used in claims 14-19 of the '151 patent means a portion of the connector configured to engage the substantially vertical members.

---

Kason's view that a "channel" is any u-like shape that can be drawn from a solid structure is contradicted by the ordinary meaning of the word "channel," the description of a channel in Claim One, the patent specifications and its prosecution history.

According to The Random House College Dictionary, a "channel" is "any structure member having the form of three sides of a rectangle." According to Webster's Third International Dictionary, a channel is "a metal beam or strip having a u-shaped section." The ordinary meaning is thus a distinct structural member or a metal beam in a u-shape.

The language of the claim does not assign any other meaning to the term "channel," rather, it too indicates that a channel is a distinct u-shaped piece, as it describes a "pair of internal channels" and a "pair of external channels." The patent specifications also indicate channels as individual elements that must be "joined together by means either of spot welding . . . or . . . double sided tape . . . or adhesive . . . ."

Finally, we know from the "Remarks" accompanying Kason's successful patent application, that what was uniquely patentable about the Katz design was the structural configuration of the four "channels."

Following Markman, this Court concludes that the term "channel" means an individual u-shaped bar or structural element, not simply any u-shape that can be imagined to exist within a unitary structure.
Claims 1, 10, and 11 of the '227 patent describe a "first interior channel in which said fluorescent tube is mounted" and a "second interior channel in which said electrical means is primarily housed." (App. To Def.'s Markman Br. Ex. B at Col. 4, L.L. 29-34, Col. 5, L.L. 10-13, and Col. 6, L.L. 12-14)(emphasis added). Lampi defines "channel" as an interior area where the fluorescent tube or electrical components are contained. APP responds that "channel" means an unobstructed tubular sleeve for enclosing and supporting the fluorescent tube or containing the wiring for the fluorescent tube. Based on the intrinsic evidence of record, there is considerable, if not abundant, support for APP's use of the term "sleeve." The '875 patent repeatedly claims (Claims 5, 6, 7, 9, 10, 16, 17, and 18) an interior space in the housing that forms "two contiguous sleeves" which extend in a direction parallel to one another. (See App. To Def.'s Markman Br. Ex. A at Col. 4, L.L. 40-50, Col. 4, L.L. 51-52, Col. 4, L.L. 55-57, Col. 4, L.L. 61-68, Col. 5, L.L. 1-8, Col. 6, L.L. 13-20, Col. 6, L. L. 22, and Col. 6, L. L. 27). The first sleeve houses the fluorescent tube and defines a window for the lamp. (Id. at Col. 4, L.L. 45-46 and L.L. 51-54). The second sleeve houses the electrical components needed to operate the fluorescent tube. (Id. at Col. 4, L.L. 46-47). The specification also describes a housing containing two "contiguous sleeves" which extend in a direction parallel to each other with one containing the fluorescent tube and the other the electrical components. (Id. at Col. 2, L.L. 35-68 and Col. 3, L.L. 1-18). Significantly, the '227 patent uses the term "channel" to describe the same structures and functions. (See App. To Def.'s Markman Br. Ex. B at Col. 2, L.L. 36-68, Col. 3, L.L. 1-20, Col. 4, L.L. 25-44, Col. 5, L.L. 5-19, and Col. 6, L.L. 5-20). Furthermore, the prosecution history reveals that "sleeve" was actually the antecedent to "channel." (See App. To Def.'s Markman Br. Ex. 1 at 7-8).

Lampi's interpretation of "channel" as an "interior area" conveniently ignores this compelling intrinsic evidence. Because "sleeve" was contemplated, and indeed claimed, by the patentee, we find that it is an appropriate interpretation of "channel."

The question remains whether "sleeve" is limited by "unobstructed" and "tubular." Lampi objects asserting that there is no support for these limitations in the claims or specification. We agree. APP summarily concludes that, given the relevant prior art, a "channel" must be both unobstructed and tubular. APP's interpretation, however, is rooted entirely in extrinsic evidence including prior art and technical dictionaries. When, as here, any ambiguity is resolved by the claims, specification, or prosecution history, there is no need to consult such extrinsic evidence. See Vitronics, 90 F.3d at 1582.

Accordingly, we conclude that "channel" means an interior sleeve where the fluorescent tube or electrical components are contained.

The district court interpreted the "first interior channel in which [the] fluorescent tube is mounted" limitation in claims 1 and 11 as meaning "an interior sleeve where the fluorescent tube is contained." Relying primarily on language in the claims and written description, the court concluded in its subsequent infringement analysis that the translucent cover of Model 7744 could not be part of the first interior channel, i.e., the court construed "first interior channel" as defined by elements of the housing that cannot include a translucent cover.

On appeal, Lampi argues that the district court erred in excluding the translucent cover, or plastic diffuser, of the 7744 model from being a part of the first interior channel. According to Lampi, the court misconstrued the words "comprising" in the preamble of claims 1 and 11, and the word "having" in the body of the claims as closed, i.e., excluding other components. In addition, Lampi contends that the court erred in construing the limitation as "an interior sleeve where the fluorescent tube is contained" because the claims themselves state that a fluorescent tube must be mounted in the first interior channel, rather than contained therein. In the alternative, Lampi argues that even if the district court's claim construction is correct, the accused device infringed under the doctrine of equivalents.

We conclude that the district court did not err in deciding that the translucent cover cannot be a part of the first interior channel, although our reasoning differs from that of the district court. Our conclusion is dictated by statements made by Lampi during prosecution of the '227 patent. "Explicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations . . . . By distinguishing the claimed invention over the prior art, an applicant is indicating what the claims do not cover." Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378-79, 49 U.S.P.Q.2d (BNA) 1065, 1069.
In the second office action, the patent examiner rejected several claims under 35 U.S.C. §§ 102(b) and 103 based in part on U.S. Patent No. 4,045,665 (the '665 patent), issued to Williams et al. Williams claims a diffuser attachment for a fluorescent lamp fixture, as demonstrated below.

GET DRAWING SHEET 1 OF 2.

The figures "show a fluorescent lamp fixture A and a diffuser attachment B." '665 patent, col. 3, ll. 56-57. The patent explains,

The fixture body cover 10 acts as a housing for a fluorescent tube and the operative components required therefor. In [figure] 3, this fluorescent tube is generally designated 26 and is maintained in a position depending on from the [body] cover by a pair of conventional end mounted tube mounting and holding members, one of which is generally designated 28 in [figure] 3.

'665 patent, col. 4, ll. 12-18. Figure 3 is a cross-sectional view of the patented device, showing the walls of the translucent cover, denoted with numbers 52, 54, and 60, surrounding the fluorescent tube 26.

In response to the rejection, the patentee argued, "although Williams provides a housing, it does not have two interior channels, one of which houses the fluorescent tube and the second of which primarily houses the electrical means. . . . Williams only has one channel in which the tube and electrical means are housed." Thus, the patentee's position during prosecution was that a "first interior channel in which [the] fluorescent tube is mounted" cannot encompass a translucent cover such as that taught by Williams. Lampi cannot now assert a contrary interpretation. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) (stating that claims may not be construed one way in order to obtain their allowance and a different way against accused infringers). For the same reasons, Lampi is estopped from asserting that Model 7744 infringes the patent under the doctrine of equivalents. For that reason, we conclude that the district court did not err in construing "first interior channel" to exclude the translucent cover of the 7744 device, and in concluding that Model 7744 does not infringe claims 1 and 11, literally or under the doctrine of equivalents.

1. "Channel" and "Fluid Impeding Channel"

Claim 1 of the Chappell patent teaches

An absorbent article comprising:

a. an absorbent; and

b. a channel positioned inward from and along at least a portion of an edge of such absorbent, said channel substantially defining in said absorbent an inner portion and an outer portion, wherein the density of said absorbent in said inner portion is greater than the density of said absorbent in said outer portion.

K-C believes that "channel" means "groove" and "fluid impeding" means "fluid slowing;" Tyco argues that "channel" means one channel. K-C also argues that "defining" means "distinguishing," whereas Tyco claims the term means "completely encircling."

A. The patent is not limited to one channel

The primary bone of contention seems to be the number of channels described in the patent or, alternately, whether "the" channel must completely encircle the napkin. K-C asserts that the invention is not limited to napkins having a single
channel, whereas Tyco believes it is. Tyco's basis for this assertion is the language of the claims themselves: the channel is discussed in the claims exclusively in the singular form as "a" or "the" or "said" channel. It also argues that only a single channel can completely encircle the napkin, and complete encirclement is required for the napkin to fully impede fluid flow.

K-C counters that in a patent the terms "a" or "the" are not dispositive of number and instead are simply inclusive terms. K-C is correct that under Federal Circuit precedent the use of singular articles does not imply anything about the number of the term that follows: "'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims containing the transitional phrase 'comprising.'" Free Motion Fitness, Inc. v. Cybex Int'l Inc., 423 F.3d 1343, 1350 (Fed. Cir. 2005) (quoting KCI Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000)). Thus, the claims' use of the term "an absorbent article comprising . . . a channel" is not dispositive of the number of channels the claim describes.

Yet Tyco is correct that "a channel" can mean only one channel if other aspects of the patent make that limitation clear. Id. Tyco argues that the figures, the specification and the claims themselves speak only of a single channel, which means the inventor "evince[d] a clear intent by the patentee to limit the article to the singular." Id. at 1350. The most glaring problem for Tyco arises in figure 3, which is described as "an alternative embodiment of the present invention" and shows what appear to be two distinct channels -- marked as 22 and 22' -- with one on top and one on the bottom of the napkin. The specification states as follows: "Referring to FIG. 3 the fluid impeding channel 22' is embossed into all three layers of the sanitary napkin 10' so that the channel 22 resides in the body facing surface 13, the garment facing surface 15, and the absorbent 14 of the sanitary napkin 10'." (3:10-14.) 1 Substantial efforts in the briefs and oral argument were made by both sides in an attempt to explain figure 3. Tyco attempts to get around the fact that figure 3 appears to describe two channels by noting that the above-quoted language states that 22' is embossed into "all three layers" of the napkin -- 13 (body facing), 15 (garment facing) and 14 (the absorbent middle). If that is true, then it is physically impossible for there to be two distinct channels. That is, if 22' is embossed into all three layers of the napkin, there is no other part of the napkin into which another channel (22) could be embossed. Under this reading, it would seem that 22' and 22 are not two distinct channels but two parts of the same channel structure: 22' is the "up" facing part in the diagram and 22 faces "down." Both parts constitute the channel that is embossed in all three parts of the napkin. This seems to be how claim 15 treats the channel(s) as well: it claims "the absorbent article of claim 12 wherein said fluid-impeding channel is embossed into said absorbent, said body facing surface and said garment facing surface." (7:38-40.) This "double-channel" aspect is echoed in the specification, which suggests "[t]he channel 22 can be formed by compressing a portion of the body facing surface 13, a portion of the garment facing surface 15 (not shown) or a portion of both the body facing surface 13 and the garment facing surface 15 as seen in FIG. 3." (4:66-67; 5:1-2.)

1 Herein I will simply refer to the column and line numbers of the patent at issue.

1-1107-
precedent, the fact that an aspect of the invention is described only in the singular does not, without more, limit the claims in the way Tyco suggests. Accordingly, I find the invention is not limited to single-channel napkins.

B. **The channel need not have particular fluid-impeding or pooling properties**

Tyco also proposes that the term "channel" is not just an ordinary channel but one that "impedes the flow of fluid and does not cause fluid to pool therein." For this proposition it relies on certain statements in the prosecution history and the specification which discuss the invention's enhancement of flow and conduction of liquid. For instance, the specification teaches that the channel should not be "so wide so as to allow the fluid to gather and pool in the channel." (5:49-50.) This statement, however, merely involves a preferential aspect of the channel size. Tyco also cites various statements in the prosecution history relating to the invention's conduction of fluids. Yet none of the statements can be read to impose a limitation that fluid does not pool ever in the channels. No one disputes that one of the goals of the patent is to teach a product having channels that conduct fluid, but Tyco presents no basis to read a purpose or functioning of the patent into the invention's physical description. Indeed, claims within the patent itself (e.g., claim 11) refer to a "fluid impeding" channel, which means that Tyco's preferred definition of embossed channel would be redundant.

C. **A channel is not a groove**

Citing a dictionary definition, K-C argues in its briefs that a channel is a groove. At argument, however, it indicated it was comfortable with the claim language as written. Rather than substitute a synonym, in my view the preferable approach is to retain the claim's own language where possible, and accordingly I will not redefine "channel" as "groove."

a. "channel for injecting fluids"

The parties have two disputes regarding this claim element. First, the parties dispute whether the "channel" element may be satisfied by the channel inherently provided by the lumen of the guide tube. Gore's proposed construction requires that the "channel for injecting fluids" must be "in addition to the lumen which is inherent in the guide tube" (emphasis added). Gore correctly observes that the only channel described in the specification is an additional channel provided within the wall of the guide tube. However, the limitations of an embodiment are not read into the claims, even if the specification describes only one embodiment. See Phillips, 415 F.3d at 1323. The specification does not suggest that this embodiment is intended to define the scope of the "channel" element or that the physical location of the channel is a significant detail. To the contrary, the only requirement found in the specification is that the channel must allow for the injection of fluids. Therefore, if the central lumen of the guide tube is a "channel" and permits the injection of fluids, it is within the scope of the claim language.

This construction is also confirmed by extrinsic evidence. Perouse cites a 1994 patent that describes administration of liquids through a guide lube lumen to the site of stent placement. (Golds Reply Decl. P 18, Ex. 29.) Though this reference postdates the filing of the patent, it nevertheless provides some support for Perouse's argument that a person of ordinary skill in the art would not have interpreted this claim term to exclude the central lumen from the scope of the "channel" element.

Gore argues that the "channel for injecting fluids" of claim 7 cannot be the central lumen because, under this construction, claim 1 and claim 10 would have the same scope. Cf. Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) ("While we recognize that the doctrine of claim differentiation is not a hard and fast rule of construction, it does create a presumption that each claim in a patent has a different scope."). The Court does not agree. Claim 10 requires a channel "for injecting fluids." Under Perouse's proposed construction, the central lumen is a "channel for injecting fluids" only if it can be used for injecting fluids. The central lumen of a guide tube may or may not be suitable for injection of fluids. While the central lumen of any guide tube falls within the scope of claim 1, only those which allow for the injection of fluids are within the scope of claim 10.
The parties also dispute whether "fluids" should be construed to mean "liquids" or "liquids and gases." The specification refers to a "liquid-tight" stent. (7'87 patent col.2 1.52). However, the patentee used the word "fluids," not "liquids," in claim 10. If the patentee had wanted to claim a channel for injecting liquids, it clearly was capable of doing so without ambiguity. The fact that the patentee used the term "fluids" instead indicates that "fluids" was chosen intentionally and was not intended to be synonymous with "liquids."

Accordingly, the Court construes "channel for injecting fluids," to mean "lengthwise running conduit or passageway (including the central lumen of the guide tube) through which liquids or gases can be forced." GO BACK

673

5. Channel Member 24

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

24 This term relates to the terms "at least partially received" and "guide means" discussed supra.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

Claim 6 of the '456 patent depends on claim 1 and reads: "... wherein said guide means of said positioning ring comprise a channel member disposed on said positioning ring and extending at least partially thereacross." Defendants offer the following construction: "a groove formed on the upper surface of the positioning ring into which a portion of the cutting head assembly fits." (Defs. Br. at 46.) Plaintiff claims this construction is improper and accuse defendants of attempting to limit the channel member to an "L" shaped structure when the specification provides for a "C" shaped structure that includes no "groove." As discussed, supra, in the context of determining the corresponding structure for guide means and guide assembly, the only embodiment disclosed in the specification is a channel member with a toothed track which mates with the propulsion shaft to guide the cutting head assembly in an arcuate path. It is the teeth of this channel (combined with the power transmitted thereto) which form the heart of the guiding process. This is true whether the channel member is "C" shaped or "L" shaped. In terms of the "C" shaped structure, the written description of the '456 patent provides: "Thus, guide means 40 in the form of a generally "C" shaped channel member 42 is comprised by the combined structure of sidewall 36 and toothed track 43." Col. 8, Ins. 1-3. As discussed above, however, the channel member need not be formed on the upper surface of the ring; rather, it is extends along at least one side of positioning ring. The question of whether a portion of the cutting head assembly fits into a groove of the toothed track was also discussed above where this Court construed "at least partially received" to mean: a portion of the cutting head assembly that goes inside the guide means. I therefore conclude that the proper construction for the term channel member is: a groove formed along at least one side of positioning ring into which a portion of the cutting head assembly fits.

Sub-element 3. Channeling structure being adapted to channel the entrained eggs toward the feeding end.

BAI argues that its working platform does not "channel" the egg slurry to the hose portals, it merely "contains" the slurry. Using an extrinsic definition from the Random House Unabridged Dictionary, BAI asserts that "channel" means to "direct toward or into some particular course," which implies an "automated fashion." By employing manual labor to move the slurry through the working platform, BAI contends that its device does not "channel" the slurry in a one-step procedure like Sanders' device, which does not require manual labor.

Claim 8 only requires the channeling structure to "receive water and entrained shrimp eggs at the channel receiving end and to channel the entrained eggs toward the feeding end." Col. 11, lines 17-20 (0'62 patent). BAI argues for limitations from the specification to be read inappropriately into the claims where the specification is providing enabling description of possible embodiments of the invention. The specification also supports a passive channeling effect of the structure. The figures in the
specification disclose the channel structure without any reference to automation or a one-step procedure. The water and entrained eggs are collected at the leading edge of the channeling structure where they fall or move into the funnel cavity. They are then drawn into the rearward feeding end where the suction holes are located. Col. 6, lines 35-39 ('062 patent). "Means are provided for maintaining the channeling structure approximately at the surface of the water … to direct brine shrimp eggs toward the narrow feeding end of the channel." Col. 2, lines 57-61 ('062 patent). The "channeling" effect is derived from the channeling structure's bottom surface, three side walls and the relative movement of the entrained eggs with respect to the channeling structure. The court declines to impose any requirement of an ambiguous one-step procedure or automated channeling structure to claim 8's channeling structure.

BAI argues an interpretation of a channeling structure which requires the structure to 1) receive water and eggs in a controlled manner, Col. 3, lines 38-40 ('062 patent); 2) allow the slurry to fall by gravitation into an inlet port, Col. 4, lines 8-9 ('062 patent); and 3) act as a concentrating funnel. Col. 5, line 13; col. 3, lines 34-35 ('062 patent). This court disagrees that these limitations be imposed on claim 8.

BAI argues that its working platform cannot receive a slurry mixture in a controlled manner and that a slurry cannot fall by gravitation to the inlet port because it has a "virtually flat bottom" and hose ports which are only 1/2 inch lower than the front of the working platform. Col. 3, lines 38-40; Col. 4, lines 8-9 ('062 patent).- Claim 8 imposes no such limitations. Preferred embodiments appearing in a specification will not be read into the claims when the claim language is broader than the specification. Electro Medical Systems v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054, 32 U.S.P.Q.2D (BNA) 1017, 1021 (Fed. Cir. 1994). While the claims are interpreted in light of the specification, not everything expressed in the specification must be read into all the claims. SRI International v. Matsushita Electric Corporation of America, 775 F.2d 1107, 1121, 227 U.S.P.Q. 577, 585 (Fed. Cir. 1985) This court declines to read language such as "controlled manner" and slurry "falling by gravity" in the specification as limitations on the claims.

Furthermore, these arguments appear to be disputes about the degree of control or ability of the slurry to fall by gravitation to the inlet ports. BAI's working platform is not flat, its hose ports are 1/2 inch lower than the front of the working platform. There is a descending slope from the front of the working platform to the inlet ports. Therefore, BAI argues that it is "virtually flat." In viewing the BAI devices contained in tabs 8, 9 and 10 of BAI's Appendix, it appears to the court that the hose ports are not located 1/2 inch below the front surface of the platform, but that the very top of the opening of each hose port is 1/2 below the platform surface. The descending surface appears more dramatic than BAI has represented and is obviously not flat. In any event, the court finds the shape of the BAI's working platform is "adapted to channel the entrained eggs toward the feeding end," as claimed in claim 8.

Claim 8 does not require the channeling structure to act as a concentrating funnel. The specification states that a funnel may be "anything that is capable of receiving a slurry mixture of salt water and eggs in a controlled manner." Col. 3, lines 37-40 ('062 patent). Claim 8 does not mention a concentrating funnel, therefore, no "concentrating" limitation will be read into claim 8's channeling structure. Even if the court interpreted the channeling structure and concentrating funnel as essentially the same structure, however, claim 8's language, "being adapted to receive water and entrained eggs … and to channel the entrained eggs toward the feeding end," would not be limited by the specification to a device that concentrates the slurry.

E. "Channels"

Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs contend that "channels" mean "grooves or furrows," while Gore claims that "channels" refers to "partial thickness openings."

Based upon the specifications of the '418 patent, a series of cuts or channels results in the individual villi and surface irregularity on the material. In a corresponding illustration, it is clear that the cuts or channels create grooves on the
material's surface. See U.S. Patent No. 6,921,418, at Fig. 12. The illustration contained within the specifications of the '418 patent shows that the inventor meant to give the term "channels" its commonly understood meaning: "grooves or furrows." Because nothing in the specifications indicates that the inventor intended to give the term "channels" a meaning other than its commonly understood meaning, the Court determines that "channels" means "grooves or furrows."

XVI. "Charger"

The Court next turns to the term "charger" from claims 9 and 10 of the '925 patent.

A. The Parties' Proposed Constructions

Black & Decker asserts that the term "charger" simply means "charger" and notes that it adopts the plain and ordinary meaning. Bosch argues that the Court should construe the term as "a device that receives the DC output voltage from the first power source and transforms that DC output voltage to a voltage equal to an input voltage of the battery to charge the battery."

B. The Parties' Arguments

Claim 9 of the '925 patent requires a "charger to charge said secondary rechargeable direct current power source from said first power source." Black & Decker contends that "charger" should simply have its plain and ordinary meaning, which Webster's New World College Dictionary, 4th Ed. (1999) provides as "an apparatus used to charge storage batteries." Bosch agrees that the "charger" charges batteries, but seeks to include additional limitations. Bosch, however, fails to point to any portion of the intrinsic record that requires a limitation on the term "charger" beyond its plain and ordinary meaning. The language of the claim itself plainly sets forth the scope of the term "charger" -- an apparatus that charges the secondary rechargeable direct current power source from the first power source. Adopting Bosch's proposed construction would render claim 9 of the '925 patent nonsensical and incorporate limitations into the claim that are not present. Accordingly, the Court adopts Black & Decker's proposed construction of "charger" which is "'charger,' having its plain and ordinary meaning, which is 'an apparatus used to charge stored batteries.'"

n16 The Court provides the construction in this format because the surrounding claim language of the term "charger" in claim 9 so thoroughly defines that term, that any proposed construction other than the term "charger," itself, would render the claim redundant when the factfinder substituted the Court's construction into the claim.

--- Footnotes ---

n16 The Court provides the construction in this format because the surrounding claim language of the term "charger" in claim 9 so thoroughly defines that term, that any proposed construction other than the term "charger," itself, would render the claim redundant when the factfinder substituted the Court's construction into the claim.

--- End Footnotes ---

b. "Chassis"

Both parties request construction of the term "chassis." This term appears in the patentee's claim that the invention comprises "a plant support frame mounted on the chassis." It also appears in the claim terms that describe the head articulation and tail articulation means as connecting the lateral conveyors such that, when folded for transport, the conveyors "do[] not project laterally beyond the chassis."

The defendant requests that the Court construe "chassis" to mean "a pair of longitudinal beams." The plaintiff opposes this construction, and requests that the Court construe the term to mean "a structure onto which other elements are attached or mounted." The plaintiff urges that this term should be additionally construed to include, with respect to a tire-mounted screener, "the tire or wheel assembly (also known as a bogie) (including the tires), the support jack legs, the tire mud guards,
the laterally extending fixed platforms, and the axles." With respect to a track-mounted screener, the plaintiff requests the term be construed to include the "two tracks, the driven, guide and idler wheels, the frame, the roll-in bogie (including its tires, frames and mudguards), and the support jack legs."

The defendants support their narrower construction of chassis with language from the patent specification that states that "[t]he plant 1 comprises a chassis 2 having a pair of longitudinal beams mounted on wheels 3(a) and supported on jack legs 3(b)." (618 patent, col. 3, lns. 46-48.) The defendants read this to mean that the "chassis", identified with structure number 2, is separate from the "wheels" and "jack legs", identified with structure numbers 3(a) and 3(b), as well as the "wheel arches", identified elsewhere in the specification by structure number 33.

Further, the defendants point out that the chassis is identified in the patent's figures with a single lead line pointing to what appear to be beams running the length of the plant. See Figure 4 (above), structure 2. The defendants assert that this is especially significant in light of 37 C.F.R. § 1.84, the provision of the C.F.R. that regulates the figures included in a patent application. Section 1.84 provides in pertinent part:

(q) Lead lines. Lead lines are those lines between the reference characters and the details referred to. . . . They must originate in the immediate proximity of the reference character and extend to the feature indicated. . . .

(r) Arrows. Arrows may be used at the ends of the lines, provided that their meaning is clear, as follows:

(1) On a lead line, a freestanding arrow to indicate the entire section towards which it points;

The defendants contrast structure 2, the chassis, with structure 1, the plant itself. While structure 1 is identified with an arrow to indicate that multiple elements are incorporated into it, structure 2 is identified with only a lead line, indicating, in the defendants' view, the incorporation of only the longitudinal beams. See, Figure 4, above.

The plaintiff contends that, notwithstanding the use of different structure numbers to identify the chassis and the wheels, the patent commonly refers to a "wheelmounted chassis," indicating that the device's wheels are part of the chassis itself. Moreover, the plaintiff contends that, notwithstanding the patentee's use of lead lines and arrows, the drawings in the patent application show that the conveyors, when folded for transport, project well beyond the "longitudinal beams." According to the plaintiff, the chassis must comprise more than the longitudinal beams identified by the defendants because the patent states that the folded conveyor "does not project laterally beyond the chassis." The plaintiff argues that this can be seen in the depiction of the lateral conveyors, 20, in Figure 4 above. The plaintiff also cites to Figures 2 and 5, below, showing the preferred embodiment of the invention in operative and transport modes, respectively:

(SEE FIG. 2 IN ORIGINAL)

(SEE FIG. 5 IN ORIGINAL)

While Figure 2 identifies structure 2, the chassis, by pointing to the end of the longitudinal beams identified by the defendant, Figure 5 shows the collapsed conveyors extending well past these longitudinal beams to the very edge of the wheel arches, structure 33.

If possible, the Court is obligated to construed a patent so that the preferred embodiment is incorporated into the patent. On-Line Techs, 386 F.3d at 1138 ("a claim interpretation that excludes a preferred embodiment from the scope of the claim is rarely, if ever, correct" (internal quotations and citations omitted)). Here, the patent's figures show that, in the preferred embodiment, the device's conveyors extend beyond the longitudinal beams when folded for transport. According to this cannon, the Court must construe the chassis as comprising more than the longitudinal beams identified by the defendant.

Nevertheless, the defendants cite to Hockerson-Halberstadt, Inc. v. Avia Group Intern., Inc., 222 F.3d 951, 956 (Fed. Cir. 2000) for the proposition that, because the diagrams are apparently not drawn to scale, they cannot be used to interpret the relative dimensions of the invention. However, Hockerson stands only for the proposition that a court should not infer "precise proportions" and "particular sizes" from un-scaled patent drawings. Id. at 957. That is not what the Court is doing here. Figures 5 and 4 both plainly show the collapsed conveyor arms extending to the very extremity of the wheel arches. This is not a "precise proportion" being shown, but rather an important component of the design. Thus, the Court finds that
"chassis" must necessarily include not just the "longitudinal beams," but also the wheels and wheel arches of the invention in its preferred embodiment.

Nonetheless, there remains the more difficult question of how "chassis" should be defined more generally. The Court is wary of explicitly defining "chassis" to incorporate structures that are found only in the preferred embodiment of the invention. For similar reasons, the Court is also reluctant to explicitly construe "chassis" to include or exclude parts of the "tracks" on a "track-mounted screener." Unfortunately, the patent itself offers little in the way of generic description of a chassis, except to state that the "plant support frame" is mounted on it.

Finding the intrinsic evidence wanting, the Court finds most helpful the defendant Powerscreen's Spare Parts Listings for its mobile screeners. In its listing, Powerscreen uses the terms "track chassis" and a "wheel chassis" to refer to the entire assembly of supports, wheels, tracks, and other related parts on which would rest the other operative structures of the screening plant. (Decl. of Michael C. Stewart, Jun. 30, 2009, Ex. 29, PS 4511, 13.; Decl. of Steven A. Whyte, Jun. 29, 2009, P 18.) In the Court's view, this is evidence that "chassis", as used by one skilled in the art, refers to the entire assembly that rests beneath the functional parts of the screener. The evidence is particularly probative because, unlike the plaintiff, Powerscreen has no vested interest in using "chassis" in this manner. The Court finds this extrinsic evidence to be consistent with the intrinsic evidence in the patent itself, particularly the requirement that the chassis incorporate the wheels and the wheel arches in the preferred embodiment. The Court therefore construes the term "chassis" to mean "the entire assembly of parts that rest beneath the plant support frame."

D. As to the Construction of the Claim Term "Chassis"

In Metso I, the Court construed the claim term "chassis" to mean "the entire assembly of parts that rest beneath the plant support frame." Id. at 321. The defendants now challenge this construction, and advance a more limited construction of "chassis" that does not comprise, among other things, the wheels, wheel arches, tires, or support jacks that rest beneath the plant support frame.

The defendants challenge the Court's ruling based in large part on the Court's use of defendant Powerscreen's spare parts catalogue in construing the term "chassis." As described in Metso I, the Court construed the term "chassis" in part based on a Powerscreen spare parts catalogue that appeared to identify as a "chassis" the entire assembly of parts resting beneath the plant support frame of a screener. Id. at 321. The Court held that this evidence was consistent with the intrinsic evidence of the meaning of "chassis"—particularly the necessity that the term include the wheels and wheel arches—and therefore construed the term as described above. Id.

The defendants maintain that the spare parts catalogue on which the Court relied was not prepared contemporaneously with the drafting of the '618 patent, and that the catalogue is thus not an appropriate source for construing the term "chassis". Generally, a claim term has the meaning ascribed to it by those skilled in the art "as of the effective filing date of the patent application." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005). The defendants interpret this rule to suggest that the Court should not consider evidence of the meaning of a claim term--such as the Powerscreen spare parts manual--that post-dates the drafting of that term.

The Court finds that the defendants' arguments do not merit any adjustment to the Court's construction of the term "chassis." First, assuming that Powerscreen's spare parts manual was drafted after the '618 patent was prepared, the Court nevertheless finds that the manual provides circumstantial evidence of the meaning of "chassis" at the time the patent was drafted. While it is possible that the understanding of the term "chassis" evolved after the '618 patent was prepared, there is no evidence to support that contention. Rather, the Court finds it more likely that the Powerscreen spare parts manual reflected the same understanding of chassis that existed at the time the '618 patent was drafted, even if the manual itself was prepared later. Moreover, even without considering this extrinsic evidence, the Court finds that the construction of the term "chassis" as set forth in Metso I is correct.

The Court has reviewed the defendants' other arguments with respect to this term and found them to be without merit. The Court therefore denies the defendants' motion for reconsideration of the construction of the claim term "chassis."
6. "a chassis comprising a front panel"

This term appears in the '408 patent claims 1 and 9. Rackable contends that "a chassis comprising a front panel" means a "frame or housing for the general purpose computer including the main board and including a front panel providing access as claimed." Supermicro asserts that "a chassis comprising a front panel" means "a frame or housing including a front panel."

The essence of the dispute is whether the "chassis" is for a general purpose computer, or whether it is simply any frame or housing. Again, Rackable argues for the narrower, more specific construction, and Supermicro the broad one.

Rackable argues that the claims themselves refer to "the computer" and the various components of the computer, supporting its construction. It further asserts that the specification and the "summary of the invention" explicitly state that the chassis is for a general purpose computer, and not simply any frame or housing. Additionally, Rackable argues that the embodiments support its construction, and demonstrate a chassis built up with certain components, including a main board.

In response, Supermicro argues that Rackable's construction is too limiting. Even if it were a chassis for a computer, Supermicro notes that contrary to Rackable's construction, it should not be construed only as a frame or housing for a "general purpose computer" or server. It argues that Rackable is attempting to import an inappropriate limitation into the term.

The court indicated at the hearing that Rackable's reference to "computer" in its construction of the term was redundant, given the fact that the broader context of the claim is the computer itself. In response to the court's inquiries, Rackable indicated agreement with Supermicro's construction. Because claims must be construed in a manner that avoids such redundancies, the court adopts Supermicro's definition, and construes the term "a chassis comprising a front panel" as a frame or housing including a front panel.

GO BACK

9. Checkerboard Pattern

The parties are in substantial agreement concerning the phase "checkerboard pattern": "parallel vertical and horizontal impressions and crossing at right angles which results in a four sided impression." But defendants contend the phrase "approximately equidistant" should be added to the definition. This argument is based on the plain and ordinary meaning of "checkerboard pattern" and on defendants' expert's testimony that such a shape is square. Plaintiffs argue that adding "approximately equidistant" improperly narrows the construction in that a checkerboard pattern is not limited to perfect squares. Because of the second-stretch capacity of the netting arrangement, the indentations may not appear on the meat products as perfect squares but the basic shape of the netting arrangement is an approximate square. The plain and ordinary meaning of the term "checkerboard pattern" includes "approximately equidistant".

The Court construes "checkerboard pattern" as: "parallel vertical and horizontal impressions approximately equidistant and crossing at right angles which result in a four-sided impression."

GO BACK

(g) "a plurality of chocks mounted to and extending downward from said primary frame members for contacting each of said cantilever sections of said arms and for transferring load from said primary frame members to said arms during dumping operations."
Boler's proposed interpretation relies heavily on its contention that the term "dumping operations" is a term of limitation. As discussed above, the court disagrees with Boler's contention. Boler also asserts that Watson limited the scope of claim 1 to "chocks" by replacing the term "chock means" with "a plurality of chocks" in element (g) in response to the examiner's initial rejection of Claim 1. Boler further argues that because Watson uses the term "chock" interchangeably with the term "saddle" on two occasions in the specification when describing a structure that is mounted to the frame members, the term "chock" should be defined as a "saddle-like structure." In contrast, Boler uses the dictionary definition of the term to define a "chock" as a block or wedge. The court concludes that simply because the preferred embodiment set forth in the specification uses the term chock and saddle interchangeably does not mean that a saddle-like structure is the only embodiment of the apparatus. Laitram Corp., 863 F.2d at 865. Accordingly, the court construes this element as "more than one block or wedge placed under a vehicular frame to keep it from moving, mounted on or attached to and extending below the primary vehicular framework members, adapted for touching the cantilever section of the arms, for stabilizing a vehicle by shifting or transferring the weight that a vehicle bears from the vehicular framework members to the arms."

To decide this appeal, this court must consider independent claims 22 and 30 and dependent claims 23, 26-29, and 31. The language of claims 22 and 30 contains no differences relevant to this appeal. For brevity, therefore, this court focuses its analysis on claim 22:

22. In a tool positioning system that is implemented as part of a workpiece processing system in which the workpieces are electronic circuit boards, the tool positioning system carrying out a method for cutting a predetermined hole pattern in at least first and second substantially identical circuit boards each having at least a first conductor layer, a dielectric layer, and a second conductor layer, comprising:

- generating at least first and second laser beams having respective first and second wavelengths;
- mounting the circuit boards on a slow positioner stage that effects a large range of relative movement between the laser beams and the circuit boards;
- providing at least first and second fast positioner stages that are coupled to the slow positioner stage to effect small ranges of relative movement between the laser beams and associated ones of the circuit boards; and
- coordinating the large and small ranges of relative movement such that the first laser beam cuts the predetermined hole pattern in the first conductor layer of the first circuit board while the second laser beam cuts the predetermined hole pattern in the dielectric layer of the second circuit board.

'960 patent, col. 20, ll. 15-37 (emphases added).

The district court construed the emphasized language to require simultaneous processing of "multiple, separated workpieces [but to] not claim a system for processing a single workpiece." Thus, the district court determined that the claim required separate "circuit boards," not a single workpiece that could be separated after processing. In that determination, the district court impermissibly limited claim scope. Properly construed, the claims require processing of multiple circuit boards without regard to whether those boards are separated or not.

To determine the meaning of "circuit boards," this court begins with the claim language. The preamble defines "circuit boards" as "at least first and second substantially identical circuit boards each having at least a first conductor layer, a dielectric layer, and a second conductor layer." References throughout the rest of the claim to "circuit boards" rely upon and derive antecedent basis from this preamble language. Therefore, this preamble definition limits the term "circuit boards" throughout the claim. Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620, 34 USPQ2d 1816, 1820 (Fed. Cir. 1995) ("[A] claim preamble has the import that the claim as a whole suggests for it."). This preamble definition narrows the meaning of "circuit boards" to at least two substantially identical boards. Nonetheless it does not state or suggest that those circuit boards must be separated.
The specification also supports the interpretation that the term "circuit boards" does not require separated workpieces: "Multilayer ECBs are typically manufactured by registering, stacking together, laminating, and pressing multiple 0.05-0.08 millimeter thick circuit board layers. Each layer typically contains a different interconnection pad and conductor pattern, which after processing constitutes a complex electrical component mounting and interconnection assembly." ‘960 patent, col. 14, l. 63 to col. 15, l. 2 (emphasis added). As the emphasized language shows, a workpiece becomes a circuit board following processing. Thus, a single workpiece could embrace multiple circuit boards. Or, in other words, the "circuit boards" need not be separate during processing.

This comports with common understanding in the field of electrical component fabrication. For example, Dr. Mark A. Shannon, expert for ESI, offered his uncontested declaration that multiple ECBs may be manufactured from a larger board or panel. Similarly, integrated circuits, such as computer processors, typically are produced many at a time from a single silicon wafer. Even before separation of the workpiece panel or wafer into separate circuit boards, design documents and software identify each ECB or integrated circuit individually, and govern their manufacture. For this same reason, a manufacturer does not separate a panel or wafer arbitrarily after processing. Having established an ECB's identity through design, the manufacturer may not ignore that identity when separating the panel without destroying the ECB.

GSI Lumonics contends, however, that the preamble and specification modify this customary meaning of ECB in this field of art to require physical separateness. Specifically, GSI Lumonics argues that the preamble defines ECBs as workpieces, ‘960 patent, col. 20, ll. 16-17, and that the preferred embodiment of the patent shows physically separate workpieces. ‘960 patent, Fig. 6.

To the contrary, neither the ordinary meaning of workpiece nor the inventor's preferred embodiment limits the claim scope. More particularly, even assuming that the preamble defines ECB as a workpiece, see Kropa v. Robie, 38 C.C.P.A. 858, 187 F.2d 150, 152, 88 USPQ 478, 480-81 (CCPA 1951) (Stating the preamble does not limit the claims unless it is "necessary to give life meaning and vitality" to the claims.), that definition imposes no separateness requirement. Workpiece is a broad term that means generally "the object which is worked on with a machine or tool." Oxford English Dictionary (2d ed. 1989); see also Robert C. Faber, Landsis on Mechanics of Patent Claim Drafting App. E-23 (4th ed. 2000) (Defining workpiece as "the thing or article operated on, altered, changed or reduced by a claimed apparatus or method."). Physical separateness, or lack thereof, simply does not enter into the ordinary meaning of workpiece. The term "workpiece" makes the ECBs the objects of work, but says nothing about physical separateness. An object may be worked upon irrespective of whether it is physically separate. The patentee has not altered this ordinary meaning. See Transclean Corp. v. Bridgewood Servs., Inc., 290 F.3d 1364, 1381, 62 USPQ2d 1865, 1877 (Fed. Cir. 2002) ("Because the patentee has not chosen to be his own lexicographer in this instance, 'resilient' should carry its ordinary meaning in the art.").

Figure 6 does depict a preferred embodiment that processes physically separate workpieces. The specification also identifies separate mounting of physically separate workpieces as one among other problems that the invention of the ‘960 patent is well suited to cure. See, e.g., ‘960 patent, col. 4, ll. 34-36, col. 13, ll. 27-28 (stating the invention "compensates for . . . workpiece placement, offset, rotation, and dimensional variations among the multiple workpieces" that is "introduced by mounting position variations among [the] workpieces."). Nowhere, however, does the specification teach that physical separateness is a required limitation of the invention. Nor does the specification teach that separate workpieces are the only source of the problems that the invention cures. The specification discusses other sources of misalignment problems. The specification simply does not narrow the claim language to require separate workpieces or circuit boards. In the context of the entire specification, the depiction of separate workpieces in Figure 6 does not limit the claim language. Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347, 49 USPQ2d 1199, 1203 (Fed. Cir. 1998) ("[A] court may not import limitations from the written description into the claims."); Electro Med. Sys. S.A. v. Cooper Life Sci., 34 F.3d 1048, 1054, 32 USPQ2d 1017, 1021 (Fed. Cir. 1994) ("Particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments."); SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121, 227 USPQ 577, 585, n.14 (Fed. Cir. 1985) ("Specifications teach. Claims claim.").

The prosecution history of the ‘960 patent is also not a source of a separateness requirement. The examiner rejected claims 22 and 30 as obvious over U.S. Patent No. 5,262,707 (Okazaki) in view of U.S. Patent No. 5,425,275 (Ogawa). In response, the inventors amended their claims. Apart from those amendments, they explained that the "independent claims repeatedly recite multiple elements," including "circuit boards, lasers, and laser wavelengths." The inventors then argued that neither Okazaki nor Ogawa "describe or suggest any of the multiple elements and are completely silent regarding cutting holes in circuit boards, using laser beams as a hole cutting tool, and employing multiple laser wavelengths." Claims 22 and 30
clearly require multiple circuit boards in view of their plural language and this prosecution history. The claimed references
to multiple circuit boards and other components, however, does not require separate workpieces or separated circuit boards
at the time of processing. A single workpiece can encompass multiple circuit boards. Or, in other words, the claimed system
can produce multiple circuit boards by processing a single panel or wafer that later separates into the multiple ECBs.

The ordinary meaning of "multiple" and the specification's treatment of that term show that multiplicity and separateness
are not synonymous. Specifically, to be "multiple" is to "consist[ ] of or [be] characterized by many parts, elements, or
individual components." Oxford English Dictionary (2d ed. 1989). The meaning of "separate" is narrower: "Parted, divided,
or withdrawn from others; disjoined, disconnected, detached, set or kept apart." Id. The human body, for example,
comprises multiple individual cells. Those cells remain multiple though not separated or detached from other cells within
the body. Similarly, the specification teaches that the invention uses multiple lasers to process multiple workpieces. The
language of multiplicity does not require separateness. In sum, claims 22 and 30 do not require physically separate circuit
boards.

C. Construing and Applying the Claim Terms

Each of the independent claims includes directly or by incorporation a description of the "axially spaced circular ribs" on
the crimp sleeves. (See, e.g., Glazer Aff. Ex. A). The claims also indicate that the circular ribs, or at least some of them, are
"deformable into a hexagonal configuration." (See, e.g., id.). For example, Claim 1 of the '106 patent provides as follows:

1. An end connector for connecting a coaxial cable to a port, said cable being of the type having an electrical inner
conductor surrounded by and spaced inwardly from an electrical outer conductor, with a dielectric insulator interposed
between said inner and outer conductors, and with a dielectric jacket surrounding the outer conductor, said end connector
comprising:

....

a tubular body supported on the front end of said post at a location adjacent to said fastener means, said body having a
cylindrical second sleeve surrounding and spaced radially from said first sleeve to define an annular chamber there between,
said second sleeve having an open rear end leading to said annular chamber, said second sleeve having discrete axially
spaced circular grooves in its interior surface defining a plurality of discrete axially spaced circular serrations and having
grooves in its exterior surface defining a plurality of axially spaced circular ribs,

....

said ribs being deformable into a hexagonal configuration with an accompanying inward twisting deformation of said
circular serrations toward said first sleeve and indented mechanical engagement with said jacket.

(Id.) (emphasis added). "Circular" is not defined in the specification or elsewhere in the patent, and thus that term must be
"given [its] ordinary and accustomed meaning." Nike, 43 F.3d at 646.

Cabel-Con argues that "circular," both in common usage and as used in Mezzalingua's claims, means round or having the
form of a circle. Cabel-Con cites Webster's New Collegiate Dictionary for this definition. In addition, Cabel-Con notes that
the claim description states that the circular ribs are deformable to a hexagonal configuration, which suggests that circular
does not mean hexagonal. Cabel-Con claims also that the specifications refer to "diameters," and diameter is a quintessential
feature of a circle. Cabel-Con also notes that the '106 patent inventor has conceded that Figure 5 of the '106 patent defines a
perfect or reasonably perfect circle before the sleeves are crimped.

Mezzalingua, on the other hand, relies on Webster's Third New International Dictionary, which defines "circular" as "having
the exact or approximate form or outline of a circle: Round." Mezzalingua argues that an object such as a "circular saw" is
not perfectly circular, but rather approximates the form of a circle. Mezzalingua also contends that Cabel-Con cannot use
the illustration in Figure 5 as evidence of meaning, because that illustration is just a preferred embodiment. See Transmatic,
53 F.3d at 1277.

As a preliminary point, I reject Cabel-Con's "diameter" argument. The fact that both Cabel-Con's and Mezzalingua's devices have specified diameters is largely irrelevant to the meaning of "circular ribs". Clearly, Cabel-Con cannot effectively argue that Mezzalingua's designation of a diameter for its device means that its device is shaped in a perfect circle, and at the same time contend that its device, which also has a diameter in its specifications, is not in a circular shape. Moreover, neither party seems to grasp the fact that diameter is a measurement applicable to many geometric shapes besides circles. See Webster's Third New International Dictionary of the English Language Unabridged 623 (1981) (diameter is "a chord passing through the center of a figure or body (as a circle, conic section, sphere, cube") (emphasis added). 1

--- Footnotes ---
1 For similar reasons, I reject Mezzalingua's alternative argument that because Cabel-Con's devices have diameters, they literally infringe on Mezzalingua's device. I also reject plaintiff's argument that Cabel-Con's description of its rib as a ring means it is circular. The definition of "ring" include circular, but is not limited to circular. Websters Third New International Dictionary 1958 (1993).
--- End Footnotes ---

Next, I must construe the meaning of "circular" in Mezzalingua's claims. One definition of "circular", that to which Mezzalingua refers, is "having the exact or approximate form or outline of a circle." Webster's Third New International Dictionary of the English Language Unabridged 409. Another dictionary defines "circular" as "in the form of a circle; round; as, the sun appears to be circular." Webster's New Universal Unabridged Dictionary 368 (2d ed. 1983). Cabel-Con relies on a definition of "circular" as "having the form of a circle: ROUND [or] moving in or describing a circle or spiral." Webster's New Collegiate Dictionary 200 (1979). Another common dictionary defines "circular" as "of or pertaining to a circle" and "having the form of a circle; round." The Random House College Dictionary 244 (rev. ed. 1984).

Although it is apparent from the various definitions that an object need not be in the exact form of a circle to be circular, it also is clear that an object is not circular just because it has a continuous edge around it. For example, a square, though the four sides are drawn around it, cannot be circular, at least not as "circular" is commonly understood. Mezzalingua appears to contest this observation, noting that "things are commonly called circular when their peripheral edges do not form exact circles." Pl.'s Opp. Def's Mot. Part. Summ. J. at 6. Citing a prominent dictionary's use of "exact or approximate form or outline of a circle" in its definition of circular, Mezzalingua seems to place great reliance on the word "approximately." However, Mezzalingua's specifications strongly support a reading of "circular" that is far from approximate.

As used in Mezzalingua's claims, "circular" must refer to a shape perceivable to the ordinary eye as a circle, and not merely any shape which proceeds around an empty center. But see Monroe Eng'g Prods., Inc. v. J.W. Winco, Inc., 915 F. Supp. 901, 906 (E.D. Mich. 1996) (holding that it could not conclude as a matter of law that an octagonally-shaped coupling element did not literally infringe a patent describing a coupling element with an "annular configuration," because "annular" meant in the form of a ring, or circular in shape, though not necessarily forming a perfect circle, and a question of material fact existed as to whether an equilaterally-sided octagon product was in the form of a ring). As Cabel-Con notes, Figure 5 to the '106 patent and the description that accompanies it depict the ribs as perfect circles deformable into hexagons. The ribs clearly are perfectly circular in Figure 1 as well. While I am wary not to rely on the preferred embodiments that are frequently depicted in specifications, see Transmatic, 53 F.3d at 1277, there is little question from the figures and the language of the claims that the ribs are in the shape of perfect circles. These products are designed and presumably described by scientists and engineers. We must assume that they use mathematical and geometric descriptors carefully and intentionally. To argue that a hexagonal ring is a circular pattern plays loose with geometry. While a hexagon may be closer to resembling a circle than a pentagon or a square, to say that it literally is a circular shape would reduce the world of equally-sided polygons to circles. This is not an appropriate result, nor one fair to geometry and the English language.

Furthermore, I am persuaded by the fact that any other reading would render the distinctions in the claim itself nonexistent. If a hexagon is a circular pattern for the purposes of the claim, then deforming the circular pattern into a hexagon would be redundant.

Applying this definition to Cabel-Con's products, a reasonable finder of fact could not find literal patent infringement.
Cabel-Con's products have end connectors with external ribs, much like Mezzalingua's products, but Cabel-Con's ribs are essentially hexagonal prior to crimping, then more circular once crimped. The crimp sleeve ribs on Mezzalingua's products are circular prior to crimping, then more or less hexagonal after crimping. Regardless of how these distinctions would fare under the doctrine of equivalents, they are enough as a matter of law to defeat literal infringement.

We also find that the trial court properly construed "circular member," "stent member," "ring," and "endovascular support member" to have the same meaning as "stent." As the trial court found, none of these terms are present in the specifications. Where they are used in the claims, however, they are employed in a manner analogous to and interchangeable with the term "stent." See, e.g., '331 patent, col. 8, ll. 6-21; '278 patent, col. 6, ll. 53-63; '382 patent, col. 6, ll. 45-57; '053 patent, col. 7, ll. 10-27. Because the claims establish that Medtronic used the challenged terms synonymously with "stent," the trial court's construction is correct.

b. The groove

First, Dethmers contends that its EXCALI-BAR tow bar does not have a groove that "circularly surrounds" the inner tube as required by the '166 patent. The pertinent limitation of the '166 patent is the following:

What is claimed is as follows:

1. Arrestably Lockable Telescoping Tow-Bar Assembly comprising:

(A) an inner-tube having an outer-surface concentrically surrounding a directionally longitudinally extending central-
Thus, the EXCALI-BAR, which has at least two grooves that together define no more than a 240-degree arc of a circle
circularly surrounding said central-axis and located in a plane perpendicular to said central-axis[.] Patent No. '166, claim 1 (emphasis added). Dethmers contends that the proper interpretation of this limitation is that "circularly surrounding" means that the groove forms a complete 360-degree circle around the inner tube. However, on Dethmers's EXCALI-BAR, the grooves (plural) only partially encircle the inner bar. See "exploded" view, page 27 (at handwritten "A"). Automatic counters that a proper interpretation of the phrase "inward-groove circularly surrounding said central-axis" in claim 1 of the '166 patent is a groove that does not intersect the central axis, but defines the boundaries of a circle, either continguously or non-continguously, around the central axis. Automatic contends that the grooves on the EXCALI-BAR literally meet this limitation, because the grooves do define the boundaries of a circle.

i. Claim interpretation and literal infringement. As explained above, "proper claim construction requires an examination of the claim language, the written description, and, if relevant, the prosecution history," see Comark Communications, Inc., 156 F.3d at 1186, 1998 U.S. App. LEXIS 22117, *10, 1998 WL 614579 at *4, and "the appropriate starting point . . . is always with the language of the asserted claim itself." See id. The claim language here leaves the court in no doubt that what was actually claimed was a single continuous groove describing a complete circle around the inner tube. "Circularly," in the first instance, suggests a continuous, complete circle, because the term "circular" means "having the form of a circle: round," or "describing a circle or spiral." See, e.g., WEBSTER'S COLLEGIATE DICTIONARY (10th ed.). Although the parties have concentrated on the meaning of "circularly," each finding support in dictionary definitions for its interpretation, they have not apparently considered the effect of "circularly surrounding," which makes plain that the groove, in the form of a circle, is "to enclose on all sides" the inner tube. See, e.g., WEBSTER'S COLLEGIATE DICTIONARY (10th ed.). "Claims terms are . . . to be interpreted so as to give the terms their ordinary meaning, absent some clear special definition." Enercon GmbH, 151 F.3d at 1384, 1998 U.S. App. LEXIS 18752, *24, 1998 WL 469892 at *9 (emphasis added); Vitrronics, 90 F.3d at 1582; Athletic Alternatives, 73 F.3d at 1578. Automatic did not give "some clear special definition" to "circularly surrounding," such as defining it to mean a groove or series of grooves that describe or define a complete or partial circle about the central-axis of the inner tube. Although Automatic asserts that it is improper to add qualifying terminology to a claim that is not contained in the claim itself, citing Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 950 (Fed. Cir. 1993), when arguing that Dethmers reads the limitation to be "completely circularly surrounding" the inner tube, it is equally improper for Automatic to argue that the absence of a qualifier means that the limitation meant "completely and partially circularly surrounding." Addition of "completely" would simply be redundant; it is addition of the further qualifier "and partially" that is improper.

Nor does use of the language "at least one . . . inward-groove" cover a series of grooves that together define a circle about the inner tube. Rather, it is clear that "at least one" means that each of the grooves must have all of the characteristics that follow, i.e., each must be a single continuous groove describing a complete circle around the inner tube. In other words, there could be a series of such grooves spaced along the inner tube to provide for various locking positions for various extensions of the telescoping locking arms.

Looking briefly at the written description, see Comark Communications, Inc., 156 F.3d at 1186, 1998 U.S. App. LEXIS 22117, *10, 1998 WL 614579 at *4 ("Proper claim construction requires an examination of the claim language, the written description, and, if relevant, the prosecution history"); emphasis added), the court notes that "circularly surrounding" is also "completely circularly surrounding," such as defining it to mean a groove or series of grooves that describe or define a complete or partial circle about the central-axis of the inner tube. Although Automatic asserts that it is improper to add qualifying terminology to a claim that is not contained in the claim itself, citing Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 950 (Fed. Cir. 1993), when arguing that Dethmers reads the limitation to be "completely circularly surrounding" the inner tube, it is equally improper for Automatic to argue that the absence of a qualifier means that the limitation meant "completely and partially circularly surrounding." Addition of "completely" would simply be redundant; it is addition of the further qualifier "and partially" that is improper.

Thus, the EXCALI-BAR, which has at least two grooves that together define no more than a 240-degree arc of a circle around the inner tube, does not literally infringe this limitation of claim 1 of the '166 patent as a matter of law.
Claim 1 of the '701 Patent includes the term "circumferential array of vanes" around the impeller. The Court construes this term to mean "a number of flat or curved surfaces arranged around the outer part of the impeller, which is generally circular in shape." 2

Performance asserts that its proposed construction and TI Group's proposed construction of this term are fundamentally the same and, therefore, the Court adopts TI Group's proposed construction. However, the phrase "a number of is vague. Because this aspect of the claim term is not in issue, the Court does not define the term further.

The term "circumferential member" is not indefinite. The parties agree that the term "member" means a structural element. 145 Circumferential, used in this context, relates to the circumferential direction. Nonetheless, Guidant submits that a circumferential member is merely a loop. This interpretation is rejected. First, Guidant does not identify any part in the intrinsic record limiting "circumferential member" to a loop. Second, as Medinol correctly notes, Guidant's proposed definition of "circumferential meander" suffers from overinclusiveness, as it would includes loops with "end points that are not displaced from each other with respect to the stent's circumferential axis, such as reference numerals 18 . . . and 20 of Figures 1-4." 146 Accordingly, the term "circumferential member" describes a structural element extending in the circumferential direction, and the first and second circumferential members identify and differentiate two different circumferential members.

56. A balloon expandable stent for implantation into a lumen to support the lumen, said stent both in the unexpanded state and in the balloon-expanded state including: a plurality of flexible cells adjacent to one another both circumferentially and longitudinally each of said flexible cells comprising:

a) a first flexible link including an arc, the first flexible link having a first longitudinal end and a second longitudinal end;
b) a second flexible link including an arc, the second flexible link having a first longitudinal end and a second longitudinal end;

c) a first circumferential member disposed between said first longitudinal end of said first flexible link and said first longitudinal end of said second flexible link and;

d) a second circumferential member disposed between said second longitudinal end of said first flexible link and said second longitudinal end of said second flexible link,

e) at least one of said first circumferential member and said second circumferential member in each of said cells having a portion with a substantial longitudinal component that is also a portion with a substantial longitudinal component of a first circumferential member or a second circumferential member in a longitudinally adjacent cell,

wherein in the expanded state the first and second circumferential members have a substantial longitudinal component to provide coverage of the lumen.

'381 Patent, col. 9, ll. 56-57-col. 10, ll. 1-18.

146 Pl. Mem. at 23. See also '381 Patent, Figures 1-4.

--- End Footnotes ---

Crown's proposed construction is "[c]an end wall encircling the center of the can end and extending from the seaming panel." 91 Rexam's proposed construction is "[t]he end wall (or chuck wall) that begins where the seaming panel ends with a portion that has a different radius than the seaming panel." 92

--- Footnotes ---

91 Id. at 8.

92 Id.

--- End Footnotes ---

The court adopts Crown's proposed construction.

For the reasons discussed in connection with 16, above, Rexam's proposed construction is rejected as inconsistent with the court's determination that the seaming panel is not limited to a single radius. The court, therefore, adopts Crown's proposed construction as consistent with a plain reading of the claim language: "can end wall encircling the center of the can end and extending from the seaming panel."

---

--- Footnotes ---

13 This term is found in dependent claims 2 and 11 of the '458 Patent and is found in dependent claims 2 and 8 of the '073
The parties ask the Court to construe this term and the term "circumferentially reinforced by a metal wire structure," found in independent claim 22 of the '736 Patent, in the same manner.

There is no dispute among the parties that this phrase should be construed to require more than one wire and that the wires are placed around the graft in a circular manner. It also is apparent that the parties agree that the wires are intended to strengthen or support the graft body, as the Court has defined that term. The parties again dispute whether the wires referenced in this phrase must be malleable. For the reasons set forth above in Section 8.2, the Court concludes that the wires are malleable.

The parties also disagree about the meaning of "along its length" and "separately spaced apart." With respect to "along its length," Cook argues that it means "from end to end," i.e. that the wires extend the entire length of the device. Cook, however, finds support for its position from a reference in the specification where the inventors state that because "the wires are arrayed along the length of the graft the complete position of the graft in the body can be continuously monitored" by X-ray. ('458 Patent, col. 3, II. 42-45.) Plaintiffs and Gore, in contrast, propose constructions that do not ascribe any special meaning to this term.

The claim language states that the wires are placed at "locations along its length." ('458 Patent, col. 6, II. 22-22.) The use of the word "locations" does not suggest that the wire must run the entire length of the device. In addition, the specification supports a conclusion that the wires do not need to run the entire length of the device. For example, in the Abstract, the inventors state that the invention may include a "plurality of wires spaced apart from each other and arranged to circumferentially reinforce said tubular graft body along a substantial portion of its length." ('458 Patent, Abstract (emphasis added).) The use of the term "substantial portion," rather than "along the entireity" or "along its entire length," support Plaintiffs' position that the phrase should not be construed to mean the wires extend from "end to end." Further support for the Court's conclusion stems from the fact that, in certain preferred embodiments, the invention includes a skirt portion that has no reinforcing wires. Thus, in these embodiments, the wires would not extend the entire length of the invention. See, e.g., Primos, Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 848 (Fed. Cir. 2006) (court normally should not interpret a claim to exclude a preferred embodiment).

Finally, Cook also argues that the inventors, in a later patent application, distinguished over prior art that disclosed wires that were located only at the end of the graft. (Cook Br. at 19-20; Cook Ex. 15.) To the extent that statement is relevant to construction of the patents-in-suit, there is nothing in the inventors' response that suggests the wires must be placed along the entirety of the device. Rather, a plausible interpretation of the inventors' remarks is that they distinguished the prior art by stating that the prior art had wires only at each end of the device, whereas the device they were claiming had reinforcing wires at additional locations and not only at the ends. (See Cook Ex. 15 at 14.)

Gore argues "separate spaced apart" means that the wires cannot touch or overlap. Plaintiffs argue that in most instances the wires will not touch one another. Plaintiffs' proposed construction draws upon the language quoted above from the Abstract, which refers to where the wires are placed along the graft body. The claim language uses the word "apart," which suggests that the wires are separated from one another, i.e. they are not touching. The figures of the patents-in-suit also show that the wires do not touch or overlap with one another. ('458 Patent, figs. 2-3, 5-7.) Further, in the "Disclosure of the Invention" the inventors state:

> It is preferred that the one wire has a greater amplitude than at least the next adjacent one or two wires. This allows the wires at the end of the graft to be positioned more closely together than would be the case if they were all of the same amplitude. … It is desirable to space the wires adjacent the end of the graft that will be placed "upstream" in the patient as close together as is possible as the neck of the aneurysm with which the graft is engaged can be quite short. Close spacing of the wires maximises the number of wires reinforcing that part of the graft in contact with the neck of the aneurysm. The spacing of the rest of the wires is desirably greater than those adjacent the one end of the graft as this avoids unnecessarily reducing the flexibility of the graft.

('458 Patent, col. 2, II. 36-48; see also id., col. 5, II. 47-57 (describing spacing of wires in manner in which wires do not come into contact with one another).) Although this portion of the specification teaches that the wires may be spaced closely together, it does not teach that the wires can come into contact with one another. Further, the description of the purpose of
spacing the wire also supports Gore's construction that the wires should not come into contact with one another.

Accordingly, the Court construes the phrase "circumferentially reinforced at locations along its length by a plurality of separately spaced apart wires" to mean: "The graft body or bifurcated base structure is strengthened by at least two malleable wires that do not contact or touch one another and that are placed circumferentially along the length of the material forming the graft body or bifurcated base structure."

3. "Each Having At Least Two Circumferentially Spaced Teeth" and "Each Disk Having At Least Two Circumferentially Spaced Teeth"

Claim 1's reference to the "cutting disks" "each having at least two circumferentially spaced teeth" is nearly identical to Claim 12's phrase "each disk having at least two circumferentially spaced teeth" and thus the two phrases will be construed together. The three parties agree that elements 1(h) and 12(e) mean, at a minimum, that "each cutting disk has at least two teeth for cutting that are spaced apart in the direction of rotation." They disagree, however, as to the function of the "spaced teeth." Fellowes submits that the "spaced teeth mean the disks are used to cross-cut paper." Michilin argues that the "spaced teeth with the additional transverse cutting edge allow for a cross-cut of the paper to occur." According to Intek, the "spaced teeth with additional cutting edges provide a cross-cut that produces a number of small, rectangular pieces."

Whatever the merit of Michilin's position that "cross-cutting" is impossible unless the "spaced teeth" have a "transverse cutting edge," see Hearing 147, the patent itself was unambiguously intended to apply to shredders that allow for "cross-cutting," as opposed to "strip cut" shredders. See '780 Patent, col. 1, line 4-5 ("The present invention relates to a cross cutting cylinder for shredding paper."); id. at col. 1 lines 11-14 ("Typically, the cutting is achieved by a pair of rotating cutting cylinders having a series of circular cutters or blades along the axis of a solid shaft."); id. at col. 1, lines 35-37 ("A cross cut shredder generally comprises a pair of parallel cutting cylinders that contain a series of offset cutting disks arranged along the axis of the cylinders."). Whatever the consequences in this litigation of the patentees' failure to include the word "transverse" in the '780 Patent, the Court finds it significant for the purposes of claim construction that the patent was approved even though the word "transverse" appears nowhere therein. Indeed, the specifications provide that ",...the particular construction and shape of the teeth is not important to the practice of the present invention so long as they provide a cross cut (i.e. chips of material)." Id. at col. 2, lines 39-42. Consequently, the Court will not add "transverse" to its construction of elements 1(h) and 12(e). For similar reasons, the Court does not see the need to specify, as Intek urges, that the "spaced teeth" have "additional cutting edges." Moreover, for reasons made clear in the Court's analysis of the "cross-cut cutting cylinder," the Court refuses to limit the '780 Patent to shredders that produce "rectangular pieces" and therefore rejects Intek's construction. See infra element 12(a). Accordingly, the Court FINDS that elements 1(h) and 12(e) both mean that "each cutting disk has at least two teeth for cutting that are spaced apart in the direction of rotation" and further that the "spaced teeth mean the disks are used to cross-cut paper." 8

--- Footnotes ---

7 The Court finds puzzling the apparent inconsistency between Michilin's definition of Claim elements 1(h) and 12(e), both of which concede that the '780 Patent relates to "cross-cut shredders," and the position taken by Michilin's counsel at the Markman hearing that the '780 Patent failed to cover a "cross-cut" shredder because it lacked a "transverse edge." See Markman Hr'g Tr. 147 ("[I]f you're going to say that their claim covers cross-cutting, you have to have that [transverse] edge.").

8 The Court notes that its use of the word "paper" in this construction is consistent with its construction of a "cross-cutting cylinder," element 12(a), and "cutting disks," element 12(d).

--- End Footnotes ---
4. "Circumscribing"

Jennmar proposes that "Circumscribing" means "Encircling or surrounding in whole." Excel originally proposed a definition of "Encircling or surrounding in whole or in part." Excel subsequently proposed to omit the last phrase, to avoid (or defer) the "in whole" versus "in part" dispute, such that the definition would simply be: "Encircling or surrounding."

After careful and deliberate consideration, the Court finds that Excel's revised construction is correct. There is no need to resolve whether the term "circumscribing," when used alone, contemplates encirclement "in whole" or "in part" because, in the '933 Patent, the author uses the term "at least partially circumscribing." (see, e.g., Abstract, Column 1) Jennmar's proposed definition would yield the awkward and self-contradictory reading "at least partially encircling or surrounding in whole." It is sufficient to construe "circumscribing" simply as "encircling or surrounding."

3. On December 22, 2000, the court issued its construction of disputed claim terms as follows:

a. "Aluminum alloy sheet product." As understood by one of ordinary skill in the art, an aluminum product with a maximum thickness of 1/4 inches.

c. "Clad" and "cladding." Structures containing an outer layer that provides protection against corrosion. Claims without reference to "clad" or "cladding" apply to both clad and unclad products.

1. "Clamp"

In this patent infringement action, two patents are at issue. The first is United States Patent No. 5,709,489 (the '489 patent), entitled "Keyboard Positioning System," issued on January 20, 1998. The '489 patent describes "a device for mounting a keyboard to a base and for positioning the keyboard in a backward tilted position." The device includes, inter alia:

a clamp engaged with said bracket said clamp being engagable [sic] with a keyboard such that the keyboard may be oriented in a backward tilted position defined by the rear end of the keyboard being disposed below the front end of the keyboard, to prevent the keyboard from falling off when the keyboard is oriented in said backward tilted position.

'489 patent, claim 1(b), col. 4, 11. 48-54.

"Clamp" is not defined in the claim itself or in the specification. Presumptively, then, the term should be given its ordinary and customary meaning, as understood by one of ordinary skill in the art. Prima Tek II, L.L.C. v. Polypap, S.A.R.L., 318 F.3d 1143, 1148 (Fed. Cir. 2003). The parties agree that "clamp" should be given its plain and ordinary meaning. Their respective proposed definitions, however, are different in one material respect. Plaintiffs' proposed definition:

A clamp is a structure that can provide gripping forces for supporting a keyboard and stops it from falling off when the key plane of the keyboard is negatively titled.

Defendants' proposed definition:
A clamp is a device that can grip or bind a keyboard by at least two opposing points to stop it from falling off when the keyboard is tilted backwards.

The dispute thus evolves around whether the clamp must grip the keyboard by at least two opposing forces.

Defendants contend the ordinary and customary meaning of clamp, as reflected in several dictionary definitions, contemplates a device or instrument designed to bind, constrict or press two or more parts together so as to hold them firmly. Indeed, the Oxford English Dictionary defines "clamp" most relevantly as "a name of various appliances, tools or instruments with opposite sides or parts which may be screwed or otherwise brought together, so as to seize, hold, compress, or pinch anything." Oxford English Dictionary Online, Oxford University Press, Second Edition (1989). Defendants thus argue that this pinching, binding or pressing action, by exertion of force at at least two opposing points, is integral to the nature and operation of a clamp, as opposed to instruments or structures that may use other means to hold an object in place. Applying the common meaning of "clamp," this Court agrees.

Plaintiffs insist that the claim language and specification do not support such a limitation. They argue that a "clamp" is any "support" or "support member" that keeps the keyboard from falling, whether or not any pinching, binding or pressing dynamic is used.

Yet, the limitation is unavoidably implicit in the term "clamp." A support member that holds an object in place without pinching, binding or pressing it between opposing points is simply not a "clamp," as that term is commonly understood. That this common, ordinary understanding prevails among those skilled in the art is attested to by Richard Benoit, a Steelcase Senior Sales Consultant, whose second declaration has, in this respect, not been rebutted. This construction is entirely consistent with the structure disclosed in the patent. It is also consistent with the prosecution history. Plaintiffs' arguments to the contrary are transparently meritless.

Accordingly, defendants' proposed definition of clamp shall be adopted by the Court for use in adjudicating plaintiffs' infringement claim:

A clamp is a device that can grip or bind a keyboard by at least two opposing points to stop it from falling off when the keyboard is tilted backwards.

With respect to the clamp means, claim 1 provides in pertinent part:

clamp means for automatically clamping an attachment end when in said predetermined alignment; …

said clamp means includes first and second resiliently biased spring means carried on said coupling and disposed within said first and second pockets, respectively, and directed to urge an element wall against a wall of said coupling upon insertion of said element wall between said outer and inner walls ….

The '243 patent, claim 1.

Again, the use of the word "means" invokes a presumption that § 112, P 6 applies. The function of the clamp means is "for automatically clamping an attachment end when in said predetermined alignment." Id. The claim fails to recite sufficient structure, material, or acts for performing the function of clamping. To perform this function, the clamp means requires "leaf springs 61 that include first and second halves 62, 64 disposed on opposite sides of spacing rib 56." Id. at col. 3: 63-65. The springs 62, 64 are biased toward the internal walls 48, and have terminal ends 65, "which are bent back to permit a leading end of the attachment ends to be inserted into the space 57." Id. at col. 3: 66 - col. 4: 1. Because additional structural limitations are required for the clamp means to perform its function, claim 1 fails to recite sufficient structure to perform the function. See Unidynamics Corp. v. Automatic Products Intern., Ltd., 157 F.3d 1311, 1319 (8th Cir. 1998); Laitram Corp., 939 F.2d at 1536 ("The recitation of some structure in a means-plus-function element does not preclude the applicability of
§ 112, P 6 [when it] merely serves to further specify the function of the means."). The presumption that § 112, P 6 applies is not rebutted.

The specification of the '243 patent describes the leaf springs as entirely placed within the spacing between the inner and outer walls. The specification calls for "leaf springs 61 placed within side space 57 on opposite sides of the coupling." The '243 patent, at col. 3: 59-62. The figures of the '243 patent confirm this interpretation.

The prosecution history provides further support for this construction. In response to a rejection, ADC asserted that the claim "calls for a coupling having inner and outer walls defining a pocket … with the spring carried completely within the pocket defined by the first and second opposing walls." Fiorella Decl., Ex. 11, Response to Final Office Action of June 23, 1992. ADC argued that both the inner and outer walls enclosed the spring means. ADC is bound by its own previous explanations in support of establishing the claim.

The proper construction of the clamp means is as a means-plus-function element to automatically clamp the attachment end in the coupler. The clamp means element includes resiliently biased spring means in the form of resiliently biased leaf springs disposed in the first and second pockets. The spring means must be entirely enclosed within the pockets and, therefore, must be entirely between the inner and outer walls of the alignment means. In order to be resiliently biased, the spring means must be under the influence of spring forces before the wall of the cable pathway defining element is inserted into the coupler.

1. Claims 1, 6, 7, and 8 ("clamp member")

Claims 1, 6, 7, and 8 (and all dependent claims) of the '286 Patent use the term "clamp member" as follows:

. "[A] clamp member supported adjacent to the cutting jaw, the clamp member being moveable in relation to the cutting jaw between an open position in which at least a portion of the clamp member is spaced from the cutting jaw and a closed position in which the clamp member and the cutting jaw are in substantially juxtaposed alignment," see '286 Patent, Claim 1(c) (emphasis added);

. "[A] rotatable member operatively associated with the vibration coupler, the clamp member and the cutting jaw, the rotatable member being rotatable to cause corresponding rotation of the clamp member and cutting jaw about a longitudinal axis of the instrument," see id. Claim 1(d) (emphasis added);

. "An ultrasonic instrument according to claim 1, wherein the clamp member includes a pair of tissue engaging stops," see id. Claim 6 (emphasis added);

. "[A] clamp member supported adjacent to the cutting jaw, the clamp member and the cutting jaw defining a tissue receiving area, the clamp member being moveable between open and closed positions in relation to the cutting jaw and having a tissue engaging stop positioned to engage tissue and prevent positioning of tissue beyond the proximal end of the cutting surface of the cutting jaw," see id. Claim 7(d) (emphasis added);

. "An ultrasonic instrument according to claim 7, further including an actuator tube slidably positioned about the vibration coupler, a distal end of the actuator tube including a cam slot configured to receive cam members formed on the clamp member, the actuator tube being moveable between advanced and retracted positions about the vibration coupler in response to actuation of the handle assembly to effect movement of the clamp member between the open and closed positions," see id.

Claim 8 (emphasis added). n4

Plaintiff proposes construing the term as: "A part configured to hold, grasp, or apply pressure to tissue, that is movable and works with a component of the instrument (e.g. the cutting jaw), for holding, grasping, or applying pressure to the tissue." Defendant proposes: "A part configured to hold, grasp, or apply pressure to tissue, that is movable and which is separate and distinct from the tissue contacting member."
The term is further utilized in dependent Claims 12, 14, 17 and 19.

The parties thus agree on the first phrase in this construction: that a "clamp member" is "a part configured to hold, grasp, or apply pressure to tissue, that is movable." Additionally, it is clear from the claim language and the specifications that the ordinary and customary meaning of "clamp member" in the context of this patent includes the feature that the "clamp member" works with the cutting jaw, for holding, grasping, or applying pressure to tissue. See e.g., '286 Patent Claim 1(c), Claim 1(d), Claim 7(d), 2:5-13.

The parties dispute, however, whether the "clamp member" is necessarily "separate and distinct from" the tissue contact surface. n5 The basis of the parties' dispute is the meaning of dependent Claim 17, which provides: "An ultrasonic instrument according to claim 7, wherein the clamp member includes a tissue contact surface removably fastened to the clamp member." Defendant argues that the "clamp member" must thus be separate and distinct from the "tissue contact surface" in order for it to be capable of being "removably fastened" to the tissue contact surface, as described in the claim and specifications. See Def. Claim Construction Br. at 16-17; Markman Tr. 124; see also '286 Patent 3:64-4:9. Plaintiff argues that it is improper to limit the claim language based on dependent Claim 17. See Pl. Claim Construction Br. at 22; Pl. Reply Br. at 5-6; Markman Tr. 25-26.

n5 While defendant proposes that the "clamp member" must be separate and distinct from the "tissue contacting member," the term actually used in Claim 17 of the '286 Patent is "tissue contact surface" and the patent's actual terminology will be used. See '286 Patent, Claim 17.

While plaintiff is correct that as a general matter claim language should not be limited by dependent claims, n6 the Federal Circuit has also held that a term used in multiple claims should be construed identically in each of those claims. See Nazomi Commun., Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005); Dayco Prods. Inc. v. Total Containment, Inc., 329 F.3d 1358, 1371 (Fed. Cir. 2003) ("If a claim term appears in more than one claim it should be construed the same in each."). Thus, because Claim 17 requires that the "clamp member" and the "tissue contact surface" be separate and distinct, such that they are capable of being "removably fastened," it is proper as a matter of claim construction for all those claims in the '286 Patent that invoke the term "clamp member" to be consistently construed to reflect that limitation. Accordingly, the Court construes the term as: "A part configured to hold, grasp, or apply pressure to tissue, that is movable, that works with a component of the instrument (e.g. the cutting jaw), and which is separate and distinct from the tissue contact surface."

n6 See Nazomi Commun., Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005) ("The concept of claim differentiation normally means that limitations stated in dependent claims are not to be read into the independent claim from which they depend.") (internal quotation and citation omitted).

III. "Clamp Member" in the '286 Patent

Lastly, Tyco seeks amendment of the Court's construction of the term "clamp member" in the '286 Patent, which includes the limitation that the clamp member is "separate and distinct from the tissue contact surface," arguing that the limitation is impermissibly imported from a dependent claim and is also inconsistent with the usage of the same term in the '050 Patent. Ethicon argues that there is no basis for the Court's construction of "clamp member" to be reconsidered because "the Court properly recognized that the plain language of Claim 17 requires that the 'clamp member' and the 'tissue contact surface' be separate and distinct, such that they are capable of being 'removably fastened.'" Ethicon Opp. at 3. Ethicon contends that the portions of the specification which "describe the clamp member and tissue contact member as separate, distinct parts are dispositive on this issue." Id.

While Ethicon contends that Tyco has simply "repackaged the same arguments it made the first time around in an attempt to persuade the Court that an error has been made," because reconsideration and amendment is appropriate where necessary to correct an error of law, the Court granted Tyco's reconsideration motion to correct any error of law. This use of a reconsideration motion is particularly valuable in the claim construction context, where the patent claims at issue are complex and difficult and any mistake is likely to affect the outcome of the infringement determination to be made in the
After reviewing the claim language and specification again, the Court believes that Tyco is correct that the original construction of "clamp member" was improperly limited by the language in dependent claim 17. See Nazomi Commc’ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (2d Cir. 2005) ("[T]he concept of claim differentiation normally means that limitations stated in dependent claims are not to be read into the independent claim from which they depend.") (internal quotation omitted). While the independent claims do not specifically describe the clamp member's relationship to the "tissue contact surface," it is dependent claim 17 which claims "an ultrasonic instrument according to claim 7, wherein the clamp member includes a tissue contacting surface removably fastened to the clamp member." Thus, the Court's prior reasoning that, in order for the clamp member to be removably fastened to the tissue contacting surface, it would have to be separate and distinct from that contacting surface, imports the limitation in claim 17 into the rest of the independent claims in the patent. As Tyco notes, there is no basis in the '286 independent claims for the "clamp member" claimed therein to be limited to a component with a removably fastened tissue contact surface, as opposed to a component including a tissue contact surface or with a permanently (i.e. not removably) fastened tissue contact surface.

Further, although the parties did not request construction of the term "clamp member" in the '050 Patent, Tyco is correct that the Court's initial construction of this term for the '286 Patent is inconsistent with the term as used in the '050 Patent and the Court will "presume, unless otherwise compelled, that the same claim term in the same patent or related patents carries the same construed meaning." See Omega Eng’g, Inc. v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003) (emphasis added). Because the '050 Patent discloses embodiments where the clamp member and the tissue contacting surface are made of the same part (as opposed to two separate parts removably fastened to each other), see '050 Patent, Figures 27, 28A, 28B, and 28C, the Court's initial construction of "clamp member" for the '286 Patent could not be applied to the '050 Patent without excluding disclosed embodiments and "a claim interpretation that excludes the device disclosed is rarely the correct interpretation." See Claim Construction at 35 (citing Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 904 (Fed Cir. 2005)).

Thus, because the Court's initial construction impermissibly imported a limitation from dependent claim 17, and because the identical term in the related '050 patent should be capable of being construed to carry the same meaning, the Court amends its construction of "clamp member" in the '286 patent to: "A part configured to hold, grasp, or apply pressure to tissue, that is movable and that works with a component of the instrument (e.g. the cutting jaw)."

The term "clamp region," element [e] of Claim 1, is a major area of dispute between the parties. Thomas and Betts asserts that this term is limited to the embodiment described in the patent specification which describes an elongated C-shaped clamp. Senior Industries argues that a broader construction should be afforded to the clamping device based upon the ordinary meaning of the claim language. More specifically, Senior Industries claims that the proper interpretation of a clamping device connected to the utility box is "a clamp (possibly including several elements) having parts which (i) mechanically fasten the clamp to the utility box and (ii) electrically connect the clamp to the utility box".

Normally, an element in a patent claim should have its broadest meaning and not be limited to the embodiment in the specification, but the term "clamping device" is a vague and ambiguous term without adequate structure for one skilled in
the art to ascertain what Senior is claiming. One may be his own lexicographer and define an ambiguous term in the patent specification or prosecution history. Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1578, 1996 U.S. App. LEXIS 4703 (Fed. Cir. 1996) Hence, one interpreting a vague or ambiguous claim must refer to intrinsic evidence to ascertain the intended definition of the term. The "clamping device" term lacks adequate structure for one skilled in the art to fully understand what Senior Industries is claiming.

Looking to the specification and file history, it is clear that the intent of this element was to embody an elongated C-shaped clamp wherein the base is longer than one of the sides of the metal box enclosure and having a pair of opposed arms so that the arms are connectable to the box on opposite sides. The specification reads as follows:

More specifically, the clamping device comprises an elongated C-shaped clamp which connects to the opposite sides of the utility box.

(Col. 2, lines 28-30).

It is a further object of this invention to provide an improved clamping device which is connectable to a metal box enclosure on opposite sides of the box and having a securing means for penetrating the outer surface of the box without penetrating the inside of the box, and including mechanism to prevent the inadvertent movement of the clamp while being clamped.

(Col. 3, Lines 3-9).

A clamp 30 having an elongated base 32 is mechanically and electrically connectable to utility box 10. The elongated base 32 is larger than one of the sides of the box so as to extend beyond the box side. A pair of arms then extend from the ends of the base to engage and clamp the box there between, as will be apparent.

(Exhibit A, Col. 4, lines 23-28)

Referring to Figs. 3-8, the novel clamp 30 can be considered an elongated C-shaped or U-shaped clamp and includes a first arm or side portion 36 and a second arm or side portion 38 extending upwardly from a common, elongated base 32.

(Exhibit A, Col. 4, lines 56-60).

Furthermore, in every figure of the patent in which the clamp appears, it is shown as an elongated C-shaped clamp having arms which are positioned on opposite sides of the metal box and the prosecution history reveals the elongated base to be substantially longer than the length of the arms. (Exhibit B, Amendment B, p.4). Therefore, it is proper to limit this term to the embodiment described in the specification. The term "clamping device" shall be defined in accordance with Thomas and Betts' construction "as an elongated C-shaped clamp wherein the base is longer than one of the sides of the hollow metal box enclosure and having a pair of opposed arms so that the arms are connectable to the box on opposite sides of the box. The base of the clamp is substantially longer than the arms".

A. "Clamping Engagement"

For the reasons stated below, the court construes the term "clamping engagement" in claims 19, 22, 37, 47, 50, and 54 to mean:

tight, high-pressure electrical contact maintained indefinitely.

To argue for their constructions, both parties cite to language from the summary of the invention section of the specification in part to argue for their constructions, which states:

The bail is rotated into its closed position with minimal effort by the installer thereby forcing the clip into tight
engagement with the outer conductor. The tight engagement between the clip and the conductor of the cable ensures high pressure electrical contact as required when a high-power condition occurs in the cable from a lightning strike.

(Ex. 3, Col. 2, ln. 29-34.) The parties agree that clamping engagement means "tight engagement," based on the first sentence of the above-quoted language. Beverly, however, relies on the second sentence's explanation that a tight engagement "ensures high pressure electrical contact as required when a high-power condition occurs in the cable from a lightning strike," (Ex. 3, Col. 2, ln. 32-34,) to argue that the construction of clamping engagement must also incorporate the requirement that high-pressure contact be maintained over a period of time. In further support of its construction, Beverly points to Andrew's description of the prior art and the failure of previous inventions to maintain high contact pressure over an extended period of time. (Ex. 3, Col 1, ln. 30-49.)

Andrew, however, argues to limit the construction of clamping engagement to mean that the "clip rests tightly against the exposed section of the electrical conductor," without reference to high-pressure contact. (Pl. Mem. at 13.) Refuting Beverly's construction, Andrew asserts that the high-pressure contact is only a desirable property and not a structural limitation. The court disagrees with Andrew's contention that the high-pressure contact was at most a desirable property. In reviewing Andrew's discussion of the prior art in the specification, the court determines that Andrew has differentiated the '056 patent from prior art in part on the invention's ability to maintain high contact pressure through the tight engagement of the clip with the outer conductor. Andrew notes that "Because grounding kits are designed for high current conditions, a high contact pressure must be maintained between the conductor and the ground wire," and that the prior art's copper straps and copper braided wires that wrapped around the conductor and attached to the ground wire would often loosen over an extended period of time. (Id. at Col. 1, ln. 30-50.) Andrew's invention was meant to address the need "for a durable grounding kit for transmission line cables that maintains high pressure contact with the cable over extended periods of time and after being subjected to multiple high-power conditions." (Id. at Col. 1, ln. 63-66.)

In support of its position that the clamping engagement does not include the definition of high-pressured contact, Andrew cites to the prosecution history where the examiner found that the "applicant does not claim any of these noted benefits," (Pros. Hist., Harwath 109), in response to Andrew's argument that the invention better retains the clip around the cable during power surges. (Pl. Reply at 12-13.) The court finds this citation to be not relevant to the issue of whether a clamping engagement should include the limitation of high-pressure contact maintainable indefinitely.

The court was also concerned with the timeframe for which the tight, high-pressured contact was maintained. At the oral argument, the court suggested that the contact be maintained over a period of multiple high-current conditions. Andrew clarified, however, that the contact was intended to be maintained "indefinitely," and so the court accepts Andrew's construction of the timeframe. (Tr. 15-16, ln.17-5.)

On March 23, 2007, prior to the commencement of discovery, Defendants filed their motion for summary judgment of non-infringement of the '305 Patent. Defendants' motion is premised entirely on the court's construction of a phrase found in each of the independent claims of the '305 Patent. The phrase requires that claimed device contain a "clamping force being sufficient to prevent sheet material from being drawn laterally inwards towards the rivet." The court construed this phrase to mean that the riveter or riveting method "significantly restrict the inward, lateral flow of sheet material that is subject to the clamping force." (10/25/06 Order at 38-40.) Now, Defendants argue that they are entitled to summary judgment because "[a]s shown by scientific testing, it is undisputable that Bollhoff's self-pierce riveter, and the riveting method performed with that riveter, do not 'significantly restrict the inward, lateral flow of sheet material that is subject to the clamping force,' as required by each of the independent claims of the '305 Patent." (Defs.' Mot. for Sum. J. at 1.) In order to support their motion, Defendants relied on the tests performed by Bollhoff's experts, Drs. Ulm and Flugge, who concluded that the clamping forces in Bollhoff's machines do not significantly decrease lateral flow, as compared to the prior art spring clamping riveter.
On appeal, Kwik argues that the district court erred in holding that §112, ¶6 applied to the term "clamping means" in claim 1 of the '666 patent. According to Kwik, because a clamp identifies a device that has a reasonably well understood meaning in the art, "clamping means" is not a means-plus-function limitation. Kwik contends that under the proper construction of "clamping means", there is no limitation that it comprise a pivotally mounted clamping member having a particularly located center of gravity, as supported by the doctrine of claim differentiation. Kwik also argues that the court erred in construing the term "spring" in claim 15 of the patent to be limited to extension and torsion springs. Kwik asserts that the ordinary and customary meaning of the term "spring" is not limited to the specific types of springs disclosed in the specification, and thus includes compression springs. Based on its construction of "clamping means" and "spring," Kwik contends that claim 1 is literally infringed and claim 15 is infringed under the doctrine of equivalents. Kwik points out that the slideably mounted clamping member of the accused device is equivalent to the pivotally mounted clamping member recited in claim 15 of the patent because it performs the same function (to clamp the string), in the same way (by being urged toward the opposed way under a spring force), to achieve the same result (fixing the string in the trimmer head).

Torvian responds that the district court correctly applied § 112, ¶6 to the term "clamping means" because the claim is written in classic means-plus-function format, and Kwik failed to rebut the presumption that § 112, ¶6 applies. According to Torvian, the court correctly limited "clamping means" to the structures identified in the specification: a pivotally-mounted clamping member, either biased by a torsion or extension spring against an opposing wall or completely unbiased (in which event the force is applied manually), and a strategically-placed center of gravity, which increases the clamping force while the trimmer head is spinning. Torvian also contends that the court correctly relied on the specification to construe the term "spring" as a torsion or extension spring, but not a compression spring because the patent's reference to a "generic" spring is ambiguous. Finally, Torvian argues that the accused device does not infringe claims 1 and 15 of the patent, either literally or under the doctrine of equivalents, because it contains a slideably-mounted clamping member, biased by a compression spring, whose clamping force is not influenced by the location of its center of gravity. Torvian points out that the accused device not only contains different structures from those disclosed in the '666 patent, but also functions in a different way, such that the force applied to hold the cutting string in place is applied rectilinearly rather than through circular or rotational application of force.

We agree with Torvian that the district court correctly construed the term "clamping means" in claim 1 as a means-plus-function limitation. A claim using the means-plus-function format will cover only the corresponding structure disclosed in the written description, as well as that structure's equivalents. 35 U.S.C. §112, ¶ 6; Personalized Media Commun., L.L.C. v. ITC, 161 F.3d 696, 703 (Fed. Cir. 1998). A claim limitation that actually uses the word "means" will invoke a rebuttable presumption that § 12, ¶6 applies. Id. at 703-04. In this case, claim 1 phrases the "clamping means" limitation in means-plus-function language, thereby triggering the presumption. Because Kwik has not rebutted that presumption, the claim must "be construed to cover corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112, ¶ 6.

Here, the specification of the '666 patent discloses a "clamping member [that] is pivotally mounted adjacent each aperture, opposite the corresponding pressing wall so that its center of gravity is disposed between the pivotal mounting and the corresponding pressing wall." '666 patent, col. 3, II. 4-7. Further, as the district court correctly observed, the specification refers to "two degrees of clamping force," one that is generated by springs that hold the string in place when the cutting head is not in use and a second that is generated when the cutting head rotates and creates a centrifugal force "that acts on the centers of gravity of the clamping members and enhances the gripping force thereof." Id., col. 3, II. 7-17. Therefore, the court did not err in construing the means-plus-function limitation "clamping means" to mean "a spring element working with a pivotally mounted clamping member with a strategically placed center of gravity." Opinion, 356 F. Supp. 2d at 318.

We reject Kwik's argument that the well understood meaning of "clamp" rebutted the presumption that § 112, ¶6 applies to the limitation "clamping means." Even assuming that the term "clamp" had a reasonably well understood meaning in the art, a clamp is not the same as a clamping means. Equally unpersuasive is Kwik's argument that claim differentiation requires a different interpretation of "clamping means." As we stated in Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533 (Fed. Cir. 1991), "[a] means plus function [element] is not made open-ended by the presence of another claim specifically claiming the disclosed structure which underlies the means clause or an equivalent of that structure." Id. at 1538. We further stated that "one cannot escape [the] mandate [of § 112, ¶6] by merely adding a claim or claims specifically reciting such structure or structures. " Id. Because we conclude that § 112, ¶6 applies to the limitation "clamping means" in claim 1, we do not address Kwik's remaining arguments as to the construction of that term.
Having affirmed the district court's claim construction of the term "clamping means," we also affirm its judgment of no literal infringement of claim 1. Kwik's argument that there was literal infringement of claim 1 depends entirely upon a finding that the term "clamping means" is not a means-plus-function limitation. Because § 112, ¶ 6 does apply to that term, the court made no clear error in determining that the accused device did not literally infringe claim 1 of the '666 patent.

B. Construction of the Claims of the '546 Patent

The parties agree that claim 1 of the patent requires two separate cleaning steps in two different locations of the machine. CoinBank contends that the term "cleaning" or "cleaning step" means the removal or separation of debris or waste from the coins and from the pathway through which the coins travel to help prevent jamming or damage to the machine. Coinstar contends that cleaning simply means the removal or separation of any non-coin material from the coins.

--- Footnotes ---

5 In its Points and Authorities in Opposition to the Motion for Summary Judgment, Coinstar seemed to concede that "foreign matter must be removed in a way that prevents jamming or damage to the machine" and that the "prior art did not adequately address this need to remove foreign matter." However, Coinstar retreated from this definition at the hearing on the motions for summary judgment.

--- End Footnotes ---

"Cleaning"

As stated above, when interpreting the meaning of the terms in a patent claim, the court looks to the claims themselves, the specification, and the prosecution history of the patent. "Cleaning" is not expressly defined within the claims of the '546 patent. However, the prosecution history contains numerous references to the purpose for the cleaning steps and why the '546 patent's cleaning steps differ from prior art.

The Federal Circuit and its predecessor, the Court of Claims, have emphasized the importance of looking to the file wrapper in interpreting the meaning of the words in a claim. In an often-quoted statement in Autogiro Company of America v. U.S., 181 Ct. Cl. 55, 384 F.2d 391, 398-399 (Ct.Cl.1967), the Court of Claims explained the purpose of examining the file wrapper:

The file wrapper contains the entire record of the proceedings in the Patent Office from the first application papers to the issued patent. Since all express representations of the patent applicant made to induce a patent grant are in the file wrapper, this material provides an accurate charting of the patent's pre-issuance history. One use of the file wrapper is file wrapper estoppel, which is the application of familiar estoppel principles to Patent Office prosecution and patent infringement litigation. The patent applicant must convince the patent examiner that his invention meets the statutory requirements; otherwise, a patent will not be issued. When the application is rejected, the applicant will insert limitations and restrictions for the purpose of inducing the Patent Office to grant his patent. When the patent is issued, the patentee cannot disclaim these alterations and seek an interpretation that would ignore them. He cannot construe the claims narrowly before the Patent Office and later broadly before the courts. File wrapper estoppel serves two functions in claim interpretation; the applicant's statements not only define terms, but also set the barriers within which the claim's meaning must be kept. These results arise when the file wrapper discloses either what the claim covers or what it does not cover.

In the prosecution history of the patent in suit, the patentee repeatedly emphasized to the examiner that the '546 patent differed from prior art in that it provided a device, that for the first time, could "accommodate the 'various other objects' that are input by untrained users." Amendment, p. 12, 13. The amendment also referred to language in the '546 patent that distinguishes it from prior art, stating prior art devices relied upon "trained personnel to avoid introducing foreign objects into the machine and thus were not constructed to accommodate a situation in which 'untrained users are likely to empty their personal containers, such as old cans or bottles, directly into the hopper without first inspecting the coins. Thus, lint, tokens, and various other objects will probably accompany the coins into the machine." The referenced passage then adds
"therefore, a method of waste management is necessary to insure that the machine is not damaged during use." The amendment emphasizes that the '546 patent, unlike prior art, has solved the "technical problem" of how to deal with "lint, tokens and other objects that accompany the coins when deposited by untrained users" by disclosing two different cleaning steps in two different areas of the machine. Amendment, p. 14, 17. The amended patent accomplished this asserted distinction of accommodating dirty coins by method and apparatus claims that specify "two steps of cleaning: a step that occurs in the 'first' (coin-receiving) area and a different cleaning step that occurs in a second, different area." Amendment, P. 17. 6

6 The original claim 1 did not provide that it was intended for use by untrained users, nor did it include either cleaning step. The original claim provided:

A method comprising the steps of: receiving from a user in a first location a plurality of coins of arbitrary denominations from a user; sorting said coins into groups, with each group being one of said denominations; determining a total amount of said coins; and dispensing a voucher redeemable in cash or merchandise for a value related to said total amount wherein said value is determined only after said steps of receiving and determining. Amendment, p. 1, 2.

The examiner initially rejected the '546 patent, in part because a prior patent (the De Meyer patent) disclosed an apertured pan which removed waste. To overcome this prior art, the patentee emphasized that the two different cleaning steps in two different locations "successfully addressed" the dirty coin problem. Amendment, p. 14.

Coinstar cannot broadly claim that the term "cleaning" is limited to simply the separation or removal of waste from coins, when it represented to the examiner that its cleaning steps went beyond the prior patent's mere removal of wastes and instead "successfully addressed" and "accommodated" the deposit of dirty coins from untrained users for the first time.

Therefore, based upon review of the claims, specification, and patent prosecution, the court interprets the term "cleaning" as the separation or removal of foreign matter from the coins in a manner that helps to prevent damage to the machine.

iii. "cleaning of semiconductor wafers"

The phrase "cleaning of semiconductor wafers" appears in the preamble of Claims 1 and 57 of the '532 patent. The parties agree, as does the court, that "cleaning of semiconductor wafers" refers to the removal of contaminants from the surface of the wafers.

iv. "treatment of semiconductor wafers"

The phrase "treatment of semiconductor wafers," appears in the preamble of Claims 54, 55 and 58. CFMT asserts that the phrase "treatment of semiconductor wafers" means all aspects of wafer processing, including but not limited to cleaning. Apparently, YieldUP agrees with CFMT's construction of the phrase because YieldUP requests an instruction that "treatment of semiconductor wafers" includes cleaning. Therefore, the court finds that the phrase "treatment of semiconductor wafers" refers to all aspects of wafer processing, including cleaning.
The parties agree that the phrase "cleaning section" has no "ordinary meaning" and must be viewed in light of the patent's specification to exclude structures that the inventor specifically disclaimed. In particular, the inventor disclaimed the use of cloth patches or rags. The parties agree that the term must be construed to exclude a cleaning section which utilizes a separate piece of cloth. They disagree, however, on the length limit and particular construction of the cleaning section.

Michaels asserts that the term "cleaning section" means a thickened integral compressible section attached to the gun barrel cleaning device sized and shaped to evenly contact and clean the inner surface of the gun barrel, and which is ready to use and does not require changing of cloths or patches to use. The phrase "cleaning section" includes foam compressible sections as shown in Figure 1 (elements 26 and 28 aligned with sheath 12) and Figure 4 (elements 26, and 28 detachably coupled to cable 30 via connectors 32 and 34). In another embodiment, the "cleaning section" comprises sections of a fabric sheath folded in on itself, which is shown in Figures 10 and 10A (elements 26, 28, and 48). Col 3, lines 55-61; Col 4, lines 22-25; Col 5, lines 7-9, 25-28, 37-38; Col 7, lines 48-50; Col 7, line 67 to Col 8, line 4; Col 9, lines 8-9; Col 10, lines 38-40. Michaels also asserts that there is no length limit, but the cleaning section cannot encompass the entire device.

Clean Gun proposes that a construction requiring that a short section of the gun barrel cleaning device have an increased diameter, such that the outer surface of the tubular sheath in the cleaning section is pressed firmly and evenly against the inside of the gun barrel as the device is pulled through the inside of the gun barrel, absorbing and removing debris from the inside of the gun barrel. The cleaning section is preceded and followed by sections of the gun cleaning device that have a smaller diameter than the cleaning section and do not press firmly against the inside of gun barrel. The cleaning section is a section of the sheath folded within itself and stitched and must be short in comparison to the gun barrel cleaning device. Abstract; Figs. 10 and 10A; Col 3, lines 24-35; Col 4, lines 30-33; Col 5, lines 7-10, 37-39; Col 6, lines 28-29, 58-63; Col 7, line 67 to Col 8, line 13; Col 9, lines 8-9; prosecution history.

In support of its construction, Clean Gun points to the patent's criticism of long cleaning sections that cause contact between most of the length of the device and the inner surface of the gun barrel:

Some cleaning devices utilize a cord which is pulled through the barrel, and drags a cloth patch, but which does not contain a metal brush feature. These pull-through devices are typically in the nature of a thick woven wick or rope-like cord. Such a wick or rope-like cord contacts the gun barrel along its entire surface. This requires that the resistance along the entire surface of the wick be a fairly low pressure against the inside of a gun barrel. A high pressure would make the wick impossible or difficult to pull through the gun barrel.

Col 3, lines 26-35.

The patent's solution to this problem is explained in a preferred embodiment which uses relatively thin body portions and brush area, and short, relatively thick cleaning sections. Col 7, line 67 to Col 8, line 1-13; Figs. 10 and 10A. With only the short thick sections pressing against the barrel, the patent avoids the criticized problem of applying too much pressure along the entire length of the device. Thus, Clean Gun argues that the patent's cleaning sections were designed to avoid these problems by having short cleaning sections with a relatively larger diameter, but with the remaining portions of the device having a relatively smaller diameter. In this way, the patent's cleaning sections are able to wipe the inner surface of the barrel clean, but the remaining sections are thinner so that they pull more easily through the barrel. All of the figures of the patent, including the elected device in Figures 10 and 10A, disclose this characteristic for a cleaning section.

However, the patent discloses two different ways to make such a short, thickened cleaning section. One type, in the embodiments of Figures 1 and 4, uses a foam insert inside the tubular sheath. The patent's other cleaning section, shown in Figures 10 and 10A, is a thickened section created by folding a sheath within itself and stitching it. As discussed above, this court is unwilling to limit the method claims to Figures 10 and 10A.

Accordingly, the phrase "cleaning section" means a thickened integral compressible section attached to the gun barrel cleaning device sized and shaped to contact evenly when cleaning the inner surface of the gun barrel, and which is ready to
use and does not require changing of cloths or patches to use. It has no length limit, but cannot encompass the entire device, and can include, but is not limited to, a fabric sheath folded in on itself.

The '359 patent has three independent claims at issue; claims one, thirteen and nineteen. All three independent claims contain the following claim limitation: "a cleaning station for . . . automatically draining and cleaning said suction canister after said suction port is disconnected from the vacuum source and said patient port is disconnected from the patient." This limitation describes the function of the cleaning station: draining and cleaning said suction canister. The "cleaning station" claim limitation is written in means-plus-function format and subject to 35 U.S.C. § 112, P 6. Therefore, the structure which drains and cleans the canister must be defined from drawings and descriptions in the specifications. See 35 U.S.C. § 112, P 6. The infringement analysis is controlled by the preferred embodiment, as there are no alternative embodiments presented in the specifications.

The draining and cleaning station claim limitation in the '359 patent has the identical function and result as the Dornoch product. Their function is to drain and clean the canister, and they both result in an empty and cleaned container. However, the process the products utilize is substantially different. The '359 patent completes the drainage process before the cleaning process begins. The drainage process begins when the operator places a full suction canister into the cleaning station and depresses the start button. A housing unit containing two probes automatically descends towards the canister. These probes are inserted into the suction canister, breaking the canister's seal. A drain pump then creates a suction inside the canister, whereupon the fluid inside the canister is pumped up the inner conduit of the main probe and out of the cleaning device to the hospital drainage line. The water pump is then activated by the controller. Water is mixed with cleaning solution and sprayed into the empty canister through the outer conduit of the main probe. The drain pump continues to create a suction and pumps the water mixture up into the probe's inner conduit and out of the cleaning device.

15 Here, "automatically" means without operator involvement.

The Dornoch product has a significantly different process of draining and cleaning its canister from the '359 patent's cleaning station element. The differences include: (1) Dornoch's plunger does not descend automatically, instead the operator pushes a flush jet downward, which in turn pushes the plunger downward and pushes the stopper out of the drain opening; and (2) the Dornoch product does not utilize suction to drain the canister by pumping fluid up a probe. Instead, spray from the flush jets and the plunger create a swirling action which, together with gravitation force, drains the canister. Due to these differences, no reasonable jury could find that the draining and cleaning station element in the '359 patent shares an equivalent method of draining and cleaning with the accused product.

The '822 patent has seven independent claims at issue; claims one, twelve, sixteen, seventeen, eighteen, twenty, and twenty-one. All seven independent claims contain a claim limitation which describes the draining process and/or the cleaning processes. These claims are all written in means-plus-function format, as they describe a function to be performed rather than a definite structure. Claim one's "draining and cleaning" claim limitation states, "a station for draining and cleaning said suction canister, . . . including a probe insertable into said suction canister to alter said indicator portion so as to provide a visual indication . . . that said suction canister has been drained and cleaned." This limitation provides no detail on the how the station cleans and drains, but rather describes the function to be performed. Similarly, claims twelve, sixteen, seventeen, eighteen, twenty and twenty-one contain a "draining station" limitation. This claim limitation describes the function the
station is to perform (draining), but does not detail how that process occurs. Therefore, under 35 U.S.C. § 112, P 6, the specifications control the scope of the "draining" claim limitation.

The specifications for the '822 patent mirror those for the '359 patent. As specified in the discussion of the '359 patent, the draining process for the '359 and '822 patents is materially different from the accused product. Therefore, the accused product's draining device does not infringe on the '822 patent.

The district court construed the term "clear" of independent claim 1 to mean "transparent" or "having the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly." Therefore, the Court construes the "clear" limitation to mean "transparent" or "having the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly," the tubular holder for the reflector must be transparent.

The district court construed the term "clear" of independent claim 1 to mean "transparent" or "having the property of
transmitting light without appreciable scattering so that bodies lying beyond are seen clearly." Order I at 7. Terlep challenges the district court's interpretation arguing that the term should be construed to also cover translucent holders. Terlep contends that the intrinsic record requires only that the word "clear" be construed to permit the passage of light. Brinkmann responds that the district court's construction is correctly informed by the written description, which states that the purpose of the holder is to maximize light output, and that any other interpretation would be inconsistent with the '433 patent. Brinkmann adds that the "translucent" argument was not made to the district court and, thus, was waived.

Claim 1 recites an omni-directional LED lamp that has three elements: an LED; a semi-spherical reflector; and a clear plastic tubular holder. The claim sets forth the positional relation between these elements such that the light emitted from the LED is rendered omni-directional after reflecting off the semi-spherical reflector. See '433 patent, col. 6, ll. 26-27. The reflected light passes through the holder, which holds the semi-spherical reflector. See id. at ll. 24-28. The text of claim 1 and the other claims provide little guidance on the meaning of the term "clear:"

The written description discloses a preferred embodiment in which the LED is surrounded by "tubular canopies" or holders that are made of "clear and pliable plastic material." Id. at col. 3, ll. 58-59. Another embodiment describes a colored lens cover that is made "from clear colored plastic." Id. at col. 5, l. 1. While these passages are not particularly helpful in discerning the meaning of the term "clear," other portions of the written description provide greater guidance. The Background and Prior Art sections state that various techniques for applying diffusion directly to the LED surfaces had been attempted in the past and were unsuccessful in rendering the light emitted from the LED omni-directional. Id. at col. 1, ll. 37-45. The Summary of the Invention section describes the invention as an omni-directional LED lamp that does not use a diffusion lens over the LEDs. Id. at col. 2, ll. 5-7. Implicit in these passages is the distinction between lenses or holders that diffuse or scatter light and those that transmit light without obstruction. The written description is thus consistent with and supports the district court's construction of the term "clear" to refer to holders that are "transparent or [have] the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly." Order I at 7.

Terlep argues that the written description also is consistent with a "translucent" holder because it refers to an embodiment in which "the lens cover … can include a phosphorescent coating which glows when the LED … is on so as to diffuse light evenly over a wide viewing angle and amplify visibility." See '433 patent, col. 5, ll. 54-57. However, the text quoted by Terlep relates to the embodiment of Figures 4A-4C, which does not include a "clear plastic tubular holder" as recited in claim 1, at issue in this case. Because the "lens cover" described supra is not the same structure as the "clear plastic tubular holder," compare id., Figures 4A-4C & col. 5, ll. 54-57, with id., Figure 2A & col. 3, ll. 57-65, Terlep's argument is misplaced. Moreover, there is nothing in the description of the phosphorescent coating embodiment to warrant construction of the term "clear" as it relates to the "clear plastic tubular holder" of claim 1 to include translucent holders.

The prosecution history further supports the district court's construction. On August 9, 1995, the application that issued as the '433 patent was filed. In a February 7, 1996 Office Action, the Examiner, inter alia, rejected claim 1 under 35 U.S.C. § 103(a) as being unpatentable over U.S. Patent No. 5,469,157 to Carpenter et al. in view of U.S. Patent No. 1,198,734 to Ludescher. In a May 6, 1996 Response ("Response"), Terlep amended claim 1 to add, inter alia, "a clear plastic tubular holder." Response at 1. Terlep distinguished the claimed invention from the prior art stating that the prior art disclosed rotating LEDs and LEDS having a top "flattened and … side surface(s) … sandblasted or otherwise roughened to diffuse the light output," whereas the "subject invention did not use any 'flattened' tops and/or 'sandblasted or roughened' sides." Response at 5. Because the "clear plastic tubular holder" limitation helped distinguish the prior art from the claimed invention, the prosecution history supports construing the term "clear" to exclude plastic holders that are translucent or otherwise diffuse the light emitted from the LED. See Seachange Int'l, Inc. v. C-Cor Inc., 413 F.3d 1361, 2005 WL 1523382, at *8 (Fed. Cir. 2005) ("Where an applicant argues that a claim possesses a feature that the prior art does not possess in order to overcome a prior art rejection, the argument may serve to narrow the scope of otherwise broad claim language.").

In construing the claims, the parties have cited several dictionaries. District courts are authorized "to rely on extrinsic evidence, which consists of all evidence external to the patent and prosecution history, including … dictionaries" as one of many claim construction tools. Phillips, 2005 U.S. App. LEXIS 13954, at *37 (internal citations omitted). The dictionary defines "clear" as "giving free passage to light or to the sight: easily seen through: not cloudy, turbid, or opaque." Webster's Third Int'l Dictionary 419 (1993). This definition lists "transparent" and "translucent" as synonyms. The definition also sets forth an express distinction between transparent and translucent: "transparent stresses complete absence of obstruction to vision" and "translucent applies to that which permits passage of light but bars clear and complete vision." Id. The distinction between these synonyms cannot be ignored. See Int'l Rectifier Corp. v. IXYS Corp., 361 F.3d 1363, 1374 (2004)
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

(holding that it was improper for the district court to adopt a definition that was attributed to a synonym of the disputed term while disregarding the distinction set forth in the usage note). Moreover, the distinction mirrors the distinction reflected in the written description and prosecution history between the unobstructed passage of light of the holder of the patented invention and the prior art structures that diffuse light. Here, the district court "attached appropriate weight" to the dictionary definitions in the context of the intrinsic evidence in reaching its construction of the claim term "clear." Phillips, 2005 U.S. App. LEXIS 13954, at *58.

Finally, Terlep argues that to define "clear" so as to exclude "translucent" is to import a functional limitation into the claim. Terlep asserts that "clear plastic tubular holder" is merely a structural limitation and that the district court erred in importing a functional limitation into a structural term. However, Terlep fails to recognize that the construction properly adopted by the district court merely assigned meaning to the claim term "clear" and did not impermissibly import a functional limitation. Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so.").

We conclude that the district court correctly construed the term "clear" to mean "transparent or having the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly," and that nothing in the claims or the written description warranted giving the term "clear" an expansive meaning that would cover "translucent" holders. Because Terlep's "translucent" argument is without merit, we need not consider Brinkmann's additional argument of waiver.

In this case, the parties disagree as to whether the district court correctly performed the first step with regard to the "clip (28)" limitation in claim 1 of the '182 patent. Teleflex contends that "clip (28)" should be construed to mean any device, of any shape, that holds two things together and also performs the functions of being manually insertable into and manually removable from a locked position. Teleflex argues that the claim language does not support the construction applied by the district court, "clip" is defined nowhere in the specification or the prosecution history, and the district court committed a "cardinal sin" of claim construction by importing limitations from the written description into the claims. See SciMed Life Sys., Inc. v. Adv. Cardiovascular Sys., Inc., 242 F.3d 1337, 1340, 58 U.S.P.Q.2D (BNA) 1059, 1062 (Fed. Cir. 2001). Ficosa argues that the district court correctly construed the claim term "clip (28)."

The parties also disagree as to whether the jury correctly performed the second step in the infringement analysis of the '182 patent. Ficosa argues that under the construction of "clip (28)" as determined by the district court, the record lacks substantial evidence on which the jury could have based its finding of infringement. Teleflex argues that under either the district court's construction of "clip (28)" or Teleflex's preferred construction, substantial evidence appears in the record supporting the jury's verdict of infringement.

We address each of the first and second steps of the infringement analysis below. Regarding the first step, we conclude that claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope. Regarding the second step, substantial evidence appears in the record to support the jury's verdict of infringement, and therefore we affirm the district court's denial of Ficosa's motion for JMOL.

A. Claim Construction

The words used in the claims are interpreted in light of the intrinsic evidence of record, including the written description, the drawings, and the prosecution history, if in evidence. Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1331, 59 U.S.P.Q.2d (BNA) 1401, 1407 (Fed. Cir. 2001). The intrinsic evidence may provide context and clarification about the meaning of claim terms. York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2d (BNA) 1619, 1622 (Fed. Cir. 1996). "Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1576.

In the absence of an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning. York Prods., 99 F.3d at 1572, 40 U.S.P.Q.2d (BNA) at 1622. We indulge a "heavy presumption" that a claim term carries its ordinary and customary meaning. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 U.S.P.Q.2d (BNA) 1658, 1662 (Fed. Cir. 2002). The ordinary meaning of a claim term may be determined by reviewing a variety of sources, including the claims themselves, see Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357, 52 U.S.P.Q.2d (BNA) 1029, 1033 (Fed. Cir. 1999), other intrinsic evidence including the written description and the prosecution history, see, e.g., DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1324, 57 U.S.P.Q.2d (BNA) 1889, 1894 (Fed. Cir. 2001), and dictionaries and treatises, see, e.g., Schaefer Fan Co. v. J & D Mfg., 265 F.3d 1282, 1288-89, 60 U.S.P.Q.2d (BNA) 1194, 1199 (Fed. Cir. 2001) (approving district court use of dictionaries to determine ordinary meaning); Maxwell v. J. Baker, Inc., 86 F.3d 1098, 1105, 39 U.S.P.Q.2d (BNA) 1001, 1005 (Fed. Cir. 1996) (citing footwear treatise for definition of shoe "upper"). But in any event the ordinary meaning must be determined from the standpoint of a person of ordinary skill in the relevant art. See Zelinski v. Brunswick Corp., 185 F.3d 1311, 1316, 51 U.S.P.Q.2d (BNA) 1590, 1593 (Fed. Cir. 1999).

Among the intrinsic evidence, "the specification is a always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1576. "One purpose for examining the specification is to determine if the patentee has limited the scope of the claims." Watts v. XL Sys., Inc., 232 F.3d 877, 882, 56 U.S.P.Q.2d (BNA) 1836, 1839 (Fed. Cir. 2000). For example, an inventor may choose to be his own lexicographer if he defines the specific terms used to describe the invention "with reasonable clarity, deliberateness, and precision." In re Paulsen, 30 F.3d 1475, 1480, 31 U.S.P.Q.2d (BNA) 1671, 1674 (Fed. Cir. 1994). Such a definition may appear in the written description, see Intellical, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388, 21 U.S.P.Q.2d (BNA) 1383, 1386 (Fed. Cir. 1992), or in the prosecution history, see Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1576 (citing Hoechst Celanese Corp. v. BP Chem. Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2d (BNA) 1126, 1129 (Fed. Cir. 1996)).

The specification may limit the scope of the claims via other routes. The specification may assist in resolving ambiguity where the ordinary and accustomed meaning of the words used in the claims lack sufficient clarity to permit the scope of the claim to be ascertained from the words alone. See Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1554, 42 U.S.P.Q.2d (BNA) 1737, 1741 (Fed. Cir. 1997), overruled on other grounds by Cybor, 138 F.3d at 1467, 46 U.S.P.Q.2d (BNA) at 1172. The patentee may demonstrate an intent to deviate from the ordinary and accustomed meaning of a claim term by including in the specification expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope. See SciMed, 242 F.3d at 1344, 58 U.S.P.Q.2d (BNA) at 1065.

Likewise, the prosecution history may demonstrate that the patentee intended to deviate from a term's ordinary and accustomed meaning, i.e., if it shows the applicant characterized the invention using words or expressions of manifest exclusion or restriction during the administrative proceedings before the Patent and Trademark Office. "Arguments and amendments made during the prosecution of a patent application and other aspects of the prosecution history, as well as the specification and other claims, must be examined to determine the meaning of terms in the claims." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2d (BNA) 1673, 1676 (Fed. Cir. 1995). In particular, "the prosecution history (or file wrapper) limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452, 227 U.S.P.Q. 293, 296 (Fed. Cir. 1985).

The role of the specification in construing the claims is in dispute in this case. As we have often stated, the claims must be read in view of the specification, see Markman, 52 F.3d at 979, 34 U.S.P.Q.2d (BNA) at 1329, but limitations from the specification are not to be read into the claims, see Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186, 48 U.S.P.Q.2d (BNA) 1001, 1005 (Fed. Cir. 1998). "That claims are interpreted in light of the specification does not mean that everything expressed in the specification must be read into all the claims." Raytheon Co. v. Roper Corp., 724 F.2d 951, 957,
220 U.S.P.Q. 592, 597 (Fed. Cir. 1983). In SRI International v. Matsushita Electric Corp., we explained that our focus must be on the claims:

If everything in the specification were required to be read into the claims, or if structural claims were to be limited to devices operated precisely as a specification-described embodiment is operated, there would be no need for claims. Nor could an applicant, regardless of the prior art, claim more broadly than that embodiment. Nor would a basis remain for the statutory necessity that an applicant conclude his specification with "claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. It is the claims that measure the invention.

775 F.2d 1107, 1121, 227 U.S.P.Q. 577, 585 (Fed. Cir. 1985) (en banc) (plurality opinion).

Ficosa argues that where only one embodiment is disclosed in the specification, claim terms are limited to the embodiment disclosed, citing Toro Co. v. White Consolidated Industries, Inc., 199 F.3d 1295, 53 U.S.P.Q.2D (BNA) 1065 (Fed. Cir. 1999), Wang Laboratories, Inc. v. America Online, Inc., 197 F.3d 1377, 53 U.S.P.Q.2D (BNA) 1161 (Fed. Cir. 1999), and Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 59 U.S.P.Q.2D (BNA) 1865 (Fed. Cir. 2001). A review of these cases and others demonstrates that our precedent establishes no such rule.

In Toro, we considered whether a claim that recited a cover "including" a restriction ring should be construed to require attachment of the ring to the cover. 199 F.3d at 1300, 53 U.S.P.Q.2D (BNA) at 1068-69. The specification described an embodiment showing the ring permanently attached to the cover and listed advantages of permanent attachment: "it automatically restricts the size of air inlet depending upon which operation is being conducted without having the operator manually insert or remove a replaceable ring." Id. at 1301, 53 U.S.P.Q.2D (BNA) at 1069. In our opinion concluding that "including" required attachment, we emphasized that the specification and drawings provided "context" for construction of the claims. Id. We noted that "clear statements of scope" in the specification and prosecution history determined the correct claim construction. Id. at 1302, 53 U.S.P.Q.2D (BNA) at 1070.

In Wang, we construed the claim term "frame" to be limited to "character-based protocols," even though the ordinary meaning of the term could arguably be applied to "bit-mapped protocols." 197 F.3d at 1382, 53 U.S.P.Q.2D (BNA) at 1166. Although we noted that the only system described and enabled in the specification used a character-based protocol, we also noted that the intrinsic evidence did not describe bit-mapped protocols as included in the invention, and a person skilled in the art would not have understood bit-mapped protocols to be included. Id., 53 U.S.P.Q.2D (BNA) at 1165. The applicant during prosecution distinguished the "pel [picture element] level" from the "character level," and presented the invention as involving a character-based system. Id. at 1384, 53 U.S.P.Q.2D (BNA) at 1165. We described the correct approach to the inquiry:

Although precedent offers assorted quotations in support of differing conclusions concerning the scope of the specification, these cases must be viewed in the factual context in which they arose. Whether an invention is fairly claimed more broadly than the "preferred embodiment" in the specification is a question specific to the content of the specification, the context in which the embodiment is described, the prosecution history, and if appropriate the prior art . . .

Id. at 1383, 53 U.S.P.Q.2D (BNA) at 1165.

In Bell Atlantic, we construed the term "modes" to be limited to the three categories described in the specification. 262 F.3d at 1273, 59 U.S.P.Q.2D (BNA) at 1875. Although the term's ordinary meaning may have supported a broader reading, id. at 1269, 59 U.S.P.Q.2D (BNA) at 1871, we found that "the patentees defined the term 'mode' by implication, through the term's consistent use throughout the '786 patent specification." Id. at 1273, 59 U.S.P.Q.2D (BNA) at 1874. We also noted that the claim language and the prosecution history supported this construction. Id., 59 U.S.P.Q.2D (BNA) at 1875. Thus, we construed "modes" based on clear indications throughout the intrinsic evidence. Id. at 1273-74, 59 U.S.P.Q.2D (BNA) at 1874-76.

In sum, the number of embodiments disclosed in the specification is not determinative of the meaning of disputed claim terms. As we explained in CCS Fitness, an accused infringer cannot overcome the "heavy presumption" that a claim term takes on its ordinary meaning simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history. 288 F.3d at 1366, 62 U.S.P.Q.2D (BNA) at 1662. We hold that claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed
meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope.

In this case, nothing in the intrinsic evidence indicates that "clip (28)" should be limited to "a single pair of legs." The language of asserted claim 1 does not support limiting the claim to a "single pair of legs." Neither "single" nor "pair of legs" appears in claim 1. Neither the specification nor the prosecution history includes an expression of manifest exclusion or restriction demonstrating an intent to limit "clip (28)" to a single pair of legs. The term "clip" is not defined in the specification or in the prosecution history, and although the specification describes only one embodiment of the clip, no "clear statements of scope" limit the term "clip" to having a "single pair of legs." Furthermore, the ordinary meaning of "clip" is not restricted to having a "single pair of legs." The expert witnesses for Ficosa agreed that the ordinary meaning of "clip" is broad enough to encompass the accused Ficosa device in this case.

The district court thus erred by importing the "single pair of legs" limitation from the specification into the claim. Instead of using the specification as context, the district court apparently limited the "clip (28)" recited in claim 1 to the embodiment described in the specification. We have "cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification." See Comark, 156 F.3d at 1186, 48 U.S.P.Q.2d (BNA) at 1005 (quoting Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563, 231 U.S.P.Q. 833, 835 (Fed. Cir. 1986)). The specification describes only one embodiment of the claimed "clip (28)," but in the circumstances of this case the record is devoid of "clear statements of scope" limiting the term appearing in claim 1 to having "a single pair of legs." Absent such clear statements of scope, we are constrained to follow the language of the claims, rather than that of the written description. See SRI, 775 F.2d at 1121, 227 U.S.P.Q. at 585. To the extent that the district court construed the term "clip" to be limited to the embodiment described in the specification, rather than relying on the language of the claims, we conclude that the district court construed the claim term "clip (28)" too narrowly. We construe the term "clip (28)" in claim 1 to mean a structure that provides the dual functions of disposing the clip around and holding the female member through the slots in the female member and extending through the slots into the groove in the male member to lock the members together.

"clips" and "cavity clip"

Claims 1 and 6 of the '767 Patent contain the term "clips" and Claim 11 of the '767 Patent contains the term "cavity clip." SHURflo contends that "clips" means "pieces that are capable of holding something (i.e., a portion of a pump in place)," while Defendants contend that "clips" means "devices that are capable of gripping something (i.e., a portion of a pump)." Thus, the parties dispute whether "clips" should be construed to "hold" or to "grip."

SHURflo argues that because the specification states "the clips . . . act to hold the pump," this describes the functionality of the clip to encompass more than just gripping. Defendants contend that the patentee distinguished "clip" from "hold" in the prosecution history, making clear that "clipping" was more specific than just "holding." Defendants cite to the following sentence in the prosecution history: "All of Hess' protruding fingers are guides only; they are not clips that are adapted to hold (i.e., grip or secure) a pump as they must do in a vertically mountable holder." Defendants' Responsive Brief, Exhibit M, at 3. Although the prosecution history is relevant in showing the patentee's use of the words "grip" and "hold" with respect to the word "clip," a disclaimer of claim scope is not clear and unmistakable and thus, the doctrine of prosecution disclaimer does not apply in this case. See Computer Docking Station Corp., 519 F.3d at 1374. Defendants further assert that SHURflo's proposed construction exceeds the ordinary and plain meaning of "clips" and broadly encompasses any pieces capable of holding something in place such as a "hook" or a "pin." The specification discloses several mechanisms for holding--"pin," "clip," "hook," etc. Because these different elements are claimed as separate structures in the patent, SHURflo's proposed construction for "clips" is clearly too broad.

Further, although Defendants' proposed construction is truer to some "clip" embodiments, the specification also discloses a "clip" embodiment that holds something by pushing against it. For example, the cavity clip 20 in Figure 5 of the '767 Patent, produced below, holds the pump 50 by pushing against it. The pushing embodiment is also consistent with the ordinary meaning of "clips," which are sometimes configured like the specification's cavity clip (e.g., a clip board). Accordingly, the Court construes the term "clips" to mean "devices that assist in holding something by gripping it or pushing against it."
With respect to the term "cavity clip," the parties recognize that a "cavity clip" is a "clip" located within a cavity, but disagree both as to the cavity clip's function and whether the item being held by the clip must also be within the cavity. SHURflo contends that the term "cavity clip" means "a piece in the hollow portion of the housing that is capable of holding something," while Defendants contend that the term means "a device that grips something (i.e., a pump) in place within a cavity." Defendants argue that SHURflo's proposed construction fails to specify that both the cavity clip and the something (i.e., a pump) that is being gripped must be within the cavity. Defendants' Responsive Brief, at 21. In view of the specification and Figure 5 of the '767 Patent, it is apparent that the "cavity clip" is a clip within the cavity. However, the specification does not disclose that the entire item being gripped must also be within the cavity. Indeed, the claim language specifically claims a "cavity clip being adapted to hold the received portion of the pump in the cavity." '767 Patent, col. 8:67 & col. 9:1-2 (emphasis added). Thus, any construction requiring that the whole clipped item exist in the cavity would be more narrow than the claim, which merely calls for a "portion" to reside in the cavity. Accordingly, the Court construes "cavity clip" to mean "a device within a cavity that assists in holding something by gripping it or pushing against it."

The central issue is whether the Eastman Carbon Venture Blind has a "closable vertical opening," as required by the nine claims of the '338 Patent. Claims 1 and 7 are the independent claims of the patent. Claim 1 reads:

1. A portable and collapsible blind or shelter structure comprising:

   (a) a flexible fabric cover having four side walls and a top; wherein each side wall includes at least one window opening; wherein each said side wall includes opposite side edges and a top edge; wherein side edges of adjacent side walls are integral with each other; and further including a closable vertical opening along one of said side edges; wherein the perimeter of each side wall and the top is non-stretchable; and

   (b) a framework comprising five support members; wherein each side support member comprises four resilient leg members hingedly connected at one end to a central hub; wherein one said support member engages and supports said top; and wherein said leg members connected to each said hub can be pivoted towards each other to collapse said structure.

   ('338 Patent, col. 4, 11. 2-21). Claim 7 reads:

7. A portable and collapsible blind or shelter structure comprising:

   (a) a flexible, integral fabric cover having four generally-square side walls and a top; wherein each side wall includes at least one window opening; and further including a closable vertical opening along one vertical corner of said structure; wherein the perimeter of each side wall and the top is non-stretchable; and

   (b) framework comprising five support members; wherein each said support member comprises four resilient leg members hingedly connected at one end to a central hub; wherein one said support member engages and supports a respective side wall in a taut condition; wherein one said support member engages and supports said top; and wherein said leg members connected to each said hub can be pivoted towards each other to collapse said structure.

   ('338 Patent, col. 4, 11. 36-52). Claims 2-6 depend on claim 1. Consequently, those claims are limited by the term "a closable vertical opening along one of said side edges." Claims 8 and 9 depend on claim 7 and are limited by the term "a closable vertical opening along one vertical corner of said structure."

The plaintiff and defendant dispute the meaning of these claim limitations. The plaintiff contends that these phrases encompass an opening of any shape having a predominately vertical dimension which is positioned along or adjacent to a side edge or vertical corner of the structure. According to the plaintiff's construction, this claim language would cover a triangular flap extending into one side wall, so long as one side of the triangle is positioned along one side edge or vertical corner of the structure. The defendant disputes that interpretation, arguing that the claim language, the specification, and the prosecution history show that a "closable vertical opening" means "a slit-like opening that runs straight up and down or
perpendicular to the horizon." Eastman further asserts that the ordinary meaning of "along one of said side edges" is "over the length of or on a line or course parallel and close to one of the side edges of the blind," and that the ordinary meaning of "along one vertical corner of said structure" is "over the length of or on a line or course parallel and close to the vertical line formed where two side walls of the blind meet at an angle."

"It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996); see also Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The words of the claims are of primary importance. Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc); Vitronics, 90 F.3d at 1582 (Fed. Cir. 1996). "[T]he words of a claim 'are generally given their ordinary and customary meaning.' Phillips, 415 F.3d at 1312 (quoting Vitronics, 90 F.3d at 1582). "[T]he ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips, 415 F.3d at 1313.

Eastman submitted the declaration of Mr. Jeffrey A. Pestrue, its chief engineer. Mr. Pestrue is person with expertise in the design, development and production of hunting blinds, and he stated that the phrase "closable vertical opening" has no special meaning in the hunting blind industry. (Pestrue dec. P 5). There is no other evidence on this point.

Resolution of this claim construction dispute involves the application of commonly understood words. The parties have focused attention on the meaning of the word "vertical." "The common-sense understanding of 'vertical' or 'vertically' is that those words convey a sense of perpendicularity with respect to the surface of the earth." Laser Diode Array, Inc. v. Paradigm Lasers, Inc., 114 F.Supp.2d 167, 172 (W.D.N.Y. 2000). General purpose dictionary definitions, which are a type of extrinsic evidence, may be considered in the context of the intrinsic evidence. See Phillips, 415 F.3d at 1314-19. The plaintiff cites Merriam-Webster's Collegiate Dictionary (10th ed. 1998) which includes the following definitions: "perpendicular to the plane of the horizon or to a primary axis: UPRIGHT … lying in the direction of an axis: LENGTHWISE." That source also states, "Vertical suggests a line or direction rising straight upward toward a zenith."

When construing claims, "the context in which a term is used in the asserted claim can be highly instructive." Phillips, 415 F.3d at 1314. In the disputed phrases, "vertical" modifies "opening." This context means that the opening itself must extend lengthwise, in a direction that is straight up and down or perpendicular to the plane of the horizon.

The claim language also requires that the closable vertical opening be along one of the side edges (claim 1) or along one vertical corner of the structure (claim 7). The position of the opening is described throughout the patent. The abstract states: "One corner of the structure includes a vertical opening to permit ingress and egress from the structure." The following statement appears in the summary of the invention: "An openable doorway is positioned vertically at one corner of the blind or shelter to enable ingress and egress. Closure means such as a zipper is used to close the opening." ('338 Patent, col. 2, II. 13-15). The following statement appears in the detailed description of the invention:

A zipper is incorporated in one corner of the structure where two side walls meet. The zipper is stitched in place with non-stretchable thread. The leg members must flex in order to enable the door opening to expand for ingress and egress. When the zipper is in an open position, the fabric adjacent to the opening can be pulled slightly away from the opening (which results in widening of the opening as the pegs flex.)

(Col. 3, II. 28-35). In Figure 1, a vertical slit-like opening positioned at the corner of the blind is shown as element 5. No other type of opening is mentioned in the patent.

The patent's prosecution history is also informative. The application claims were allowed without amendment. The Notice of Allowability included the following Examiner's Statement of Reasons for Allowance:

The primary reason for the allowance of the claims is the claimed foldable tent structure having a cover which includes a top wall and 4 side walls and a zipperred vertical opening at a cornered side edge, 5 frame members each has four resilient legs hingedly connected at one end to a central hub; each frame member engages and supports a respective side wall and the top wall in a taut condition; each leg is pivotable at the hub toward each other to collapse the tent structure. Said tent structure is not shown or taught by the prior art of record.
(Def's Ex. A-2). This statement demonstrates that the Examiner considered a vertical opening positioned at a cornered side edge to, be a distinguishing feature of the invention. Among the prior art patents cited as references in the '338 Patent are U.S. Patent No. 3,810,482 to Beavers (the "482 Patent") and U.S. Patent No. 4,819,680 to Beavers ("the '680 Patent"). These patents disclose a cube-shaped collapsible tent structure having a hub-style framework similar to that of the plaintiff's invention. One of the few distinctions between the plaintiff's invention and these prior art patents is that the plaintiff's invention has a vertical opening at a cornered side edge.

The plaintiff has provided the declaration of Rex E. Paulsen, Ph.D., P.E. Mr. Paulsen is a registered professional engineer and has some expertise relating to collapsible tents and patents. Mr. Paulsen's declaration constitutes extrinsic evidence, a category that is less significant than the intrinsic evidence. See Phillips, 415 F.3d at 1317. Mr. Paulsen's declaration suffers from errors and deficiencies and is not useful in ascertaining the meaning of the disputed terms. In his discussion of the prosecution history, Mr. Paulsen dismissed the significance of Examiner's Reasons for Allowance without any review of the prior art. Where he did address the '482 Patent, Mr. Paulsen mistakenly stated that the '482 Patent shows a three-sided tent, whereas the specification of the '482 Patent expressly states that the invention is not limited to a structure having three sides and a top. See '482 Patent, col 3, 11. 24-38 ("The frame 12 comprises a minimum of four and a maximum of six nearly identically constructed subframe assemblies ... [in the preferred embodiment] the subframe assemblies which could be positioned in the entryway 18 as well as in the floor area are both left out."). Figure 2 of the '482 Patent shows a tent having four side walls and top, with a triangular entryway in one of the side walls. A similar drawing is shown in the '680 Patent. Mr. Paulsen failed to appreciate the full teachings of the Beavers patents and other references cited in the '338 Patent.

The language of the '338 Patent claims, the specification, and the prosecution history support the construction urged by Eastman. The term "a closable vertical opening" means "a slit-like opening that runs straight up and down or perpendicular to the plane of the horizon." "Along one of the side edges" means "over the length of or on a line or course parallel and close to one of the side edges of a wall of the blind." "Along one vertical corner of said structure" means "over the length of or on a line or course parallel and close to the vertical line formed where two side walls of the blind meet at an angle." We agree with the district court that the term "a closable vertical opening" is properly construed as "a slit-like opening that runs straight up and down or perpendicular to the plane of the horizon." See, e.g., Ameristep, 2007 U.S. Dist. LEXIS 5436, 2007 WL 219961, at *5.

When construing claims, a court must begin by "look[ing] to the words of the claims themselves ... to define the scope of the patented invention." Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)). Words of a claim "are generally given their ordinary and customary meaning" as understood by a person of ordinary skill in the art in question. Id. at 1312-13. For this reason, "claims must be read in view of the specification, of which they are a part." Id. at 1315 (internal quotations omitted). Hence, the specification "is the single best guide to the meaning of a disputed term." Id. "In examining the specification for proper context, however, this court will not at any time import limitations from the specification into the claims." CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1231 (Fed. Cir. 2005) (citing Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1326 (Fed. Cir. 2002)).

The district court concluded, based on expert testimony that Stumbo does not dispute on appeal, that the phrase "closable vertical opening" does not have any special meaning in the hunting blind industry. See, e.g., Ameristep, 2007 U.S. Dist. LEXIS 5436, 2007 WL 219961, at *3. Stumbo does not contest the common sense meaning of "vertical," defined as "perpendicular to the plane of the horizon or to a primary axis." Merriam-Webster's Collegiate Dictionary (10th ed. 1998). Rather, Stumbo contends that the district court misapplied the word "vertical" to the slit-like shape of the opening in the blind instead of to its orientation. In other words, according to Stumbo, the word "vertical" limits the opening only to shapes.
that are taller than wide. Under Stumbo's definition, a "vertical opening" would cover any shape of opening--i.e., rectangular, oval, or triangular--as long as the vertical height of the opening was greater than the horizontal width. The claims of the '338 patent read in light of the specification do not support such assertions.

Starting with the text of the claims, the phrases "along one of said side edges" in claim 1 and "along one vertical corner of said structure" in claim 7 are used to describe the word "opening" separately and in addition to the word "vertical." Therefore, construing the word "vertical" as referring to merely the orientation of the opening would render the phrases "along one of said side edges" and "along one vertical corner of said structure" superfluous, a methodology of claim construction that this court has denounced. Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."); see also Bicon, Inc. v. Straumann Co., 441 F.3d 945, 950 (Fed. Cir. 2006); Cross Med. Prods., Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293, 1307 (Fed. Cir. 2005). Only if "vertical" refers to the shape of the opening instead of redundantly to the orientation of the opening would each claim term have a distinct meaning.

That the word "vertical" refers to the slit-like shape of the opening is further supported by the specification of the '338 patent. The written description explicitly states that:

> [a] zipper is incorporated in one corner of the structure where two side walls meet. . . . The leg members must flex in order to enable the door opening to expand for ingress and egress. When the zipper is in an open position, the fabric adjacent to the opening can be pulled slightly away from the opening (which results in widening of the opening as the pegs flex).

'338 Patent col.3 ll.29-36 (emphasis added). The fact that the leg members must flex to enable entry and exit indicates that the opening in the '338 patent is a slit. Triangular loose door flaps, such as the openings in the accused products, certainly would not require leg members to flex.

In support of his construction, Stumbo points to the summary of the invention, which reads "an openable doorway is positioned vertically at one corner of the blind or shelter to enable ingress and egress." Id. col.2 ll.13-15. This sentence does not support Stumbo's proposed construction. An entry and exit pathway positioned along the side edges or vertical corners of a cube-shaped blind will necessarily be vertically positioned.

Stumbo also relies on CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359 (Fed. Cir. 2002), to argue that the district court improperly imported a limitation from the specification into the claims. CCS Fitness involved the construction of the claim term "reciprocating members," used to describe the longitudinal structures that facilitate the reciprocating elliptical motion of the footpads on a stationary exercise device commonly known as the elliptical trainer. Though the district court noted that nothing in the claims, specification, or prosecution history of the patent indicated what shape these structures had to take, it reasoned that the figures of the claimed invention illustrated the reciprocating members as single-component straight bars only and restricted the claim term as such. Id. at 1364. On review, we determined that the district court had erred. The drawings merely illustrated a particular embodiment, as the specification never required a certain number of components or shape for the reciprocating members. Id. at 1367. Because nothing in the intrinsic evidence narrowed the sub-structures encompassed under "reciprocating members," we concluded that the claim term covered all possible configurations, including a multi-component, curved beam or lever. Id.

By contrast, the specification of the '338 patent inherently requires a slit-like shape for the opening. The specification explicitly discloses that the "legs must flex in order to enable the door opening to expand for ingress and egress." 338 Patent col.3 ll.31-36. The fabric adjacent to the opening is then pulled slightly away from the opening, which results in a widening of the opening. Id. A linear slit is the only fathomable shape of an opening with the described characteristics. Figure 1, the only figure of an opening in the '338 patent, illustrates a vertical slit-like opening, further supporting this construction. Id. fig.1. There is nothing in the specification to suggest that the patentee contemplated that any other shape of opening could work with this invention.

In sum, the district court correctly interpreted the claims in the context of the claim language and the specification.
2. "In close proximity to" is construed to mean "near or close to."

B. 863/475 Patents. Only one term in these patents requires interpretation. The claim language requiring interpretation states: "a plurality of selectively removable mulcher baffles which close said throat portions to define a substantially cylindrical mulching chamber around each of said cutting blades." Filing No. 61, Ex. A, col. 6, lines 32-35, col 8, lines 1-4 ('475 patent); Ex. B, col. 6, lines 57-59, col. 8, lines 34-36 ('863 patent). At issue is the phrase "close said throat portions."

Toro contends that the phrase is an unambiguous functional description of what the removable mulcher baffles do: they "close the space between the first and second flow control baffles so that grass clippings are generally confined to the defined area of the cutting chamber for each cutting blade of the mower." Plaintiffs' Markman Brief at 25-26. By closing the throat portions, the pair of Y-shaped mulcher baffles defines a cylindrical mulching chamber around each blade. Neither the claims nor the prosecution history limit the height of the removable mulcher baffles.

Scag, for its part, moves beyond the language of the patent claims to consider how high the removable mulcher baffles must be to "close" the throat portions between the fixed front and back flow control baffles. Scag maintains that the claim language, as written, requires a removable mulcher baffle to close off the throat portion -- regardless of its height in relation to other baffles. Scag contends that the height issue arises because Exmark allegedly failed to disclose to the PTO its prior art removable mulcher baffles found in a mulching accessory. Toro, for its part, insists that Exmark did not disclose to the PTO the details of the prior art mulching accessory because its structure was different than the structure claimed in the '475 patent: the mulching accessory's removable mulching baffles could not "close" the throat portions since they were lower than the rear bird wing baffles. Toro's Brief in Support of Its Motion for Preliminary Injunction at 7, 10.

Pointing to Figure 3 of the '863/475 patents, Scag argues that the removable mulcher baffles in the patents are still lower than the rear bird wing baffles. Consequently, Scag says that the mulcher baffles cannot "close" the throat portions as required by the patents' claims. Scag therefore insists that the claims as written must be interpreted to mean that the removable mulcher baffles close the throat portions no matter what size they are in relation to the rear baffle.

I agree with Toro that the precise height of the removable mulcher baffles has nothing to do with their function when placed between the fixed front and back flow control baffles. The goal of a Markman hearing is to interpret claim language, not to make rulings about a patent's validity based on prior art. I here determine whether the removable mulcher baffles function to close the throat portion, not whether Exmark's prior art mulching kit also had removable mulching baffles that did or did not close the throat portions, and not whether the removable mulcher baffles claimed in this patent work correctly to close off the throat portions. Scag is free to raise the latter issues in a summary judgment motion or at trial when matters of validity are more properly addressed.

Accordingly, I adopt Toro's proposed definition: the phrase "close said throat portions" means that the removable mulcher baffles close the space between the first and second flow control baffles so that grass clippings are generally confined to the defined area of the cutting chamber for each cutting blade of the mower.

I.

Pactiv is the assignee of the 143 patent, which relates to a zipper profile for opening and closing plastic bags. The patent describes and claims a "rolling action zipper profile" that closes a bag, point by point, as a plastic U-shaped slider moves the zipper across the bag. 143 patent, col. 1, ll. 6-11. The moving action presses a male rib element together with a female groove element at the bottom of the profile and then "roll[s]" the profile closed toward the top. Id. at col. 5, ll. 16-21. The
exact same sequence in reverse opens the bag. A series of figures from the 143 patent depicts the rolling and interlocking of the male rib and female groove elements.

GET DRAWING SHEET 2 OF 3.

Viewing Figures 5-7 sequentially as the zipper moves across the profile at a single point on the bag, as the profile begins to close (figure 5), 1 a part of the fastener apparatus called the "separator finger" (23) holds the top of the profile open while the slider's "shoulders" (21 and 22) push the bottom of the profile together. 143 patent, col. 5, ll. 61-66, Fig. 5. Meanwhile, this pushing action causes a realignment so that the rib (16) moves partially into the groove (17). Id. at Col. 6, ll. 8-10, Fig. 5. Then, as seen progressively from Figure 5 to 6 to 7, as the separator finger (23) becomes smaller, the groove element (17) rotates counter-clockwise until the rib (16) and groove (17) elements are interlocked and the profile is closed.

--- Footnotes ---
1 Figure 4 shows the profile completely open, as the rib element (16) is not connected to the groove element (17).
--- End Footnotes ---

Claim 1 of the 143 patent (with the crucial claim language emphasized) reads in pertinent part as follows: 2

A plastic reclosable fastener with slider particularly suited for thermoplastic bags and the like comprising a pair of flexible plastic strips having separable fastener means extending along the length thereof comprising reclosable interlocking male and female profile elements on the respective strips, said strips including profiled tracks extending along the length thereof parallel to the male and female elements, said male and female elements having complementary cross sectional shapes such that they are closed by pressing the bottom of the elements together first and then rolling the elements to a closed position toward the top thereof . . . .

Col. 6, ll. 53-64. SCJ's accused Slide-Loc bag has a U-shaped profile and a "plastic reclosable fastener" with at least one pair of interlocking rib and groove elements (the Slide-Loc has two rib and groove elements).

--- Footnotes ---
2 Though Pactiv asserts that SCJ's accused Slide-Loc bag infringes numerous claims of the 143 patent, the presence of the critical element requiring "rolling" appears in all but one of the asserted claims, which instead includes the phrase "rolling action." Neither party has asserted that the terms "rolling" and "rolling action" have different meanings.
--- End Footnotes ---

On November 12, 1999, the district court issued an order construing, inter alia, the claim term "rolling." See Tenneco Packaging Specialty & Consumer Prods., Inc. v. S.C. Johnson & Son, Inc., 1999 U.S. Dist. LEXIS 17937, No. 98 C 2679 (N.D. Ill. 1999) (claim construction order). After considering and rejecting the alternative definitions proffered by the parties, the district court relied on the patent specification and the term's ordinary meaning to construe "rolling" to mean "a rotational motion which is achieved because of the shape of the elements and because of the materials from which the elements are made, i.e., flexible plastic." Id.

Based on the district court's construction of the term "rolling," SCJ moved for summary judgment of non-infringement, while Pactiv filed a cross-motion for partial summary judgment of infringement. Ruling on the motions, the district court compared the rolling limitation, as construed, to the accused Slide-Loc bag and concluded, as a matter of law, that SCJ's product did not infringe the 143 patent either literally or under the doctrine of equivalents. Pactiv Corp. v. S.C. Johnson & Son, Inc., No. 98 C 2679 (N.D. Ill. 2000) (order granting summary judgment of non-infringement).

Instead of framing the infringement inquiry as whether the accused Slide-Loc bag exhibits "rolling" at some point during the closing process, the district court sought to determine whether the rib and groove elements in the accused device are "closed . . . by rolling." 143 patent, col. 6, ll. 63-64. After viewing computer animations depicting the closing of the accused device and considering the opinions of the parties' experts, the court determined that any rolling that satisfies the definition
noted above is "incidental" to the process of closing the Slide-Loc bag. Pactiv Corp. v. S.C. Johnson & Son, Inc., 2000 U.S. Dist. LEXIS 18877, No. 98 C 2679 (N.D. Ill. 2000). The court found that the testimony offered by Pactiv's experts described two types of rotational movement in the accused device. The first type of rotation consists of an arcing movement that necessarily occurs as a result of the Slide-Loc closing from the bottom of the zipper profile to the top. According to the district court, this tracing of an arc, which positions the rib and groove elements next to each other, "is outside the definition of the claim term as determined by the court." Id. The second type of rotational movement occurs after the rib element both deforms and enters the groove. That occurs when the groove rotates counterclockwise and returns to its original shape and the rib rotates downward to engage the groove and "settles into its final closed position." Id. The district court appeared to agree that this rotational motion occurs because of the shape of the rib and groove elements and because of the materials from which they are made and that the motion thus may fit within the definition of the claim term "rolling." The court determined, however, that the incidental nature of the rolling to the closing process precluded a finding that the "Slide-Loc device closes by rolling as that term is used in the 143 patent." Id. Simply put, since a device that rolls only incidentally in the closing process does not close by rolling, as the 143 patent requires, the district court held that the Slide-Loc bag does not infringe the patent literally as a matter of law.

As for infringement under the doctrine of equivalents, the district court applied the familiar standard that "the claim element and accused component 'perform substantially the same function in substantially the same way to achieve substantially the same result.'" Id., quoting Kraft Foods, Inc. v. Inl'l. Trading Co., 203 F.3d 1362, 1371, 53 U.S.P.Q.2D (BNA) 1814, 1820 (Fed. Cir. 2000). The district court determined that because the Slide-Loc bag does not close by the rolling process described in the 143 patent, it necessarily does not close in substantially the same way as the claimed device.

II.

Pactiv argues that the district court made two crucial errors in reaching the conclusion that the Slide-Loc bag does not infringe the 143 patent. First, it contends that the district court improperly added a limitation to the claims by requiring that "rolling" be non-incidental to the closing process. Such a construction, according to Pactiv, erroneously reads an unstated limitation into the claims in contravention of this court's settled precedent. See N. Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1290, 55 U.S.P.Q.2D (BNA) 1065, 1072 (Fed. Cir. 2000). Second, Pactiv contends that irrespective of the presence of a non-incidental rolling requirement, the district court misapprehended the computer animations depicting the Slide-Loc's closing process and ignored Pactiv's expert testimony, both of which present substantial evidence of literal infringement and infringement under the doctrine of equivalents, so as to preclude a grant of summary judgment in favor of SCJ. We address these arguments in turn.

First, we do not agree that the district court improperly imported a limitation into the claims. On the contrary, we believe the non-incidental closing requirement follows clearly from the "closed . . . by rolling" language of the claims. 143 patent, col. 6, ll. 63-64. As the district court properly recognized, claim construction does not involve interpreting the claim language as a series of disjointed words. Instead, viewed in their proper context, the claims not only require the presence of rolling, but also that the profile be "closed . . . by rolling." Id. The non-incidental rolling requirement gives meaning to this claim limitation; the district court properly construed the claim in accordance with its plain language. 3

3 We also reject Pactiv's argument that the "such that [the elements] are closed . . . by rolling" language contains an open transition phrase ("such that"), thus permitting the profile to close by rolling as well as other methods. 143 patent, col. 6, ll. 63-64. Even if other motions, including snapping and deformation, may be present in the claimed invention, the open language does not obviate the requirement that the profile be "closed . . . by rolling." Simply put, an open-ended transition "does not free the claim from its own limitations." Kustom Signals, Inc. v. Applied Concepts, Inc., 264 F.3d 1326, 1332, 60 U.S.P.Q.2D (BNA) 1135, 1139 (Fed. Cir. 2001).
The district court construed the term "a closed chamber . . . adapted to retain a quantity of fluid" to mean "an enclosed cavity, or some other enclosure or system of enclosures, which is capable of being sealed or set apart from its surroundings to retain a quantity of fluid." SJ Order, 2008 U.S. Dist. LEXIS 109423 at *32. The district court arrived at this construction by referring to Figure 28 of the Besemer application. The district court created the following markup of Figure 28 to demonstrate its understanding of the "closed chamber":

Id. at 20. As the above figure shows, the district court concluded that the claimed closed chamber includes not only the cavity 310, but also "containers 2810 and 2820, and associated tubes." Id. at 18. Agilent challenges two aspects of the district court's construction.

A.

First, Agilent argues that the district court erroneously interpreted "a closed chamber" to mean a "system of enclosures." According to Agilent, the term is defined by the language of the claim itself, and should mean "the space between the inner surfaces of the first and second substrate, wherein at least one of the inner surfaces is functionalized." Appellant's Br. 43.

This court reviews a district court's claim construction without deference. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1451 (Fed. Cir. 1998) (en banc). This court generally assigns claim terms their ordinary and customary meanings, according to the customary understanding of a person of ordinary skill in the art who reads them in the context of the intrinsic record. See Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005) (en banc). "[T]he claims themselves provide substantial guidance as to the meaning of particular claim terms." Id. at 1314.

The claim language in this case makes the district court's definition dubious. The district court's definition includes a "system of enclosures." The claim itself recites a closed chamber "define[d]" by "a first substrate and a second substrate having inner surfaces." Thus, the claim requires that the chamber be bounded by two discrete substrates. The chamber is not a nebulous space that could ambiguously span a "system of enclosures." Instead, it is an enclosure explicitly defined by two surfaces.

The specification further impeaches the trial court's definition. As discussed above, the district court erred by looking to the Besemer specification to derive this claim term's meaning. Because the specification "is the single best guide to the meaning of a disputed term," Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996), this was an error of no small consequence. The "closed chamber . . . " term should have been construed in light of Schembri's specification, which consistently uses this term to refer simply to the space between a first and second substrate. As the Summary of Invention section states:

The invention, in one embodiment, is an apparatus for mixing a film of fluid, particularly a chemical, biochemical, or biological fluid which typically comprises a reaction mixture, the apparatus comprising a first substrate having an inner surface and a substantially parallel second substrate having an inner surface that defines a closed chamber therebetween. The closed chamber is adapted to retain a quantity of fluid so that the fluid is in contact with both inner surfaces.

Schembri Patent col.2 II.44-52 (emphasis added). Indeed, the closed chamber is "define[d]" by two substantially parallel substrates with inner surfaces. Id. The Schembri specification provides no indication that a closed chamber is a "system of enclosures." Rather, it is an enclosure.

Consistent with the disclosure's focus on a method of mixing precise quantities of fluid, Schembri indicates at many points that the closed chamber is an interstitial space defined by two surfaces in which nucleated bubbles move in response to a temperature gradient to achieve mixing. See, e.g., id. col.6 II. 36-38 ("a second substrate 11 . . . is placed on top of the seal where the substantially parallel substrates define a closed chamber"); id. col.6 II.38-41 ("The closed chamber may be a micron to several millimeters in thickness, preferably from about 5 microns to about 100 microns in thickness."); id. col.7 II.9-15 ("The apparatus having closed edges, shown in FIG. 3, may additionally include a seal 15 between the two opposing inner surfaces . . . The apparatus preferably includes an opening in one of the substrates or in the seal for introducing fluid into the closed chamber.").

Moreover, the district court's interpretation ignores, or at the least frustrates, the explicit requirement that "at least one of
said inner surfaces is functionalized with [probe materials].” This language requires that probes attach to at least one (possibly both) of the chamber's two substrate surfaces for hybridization. Under the district court's 2008-1466 13 "system" definition, however, it makes little sense to speak of a hybridization chamber with only two microarray chamber substrates, let alone functionalizing "at least one" of these two substrates. In this context, if a chamber really means several chambers, the Schembri specification provides no guidance as to where, amongst the several chambers, the first and second substrates are located. Indeed, the Schembri patent uniformly teaches that a closed chamber is simply an enclosure formed by two substrates, at least one of which is functionalized. Thus, for various reasons, this court rejects the district court's expansive interpretation of "closed chamber." Instead the language of the claim and specification defines the chamber.

B.

Agilent further argues that the district court erred by construing a "closed chamber . . . adapted to retain a quantity of fluid" to mean a chamber that is "capable of being sealed or set apart from its surroundings to retain a quantity of fluid." As per Agilent, a "closed chamber" is a "chamber from which there is no egress of fluid." Appellants' Br. at 47.

Again, this court finds error in the district court's construction. A "closed chamber . . . adapted to retain a quantity of fluid" must mean something different than just a "chamber . . . adapted to retain a quantity of fluid." Otherwise, the word "closed" becomes superfluous. See Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."); Mangosoft, Inc. v. Oracle Corp., 525 F.3d 1327, 1330-31 (Fed. Cir. 2008) (rejecting claim construction that "ascripts no meaning to the term . . . not already implicit in the rest of the claim."). At best, the district court's construction equates the term "closed" with "closable," contrary to the plain language of the claim.

Notably, the district court explicitly recognized that the ordinary meaning of "closed" in the context of a fluid retention chamber is simply "not open" or "sealed." SJ Order, 2008 U.S. Dist. LEXIS 109423 at *19. A sealed chamber does not allow fluid to escape. However, the district court compromised this ordinary meaning out of a need to harmonize its own assumptions that a) the claims should be construed in light of the Besemer application, and b) a "closed chamber" can be a "system of enclosures." No doubt, the various enclosures (containers, valves, channels, etc.) of Besemer's agitation systems are not always closed or sealed. But, as discussed above, Schembri, not Besemer, is the proper reference point for claim construction, and a "closed chamber" is not a system of enclosures.

In Schembri's disclosure, the closed chamber is not merely capable of being set apart from its surroundings - it is in fact set apart. Indeed, the hybridization chamber, once closed or sealed, allows no fluid to escape. At column 6, Schembri teaches that "a seal 15 can be attached to the outer periphery of the substrate, thus creating a chamber for the fluid with a defined thickness." Schembri Patent col.6 II.28-30. At this point in the explanation, the patent describes only a "chamber" that is capable of retaining a film of fluid. Next, however, "a second substrate 11, or a simple glass cover slip is placed on top of the seal where the substantially parallel substrates define a closed chamber 16." Id. col.6 II.36-38 (emphasis added). Thus, whereas a hybridization "chamber" is formed by attaching a seal to the substrate, that chamber becomes "closed" once another substrate is placed over the seal. This teaching of closing a chamber is repeatedly discussed in each example provided in Schembri. See id. col.7 II.49-53; col.8 II.20-25; col.8 II.53-55.

Thus, this court reverses the district court's construction, which was not grounded in the right disclosure and did not honor the customary meaning of the claim language to one of skill in the art. The proper meaning of a "closed chamber . . . adapted to retain a quantity of fluid" is "an enclosed cavity defined by the inner surfaces of the first and second substrates, from which there is no egress of fluid."

717

c. "in a closed circulation process stream"

The phrase "in a closed circulation process stream" appears in Claims 1, 19, 20, 22 and 23 of the '123 patent, CFMT asserts that the phrase refers to the flow of process fluids in a closed manner into a vessel from a source, or inlet, and out of a vessel through a drain, or outlet. CFMT argues that the term "circulation" does not require that fluids travel in a complete loop or circle, or that they re-circulate. YieldUP, on the other hand, contends that the phrase "in a closed circulation process stream"
requires that the process fluids move in a circle.

The language of the independent claims in the '123 patent does not require movement of fluid in a circle. The '123 patent, however, includes dependent claims, such as Claims 2 and 11, that require "recirculation" or "recycling" of process fluids. The broader independent claims cannot properly be construed to include the limitation of re-use or recirculation of process fluids, when those additional limitations are set forth in dependent claims. See United States v. Teleelectronic, 857 F.2d 778, 783 (Fed. Cir. 1988) (holding that construction of a claim that renders another dependent claim superfluous is presumptively unreasonable). As advocated by CFMT, the court finds that the phrase "in a closed circulation process stream" refers to the flow of process fluids in a closed manner into a vessel from a source, or inlet, and out of a vessel through a drain, or outlet, but the phrase does not require that fluids travel in a complete loop or circle, or that they re-circulate.

1. "A generally cylindrical housing closed on one end and open on its other end"

Plaintiffs contend that the base of the accused devices, the Morton and TRW driver's side inflators, is the "housing" required by claim 1 of the '715 patent. Plaintiffs argue that "closed" means sealed to the passage of gases and, when the accused device is assembled, the base is sealed to the flow of gas. Defendants assert that the accused devices do not contain "a generally cylindrical housing closed on one end and open on its other end." Instead, Defendants claim that the bases of the Morton and TRW driver's side inflators are open on both ends, since each device's base has an opening through which the igniter is inserted. Further, Defendants argue that Plaintiffs are estopped from arguing equivalency because Lynch obtained the patent by limiting the housing element to exclude the type of housing with an opening through which a shaft extends.

The Magistrate Judge rejected Plaintiffs' interpretation as overbroad and rejected Defendants' interpretation as too narrow. First, the Magistrate Judge found that under Plaintiffs' interpretation the Stephenson device itself is closed on one end since the Stephenson opening is sealed to the flow of gas by a lip seal between the "housing" and the steering wheel shaft. Thus, the Magistrate Judge concluded that Plaintiffs cannot rely on an interpretation of "closed" as meaning only sealed to the passage of gases when the prosecution history of the patent show that they intended just the opposite. Second, the Magistrate Judge rejected Defendants' interpretation as too narrow, since it "would exclude a device from being 'closed on one end' if any part of the inflator assembly itself could be removed and thus 'open' the housing." (R&R at 22). The Magistrate Judge reasoned that "the Stephenson patent is directed to a device wherein the shaft through the center of the inflator is entirely separate from the inflator assembly. Thus if the inflator were removed from the steering column, the hole in the inflator would be exposed, e.g., the inflator assembly itself is open on both ends. Nothing in the '715 patent specification, claims, or prosecution history further limits interpretation of the claim language in question." (R&R at 21). In other words, the Magistrate Judge reasoned that the steering shaft of the Stephenson patent is "entirely separate from the inflator assembly," whereas the igniters in the accused inflators are a "part of the assembly itself."

Defendants object to the Magistrate Judge's recommendation, arguing that "the Report misinterprets the Stephenson Patent and the accused inflators in concluding that a claim interpretation is possible that distinguishes the Stephenson Patent but that may in fact cover the accused inflators." (Def.'s Obj. at 4). Rather, argue Defendants, there is no substantive difference between the steering column of the Stephenson patent and the igniter of the accused devices, because in each case the alleged "housing" has a central opening that becomes "closed" when a separate piece is inserted into the opening.

Accordingly, Defendants assert that Plaintiffs cannot establish literal infringement because either Defendants' interpretation, which excludes both the Stephenson Patent and the accused inflators, is correct, or else claim 1 is invalid in light of the Stephenson Patent. Further, Defendants argue that the prosecution history estops Plaintiffs from invoking the doctrine of equivalents because Lynch limited the "housing" required by claim 1 to exclude the type of housing disclosed in Stephenson, which Defendants assert is the only type of housing alleged to be present in the accused inflators. In response, Plaintiffs emphasize that the phrase "closed on one end" appeared in the original version of claim 1, so that it was not added to overcome the Stephenson patent. Further, Plaintiffs contend that patentability was established by the combination of elements which defined a system totally different from that of the Stephenson patent and, thus, the remark distinguishing Stephenson as not "closed on one end" does not create a separate estoppel respecting the individual distinction, but rather creates an estoppel only regarding the combined distinctions.
(a) Claim Interpretation

Because Defendants do not dispute that the base of the accused devices is "generally cylindrical" and "open" on one end, the key issue here becomes whether the other end of the base is "closed" as that term is used in the first limitation of claim 1. Defendants argue that the prosecution history limits the scope of the term "closed" because the first limitation "was crucial in distinguishing claim 1 from the prior art." (Def.'s Mem. in Supp. of Mot. for Summ. J. at 25). Defendants refer to the portion of Lynch's remarks to the PTO that "Claim 20 also recites that the housing is closed at one end and open at its other end. Stephenson's cuplike member is open at both ends since the steering shaft must enter one end and the gas must escape from the other end." Defendants argue that in order to obtain the '715 patent Lynch limited the "housing" element to exclude the type of housing disclosed in Stephenson -- a cylindrical housing with a central opening through which another element must extend during assembly.

However, Plaintiffs point to the claim language and argue that the housing "is sealed, or 'closed,' along one end with respect to the flow of gas generated within the inflator." (Resp. to Mot. for Summ. J. at 21). In other words, Plaintiffs contend that the Court should construe "closed" to mean sealed to the flow of gas. Further, Plaintiffs argue that "not one distinction over Stephenson was relied upon. Rather, a list of distinctions between the invention of claim 1 and the Stephenson patent was set forth to demonstrate the lack of materiality of the Stephenson patent." Thus, Plaintiffs conclude that the distinction in the prosecution history did not limit the term "closed."

Plaintiffs are correct to begin with the claim language itself. Significantly, Defendants' proffer an interpretation which implies that the limitation applies only to the unassembled inflator, arguing that the "housing" is open at both ends if an opening is present in which another element, such as a steering shaft, is inserted during assembly. The Court finds that the claim language itself intends "closed on one end and open on its other end" to describe the unassembled housing, as evidenced by the fourth limitation of claim 1, which recites "a plate member for closing the open end of the housing connected to the housing around its periphery, said member including gas passage means leading from the interior of the housing to the exterior thereof." (emphasis added). In other words, claim 1 discloses a "housing" element that, when separated from the assembled inflator, is closed on one end and open on the other, and, when assembled, is "closed" on both ends as that term is used.

The claim language similarly refutes Plaintiffs' interpretation of "closed" as meaning sealed to the flow of gas. The fourth limitation, discussed above, recites that the open end becomes closed, yet allows for the flow of gas. In other words, the term closed was explicitly used in the fourth limitation to mean not sealed to the flow of gas. Thus, to construe "closed" in the first limitation to mean sealed to the flow of gas would render claim 1 internally inconsistent in that the term closed would be used differently in different limitations within the same claim. As the Federal Circuit has explained, a term "cannot be interpreted differently in different claims because claim terms must be interpreted consistently." Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir.), cert. denied, 133 L. Ed. 2d 424, 116 S. Ct. 515 (1995) (emphasis added). Thus, the Court rejects Plaintiffs' proposed construction of the term "closed" as meaning sealed to the flow of gas. In the Court's view the phrase "closed on one end and open on its other end" describes the housing element before it is assembled with the other elements of the inflator, such that a housing with an opening through which another element of the inflator is inserted during assembly is "open" on the end with the opening.

The prosecution history corroborates this interpretation of the term "closed" found in the first limitation of claim 1. Defendants argue that Lynch's remarks during prosecution of claim 1, which distinguished the "housing" from the Stephenson patent, disclaimed an interpretation of "closed on one end" that reads on a housing with a central opening through which another element must extend during assembly and, thus, limited the interpretation of "closed on one end" so as to exclude that interpretation. Plaintiffs respond, albeit in opposing the application of prosecution history estoppel, that the distinction regarding "closed on one end" was not relied upon to obtain the patent. Notably, the use of prosecution history in claim construction is analytically distinct from prosecution history estoppel, which is relevant only to the doctrine of equivalents. Southwall, 54 F.3d at 1578. However, as another District Court has noted, "in practice, there does not appear to be a meaningful distinction between the use of prosecution history in claim interpretation and the operation of prosecution history estoppel." Abtox, Inc. v. Exitron Corp., 899 F. Supp. 775, 781 (D. Mass. 1995). Accordingly, the Court will construe Plaintiffs' grounds for opposing the application of estoppel as grounds for opposing the use of the prosecution history to limit the interpretation of "closed" as well. Indeed, both applications of the prosecution history are triggered by a distinction made in order to obtain the patent. Zenith Lab., Inc. v. Bristol-Myers Squibb Co., 19 F.3d 1418, 1422 & 1425 (Fed. Cir.), cert. denied, 130 L. Ed. 2d 409, 115 S. Ct. 500 (1994). Thus, in Zenith the Federal Circuit held that the
prosecution history did not limit the claim and did not estop the patentee from establishing infringement under the doctrine of equivalents because, inter alia, the distinctions were not relied upon by the examiner in allowing the patent to issue. Id. However, the instant matter is distinguishable from Zenith, where the Federal Circuit found that the examiner did not rely upon the distinction because the inventions distinguished "were never asserted as prior art by the examiner, and the examiner expressly indicated that [the applicant]'s assertions were not a factor in determining patentability." Id. at 1425. Moreover, the Federal Circuit has more recently explained that "clear assertions made during prosecution in support of patentability, whether or not actually required to secure allowance of the claim, may also create an estoppel." Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1570, 1583 (Fed. Cir. 1995), cert. denied, 133 L. Ed. 2d 424, 116 S. Ct. 515 (1995). Therefore, the Court finds that the inventor's remarks limited the interpretation of "closed on one end," such that a housing in not "closed on one end" if it has an opening on that end through which another element is inserted during assembly.

Plaintiffs rely upon Read Corp. v. Portec, Inc., 970 F.2d 816 (Fed. Cir. 1992) for the proposition that prosecution history estoppel does not apply to the first limitation because patentability was based upon a combination of distinctions rather than the individual distinction of the prior art's housing. Plaintiffs include this argument in the portion of their brief regarding claim interpretation, thus conflating the two analyses that apply the prosecution history. As explained above, the two analyses are distinct, yet similar in application. However, the Court is not persuaded that Read applies equally well to the use of prosecution history in claim construction, nor have Plaintiffs even articulated such a proposition. Accordingly, the Court will not consider the proposition for which Plaintiffs cite Read as proffered grounds for not applying the prosecution history to the claim construction analysis.

The R&R concludes that the prosecution history only excludes a housing with an opening for an element that is separate from the inflator assembly, because "the Stephenson Patent is directed to a device wherein the shaft through the center of the inflator is entirely separate from the inflator assembly. Thus, if the inflator were removed from the steering column, the hole in the inflator would be exposed, i.e., the inflator assembly itself is open on both ends." (R&R at 21). However, the Court does not construe the Stephenson steering shaft to be entirely separate from the inflator, as the product does not function without the steering shaft.

719

A. Claim 1: "closely disposed about said outer periphery exhaust region"

The parties next dispute the construction of a phrase in paragraph five of claim one of the '843 patent: "closely disposed about said outer periphery exhaust region."

Johnson argues that "closely disposed about said outer periphery exhaust region" means "near and on the same plane as the outer boundary of the fan." Johnson argues that during the prosecution of the '843 patent, Ametek "disclaimed the distinguished structure" of the prior art and thereby disavowed the full meaning which the disputed claim language would ordinarily have.

Ametek responds first that Johnson's proposed definition "reads extraneous limitations from the specification into the claim." Ametek next responds that Johnson's proposed definition is improper because the "claim term at issue address[es] only proximity to the outer periphery exhaust region, and is totally silent as to any planer relationship."

Instead, Ametek argues that "closely disposed about said outer periphery exhaust region" means "placed near and all around the outside perimeter of the area where the air is let out." Specifically, Ametek argues that this definition is proper because it gives the disputed phrase its "ordinary and customary meaning" and is "consistent with the specification and drawings of the '843 patent."

The court agrees with Ametek that Ametek did not disavow claim scope. Specifically, the court concludes that in the context of claim one paragraph five of the '843 patent, the phrase "closely disposed about said outer periphery exhaust region" means "placed near to the outside perimeter of the area of the fan where the working air is let out of the fan."
12 The court has adopted Ametek's proposed construction of the disputed claim term with certain modifications. Ametek argued that the phrase means "placed near and all around the outside perimeter where the air is let out." The court construes the phrase to mean "placed near to the outside perimeter of the area of the fan where the working air is let out of the fan."

1. Claim Language

The court will first analyze how claim one of the '843 patent uses the phrase "closely disposed about said outer periphery exhaust region." Claim one of the '843 patent claims a "bypass motor assembly" containing, inter alia, with disputed language in italics,

[an] end bracket having a plurality of vanes [blades] that form a fan chamber that receives said working air fan wherein said plurality of vanes [blades] are closely disposed about said outer periphery exhaust region such that air expelled by said working air fan is re-directed by said vanes [blades] toward at least one exhaust aperture.

'843 patent, Cl.7, Ll.27-32 (emphasis added). This claim language describes how the working air fan (26) and the diffuser end bracket (24) function together in the '843 patent. First, the fan (26) expels air used by the motor, working air, through the fan's exhaust region (86). Next, the vanes (52) of the diffuser end bracket (24) re-direct the air toward the diffuser's "exhaust aperture[s]". See Exhibit 3: '843 patent.

The phrase "closely disposed about said outer periphery exhaust region" describes the placement of the vanes (52) in relation to the exhaust region (86) of the fan (26). The closeness of the vanes to the fan's exhaust region allows the "air expelled by" the "working air fan" to be "re-directed by said vanes toward at least one exhaust aperture" so that the air can flow out of the diffuser end bracket (24).

The court's construction of the disputed phrase reflects the way in which the claim uses the disputed language. It is the vane's "placement near to the outside perimeter of the area of fan where the working air is let out of the fan" that allows the vanes to re-direct the working air to the exhaust apertures. Furthermore, in contrast to Johnson's proposed definition, the claim is notably silent as to the planer relationship between the vanes and the exhaust region.

2. Specification

The specification supports the court's construction of the disputed language. The specification recites language similar to the disputed claim language:

The leading ends 56 of the vanes 52 are disposed closely about the outer periphery of the fan 26 around the exhaust region 86. Indeed, each vane 52 has a top edge 54 which is of such a height so as to be equivalent to or larger than the height of the exhaust region 86. Accordingly, almost as soon as the working air is expelled from the fan exhaust ports 84, it is deflected and captured by the leading ends 56 and received in the channels 64 formed by the adjacent vanes 52 and the shroud 94.

'843 patent, Cl.5-6, Ll. 60-1(emphasis added). See Exhibit 3: '843 patent. It is because the vanes are "disposed closely about the outer periphery" of the exhaust region, with "each vane" having a "top edge 54 which is . . . equivalent or larger that the height of the [fan's] exhaust region," that the air can flow from the fan, between the vanes, and out the exhaust openings.

In contrast to Johnson's proposed definition, the specification, like the claim, is silent about the planer relationship between the vanes and the fan's exhaust region. The court finds "nothing in the written description of the ['843] patent, much less the claim language" that dictates that the vanes must be located on the same plane as the fan's exhaust region. Superguide Corp. v. DirecTV Enters., 358 F.3d 870, 880 (Fed.Cir. 2004).

3. Prosecution History: Disavowal of Claim Scope

Johnson, however, argues that the prosecution history reveals that Ametek disavowed the full meaning of the disputed claim.
language and thereby limited the definition of "closely disposed about said outer periphery exhaust region" to mean "near and on the same plane as the outer boundary of the fan." Ametek argues that it did not disavow claim scope and the court agrees.

A patent's prosecution history may, in some instances, reveal that the patent holder "disclaimed or disavowed subject matter" thereby "narrowing the scope of claim terms." Superguide Corp. v. DirectTV Enters., 358 F.3d 870 (Fed.Cir. 2004) (quoting ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1091 (Fed.Cir. 2003)). In Superguide Corp. v. DirectTV Enters., 358 F.3d 870 (Fed.Cir. 2004), the Federal Circuit noted, however, that a "prosecution history may not be used to infer the intentional narrowing of a claim absent the applicant's clear disavowal of claim coverage." Superguide Corp. v. DirectTV Enters., 358 F.3d 870, 875 (Fed.Cir. 2004)) (quoting Amgen Inc. v. Hoechst Marion Roussel Inc., 314 F.3d 1313, 1327 (Fed.Cir. 2003)). In other words, a disavowal of claim coverage "must be made with reasonable clarity and deliberateness." Superguide Corp. v. DirectTV Enters., 358 F.3d 870, 875 (Fed.Cir. 2004)(quotation marks and citation omitted).

On March 12, 2002, Ametek wrote to the USPTO in an apparent attempt to distinguish the proposed '843 patent from the prior art:

A close review of the '462 patent clearly shows that the 'vanes' of that particular ['462 patent] diffuser are disposed in a plane below the bottom ring of the working air fan and nowhere near the outer periphery of the fan. In distinct contrast, the present invention ['843 patent application] now sets forth the vanes of the end bracket are closely disposed about the outer periphery exhaust region of the working air fan. This feature is clearly not taught or suggested by the '462 patent

(emphasis added). Ametek then requested that the USPTO amend proposed claim one (issued claim one) of the '843 patent application to add the phrase "wherein said plurality of vanes are closely disposed about said outer periphery exhaust region."

In the initial sentence of Ametek's statement to the USPTO, Ametek described two characteristics of the vanes in the prior art '462 patent. First, the vanes in the '462 patent were located "in a plane below" the bottom ring of the working air fan. Second, the vanes in the '462 patent were located "nowhere near the outer periphery of the fan." Ametek then contrasted the '843 patent with the '462 patent by pointing out one characteristic of the '843 patent: the "vanes of the end bracket are closely disposed about the outer periphery exhaust region of the working air fan." Ametek made no statement about whether or not the vane and the working air fan were on the same plane in the '843 patent.

Johnson asks the court to infer from Ametek's use of the phrase "in distinct contrast" in the prosecution history, that Ametek meant to disclaim coverage of all products in which the vane and working air fan are not on the same plane. Analysis of Ametek's statement as a whole, however, reveals that Ametek did not clearly or deliberately disclaim coverage of products in which the vane and working air fan are not on the same plane. Rather, Ametek described two characteristics of the prior art: (1) planer location, and (2) proximity. Ametek then distinguished the '843 patent on the basis of only one of these characteristics: proximity. In light of this analysis, the court declines to conclude that Ametek deliberately disavowed the scope of the disputed claim language.

4. Drawings 13

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

13 Because the court has concluded that it can determine the meaning of the disputed terms through examination of the intrinsic evidence, the court need not turn to extrinsic evidence. See Phillips Petroleum Co. v. Huntsman Polymers Corp., 157 F.3d 866, 870 (Fed.Cir. 1998) (noting if "intrinsic evidence unambiguously delineates the scope of the patent, resort to extrinsic evidence . . . is unnecessary").

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Finally, the court's construction of the disputed phrase is consistent with the '843 patent drawings. See Exhibit 3: '843 patent. The drawings illustrate that the vanes (52) are located are "near to the outside perimeter" of the fan's (26) exhaust region (86). See Rexnord Corp. v. The Laitram Corp., 274 F.3d 1336, 1342 (Fed.Cir. 2001).
1. "Closely Fit In and Extend Through"

Osteonics first contends that the "closely fit" language of the patent claim indicates that the Whiteside patent requires a rod that, as closely as possible, fills up the entire intramedullary canal, i.e., that it fits snugly. This, according to Osteonics, comports with the general desire of the Whiteside system that its intramedullary rod be collinear with the central long axis. Osteonics, on the other hand, asserts that its system relies on no such close fit because it seeks only an approximation of the central long axis and does not aim to duplicate it.

The Court agrees with Osteonics. The language in claim 6, especially when viewed in conjunction with the general methodology described in claims 1 through 5, indicates that "closely fit" means what it says. DCW attempts to avoid this common meaning of the words by pointing out that a tight fit is not often achieved because the people on whom knee replacements are most commonly performed, the elderly, tend to have canal spaces 1/2 inches or more in diameter at their narrowest parts. But whatever the practice might be, the patent claim is what matters. Moreover, the drawings submitted in the Whiteside patent specification certainly show a rod that is snugly fit into the intramedullary canal. See Whiteside patent, Fig. 16; see also Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985) ("The descriptive part of the specification aids in ascertaining the scope and meaning of the claims inasmuch as the words of the claims must be based upon the description."). The fact that the Whiteside patent description envisions the use of a smaller rod when a larger one is not practical does not loosen the meaning of the description "closely fit."

Similarly, the whole nature of the reaming process, which is absent in Osteonics' product, points toward Osteonics' suggested interpretation. The reamer's main purpose, according to Dr. Whiteside's own testimony, "is to clear the contents of the bone. So when you put the rod in, you don't push those intramedullary contents into the patient's veins." Exhibits to DCW's Oppos. to Osteonics' Mot. for Partial Summ. J., Ex. 2 at 305. That process makes more sense--and is more necessary--in the context of a rod designed to "closely fit" than in one merely inserted into the femur shaft.

3 DCW complains that relying on the reamer improperly reads a claim limitation from an earlier claim into claim 6, thereby violating the doctrine of claim differentiation. See D.M.I. Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir. 1985). While a limitation may not be read from one claim into another, different claims within the same patent may certainly be used to shed light on how other claims are best construed. Minnesota Mining & Mfg. Co. v. Johnson & Johnson, 976 F.2d 1559, 1566 (Fed. Cir. 1992).

In 1991, Wright 1 sued Osteonics for patent infringement, alleging that Osteonics' STAT-IM artificial knee surgery device infringed claims 6-8 and 10. Independent claim 6, from which the other asserted claims depend, reads in pertinent part (with emphasis on the disputed claim terms):

1 The original suit was brought by Dow Corning Wright Corp. During the pendency of the first appeal, Wright Medical Technology, Inc. acquired the assets of Dow Corning Wright Corp., including the '177 patent.

As an article of manufacture, a distal femoral surface shaping guide comprising the combination of
(A) an intramedullary alignment guide comprising (1) an intramedullary rod portion adapted to closely fit in and extend through the narrowest portion of the human femur such that the central long axis of said femur passes through the central long axis of said intramedullary rod portion, (2) a guide handle attached to and set at a preselected angle with respect to said axis of the intramedullary rod portion and being adapted to receive at least one femoral surface modifying instrument in proper alignment with respect to said handle and (3) a means for securing the combination of (1) and (2) in a fixed position in the femur with

(B) at least one femoral surface modifying instrument which is adapted to cooperatively engage such handle and to assume an appropriate fixed relationship with respect to the distal femoral surface and to the central long axis of the femur . . . .

In 1993, the district court conducted a trial limited to the issue of infringement. Although the parties did not dispute how the STAT-IM device worked, they did contest the proper construction of the claims and, in particular, the terms "closely fit in," "extend through," and "in proper alignment." The jury returned general verdicts stating that each of the asserted claims was not infringed literally or under the doctrine of equivalents. Wright appealed from the denial of its motion for a new trial. Relying on the recently-decided Markman v. Westview Instruments, Inc., 52 F.3d 967, 983-84, 34 U.S.P.Q.2D (BNA) 1321, 1333 (Fed. Cir. 1995) (in banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384, 38 U.S.P.Q.2D (BNA) 1461 (1996), we held in a non-precedential opinion that the district court abused its discretion in denying the motion for a new trial because it did not construe the claims as a matter of law before submitting the issues of infringement to the jury. See Dow Corning Wright Corp. v. Osteonics Corp., 57 F.3d 1082 (table, text at 1995 WL 250991) (Fed. Cir. Apr. 28, 1995). We therefore vacated the jury verdict and remanded for a new trial.

On remand, the district court adopted all of Osteonics' claim construction arguments and granted Osteonics' motion for summary judgment of no literal infringement. The court also granted Osteonics' motion for summary judgment on Wright's claim for infringement under the doctrine of equivalents, holding that the doctrine of equivalents . . . is not relevant to this case. [Wright] admitted to the Federal Circuit that if Osteonics' claim interpretation were correct, there would be no infringement at all, whether literal or pursuant to the doctrine of equivalents, a fact noted by the Federal Circuit in its remand to this Court. Even without the concession, however, that seems to be an appropriate assessment of the situation at hand. "The doctrine of equivalents is not a license to ignore or 'erase structural and functional limitations of the claim' limitations 'on which the public is entitled to rely in avoiding infringement.'" If Osteonics is correct in its claim construction arguments, there is nothing in its system that is the functional equivalent of those claims.

No. 91-10962-GAO, slip op. at 9-10 (citations omitted). This appeal followed. We have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1) (1994).

DISCUSSION

We review a district court's grant of summary judgment de novo. Conroy v. Reebok Int'l, Ltd., 14 F.3d 1570, 1575, 29 U.S.P.Q.2D (BNA) 1373, 1377 (Fed. Cir. 1994). Summary judgment is appropriate when there is no genuine issue as to any material fact and the moving party is entitled to judgment as a matter of law. Fed. R. Civ. P. 56(e); Johnston v. IVAC Corp., 885 F.2d 1574, 1576-77, 12 U.S.P.Q.2D (BNA) 1382, 1383 (Fed. Cir. 1989). Thus, summary judgment may be granted when no "reasonable jury could return a verdict for the nonmoving party." Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). In deciding whether summary judgment was appropriate, we view the evidence in a light most favorable to the party opposing the motion with doubts resolved in favor of the opponent, which in this case is Wright. See Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1274, 35 U.S.P.Q.2D (BNA) 1035, 1038 (Fed. Cir. 1995).

Regarding literal infringement, Wright first argues that because the phrase "adapted to closely fit in and extend through the narrowest portion of the human femur" is modified by the phrase "such that the central long axis of said femur passes through the central long axis of said intramedullary rod portion," the "closely fit" and "extend through" limitations are met by any intramedullary rod that meets the functional objective of the invention. See Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 858, 9 U.S.P.Q.2D (BNA) 1289, 1292 (Fed. Cir. 1988) (describing a phrase beginning with the term "so that" as a "definitional parameter"); Bausch & Lomb, Inc. v. Barnes-Hind/Hydrocurve, Inc., 796 F.2d 443, 450, 230 U.S.P.Q. (BNA) 416, 421 (Fed. Cir. 1986) ("We hold that smooth means smooth enough to serve the inventor's purpose."). Thus, Wright argues that an infringing rod, provided it is sufficiently co-linear with the central long axis of the femur, need
only "engage" (i.e., enter into) the isthmus of the femur. Osteonics responds that the terms "closely fit" and "extend through" mean exactly what they say: an infringing rod must fit tightly into and extend all the way through the isthmus of the femur. We agree with Osteonics regarding the construction of these claim terms.

A determination of infringement requires a two-step analysis. The first step, claim construction, is a question of law which we review de novo. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 983-84, 34 U.S.P.Q.2D (BNA) 1321, 1329, 1333 (Fed. Cir. 1995) (in banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384, 38 U.S.P.Q.2D (BNA) 1461 (1996). The proper construction of the claims is based upon the claim language, the written description portion of the specification including any relevant drawings, the prosecution history, and if necessary to aid the court's understanding of the patent, extrinsic evidence. See id. 52 F.3d 967 at 979-81, 34 U.S.P.Q.2D (BNA) at 1329-31. Claim terms are given their ordinary and customary meaning in the field of the invention, unless a special definition is clearly stated in the specification. See id. at 980, 34 U.S.P.Q.2D (BNA) at 1330. Thus, "usually, [the specification] is dispositive; it is the single best guide to the meaning of a disputed claim term." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996).

The second step in an infringement analysis is determining whether a particular device infringes a properly construed claim, which is a question of fact. See Fromson v. Advance Offset Plate, Inc., 720 F.2d 1565, 1569, 219 U.S.P.Q. (BNA) 1137, 1140 (Fed. Cir. 1983). "Literal infringement exists if each of the limitations of the asserted claim(s) reads on, that is, [is] found in, the accused device. " Baxter Healthcare Corp. v. Spectramed, Inc., 49 F.3d 1575, 1583, 34 U.S.P.Q.2D (BNA) 1120, 1126 (Fed. Cir.), cert. denied, 516 U.S. 906, 133 L. Ed. 2d 194, 116 S. Ct. 272 (1995). Infringement may be found under the doctrine of equivalents when, absent stopgap, every limitation of the asserted claim, or its equivalent, is found in the accused subject matter, the latter differs from what is literally claimed only insubstantially, and it performs substantially the same function in substantially the same way to achieve substantially the same result. See Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 137 L. Ed. 2d 146, 117 S. Ct. 1040, 1054, 41 U.S.P.Q.2D (BNA) 1865, 1875 (1997); Graver Tank & Mfg. Co. v. Linde Air Prods. Co., 339 U.S. 605, 608-09, 85 U.S.P.Q. (BNA) 328, 330-31, 94 L. Ed. 1097, 70 S. Ct. 854 (1950).

The district court did not err in construing the "closely fit" and "extend through" limitations. Because these terms are not given any special definition in the specification, we must give them their ordinary meaning. Thus, "closely fit in and extend through" mean more than merely "fit into" or "engage." Wright's argument would render the contested terms surplusage, leaving claim 6 to cover any "intramedullary rod portion adapted . . . such that the central long axis of said femur passes through the central long axis of said intramedullary rod." Wright does not seek to interpret the claim terms, as we did in Laitram and Bausch & Lomb, but seeks to eviscerate them. We therefore conclude that the district court did not err in construing the words "closely fit" to require a tight or snug fit between the rod and the isthmus of the femur or in construing the words "extend through" to require that the rod pass through the entire length of the isthmus. Because the parties agree that the intramedullary rods of the STAT-IM device do not fit tightly against or extend through the isthmus of the femur, the district court also did not err in granting summary judgment that there was no literal infringement.

722

C. Claim language to be construed from Claims 3 and 6 -- "an electrical connector closing said connector end of said tube"

HEN contends that the term "closing" should be constructed to mean "spanning a diameter of the tube." (HEN CC Br. at 19.) HEN argues that its proposed construction would mean that the electrical connector does not necessarily seal the tube, and thus can have openings into the internal cavity of the tube. Minco, on the other hand, proposes that the term "closing" should be construed to mean "attached to the final physical endpoint of the tube without openings into the internal cavity of the conductive tube." (Minco CC Br. at 27.)

Minco asserts that it does not claim that "closed" means "sealed." (Id. at 30.) However, Minco's proposed construction is effectively a construction that the tube must be sealed by the connector because Minco's proposed construction states that the connector cannot have any openings into the internal cavity of the conductive tube. Other courts have found, and we agree, that there is a difference in the ordinary meaning of the terms "closed" and "sealed." See Pharmacia & Upjohn Co. v. Sicor, Inc., 447 F. Supp. 2d 363, 374 (D. Del. 2006) ("ordinary meaning of the term 'sealed' is different from, and encompasses something more than, the ordinary meaning of the term 'closed.'"); Protective Optics, Inc. v. PanOptix, Inc.,
the tube, regardless of whether there are or are not openings in the connector into the internal cavity of the conductive tube.

Consequently, based on the claim language and the specification, we construe "closing" to mean "spanning the diameter of the tube, regardless of whether there are or are not openings in the connector into the internal cavity of the conductive tube."

458 F. Supp. 2d 1053, 1063-64 (N.D. Ca. 2006) (noting that "close" is different from "close hermetically"); HBB Limited Partnership v. Ford Motor Co., 1996 U.S. Dist. LEXIS 4047, *17-18 (E.D. Ill. Mar. 29, 1996) ("closed" does not mean "sealed" to the flow of gas). The patent applicants in this case also understood that there was a difference between "closed" and "sealed" because the applicants state in the patent that the immersion end is "sealed by a plug of refractory heat resistant material such as cement," (Minco Ex. A, col. 2, ll. 30-32), but only refer to the connector as "closing said connector end." (Minco Ex. A, col. 4, ll. 42-43.) HEN argues that the figure in the specification supports its contention that the connector merely closes and does not seal the conductive tube. However, we find that the figure is inconclusive on this point because there is nothing in the figure to indicate that there is a difference between the refractory heat resistant plug (see id. at Figure 1, number 4), which "seals" the immersion end, and the connector plug (see id. at Figure 1, number 17), which "closes" the connector end.

Minco contends that the specification and prosecution history both support its contention that the connector must be located at the final physical endpoint of the conductive tube and that it cannot have openings into the internal cavity of the tube. However, it would be improper for us to use the specification to import a limitation into the claim that does not appear in the claim itself, and therefore, we find it inappropriate to conclude based on the specification that the connector must be located at the final physical endpoint of the conductive tube. See Electro Med. Sys., 34 F.3d at 1048 (stating that a court cannot add limitations appearing only in the specification). Moreover, we find that the specification does not show the connector only at the final physical endpoint of the conductive tube. The specification states that the connector has an electrically conductive sleeve in intimate contact with the conductive tube, and, in the figure contained in the specification, the connector sleeve extends up into the tube. (Minco App. A at Figure 1, number 13 and col. 2, ll. 51-53.) Consequently, we reject Minco's arguments based on the specification that the connector must be at the final physical endpoint of the conductive tube, opposite the immersion end.

With respect to the prosecution history, Minco argues that the PTO initially rejected the application in part because Jackson disclosed "an electrical connector (46/58/60/62/70) closing the connector end of the tube and providing electrical connections for the cell and the tube." (Minco App. 5E at HEN000312-313.) Minco contends that, in order to overcome Jackson, HEN distinguished Jackson as follows:

The Examiner is of the position that Jackson discloses a hollow electrically conductive tube 72 having an immersion end, connector end and an electrical connector 46/58/60/62/70 closing the connector end of the tube.

Jackson disclosed a spring collet 46 which encircles and engages the tube 72. (See Fig. 2). As shown in Fig. 3, the spring collet 46 has fingers 48 spaced apart by slots which extend up from the end of the collet 46 and open into the cavity of the device 10. Element 58 closes the cavity at a distance up the cavity from the end of the tube 72. Requestor respectfully submits that since the spring collet 46 has openings into the cavity of the probe, Jackson does not disclose an electrical connector providing electrical connections which closes the end of the tube 72, as recited in claims 1, 3, 5, and 6.

(Minco App. 5F at HEN000297-298.) Therefore, according to Minco, HEN argued that the electrical connector disclosed in Jackson with holes opening into the internal cavity of the conductive tube could not close the conductive tube as claimed in the '736 patent, because the connector had openings into the internal cavity of the probe. In response, HEN argues that Jackson does not have a connector at all, and therefore, HEN could not have distinguished Jackson by discussing its connector in comparison to the '736 invention. In the portion of the prosecution history relied upon by Minco, the applicant did not acknowledge that Jackson has a connector, rather it stated Jackson discloses a spring collet that has openings into the cavity of the probe, and therefore, does not disclose an electrical connector which closes the end of the tube as recited in the '736 patent. The Federal Circuit has warned that prosecution history often lacks clarity. See Phillips, 415 F.3d at 1317. We find that to be the case here. Thus, it does not help explain how the applicant understood the invention. Nevertheless, we do not find that the applicant made a clear disavowal of claim coverage that would require us to construe "closing" to mean that there cannot be any openings in the connector into the internal cavity of the conductive tube.

Consequently, based on the claim language and the specification, we construe "closing" to mean "spanning the diameter of the tube, regardless of whether there are or are not openings in the connector into the internal cavity of the conductive tube."
II. "Closure Device" as Used in the '689 Patent's Claims

Kensey submits that "closure device" as used in the claims is a general term that refers to "any type of closure device that can be arranged and positioned to enable the effective sealing of a puncture [in a vessel, lumen, or duct]." PIs. Mem. 2 at 34. Perclose submits a significantly narrower definition: a "closure device," as used in the claims, is "[a] device for sealing a percutaneous puncture in a vessel, duct, or lumen [and is] comprised of a sealing member within the puncture tract, an anchor member within the vessel, duct, or lumen, and a filament member connecting the anchor and sealing members in a pulley-like arrangement." Def.'s Mem. 3 at 35. Each party argues that the intrinsic evidence of record supports its favored definition.

Dr. Jerome Segal, a cardiologist and one of Kensey's experts, states that "closure device" can refer to any known means of wound closure, including an anchor-plug-and-filament closure, "a collagen plug, a needle and suture, a surgical staple, an adhesive, [or] a cauterization device." See Dec. of Dr. Jerome Segal (Doc. No. 33) at P 29. The court uses Segal's declaration as an indication of the term's meaning when used in isolation. Hence, at the outset, "closure device" is a general term that has one meaning. 4 It, of course, remains for the court to determine whether the term as used in the patent retains this definition.

A. Claim Language

Asserted Claims 1 and 25, the only independent claims in the patent, both use the term "closure" or "closure device." The pertinent parts of Claim 1 read as follows:

"A system for sealing a percutaneous puncture in the wall of a [fluid-filled] vessel, duct or lumen of a living being…

the puncture comprising an opening in the wall of the vessel, duct or lumen and a tract contiguous with the opening and extending through tissue overlying the vessel, duct, or lumen,

[a] said system comprising a closure device and a location detector,

[b] said location detector being arranged for introduction into the puncture to provide a perceptible signal indicative of the location of the wall of the vessel, duct or lumen, whereupon a desired position for said closure with respect to the vessel, duct or lumen may be determined…

[c] said closure device being arranged to be positioned within a portion of the puncture in accordance with said desired position to enable the effective sealing of the puncture by said closure device."

---

2 Mem. of Law in Supp. of PIs.' Mot. for a Markman Ruling on Claim Interpretation (Doc. No. 33).

4 Perclose argues that Dr. Segal admits that "closure device" is an ambiguous term. However, the portions of deposition transcript cited to substantiate the claim fail to make Perclose's point. See Perclose's Opposition Mem of P. & A. on Claims Construction (Markman) Issues (Doc. No. 45) at 8-10. The transcript portions cited only confirm that Dr. Segal believes that "closure device" is a general term. Perclose also seems to argue that "closure device" is too vague to be meaningful. See id. at 6. This argument receives little substantiation, and certainly, general definitions may be vague but are not therefore meaningless.

---
'689 Patent at 14:56-15:8 (emphasis and sentence division added). The pertinent parts of Claim 25 read as follows:

"A method for sealing a percutaneous puncture in the wall of a [fluid-filled] vessel, duct, or lumen of a living being,…

the puncture comprising an opening in the wall of the vessel, duct, or lumen and a tract contiguous with the opening and extending through tissue overlying the vessel, duct or lumen, said method comprising:

(a) providing a closure device and location detector;

(b) introducing the location detector into the puncture… [so as to] provide a perceptible signal indicative of the location of the wall of the vessel, duct, or lumen, whereupon a desired position for the closure with respect to the vessel, duct or lumen may be determined; and

(c) introducing the closure device within a portion of the puncture in accordance with the desired position to enable the effective sealing of the puncture by said closure device."

Id. at 16:47-68 (emphasis and sentence division added).

Parsing the claims' language makes more apparent the limitations imposed on the definition of "closure device." First, sections (b) of both claims state that the closure device's positioning is informed by a determination of the position of the punctured vessel, duct, or lumen wall. Second, sections (c) both claims state that the closure device envisioned by the patent is "positioned within a portion of the puncture" in such a way as to "enable the effective sealing of the puncture." Section (a) of Claim 1 clarifies that "puncture" refers to the opening in the vessel, duct, or lumen as well as the tract that leads to the opening. Thus, "closure device," as used in these claims, refers to the class of devices

(1) whose positioning can be informed by the determination of the position of the punctured vessel, duct, or lumen wall; and

(2) that effectuate wound closure by being positioned within a portion of the "puncture."

As compared to the definition of "closure device" as used in isolation, "closure device" as used in the claims bears a relatively narrower definition. For example, the term, as used in isolation, could refer to a band-aid; the term as used in these claims excludes bandages. However, despite this slight narrowing, the term as used in these claims nonetheless bears a definition broader than that submitted by Perclose.

Perclose argues that the phrase "positioned within a portion of the puncture..." requires that the closure device be entirely "located in the internal luminal space of, and [be] bounded by the wall of the vessel, duct, lumen, puncture or puncture tract[.]") Def's Mem. at 29. "Closure device" cannot, according to Perclose, refer to any device that "extends through the [vessel, duct, or lumen] wall." Id. This interpretation of the phrase would be accurate were "puncture" to refer only to a puncture in a vessel, duct, or lumen. However, the text of Claims 1 and 25, plainly uses "puncture" differently. "Puncture" refers to the class comprising the "opening in the wall of the vessel, duct or lumen" and the tract leading to the opening. A class "comprising" some list of features includes all things with those features and does not exclude things that have those along with other. See, e.g., Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261 (Fed. Cir. 1986). Hence, "puncture" refers to the vessel, duct, or lumen opening as well as the tract leading to the opening. Furthermore, although the opening and tract are the essential features of a "puncture," the use of the term does not exclude other features. Consequently, an item that is "within the puncture" must be within a feature, namely the opening or tract, and may also be within any nonessential feature, such as the body of the vessel, duct, or lumen wall.

Some of the remaining claims - all of which are dependent claims - can be read to define "closure device" consistently with or more narrowly than Claims 1 and 25. See, e.g., '689 Patent at 15:24-35 (Claim 7) ("… said closure comprising a first portion and a second portion coupled to said first portion.…"); 15:56-60 ("… said closure comprises an anchor member…."). The Federal Circuit endorses the common sense rule that a dependent claim, by nature, incorporates all the limitations of the claim to which it refers[.]" Jeneric/Pentron, Inc. v. Dillon Co., Inc., 205 F.3d 1377, 1383 (Fed. Cir. 2000) (citing 35 U.S.C. § 112, P 4 (1994)); but an independent claim does not ordinarily incorporate the limitations of a dependent
claim, see Karlin Technology Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999). Here, nothing in the dependent claims suggests that the general definition of "closure device" imposed by Claims 1 and 25 is inconsistent with the term's use in these dependent claims. Although a narrower definition of closure device, such as the definition suggested by Perclose, would be consistent with the use of the term in these claims, the claims' language does not necessitate such a narrow definition. Consequently, the only claim language relevant for determining the meaning of "closure device" is the language of Claims 1 and 25.

B. Specification

Perclose argues that Kensey acted as its own lexicographer and narrowly defined "closure device" in the patent's specification. Def.'s Mem. at 32-43. Kensey, on the other hand, argues that it did not act as its own lexicographer. Pls.' Mem. at 41; Pls.' Resp. 5 at 6-8. A patentee only acts as a lexicographer where the patentee "with reasonable clarity, deliberateness, and precision[""] gives a term a special definition. Renishaw, 158 F.3d at 1249; accord, e.g., Johnson Worldwide Assocs. Inc. v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999) (Patentee must "clearly" set forth special definitions for claim terms.); Karlin, 177 F.3d at 973 ("The claims of a patent are not limited to the preferred embodiments, unless by their own language.").

Here the specification does not show with clarity and precision that Kensey specially defined "closure device." Perclose points out that the specification section entitled "Detailed Descriptions of the Preferred Embodiment" states that

"… [the] closure has three basic components, namely, a sealing member, an intra-arterial anchor member, and a positioning member…. The positioning member comprises a filament…. The [filament] connects the anchor member and the collagen plug (sealing member) via a pulley-like arrangement which serves to move the anchor and plug together, to sandwich and lock the artery wall between the anchor and plug."

'689 Patent at 5:25-28; accord 6:65-7:40; 5:50-61; 6:11-15. Also, as Perclose emphasizes, the patent's sheet drawings also clearly indicate an anchor, plug, and filament closure device. See 2:56-3:2 (figs. 1-5); 3:30-33 (figs. 19-24); 3:66-4:2 (figs. 34-35); 4:8-12 (fig. 38). Furthermore, the specification does not envision alternative embodiments that are not anchor-plug-and-filament type closures. See id. at 7:40-46 (The only alternative embodiment in the specification is a closure with a plug, filament, and anchor that can be radiographically imaged.).

However, the specification's "Summary of Invention" section can be read to explicitly indicate that the anchor, plug, and filament closure device is just one example of a closure device:

"The closure device, e.g., an anchoring means, sealing means, and filament means connected between the anchoring means and the sealing means, is arranged for location within a portion of the puncture at a desired portion with respect thereto, e.g., the anchoring means within the vessel and the sealing means within the puncture tract, to enable the effective sealing of the puncture by the closure device."

Id. at 2:36-42 (emphasis added). Furthermore, the fact that the specialized definition to which Perclose points appears in a section of the specification entitled "Detailed Descriptions of the Preferred Embodiment" makes it apparent that the "closure device" described therein is a preferred embodiment but not necessarily the sole embodiment.

Perclose also argues that the root term "seal-," as used in the claims, refers to preventing or obstructing the passage of fluid from the interior of a vessel, duct, or lumen into and through a puncture tract, by placing a mass of material within the puncture tract. See Def.'s Mem. at 32-34. In support of this specialized definition, Perclose points out that wherever "seal" or "sealing" is used in the preferred embodiment section of the specification, it is used in conjunction with a reference to a plug or sealing member and that this plug or sealing member acts as a stop in the puncture tract. See '689 patent at 5:25-30;
13:66-14:1. Perclose's arguments again fall short of the mark. Although "seal" may mean what Perclose suggests, the specification does not necessitate such a definition. "Seal" may be read to bear its ordinary meaning - namely as a synonym of words or phrases like "tighten," "close," "bond," or "bring together" - or a special meaning. But the regular appearance of "seal" alongside references to a plug does not clearly give "seal" a special meaning.

C. Prosecution History

Kensey argues that the prosecution history confirms that "closure device" is a general term. See Pls.' Mem. at 45-46. Perclose, on the other hand, argues that the prosecution history indicates that "closure device" carries a more limited meaning. See Def.'s Mem. at 43-46. Of primary significance here is the line of continuation applications from which the '689 patent derives. See '689 patent at 1:6-25.

The bulk of Perclose's prosecution history arguments amount to patent invalidity arguments. Perclose argues that if "closure device" is understood as a general term, the application for the '689 patent fails to meet the requirements of 35 U.S.C. § 112. Perclose goes on to argue that because the court must make every attempt to construe the meaning or scope of a patent so as to preserve validity, "closure device" must be interpreted narrowly so as to meet the requirements of 35 U.S.C. § 112. In essence, Perclose urges the court to assess validity in rendering its claim construction. However, as specified in a prior order (Doc. # 51), this opinion addresses only claim construction.

The '689 patent issued in 1997 from an application that was filed as a continuation of the now abandoned application Serial No. 08/604,205, which in turn was filed as a continuation of the now abandoned application Serial No. 08/426, 371. This last abandoned application was a continuation of application Serial No. 07/154,882, which was a continuation of application Serial No. 07/846,322. These last two applications, respectively, yielded Patents 5,441,517 (" '517") in 1993 and 5,282,827 (" '827") in 1992. The earliest of these continuation applications, the 846,322 application, was a continuation-in-part of application Serial No. 789,704, which yielded Patent 5,22,974 (" '974"). Hence, the '517 patent is the '689 patent's parent and the '827 patent is the '689 patent's grandparent. And the '827 patent and its progeny owe their existence, via the continuation-in-part relation, to the '974 patent.

Kensey explicitly defines the term "closure means" in the '974 patent. The '974 patent's summary of invention states "the closure means comprises anchoring means, sealing means, and filament means. The filament means is connected between the anchoring means and the sealing means… The filament means is arranged to pull the anchoring means and the sealing means relative to each other to cause the sealing means to engage tissue contiguous with said puncture outside of the vessel," '974 patent at 2:3-29. Given that the '974 patent explicitly gives "closure means" a narrow definition, it is unlikely that the application for the '974 patent's application included a broader definition. Certainly, Kensey presents no arguments suggesting that the '974 patent's application or prosecution history justifies a definition broader than that contained in the patent itself. Furthermore, Kensey's November 8, 1991 amendment to the application that became the '974 patent disclaims a broader definition of "closure means." In response to the PTO rejection of Claim 1 of the application, Kensey specified that "closure means" included a filament that was arranged to "move the anchoring means and the sealing means relative to each other," Furniss Dec. at PO46865. 7 The amendment was issued in order to distinguish the closure from a prior Kensey patent which described a filament that connects an anchoring means and sealing means. It is amply clear that the '974 patent's invention was limited to an anchor, plug, and filament device arranged in a pulley-like configuration.

Kensey also explicitly defines "closure means" in the same way in the '827 patent. The '827 patent's summary of invention
states that the "closure means comprises anchoring means, sealing means, and filament means. The filament means is connected between the anchoring means and the sealing means…. The filament means is arranged to pull the anchoring means and the sealing means relative to each other to cause the sealing means to engage tissue contiguous with the puncture outside the vessel." '827 patent at 2:15-44. Finally, the '517 patent's summary of invention describes the "closure means" in exactly the same way. See '517 patent at 2:22-50. It is amply clear that the initial application's inventive concept involved a specific type of closure device.

The '689 patent does not use the term "closure means" but instead uses the term "closure device." However, the '689 patent's prosecution history establishes that the two terms must be understood to be synonymous. A continuation application is based solely on the disclosures of a parent application. See Transco Products, Inc. v. Performance Contracting, Inc., 38 F.3d 551, 555 (citing the Manual of Patent Examining Procedure § 201.07). The '827 patent's inventive concept is a design and method for use of a mechanism for sealing percutaneous incisions or punctures in blood vessels through the use of a closure means." See, e.g., '827 Patent 2:10-44 (invention summary); 15:21-48 (sole independent system claim); 18:19-46 (sole independent method claim); see also '827 Patent Abstract. The closure means comprises "anchoring means, sealing means, and filament means, [where] said filament means [is coupled to] said anchoring means and said sealing means…. "827 Patent 15:25-29. In order for the '689 patent to refer to the '827 patent's inventive concept, "closure device" must be understood to refer to "closure means." 8 Were "closure device" a broader term than "closure means," the '689 patent would refer to a different inventive concept.

8 During the Markman Hearing, Kensey's counsel stated that the closure means described in the '974 patent and the '689 patent were both "three-piece devices" composed of an anchor, collagen plug, and filament. See Kensey Nash v. Perclose, No. 98-1629 (EDPA March 2000) (Docket item 54, hearing transcript) at 37-39.

Furthermore, the '689 patent's prosecution history shows that Kensey did not seek to use "closure device" to include more than "closure means." "The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Tech, Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). Initially, the PTO's examiner determined that Kensey's initial application, if approved, would lead to a double patenting. See PTO Office Action Summary in Dec. of Daniel Furniss (Doc. 40) at 45776. The examiner noted that a claim in Kensey's '974 patent describes an instrument that seals percutaneous punctures in blood vessel walls through use of a closure means "comprising" an "anchoring means, sealing means, and filament means, wherein the filament means is operatively connected between the anchoring means and the sealing means for moving the anchoring means and the sealing means relative to each other …" Id. The inventive concept disclosed by all of the claims in the '689 application covers a percutaneous vessel-puncture sealing instrument "comprising a closure device of resorbable collagen and vessel location means having a valve." Id. The examiner reasoned that because the term "comprising" in the '974 patent does not exclude other elements, the prior patent's "closure means" covered the class of devices referred to by the '689 patent's "closure device." In other words, the examiner understand "closure device" to be either equivalent to a "closure means" as described in the '974 patent or a particular type of "closure means." Consequently, the examiner understood "closure device" to mean a closure device comprising an anchor, plug, and filament. At no point, in the remainder of the prosecution history, does Kensey attempt to assert a broader definition for "closure device."

In sum, based on the '974 patent's application's use of "closure means," "closure device" as used in the '689 patent must necessarily refer to the class of closure devices that use an anchor, plug, and filament bound together in a pulley like arrangement whereby the filament draws the anchor and plug together so as to effectuate a seal.

The district court construed "closure device," as recited in the '689 patent, to require that the device use "an anchor, plug, and filament bound together in a pulley like arrangement whereby the filament draws the anchor and plug together so as to effectuate a seal." Kensey Nash Corp. v. Perclose, Inc. 2000 U.S. Dist. LEXIS 18393, 2000 WL 1868391 (2000). Thus, the court restricted the meaning of closure device to a device using an anchor-plug-filament (A-P-F) setup.
The specification of the '689 patent supports the district court's construction of "closure device." The specification repeatedly refers to the "closure device" as having an anchor, a seal (i.e., plug), and a filament. For example, in the background section, the specification refers to an earlier Kensey patent as having a closure device. It then states: "The closure device comprises three components, namely, an anchor member, a sealing member, and a filament, e.g., suture." '689 patent, col. 1, ll. 45-47. While the background section normally refers to the prior art and not the claimed invention, here Kensey ascribes a definition to "closure device" in the background section and never alters that definition throughout the specification -- even when using that term in reference to the invention of the '689 patent.

Moreover, the prosecution history limited "closure device" to an A-P-F device. Original claim 1 of U.S. Pat. No. 5,441,517 (‘517 patent), the great-grandparent of the '689 patent, recited a "closure device" without reciting an anchor, seal, or filament. In a Rule 131 declaration filed during prosecution of the ‘517 patent, however, Kensey stated:

The claimed invention of this application is a closure device . . .

The broadest claims of this application call for the closure comprising a sealing portion arranged to be located outside of the interior of a blood vessel and an anchor portion to be located inside of the interior of the blood vessel. The detailed dependent claims call for among other things, the anchor portion including at least one chamber in which a radiopaque material is located.

Thus, even though claim 1 (the only independent claim of the ‘517 patent) refers only to a "closure device," Kensey represented to the examiner that the closure device had a seal on the outside and an anchor on the inside of the blood vessel. Relying on the doctrine of claim differentiation, Kensey argues that this representation is not limiting because dependent claims 2 and 4 add the anchor, seal, and filament as additional limitations. The doctrine of claim differentiation, however, is a guide only and does not trump a clear and express limiting reference made during prosecution.

Further, other portions of the prosecution history demonstrate that "closure device" is limited to an A-P-F device. During prosecution of the '689 patent, Kensey attempted to get a dependent claim directed to a suture type closure device (i.e., one using filament without an anchor and plug). The examiner rejected the claim on the basis that no such arrangement was shown or described in the specification. In other words, Kensey failed to obtain even a dependent claim from the United States Patent and Trademark Office that would cover a suture type closure device. Nevertheless, appellant's asserted claim construction before this court attempts to recapture the very scope rejected by the examiner.

The district court also relied on a double patenting rejection made during prosecution of the '689 patent to support its holding that "closure device" is limited to an A-P-F device. The '689 patent claims priority to U.S. Patent No. 5,222,974 (‘974 patent). The examiner rejected original claims 1-50 of the '689 patent as amounting to double patenting over claim 8 of the '974 patent. Claim 8 included language expressly limiting the closure to an A-P-F device. The examiner found that claim 8 would cover the invention in the pending claims, and likewise, that if allowed, the pending claims would cover claim 8. Kensey argues that this rejection is based on the fact the pending claims were broader than claim 8 of the '974 patent (i.e., genus claims for earlier species claim) -- rather than a finding that both claims covered an A-P-F device. Based on the examiner's rejection, however, it is clear that the examiner viewed the "closure device" of the pending claims as an A-P-F device.

This court has considered all of Kensey's arguments, but finds them unpersuasive given the clear limitation of "closure device" in the specification and prosecution history of the '689 patent. In this case, Kensey clearly ascribed a narrower meaning to "closure device" as being an A-P-F device, and it cannot escape that definition now. Thus, the district court's construction of "closure device" is correct.

III.

Sage's '849 patent covers a needle removal and disposal device. Figures 1 and 3 of the '849 patent illustrate the claimed device.
The claimed device includes a storage container 19 with cap 20. The cap 20 has a slot 22 therein, which is notched so that it grasps the hub 12 of a syringe needle 11 and allows the user to unscrew the needle 11 without touching it. Particularly important to the present dispute, the claimed device also includes a movable closure means that may control access to the slot. In the figures above, the closure means is element 21, a flat disc that rotates about its center point to selectively allow or deny access to slot 22. In another embodiment illustrated in the patent, the closure means is a hinged lid that drops downward into a locked position to prevent access to the slot or alternatively lifts upward to allow access.

The '849 patent contains two independent claims, both of which are at issue in this appeal. Claims 1 and 10 read (with emphasis to highlight disputed limitations):

1. A needle removal and disposal device for detaching single or double-ended sampling needles which are thread engaged to a syringe body and storing detached sampling needles, said device comprising:

   - storage container means;
   - cap means associated with said storage container means, said cap means having a plate means with slot means opening therethrough, said slot means including integral wall means depending into said storage container means, entry port means and a plurality of stepped notches each having a different gap dimension for accommodating different sized needle hub portions; and
   - closure means pivotably associated with said plate means and being movable with respect to said slot means for controlling access thereto;

   wherein said device is capable of engaging a sampling needle hub portion at a stepped notch whereby a syringe thread-engaged to a hub portion may be rotated with respect to the hub portion for detachment of a sampling needle, whereby detached needles and hub portions may be deposited through said entry port means into said storage container means, said device providing said storage container means for accumulation of sampling needles subsequent to detachment from syringes, and whereby said pivotable closure means is capable of moving to close access to said slot means and provide safe storage of sampling needles within said storage container means.

10. A needle removal and disposal device for use with single or double-ended sampling needles having hub portions thread-engaging a syringe at the hub portion, said device comprising:

   - cap means having a plate means with slot means opening therethrough, said slot means including entry port means and a plurality of stepped notches, each notch having a different notch gap dimension permitting engagement with different sized needle hub portions, said slot means further including depending wall means integral with said plate means,
   - movable closure means pivotably associating with said cap means at pivot means thereof, said movable closure means being selectively movable between an open access and closed access position with respect to said slot means,
   - storage container means, associating with said cap means, said slot means opening to said storage container means, and said wall means depending into said storage container means,

   wherein said device facilitates detaching a sampling needle from a syringe by engagement of a needle hub portion at a stepped notch and rotation of the syringe with respect to said sampling needle hub portion, whereby a detached sampling needle and associated hub portion may be deposited through said entry port means for storage within said storage container means therebelow.

The parties' dispute centers on the undisputed fact that Devon's accused product has a flat hinged lid that can be left open, or alternatively placed in a closed position. However, once closed, Devon's lid locks in place and does not reopen. Thus, the parties argue about whether the claims require the "closure means" or "movable closure means" to move freely from a closed position to an open position. This court upholds the district court's conclusion that the claims require this movable
As a starting point, the parties dispute whether the relevant element in each claim invokes means-plus-function treatment. The use of the word "means," which is part of the classic template for functional claim elements, gives rise to "a presumption that the inventor used the term advisedly to invoke the statutory mandates for means-plus-function clauses." York Prods., 99 F.3d at 1574, 40 U.S.P.Q.2D (BNA) at 1623; see also Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584, 39 U.S.P.Q.2D (BNA) 1783, 1786-87 (Fed. Cir. 1996). However, the presumption is not conclusive. For example, where a claim uses the word "means," but specifies no corresponding function for the "means," it does not implicate section 112. See, e.g., York Prods., 99 F.3d at 1574, 40 U.S.P.Q.2D (BNA) at 1624 (construing "means" in claim without reference to section 112, paragraph 6). Likewise, where a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format. See, e.g., Cole v. Kimberly-Clark Corp., 102 F.3d 524, 41 U.S.P.Q.2D (BNA) 1001 (Fed. Cir. 1996).

In the present case, the "closure means" of claim 1 and the "movable closure means" of claim 10 use the word "means" and, thereby, presumptively implicate section 112, paragraph 6. Both claims recite a function for the "means" -- that is, closing the slot means. They also require that the closure means perform the additional functions of "controlling access" to the slot (claim 1) or being "selectively movable between an open access and closed access position" (claim 10). Neither claim explicitly recites the structure, material, or acts needed to perform these functions. Thus, the means-plus-function limitations invoke the interpretation regimens of section 112, paragraph 6.

After identifying the "specified function" of the unrecited means, a court must consult the specification to define the structure, material or acts corresponding to this claimed function. 35 U.S.C. § 112, P 6. As the district court observed, the specification makes clear the structure that corresponds to the "closing" function. There are two embodiments. In the first, a rotatable disc with an opening sits above the container cap. The disc rotates so that its opening exposes the slot means in the cap, or alternatively, so that it blocks access to the slot means. In this way, the rotatable disc allows the user selective access to the container. The second embodiment uses a hinged flap that can be pressed down to cover the slot means, or alternatively pulled up to allow access to the slot means. Both embodiments allow the user to move the closure means from the closed position to the open position and back.

B. Construction of the Claims

The essence of the dispute between the parties is whether the claims of the plaintiffs are construed to limit the patent grant to devices using a closure device fastenable at the surface of the backrest or equivalents, and, whether the claims are construed to require an armrest guard, or equivalents. Both of those disputed matters are within the scope of claim construction.

The plaintiffs' patent includes nine claims, with Claims Two through Nine dependent upon Claim One. Claim One includes a convertible seat including an adult size seat with a horizontal cushion for support, with the back support surface "having an aperture as an entrance to a cavity therein, with the operative having a closure means fastenable at the surface of the backrest." [emphasis added]. Claim One also includes "an armrest guard encircling the second cushion position when unfolded substantially parallel therewith and substantially vertical when folded."

The plaintiffs assert that the novelty of its claims are not dependent upon either the closure device (the method by which the smaller child's seat fits into the adult-sized seat) or the armrest. Relying upon the affidavit of Jerome Koziatek, the plaintiffs' assert that the "new and novel" aspect of the '216 Patent is the integration of a child seat into an adult seat.

The language of the claim itself, the prosecution history, and the prior art all refute the plaintiffs position. No fewer than three patents were issued prior to the '216 Patent which described various types of built-in automotive child seats. Previously issued patents clearly show an integrated child seat built into an adult size seat. The Bernier Patent (No. 3,094,354), for example, issued in 1963, shows one integrated child's seat which is pulled down from the back of an adult seat. (Appendix A) The same is true with respect to the Strahler Patent (No. 2,966,201) which describes an adult automotive opening and closing feature.
Further, in the "Background of Invention" accompanying the '216 Patent, it is expressly noted that "the possibility of storing a child's seat within the normal built-in seats of the automobile has not been overlooked in the past…" (Def. Ex. 1, column 1, lines 39-43) The plaintiffs themselves admitted as much when, in response to the initial patent application, an amendment was submitted which noted that "the prior art does not show an aperture having a closure means fastenable at the surface of the backrest…" (Def. Ex. 5, p. 51)

Moreover, the plaintiffs noted to the PTO in their amended filing that "…none of the references [to prior patents] have a construction wherein the armrest is foldable to a position encircling the top of the second backrest in the folded position." (Def. Ex. 5, p. 51) Only after the plaintiffs submitted such limiting descriptions of the invention did the patent actually issue.

In this case, the precise language of the claim, the state of the prior patents, the prosecutive history of the original application, and the specifications of the claim, all dovetail in the process of construing the claim. Claim One clearly references an aperture having a closure means fastenable at the surface. The claim does not limit the precise closure means. The claim therefore includes snaps, zippers, buttons, and similar devices fastenable at the surface. 3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
3 "Closure" is defined in Webster's Dictionary, Third Edition, as ".(1) a means of enclosure, (2) the action of confining…in an enclosed place…"
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

Other methods, such as an oversized cushion placed and maintained in the aperture through friction, are not fastenable at the surface but are instead held in place by pressure between the inserted cushion and the permanently placed surrounding seat cushion. Such pressure is asserted between the two at all points except the surface of the child's seat and the adult seat.

Claim One also includes specific reference to an armrest. The claim refers to an armrest which is substantially vertical when folded into the adult seat and substantially parallel to the child's seat when deployed. The armrest is described as "encircling the second cushion position when unfolded."

Under the heading "Background of the Invention," the patent document itself refers to "a secure guard encircling the child's upper body, a guard to receive the impact of the child's face in the event of a rapid deceleration." (Def. Ex. 1, column 1, lines 30-32) Further, in the description of the invention, it is noted that, "the armrest as it passes around the upper torso of the child serves as a guard for the descending face of the child if it [sic] should be thrown forward." (Def. Ex. 1, column 3, lines 18-21)

With respect to the elements of the claim at issue in this case, the Court construes the '216 Patent to require (1) a closure device fastenable at the surface which, through use of a zipper, buttons, hooks, or similar device, physically connects the surface of the backrest to the surface of the second cushion used as the foldable child's seat, and (2) an armrest guard which folds down from a vertical position and encircles the child, once such child is placed in the pulled down seat.

F. "Closure member for selectively closing said drinking hole"

The Defendants' proposed construction is "a closure member that the user chooses to engage or disengage in which the closure member, when engaged, completely covers the drinking hole (subject to the definition of 'drinking hole'). Sunbeam's proposed construction is "a structure adapted to cover the drinking hole to some extent ('drinking hole' being defined above)." Thus, the parties agree that this term incorporates the definition of the term "drinking hole," but dispute whether the "closure member" operates as a binary open/closed switch, or as a device that allows for varying degrees of closure. Sunbeam also asserts that the member need not effect only a complete closure.
1. Words of the Claim

Claims 9 and 10 of the ‘592 patent provide the relevant claim language framework for construction:

9. The assembly of claim 4 ["beverage container assembly for use with a blender"], wherein said cap has a drinking hole formed therein.

10. The assembly of claim 9, wherein said cap further comprises a closure member for selectively closing said drinking hole.

'592 Patent at 21:6-10 (emphasis added).

2. Specification and Prosecution History

The specification includes minimal discussion of this disputed claim term. The '592 patent does note that "[t]he removable cap 198 may include a drinking hole, and/or may include a closure tab to avoid spillage." '592 patent at 11:44-45.

In terms of the prosecution history, the Defendants cite the "Flores Reference," Def. Memo, at 23-24. The patent examiner references "Flores," which is a shorthand reference to a patent that discusses a "selectively actuated closure member for [a drinking] hole." The examiner observed that "a container . . . may be used for either storage or drinking of beverages," and, as such, the closure member is designed with these two types of uses in mind, "to allow for selective drinking and dispensing of the stored beverage." PI. Exh. 6, Part 2, at SB000171. The Defendants argue that, because the prosecution history references two types of uses, that supports a limitation that the closure member should have only two settings: open and closed. Sunbeam responds that "[t]he Examiner said nothing about the extent to which the closure member closes when actuated, nor did he indicate that the closure member completely covers the hole when actuated or engaged."

3. Extrinsic Evidence

Neither party has submitted extrinsic evidence pertinent to this claim term.

4. Proper Construction of "Closure member for selectively closing said drinking hole"

Neither Sunbeam's nor the Defendants' proposed construction is accurate in its entirety. There is nothing in the language of the claim or specification that limits "selective" closure to binary on/off selection. The claim encompasses degrees of closure that may include partial closure. However, Sunbeam's argument that "closure member" could refer to a device that does not allow for complete closure of the drinking hole is not reasonable.

Thus, the proper construction of the claim term is "a structure adapted to cover the drinking hole to an extent that the user may select, including fully open and fully closed, and which may allow the user to select a degree of opening somewhere between fully open and fully closed."

b. Meaning of "Closure Member Releasably Secured to Said One End of the Main Body"

The Court has not found, nor have the parties referred the Court to, anything in the patent specification that conveys an "express intent to impart a novel meaning," Optical Disc, 208 F.3d at 1334, to the claim term "closure member releasably secured." The term "closure member releasably secured" therefore takes on its ordinary meaning. Id.

The dictionary defines "closure" as "2. Something that closes or shuts" and "close" as "4. Having little or no space between elements or parts; tight and compact . . . 13. Fitting tightly." American Heritage(R) Dictionary. Therefore, the ordinary meaning of "closure member" is something whose purpose is to cause other parts either to fit tightly together, or to fit together such that the parts have little or no space between them.
"Secure" is defined as: "2. To make firm or tight; fasten." American Heritage(R) Dictionary. "Releasably" is the adverb form of "releasable," which the dictionary defines as: "2. Intended or configured to release." Id. The dictionary defines "release" as: "2. To free from something that binds, fastens, or holds back." Id. Thus, the ordinary meaning of "releasably secure" is something that is bound, fastened, or held back, but is configured such that it can be freed from being bound, fastened or held back.

Combining the ordinary meaning of "closure member" and "releasably secured" yields the following ordinary meaning for "closure member releasably secured": something whose purpose is to cause other parts either to fit tightly together, or to fit together such that the parts have little or no space between them; and whose configuration is such that the parts can be freed from being fit together.

4) "generating a clothes twist signal"

The parties also dispute the term "generating a clothes twist signal," which appears in Claims 1, 3, and 4. LG proposes construing the term to mean "generating a signal indicative of the bundling [i.e., uneven distribution] of clothes." (Id.) Whirlpool proposes instead that the term be construed to mean "generating a signal indicative of clothes that are entwined together." (Id.) For reasons already discussed, the Court will adopt Whirlpool's proposed construction. The term "generating a clothes twist signal" is therefore construed as "generating a signal indicative of clothes that are entwined together."

Claims 1, 23, 33, 59, 62, and 64 all recite some form of modulating clutch means. For example, Claim 1 recites:

a transfer case having a primary output shaft adapted to drive said primary wheels, a secondary output shaft adapted to drive said secondary wheels, modulating clutch means for selectively transferring torque from said primary output shaft to said secondary output shaft and substantially inhibiting torque transfer from said primary output shaft to said secondary output shaft.

Claims 23, 33, 62, and 64 all include similar limitations, which may be phrased "clutch means" or "adjustable clutch means." The use of the term "means" in each of the claim limitations, along with the recitation of a function, such as "selectively transferring torque . . ." raises the issue of the applicability of 35 U.S.C. § 112, paragraph 6, which deals with "means-plus-function" claims. 5 The parties' disagreement over the interpretation of this claim concerns the applicability of "means-plus-function" interpretation rules.

5 The paragraph provides that: "an element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material or acts described in the specification and equivalents thereof."
BorgWarner:

"Modulating clutch means" is a clutch that can transfer different amounts of torque from the primary output shaft to the secondary output shaft. The "modulating clutch means" may be a disk-pack-friction-plate clutch. The "modulating clutch means" does not include an actuator and may be actuated by any type of acceptable actuator. (Plaintiff's Markman Brief, at 20).

NVG:

A means-plus-function element, properly interpreted under § 112 P6 to be the structure described in the specification that performs the recited function, or its equivalent. The structure for performing the function must include clutch assembly 124, which includes an electromagnetic ball/ramp actuator, the drive and driven sprockets 160 and 166 and chain 164. (Markman Brief of NVG, at 16).

The use of the word "means" triggers a presumption that the inventor used the term advisedly to invoke the statutory mandate for "means-plus-function" clauses. Allen Engineering Corp. v. Bartell Industries, 299 F.3d 1336, 1347 (Fed. Cir. 2002). This area of patent law is a bit counterintuitive from the court's perspective. According to the Federal Circuit:

the question whether a claim element triggers section 112(6) is ordinarily not a difficult one. Claim drafters conventionally use the preface "means for" (or "step for") when they intend to invoke section 112(6), and there is therefore seldom any confusion about whether section 112(6) applies to a particular element.

Geenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996). It would seem to be a well-settled and simple rule and, consequently, it is puzzling why the patent in this case would employ the terminology if it was not meant to invoke § 112, P 6. That is what BorgWarner claims the patent does here, however, thereby creating the confusion which "seldomly" occurs.

True, there are two circumstances, however, in which courts have allowed that the presumption is not controlling. First, if a claim element employs the word "means" but recites no corresponding function, then § 57 Or. 541, 57 Or. 541, 112 P 6 is not applicable. Allen Engineering, 299 F.3d at 1347. Second, even if the claim recites a function, if it also recites sufficient structure or material for performing that function, § 112 P 6 does not apply. Id. It is this second circumstance that BorgWarner hopes to take advantage of in this case: according to it, a "modulating clutch means" is a structure sufficient to perform the stated functions of "selectively transferring torque . . . and substantially inhibiting torque . . . " from the primary output shaft to the secondary output shaft. NVG disagrees, but the difficulty here seems to be that both sides have support in the applicable case law.

Part of the problem here stems from somewhat murky, or at least less than specific, case law. As already noted, the court in Allen Engineering held that § 112 P 6 did not apply if the claim element "recites sufficient structure or material for performing that function." 299 F.3d at 1347. Then, the court went on to state that "[a] claim term recites sufficient structure if the term, as the name for the structure, has a reasonably well-understood meaning in the art." Id. In this case, we would be hard-pressed to disagree with BorgWarner that the term "modulating clutch" has a well-understood meaning in the art. Understandably, then, BorgWarner argues that "the clear reasoning of Allen Eng'r dictates that "modulating clutch means for . . . " does not invoke § 112 P 6 because it recites structure that has a reasonably understood meaning in the art." (Plaintiff's Post Markman Hearing Brief, at 10).

While the language of Allen Engineering might appear to allow such an argument, we feel it skips a step. The court was relying in part on Watts v. XL Systems, Inc., 232 F.3d 877 (Fed.Cir. 2001), which stated that "as an aid in determining whether sufficient structure is in fact recited by a term used in a claim limitation, this court has inquired into whether the term, as the name for structure, has a reasonably well understood meaning in the art." 232 F.3d at 880-81 (emphasis added). As such, we begin with the term, and we first query whether that term has a reasonably well understood meaning in the art. Certainly, "modulating clutch" is such a term. The analysis is not complete, however: the term may have a reasonably understood meaning, but it must "be understood by one skilled in the art as being adequate to perform the recited function." Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1377 (Fed. Cir. 2001). Based on the court's reading of these cases, it is not
enough that the term at issue simply have a reasonably well understood meaning in the art, as it is understood, it must also be adequate to perform the recited function.

With this understanding in mind, we can review what evidence the parties have compiled to support their contentions as to whether "modulating clutch" is a sufficient structure to perform the recited function. They rely, essentially, on expert reports (Plaintiff's Markman Brief, at 20-21; Markman Brief of NVG, at 20-21) although, as noted above, neither party presented expert testimony at the Markman hearing. As a result, the court is left to choose between dry statements, neither of which is subject to questioning from the court or cross-examination. According to BorgWarner, a "modulating clutch means" is a structure sufficient to perform the recited functions of "selectively transferring torque . . . and substantially inhibiting torque . . ." Its expert, John Starkey explains that:

A "clutch" is a device that provides an interruptible torque connection between two rotating elements. A "clutch" can use positive contact, friction, magnetic forces, or fluid pressure to transfer torques between two elements. A "modulating clutch" is an even more specific type of clutch that can transfer different amounts of torque. The dictionary definition of modulate is "to vary the amplitude." This is exactly what the modulating clutch does, i.e., vary the amount of torque transferred from none to full capacity. Such clutches use magnetic fields, fluid pressure, or friction plates to transfer the torque.

(Plaintiff's Markman Brief, at 20-21, citing App. V, Ex. A, pp. 6-7). NVG argues that this structure -- the modulating clutch -- cannot perform the function without an "actuator" which turns the clutch on and off, relying on its expert, Jeffrey Stein.

(Markman Brief of NVG, at 20, citing Ex. 9a, P 54). In his report, Mr. Stein stated:

a "friction clutch with multiple plates"-- is insufficient to perform the claimed function. One reason . . . is because the this[sic] "friction clutch" requires an actuator in order to "selectively" transfer torques (or as stated in some of the claims, "modulate or "adjust" torque levels). Dr. Starkey's "friction clutch with multiple plates" . . . would fail to perform this function this structure is missing an actuation mechanism (e.g. the electromagnetic actuation mechanism described in the specification). Additionally, the recited function requires that the torque is selectively transferred from the primary output shaft to the secondary output shaft. . . . a "friction clutch" alone cannot accomplish this function -- a chain and sprocket assembly is necessary to transfer torque from the "friction clutch" to the secondary output shaft.

(Id.). Indeed, another of BorgWarner's experts -- in patent law if not transfer cases -- Gerald Bjorge, testified -- tentatively, as he put it-- "that the term modulating clutch means by itself would not recite enough structure to be a nonmeans plus function element." (Markman Brief of NVG, Ex. 16, at 72). This automotive engineering version of "he said, he said" culminated at the deposition of BorgWarner's expert, who testified as follows:

Q: Now, what components make up that friction clutch with multiple plates?

A: The components which transmit the torque through the clutch.

Q: Can the friction plates transmit torque without an actuator of some type?

A: Clearly they need other enabling components to transmit the torque, but they are the ones that transmit the torque through the clutch.

(Markman Brief of NVG, App., Ex. 11 at 123-24). This is the type of thing that just goes back and forth and, unfortunately, the court did not have the opportunity to question the experts, and perhaps force them to commit to one position, at the Markman hearing. Significantly, though, for our purposes, the plaintiff's expert testimony stops short of asserting that the "modulating clutch" is sufficient to perform the recited function. 6 Considering all the evidence, and the varying opinions, it appears that, while "modulating clutch" may have a well understood meaning in the art, it is not a sufficient structure to perform the recited function. Accordingly, we find that § 112, P 6 is applicable.

--- Footnotes ---

6 Indeed, plaintiff's argument regarding the sufficiency of the structure to perform the recited function is without citation to the record:
The structure identified by the limitation "modulating clutch means" is sufficient to perform the functions identified in the claims. A modulating clutch clearly enables torque to be transferred from the primary output shaft to the secondary output shaft when the clutch is engaged a certain amount. Likewise, a modulating clutch will "substantially inhibit torque transfer" if the clutch is not engaged or only slightly engaged. Because a "modulating clutch" is a specific structure that both transfers torque and inhibits torque transfer from the primary output to the secondary output shaft, this limitation should not be interpreted under 35 U.S.C. § 112 P 6.

(Plaintiff's Markman Brief, at 21). These are all conclusory, unsupported assertions, however, and are inadequate, without more, to bolster BorgWarner's position.

Construction of a means-plus-function limitation involves two steps. First, the court must identify the claimed function. Cardiac Pacemakers, Inc. v. St. Jude Medical, Inc., 296 F.3d 1106, 1113 (Fed. Cir. 2002)(citing Telemac Cellular Corp. v. Topp Telecom, Inc., 247 F.3d 1316, 1324 (Fed.Cir.2001)). The court must construe the function of a means-plus-function limitation to include the limitations contained in the claim language, and only those limitations. Cardiac Pacemakers, 296 F.3d at 1113. The court may neither narrow the scope of the function beyond the claim language, nor broaden the scope of the claimed function by ignoring clear limitations in the claim language. Id. Here, "modulating clutch means" must be interpreted to be the structure set forth in the specification that performs the claimed function of "selectively transferring torque from said primary output shaft to said secondary output shaft and substantially inhibiting torque transfer from said primary output shaft to said secondary output shaft."

Second, the court must determine what structure, if any, disclosed in the specification corresponds to the claimed function. Id. In order to qualify as corresponding, the structure must both perform the claimed function, and clearly associate the structure with performance of the function. Id. The court does this -- or at least attempts to -- from the perspective of a person of ordinary skill in the art. Id.

The parties, with some reliance on their respective experts, direct the court to two different structures disclosed in the specification that purportedly perform the claimed function. BorgWarner submits that:

the components that actually transfer torque and inhibit the transfer of torque are the components of the disc pack clutch assembly 150 described in the specification. Those components include interleaved friction plates or discs 152, clutch hub 155, and annular housing 156.

(Plaintiff's Markman Reply Brief, at 14 (citing Patent '024, col. 8, ls. 52-58)). NVG claims that this interpretation ignores the requirement that torque be selectively transferred, and that it be transferred between the two shafts. As NVG would have it:

The specification makes clear that the claimed function is performed by the clutch assembly 124 (including ball/ramp device), the chain drive sprockets 160 and 166, and the drive chain 164. The specification states that these components transfer torque from the primary output shaft 40 to the secondary output shaft 26 of the transfer case when energized, as is required by the claims.

(Markman Brief of NVG, at 21 (citing Patent '024, col.9. ls. 34-42). BorgWarner criticizes this interpretation as confusing the performance of the function with the enablement of that performance. Through several rounds of briefing, the parties offer no response to these respective criticisms.

In Asyst Technologies, Inc. v. Empak, Inc., 268 F.3d 1364 (Fed. Cir. 2001), upon which BorgWarner relies, the court attempted to differentiate between a structure that actually performed a recited function, and one that merely enabled the pertinent structure to operate as intended. In that case, the recited function was "receiving and processing digital information . . ." and the disputed structure was the line that transferred the information. Obviously, the line did not "receive and process" but merely enabled that function by transmitting, so it was found not to be pertinent structure. 268 F.3d at 1370-71. BorgWarner fails to expound upon the purported analogy to its position, however. (Plaintiff's Markman Brief, at 14). The function at issue is the selective transfer of torque between the two shafts. The structure cited by NVG is directly involved in the function, along with the clutch. If "transferring" were part of the function in Asyst, we suspect the line would
be pertinent structure. Accordingly, we must find that the structure for performing the function must include clutch assembly 124, which includes an electromagnetic ball/ramp actuator, the drive and driven sprockets 160 and 166 and chain 164.

We must address one final point regarding this claim dispute. After two rounds of briefing, BorgWarner came up with a new argument at the Markman hearing and in its post-Markman hearing brief: that NVG's interpretation violates the doctrine of claim differentiation. Under the doctrine of claim differentiation, there is a presumption that each claim in a patent is different in scope, especially if "there is a dispute over whether a limitation found in a dependent claim should be read into an independent claim, and that limitation is the only meaningful difference between the two claims." Ecolab, Inc. v. Paraclipse, Inc., 285 F.3d 1362, 1375 (Fed. Cir. 2002). BorgWarner submits that claim 1, an independent claim, must be broader that its dependent claims, such as claim 10. It argues that NVG's interpretation -- that the "modulating clutch' of claim 1 must have a "electromagnetic ball/ramp actuator" -- renders claim 1 impermissibly narrower than claim 10.

The doctrine of claim differentiation, however, only guides the court's interpretation of the claims, it is not a "hard and fast rule of construction." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368, (Fed. Cir. 2000). Indeed, it is settled law that independent claims containing means-plus-function limitations do not have the same literal scope as dependent claims reciting specifically the structure that performs the stated function. Medtronic, Inc. v. Advanced Cardiovascular Systems, Inc., 248 F.3d 1303, 1313 (Fed. Cir. 2001). In Laitram Corp. v. Rexnord, Inc., the court held that "[a] means-plus-function limitation is not made open-ended by the presence of another claim specifically claiming the disclosed structure which underlies the means clause or an equivalent of that structure." 939 F.2d 1533, 1538, (Fed.Cir.1991). Thus, claim differentiation will not be applied to a situation where, as here, a dependent claim recites the only structure disclosed in the specification that could correspond to the means claimed in the independent claim. 7 Accordingly, our interpretation of this claim, then, remains unchanged: the structure for performing the function must include clutch assembly 124, which includes an electromagnetic ball/ramp actuator, the drive and driven sprockets 160 and 166 and chain 164.

7 BorgWarner argues that the case of Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225 (Fed. Cir. 2001) mandates that the doctrine of claim differentiation be applied in a means-plus-function situation, such as in this case. (Plaintiff's Post Markman Hearing Brief, at 12). In Wegner, unlike here, the court was dealing with a dependent claim that recited a separate and distinct function from the independent claim. 239 F.3d at 1234. Accordingly, the court found that the structure that performed the function recited in the independent claim should not be interpreted as requiring structure to perform the additional function of the dependent claim. Id. Plaintiff does not explain how the holding applies to the instant case, which is more akin to the situation in Laitram.

4. "a pair of actuators that . . . co-act with the wings"

This phrase is used in claim 13 of the '992 Patent. WG seeks to construe this phrase as "two actuators that act together on each wing." Ion seeks to construe this term as "a pair of actuators that interact with the wings."

WG once again points out that the specification discloses one roll actuator and one pitch actuator, each of which are linked to both wings. Ion argues that its construction finds support in the prosecution history of this patent, which describes first and second actuators that "interact" with the wings to control the depth and lateral position of the underwater cable. Ion also points out that it is not necessary for both actuators to act on each wing. This Court once again agrees with Ion that it is not necessary to construe this term such that both actuators act on each wing by definition. While this is clearly the preferred embodiments of the invention, as explained above, there is no disavowal of the possibility left open by the claim terms that the each actuator may be assigned to a different wing. Moreover, although WG argues that its construction is more consistent with the plain and ordinary meaning of the term because "co-act with the wings" clearly means that the actuators are acting together on the wings, the Court does not find that this interpretation to be so obvious. The language of the claims does not make clear that the "co-actors" are the two actuators, rather than a single actuator co-acting with a single wing. Accordingly, absent a disavowal of claim scope, the Court will not construe this term as WG argues in order to limit its
scope. Therefore, the Court rejects WG's construction to the extent that it suggests that both actuators must act on each wing.

Furthermore, the Court notes that the context in which this claim term is used refers to the actuators co-acting with the wings "to adjust angular positions of the wings to control the depth and lateral position of the underwater cable in the water." (‘992 Patent, col. 30 ll. 41-44.) Accordingly, Ion's construction, which finds some support in the prosecution history, seems to offer the most logical construction of the term "co-act" as it is used in the context of the claim language. What is being described in the claim is clearly a device in which the actuators are interacting with the wings in order to adjust their angle, thereby influencing the position of the streamer. WG's use of the verb "act together," by contrast, does not offer a clear construction of the claim language, as it is not clear which mechanisms are acting together with what. Accordingly, because it most accurately reflects what is being described with the use of this claim term, the Court adopts Ion's construction, and construes this phrase as "a pair of actuators that interact with the wings."

733

B. "Co-extrusion . . . within, or co-extruding . . . within" (Claims 1, 17, 25, 78, and 89)

Plaintiff contends that this claim limitation means a technique where two dissimilar materials, coming from an extruder and a pump, are combined within an extrusion die forming a first/inner component within a second/shell component. Defendants contend that based on the intrinsic evidence, the claim limitation means the act of forming components by jointly extruding two dissimilar materials such that the inner component is introduced into the interior of the formed shell component.

In support of their more limited construction, Defendants argue that the term "within" means "in or into the interior." Webster's Collegiate Dictionary 1359 (10th ed. 1996). Thus, "co-extrusion within" the shell component means "co-extrusion into the interior" of the shell component, and the shell component must already be in existence when the inner component leaves its extruding tube.

Defendants also argue that during the prosecution of the patent-in-suit, Plaintiff added the "co-extrusion within" limitation in response to the first rejection by the Examiner, in order to gain allowance of its claims over the prior art as patented by Repholz ("Prior Art"). According to Defendants, the Prior Art used slightly recessed tubes that extruded the inner component into the outer component, which was also extruded, and the combined components exited a die to form a third center-filled extrudate. See Defendants' Memorandum of Points and Authorities in Support of its Construction of the Asserted Claims, pg. 21, lines 4-17. Plaintiff stated to the Examiner that its claims were distinctly different from those of the Prior Art. See Jt. App., Exhibit B, pg. 136. Therefore, Defendants assert that the prosecution history, in combination with the ordinary meaning of the word "within," support their construction of the claim.

The intrinsic evidence in this case makes clear that "co-extrusion . . . within, co-extruding . . . within" simply means "a technique where two dissimilar materials are combined by means of two extruders or an extruder and a pump to form a product wherein one material is contained within the other." This interpretation is supported by the extrinsic evidence offered by Plaintiffs. See Scheider Decl., Exhibit 10, pg. 63 and Herberst Decl. P 11; see also Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1308-09 (Fed. Cir. 1999) (holding that a court may consider extrinsic evidence to ensure that the court's understanding of the technical aspects of the invention is not at odds with the understanding of one skilled in the art). In the section entitled, "Detailed Description of the Invention," the written specification states, "in one preferred embodiment of the invention, an extruded shell product includes an inner cream material pumped into a shell extruder die plate and distributed evenly within extruded ropes." Jt. App., Exhibit A, col.4, lines 55-58. Nowhere in this description or in any of the claims is there a detailed description of the exact mechanical process by which the extrusion technique is completed, or the type of apparatus by which the product is formed. While, as Defendants point out, Plaintiff did distinguish its proposed patent from the Prior Art in the prosecution history, there is no indication that the distinction is based on a difference between extruding the inner component in an already existing extrudate shell component, or combining the two components within an extrusion die. See Jt. App., Exhibit B, pg. 136. Therefore, importing Defendants' proposed limitation into the phrase is improper.
734

I. Construction of "Coalesce," "Coalescence" and "Completion of Coalescence"

The '963 patent uses a form of the word "coalesce" 47 times in the specification and claims, but the term is not specifically defined in the patent. Both parties urge the court to apply the ordinary meaning of the term but disagree as to what that is. Plaintiff urges the court to adopt the following definition of "coalescence":

"The process of forming a uniform, homogeneous body, or combining into one body or growing together, through the merger of smaller particles of the same material."

Plaintiff's Memorandum in Support of Markman Hearing ("Plaintiff's Brief"), pp. 17-18. Defendants urge the following definition of "coalescence": "the uniting together of plastic particles to form a layer." Defendants' Markman Brief ("Defendants' Brief"), p. 15.

There is no dispute that "coalescence" is a process, but the parties disagree as to what that process encompasses. The parties illustrate their respective positions through reference to an illustration by defendants' expert, Paul Nugent. Plaintiff's Brief, p. 6; Defendants' Response Brief, Ex. 8, p. 4. The illustration shows plastic particulate adhering to the interior wall of a mold at seven successive stages. The parties agree that defendants' definition of "coalescence" corresponds to stages one though two or three, during which the particles form a layer on the interior wall of the mold or preceding layer. The caption under stage two is "Powder and Molten Layer," and the caption under stage three is "Uneven and Bubbles." The parties further agree that plaintiffs definition of "coalescence" corresponds to stages one through five, during which the particles form a smoother and denser layer then is present at the end of stage two or three. The caption under stage five is "Optimum." Stages 6 and 7 consist of undesirable over-curing.

The parties cite definitions from various sources in existence at the time the patent was issued to support their respective positions. Among these are the definitions of "coalesce" from: (1) Webster's Third New International Dictionary (1971), "1: to grow together . . .: unite by growth into one body . . . 2 a: to unite or join together into one body or product: become integrated into a whole"; (2) The Phillips Petroleum Glossary of Plastic Terms, 4th Ed. (1965), "[t]o combine into one body or to grow together"; (3) The Random House Dictionary of the English Language, 2nd Ed. (1987), "1. to grow together or into one body . . . 2. to unite so as to form one mass, community, etc . . . 3. to blend or come together . . . 4. to cause to unite in one body or mass."

Plaintiff asserts that defendants seek to impose a limitation that is not supported by the definitions-specifically that "coalescence" does not include any part of the process after the articles have formed a layer. The definitions support plaintiff's position that "coalescence" may include the subsequent part of the process leading to a more homogeneous body, i.e., one that is more dense and smooth. Plaintiff's position is supported by the inclusion in the definitions of the concepts of growing together, integrating or blending into one body, mass or product.

The parties also rely on the prior art to support their respective positions, including patent No. 3,936,565 obtained by Elmer Good in 1976 for a molded plastic article and method ("the Good patent"). Among other instances, the Good patent uses the term "coalesce" in the following manner:

"During the rotation of the mold assembly, with the first charge of plastic material in the interior of the mold, the particles initially adhere to the heated mold surface, and thereafter coalesce into a continuous skin element which follows the contour of the interior of the mold. Thereafter, and in sequence and while the mold assembly is still within the heated oven the second charge of plastic is introduced in to the interior of the mold, and the rotation continued until the second material coalesces over the first. In the event that a third charge is used, the third charge is thereafter sequentially released to form the inner skin element."

First Lee Aff., Ex. E, p. 6, Col. 7, ll. 21-33 (emphasis supplied). The Good patent describes the particles as initially adhering to the heated mold surface and thereafter coalescing into a continuous skin element. That use supports plaintiff's position that "coalescence" encompasses more than the forming of a layer, because the Good patent describes coalescence to include the process following the particles adhering to the mold surface, i.e., following their forming of a layer.
Likewise, the Good patent also provides:

"For purposes of explanation, and referring to FIG. 5b, a point is reached during the processing of the first introduced plastic material in which a continuous skin 36 is formed on the interior wall 33 of the mold, and an assemblage of particles 32 is adhered to the continuous skin 36 but not yet coalesced since the heat transfer through the mold wall and the skin is a progressive transmission of heat."

Id. at Col. 7, ll.60-67 (emphasis supplied). Here too the Good patent uses "coalescence" to include the process that follows the particles adhering the mold wall to form a layer. Figure 5b shows particulate plastic united to form a layer (32) over the continuous skin (36), and the description specifies that, at that point, the layer (32) has not yet coalesced. This supports plaintiff's position that "coalescence" is a process that includes more than the particles uniting to form a layer.

The parties also cite patent No. 3,455,483 obtained by P.A. Inklaar in 1969 for a "foam-sintering" molding process and products ("the Inklaar patent"). The Inklaar patent uses "coalesce" to describe a process that includes melting and fusion:

"The finely divided thermoplastic material to be used is one that will coalesce into a fused layer or film by melting." First Lee Aff., Ex. R, p. 3, Col. 3, ll. 37-39. Likewise, the Inklaar patent also provides:

"while heating the mold externally at a temperature above the melting range of the material of the charge until the heat passed through the mold and by conduction from said surface has coalesced such particles into a shape-retaining coherent fused layer of required thickness over said surface . . . ."

First Lee Aff., Ex. R, p. 6, Col. 10, ll. 40-45. Here too the Inklaar patent uses "coalesced" to refer to a process that produces a "coherent fused layer of required thickness." Inklaar's usage supports plaintiff's position that "coalescence" includes the process beyond the formation of a layer, in which the layer becomes more homogeneous and smooth.

Also at issue is the meaning of "completion" as used in the phrase "completion of the coalescence" contained in Claims 1 and 9. Specifically, Claim 1 provides:

"removing the mold assembly from the oven for cooling prior to completion of the coalescence of said second charge;"

"whereby the cooling of the mold assembly and the first layer is concurrent with completion of the coalescence of the second layer so as to shorten the elapsed time during the molding process."

First Lee Aff., Ex. J, p. 7, Col. 7, ll. 4-11 (emphasis supplied). Similarly, Claim 9 provides:

"removing the mold assembly from the oven prior to completion of the coalescence of the third charge;"

"air cooling the mold assembly after removal of the mold assembly from the oven while continuing mold assembly rotation during continued coalescence of the third charge; and"

"opening the mold assembly after coalescence of the third charge is completed while continuing to air cool the mold assembly so as to expose the mold cavity to cooling air."

Id. at Col. 8, ll. 37-47 (emphasis supplied). The meaning of "completion" is provided by dictionary definitions, since there is no indication that the '963 patent used the term in any sense other than its ordinary meaning. Thus, completion means: having all necessary parts, elements or steps; brought to an end; fully carried out. See First Lee Aff., Ex. X, p. 4.

In light of the intrinsic record and published definitions at the time of the invention, "coalescence" is the process of forming a uniform, homogeneous body, or combining into one body or growing together, through the merger of smaller particles of the same material. "Coalescence" is "complete" when it has all necessary parts, elements or steps, or is fully carried out.

This construction of "coalescence" and "completion of coalescence" is supported by the specification, which provides:

"Before completion of coalescing of the third charge as inside layer 16, the rotating mold assembly 22 is removed from
the oven 20 when door 32 is opened. Rotation continues in cooling area 30 as fans 34 blow air at mold assembly 22. During such early portion of the cooling time, the mold cavity remains closed and coalescing of the third charge continues. Inside layer 16 formed by the coalescing third charge will be intimately joined with insulating layer 14.

"When coalescing of the third charge is completed, the mold cavity is opened and rotation of mold assembly 22 continues as fans 34 continue to blow air on the assembly."

First Lee Aff., Ex. J, p. 6, Col. 6, ll. 3-16 (emphasis supplied). Here, inside layer (16) is described as being formed by the "coalescing" third charge. As such, it would be understood that "coalescence" is not complete merely because a layer has been formed. Furthermore, the specification teaches to open the mold cavity when coalescence of the third charge is complete. Under the construction urged by defendants, the specification would teach that the cavity should be opened for cooling when the inside layer consists of a powder and molten layer, or is uneven with bubbles, i.e., at stage two or three of the Nugent diagram. One of ordinary skill in the art would not understand that to mean that the mold cavity should be opened for cooling as soon as the particles had united to form a layer, because that would produce an unusable part. Rather, one of ordinary skill in the art would understand that to mean that the mold cavity should be opened for cooling when the particulate had reached its optimum state, such that the inside layer is appropriately smooth and homogeneous, to produce a useable part.

Defendants cite portions of the specification to support that "coalescence" means only to unite to form layer. These include:

"the first charge will begin to melt and coalesce on the mold cavity wall to form outer layer 12 of the laminate."

"After coalescing of the first charge in this manner and before cross-linking of outer layer 12 is completed, the second charge will be released from the insulating box. . . .

"After coalescence of the second charge as insulating layer 14, the third charge is released. . . ."

First Lee Aff., Ex. J, p. 6, Col. 5, ll. 51-68 (emphasis supplied). Defendants argue that, because "coalesce" is repeatedly used in tandem with terms describing the formation of a layer, it means to form a layer. However, if that were the case, it would not be necessary to include the words of limitation about the formation of a layer because it would be implicit in the term "coalesce" itself. The more reasonable interpretation is that the words of limitation were included to direct the user to a specific point in the longer coalescence process, which is consistent with plaintiff's position that "coalescence" incorporates the process beyond the formation of a layer, to the point when the plastic reaches its optimum state.

In sum, "coalescence" is the process of forming a uniform, homogeneous body, or combining into one body or growing together, through the merger of smaller particles of the same material. "Coalescence" is "complete" when it has all necessary parts, elements or steps, or is fully carried out. The construction of these terms bears on the next major issue: what does the patent teach regarding when to release successive charges? This issue, which the parties refer to as the "sequencing of steps," is addressed below.

With one minor exception, discussed later, both parties agree that the term "heat treated coated article" should be interpreted as "a coated article that has been heated to a temperature for a sufficient period of time to enable thermal tempering, bending or heat strengthening of the articles."

The parties major point of contention is how to interpret the claim term "coated article" by itself. AFG argues that the unmodified term "coated article" when used alone should be interpreted as an article "coated with a heat treatable coating." Guardian argues that AFG is impermissibly reading a limitation ("coated with a heat treatable coating") into the claim term.

Only the '050 patent, claims 9-22 and 24 use the unmodified "coated article," i.e. without any reference to the coated article being either heat treated or coated with a heat treatable coating. In contrast, claims 1-8 specifically refer to the coated article
as "after being heat treated (HT)." Similarly, claim 23 also states the "the coated article of claim 21, wherein the article is heat treated."

AFG argues that the '050 patent term "coated article" must be interpreted consistently throughout the patents. The consistent definition, according to AFG, would be that the term "coated article" refers to articles that are either heat treated or have a heat treatable coating. AFG also points to the invention's function to reduce haze and improve durability through heat treatment. "This invention is to provide a heat treatable low-E coating (or layer system) which is mechanically and/or chemically durable before and after heat treatment, the coating system having a visible transmittance of at least about 70%." '050, Col. 1 line 66 through Col. 2 line 4. Moreover, the specifications of the '050 patent describes the invention as relating to "heat treatable (low-E) coated articles." '050, Col. 1, lines 9-10. AFG's argues that their definition would support both the goals and description of the patents.

Guardian claims that no special interpretation is necessary for the claim term "coated article" and that the patent principle of claim differentiation should be employed.

The concept of claim differentiation . . . states that claims should be presumed to cover different inventions. This means that an interpretation of a claim should be avoided if it would make the claim read like another one. Claim differentiation is a guide, not a rigid rule. If a claim will bear only one interpretation, similarity will have to be tolerated.

The case for claim differentiation is supported by Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). In that case, the Federal Circuit found that the patent principle of claim differentiation gave further support to the Plaintiff's interpretation where "the presence of a dependent claim that adds a particular limitation raises a presumption that the limitation is not found in the independent claim." Id. (citations omitted).

Guardian argues that by not reading the limitation of "heat treated" or "heat treatable coating" into the term in the '050 patent, the court would be adhering to the claim differentiation principle that ordinarily, different words in a patent have different meanings. Here the same type of relationship is present. For example, claim 21 is an independent claim without the "heat treatable coating" limitation. The dependent claim 23, then adds the particular limitation of "wherein the coated article is heat treated." Moreover, independent claim 9 and all of its dependent claims 10-17 never limit the term "coated article" as either being heat treated or being coated with a heat treatable coating.

AFG argues that claim differentiation should apply to the term "heat treated" since dependent claim 23 only differs from claim 21 in that it is "heat treated." However, AFG argues that this principle should not apply to the limitation it proposes to the term "coated article," i.e. "which has been coated with a heat treatable coating." The reason is that the limitation of claim 23 ("wherein the coated article is heat treated") relates to something that has already been heat treated, not whether the coated article can be heat treated or has a heat treatable coating. AFG argues that if claim 21 were not coated "with a heat treatable coating," then claim 23 would make little sense, since claim 23 is merely a coated article that has been heat treated. If the coated article were not coated with a heat treatable coating, then it could not have been heat treated in claim 23. Thus, according to AFG, the definition of "coated article" necessarily includes the limitation "which has been coated with a heat treatable coating."

If the court is to read the term "coated article" consistently and in line with the invention's goals and functions, the court agrees that the "coated article" must be able to withstand heat treatment. Since the generic "coated article" could be modified by being heat treated in claim 23, the "coated article" interpretation should include that it can be heat treated. However, the claim's terms and the specifications never discuss whether it is the coating that causes the article to be able to withstand heat treatment. Thus, this court will not read this particular limitation, "which has been coated with a heat treatable coating," into the claim. Instead, the court adopts the interpretation: a "coated article" is an "article that is coated and is heat treatable."

In their briefs, the parties present a subsidiary question of whether the definition of "heat treated coated article" should include the phrase "for a sufficient period of time" in its definition, "heating an article to a temperature for a sufficient period of time to enabling thermal tempering, bending, or heat strengthening." It is apparent from the face of the words that
heat treatment will take time. If the purpose of heat treatment is to allow for certain properties to come out (thermal tempering, bending or heat strengthening), it is clear that the heat treatment will require certain amount of time. Moreover, in the examples for both the '349 and '050 patents it states explicitly that the heat treatment definition includes heating a coated article to a temperature of at least 1100 degrees F "for a sufficient period to enable tempering." '349 Col. 23, lines 39-40 and '050 Col. 20, lines 16-17. The phrase "for a sufficient period of time" is properly included in the claim interpretation.

H. "at least one coating"

The term "at least one coating" appears clear and unambiguous on its face and should be construed as "a coating of one or more layers." There is nothing in the specification that limits the patent to a "coating which reflects electromagnetic radiation (specifically, infrared radiation emitted by the light-emitting element) back to the light-emitting element." See Sylvania's Br. at 18. The infrared reflective coating discussed by Sylvania is merely a preferred embodiment but is clearly not the only embodiment for the patented invention. As explained, unless the preferred embodiment is the exclusive invention disclosed by the patent, the patented invention is not limited to the preferred embodiment. Unless there is limiting language in the specification suggesting that the patented invention would not work with more than one coating on the envelope, or that such a requirement is an improvement over the prior art, then the scope of the claim is not limited to the preferred embodiments described in the specification. See Fuji Photo, 386 F.3d at 1106.

Further, the doctrine of claim differentiation, once again, does not support Sylvania's proposed construction. See Comark, 156 F.3d at 1187 (claim differentiation "create[s] a presumption that each claim in a patent has a different scope"). Here, Sylvania's proposed claim construction impermissibly reads into independent Claim 1 limitations that are explicitly present in dependent Claims 8, 10 and 11 but not present (explicitly or otherwise) in Claim 1. Accordingly, imposing such a construction on Claim 1 would render superfluous the language in Claims 8, 10 and 11.

For example, Claim 8 of the '017 Patent states:

A lamp according to claim 1, and further comprising a second coating on said envelope, one of said coatings comprising an infrared coating on one of the surfaces of the envelope, and the other coating including an ultraviolet reflecting layer on the other surface of the envelope.

See '017 patent, Claim 8. In addition to having all of the same limitations as Claim 1, Claim 8 requires that in addition to having "one or more coating" as required by Claim 1, the coating is an infrared coating. This is the exact same limitation Sylvania wants to read into Claim 1. Thus, I find that the doctrine of claim differentiation is applicable and imposing such as a construction on Claim 1 would render Claims 8, 10 and 11 superfluous.

6. "Coating At Least One of Said Outer Surfaces of Said Core With a Layer of Ink"

"Coating at least one of said outer surfaces of said core with a layer of ink" means, "Covering at least one of said outer surfaces of said core with a finishing layer of ink."

The only term in this phrase requiring construction is the word "coating."

Plaintiff's proposed definition is that "coating" means "covering." (Pl. Br. at 24.) Plaintiff cites Webster's, p. 219, for the ordinary meaning of "coating" as "2: to cover or spread with a finishing, protecting, or enclosing layer," and notes that the claims in the Patents specify that the layer is ink. (Pl. Br. at 24.)

Claim one of the '207 patent recites the coating step as follows:
(b) positioning said at least one electronic element . . . directly between said first and second plastic core sheets to form a core, said plastic core sheets defining a pair of inner and outer surfaces of said core, (c) positioning said core in a laminator apparatus, and subjecting said core to a heat and pressure cycle . . ., (d) coating at least one of said outer surfaces of said core with a layer of ink, and (e) applying a layer of overlaminate film to at least one of said outer surfaces of said core.

'207 patent, col. 6:22-38. The specification further provides, "... the use of matte finished laminator plates provides surfaces with a slightly roughened or textured quality which will facilitate the application of a coating thereto..." '207 patent, col. 4:54-58. The Summary of the Invention in the '207 patent describes that "at least one of the upper and lower surfaces of the core comprises a coating printed or otherwise applied thereon," '207 patent, col. 2:20-24, and further explains that the "core is coated on at least one of it's [sic] upper and lower surfaces with a layer of printing ink. This may be accomplished by a wide variety of printing techniques." '207 patent, col. 5:6-12.

The '099 patent contains similar language, using "coating" and "covering" interchangeably--"the sheet of plastic card stock . . . comprises at least core with at least one surface thereof covered by a layer of ink." '099 patent, col. 7:45-51 (numerical references omitted). The prosecution histories of the '207 patent and the '099 patent clarify that "coating" is used to mean more than merely "printing on."

It is important to note that the word "core" is used in all of the patents to describe what I have termed the "sandwich" -- that is, the electronic element and the two plastic sheets that directly touch it. Nothing more is included in the definition of the word "core." 9

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 Note that the "book," referred to earlier, is comprised of the "sandwich" -- that is, the electronic element and the two plastic sheets that directly touch it. Nothing more is included in the definition of the word "core." 9

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Defendant proposes that "coating... with a layer of ink" means that "the ink layer must directly contact at least one of the 'outer surfaces' of the 'core.'" (Def. Br. at 34.) Defendant cites to the claim and specification language cited above in support of its definition. Defendant also notes that the '207 specification states that, "This printing step is performed to coat at least one surface of core with a layer of aesthetically pleasing ink." (Def. Br. at 35, quoting '207 patent, col. 5:6-17. (numeric references omitted.) Finally, Defendant notes that Leighton "did not disclose applying another layer with ink imprinted on it to an outer surface of the core itself," and then quotes the '207 patent, "This layer of ink cosmetically hides the one or more electronic elements that are embedded within core, and prevents these one or more electronic elements from showing through the relatively thin core." (Def. Br. at 35, quoting the '207 patent, col. 5:17-21 (numerical references omitted.) In sum, Defendant argues that the intrinsic evidence leads to the conclusion that "coating... with a layer of ink" means the ink is applied to at least one of the "outer surfaces" of the "core," so the layer of ink "directly contacts that outer core surface." (Def. Br. at 25.)

As is clear from the above language, Defendant is trying to preclude Plaintiff from claiming that the patent covers a process wherein something is applied directly to the surface of the core before the surface is covered with ink. The analogy used by the parties at the Markman hearing was as follows: Assume we are interpreting the sentence, "The table is covered with ink." Obviously, if a layer of ink is applied directly to the top surface of the table, the table is covered with ink. The question posed by the parties was whether, if a tablecloth were placed over the top surface of the table and the cloth were then covered with ink, the table would be covered with ink.

The answer is no. The table would then be covered with an ink-stained tablecloth. The ink would cover the cloth, and the cloth would cover the table. But the ink would not coat the table -- it would coat the cloth. This notion of immediacy (or what Defendant calls direct contact) is implicit in the dictionary definition of "coat," which is "to cover or spread with a finishing, protecting or enclosing layer." Ink applied otherwise than to the surface of the core itself would not "finish" or "enclose" the core.

GO BACK
7. "coating layer"

Claim 1 recites a "coating layer substantially enveloping said plurality of cords." Otis asserts that "coating layer" should mean "a layer of material that separates individual cords and defines an engagement surface for engaging a traction sheave." Schindler proposes that the term be defined as "a material which surrounds, fully encases or encapsulates the cords at least around the circumference of the cords." Schindler asserts that Otis' interpretation is incorrect as the "separates individual cords" and "defines an engagement surface for engaging a traction sheave" language imports extraneous limitations into the term.

The Court will adopt a construction of "coating layer" that is similar to Schindler's proposed definition. First, as Schindler argues, the "separates individual cords" limitation should not be read into the term. See Sram Corp. V. AD-II Eng'g. Inc., 465 F.3d 1351, 1358 (Fed. Cir. 2005). Although it is true that most embodiments of the claimed tension member might have a coating layer that separates the individual cords, this separation is not mandatory. Otis listed the required functions of the coating layer in the specification and in an amendment to the patent-in neither instance did Otis recite a "separation" function. Just as the Court rejected Schindler's argument that the cords must be touching each other (see section III.A.6 above), it rejects Otis' assertion that the wires cannot be in contact with each other in any potential embodiment of the claim.

The Court will construe "coating layer" as "a layer of material that substantially surrounds, encases or encapsulates the cords, and defines an engagement surface for engaging a sheave."

5. "Coating of one or more inks forming a design on the lower surface and adapted to show through the plastic sheet to be seen through the top surface."

Microthin proposes that the phrase "coating of one or more inks forming a design on the lower surface and adapted to show through the plastic sheet to be seen through the top surface" should be construed to mean "coating of one or more inks forming a design that is reverse printed on the lower surface of the plastic sheet such that it can be seen through the plastic sheet on the upper surface and can be viewed correctly through the upper surface of the plastic." Here again, SiliconeZone argues that the phrase requires no special construction but should be construed according to its plain and ordinary meaning in the context of the claim language.

Microthin's proposed construction is only slightly different from the plain and ordinary meaning of the disputed phrase. The potentially confusing language in the phrase, as written in claim 1, is that the design is "adapted to show through the plastic sheet." Microthin's construction interprets this phrase to mean that the design is reverse-printed on the lower surface such that it may be viewed correctly through the upper surface. Microthin's construction is partially supported in the specification for the '311 Patent where it specifically speaks of a "reverse printing process" as the means for the mat to "contain suitable advertising, such as a multicolor logo, or a design, such as a picture, school emblem or logo, or other pictures or scenes, etc." Memorandum, Ex. F(a), Patent No. 5,942,311, at 3:45-54. However, the specification also discloses more general designs on the lower surface made through a series of screens for multiple colors that are visible through the upper surface of the mat. See Memorandum, Ex. F(a), Patent No. 5,942,311, at 3:40-44. Therefore, while the patent does mention "reverse printing" to achieve a "correctly viewed" picture or image, such a limitation is not required by the patent and the Court will not read such a limitation into the claim. See Johnson Worldwide Assoc., Inc. v. Zebeho Corp., 175 F.3d 985, 992 (Fed. Cir. 1999) ("[J]ust as the preferred embodiment itself does not limit claim terms . . . mere inferences drawn from the description of an embodiment of the invention cannot serve to limit claim terms."). Because there is a reasonably plain and ordinary meaning for the disputed phrase in the claim, and because Microthin's construction would effectively add a limitation to the claim, the Court construes the disputed phrase to mean exactly what the claim already says: "coating of one or more inks forming a design on the lower surface and adapted to show through the plastic sheet to be seen through the top surface."
Plaintiffs submit that the term "coaxially arranged" needs no construction because one skilled in the relevant art would know "that a coaxial arrangement of a pipe-in-pipe system merely requires that one pipe be fitted within another and generally centered." 11 Defendant originally proposed that the term "means that the inner tube and the outer tube share the same central axis for their entire lengths." 12 At the Markman hearing, Defendant retracted its suggestion that the tubes must be centered for the entire length of the pipeline, contending instead that the ordinary interpretation of the term means that "the inner and outer tubes are on a common axis." 13 Defendant particularly takes issue with Plaintiffs' attempt to interject the modifier, "generally," to broaden the claim meaning.

Although the definition of "coaxially arranged" may be obvious to one skilled in the art, as argued by Plaintiffs, it may not be so clear to a member of the jury. The term, therefore, requires construction in order to obviate the parties' desire to educate the jury regarding the understandings of one skilled in the art.

"Coaxially arranged" is not defined by the patentee in the claims themselves or anywhere in the intrinsic evidence. The court, therefore, finds it appropriate to turn to a dictionary definition. The 1994 edition of a scientific dictionary defines "coaxial" as "sharing the same axes." McGraw-Hill Dictionary of Scientific and Technical Terms 394 (5thed. 1994). Similarly, a Webster's desk-reference dictionary defines "coaxial" as "having or mounted on a common axis." Webster's II New Riverside University Dictionary 275 (1984). The term "arrange" is not defined in the scientific dictionary, but is given the following meaning by the Webster's dictionary: "to put in a specific order or relation." Id. at 126. Combining the two, "coaxially arranged" can be defined as associated in such a way as to share a common axis. The common axis in a pipe-in-pipe design is an imaginary line down the center of the inner pipe. Accordingly, the shared axis is "central."

Looking to the specification for confirmation, the court notes that the purpose of the coaxial pipe-in-pipe arrangement is to allow free space between the insulation and the outer pipe all the way around so that low pressure can be achieved and maintained between the pipes. 14 On the whole, the description suggests that some amount of space is critical to successful implementation of the invention, but not that absolute uniformity is required. In fact, the limitation in dependent clause 10, which teaches the use of centering spacers, suggests the patentee's recognition that, absent spacers, the pipes in claim 9 may not remain perfectly centered throughout the length of the pipeline. 15 On this point, the specification states, "According to still another feature of the invention, there is provided with advantage spacers aimed at centering the inner tube inside the outer tube by maintaining an adequate minimal gap between the inner and the outer tube sequentially from one portion to another through the entire length of the pipe." 16 Furthermore, the patent description recognizes that variations in wall thickness and roundness may occur during pipe manufacturing and are tolerated by persons skilled in the relevant art. 17

11 Plaintiffs' Brief in Opposition to Defendant's Opening Claim Construction Brief, Docket Entry No. 27, p. 3.

12 Defendant's Brief on Claim Construction, Docket Entry No. 23, p. 9.

13 Defendant's Markman hearing arguments.

15 See id. at 9:56-10:2.

16 Id. at 5:61-66.
From these references, the court concludes that an annulus of perfectly equal free space throughout may be ideal, but is not necessary. On the other hand, the amount of free space called for by the patent is measured in millimeters, 18 which leaves little room for variance. The court certainly would not consider such a small deviation to warrant the interjection of the term "generally" into the definition. Overall, the court finds no justification for narrowing the term by requiring the pipes to be perfectly centered or for broadening the term by adding the modifier "generally."

Accordingly, the court recommends that "coaxially arranged" can be defined as put together in such a way as to share a common central axis.

"Cockpit":

The depression toward the center of the watercraft in or on which the paddler or paddlers sit.

(K) Reduced coefficients of friction

A ratio of the force that maintains contact between an object and a surface, and the frictional force that resists the motion of the object in the static state and in the dynamic state.

The court heard oral argument on the issue of claim construction in order to better understand the extent of the parties' disagreement about the construction of the claims. During oral argument, both parties focused primarily on the '273 patent. Since neither party has distinguished the facestock claims of the '273 patent from the facestocks claimed as part of the process patents, the court's reasoning in this opinion regarding construction of the '273 patent should be considered applicable to the '532 and '669 patents.

When considering the claims, the "terms of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently." ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988) (citation omitted). Claim 19 of the '273 patent provides:

19. A multilayer facestock for use in pressure-sensitive label, tape or sign applications comprising a coextrudate of cojoined layers comprising a relatively thick core or base layer of polymeric film material of a stiffness of between 10 and 100 Gurley and which contributes the majority of the dimensional stability and stiffness of labels or signs cut or formed from the facestock, and at least one relatively thin skin layer, said skin layer being on the face side of the coextrudate and having an ink-printable surface, and a pressure-sensitive adhesive layer combined at the side of said coextrudate opposite said face side.
Claims 20 and 21 are dependant on claim 19 and necessarily incorporate by reference all the elements of claim 19. Claims 19-21 cover a plastic multilayer facestock or film. Claim 1 of the '532 patent provides:

1. A method of economically manufacturing die-cut labels or signs using roll or sheet facestock, comprising the steps of providing a plurality of at least two charges of film-forming resin, coextruding said charges to thereby form a construction in the form of a multilayer extrudate comprising a relatively thick core layer and at least one relatively thin skin layer, the former layer providing the majority of the dimensional stability and stiffness of the construction, preselecting the charge for said core layer, as by selection of density or flex modulus, to provide a degree of stiffness suitable for the label or sign application, preselecting the charge for said skin layer to provide a skin adapted to the intended decorating process, such as printability, or surface performance characteristics, such as weatherability of the facestock, and combining said extrudate with a pressure-sensitive adhesive layer to form label or sign facestock, combining said facestock with a liner, die-cutting said facestock to form a label or sign releasably adhered to said liner and surrounded by a matrix of excess facestock material to utilize non-tearing self-supporting properties of said material to pull said matrix away from the die-cut label or sign.

Claims 3 and 8 are dependent on claim 1 and claim 9 is dependent on claim 8. Claim 14 of the '532 patent provides:

14. A method of economically manufacturing die-cut labels or signs using roll or sheet facestock, comprising the steps of providing a plurality of at least two charges of film-forming resin, coextruding said charges to thereby form a construction in the form of a multilayer extrudate having a face side and a back side, said multilayer extrudate including stiffening layer means which contributes the majority of the stiffness of the construction, preselecting at least one of the charges, as by selection of density or flex modulus, to provide said stiffening layers means with a degree of stiffness suitable for the label or sign application, and combining said multilayer extrudate with a pressure-sensitive adhesive layer and release liner to form linered label or sign facestock, die-cutting said facestock to form a label or sign releasably adhered to said liner and surrounded by a matrix of excess facestock material, and stripping said matrix of excess facestock material to utilize non-tearing self-supporting properties of said material to pull said matrix away from the die-cut label.

Claim 16 is dependent on claim 14. Claim 1 of the '669 patent provides:

1. A method of economically manufacturing die-cut labels or signs using roll or sheet facestock, comprising the steps of providing a plurality of at least two charges of film-forming resin, coextruding said charges to thereby form a construction in the form of a multilayer extrudate comprising a relatively thick core layer and at least one relatively thin skin layer, preselecting the charge for said core layer, as by selection of density or flex modulus, to provide said facestock with a degree of stiffness suitable for the label application, preselecting the charge for said skin layer to provide a skin adapted to the intended decorating process, or surface performance characteristics, of the facestock and combining said extrudate with a pressure-sensitive adhesive layer and release liner to form linered label or sign facestock, die-cutting said facestock to form a label or sign releasably adhered to said liner and surrounded by a matrix of excess facestock material, and stripping said matrix of excess facestock material to utilize non-tearing self-supporting properties of said material to pull said matrix away from the die-cut label.

Claims 2, 3, 7, 8 and 9 are dependent on claim 1. Claim 11 of the '669 patent provides:

11. A method of economically manufacturing die-cut labels using roll or sheet facestock, comprising the steps of providing a plurality of at least two charges of film-forming resin, coextruding said charges to thereby form a construction in the form of a multilayer extrudate comprising a relatively thick core layer and at least one relatively thin skin layer, preselecting the charge for said core layer, as by selection of density or flex modulus, to provide said facestock with a suitable degree of stiffness and sufficient body and strength for the label application, preselecting the charge for said skin layer to provide a skin adapted to the intended decorating process, or surface performance characteristics, of the facestock, hot-stretching and combining said extrudate with a pressure-sensitive adhesive layer to form label facestock, combining said facestock with a liner, die-cutting said facestock to form a label, releasably adhered to said liner and surrounded by a matrix of excess facestock material, and stripping said matrix of excess facestock material to utilize non-tearing self-supporting properties of said material to pull said matrix away from the die-cut label.

The construction of the facestock claims' terms and phrases desired by the parties, especially "coextrudate of cojoined layers" and "comprising a relatively thick core or base layer," require the court to look beyond the language of the claims.
To aid in construction of the claims, the court must look at the patent specifications. "The specification acts as a dictionary when it defines terms used in the claims or when it defines terms by implication." Vitronics at 1582. The patent inventor is his or her own "lexicographer." ZMI at 1580. Therefore, "the specification aids in ascertaining the scope and meaning of the language employed in the claims inasmuch as words must be used in the same way in both the claims and the specification." Id. (citation omitted).

The patent specifications for the '273 patent offer several illuminating claim descriptions. The specifications for the facestock offer two prototypical examples in Figures 5 and 6. The coextrudates in these examples "comprise polymeric film materials, are formed by simultaneous extrusion from a suitable know type of coextrusion die, and are adhered to each other in a permanently combined state to provide a unitary coextrudate." Patent '273, Column 9, Lines 21-26. The elements of the facestock, as described in the specifications, are as follows: "a relatively thick core layer of polymeric film material . . . having a cojoined, relatively thin, ink-printable skin layer at least at the face side of the construction, and having a pressure-sensitive adhesive layer combined at the sides of the construction opposite the face side." Patent '273, Column 10, Lines 59-66. The facestock is produced "by coextruding a plurality of at least two charges of film-forming resin to form a coextrudate having a relatively thick core layer and at least one relatively thin skin layer . . . and combining the coextrudate with a pressure-sensitive adhesive layer." Patent '273, Column 10, Lines 67-68; Column 11, Lines 1-8.

The prosecution history of the patents provides similarly helpful evidence for this court. A patent's "prosecution history (or file wrapper) limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985). The prosecution history reveals that in the application for the '273 patent, Serial No. 06/853,772, the inventor, Melvin S. Freedman, distinguished his facestock from a product which is "formed by adhering preformed layers." The patent examiner issued a restriction requirement on October 17, 1986 stating: "the product as claimed can be made by a materially different process such as by adhering pre-formed layers." Def's Resp. Ex. W. In an amendment filed October 27, 1986, Freedman responded: "The process pointed out by the Examiner, namely adhering preformed layers, cannot be used to form the claimed coextrudate, since if the layers were preformed they would not have been coextruded and would not constitute a coextrudate as called for in [the] independent product claims." Def's Resp. Ex. X.

Based upon a review of the entirety of the patent, including the claim language, specifications and prosecution history, the court concludes that claims 19-21 of the '273 patent should be plainly construed to cover a coextrudate which is a facestock, or plastic film, formed solely by simultaneous, or joint, extrusion of several materials through a die. The immediate result of this simultaneous extrusion, or coextrusion, is a multilayer film wherein the layers are firmly adhered to one another in a permanently combined state, i.e., the patented coextrudate. A facestock formed by adhering preformed layers is not within the scope of claims 19-21 of the '273 patent. Further, in claim 19, the coextruded product must have (1) a thick core or base layer (with a stiffness of between 10 and 100 Gurley); (2) at least one thin ink-printable skin layer on the face side of the product; and (3) a pressure-sensitive adhesive layer on the side opposite the face side. In claim 20, the product is the same as in claim 19 with the addition of a second skin layer between the core or base layer and the adhesive layer. In claim 21, the product is the same as in claim 19 with the addition of a releasable liner on the adhesive.

The parties, especially UCB Films, have also devoted substantial time to arguing that the phrase "core or base layer" in the claims must mean "core layer or base layer" (meaning the core must be made up of only one layer) and not, as Avery argues, "core" (which could have one or more layers) or "base layer." However, the court finds that the patent specifications, on which UCB Films primarily relies, use both the term "core" (e.g. '273 Patent; Column 10, Line 46) and the phrase "core layer" (e.g. '273 Patent, Column 10, Line 60). This court is thus unwilling to apply UCB Films' reading to the claims and cannot find on the basis of this argument that the claims are limited to a core composed of a single layer.

As stated previously in this opinion, the court's construction of the claims of the '273 patent is largely applicable to the facestock portions of the process patents. In light of the above claim construction, this court finds that there are disputed issues of material fact as to whether UCB Films infringed the patents and that infringement remains a question of fact to be submitted to a jury. The motions for summary judgment [154-1, 250-1] are therefore denied.
The Avery patents are directed to a facestock used for adhesive labels, tapes or signs. The claimed facestock is a multilayer coextrudate of a core layer, and at least one skin layer suitable for receiving printing. Claim 19 of the '273 patent is representative:

19. A multilayer facestock for use in pressure-sensitive label, tape or sign applications comprising a coextrudate of cojoined layers comprising a relatively thick core or base layer of polymeric film material of a stiffness of between 10 and 100 Gurley and which contributes the majority of the dimensional stability and stiffness of labels or signs cut or formed from the facestock, and at least one relatively thin skin layer, said skin layer being on the face side of the coextrudate and having an ink-printable surface, and a pressure-sensitive adhesive layer combined at the side of said coextrudate opposite said face side.

(Emphasis added). The patent specifications, which are substantially identical, state that the facestock is "formed by simultaneous extrusion" such that the layers of the facestock "are firmly adhered to each other in a permanently combined state to provide a unitary coextrudate." '273 patent, col. 2, ll. 57-63.

Before filing suit against FLEXcon, Avery asserted the same patents and claims against UCB Films. UCB Films manufactures a facestock film having the brand name "Rayoface" in England, and sells it to entities in the United States, including FLEXcon, who laminate an adhesive layer and removable liner to the UCB Films facestock and resell it. Because the same products and patents are involved in the UCB Films and the FLEXcon cases, the district court herein adopted the claim construction in the UCB Films case, Avery Dennison Corp. v. UCB Films, et al., No. 95-C-6351 (N.D. Ill. June 8, 2000).

The critical section of the UCB Films claim construction focuses on the "coextrudate" limitation, as follows:

The court concludes that claims 19-21 of the '273 patent should be plainly construed to cover a coextrudate which is a facestock, or plastic film, formed by simultaneous or joint extrusion of several materials through a die. The immediate result of this simultaneous extrusion, or coextrusion, is a multilayer film wherein the layers are firmly adhered to one another in a permanently combined state, i.e., the patented coextrudate.

The district court ruled that:

A facestock formed by adhering preformed layers is not within the scope of claims 19-21 of the '273 patent. Further, in claim 19, the coextruded product must have (1) a thick core or base layer (within a stiffness of between 10 and 100 Gurley); (2) at least one thin ink-printable skin layer on the face side of the product; and (3) a pressure-sensitive adhesive layer on the side opposite the face side.

The district court in UCB Films held that this construction also applied to the '532 and '669 process patents. Avery stipulated that it could not prove infringement by FLEXcon under the claim construction of the UCB Films case.

Avery's position is that the court erred in ruling that "A facestock formed by adhering preformed layers is not within the scope of [the claims]." That is the issue before this court.

DISCUSSION

It is not disputed that the Rayoface product is made by laminating two sheets of multilayer, coextruded film. Avery states that the UCB Films' lamination is an additional step in a process from which facestock is made by blown coextrusion and thus does not preclude infringement of the claims. Avery further states that the district court's requirement that the facestock be the "sole" and "immediate" result of coextrusion is an incorrect restriction of the claims' scope.

Claim interpretation is a matter of law that is reviewed de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2d (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). Each of the asserted claims requires that the facestock either be a "coextrudate of cojoined layers" or be manufactured by "coextruding . . . to thereby form . . . a multilayer extrudate." Avery's proposed construction would have the claims read on any product used as facestock if it contains any coextruded layers, as opposed to products wherein the facestock itself is a coextrudate.
The district court's construction, that the facestock is the "immediate result of this simultaneous extrusion, or coextrusion," recognizes the specification's teaching that the facestock layers are "formed by simultaneous extrusion from a suitable known type of coextrusion die, and are adhered to each other in a permanently combined state to provide a unitary coextrudate." '273 patent, col. 9, ll. 23-26. Figure 8 of the '273 patent further illustrates the Avery process, wherein plastic components D, E, and F, are coextruded through die 70 to form a coextruded facestock with joined layers 54, 52, and 56:

[SEE FIGURE 8 IN ORIGINAL]

The district court's claim construction is also required by the prosecution history of the patents in suit. The patentee, in response to a restriction requirement for the parent application, explained that the claimed coextrudate is distinguished from a material "formed by adhering preformed layers," stating that "if the layers were preformed they would not have been coextruded and would not constitute a coextrudate as called for in independent product claims." These statements, and the undisputed fact that the UCB Films coextruded product does not literally infringe the Avery claims before it is laminated to form a facestock, negate Avery's argument that the UCB Films lamination is merely an extra step in the formation of an infringing product, and also bar access to the doctrine of equivalents to reach the laminated product. We have carefully considered all of the arguments and authorities presented by Avery, and conclude that the district court's judgment is correct.

C. The '136 Patent - Claim 6

Claim 6 of the '136 patent provides:

The method of claim 5 where said step of electrolytically disintegrating said connecting segment comprises the step of electrolytically corroding away at least a portion of a coil segment.

Claim 6 introduces a new phrase, namely, "coil segment." The parties dispute the proper construction of that phrase. Claim 6 depends from Claim 5. Thus, Claim 6 is a further limitation on the "electrolytically disintegrating" step of Claim 5.

By its language, Claim 6 requires that the step of Claim 5 of "electrolytically disintegrating of at least one portion of a connecting segment" be performed by "electrolytically corroding away at least a portion of a coil segment." There is no limitation in Claim 5 or 6 disclosing the connecting segment of Claim 6 as a coil. 7 Without such a limitation, Claim 6 is arguably indefinite because there is no disclosure that "said connecting segment" is a "coil."

--- Footnotes ---

7 It is permissible for an inventor, who has disclosed a device in general terms in an antecedent claim, to state in a subsequent dependent claim that the device is made in a particular configuration as a limitation on the device already disclosed. For example, in a claim, an inventor may specify a "connecting segment." The inventor may introduce in a dependent claim "where said connecting segment is a coil." Claim 6 refers to the "connecting segment" of Claim 5 as "said connecting segment" but does not state that the "connecting segment" is a "coil."

--- End Footnotes ---

In general, a claim ought to be construed to sustain its validity. Liebel-Flarsheim Co. v. Medrad, 358 F.3d 898, 911 (Fed. Cir. 2004). In this case, to preserve the validity of Claim 6, the Court interprets "coil segment" of Claim 6 to be a limitation on the "connecting segment" of Claim 5. This is because without the two phrases referring to the same element, there is no logical way for the corrosion of the "coil segment" to electrolytically disintegrate the "connecting segment."

The Court construes "coil segment" as it is used in Claim 6 of the '136 Patent the to mean:

- a connecting segment that is a coil, at least a portion of which can be corroded electrolytically
"coin type"

"Coin type" is used throughout claim 1 and the rest of the '799 patent. JVL argues that this term should be construed to mean that "coin types cannot be changed by the operator." Merit proposes a simpler construction, "type of coin."

Although the substance of JVL's construction is not inaccurate, it is unnecessary. In the description of the preferred embodiment found in Figure 3, which shows a designation for coin type, the patent states that the coin input is "set at the factory and cannot be changed by the game operator." '799 patent, at 5:38-40. In this context, this language indicates that the game operator cannot adjust the coin input column; but, it does not provide a basis for reading this limitation into the term "coin type" as used throughout the patent.

The meaning of "coin type" is clear from the surrounding claim language. It means, as Merit suggests, "type of coin" which is synonymous with "coin type." Therefore, the term requires no construction.

OO. "LEADING SURFACE BEING PLANAR AND COINCIDENT WITH A PLANE, THE PLANE INTERSECTING THE HANDLE PORTION"

In claim 27, the Court must also construe the claim term "leading surface being planar and coincident with a plane, the plane intersecting the handle portion." Plaintiff suggests that the claim term means "leading surface is planar and the reference plane containing the leading surface intersects the handle portion." Defendants divided the claim term, and suggest that "the leading surface of the pet engageable portion is planar" means "the leading surface of the pet engageable portion is flat"; "coincident with a plane" means "occupies part of the same place or plane"; and "the plane intersecting the handle portion" means "the plane having at least one point in common with the handle portion." The Court notes that this claim term is substantially similar to a previous claim term, "leading surface of the pet engageable portion is planar and is coincident with a plane, and the plane intersects the handle portion," which was construed to mean "the leading surface of the pet engageable portion is flat and occupies part of the same place or plane, and the plane intersects the handle portion."

Plaintiff's proposed construction of "leading surface being planar and coincident with a plane, the plane intersecting the handle portion" would be inconsistent with this earlier construction. On the other hand, Defendants' proposed construction is more in line with the previous construction, but the Court will impose a few changes for consistency. The claim term "leading surface being planar and coincident with a plane, the plane intersecting the handle portion" is construed to mean "the leading surface is flat and occupies part of the same place or plane, the plane intersecting the handle portion."

7. "A cold pan"

For the term "a cold pan," Foodie offers "a refrigerated container," while Jamba Juice offers "an open, shallow, refrigerated bin." The primary dispute over this term was whether or not to include "shallow" and "open" as descriptive modifiers, and whether the noun term should be "pan" or "container." At the Markman hearing, Foodie agreed to allow for the adjective "open" to be included, but only if "container" was the noun. Foodie objected to the use of "shallow" in the definition. Jamba Juice objected to the term "container" on the grounds that "pan" is narrower. In support of its argument for including "shallow," Jamba Juice argues that "the term container, which appears in the definition of the word pan, is modified by the adjective shallow in the definition." 5 (Def.'s Resp. Claim Constr. Br. 21.) Foodie argues in response that "shallow" need not be part of the construction because doing so would be reading a limitation in the claim unnecessarily. The Court agrees with Foodie.
5 At the Markman hearing, Jamba Juice also argued that the definition of "pan" includes "shallow."

The specification does not define "pan," nor does it discuss the cold pan in terms of being open or shallow. Adding such limitations would be based on purely extrinsic evidence. While the dictionary definition of "pan" does include "container," "open," and "shallow," the Court is hesitant to read those terms into the claim. There is little risk of jury confusion by failing to further elaborate on the term "pan," and potentially greater risk for the parties in narrowing or broadening the term with the other modifiers. Given the above considerations, and since both parties suggested "refrigerated" in their proposed definitions, the Court construes "cold pan" to mean "a refrigerated pan."

Literal Infringement

The '389 patent contemplates a CVD process sequence that starts with a cold reactor chamber, the chamber having been cooled in order to permit the operator to remove the coated substrates and insert uncoated ones. The '389 claims are directed to the removal of static attraction during the gaseous purge of the cooled chamber within which electrostatic contamination has formed. Although the parties dispute whether this requires treating at a "relatively low" temperature that is high enough to eliminate the static charges, or is accomplished solely by an infrared photon flux at low intensity, claim 1 appears to include both mechanisms, while claim 4 is specific to heating the wafer above about 180 degrees C. The '389 patent describes about 180 degrees C as the temperature above which static electricity does not form or exist.

The ASM Epsilon One reactor process also conducts an initial purge with inert gases as the first step in the deposition cycle. However, this purge is conducted at about 850 degrees C. Since in the Epsilon One reactor the substrates are removed and replaced mechanically, the chamber need not be cooled significantly to perform this step and does not acquire electrostatic contamination during the processing cycle. Thus although the Epsilon One process includes an initial gaseous purge below the deposition temperature, the temperature of this purge is stated to remain above 850 degrees C. ASM argues that this can not reasonably be deemed a "cold purge process." ASM states that the problem solved by the '389 invention does not exist at the Epsilon One operating conditions, and that the '389 specification makes clear that the invention relates to a process wherein the chamber is cooled to ambient temperatures, permitting electrostatic contamination to form, in order to remove it by raising the temperature to above 180 degrees C, but still at relatively low temperatures. ASM points out that the prior art shows the initial cold purging with inert gases, and that the sole "inventive" contribution of the '389 patent is removal of the electrostatic contamination that occurred below about 180 degrees C. ASM states that under its operating conditions, which do not drop below 850 degrees C during or between processing cycles, electrostatic contamination does not occur, and thus that it does not practice the invention of the '389 patent.

Applied Materials states that "cold purge" is a word of art for the initial gas purge step, and that "cold" is understood in this art as a relative term and means a temperature below the processing temperature. Applied Materials states that the claims require only that the initial gaseous purge is conducted below the processing temperature, and that ASM does so, literally. Applied Materials states that it is the claims that define the invention, and that it is incorrect to limit the claims to any specific temperature mentioned in the specification. Thus Applied Materials states that claim 1 reads literally on the Epsilon One process.

The construction of patent claims, as well as the meaning and scope of a disputed technical term or terms of art in a patent claim, are deemed to be questions of law and are determined de novo on appeal. Markman v. Westview Instruments, Inc., 52 F.3d 967, 34 U.S.P.Q.2D (BNA) 1321 (Fed. Cir. 1995) (en banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Although this court requires that no deference be given to the testimony of experts, id. at 983, 34 U.S.P.Q.2D (BNA) at 1333 ("when legal 'experts' offer their conflicting views of how the patent should be construed, or where the legal expert's view of how the patent should be construed conflicts with the patent document itself, such conflict does not create a question of fact nor can the expert opinion bind the court or relieve the court of its obligation to construe the claims according to the tenor of the patent. This opinion testimony also does not change or affect the de novo appellate review standard for ascertaining the meaning of the claim language."), we take note that extensive expert testimony was adduced at trial.
The district court first considered Applied Materials' argument that since the phrase "cold purge" appears only in the preamble of claim 1, it does not limit the claims as applied to the accused process. The district court concluded that "cold purge" is indeed an element of the claims, and "establishes a limitation which the accused device must meet in order to literally infringe the '389 patent." We reach the same conclusion.

Whether a preamble stating the purpose and context of the invention constitutes a limitation of the claimed process is determined on the facts of each case in light of the overall form of the claim, and the invention as described in the specification and illuminated in the prosecution history. See In re Stencel, 828 F.2d 751, 754, 4 U.S.P.Q.2D (BNA) 1071, 1073 (Fed. Cir. 1987) (the preamble is interpreted in light of the invention as a whole); Perkin-Elmer Corp. v. Computervision Corp., 732 F.2d 888, 896, 221 U.S.P.Q. (BNA) 669, 675 (Fed. Cir.), cert. denied, 469 U.S. 857, 83 L. Ed. 2d 120, 105 S. Ct. 187 (1984) (the limitations stated in the preamble give meaning to the claim and can serve to define the invention). It is thus appropriate to determine whether the term in the preamble serves to define the invention that is claimed, or is simply a description of the prior art.

The term "cold purge" has its roots in the specification, which states that in a typical deposition process of the prior art "both the nitrogen prepurge and hydrogen purge are carried out 'cold', that is, without heating." The specification explains that in the '389 process these initial purges are carried out at low radiant energy or low thermal energy. The district court found that "cold purge process" means temperatures below 180 degrees C, and that the '389 invention was directed to the use of heat sufficiently high to remove electrostatic contamination in the initial purge steps, that is, heat above about 180 degrees C, in a reactor whose operating conditions include temperatures below 180 degrees C. "Cold purge" is interpreted in light of the problem the '389 patent solved: the elimination of electrostatic contamination during the initial purge step. The specification states:

During the use of the above outlined process sequence, electrostatic attraction is operative almost exclusively during the cold purging steps (steps 1 and 2). It is substantially non-existent when the susceptor/wafer is at an elevated temperature, such as for example above about 180 degrees C.

'389 patent, column 9, lines 17-22. The specification also states that the purpose of the invention is the removal of contamination caused by this electrostatic attraction. Claims 1 and 4 include this requirement.

The district court correctly placed the term "cold purge process" in the context of the state of the art when the '389 invention was made. This context requires construing the literal meaning of the claims as limited to the process wherein electrostatic contamination is formed and removed. The Epsilon One reactor does not meet this criterion. We affirm the court's ruling that claim 1 is not literally infringed.

A. Cold UV

L&P's proposed construction of "cold UV" is "a UV light source which: (i) employs selected wavelengths to limit; or (ii) has been adapted to selectively reduce the amount of; radiation (and thus heat) that impinges upon a substrate." Vutek agrees with the first part of L&P's proposed construction, but wishes to qualify the radiation reduction referred in the second part to read "(ii) has been adapted to selectively reduce by at least 80% the amount of unwanted radiation (and thus heat) that impinges upon a substrate." Thus, the only issue for me to resolve is whether a UV light source must reduce unwanted radiation, or IR, by 80% -- or by any other specific amount -- in order to qualify as "cold UV." After reviewing both the intrinsic and extrinsic evidence, I find no basis to read such a limitation into the term "cold UV" and thus will adopt the proposed construction offered by L&P.
Turning first to the intrinsic evidence, neither the claims nor the specification support Vutek's narrow construction of "cold UV." Throughout the claims and specification, "cold UV" is defined broadly to encompass various types of UV light sources including selective bandwidth sources, as well as UV lights that use cold mirrors, filters, and water-cooling systems to reduce unwanted IR. The specification defines these sources by the types of adaptations they use and the effect that they have on heat-sensitive substrates, not by a common threshold of IR reduction that they all achieve. According to the specification, as long as a light source "limit[s] energy of wavelengths that are not effective to cure ink from otherwise striking or heating the substrate," the source is considered "cold UV."

While it is true that the preferred embodiment teaches the use of "cold UV" source that "absorbs approximately 80-85% of the infrared energy passing therethrough," there is no indication that this or any other specific percentage reduction is common to all "cold UV" sources. Indeed, such an inference would contradict the general rule that "claims of a patent are not limited to the preferred embodiment … or to the examples listed within the patent specification." Dow Chemical Co. v. United States, 226 F.3d 1334, 1342 (Fed. Cir. 2000).

Moreover, a review of the extrinsic evidence reveals that L&P's broad construction of "cold UV" is the only construction that would make sense to a person of ordinary skill in the art. Neither Richard Codos, the inventor of the '518 Patent, nor Daniel Whittle, Vutek's expert, could identify a specific range of IR reduction that is common to all "cold UV" sources. A survey of industry literature supports their understanding of the term, as "cold UV" is used to describe a variety of adaptations that reduce IR by a wide range of percentages. Additionally, the Patent Examiner identified two previous patents which taught the use of "cold UV," the Troue Patent, No. 4,048,490, and the Scheffer Patent, No., 4,563,589, yet neither of these patents mentions a specific percentage of IR reduction that is achieved with the use of the patent. In sum, after applying the available tools of claim construction, I find that L&P's proposed construction of "cold UV" appropriately captures the use of the term in both the intrinsic and extrinsic evidence.

Footnotes

2. For example, L&P produced evidence of various "cold UV" sources that were reviewed by Codos during his research and development of the '518 Patent. These sources include a Maxim TM UV-curing lamp which uses a "dichroic-coated quartz reflector" that reduces IR "by up to 50%," and an EYE UV brand UV-curing lamp which combines cold mirror and cut IR filter technology to reduce the "heat rise" in a substrate by "over 60%." L&P also introduced a technical paper written in 1983 which concludes that at best, use of a dichroic filter in a UV-curing lamp will reduce IR by 75%.

End Footnotes

Despite the lack of support for Vutek's narrow construction, Vutek contends that I must construe "cold UV" with the 80% restriction in order to maintain the validity of the '518 Patent. Generally, "[c]laims should be so construed, if possible, as to sustain their validity," Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999) (quoting Carman Indus., Inc. v. Wahl, 724 F.2d 932, 937 n. 5 (Fed. Cir. 1983)). Nevertheless, the Federal Circuit stated in Phillips that "we have certainly not endorsed a regime in which validity analysis is a regular component of claim construction." 415 F.3d at 1327 (citations omitted). Indeed, "claims can only be construed to preserve their validity where the proposed claim construction is 'practicable,' is based on sound claim construction principles, and does not revise or ignore the explicit language of the claims." Generation II Orthotics Inc. v. Med. Tech. Inc., 263 F.3d 1356, 1365 (Fed. Cir. 2001).

The Federal Circuit has instructed courts to refrain from rewriting claims so as to preserve validity. Rhine, 183 F.3d at 1345. I see no reason to disregard that instruction here. Not only is there no support in the intrinsic or extrinsic evidence for narrowing the term "cold UV" in this way, such a restriction would not be practicable. As Codos explained, there are many variables which determine the effect that a "cold UV" source will have on a substrate, including bulb type (mercury or halide), bulb wattage, heat tolerance of the particular substrate, printing speed, and print type, among others. These variables make it difficult to pin down a specific percentage of IR that must be reduced to qualify as "cold UV." Vutek's proposal is not practicable, and I lack a sufficient basis to conclude that it is necessary to preserve validity. I leave validity issues for determination at a later stage of this case, if necessary.

In the end, I am convinced that a person of ordinary skill in the art would understand the term "cold UV" to not be limited to sources that reduce IR by any specific percentage. For all these reasons, I reject Vutek's arguments in support of a narrow definition of "cold UV," and will adopt L&P's proposed construction.
Cordis contends that a "collapsed" balloon or sleeve is a balloon or sleeve that has been reduced in bulk by being folded (i.e., doubled over) into a more compact space. Cordis relies on the definition of "collapsed" as "[t]o fold compactly," provided in the American Heritage Dictionary of the English Language (1980). Cordis further relies on the definitions of fold as "to lay one part over another part of: double upon itself" (Webster's Third New International Dictionary of the English Language Unabridged (1986)) (hereinafter "Webster's Third"), or "to reduce the length or bulk of by doubling over." (Webster's New Collegiate Dictionary (1981)). In contrast, AGR proposes the following definitions of "collapsed": (1) "[t]o fold or come together compactly" (Webster's Twentieth Century Dictionary (1977)) (hereinafter "Webster's Twentieth"); (2) "to fall together or in" (Webster's Twentieth); (3) "[t]o fold compactly" (American Heritage Dict.); (4) "[t]o be made so that parts can be folded, placed, etc., together" (Random House); and (5) "to fall or shrink together abruptly and completely; fall into a jumbled or flattened mass through the force of external pressure" (Webster's Ninth).

The Court has reviewed all of the foregoing dictionary definitions of the word "collapsed" in the context of the other words used in the '1,653 Patent, as well as the corresponding specification and file history. The surrounding text, specification and file history support the following construction of the word "collapsed," which is the one the Court adopts: folded together compactly so that one part is laid over another part. The following statements included in the Patent claim and specification support such a construction of the word "collapsed" that is limited to materials that may be "folded" or "doubled over" to fit into a more compact space:

1. "[T]he sleeve is sufficiently flexible to be collapsed into a unit of relatively low bulk for ease of passage through the posterior pharynx and esophagus." (Summary of the Invention, 2:19-23) (emphasis added).

2. "Figure 5 of a view of the sleeve unit in a compacted condition . . ." (Brief Description of the Drawings, 3:3-4) (emphasis added). Figure 5 is a drawing showing the disclosed sleeve with its parts folded compactly with some of it parts laying over on or other parts and contained in what is referred to as a "dilator shell or cup." Figure 6 shows the parts of the sleeve unfolding, or coming apart, after the dilator shell or cup is removed. Dr. Rockey describes the process in Fig. 6 as follows: "Lower sections of the filaments . . . associated with the sheath [sleeve] 11 . . . unfold themselves along with the sheath [sleeve]." (Description of the Preferred Embodiment, 4:24-27) (emphasis added).

4. Referring to Figs. 5, 6 and 7, Dr. Rockey instructed that "[t]o facilitate introduction of the sleeve unit 10 into the stomach 32, the sleeve unit is folded on itself accordion fashion to reduce its length and diameter." (Description of the Preferred Embodiment, 4:9-12) (emphasis added).

5. "In its folded or compacted state, the sleeve unit 10 . . ." (Description of the Preferred Embodiment, 4:12-13) (emphasis added). Here, Dr. Rockey uses the words "folded" and "compacted" as synonyms.

6. In the preferred embodiment in Fig. 9, Dr. Rockey indicates that "[t]he collapsed state can be maintained by wrapping the sleeve 51 on itself." (Description of the Preferred Embodiment, 4:11-13; 6:43-44) (emphasis added), which is followed by insertion of the pressure of a liquid that inflates the balloon. "The pressure of this inflating fluid is sufficient to break the light heat bonds holding the folds of the sleeve . . . together and to expand the sleeve . . ." (Description of the Preferred Embodiment, 6:48:51) (emphasis added).

7. "The balloon . . . is formed of any suitable plastic or rubber material which may be folded and/or expanded." (Description of the Preferred Embodiment, 6:7-9) (emphasis added).

Thus, Dr. Rockey used the word "folded" to describe multiple drawings and embodiments disclosed in the '1,653 Patent, not just one preferred embodiment. The '1,653 Patent file history also uses the words "collapsed" and "folded" interchangeably.
The instances where Dr. Rockey uses the words interchangeably are numerous and will not recited here, but one example may be found in Dr. Rockey's '010 Application. The '010 Application is similar to the '1,653 Patent in its description of the preferred embodiment of the sleeve as being "sufficiently flexible to be collapsed into a unit of relatively low bulk" for ease of delivery through narrow body passageways. As advanced by Cordis, the original claims of that application call for a sleeve that is "sufficiently flexible to be folded on itself to thereby reduce its bulk... to facilitate initial placement of the sleeve into the body vessel." Although neither the word "fold" nor the phrase "folded on itself" was actually included in the language of Dr. Rockey's Patent claims, this language chosen by Dr. Rockey and included in his first application and throughout his three related patent file histories constitutes further evidence that when Dr. Rockey wrote "collapsed," he meant "folded," i.e., "doubled over." Accordingly, the requirement that the balloon and the sleeve must be "folded together compactly" may properly be read into claim 2 of the '1,653 Patent.

6. wherein the liner collapses when fluid is withdrawn from within the liner during operation of the gun

3M wherein the liner distorts without being ruptured when fluid is withdrawn from within the liner during operation of the gun

ITW the base of the liner keeps its shape while the side walls distort without rupture

The final disputed definition concerns the term collapses as it relates to base of the liner. ITW contends that the claim describes the base of the liner maintaining its shape when the paint is withdrawn. 3M contends that no such requirement exists. ITW finds support for its position in the specification because the need for a sturdy base is often highlighted and because the side walls are the only parts of the liner described as being distorted. The Court has already noted that the terms of a specification should not be used to make restrictions on the claims of a patent when the terms as used in the claims do not have such restrictions, and it will not do so for this term. Given that there is no requirement in the claims that the base maintains its exact shape when fluid is withdrawn, the Court adopts the definition proposed by 3M.

10. "Collar" This term shall be construed with its ordinary dictionary meaning, therefore "collar" shall mean "any of various ringlike devices used to limit, guide, or secure a machine part." 7

7 The American Heritage Dictionary 291, (2d ed. 1982). The patent specification is quite confusing and contradictory when discussing the "collar" component of the invention. At col. 6, 1. 64, the patentee first introduces "a crimped collar 82." However, at col. 6, 1. 65, and col. 7, 11. 2-4, the patentee proceeds to discuss another "collar 78." Most confusing, however, is that the patentee previously introduced component 78 as an "annular rib 78" or "rib 78." Col. 6, 11. 61-62. Similarly unclear, the patentee uses the term rib without a label or definition throughout the patent. See e.g., col. 2, 1. 28; col. 3, 1. 52; col. 6, 1. 10.

3. "collecting light scattered along said path for detecting anomalies"

The parties' arguments in regard to the phrase "collecting light scattered along said path for detecting anomalies" centers on whether the '710 and '551 patents require that collection of light and detection of anomalies occur within the same instrument or device such that the two operations are inseparable. D.I. 340 at 19-21; D.I. 314 at 23-26. The prepositional
phrase "for detecting anomalies" does modify "collecting light scattered along said path." The question, however, is whether or not said modification also imparts a single collecting/detecting device limitation on the claim element. In other words, since the claim element is not further modified by the phrase "in a single device," this court must determine whether the inventors nonetheless taught such an understanding of their invention. To make this determination, one must look to the intrinsic record.

Figure 3, as reproduced below, depicts one embodiment of the '710 and '551 inventions.

[SEE FIGURE 3 IN ORIGINAL]

In Figure 3, 110a, 110b, 111a, and 111b represent different instrumentalities connected to a processor 200 for the collection and detection of light scattered by anomalies on the surface of the inspected article. '710 at 7:19-24; '551 at 7:19-24 ("Detectors such as detector 111b collects light scattered by anomalies as well as the surface and other structures thereon along scan line 50 [See Figure 4 Above] and provides output signals to a processor in order to detect and analyze the characteristics of the anomalies."). Later in the disclosure, the '710 and '551 written description provides that "the processor 200 in FIG.3 for processing light detected by the collection or collector channels 110a, 110b, 111a, and 111b is such that a sample is taken…." '710 at 9:13-16; '551 at 9:13-16. The '710 and '551 disclosures clearly teach collection of scattered light in the collector channels represented by 110a, 110b, 111a, and 111b in Figure 3. The disclosures further specify that these collector channels produce signals sent to the processor "in order to detect and analyze the characteristics of the anomalies." '710 at 7:19-24; '551 at 7:19-24. The inventors having taught processing of the collected light by the processor 200, this court will not read the phrase "collecting light scattered along said path for detecting anomalies" as requiring collection of light and detection of anomalies to occur within the same instrument or device such that the two operations are inseparable.

4. Element 2

The parties agree that this element requires two or more collection elements. Defendants generally agree with Plaintiff's description of a "collection element" with the exception that Defendants would interpret "collection element" to be a pipe. Plaintiff responds that a collection element is a device, formed from a piece of pipe or something else and that nothing in the claim language limits the device to be formed specifically from pipe. Thus, "collection element" should be construed to include any device or apparatus having perforations that allow contaminant vapors to enter into the interior of the device or apparatus while preventing substantial soil entry.

The specification explicitly provides the meaning of "collection elements."

Each collection element is characterized by having a wall which defines a closed-end tube which has one end open to a chamber. The wall should be a thickness which will not be crushed under the use conditions herein defined. The wall materials should be selected to make the collection elements crush-resistant and not easily deformable in the use conditions described. Elongate collection elements formed of metal such as iron or steel and rigid plastic are preferred.

'407 Patent, Column 2, Lines 17-19. The specification further provides that the perforations "should be large enough to permit vapor entry but not so large as to permit substantial soil entry." '407 Patent, Column 1, Lines 27-28. Based on this language in the specification, the Court finds that "collection elements" means two or more perforated structures with a wall that defines a closed-end tube that has one end open to a chamber. The perforations in the structure should be large enough to permit vapor entry but not so large as to permit substantial soil entry.
The word "collector" is used in claims 1, 21, 25, 29, and 30 of the '259 patent.

1. ADE's Position

ADE asserts that "collector" should be construed consistent with its ordinary and plain meaning to mean "a structure capable of collecting scattered light." (D.I. 613 at 16.) In support, ADE argues that this meaning is consistent with the dictionary definition of the word. (Id. at 16-17.) ADE further asserts that nothing in the specification or prosecution history of the '259 patent would suggest limiting the construction of "collector" to "a lens," as proposed by KLA. (Id.)

2. KLA's Position

KLA suggests that the term "be construed to mean: 'a lens.'" (D.I. 594 at 17.) In support, KLA directs the Court to the '259 patent specification where the inventors describe collectors as lenses. (Id. at 18.) KLA also points to Figure 6 of the '259 patent. (Id.) In addition, KLA argues that, although the specification describes other lens arrangements, it makes clear that "these alternative embodiments merely envision different 'lens arrangements.'" (Id.)

3. Analysis

The '259 specification teaches that a "collector" "will be understood by those skilled in the art to be compound lenses . . ." (D.I. 627 at '259 Patent col. 7 II. 31-33.) The specification also provides that "other lens arrangements may also be used according to the present invention." (Id. at II. 33-34.) The inventors specifically defined a "collector" as "compound lenses . . . [and] other lens arrangements . . .." (Id.) Claims 1, 21, 25, 29, and 30, in which the term "collector" appears do not alter that definition of the term. (See id. at col. 12 I. 18 to col. 15 I. 36.) There is also nothing in the remainder of the '259 specification or prosecution history that a person of ordinary skill in the art could refer to that would create confusion as to what the inventors' intended when they used the word "collector" to claim their invention.

The Court, therefore, construes "collector," as the inventors defined the term, to mean compounded lenses or other lens arrangements. Serrano v. Telular Corp., 111 F.3d 1578, 1582 (Fed. Cir. 1997) ("The inventors' definition and explanation of the meaning of the [claim] word[s] . . ., as evidenced by the specification, controls the interpretation of . . . claim term[s].") (citing Vitronics, 90 F.3d at 1582).

757

q. "colored textured material" Claim 8

The term "colored" means "having color." Merriam-Webster Online Dictionary (visited May 15, 2007) <http://www.m-w.com/dictionary/colored>. "Color" is defined as "a specific combination of hue, saturation, and lightness or brightness." Merriam-Webster Online Dictionary (visited May 15, 2007) <http://www.m-w.com/dictionary/color>. The Patent describes the color as one "desirable to the user." (‘514 Patent, col. 5, ln. 22) In addition, the Merriam-Webster Online Dictionary defines "texture" as "the visual or tactile surface characteristics and appearance of something." Merriam-Webster Online Dictionary (visited May 15, 2007) <http://www.m-w.com/dictionary/texture>. The Patent provides for a variety of surface textures, including "smooth with a few edges similar to pea gravel, . . ., or rough like tree bark, . . ., so that the surface has numerous ridges and valleys of differing heights and depths. Additionally, the texture can have only a few ridges on the surface texture resulting in a rubber particle having a surface similar to a wood chip." (‘514 Patent, col. 3, Ins. 56-62) The Patent also calls for "a variety of other natural mulches." (‘514 Patent, col. 3, Ins. 52-53) Thus, the undersigned construes the term "colored textured material" as "rubber particles with a specific combination of hue, saturation, and lightness or brightness that has the visual or tactile surface characteristics and appearance of pea gravel, tree bark, wood chips, and other natural mulches."
b. "Combination" (Claims 34, 43)

77. Claims 34 and 43 of the '656 patent define certain claim elements, particularly the movable link member, the movable element, and the movable projecting element, in terms of their functional operation before and after entry of a "combination". Consequently, the claim term "combination" represents a limitation on the functional definition, since the claims use the word "combination" as part of functional phrases.

78. The '656 patent specification speaks to a combination code. Col. 2, line 48; Col. 4, line 61; Col. 5, line 33; Col. 6, line 40, Col. 7, line 24. The code is entered by entering the proper sequence. Col. 7, line 19. The '656 patent incorporates by reference U.S. Patent No. 4,745,784 for some of the lock details. The '784 patent defines the combination in terms of "a predetermined sequential series of rotations". PX 9, col. 1, lines 19-21. The combination is also defined in terms of a "predetermined, sequential order corresponding to the code". Col. 4, lines 66-68.

79. The prosecution history of the '656 patent also describes a "combination code". PX 45, p. 111. The prosecution history references a number of prior art "combination" lock patents which require a sequence of letters or numbers to be entered to open the lock, e.g., PX 45, p. 49 (Diesel '702); p. 50 (Lee '114); p.50 (Gartner '667); p.51 (Uyeda '785); p.51 (Yueda '176); p.52 (Gartner '984); p. 172 (Herlong). Prior art, whether or not cited in the specification or the file history, may be used to demonstrate how a disputed term is used by those skilled in the art. McGill, Inc. v. John Zink Co., 736 F.2d 666 (Fed. Cir. 1984).

80. General and technical dictionaries may be relied upon to determine the meaning of technical and other terms. Hoescht Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1580 (Fed. Cir. 1996).

81. According to dictionary definitions, a "combination" is a "sequence of letters or numbers chosen in setting a lock". Thus, the Court finds that as used in the claims of the '656 patent, "combination" means an ordered sequence of letters or numbers which must be entered to open the lock. This term cannot be construed merely to cover a single switch closure.

A. Combining Region

The defendants contend that the patent requires a combining region to be a separate structure, such as a combining tube. In support of this contention, the defendants point to the fact that in the description of the drawings in the patent, it appears that combining region and combining tube are used interchangeably; both terms are utilized in describing Number 24 on the drawings. The plaintiff contends that a combining tube is simply one embodiment of a combining region and although the drawings depict the invention with a combining tube for the combining region, the claims do not require this or any other structure to be used as the combining region.

The defendants point to the prosecution history of the patent in an effort to support their contention that the combining region must be a separate structure and specifically the fact that in response to rejections by the Patent and Trademark Office ("PTO") the inventor made certain changes to its application.

For example, it added "a combining region" to its initial description of the direct contact steam injection heater so that it read as it read "a heater body having a steam inlet, a liquid inlet, a combining region and a heated liquid discharge outlet," as it does in the patent. The defendants contend that this change was necessary to distinguish the invention from the prior art, specifically United States Letters Patent No. 3,197,337 ("Schink"). However, the prosecution history of the '712 patent disproves this contention.

Schink also has a combining region. However, utilizing a combining tube as the combining region was not necessary to distinguish the '712 patent from Schink. Rather, what distinguished the '712 patent from Schink, in the view of the PTO, was
the direction of the flow. In Schink, the flow was helical; in the '712 patent, after the claims were amended, the flow is limited to being axial. The amendments made in response to the PTO's rejection of the application on the basis of obviousness, (see Docket No. 58 at 3-4), as well as the PTO's statements in rejecting the application, (Docket No. 58-4 at 6-7), demonstrate that it was the absence of this axial flow limitation that resulted in the rejection of the prior applications. Once these axial flow limitations were added, the application was approved. The court finds nothing in the prosecution history to indicate that these modifications somehow indicate that that the combining region must be a structure separate from the heater body.

In fact, the patent itself clearly supports the plaintiff's contention that a combining tube is simply one embodiment of the combining region. In the detailed description of the drawings, at column 5, lines 35-36, the patent states, "As depicted in FIG. 2, the combining region may take the form of an adjustably positionable combining tube." Column 5, lines 35-36 (emphasis added). If it may take the form of "an adjustably positionable combining tube," necessarily, it also may not.

Perhaps the argument could be made that the use of "may" still requires that the combining region be an independent structure, but not necessarily a tube. However, the court rejects this contention. The common and ordinary use of the word "region" connotes something amorphous as opposed to "structure," "unit," "device," or any number of other words including "tube" that would indicate a need for the combining region to be separate from the heater body. Thus, the court finds that the use of the word "region" is persuasive evidence that the combining region may be an ill-defined area within the heater body as opposed to discrete independent structure.

Further support for the conclusion that the combining region need not be a structure that is separate and distinct from the heater body can be found in the patent. The patent notes: "Alternatively, the invention can be carried in a heater in which the combining region is not an adjustably positionable combining tube." Column 5, lines 46-48. The patent then continues: "For example, see above incorporated U.S. Pat. No. 5,622,655 entitled 'Sanitary Direct Contact Steam Injection Heater 50 Method', by Bruce Cincotta et al. issuing on Apr. 22, 1997, which shows a combining region integral with the heater body." This patent, referred to here as the '655 patent, depicts a similar heater where there is no allegation that there is any structure in which the combining occurs other than the heater body, and thus it is clear that the '712 patent anticipates the combining region being an area within the heater body and not any sort of a separate structure.

The court finds further support for the conclusion that a combining tube, or any other structure, is not required for the combining region, in the fact that the term "combining tube" appears in the patent almost exclusively in the descriptions of the drawings. Although the drawings depict an embodiment of the invention where a combining tube is used as the combining region, and figures 2-5 depict a preferred embodiment of the invention, the patent is careful to note that "the invention is not limited to this specific embodiment." Column 6, lines 36-38. The only other use of the term "combining tube" is a single use in the abstract. Significantly, the term is entirely absent from the claims. In the claims, only "combining region" is used. Thus, the patent makes clear that a combining tube is a combining region but not all combining regions are combining tubes.

Finally, the court finds unpersuasive the defendants' contention that because the claims identify the heater body and the combining region as each having inlets and outlets means that the combining region must be a separate structure. Claims 1 and 16 state:

a heater body having a steam inlet, a liquid inlet, a combining region and a heated liquid discharge outlet;

the combining region having an inlet and an outlet located within the heater body in which steam and liquid are combined to generate heated liquid;

Even if the combining region is simply an amorphous space within the heater body, the fluid to be heated must come into it, and after combining with the steam, the heated fluid must exit. Likewise, the fluid to be heated and the heated fluid must enter and exit the heater body. Thus, the heater body and the combining region will necessarily have inlets and outlets. However, the patent does not require separate inlets and outlets for both the heater body and the combining region. The inlets for the combining region may be the same as those for the heater body and likewise the same single outlet may be the outlet for the combining region and the heater body. Even if a separate structure is used for the combining region, such as a tube, as is made clear by the defendants' Exhibit 2, the boundaries of the inlet and outlet for the combining region are merely arbitrary divisions along the path the liquid to be heated flows. There is nothing to indicate that the patent requires
an inlet or outlet to be a structure; rather, the inlet and outlets of the combining region may nothing more than arbitrary distinctions along the path the fluid flows through the heater.

Having determined that "combining region" means the area within the heater body, which may or may not be a structure separate from the heater body, where the fluid to be heated mixes with the high pressure steam, the court shall now turn to the remaining disputed claims.

3. "combining the associate value and the additional parameter to determine motion control commands" (claims 9 and 23)

Omax proposes to construe this phrase to mean "a computerized, mathematical combination of the associated value and the additional parameter to determine motion control commands provided to the machine tool to automatically adjust velocity or acceleration to achieve the desired quality of result." Flow argues that the phrase should be construed to mean "the mathematical combination of the associated value and the additional parameter to calculate the velocity (U) for a segment. It is insolubly ambiguous as to how the patented system utilizes the resultant velocity (U) for the segment to determine the incremental instructions to be sent directly to the machine tool."

Flow's proposed construction of this claim term has many shortcomings. First, by describing the claim as "insolubly ambiguous," the construction renders the claim invalid, despite the existence of a valid, equally plausible interpretation of the claim term. Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir. 1996) ("When claims are amenable to more than one construction, they should when reasonably possible be interpreted so as to preserve their validity."), abrogated on other grounds, Festo Corp. v. Shoketsu Kinzoku Kabushiki Co., Ltd., 234 F.3d 558 (Fed. Cir. 2000) (en banc). Second, Flow arrives at its construction improperly by importing an embodiment described in the specification, the formula at col. 15, 1. 9, to limit the terms of the claim to only providing for velocity along a straight line. Phillips, 415 F.3d at 1323. Finally, Flow's proposed construction contradicts other claim terms, which claim a method that adjusts velocity and acceleration, for the purpose of, among other things, improving dimensional accuracy around corners and curves. See, e.g., '596 Patent, claim 13; see also, Phillips, 415 F.3d at 1316 (requiring clear, intentional disclaimer to limit claim term). The Court adopts Omax's proposed construction of this claim, which is consistent with its ordinary meaning.

C. Commensurate

Claims 1(d) and 2(d) disclose a first internal bore of the compression ring with a diameter that is "commensurate" with the first diameter of the outer wall of the cylindrical sleeve "for allowing the first end of said compression ring to extend over the first end of said cylindrical body member." The ordinary meanings of "commensurate" include "equal in measure or extent," "proportionate," "adequate" or "corresponding in size, extent, amount or degree." See July 25, 2003 Op. and Order, dkt. # 41, at 10 (citing Merriam-Webster Dictionary online and Oxford English Dictionary online). In the context of the claims, I concluded in the July 25 opinion and order that "commensurate" means "just slightly larger than the cylindrical sleeve" so that it can "slide over the cylindrical sleeve encasing the tubular post."

Defendant contends that the full definition of "commensurate" should be "just slightly larger." However, such a definition would be incomplete. At the very least, the meaning of commensurate requires that there be a relationship or correspondence between the two diameters. A definition of "just slightly larger" would eliminate any such requirement.

At the same time, I recognize that there are ways that two diameters could correspond besides a situation in which one is just large enough to slide over the other. Defendant takes this observation one step further, seizing on the language "to extend over" to argue that there is no limitation in claims 1(d) and 2(d) that the compression ring slide over the cylindrical sleeve. I agree with defendant that defendant the claims do not contain a sliding limitation, but I do not agree that the phrase "extend over" should be read in isolation. The claims describe a compression ring that extends over a sleeve that is
"deformable." The parties do not suggest that a "compression ring" is anything but what it sounds like, namely, a ring that compresses the cylindrical sleeve. There are a limited number of ways that the diameter of a compression ring could be commensurate with the diameter of the object it compresses or deforms. Accordingly, I construe the term "commensurate" to mean that the diameter of the first internal bore of the compression ring is "large enough to extend over the cylindrical sleeve while compressing the deformable rear end portion of the cylindrical sleeve." As plaintiff points out, this construction is consistent with each of the preferred embodiments in the specification, which all refer to the compression ring as being "press-fitted" or "securely-attached" to the cylindrical body member. See Pat. '194, col. 2, lines 48-49; id. at col. 7, line 54-55; id. at col. 10, line 1-3.

**762**

Claims 1-7 of the '376 Patent and Claims 1-5 of the '661 Patent

First, Claims 1 through 7 of the '376 patent and Claims 1-5 of the '661 Patent describe the corner piece apparatus. Claims 1, 4, 6 and 7 of the '376 patent contain the limitation that "... said corner pieces each having a corner section and a pair of legs extending angularly from said corner section, said corner piece corner section and said legs having a common front planar surface portion and a common rear planar surface portion. ..." (Emphasis added). Similarly, Claims 1 and 4 of the '661 patent contain the limitation that "... said corner section and said legs having a common front planar surface portion and a common rear planar surface portion. ..."

The Court construes the language "common front planar surface portion" to mean that the corner piece corner section has a front surface in the same plane as the plane of the front surfaces of the legs which contact the inside front wall of the flange. The Court finds that surfaces displaced out of that common front planar surface, except surface displacements that result from normal manufacturing tolerances, are not surfaces in that plane.

Next, the Court construes the language "common rear planar surface portion" to mean that the corner piece corner section has a rear surface in the same plane as the plane of the rear surfaces of the legs. The Court finds that surfaces displaced out of that common rear planar surface, except surface displacements that result from normal manufacturing tolerances, are not surfaces in that plane.

This construction gives ordinary meaning to the terms used in the patent claims and is consistent with the prosecution history and patent specifications. 3 Also, this construction is consistent with Plaintiff Ductmate's August 16, 1983 amendments to the '376 patent claims. There, Ductmate amended certain claims and distinguished the '376 patent from the Smitka '094 patent. Ductmate argued that "that there is no disclosure in Smitka of a corner piece that has a corner section with a planar portion and a pair of legs extending angularly from the corner section in substantially the same plane as the planar portion of the corner section. ..." Id. With this argument, Ductmate is stopped from arguing for a construction that includes corner piece corner sections that are not in the same front or rear planar surface as the corner piece legs, as the Court has construed those terms. 4

--- Footnotes ---

3 See Webster's Third New International Dictionary (Unabridged 1993), defining relevant terms. "Plane" (noun) means "a surface such that the straight line that joins any two points lies wholly in that surface"; (adj.) "having no elevations or depressions." Id. at 1730.

4 See File History to the '376 patent, Amendment to Ductmate's '376 patent dated August 16, 1983 at 20.

**763**

8. Common Plane of Tangency
The parties request that the Court interpret "common plane of tangency" which appears in claims 1, 32, and 52 of the '486 patent and claim 23 of the '836 patent. Unilin states that "common plane of tangency" is "a plane that is tangent to a contact surface of the lower lip at a point of contact with a contact surface of the tongue." (Unilin Open. Br. 19.) Unilin states that the term is defined in the specification. (Id.)

Alloc posits that "common plane of tangency" should be defined as "the common plane which is shared by the contact surfaces when they are abutting up against each other when the panels are coupled together." (Alloc Initial Mem. 17.) Alloc indicates that the term is defined in the '486 patent specification, which states "the common plane of tangency L which is determined by the common tangent at the meeting point or area of surfaces 38-39, hereby forms an angle A sloping inwardly and downwardly from an outer region to an inner region relative to the underside 7, which angle is smaller than 90 [degree]." (Id. (quoting '486 patent, 6:60-63).)

The term "common plane of tangency" appears in claim 1 of the '486 patent as follows:

said cooperative contact surfaces defined respectively by said protrusion and said recess, and configured, when engaged in a cooperative relationship upon coupling in a common plane of two identical ones of said panel, to meet each other at a common plane of tangency that with respect to the lower lip is inclined at an angle other than 90 [degree] relative to the common plane of the coupled panels, said angle extending inwardly and downward from a distally outer location to a proximal inner location.

('486 patent, 14:18-26)(emphasis added.)

In discussing figures 5 through 7 of the '486 patent, the specification states: "the common plane of tangency L which is determined by the common tangent at the meeting point or area of surfaces 38-39, hereby forms an angle A sloping inwardly and downwardly from an outer region to an inner region relative to the underside 7, which angle is smaller than 90 [degree]." ('486 patent, 6:60-63.) 11 In discussing figure 9 of the '486 patent, the specification states "the common plane of tangency L forms an angle A which is smaller than 90 [degree], and more preferably is smaller than 70 [degree]." ('486 patent, 7:37-38.)

The relevant figures of the '486 patent and '836 patent, which diagram L, the common plane of tangency, and A, the angle, are included at pages 65 through 66 and 68 through 69 of this decision.

Claim 23 of the '836 patent states, in pertinent part:

wherein said locking elements comprise a protrusion extending from the lower side of a tongue of said pairs of edges and a cooperating recess in said lower lip, said protrusion and recess fitting together when ones of said panel are coupled by said tongue and groove; wherein, when a complementary tongue and groove are coupled, said protrusion and recess meet each other at contiguous contact surfaces at a common plane of tangency that with respect to a common plane of the coupled panels is inclined inwardly from a distally outer area towards a distally inner area at an angle less than 90 [degree].

('836 patent, 19:8-19)(emphasis added.) In discussing figures 5 through 7, the '836 patent specification states: "[t]he common plane of tangency L which is determined by the common tangent at the meeting point or area of surfaces 38-39, hereby forms an angle A sloping inwardly and downwardly from an outer region to an inner region relative to the underside 7, which angle is smaller than 90 [degree]." ('836 patent, 6:62:67.) In discussing figure 9, the specification for the '836 patent states: "[t]he common plane of tangency L forms an angle A which is smaller than 90 [degree], and more preferably is smaller than 70 [degree]." ('836 patent, 7:39-41.)"Tangency" is defined as the quality or state of being tangent. (Jt. App. Ex. 4 1205.) "Tangent plane" is defined as "the plane through a point of a surface that contains tangent lines to all the curves on the surface through the same point." (Id.) Unilin's suggested definition of the "common plane of tangency" is supported by the claims and is consistent with the specifications.
Alloc also indicates that the parties do not have "a substantive disagreement" on the meaning of the phrase. (Alloc Resp. Mem. 19.) Therefore, the Court construes the "common plane of tangency" as "a plane that is tangent to a contact surface of the lower lip at a point of contact with a contact surface of the tongue."

Before the Court are the parties' respective proposed constructions for the term "common surface" in U.S. Patents Nos. 6,394,138 ("'138 Patent") and 6,435,215 ("'215 Patent"). 1 Having considered the parties' respective submissions, the Court rules as follows.

1 Neither party suggests the construction of "common surface" should vary based on either the claim or patent in which it is contained.

The Court declines to adopt either party's proposed construction.

Ultra Clean Technology Systems and Service, Inc. ("UCT") proposes that "common surface" be construed as "an undivided, continuous area." Such proposed construction, however, is inconsistent with the patents's use of "common surface" in Claims 1 and 6 of the '215 Patent, each of which includes as a limitation a "bridging component having an inlet and an outlet accessing a common surface of the bridging component." See '215 Patent col. 12 ll. 33-35; id. col. 13 ll. 1-3. The specification provides, as examples of bridging components, "U-tube type bridge connectors, having long connector legs and short cross tubes connected together by Cajon elbows," see id. col. 4 ll. 19-21, and contains an illustration of a "jumper," in the shape of a U, with an inlet accessing the base of one leg and an outlet accessing the base of the other leg, see id. col. 8 ll. 61 - col. 9 ll. 20; id. Figs. 17, 18. In other words, a preferred embodiment of the invention has a "bridging component" with an inlet and outlet accessing a "common surface" that is not continuous and undivided. The Court finds no basis to construe the claims in a manner that would exclude such preferred embodiment. See Vitronics Corp. v. Conceptronic, Inc., 90 F. 3d 1576, 1583 (Fed. Cir. 1996) (providing claim construction that excludes preferred embodiment "is rarely, if ever, correct and would require highly persuasive evidentiary support").

Celerity, Inc. ("Celerity") proposes that "common surface" be construed as "one or more surfaces lying in a common plane." Celerity's proposed construction likewise is inconsistent with the patent's use of "common surface" in Claims 1 and 6 of the '215 Patent, each of which includes the following limitations: "a first manifold having an inlet and an outlet accessing a common surface of the first manifold" and "a second manifold having an inlet and an outlet accessing a common surface of the second manifold." See '215 Patent col. 12 ll. 20-21, 26-27; id. col. 12 ll. 55-56, 61-62 (emphasis added). Such limitations cannot reasonably be interpreted as including an inlet and outlet accessing multiple surfaces of a single manifold. Similarly, Celerity's proposed construction is at odds with the specification of the '138 Patent, which describes "the common surface for each of the respective adjacent manifold blocks." See '138 Patent col. 3 ll. 41-43 (emphasis added).

In determining the proper construction of "common surface", the Court focuses on the specification. See Phillips v. AWH Corporation, 415 F. 3d 1303, 1315 (Fed. Cir. 2005) (holding specification is "usually dispositive" in claim construction analysis). Here, although at least one preferred embodiment described in the specification of the '138 Patent includes a "manifold block" with an inlet and outlet accessing a "common surface," see '138 Patent col. 14 ll. 19-21, that is continuous and uninterrupted, see id. Fig. 3 (illustrating inlet and outlet accessing upper surface of manifold), the specification of the '215 Patent, as discussed above, discloses at least one preferred embodiment that includes a U-shaped bridging component with an inlet and outlet accessing a "common surface," see '215 Patent col. 12 ll. 33-35, that is divided, see id. Fig. 17 (illustrating inlet and outlet located on bottom surface of said U-shaped component).

Accordingly, the Court finds "common surface" is properly construed as "the same surface, which surface may be either continuous or divided." 2

- 1203 -
2 The Court previously construed the term "each manifold block having a fluid passageway with an entrance port and an exit port accessing only a common surface," see '138 Patent, col. 14 ll. 19-21, as "each manifold block having a channel or fluid passageway and an inlet and outlet on the same surface of the manifold block," (see Order Construing Claims, filed September 29, 2006, at 2:16-19.) In its opposition to UCT's claim construction brief, Celerity requests, for the first time, that the Court reconsider such construction, specifically, to eliminate "of the manifold block" from the construction. Because Celerity has failed to comply with Civil Local Rule 7-9, Celerity's request for reconsideration is procedurally improper. In any event, Celerity fails to offer an adequate explanation as to why its proposed revision is necessary. Accordingly, such request is hereby DENIED.

iv. "communicates with"

180s urges this Court to define "communicates with" as "provides access to." In contrast, Gordini seems to--again, based on its construction of "an opening that communicates with the receptacle . . ."--urge two constructions: "[allows] for something such as a wire or jack to pass through the port when the apparatus is worn by a user" and/or "[provides] continued, unimpeded access by the wearer during use to allow the user to connect and disconnect a device such as an iPod."

I construe "communicates with" as "provides access to." Again, "continued, unimpeded access by the wearer" is imprecise and unnecessary. See supra Section II.B.iii. In claim 1, "the opening . . . communicates with receptacle." That is, the "opening" must "provide access to" the "receptacle." Whether that access is "impeded" or "continuous" is irrelevant and extraneous.

A more difficult question is whether "communicates with" means "provides access to [the receptacle] . . . for something such as a wire or jack to pass through the opening." First, Gordini's argument that the doctrine of prosecutorial disclaimer is applicable here is unpersuasive. This doctrine precludes a patentee from "recapturing through claim interpretation specific meanings disclaimed during prosecution." See Omega Eng'g, 334 F.3d at 1323-26. To trigger this rule, the disclaimer must be unambiguous. Id. Even if this the doctrine does not apply, however, prosecution history is relevant intrinsic evidence for claim construction, though less so than the claim language or specification. See Phillips, 415 F.3d at 1313-17. The Patent Office initially rejected the '645 patent as anticipated by the Siskin headphones/ear warmer, U.S. Patent No. 6,888,950 ("Siskin Patent"). In response, to distinguish it from the Siskin Patent, 180s amended its claim to require that the opening be "disposed proximate the interior side of the frame." (Def.'s Mem., Ex. 14 at 3; Rebuttal Claim Constr. Brief of Pls. 180s, Inc. and 180s, LLC ("Pls.' Response") at 15.) Although not entirely clear, Gordini seems to argue that 180s, in amending the '645 patent and responding to its initial rejection, accepted "provid[ing] access for something such as a wire or jack to pass through" as the meaning of "communicates with." More specifically, 180s allegedly distinguished the '645 patent from the Siskin Patent by noting that the Siskin Patent has "an opening (110), through which the control portion (108) of the electronic component is extended," whereas the corresponding "opening" in the '645 patent is on the "interior" side of the frame. Accordingly, Gordini argues "180s explicitly argued . . . that the purpose of the claimed opening is to allow for components of the apparatus to pass from the interior to the exterior so that they are accessible to a wearer during use." Although 180s may have unambiguously disclaimed any embodiment in which the "opening" was not on the interior of the ear warmer, 180s did not unambiguously disclaim any definition of "opening" that lacked a wire or jack passing through.

The claim language also supports the "provides access to" construction. To be sure, the claim language--"an opening that communicates with the receptacle"--is ambiguous, and 180s perhaps should have used the clearer phrase "provides access to." Additionally, "communicates with" is not a widely accepted synonym for "provides access to," but implicates the idea of facilitating communication (such as electrical communication). However, "communicates with" is also not synonymous with "provides access to for something such as a wire or jack to pass through." More importantly, as 180s stressed at the Markman hearing, the configuration of the ear warmer's electrical components are discussed in a different section of claim 1. Two paragraphs after "communicates with," claim 1 reads:
[A] first electrical wire having a first end electrically coupled to the speaker and a second end including a connector, the connector being disposed proximate to the opening of the receptacle and configured to be electrically coupled to a second electrical wire disposed outside of a housing of the device associated with sound generation.

(Pl.'s Mem., Ex. B at col. 10, ll. 14-20.) Nothing suggests that the portion of claim 1 that includes "communicates with" was intended to provide guidance regarding the electrical configuration of the patent. If Gordini wants to limit the '645 patent to a certain electrical configuration, it must find such a limitation in the claim language that pertains to the electrical configuration. Lastly, there is extrinsic support for the "provides access to" construction. One dictionary definition--though the third and last listed--of "communicate" is "to open into each other; connect." See MERRIAM-WEBSTER ONLINE DICTIONARY, http://www.merriam-webster.com/dictionary/communicate.

B. Construing Terms in the 420 Patent

1. "[A]n aperture communicating between . . ." and a "second opening communicating between . . ."

"An aperture communicating between the housing drive surface and the recess" means an opening through the housing where the housing drive surface is aligned with the recess. A "second opening communicating between the concavity and the external reaction drive surface" means an opening through the housing where the housing drive surface is axially aligned with the recess.

The court's construction of the terms adopts those provided by NPI in the Amended Joint Claim Chart (Dkt. # 49).

For both terms, the claim language and specification do not exclude the possibility of more than one opening or aperture. First, both Claims 1 and 15 use the transitional phrase "comprising" in their respective preambles. "Comprising" is an open-ended term which creates a presumption that the invention is made up of at least as many elements as described. Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1371-73 (Fed. Cir. 2005) (holding that "comprising . . . a group of first, second, and third blades" in patent for safety razors encompassed a four-bladed razor). Moreover, the use of the article "an" before "aperture" in Claim 1 tends to suggest the possibility of more than one such opening. Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999).

Claim 15 assigns an ordinal to the aperture element: "a first opening on the surface [of the housing concavity] . . . and a second opening communicating between the concavity and the external reaction drive surface . . ." 420 Patent, col. 13, lines 4-6 (emphasis added). The court construes the numbering in this instance as merely differentiating between multiple references to an element; as such, the term "second" does not confine the claim to include only one such opening. See Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1371 (Fed. Cir. 2003) ("use of the terms first' and second' is common patent-law convention to distinguish between repeated instances of an element" and should not necessarily be interpreted to impose a serial limitation on a claim).

Without intrinsic support, Palmetto argues for an additional limitation that the opening's "entire purpose" is to provide a direct connection between two surfaces. Palmetto Resp. at 5. The specification teaches, however, that the purpose of the aperture is to allow for a drive shaft to pass through, a point which Palmetto conceded at oral argument. 420 Patent, col. 4, lines 66-67; 420 Patent, col. 4, lines 28-31. There is no indication from the claim language or the specification that such
purpose must be met via a pathway that provides a direct connection between the housing recess and the external reaction drive surface. Both Claims 1 and 15 refer to an opening that simply communicates between two "aligned" surfaces. 420 Patent, col. 11, line 8; id., col. 13, line 6. Palmetto's dictionary definition appears to undermine its argument: "communication" is a "means of connecting different places, such as a door, passage, road, or railway." The Concise Oxford Dictionary 268 (9th ed. 1995). By this definition, an aperture could provide a means for connecting two surfaces via a direct pathway or a passage that spans two distant places. Accordingly, the court declines to adopt Palmetto's limitations.

767 (9) "Communicating with." To have a common part, to be connected, join.

2. said passageway communicating with said reservoir

The term "said passageway communicating with said reservoir" appears in claim 1 and claim 12. Chip-Mender contends that it means "said channel open to said reservoir." Sherwin-Williams asserts that it means "a passageway [28] from the reservoir [22] that separates this fluid storage body from the nib and that allows paint to flow from the fluid storage body to the upper part of the nib."

According to Chip-Mender, the parties originally agreed on the definition of "passageway" as "channel," but Sherwin-Williams changed its proposed construction back to the undefined "passageway." In its papers, Chip-Mender asserts that it is not important whether "passageway" is construed as "channel," or simply left as "passageway." At the hearing, counsel for Chip-Mender stated that "channel" and "passageway" are the same term.

Chip-Mender bases its proposed construction of "communicating with said reservoir" on the specification, including Figure 2, and on the language of claims 1 and 12. In particular, Chip-Mender argues that the "passageway" must be "open" to the "reservoir." Chip-Mender asserts that the specification makes clear that the paint flows from the reservoir through the passageway to the nib. See '299 patent, col. 2, ll. 7-12. Chip-Mender also contends that extrinsic evidence also supports this construction, citing an Internet dictionary definition of "passageway" as "a path or channel or duct along which something may pass."

In its opposition, Sherwin-Williams argues that the plain and ordinary meaning of "passageway" does not require a structure that is always "open," and that Chip-Mender's proposed construction is inconsistent with the other claim language and the specification. Sherwin-Williams bases its proposed construction on the description of Figure 2. See '299 patent, col. 3, 48-60. In particular, Sherwin-Williams notes that the "passageway… permits the paint composition to flow." Sherwin-Williams contends that because the upper part of the nib is shown as residing inside the passageway, the "passageway" depicted in Figure 2 is not always unobstructed and is therefore not "always open."

Sherwin-Williams argues that the term "said passageway communicating with said reservoir does not prohibit a flow regulator or valve in the passageway, based on the fact that the claims require that the passageway include a part of the nib, and also based on the specification, which depicts a passageway including a structure in the passageway that would restrict flow (the nib).

The court finds that "said passageway communicating with said reservoir" means "said channel open to said reservoir." According to the claim language and the specification, the paint flows from the reservoir to the nib through the passageway. See '299 patent, col. 5,II. 35-37; col. 6, II. 24-26; col. 2, II. 7-10, 27-30. Therefore, the passageway must at some point be "open to the reservoir." There is no requirement in the patent claims and specification that the passageway be "always open," just that it be "open" in the sense that "when a force is applied to the paint composition in the reservoir either by gravity or by squeezing the housing," the paint "flows from the reservoir to the passageway and outwardly from the housing at the nib." Id., col. 2,II. 7-10.
CLAIM 15

The parties have requested construction of essentially all of the language of the claim, other than the "engine," as follows:

15. A fuel delivery system for removing undesired components from fuel delivered from a fuel tank to an engine comprising, in combination: [issue # 1]

an engine;

initial fuel filter means for removing water from fuel received from the fuel tank; and [issue # 2]

secondary fuel filter means including vessel walls defining an interior chamber having an outlet in fluidic communication with said engine, an inlet in fluidic communication with said initial fuel filter means for receiving fuel containing an undesired gas from said initial fuel filter means, and a return line opening; [issue # 3]

a filter element dividing said chamber into an inlet side and an outlet side, and providing means for preventing substantially all undesired gas in said fuel from passing through said outlet, said preventing means including said filter element separating said inlet side from said outlet side and having substantially no openings having a greater dimension than about 25 microns passing from said inlet side to said outlet side, said return line opening communicating with said chamber on said inlet side to receive air and fuel therefrom; and [issue # 4]

a fuel return line communicating with said return line opening and said fuel tank for delivery of air and fuel to said fuel tank. [issue # 5]

Claim 15; Issue 5 - The Fuel Return Line

Defendants again suggest the word "communicate" be construed as a connection with regard to this final element, while Plaintiffs assert no further definition is necessary. Although it is hard for the undersigned to envision how the fuel return line could provide communication between the return line opening and the fuel tank without it being "connected to" such elements, others skilled in the art may envision such a method, and such a limitation is not necessarily required by the claim's usage of the word "communication." The Court therefore adopts the same meaning of "communication" as with issue # 4, above, which meaning is similar to that used with regard to other claims, namely, permitting transfer between elements. As such, the Court finds that one skilled in the art would understand the final element of Claim 15 to mean as follows:

"A fuel return line provides communication or transfer between the return line opening and the fuel tank for delivering air and fuel from the opening to the fuel tank."

GO BACK

6. "commutator bar"

This term appears in Claims 1 and 16. Plaintiff proposed construction is "a bar or segment connected to an armature of a motor or generator, which may include a carbon block bonded thereto." Defendant asserts that the term need not be construed, but, alternatively, proposes a construction as follows: "rigid piece of metal used for the electrical connection to the moving part of a motor." Again, both parties cite general purpose dictionaries in support of their proposed constructions, and Plaintiff also cites a portion of the specification that refers to commutator bars that have "been covered with a block of carbon material." Buckingham Decl. at Ex. A, col. 2:31-40. Webster's New Collegiate Dictionary (cited by Plaintiff) defines
"commutator" as "a series of bars or segments so connected to armature coils of a dynamo [i.e., a motor or generator] that rotation of the armature will in conjunction with fixed brushes result in unidirectional current." Buckingham Decl. at Ex. C. Similarly, Webster's College Dictionary (cited by Defendant) defines "commutator" as "(in a DC motor or generator) a ring or disk assembly that works to change the frequency or direction of current in the armature windings." Pospis Decl. at Ex. J.

"Bar" is defined as "a relatively long, evenly shaped piece of . . . metal . . . for some mechanical purpose." Id. Further, "armature" is defined as "the rotating part of a dynamo." Taking into account these common understandings of the relevant terms, the Court shall construe "commutator bar" consistent with Defendants' proposed construction as "rigid piece of metal used for the electrical connection to the moving part of a motor."

**771**

B. "Compacting" (claims 1 and 11)

Plaintiff's proposed construction:

Extrusion under pressure, pressure rolling, prilling or other techniques which compact the agglomerated material into a form which has some degree of structural integrity, and which, following drying, can maintain its shape or be comminuted appropriately.

Defendant's proposed construction:

Extrusion under pressure, pressure rolling, prilling or other techniques which compact the agglomerated material into a form which has some degree of structural integrity, and which, following drying, can maintain its shape or be comminuted appropriately.

It is necessary, regardless of the means of compacting, that the uncompacted precursor contain enough binder, surfactant, water absorber, and like compounds, to produce a product which can withstand the rigors of further comminution (when practiced), storing, without breakdown into fine particles. The flakes, prills, etc., which are produced must also be a limited period of time as is well known.

The parties agree that the term "compacting" should be construed to include the requirements described in a definition of the term located in the patent specification, '499 pat., col. 6, lns. 42-47, which is why each parties' construction includes an identical paragraph. However, defendant contends that elsewhere the specification sets additional requirements on "compacting," '499 pat., col. 4, lns. 15-21, which explains the second paragraph defendant proposes.

I will not adopt defendant's proposed construction because the additional limitation does not add anything to what is already required. The two independent claims, claims 1 and 11, require the mulch product to undergo agglomeration and compaction. The parties agree that agglomeration, which occurs before or simultaneously with compaction, involves a "treatment . . . effective to allow the compacted and dried material to have sufficient integrity to withstand subsequent comminution, storage and shipment without generating excessive fines." Def.'s Br., dkt. 22, at 4. (The term "excessive fines," as it is used, appears to mean "too many fine particles.") Thus, by agglomeration, the product will come to "withstand the rigors" described in defendant's proposed construction. Although the limitation defendant requests emphasizes that the product must "contain enough binder, surfactant, water absorber, and like compounds" to withstand the rigors, it does nothing to specify how much of these compounds is "enough" or explain the scope of acceptable "like compounds" such that it could be said to impose a limitation on the type of materials that may be present in the mulch product before compaction. The language defendant identifies is more of a throw-away statement intended to summarize what is required of "agglomeration" than an additional limitation on "compacting." Defendant's proposed construction will be rejected and plaintiffs' proposed construction will be adopted.

**Court's construction:**

Extrusion under pressure, pressure rolling, prilling or other techniques which compact the agglomerated material into a form which has some degree of structural integrity, and which, following drying, can maintain its shape or be comminuted appropriately.
(2) "comparing a reference value with a difference between a slow spinning speed and a fast spinning speed of the drum"

The parties also dispute the term "comparing a reference value with a difference between a slow spinning speed and a fast spinning speed of the drum," which appears in Claims 3 and 10. LG proposes construing the term to mean "comparing a reference value [i.e., a known value for measuring against] with a difference [i.e., change] between a slow spinning speed and a fast spinning speed of the drum." (Chart at 26.) Whirlpool proposes instead that the term be construed to mean "subtracting a slow measured drum speed from a fast measured drum speed and comparing the result with a standard value." (Id.)

According to the written description for Figures 5 and 6, "[t]he imbalance sensing operation is performed by calculating the difference between a speed X2 at which the drum spins fastest so that the laundry is placed on the top of the drum, . . . and the speed X1 at which the drum spins slowest so that the laundry is placed in the lower part of the drum, . . . and then comparing the calculated difference with a reference value in step 55S." ('731 Patent, col. 3, ll. 49-55.) Figure 5 shows this calculation in step 55S as "X[2] -X[1]>reference value."

The summary of the patent describes "a drying method for a drum-type washing machine, the method including the steps of . . . comparing a reference value with a difference between a slow spinning and a fast spinning speed of a drum . . . and based on a result of the comparing step, controlling a spinning operation of the drum." (Id., col. 2, ll. 44-53.)

Based on the patent's use of the term "difference" when describing the comparison of values X[1] and X[2], and its use of a subtraction calculation to describe the comparison performed, the Court agrees with Whirlpool that the term refers to the subtraction of the two values.

With respect to the terms "slow spinning" and "fast spinning," however, Whirlpool has failed to identify any intrinsic support for construing the terms to mean "slow measured" and "fast measured." With respect to Whirlpool's argument that the term "standard value" should apply, the Court also finds no basis to support that argument.

The Court will therefore construe the term "comparing a reference value with a difference between a slow spinning speed and a fast spinning speed of the drum" to mean "subtracting a slow spinning speed from a fast spinning speed of the drum and comparing the result with a reference value."

3. "Comparing" fluorescence polarization

After the polyionic compound has been added to the reaction mixture and differentially associates with either the first reagent or the reaction product, the patents instruct that the fluorescence polarization of the first and second mixtures be compared. Caliper proposes that the term "comparing" be construed as: "The fluorescence polarization of the mixtures, which may be determined directly or indirectly, is compared."

MDC proposes: "The fluorescence polarization of each of the two things being compared is measured, and the difference is calculated to provide a measure of the amount of product produced or first reagent consumed." The central dispute is whether both mixtures, before and after the reaction has occurred, must be measured and directly compared, or whether the comparing may be done indirectly, or against a known value.

It is quite clear that the patent instructs that the first mixture (which comprises a first reagent having a fluorescent label) is compared with the second mixture (the first mixture converted to the second mixture by the addition of a second reagent, to produce a fluorescently labeled product having a substantially difference charge than the first reagent). ('774 Patent at 29:13-23.) In Claim 20, the first fluorescently labeled reagent is compared with the second mixture. ('774 Patent at 30:20-
30.) Again, in Claim 50, the patent instructs to compare the first and second levels of fluorescent polarization. ("774 Patent at 33:4-34:4.) There is no indication in the claim language itself regarding the timing of the measurement of the fluorescent polarization values of the first mixture. The specifications indicate that it was contemplated that the measurement of the polarization value may be either an absolute quantitative measurement, "where one has to determine or is already aware of the P value for completely bound label and completely free label. Alternatively, . . . one can measure the pre-reaction and post reaction fluorescence polarization, using the difference between the two as an indication of the amount of product produced." ("774 Patent at 10:2-7.)

The clear language of the claim is broad enough to encompass both methods of comparing the fluorescent polarization values of the first and second mixtures. The claim language merely instructs to compare the values of the first and second mixtures, but does not indicate whether the value of the original reagent is known or must be measured during the same process. However, although the Court agrees with Caliper's understanding of the term "comparing," the Court will not adopt the construction Caliper proposes which ambiguously defines the claim term to instruct that the polarization values of the mixtures could be determined either "directly or indirectly." Instead, the Court adopts a modified construction of the term "comparing the fluorescence polarization in the second mixture relative to the first mixture" to mean: comparing the fluorescence polarization of emitted light from the second mixture with the fluorescence polarization of the emitted light from the first mixture, which may be either measured or may be a known value.

1. "battery compartment"

Claims 1, 3, and 10 of the '571 Patent describe a "battery compartment." Philips asserts that this term should be construed as "a part of an enclosed space within the defibrillator case to hold the battery." Cardiac Science contends that this term should be construed as "a defined space for containing batteries."

Similar to its arguments regarding the electrode compartment of the '969 Patent discussed above, Philips asserts that the battery compartment needs to be enclosed. Cardiac Science notes that the unenclosed nature of the battery compartment is demonstrated by the fact that the battery compartment still remains a compartment even when the AED lid is open.

The specification states that "electrical power is provided by a rechargeable twelve volt lead-acid cartridge battery 80 and a nine volt battery 82 which are removeably positioned within the battery compartment and connected to power generation circuit 84." ("571 Patent at c. 3, ll: 13-16.) Cardiac Science is correct in asserting that neither the claim language nor the specification requires the battery compartment to be enclosed. Consistent with the Court's construction of the term "electrode compartment" discussed above, the Court construes "battery compartment" as "a section within the defibrillator case that contains the battery or batteries."

**GO BACK**

**775**

3. "electrode compartment"

Claim 1 of the '969 Patent describes an "electrode compartment." Philips asserts that this term should be defined as "a part of an enclosed space within the defibrillator case to hold the electrodes." Cardiac Science contends that the term "compartment" is commonly understood and need not be construed. Alternatively, Cardiac Science asserts that the term should be construed as "a defined space for containing electrodes."

The heart of the parties' dispute is whether the space of the compartment needs to be completely enclosed or not. Philips asserts that the defibrillator case lid 28 encloses the electrode compartment in the '969 Patent. ("969 Patent at c. 2, ll: 26-33.) However, Cardiac Science maintains that the space need not be enclosed. Specifically, Cardiac Science asserts that the electrode compartment is still referred to as a compartment even when the lid is open, thus demonstrating that Philips' construction is inappropriate. (Id. at c. 2, ll: 26-29.) The dictionary definition could support either party's construction. Merriam-Webster's defines "compartment" both as "a separate division or section" and "one of the parts into which an
TheCourtfindsthatPhilips'proposedconstructionismisguided. The "enclosed space" to which Philips refers, if anything, isthatofthedefibrillatorcase. Evenfollowingthedictionarydefinitionof"compartment"thatPhilipsadvances, the electrode compartment would merely be a division of an enclosed space, that enclosed space being the defibrillator case. But the compartment itself need not be enclosed, as Cardiac Science is correct in asserting that the electrode compartment stillremainsa "compartment" even when the lid is open.

Withtheseconsiderationsinmind, theCourtconstrustheterm "electrode compartment" to mean "a section within the defibrillator case that contains the electrodes."

776

C. "So as to Compensate for Thermal Expansion of Said Chip" and "To Compensate for Differential Thermal Expansion of the Chip and Substrate"

Tessera proposes that the meaning of both "so as to compensate" terms is "to appreciably relieve the thermally induced stresses (strains) caused by the difference in thermal expansion of the chip and the substrate." Samsung proposes that the "so as to compensate" term shouldmean "to neutralize or counterbalance thermal expansion." Joint Claim Construction Statement at B3:1-2. Samsung contends that its proposed construction should prevail because the ordinary meaning of "compensate" is to "neutralize or counterbalance." Joint Claim Construction Statement at B3:1-2; B5:2. However, the specifications of the '304 patent do not require "so as to compensate" to go so far as complete neutralization or counterbalancing. Tessera's proposed construction of appreciable relief is supported by the specification, which refers to the terminals "accommodating" thermal expansion. See '304 patent at 15:57; 20:47.

TheCourtconstrusthemeaningofboth "so as to compensate" terms to be "to appreciably accommodate the thermally induced stresses (strains) caused by the difference in thermal expansion of the chip and the substrate."

777

1. Complementary Coupling Part

The first term to be interpreted is "complementary coupling part." The phrase appears in claims 1 through 3, 10, 23, 26 and 27 of the '836 patent. Unilin's proposed construction is "a part that cooperates with another complementary coupling part to connect two panels together in the vertical and horizontal directions." (Unilin's Open. Br. 12.) Alloc's proposed construction is "the parts by which the panels are connected cooperate with one another while the panels are connected." (Jt. Claim Constr. Charts, '836 patent chart 1.)

A representative use of the "complementary coupling part" appears in claim 1 of the '836 patent as follows: "said side edges including complementary coupling parts configured to cooperate with identical cooperative complementary coupling parts of another one of said panel." (836 patent, 13:62-64) 2 (emphasis added).

Footnotes

2 The citation format used throughout this opinion for the patents is that the number preceding the colon denotes the column and the number(s) following the colon denote(s) the line(s).

End Footnotes

In construing the phrase, the Court is to give the words the ordinary and customary meaning that would have been attributed to them by a person of ordinary skill in the art at the time the invention was made. Phillips, 415 F.3d at 1312-13. Such a person is deemed to have read the term in the context of the entire patent, including the claims themselves, the specification,
and the prosecution history. Id. at 1313.

The specification discusses the coupling parts in the brief summary of the invention as follows:

To this aim, the invention relates to a floor covering, consisting of hard floor panels which, at least at the edges of the two opposite sides, are provided with coupling parts, cooperating which each other, substantially in the form of a tongue and a groove, wherein the coupling parts are provided with integrated mechanical locking elements which prevent the drifting apart of two coupled floor panels into a direction perpendicular to the related edges and parallel to the underside of the coupled floor panels.

('836 patent, 2:17-25)(emphasis added.)

The parties are in apparent agreement that "coupling" means some form of "connect." However, neither definition suggested by the parties is entirely consistent with the principles of claim construction. Alloc's proposed construction adds the limitation -- while the panels are connected. The limitation is inconsistent with the language of the claim which states that such parts are "configured to cooperate" indicating that there is a passive element to the complementary nature of the part. Such limitation is contrary to the '836 specification which states that the coupling parts also cooperate with each other while they are in the process of being coupled. (See '836 patent, 5:37-38.)

Unilin's interpretation is consistent with the patent claims and specification but is circular because the definition uses the term -- complementary coupling part -- which it is intended to define. Complementary means "as forming or serving a complement: complete." Webster's II, New Riverside University Dictionary, 290 (Riverside Publishing Co. 1984). "Part" means "component." Id. at 856. Thus, the Court interprets "complementary coupling part" as meaning "a completing component that cooperates with another completing component to connect two panels together in the vertical and horizontal directions."

778

A

Rail fasteners typically keep rails in place on railroad ties by exerting a downward force on the flange of a rail. The '898 patent is directed at an improved rail fastener which is able to exert both a horizontal force as well as a downward force on the rail. The additional horizontal force helps reduce "rail creep," or the tendency of the rails to move in the direction of the train's travel.

The claim at issue in the '898 patent is claim 1, which reads in relevant part:

A rail fastening system comprising an elastic rail clip, a clip holder adapted to hold the clip in position on the flange of the rail and a locking element being adapted to lie between the rail flange, the rail clip and the clip holder,

....

said clipholder having an external face complementary in shape with said locking element to provide a wedge-like interfitting, the complementary shape being in the form of a U wherein the corners of the U have a radius of curvature sufficient to provide a wedging action which translates said movement of said locking element into said lateral pressure and where each side of the U is inclined at an angle to the base of the U sufficient to provide a wedging action which translates movement of said locking element into said lateral pressure.

'898 patent, col. 3, line 43 - col. 4, line 20.

The following figures depict the claimed rail fastener from a side and top view, respectively:

GET DRAWING SHEET 1 OF 1.
In brief, claim 1 of the '898 patent calls for a "locking element" (7) that is held in place on the rail flange by an elastic rail clip (12). The rail clip, in turn, is held in a clip holder (15) which itself is anchored into the concrete rail tie. The downward force is produced by the rail clip bearing down on the locking element, which sits atop the rail flange. The additional horizontal force is produced when the locking element, with its unique wedge-shaped ends (8), is dragged by the "creeping" rail in one direction or another, thereby causing a "wedging" action to occur between the rail clip and the rail flange.

* * *

A

With respect to the '898 patent, Pandrol concedes that if the district court was correct in construing the term "complementary" so as to require both the locking element and the clip holder to have faces in "the shape of a U with curved corners," then Airboss's accused locking element, having no curves, does not infringe. Hence, we must determine whether the district court's construction of "complementary" was in fact correct.

Pandrol urges us to adopt a construction of the term "complementary" that would simply mean "a shape that accomplishes the function specified in the claim." Specifically, Pandrol argues that infringement should turn on "whether the accused [locking element] provides the lateral force that reduces rail creep." Under this construction, any conceivable shape would suffice, so long as the "wedging action" is produced. This construction is too broad.

The fact that the patentee chose to include the term "complementary" in the claim language must be given due significance. Perhaps, the term by itself does not require that the two faces be congruent, but at the very least, it indicates that the inside face of the locking element should bear some resemblance to the outside face of the clip holder. The actual claim language refers to the clip holder's outside face as "being in the form of a U wherein the corners of the U have a radius of curvature sufficient to provide a wedging action . . . ." '898 patent, col. 4, ll. 12-15. As noted by the district court in its claim construction order, this language indicates that a "complementary" locking element would at least have "a shape that is rounded to fit the clip [holder]." Pandrol II, slip. op. at 5. Hence, we hold that the district court did not err when it construed claim 1 so as to require both the locking element and the clip holder to possess "the shape of a U with curved corners."

Since Pandrol concedes that the accused locking element does not have curved corners, the accused device does not fulfill the requirement that the locking element be "complementary" with the clip holder.

2. The "Complementary Processing Head" Limitation

Semitool also argues that the district court erred by construing the "complementary base head" limitation in the '310 patent to require that the head and the bowl form a single unitary structure when in the closed position because neither the ordinary meaning of the word "complementary," the specification, nor the prosecution history support that interpretation. Novellus responds that Semitool did not raise this argument before the district court and therefore waived it on appeal.

Even assuming that Semitool failed to argue the meaning of the "complementary processing head" limitation to the district court, the court did construe that limitation, and in light of the continued vitality of the patent and the public interest in clarifying the scope of the claims, we exercise our discretion to review the district court's construction of that limitation. We agree with Semitool that the district court erred in its interpretation. It is undisputed, and in fact was so determined by the district court, that the head and the bowl in both patents do not form a "gas-tight" seal. Semitool I at 19. Thus, the head and the bowl cannot be said to form a "single component" when in the closed position. Rather, as taught in the '310 and '708 patents, the head is only "complementary" to the extent that, when lowered into the closed position, it forms a seal with the bowl that is sufficiently closed to permit effective gas processing. We therefore interpret the "complementary processing head" limitation to be synonymous with the "substantially closed" limitation, which does not require the head and the bowl to form a single component when in the closed position.
2. The "Complementary Processing Head" Limitation

Semitool also argues that the district court erred by construing the "complementary base head" limitation in the '310 patent to require that the head and the bowl form a single unitary structure when in the closed position because neither the ordinary meaning of the word "complementary," the specification, nor the prosecution history supports that interpretation. Novellus responds that Semitool did not raise this argument before the district court and therefore waived it on appeal.

Even assuming that Semitool failed to argue the meaning of the "complementary processing head" limitation to the district court, the court did construe that limitation, and in light of the continued vitality of the patent and the public interest in clarifying the scope of the claims, we exercise our discretion to review the district court's construction of that limitation. We agree with Semitool that the district court erred in its interpretation. It is undisputed, and in fact was so determined by the district court, that the head and the bowl in both patents do not form a "gas-tight" seal. Semitool I at 19. Thus, the head and the bowl cannot be said to form a "single component" when in the closed position. Rather, as taught in the '310 and '708 patents, the head is only "complementary" to the extent that, when lowered into the closed position, it forms a seal with the bowl that is sufficiently closed to permit effective gas processing. We therefore interpret the "complementary processing head" limitation to be synonymous with the "substantially closed" limitation, which does not require the head and the bowl to form a single component when in the closed position.

B.

On appeal, defendants also challenge the district court's construction of the term "complete hermetic seal" in the limitation of claim 12 relating to a "flexible circular diaphragm." As seen, the court construed this term to mean "a seal that does not require any additional parts to retain nearly or largely all of the air in the bed." Markman Order, 2004 U.S. Dist. LEXIS 1202, at *16-17. Defendants argue that the court's construction of "complete hermetic seal" is inconsistent with the specification because the specification indicates that the language "complete hermetic seal" relates to the quality of the seal and not its mechanical completeness. They argue in addition that the prosecution history expressly indicates that the phrase "complete hermetic seal" refers to the degree of sealing, so a complete hermetic seal is one that is "impervious to air." Aero responds that the district court did not err in construing "complete hermetic seal" in claim 12 to mean that the valve does not require any additional parts to form a seal. It urges that the court's construction is not inconsistent with the specification and that the term "complete hermetic seal" was added during prosecution to distinguish prior art that required additional parts to form a seal, such as a lid.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

7 Defendants assert that there would be no infringement under their proposed claim construction of "complete hermetic seal"--namely, a seal that is "impervious to air"--because the accused Intex device leaks some air and thus is not "impervious to air."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
the one-way valve provides a "substantially hermetic seal." Second, it explains to the reader how that "substantially hermetic seal" comes about: specifically, by air pressure causing a region of the outer surface of the diaphragm to become engaged against the valve seat. In other words, the claim language tells one of skill in the art the manner in which the claimed "substantially hermetic seal" is accomplished. While defendants' argument would have been squarely foreclosed had the inventor referred to "a completed hermetic seal," we are not prepared to hold that the inventor's less-than-perfect wording undermines the claim construction that emerges from the otherwise clear language of claim 12. We also think the district court was correct when it stated that interpreting the claimed seal as being a seal that does not allow any air to leak through would render the term "substantially" illusory. Markman Order, 2004 U.S. Dist. LEXIS 1202, at *16; see Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so.

In sum, the claim language supports the district court's construction that "complete hermetic seal" means "a seal that does not require any additional parts to retain nearly or largely all of the air in the bed." Markman Order, 2004 U.S. Dist. LEXIS 1202, at *16-17.

We are not persuaded by defendants' argument that the district court's claim construction is at odds with the specification and the prosecution history. The specification requires little discussion. Referring to Figure 3 above, it simply states that, "[w]hen air has been placed within the mattress 10 under modest pressure, . . . and air pressure is removed from inflation input 322, the pressure of air in the mattress 10 urges the diaphragm 34 against valve seat 36 and produces a positive seal against the exit of air from the mattress." '726 patent, col.4, ll.12-18. This language does not, in any way, suggest that the seal of claim 12 must be "complete" in terms of being air-tight.

Turning to the prosecution history, the '726 patent issued from U.S. Patent Application No. 992,814 ("the '814 application"), which was filed on December 16, 1992, as a continuation-in-part of U.S. Patent Application No. 384,786 ("the '786 application"). As originally filed, independent claim 12 of the '814 application required a "substantially hermetic seal":

An inflatable bed comprising:

an inflatable bed having an interior and an inflation input;

a one-way valve disposed between the interior and the inflation input providing a substantially hermetic seal under low pressure conditions, such valve including:

a passageway having a generally circular cross section and a first end in communication with the interior and a second end in communication with the inflation input;

a circular lip, disposed peripherally in the passageway and protruding radially inward, having a first surface generally facing the interior, defining a valve seat; and

a flexible circular diaphragm, having an inner surface generally facing interior and an outer surface facing away from the interior, mounted for axial movement in the passageway away from and against the valve seat in respectively open and closed positions of the valve, so that an outer annular region of the outer surface of the diaphragm engages, against the valve seat when the valve is in the closed position.

(Emphasis added). Claim 12 and dependent claims 13 through 15 of the '814 application were rejected under 35 U.S.C. § 103 as being obvious in view of U.S. Patent No. 4,579,141, which issued to Heino Arff ("the Arff patent"). 8 The Examiner explained that it would have been obvious to a person of ordinary skill in the art to use the check valve taught by the Arff patent:

Arff shows a filling and discharge valve used for an inflatable body that comprises an annular flange . . . that includes a cylindrical portion . . . upon which a cap . . . can be screwed. A passage is defined through the flange which receives a spring loaded check valve . . . that includes an annular diaphragm . . . . The diaphragm rests against an annular sealing face defined by an annular sealing ring . . . . Note that the lower end of the sealing ring is defined by an annular surface that faces down and into the inflatable body, the valve diaphragm rests against this face to form the seal. While the Arff valve is used upon an inflatable boat, it is clear that its use is not so limited. Since it is well known in the art to use a one way check valve similar to Arff's upon an air mattress, it would have been obvious to one of ordinary skill in the art [to] use the specific check valve taught by Arff upon an air mattress.
In response to this rejection, the inventor amended claim 12 so that it reads, in its present form, as follows:

An inflatable [bed] body comprising:

- an inflatable bladder having an interior and an inflation input;
- a one-way valve disposed between the interior and the inflation input providing a substantially hermetic seal under low pressure conditions, such valve including:
  - a passageway having a generally circular cross section and a first end in communication with the interior and a second end in communication with the inflation input;
  - a circular lip, disposed peripherally in the passageway and protruding radially inward, having a first surface generally facing the interior, defining a valve seat; and
  - a flexible circular diaphragm, having an inner surface generally facing the interior and an outer surface facing away from the interior, mounted for axial movement in the passageway away from and against the valve seat in the respectively open and closed positions of the valve, so that (i) the act of inflation of the bladder under low pressure is sufficient to cause axial motion of the valve into the open position to permit the large influx of air and (ii) following inflation of the bladder, air pressure created in the interior the bladder by inflation thereof causes an outer annular region of the outer surface of the diaphragm to be urged into engagement against the valve seat to provide a complete hermetic seal when the valve is in the closed position; and
- stiffening means for reducing flexing of the diaphragm except in its outer annular region.

(Bracketed material removed, underlined material added). Aero explained that claim 12 had been amended to "claim the subject matter of the invention more distinctly." It also explained that claim 12 "as amended now requires stiffening means for reducing flexing of the diaphragm except in its outer annular region." Aero asserted that the amendment was supported by the specification. The Examiner thereafter issued a Notice of Allowance.

As seen, the term "complete hermetic seal" was added to claim 12 after a rejection based on the Arff patent. However, the Examiner did not cite the Arff patent against claim 12 because of the quality of the seal in claim 12. The inventor explained that claim 12 was being amended, in light of the Arff patent, to require a stiffening means. There is nothing in the prosecution history to suggest that claim 12 was being modified to add a requirement for a completely hermetic seal. Thus, contrary to defendants' argument, the language "complete hermetic seal" was not added to distinguish the Arff patent based on the limitation of a seal that is completely impervious to air, as defendants urge. In short, the prosecution history does not support defendants' claim construction argument.
material of the skirt, said skirt being completely free with respect to the pan with the exception of a ring which joins only the top edge of the skirt to the top edge of the pan and to which the latter is attached, said ring being of heat-insulating material which is continuously resistant to the temperature of the top edge of the pan.

13. The specification of the '312 Patent describes the metal pan spaced from the plastic skirt with at least three points of contact between the metal pan and the plastic skirt: a heating element, a thermostat, and the stabilizing connection at the bottom. Those elements are discussed in the text and shown in the drawings.

14. Claim 8 of the '312 Patent, which relates to independent claim 1, recites, in part, "the base of the pan has a vertical rod engaged in an opening formed in the base of the outer skirt and separated from the rod by a sleeve of heat-insulating material which affords resistance to the temperature of said rod."

15. The prosecution history of the '312 Patent shows that the phrase "completely free with respect to the pan" in claim 1 means that the skirt is thermally insulated from the pan with an air gap, not that it is free from any other contacts with the pan:

   . . . the skirt 3 is practically free with respect to the pan 1 or in other words that no thermal bridge is created between the pan and the skirt . . . .

16. In connection with the prosecution of the '312 Patent, SEB did not change the original language of the claims in any material respect. In the prosecution history, SEB distinguished the "cool wall" invention from a cited Onishi patent, which shows the use of the adiabatic (insulating) material between the pan and the skirt. That discussion had essentially nothing to do with the presence or absence of a thermally insignificant stabilizing element.

    *    *    *

33. SEB is likely to succeed on the merits because that test is met here: the accused product contains each element of claim 1 of the '312 Patent. Consequently its use and sale in the United States infringes the patent.

34. Montgomery Ward and Pentalpha, in essence, argue that the accused product does not infringe claim 1 because its skirt is not "completely free with respect to the pan" as stated in claim 1. Claim 1 recites in part:

   . . . said skirt entirely surrounding the lateral wall (1a) and the base (1b) of the pan and being separated from said wall and said base by an air space (4) of sufficient width to limit the temperature of the skirt (3) . . . . said skirt (3) being free with respect to the pan (1) with the exception of a ring (5) which joins only the top edge (3a) of the skirt to the top edge (1c) of the pan and to which this latter is attached, said ring (5) being of heat-insulating material . . . .

35. According to the '312 Patent, there are other points of contact between the skirt and the metal pan, such as a heating element, a thermostat and a stabilizing element at the bottom. These points of contact do not create the thermal bridges, which the patented invention seeks to prevent. Defendants contend, nonetheless, that the bottom of the fry pan is stabilized to the bottom of the skirt and, therefore, is not "completely free with respect to the pan." The intrinsic patent evidence, however, does not permit this claim interpretation.

36. When properly construed, claim 1 cannot mean that the skirt has no connection with the pan other than the heat-resistant ring. The specification of the '312 Patent unambiguously describes at least three other points of contact: a heating element, a thermostat, and a stabilizing connection at the bottom. Those elements are discussed in the text and shown in the drawings. According to defendants, claim 1 should be construed in a manner that would exclude the embodiment of the invention shown in the specification itself. This asserted claim construction is not correct. See Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1581 (Fed. Cir. 1996), cert. denied, 519 U.S. 911, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996); Burke Inc. v. Bruno Independent Living Aids, Inc., 183 F.3d 1334, 51 U.S.P.Q.2D (BNA) 1295, 1300 (Fed. Cir. 1999).

37. The prosecution history confirms that the phrase "completely free with respect to the pan" means that the skirt is thermally insulated from the pan with an air gap, and not that it is free of any other contacts with the pan:

   . . . the skirt 3 is practically free with respect to the pan 1 or in other words that no thermal bridge is created between the
pan and the skirt.

38. Moreover, a connection between the skirt and pan is recited in dependent claim 8. Thus, it is clear that the claims of the '312 do not exclude all connections between the skirt and the metal pan.

39. This intrinsic patent evidence constitutes the public record on which competitors rely to determine the scope of the patented invention. Vitronics, 90 F.3d at 1577. Competitors who read the '312 Patent, look at its drawings and review its prosecution history, will learn that the claims cover a plastic skirt that is thermally insulated from the metal pan. They will understand that thermally insignificant contacts from the heating element, the thermostat and any stabilizing element do not create thermal bridges, and the appearance of these elements in a deep fryer does not remove it from the scope of the claimed invention. Defendants' asserted claim construction seeks to change the unambiguous public record, in violation of the principles of claim construction. Markman, 52 F.3d at 980-81.

40. Thus, SEB is likely to prove at trial that the Admiral deep fryer infringes at least claim 1 of the '312 Patent.

41. In addition to literal infringement, infringement may exist under the doctrine of equivalents, which applies where the differences between the claimed invention and accused device are insubstantial. Hilton Davis Chemical Co. v. Warner-Jenkinson Co., Inc., 62 F.3d 1512, 1517 (Fed. Cir. 1995).

42. Independent claim 1 is to be construed to cover the embodiment of the invention shown in the specification and drawings, which includes a vertical stabilizing rod which extends from the metal pan through an insulating sleeve into the plastic skirt.

43. The phrase "completely free with respect to the pan," as recited in claim 1 of the '312 Patent, means that the outer plastic skirt is thermally insulated from the hot oil frying pan. In other words, claim 1 means there are no thermal bridges between the skirt and the pan. Claim 1 of the '312 Patent covers a deep-fat fryer with a thermally insulated stabilizing element at the bottom of the hot oil pan.

III.

As a threshold matter, this court needs to address a claim construction issue. The district court, as a part of its preliminary injunction order in 1999, construed the limitation "completely free with respect to the pan" in claim 1 to mean "there are no thermal bridges between the skirt and the pan." Preliminary Injunction Opinion, 77 F. Supp. 2d at 405. A thermal bridge is an element that conducts heat. As a matter of context, this court notes that a vertical stabilizing screw secures the skirt of Pentalpha's fryer to the base of the pan. This screw, however, is not a thermal bridge. Thus, the stabilizing screw does not preclude the conclusion that the skirt is "completely free with respect to the pan" under the district court's claim construction. But if "completely free" means instead "no solid material between the pan and the skirt," as Pentalpha contends, then the stabilizing screw absolves Pentalpha's deep fryer of infringement.

This court, of course, reviews claim construction without deference. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1455-56 (Fed. Cir. 1998) (en banc). This court's prior affirmance of the district court's preliminary injunction order does not make the district court's claim construction in its 1999 opinion the law of the case. See Int'l Commc'n Materials, Inc. v. Ricoh Co., 108 F.3d 316, 319 (Fed. Cir. 1997) (claim construction for a preliminary injunction is not definitive "without the more complete record that the district court deemed necessary to its own final decision"). The words of a claim receive the meaning discernible by a person of ordinary skill in the art who has read the entire patent, including the specification, at the time of the invention. Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005) (en banc). The claims themselves, both asserted and unasserted, govern the meaning of claim terms. Id. at 1314.

This court perceives a slight internal inconsistency with the district court's claim construction of "completely free" in the phrase "said skirt (3) being completely free with respect to the pan (1) with the exception of a ring (5)." The claim requires the ring to be "heat-insulating" and "continuously resistant to the temperature of the . . . pan." Thus, the ring is not a thermal bridge. If "completely free" merely meant "no thermal bridges between the skirt and the pan," the claim would not need to
exclude expressly the ring from the completely free limitation.

Despite this minor inconsistency, the district court's construction of "completely free" rings true. Claim 8 of the '312 patent, which depends from claim 1, adds an insulated stabilizing screw between the base of the pan and the base of the skirt. '312 patent col.6 ll.19-24. With this context, a person of ordinary skill in the art would not read the "completely free" limitation of claim 1 to mean "no solid material between the pan and the skirt" because that reading would not allow for the vertical rod of claim 8. See Phillips, 415 F.3d at 1314 ("Differences among claims can . . . be a useful guide in understanding the meaning of particular claim terms.").

Moreover, the only embodiment in the specification includes solid material between the pan and the skirt, namely, the vertical rod, id. at col.3 ll.55-65, as well as a thermostat attached to the base of the pan, id. at col.4 ll.3-7. "[A] construction that would not read on the preferred embodiment would rarely if ever be correct and would require highly persuasive evidentiary support." Chimie v. PPG Indus., Inc., 402 F.3d 1371, 1377 (Fed. Cir. 2005) (internal quotations and alterations omitted). Thus, with the preferred embodiment showing a vertical stabilizing screw, the "completely free" limitation cannot be read so broadly as to exclude this preferred embodiment.

Finally, the specification repeatedly highlights the inventiveness of eliminating thermal bridges to prevent heat transfer to the plastic skirt. For example, the specification notes that in the prior art, "the attachment of the metal pan within the plastic skirt is such that numerous thermal bridges exist between said pan and said skirt." '312 patent col.1 ll.38-40. Those thermal bridges required the skirt to be "formed of [costly] plastic material." Id. at col.1 ll.41-42. Following the theme of preventing heat transfer, the specification discusses a thermostat between the pan and the skirt but emphasizes its placement "remote from the base 21 of the skirt 3 of plastic material in order to prevent any thermal bridge which would be liable to heat this plastic material to an excessive extent." Id. at col.4 ll.3-8. Thus, the patent stresses that eliminating thermal bridges is not the same as eliminating any solid material.

Read in light of the entire specification and with an eye to the preferred embodiment, then, the term "completely free" means "practically or functionally free." Indeed, the specification uses the terms "completely" and "practically" interchangeably. Compare '312 patent col. 1 ll.65-66 ("Said skirt is completely free with respect to the pan . . ."). (emphasis added) with id. at col. 4 ll.28-35 ("[I]n addition to the fact that the skirt 3 is practically free with respect to the pan 1 or in other words that no thermal bridge is created between the pan and the skirt, this latter can be fabricated from inexpensive ordinary-grade plastic material, which does not afford resistance to high temperatures.") (emphasis added). This court often assumes that different terms convey different meanings. Symantec Corp. v. Computer Assocs. Int'l, Inc., 522 F.3d 1279, 1289 (Fed. Cir. 2008). That assumption, however, carries less weight when comparing a term in the claim to a term in the specification, especially where, as here, the specification only describes one embodiment. Cf. id. ("[T]here is nothing in the claims, the specification or the prosecution history that suggests that the preamble language 'as it is being transferred' has any different meaning than [the claim term] 'prior to storage.'").

Pentalpha supplies some evidentiary support for its proposed construction, but that support is not "highly persuasive" or sufficient to overcome the meaning that embraces the preferred embodiment. During prosecution of the '312 patent, the examiner rejected the proposed claims as anticipated by or obvious over U.S. Patent No. 4,672,179 ("Onishi"). Onishi discloses a rice cooker with the side walls of the pan and the side wall of the skirt separated by an adiabatic material, or a material that does not gain or lose heat:

[SEE FIG IN ORIGINAL]

Onishi at Fig. 1, col.2 ll.49-53.

To distinguish Onishi, the applicant stated

in ONISHI . . . , the two walls 1 and 3 are separated by an adiabatic material 2 (whose nature is not specified) whereas in the case of the present invention, the outer plastic skirt 3 is completely free with respect to the pan 1 with the exception of a ring 5. This means that the space comprised between the skirt 3 and the pan 1 is entirely occupied by air and that there is no solid material therebetween.

A-119 (emphasis added). Pentalpha argues that SEB thereby narrowed the claim limitation "completely free" during
prosecution and that the doctrine of prosecution disclaimer should preclude the district court's construction. See N. Am. Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1346 (Fed. Cir. 2005) ("[W]e have previously explained that limitations may be construed to exclude a preferred embodiment if the prosecution history compels such a result.").

Contrary to Pentalpha's contentions, however, this court interprets this prosecution history as consistent with the district court's claim construction. As noted, this also allows this court to account for the only embodiment provided in the '312 patent's specification. Thus, read in context, the applicant's reference to "no solid material" refers only to the volume between the sides of the pan and skirt. As the quote from the prosecution history reveals, the applicant was only addressing the lack of "adiabatic material" in his invention to distinguish the Onishi reference. Indeed the applicant could not have intended his comment to preclude any solid material between the base of the pan and the base of the skirt because both Onishi and his own invention include a vertical stabilizing element.

Thus, this court does not read the prosecution history to alter or disclaim the district court's interpretation of the claim language. Pentalpha's attempt to create a disclaimer simply stretches this prosecution history too far. At most, the prosecution statement requires "completely free" to mean "no solid material between the sides of the pan and the sides of the skirt and no thermal bridges between the base of the skirt and the base of the pan." The additional precision of this construction would also avoid the slight internal inconsistency of excepting the ring from the "completely free" limitation. In any event, this court detects no reversible error in the district court's claim construction.

B. Claim Construction

Old Town argues in the alternative that JMOL of noninfringement was wrongly entered because the district court erred in its construction of the limitation "after coalescence of the third charge is completed." Although Old Town maintains that coalescence is a process that encompasses stages 1 through 5 of the Nugent diagram, Old Town urges that "coalescence can be completed by bringing the process 'to a halt.'" Old Town argues that because a dictionary definition includes "brought to an end" as a definition for "complete," the "completion of coalescence" limitation does not necessitate that coalescence reach its optimal state, but includes other stages at which an operator brings the process to a halt, such as stage 4 of the Nugent diagram, so long as a usable product is produced.

Confluence counters that Old Town admitted to the district court that coalescence is a process that ends at optimal stage 5 of the Nugent diagram, and that Old Town's proffered construction here attempts to define "complete" as "not complete." Confluence argues that the district court correctly held that the limitation requires the plastic laminate to reach the end of coalescence, that is, its optimum state at stage 5.

We begin our claim construction analysis with the words of the claim, which are generally given their ordinary and customary meaning. Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005) (en banc) (citation omitted). Claim 9, the only independent claim at issue in this appeal, recites:

A rotational molding method for making a laminated plastic boat hull in a mold assembly mold cavity, comprising:

rotating the mold assembly containing the first charge of particulate thermoplastic material within the mold cavity within an oven heated to a temperature to coalesce the first charge along the cavity wall to form a first layer;

releasing into the mold cavity a second charge of a particulate thermoplastic material that includes a blowing agent while continuing rotation of the model assembly within the oven;

continuing such mold assembly rotation within the oven until the blowing agent foams and the second charge coalesces along the first layer to form a second layer;

releasing into the mold cavity a third charge of particulate thermoplastic material while continuing rotation of the mold assembly within the oven;
removing the mold assembly from the oven prior to the completion of the coalescence of the third charge;

air cooling the mold assembly after removal of the mold assembly from the oven while continuing mold assembly rotation during continued coalescence of the third charge;

opening the mold assembly after coalescence of the third charge is completed while continuing to air cool the mold assembly so as to expose the mold cavity to cooling air.

'963 patent, col. 8, ll. 18-46 (emphasis added).

In Phillips, we held that

there is no magic formula or catechism for conducting claim construction. Nor is the court barred from considering any particular sources or required to analyze sources in any specific sequence, as long as those sources are not used to contradict claim meaning that is unambiguous in light of the intrinsic evidence. For example, a judge who encounters a claim term while reading a patent might consult a general purpose or specialized dictionary to begin to understand the meaning of the term, before reviewing the remainder of the patent to determine how the patentee has used the term. The sequence of steps used by the judge in consulting various sources is not important; what matters is for the court to attach the appropriate weight to be assigned to those sources in light of the statutes and policies that inform patent law.

Phillips, 415 F.3d at 1324 (internal citations omitted). In construing the claim terms in this case, the district court began its analysis by referring to dictionary definitions presented by the parties. The district court's reference to the dictionary was not an improper attempt to find meaning in the abstract divorced from the context of the intrinsic record but properly was a starting point in its analysis, which was centered around the intrinsic record consistent with Phillips. The consulted dictionary definitions of "coalesce" include: (1) 1: to grow together . . . : unite by growth into one body . . . 2 a: to unite or join together into one body or product; become integrated into a whole. Webster's Third New International Dictionary (1971); (2) to combine into one body or to grow together. The Phillips Petroleum Glossary of Plastic Terms (4th ed. 1965); (3) 1: to grow together or into one body . . . 2: to unite so as to form one mass, community, etc . . . 3: to blend or come together . . . 4: to cause to unite in one body or mass. The Random House Dictionary of the English Language (2d ed. 1987). The consulted dictionary definition of "completion" is: having all necessary parts, elements, or steps; brought to an end; fully carried out. See Claim Construction Order, slip op. at 8-9.

The claim does not state explicitly whether the completion of coalescence means that the plastic particulate must reach its optimum state. However, the written description provides guidance in describing coalescence as being complete when it reaches an optimal state as opposed to when the process is brought to a halt. It states that "[d]uring such early portion of the cooling time, the mold cavity remains closed and coalescing of the third charge continues. Inside layer 16 formed by the coalescing third charge will be intimately joined with insulating layer 14." '963 patent, col. 6, ll. 7-11. Layers 14 and 16 are "tightly interconnected at their respective interfaces by virtue of the rotational molding process." Id., col. 5, ll. 9-11. The written description further describes the invention with reference to and as an improvement over the coalescence process shown in U.S. Patent No. 3,936,595 (filed May 3, 1974) ("the '595 patent"). The '595 patent describes the coalescing charge as initially adhering to the heated mold surface (i.e., forming an uneven layer) and thereafter coalescing into a continuous skin element. The '595 patent uses "coalescence" to include the process that follows the particles adhering to the mold wall, i.e., the process following the formation of a layer. It describes the process as a transformative one in which particles adhering to the mold surface (i.e., forming an uneven layer) progress to a point where the particles have become united to form a skin-like state (i.e., optimum stage 5). This supports the conclusion that one of ordinary skill in the art would understand the ordinary and customary meaning of coalescence to refer to a process that evolves beyond the point at which a layer is first formed, which marks not the completion of coalescence, but the start of the transformation of the particulate material from discrete particles to a consolidated layer. This is also consistent with the dictionary definitions, which indicate that "coalescence" is "completed" when the layer formed by the particulate is united to possess all necessary parts, elements, or steps, i.e., when it reaches its optimal state.

Nothing in the written description suggests that to achieve the stated objects of the invention, namely to shorten the time of the molding cycle and to reduce warping problems, coalescence could or should be stopped at some unspecified point prior to the optimum conclusion of the process. Indeed, the written description teaches that the molding time is not reduced by stopping coalescence prior to its completed state, but rather by removing the mold from the oven prior to the completion of...
coalescence and keeping the mold cavity closed to allow coalescence to continue to completion. '963 patent, col. 3, ll. 34-40. The written description also teaches that warping problems are reduced by providing a "cooling headstart" while coalescence continues to completion. Id., col. 4, ll. 39-45. As the district court found, if coalescence were complete merely because a layer had been formed, the mold assembly would be opened prematurely and that would produce an unusable part. See Claim Construction Order, slip op. at 8-9.

The prosecution history supports the conclusion that completion of coalescence means progress of coalescence to the optimum state as opposed to being brought to a halt at an arbitrary point by operator intervention. Originally, claim 1 recited that cooling was concurrent with coalescence, but did not specify whether coalescence would reach a point of completion. Concerned whether coalescence would continue to completion while the mold is cooling (versus come to a halt by virtue of the mold having been removed from the oven), the examiner rejected the pending claim. In response, the applicant amended claim 1 to require that cooling be concurrent with the completion of coalescence. The examiner also rejected claim 1 because "the times of removal and the temperature conditions are indeterminent [sic] and not understood." In response, the applicant argued that the removal times and temperature conditions "are matters within the ordinary skill in the art." The applicant stated that the understanding of those skilled in the art is illustrated in the '595 patent, which describes coalescence as a process that begins with particulate material, '595 patent, col. 7, ll. 15-21, "and [is] progressively formed into a skin," id., col. 8, ll. 19-21. Similarly, the applicant argued that U.S. Patent No. 3,455,483 (filed Nov. 3, 1964), also cited as prior art, uses "coalesced" to refer to a process that produces a "coherent fused layer of required thickness."

From the foregoing discussion of the written description and prosecution history, we conclude that the district court's constructions of "coalescence" and "complete" are correct and do not cover a process of coalescence that fails to reach optimum stage 5. Old Town is not entitled to a claim construction divorced from the context of the written description and prosecution history. See Nystrom v. Trex, Co., 424 F.3d 1136, 1145 (Fed. Cir. 2005) ("In the absence of something in the written description and/or prosecution history to provide explicit or implicit notice to the public -- i.e., those of ordinary skill in the art -- that the inventor intended a disputed term to cover more than the ordinary and customary meaning revealed by the context of the intrinsic record, it is improper to read the term to encompass a broader definition simply because it may be found in a dictionary, treatise, or other extrinsic source."). Nothing in the context of the intrinsic record explicitly or implicitly indicates that one of ordinary skill in the art would consider coalescence to be complete before the particulates have fully melted, flowed together, become cross-linked, and reached optimum stage 5. Thus, there is no basis to conclude that one of ordinary skill would have understood completion of coalescence, as used in claim 9, to mean anything other than reaching an optimum stage. See Phillips, 415 F.3d at 1316 ("The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." (citation omitted)).

We reject Old Town's argument that the completion of coalescence would include instances where coalescence is brought to an end through intervention to produce a product that is other than at its optimum stage. That definition would sweep within the scope of the claims points during coalescence that are beyond the ordinary meaning of the expression "completion of coalescence" and that find no support in the intrinsic record. For the foregoing reasons, we affirm the district court's construction that "coalescence" is "complete" when the process of forming a uniform, homogeneous body has all necessary parts, elements or steps, or is fully carried out, i.e., the layer formed from the particulate reaches its optimum state.

785

A. "Compliance Structure."

The disputed term "compliance structure" was recited in claims 1, 2, 3, 16, and 17 of the patent in suit. It recited (col. 16:50-17:19):

1. An improvement in a bundle breaker for separating bundles from a log having a generally planar top surface, said log including a plurality of sheets each having a generally planar top surface and each sheet is formed with at least one weakened line, said weakened lines are vertically aligned in said log forming a weakened plane in said log, said bundle breaker including a first conveyor for conveying said log and having an upstream end for receiving said log and a downstream end, and a second conveyor having an upstream end positioned immediately adjacent to said downstream end of said first conveyor providing a gap therebetween defining a bundle breaking plane, said bundle breaker including first
clamp means mounted for vertical reciprocating movement above said first conveyor, and second clamp means mounted above said second conveyor and said second clamp means mounted for conjoint pivotal movement in relation to said bundle breaking plane for progressively breaking a bundle from said log along said weakened plane in said log, said improvement comprising:

a. a first compliance structure mounted on said first clamp means including,

(1) a first fluid pressurized structure having a first flexible member presenting a first engagement area for operative engagement with an upstream portion of said generally planar top surface of said log and on the upstream side of said weakened plane in said log; and

b. a second compliance structure mounted on said second clamp means including,

(1) a second fluid pressurized structure having a second flexible member presenting a second engagement with a downstream portion of said generally planar top surface of said log and on the downstream side of said weakened plane in said log.

Plaintiffs propose that "compliance structure" should mean "a structure that deforms to allow for a more uniform distribution of force." Defendant disagrees. Originally it argued that it should mean "a structure composed of deformable material that yields to changes in pressure and distributes substantially equal force across the structure."

Defendant concedes that the points of disagreement are actually quite small. In its opposition brief, defendant departs from the claim construction it proposed in the prehearing statement. According to defendant, both sides agree that the compliance structure is made of deformable material, and defendant says that it is willing to accept the second portion of plaintiffs' construction -- "allow for a more uniform distribution of force" -- and abandon its requirement that the force exerted by the compliance structure be substantially uniform. Defendant now proposes the construction "a structure composed of deformable material that yields to changes in pressure and allows for a more uniform distribution of force." The word "material" cuts a large figure in defendant's proposal.

Leaving aside the propriety of amending proposed constructions at this late stage, plaintiffs have a number of objections to this new construction. Looking at the claims, claim 1 describes the compliance structure as having a "fluid pressurized structure having a first flexible member presenting a first engagement area for operative engagement" with the log (col. 17:6-10). Claim 3 recited further that "said first and second compliance structures respectively having first and second fluid pressurized structures for engaging a plurality of logs in side by side relation with at least one log having a height greater than at least one other log" (col. 17:30-34). These claims indicate that the compliance structure can deform in shape to put pressure on logs of different heights simultaneously. This is consistent with the invention's stated purpose -- modifying the clamp means to secure logs of different heights at the same time. The specification taught that "the present invention can reliably process a plurality of side by side logs . . . which are of substantially equal height . . . when one or any number of logs have a different height" (col. 8:21-25).

Defendants' proposed construction, as originally expressed, would exclude one of the patentee's preferred embodiments because it would require the entire compliance structure to be made of deformable material. * One preferred embodiment taught a compliance structure that was formed of a flexible member attached to the downward extension of an upper rigid wall (col. 8:51-60). Clearly, this preferred embodiment did not entirely consist of deformable material since the upper wall is rigid. Additionally, nothing in the specification required that the compliance structure be made entirely of deformable material. Defendant so conceded at the hearing.

* "A claim construction that excludes a preferred embodiment . . . is rarely, if ever, correct." Sandisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005) (internal quotations omitted).

Defendant then proposed that the construction should make clear that the compliance structure need not be made entirely of
deformable material, so long as some of the structure was made of deformable material (like rubber). The problem is that although something within the compliance structure has to deform, it is far from clear that anything must be made of deformable material. A structure can be made of entirely of say, steel, and still be flexible, as in a tank tread that deforms to the earth. Even with the eleventh-hour caveat that the compliance structure need not be made entirely of deformable material, adding that requirement would not be helpful to the trier of fact. The functional construction proposed by plaintiffs is sufficient here to capture the need for the compliance structure to deform under pressure.

Accordingly, the term "compliance structure" is held to mean "a structure that deforms to allow a more uniform distribution of force."

F. Compliant

Tessera proposes that "compliant" means "ready, disposed, or likely to yield." Samsung advances that "compliant" means "a material with low elastic modulus that easily yields to an applied force." Joint Claim Construction Statement at B1:13-15. The essential difference between the parties' proposed constructions is that Samsung's construction includes "low modulus" material. Tessera's does not. The specification of the '977 patent describes one embodiment of a compliant material as having a low Young's modulus. '977 patent at 17:40-42. Young's modulus is a measure of elasticity. However, the specification describes another embodiment as a material with holes. Id. at 4:2-5; 4:31-36. Thus, the claim term "compliant" does not require a particular elasticity. The Court construes "compliant" to mean "yielding to an applied force."

Compliant, Compliant Layer, Compliant Material

The term "compliant" appears in the intrinsic record several times to describe materials or layers of materials with differing functions, and the parties have developed sharply divergent constructions as a result of the term's broad use. Tessera suggests that "compliant" should be defined as, "yielding to applied force," but Defendants argue that Tessera's definition is unhelpful because all materials in the universe yield to applied force, and submit that "compliant" should be defined as, "[a] layer/material, such as soft rubber, that can be appreciably compressed in the direction toward the chip sufficient to accommodate tolerances in typical semiconductor components and test equipment."

The Court finds that Tessera's construction would not provide sufficient guidance to a juror struggling to understand "compliant." See Sulzer 358 F.3d at 1366. If all known materials yield to an applied force, the term compliant provides no limitation and is effectively read out of the patent, rendering its presence superfluous and potentially confusing to a jury. See Curtiss-Wright Flow Control Corp v. Velan, Inc., 438 F.3d 1374, slip op. at 9 (Fed Cir. 2006) (rejecting a construction so broad as to render the limitation "nearly meaningless"). In addition to being unhelpful and possibly confusing, Tessera's construction is simply a modified dictionary definition, which after Phillips, is suspect in cases where the ordinary meaning of the claim language is not readily apparent to those not skilled in the art. Phillips, 415 F.3d at 1314; see also Brown v. 3M, 265 F.3d 1349, 1352 (Fed. Cir. 2001). Here, the meaning of the term compliant is not readily apparent because the patentee has used the term idiosyncratically and the Court must look to the claims, specification, and prosecution history to determine what a person skilled in the art would understand compliant to mean. Phillips, 415 F.3d at 1314; Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1116 (Fed.Cir. 2004).

However, arriving at an appropriate and reasonably precise construction of compliant is not easily done because the construction must be exclusive enough to be helpful while successfully accommodating the myriad of uses of the term in the patents in suit. For example, a compliant layer can facilitate movement of the terminals in a parallel or perpendicular direction with regard to the chip (ITC Order at 154; '977 Specification at 7:57-61; '977 Patent Figure 3); a compliant encapsulate allows the flexible lead to facilitate the movement of the terminal relative to the chip as the interposer buckles and wrinkles during thermal cycling (‘977 Specification 11:13-17); compliant material may include elastomers or elastomeric material (Id. at 17:40-42, '977 Claim 3), a compliant layer may incorporate adhesives (Id. at 22:1-2) or be
incorporated by a flexible sheetlike element (‘977 Claims 1-2), and compliant materials can even include intermittent holes (‘977 Claim 4). Tessera's construction does not exclude any of these uses, but its wording is overly broad and unhelpful.

Although much of Defendants' construction is unnecessary and confusing, the concept that compliance requires compressibility is born out by the intrinsic evidence. Despite their differences, both parties' constructions embrace the idea that a compliant material or layer must yield because compliance is closely related to movement, and the Court agrees that this concept is at the heart of compliance. After reviewing the intrinsic evidence, the Court finds that compliance necessarily requires compressibility in a direction perpendicular to the substrate's surface.

Tessera disputes that compliance necessarily implies compressibility, and points out that the 977 specification provides for a "compliant, compressible layer." 977 Prosecution History, 10:43-44. If compliance necessarily implied compressibility, Tessera argues, "compressibility" would not have been included. Further, 627 Claim 4 provides, "[a] chip assembly as claimed in claim 1, wherein said dielectric element includes a compliant layer of a low modulus material, said compliant layer being disposed beneath said terminals," and Claim 7 provides, "[a] chip assembly as claimed in claim 4, wherein said compliant layer is formed from a compressible foam." When a dependent claim contains a limitation, a presumption arises that the limitation was not present in the independent claim. Phillips, 415 F.3d at 1314-1315; Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). However, "that presumption can be overcome if the circumstances suggest a different explanation, or if the evidence favoring a different claim construction is strong." Medrad, 358 F.3d 910. Here, claim 7 adds the additional limitation of specifying the type of compliant material -- namely foam. Thus, Tessera's claim differentiation argument is without merit. Moreover, in this case, the evidence favoring a different construction is sufficiently clear to overcome any presumption and Tessera's reference to a "compliant, compressible layer" in the 977 specification.

Specifically, the Defendants highlight evidence from the prosecution of the parent application to the patents-in-suit and a divisional of that parent application whereby Tessera repeatedly defined that materials and layers are compliant because they deform by compressing in the direction perpendicular to their surfaces. For example, Defendants point to the prosecution history and specification of a divisional of the parent to the patents in suit, U.S. Patent No. 5,346,861 ("the 861 patent"). In Tessera's Response to the PTO distinguishing the Saito reference, it expressly defined compliant as, "compressible in the directions perpendicular to its first and second surfaces." App. No. 865,984 -- 10/26/92 Amendment and Response at 8. See also, App. No. 673,020 -- 1/10/92 Amendment and Response at 10-11 (explaining to the examiner that an ordinary sheet of note pad paper, placed atop the examiner's desk, was flexible, but not compliant because it was not appreciably compressible to forces applied perpendicular to its surface.). The 861 patent specification further provides that, "soft materials and foams provide a highly compliant interposer, i.e., an interposer which is readily compressible in the directions perpendicular to its surfaces and which therefore permits movement of the terminals in these directions." 861 Specification 14:40-46.

Defendants' evidence is express and on point, and the claims and specification require the same conclusion. It is clear that compliance is inextricably intertwined with movement, and that while compliant materials and layers can be flexible, they must be appreciably compressible in order to facilitate movement by some means other than just flexibility. Based on a thorough reading of the patents in conjunction with the express guidance in the prosecution history regarding compressibility, the Court is of the opinion that compliance necessarily implies compressibility, and construes a compliant layer/material to mean, "a layer/material that is appreciably compressible in a direction perpendicular to its surface."
Nothing in claims 1, 6 or 7 dictates a particular shape; instead, these claims demonstrate that the shape is defined by the function. To the extent other shapes would satisfy the functional specification (i.e., to the extent shapes other than those shown in the figures are "complimentary cross sectional shapes" that close "by pressing the bottom of the elements together first and then rolling the elements to a closed position toward the top thereof") those shapes fall within the scope of the '143 Patent. This conclusion is supported by claim 8, which is dependent on claim 7. Claim 8, unlike the other claims, does specify a particular shape for at least one of the elements: it discloses "[a] plastic reclosable fastener according to claim 7 wherein said groove element comprises a straight projection and a hook-shaped projection . . . ." U.S. Patent No. 5,007,143 at col. 8, lines 20-22 (emphasis added). To read the shape requirement into claim 7, the independent claim, would render claim 8 redundant in part, and we are unwilling to adopt such a construction. See Robotic Vision Systems, Inc. v. View Engineering Inc., 189 F.3d 1370, 1376 (Fed. Cir. 1999). See also Karlin Technology, Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999) (under doctrine of claim differentiation, limitations stated in dependent claims are not to be read into independent claim from which they depend) (citing Transmatic, Inc. v. Gulton Industries, Inc., 53 F.3d 1270, 1277 (Fed. Cir. 1995)). Accordingly, the Court finds that claims 1, 6 and 7 cover elements of any shape as long as they satisfy the function articulated in those claims.

789

1. "[C]omponent: 1 "A single- or multiple-part structure having a cross-section in the shape of a triangle or wedge." This construction is consistent with the claims as well as the specification. (col. 2:21-23; col. 3:33; col. 4:41) The court finds no support for defendant's proposed construction requiring the component to be "solid." Defendant also seeks to limit this construction according to one embodiment of the invention which requires the component to have a hardness no greater than the hardness of the wiper strip. (col. 3:27-28) However, such an interpretation would render superfluous the hardness limitation of dependent claim 6, which requires that the component have "a hardness which is no greater than a hardness of said [] wiper strip." Moreover, in its traversal of Ludwig, the patentee explained the hardness relationship of these two items, noting that the wiper strip and the component "can have different hardnesses, which on the other hand they must not necessarily have as well." (D.I. 162 at JA00190-91)

B. "Composite"

Defendant asks the Court to construe "composite" primarily for purposes of contrasting the term "integral." However, "composite" does not require construction. In Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 2004), the court noted: "If . . . the body of the claim fully and intrinsically sets forth the complete invention, including all of its limitations, and the preamble offers no distinct definition of any of the claimed invention's limitations, but rather merely states, for example, the purpose or intended use of the invention, then the preamble is of no significance to claim construction because it cannot be said to constitute or explain a claim limitation." Such is the case here. The preamble to claim 1, where "composite" is found, adds nothing to the description of the invention claimed. Therefore, "composite" need not be construed.

--- Footnotes ---

4 The noun "composite" is defined by The Oxford Dictionary of English as "made up of several parts or elements" or, with respect to constructional material, "made up of recognizable constituents." This does not offer contrast to the construction of "integral." In fact, it supports the construction given by the Court. The claimed invention is a composite consisting of an
insulation roof board member (which itself has components: a main portion, and a top portion consisting of blocks) and a hard protective top layer.

A Group I comprises four patents, each of which includes claims to a polymer and wood fiber composition. The patents are: U.S. Patent Nos. 5,827,607 ("the '607 patent"); 5,932,334 ("the '334 patent"); 6,015,611 ("the '611 patent"); and 6,015,612 ("the '612 patent"). The four patents each contain claims to compositions in the form of a pellet, claims to compositions in the form of a linear extrudate, and claims to a "composite composition" without an explicit form limitation. Andersen concedes that the Fiberon products do not infringe any of the claims containing explicit pellet or linear extrudate limitations; thus, only the composite composition claims are at issue in this case.

A representative example of the asserted claims is claim 19 of the '334 patent, which provides as follows:

19. A thermoplastic composite composition, capable of extrusion into a dimensionally stable structural member, which consists essentially of a thermoplastic composition which comprises:

   (a) a continuous phase comprising a polyvinyl chloride homopolymer;

   (b) an effective amount of wood fiber having a minimum width of 0.1 mm and an aspect ratio of greater than about 1.8 to provide structural properties to the composite;

   (c) about 0.01 to 25 wt % of an intentionally recycled impurity comprising thermoplastic polymer, an adhesive, a paint, a thermoplastic resin or mixtures thereof; and

   (d) less than about 10 wt % water;

   wherein the polyvinyl chloride homopolymer and wood fiber are mixed at elevated temperature and pressure such that an intimate admixture is formed and the wood fiber is dispersed throughout the continuous thermoplastic polyvinyl chloride homopolymer phase and the composite has a Young's modulus of at least about 600,000 psi.

The relevant claims of the '607 and '611 patents similarly claim a "composite composition, capable of extrusion into a dimensionally stable structural member," while the '612 patent claims a "thermoplastic polymer composite composition capable of formation into a structural profile or member." The parties agree that the term "composite composition" has the same meaning in all four patents.

After considering the claim language, the specification, and the prosecution history, the district court determined that "composite composition" means "a solid pellet or a solid linear extrudate, which may subsequently be remelted and extruded to make a structural member." We agree with that construction. While nothing on the face of the asserted claims states that the term "composite composition" is limited to a mixture that is in pellet or linear extrudate form, the specifications make clear that the term, as used in the Group I patents, must be construed to be limited in that manner.

The asserted claims all recite that the "composite" or "composite composition" must have certain properties and be capable of extrusion into a structural profile or member. The common specification of the four Group I patents, which differs only slightly from patent to patent, describes how those properties are achieved. The specification explains that the claimed properties are attributable to the reduction of water content in the polyvinyl chloride and wood fiber composition and the "intimate mixing" of the components. The required "intimate mixture" is achieved, according to the specification, "by extrusion of the polyvinyl chloride and wood fiber composite through an extrusion die resulting in a linear extrudate that
can be cut into a pellet shape.” '607 patent, col. 4, ll. 45-47; ’334 patent, col. 5, ll. 6-8; ’611 patent, col. 4, ll. 38-40; ’612 patent, col. 4, ll. 39-41. As the specification explains:

During the pelletizing process for the composite pellet, the polyvinyl chloride and wood fiber are intimately contacted at high temperatures and pressures to insure that the wood fiber and polymeric material are wetted, mixed, and extruded in a form such that the polymer material, on a microscopic basis, coats and flows into the pores, cavity, etc., of the fibers. The fibers are preferably substantially oriented by the extrusion process in the extrusion direction.

'607 patent, col. 3, ll. 54-61; ’334 patent, col. 4, ll. 15-22; ’611 patent, col. 3, ll. 47-54; ’612 patent, col. 3, ll. 49-56. The composition, which is in pellet or linear extrudate form, is then remelted and re-extruded to produce the desired structural members. The specification explains that in the manufacturing process,

[T]he successful manufacture of structural members for windows and doors requires the preliminary manufacture of the polyvinyl chloride wood fiber composite in the form of a pellet wherein the materials are intimately mixed and contacted in forming the pellet prior to the extrusion of the members from the pellet material. We have found that the intimate mixing of the polyvinyl chloride, wood fiber, and waste in the manufacture of the pellet process with associated control of moisture content produces a pelletized product that is uniquely adapted to the extrusion manufacture of PVC/wood fiber components and achieves the manufacture of a useful wood replacement product.

’607 patent, col. 3, ll. 1-13; ’334 patent, col. 3, ll. 30-42; ’611 patent, col. 2, line 62, through col. 3, line 7; ’612 patent, col. 2, line 65, through col. 3, line 10. Although the specification generally refers to the process of pelletization and the use of pellets in the later extrusion step, it makes clear that the formation of pellets is convenient but not necessary, and that the linear extrudate from which the pellets are normally cut can be used without pelletization in the later extrusion step. See ’334 patent, col. 1, ll. 40-43 (“Alternatively, the extruded thermoplastic mass, in the form of a [sic] elongated linear extrudate without a pelletizing step, can be immediately directed after formation into an extruder or injection molding apparatus.”); ’612 patent, abstract (same). 1

1 Andersen argues that the statement that a pelletizing step is not required proves that the patent is directed to a composite composition unlimited to any particular form. A fair reading of that passage, however, indicates that it merely refers to the possibility of re-extruding the linear extrudate without first cutting it into pellets. Moreover, the quoted material supports the district court's claim construction by emphasizing that the thermoplastic mass must be extruded in pellet or linear extrudate form, thus implicitly excluding all other forms. The same answer applies to Andersen's argument based on the reference in the specification to "the composition material or pellet," '607 patent, col. 6, line 27; ’612 patent, col. 6, line 33, and to the pellet form as "preferred," '607 patent, col. 2, line 55. In context, it is clear those statements simply reflect that the extruded composite composition may be in either pellet or linear extrudate form.

Contrary to Andersen's contention, the district court's construction of the Group I claims as limited to compositions in pellet or linear extrudate form does not impermissibly limit the invention to particular embodiments. The district court did not construe the Group I claims to be limited to "composite compositions" in the pellet and linear extrudate forms on the ground that those are the only disclosed embodiments. Rather, the court construed the claims in that way because the patents use the term "composite composition" restrictively and state that the step of extruding the composite in pellet or linear extrudate form is "require[d]" in order for the composite composition to be capable of extrusion into a structural member having the claimed physical properties.

The Group I common specification repeatedly states that the steps of linear extrusion or pelletization are not merely embodiments, but are essential features of the claimed composite composition. For example, the specification of the ’334 patent states that "[t]he invention relates to a composition comprising a polymer and wood fiber composite that can be used in the form of a linear extrudate or thermoplastic pellet to manufacture structural members.” ’334 patent, col. 1, ll. 10-13; see also ’607 patent, abstract ("The composite can be used in the form of a linear extrudate or a thermoplastic pellet to manufacture structural members."); ’612 patent, abstract (same); ’611 patent, abstract ("A composition in the form of pellets
comprising a thermoplastic and wood fiber composite material suitable for forming structural members as a replacement for wood in the manufacture of doors and windows.”). The invention, according to the specifications, "relates to the use of polyvinyl chloride and wood fiber composite materials with a controlled water content in the form of a pelletized material wherein the wood fiber is intimately contacted and wetted by the organic materials." ‘607 patent, col. 3, ll. 11-15; ‘612 patent, col. 3, ll. 14-18.

The portions of the specification that describe how the physical properties of the claimed composite composition are obtained make clear that the formation of linear extrudates or pellets is not merely a preferred embodiment, but is a critical element in the process that produces those properties. See ‘607 patent, col. 3, ll. 1-7 ("[T]he successful manufacture of structural members for windows and doors requires the preliminary manufacture of the polyvinyl chloride wood fiber composite in the form of a pellet wherein the materials are intimately mixed and contacted in forming the pellet prior to the extrusion of the members from the pellet material.") (emphasis added); ‘334 patent, col. 3, ll. 30-36 (same); ‘611 patent, col. 2, line 62, through col. 3, line 1 (same); ‘612 patent, col. 2, line 65, through col. 3, line 4 (same). Those statements are not descriptions of particular embodiments, but are characterizations directed to the invention as a whole. As such, they make clear that the term "composite composition," as used in the Group I patents, does not encompass broader subject matter. See Phillips v. AWH Corp., 415 F.3d 1303, 1316 (Fed. Cir. 2005) (en banc) ("[T]he specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess."); Microsoft Corp. v. Multi-Tech. Sys., Inc., 357 F.3d 1340, 1348 (Fed. Cir. 2004) (statements in common specification serve to limit claim language because they "are not limited to describing a preferred embodiment, but more broadly describe the overall inventions of all three patents"); Alloc, Inc. v. Int'l Trade Comm'n, 342 F.3d 1361, 1370 (Fed. Cir. 2003) ("[T]his court looks to whether the specification refers to a limitation only as a part of less than all possible embodiments or whether the specification read as a whole suggests that the very character of the invention requires the limitation be a part of every embodiment.").

Andersen argues that the Group I specification cannot be read to require that the composite composition be extruded in linear extrudate or pellet form, because on several occasions the specification refers to the invention as a "composite material," without adding any reference to the linear extrudate or pellet form. See, e.g., ‘612 patent, col. 1, ll. 14-29. That argument is unpersuasive, however, as the term "composite material" is just a synonym for "composite composition," and the use of that alternative term in the "Field of the Invention" portion of the specification is not inconsistent with the restrictive definition provided in the body of the specification where the invention is described in more detail.

2

The district court's claim construction finds additional support in the prosecution history. The Group I patents all stem from continuations based on U.S. Patent Application Serial No. 07/938,364 ("the '364 application"). The prosecution history of that parent application is highly instructive in light of the similarity between the claims of the application and those of the patents in suit. See Masco Corp. v. United States, 303 F.3d 1316, 1324 (Fed. Cir. 2004) (prosecution history of a parent application "may be considered in construing claim terms"); Biovail Corp. v. Andrx Pharmns., Inc., 239 F.3d 1297, 1301 (Fed. Cir. 2001) (claim language "must be read consistently with the totality of the patent's applicable prosecution history," including parent applications); see also Microsoft Corp., 357 F.3d at 1349; Elkay Mfg. Co. v. Ebo Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999) ("When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same limitation.").

The '364 application contained all three types of claims (pellet form, linear extrudate form, and "composite composition" form), and the language of the application claims is nearly identical to the language of the claims that eventually issued in the Group I patents. Responding to the examiner's rejection of all three types of claims, the applicants repeatedly distinguished the invention from the prior art by referring to the pellet form or the pelleting process as an essential part of the invention. For example, the applicants distinguished two prior art references by relying heavily on the role of pelleting in the claimed invention:

The invention resides in part in a thermoplastic composite pellet. The invention also resides in a vinyl chloride polymer and wood fiber composite material, with a controlled water content, in the form of a thermoplastic pellet, wherein the wood fiber is intimately contacted and wetted by the thermoplastic polymer. The moisture control combined with the intimate contact and wetting between the components in the pelleting process and other pellet characteristics ensures high quality physical properties in the extruded composite material after manufacture. . . . Applicant's invention comprises a pellet . . . .
The applicants further distinguished one of the two cited references by noting that it "does not teach the pelletizing of the composite material," while the claimed invention "first pelletizes the thermoplastic composite material, and then, manufacturer[sic] a structural member from the pelleted materials by melting and extruding the composite. Thus, [the reference] does not teach or suggest the manufacture or composition of the thermoplastic pellet materials of the Applicant's invention."

The applicants subsequently filed a continuation application, U.S. Patent Application Serial No. 08/224,396 ("the '396 application"), which is also common to all four Group I patents. Again, responding to a rejection of all three types of claims, the applicants distinguished their invention by stating (emphasis added):

[N]one of [the cited] prior art teaches the manufacture of a pellet intermediate between mixing the polyvinyl chloride and wood fiber and the final manufacture of a finished composite member. The manufacture of the pellet intermediate in this process, provides the opportunity to obtain an intimate mixing of a thermoplastic and fiber. The manufacture of the pellet is important in obtaining the final structural properties of the composite member... Applicants assert that the combination of the selection of polyvinyl chloride, the critical selection of particle size and aspect ratio, the water content and preparation of the pellet by ensuring that the polymer wets and penetrates the fiber and the fiber pores, results in a structural material with mechanical properties significantly superior to the prior art materials.

Throughout the prosecution of the Group I patents, the applicants continued to distinguish the claimed inventions from prior art references in the same manner. Thus, in the prosecutions leading to the patents at issue in this case, the applicants variously characterized their invention (including claims that referred only to the composition), by stating that the invention consists of "a resin and fiber composite thermoplastic pellet," that the invention "resides in a material that is a thermoplastic pellet," that the "recited invention is a composite thermoplastic pellet," and that the "manufacture of the pellet is important in obtaining the final structural properties of the composite member."

Those statements serve to limit the scope of the applicants' claimed subject matter. The statements about pelletizing were global--they applied to all the claims of the patent--and thus they served to limit all the claims.

3

Andersen challenges the district court's form-limited claim construction of the Group I claims on several additional grounds. First, Andersen argues that the court's construction violates the doctrine of claim differentiation. That doctrine is based on "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999). "To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987).

Andersen argues that because the Group I patents claim pellets, linear extrudates, and composites (or composite compositions), the third category must be assumed to be different from the first two, and thus the composite composition claims must not be limited to pellets and linear extrudates. That inference would be a plausible one in the absence of evidence to the contrary, but here there is powerful evidence to the contrary, as we have discussed. In such cases, we have held that "the written description and prosecution history over come any presumption arising from the doctrine of claim differentiation." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000); see also Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1480 (Fed. Cir. 1998) ("[T]he doctrine of claim differentiation can not broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence... [C]laims that are written in different words may ultimately cover substantially the same subject matter.").

A further reason for not applying the doctrine of claim differentiation in this case is that the Group I claims are not otherwise identical but for the references to pellets, linear extrudates, and composite compositions, and thus the district court's construction does not make the composite composition claims redundant. Instead, there are numerous other differences varying the scope of the claimed subject matter. For example, in the '611, '607, and '334 patents, the pellet and linear extrude claims all require that the composition consist of "less than about 8 wt % water," while the composite
composition claims require "less than about 10 wt % water." The composition claims also include an additional limitation with regard to the amount of the impurities in the mixture, a limitation that is not found in the pellet and linear extrudate claims. Moreover, although Andersen argues that the district court's claim construction would render the '612 patent superfluous, that is not so, as the composite composition claims of each of the other Group I patents contain limitations not found in the '612 patent claims.

Even though the "composite composition" claims, as construed by the district court, cover substantially the same subject matter that is covered by the "pellet" and "linear extrudate" claims, overlapping patent claims are not unusual, and the overlap does not require us to construe the "composite composition" claims to cover subject matter that differs from the subject matter covered by the other two sets of claims. Under these circumstances, the doctrine of claim differentiation does not require rejection of the district court's construction of the claims.

Andersen also argues that the district court's claim construction is contrary to a 1996 restriction requirement issued with respect to the application that led to the '607 patent, in which the patent examiner found the "pellet and composite" claims to be patentably distinct from the "composition" claims. That distinction, which was based on the examiner's perception that the two groups of claims "are related as mutually exclusive species in intermediate--final product relationship," is not one that is pressed by Andersen, and it is unclear how the difference between "composite" and "composition," even if one could be discerned, furthers Andersen's argument. The argument based on the restriction requirement therefore does not support Andersen's position.

In sum, a review of the text and the prosecution history of the Group I patents leads us to agree with the district court that the "composite compositions" of those patents must be in the form of either pellets or the linear extrudate from which pellets may be cut.

III. "Composite Structural Member"

The Group II patents claim a "polymer wood thermoplastic composite structural member, suitable for use as a replacement for a wood structural member." ( '553, c. 17, 11: 1-2 & '027, c. 15, 11: 57-58 (using slightly different language).) The key disputed term in the Group II patents is "composite structural member." (Id.) The parties disagree about whether the composite structural member is limited by how it is formed. Fiber Composites proposes that this term is "limited to such parts, which are extruded or otherwise made, only by first forming the composite composition into a solid pellet or a solid linear extrudate from which the pellet can be made, and then using the solid pellet or linear extrudate to form the 'member.'" (Fiber Proposed Claim Construction Order at 2.) Andersen proposes that the term is defined as "an article having load bearing capability ('structural member'), made of polymer and wood fiber ('composite') and that is capable of being melted, shaped, remelted, and reshaped." (Andersen's Proposed Claim Construction and Br. in Supp. at 11.) Andersen also proposes that the term is directed to a "composite structural member obtained through an extrusion process." (Andersen's Proposed Claim Construction Order at 3.)

The Court first looks to the claim language itself. 8 Itron, 169 F. Supp. 2d at 1081. Claim 1 of the '553 patent describes a structural member "suitable for use as a replacement for a wood structural member." ( '553, c. 17, 11: 1-2.) There is no reference to a pellet or linear extrudate in the claim language. Rather, the claim language describes the product itself, which is a composite structural member that is a replacement for a wood structural member. The claim-at-issue is not claiming a product made by a specific process; it is claiming the product itself--the structural member. Giving the words their ordinary and accustomed meaning, the words of the claim define the structural member as a product that is a replacement for a wood structural member.

8 When the claims-at-issue use the same or similar language, reference will be made to only one of the Group II patents.
This definition, however, must be viewed in light of the specification and the prosecution history. See KCJ Corp., 223 F.3d at 1355. For the purposes of this construction issue, the specifications of the '553 and '027 patents are identical. Specifically, the specification defines the term "structural member" to mean "a linear member with a regular cross-section or complex cross-section." (‘553, c. 3, 11: 21-23 (emphasis added).) The specification teaches that it relates to "an improved structural member that can be used as a direct replacement for wood and metal components" (id., c. 1, 11: 13-15 (emphasis added)) and that the "structural members of the invention can also be extruded in complex shapes adapted to the assembly of windows and doors used in both residential and commercial structures." (Id., Abstract (emphasis added).) The superior qualities of the structural member include "strength, workability, faster retention, resistance to rot and insect attack, and thermal properties." (Id.) Thus, the specification teaches that the invention covers a structural member with specific structural properties that is used as a wood replacement. It does not teach that the structural member must be made by a certain process.

Andersen contends that with this intrinsic evidence as the guide, the preamble language of the claim-at-issue is properly construed as follows: "an article having load bearing capability . . ." (Andersen's Markman Br. at 12-13.) Fiber Composites disputes this and argues that the specifications of the Group II patents limit the claims to pellets or pelletizing. (Fiber Composites' Markman Br. at 24.) Fiber Composites, however, misapplies what the specification teaches. The specification details the preferred embodiment of the materials used to make the structural member. (See e.g., '553, c. 5, 11: 64-66.) It does not, however, limit the claimed invention to that preferred embodiment nor does it claim anything other than a "structural member" with superior strength, resistance to rot and insect attack, and other structural features.

In addition, Fiber Composites argues that the prosecution history of the Group II patents shows that Andersen "told the Patent office that the 'composite structural member' in the claims did not cover articles that were directly extruded from thermoplastic polymers and wood composite." (Fiber Composites' Reply Br. at 7, citing Ex. 32; pp. 7-8 (emphasis in original).) The Group II patents are continuations from the same parent application, the '365 Application, and like claims of the parent application of the Group I patent, the claims of the '365 Application were rejected as anticipated by several prior art references, including the Miani patent. Andersen states that Fiber Composites "misconstrues" the prosecution history because Andersen merely distinguished the prior art cited by the Patent Examiner based upon "structural properties [of the invention] and not any method of processing." (Andersen's Post Markman Br. at 6.) Thus, Andersen argues that the prosecution history reveals that it received its patent not because it disclaimed or claimed any method or process but rather because its invention had superior structural properties. (Id. at 5.) The Court agrees with Andersen. The prosecution history supports the construction that the subject of the Group II patents is the structural member itself, with its superior structural properties, without a limitation for how the member is formed.

Therefore, the Court finds that the term "composite structural member," when viewed in light of the claim language, the specification, and the prosecution history, means a polymer and wood article having load bearing capability, which can be obtained through a direct extrusion process or made from a composite material without a particular form.

C. Compressed Position

ICU argues that the term "compressed position" should be interpreted to mean "location in which the flexible element is depressed into less space in the cavity." RJCCPS at 4. Braun contends that the proper definition of the phrase is "the position of the flexible element when it is under axial compression and fully opens the valve." Id. The parties' central point of contention on this issue is whether "compressed position" requires full or complete compression, or put differently, whether partial compression is within the scope of the term. The parties also dispute whether the compression referred to is necessarily axial compression, or includes other directions of compression as well.

1. Fully Open

Reading "compressed position" in the context of the claim and specification, 4 it becomes clear that the term refers to a configuration of the flexible element in which the valve is in an open state and fluid is allowed to move through it. Col. 16:5-8 (describing "a compressed position in which fluid flow is permitted through said valve"). Thus the parties' disagreement can be described as whether the flexible element can be in a "compressed position" even though the flexible
element may still be partially obstructing the fluid from flowing through the valve.

--- Footnotes ---

4 The parties agree that the terms "compressed position" and "uncompressed position" in the claim are equivalent to the terms "compressed state" and "decompressed state," respectively, in the specification. Therefore, the use of the latter terms in the specification is relevant to the construction of the former terms.

--- End Footnotes ---

Braun's argument focuses on Claim 1's use of the word "between" in its statement that the flexible element is "movable between an uncompressed position... and a compressed position..." Col. 16:5-8. According to Braun, this requires that there is only one single compressed position in which the flexible element is fully compressed. However, there is nothing inherent in the word "between" that implies that the valve be fully opened. The flexible element could just as easily be understood to move "between" a closed position and a partially open position. Although Braun insists that ICU's understanding is an attempt to rewrite the claim language, it is Braun's interpretation that seeks an impermissible revision. Under Braun's construction the claim would be rewritten from "a compressed position in which fluid is permitted through said valve" to "a fully compressed position in which maximum fluid flow is permitted through said valve." This Court is not permitted to do so, and thus Braun's proposed limitation is rejected.

2. Axial Compression

Braun also argues that the compression referred to by the terms "compressed position" and "uncompressed position" may only be axial compression. This time Braun is correct. ICU contends that the claim contains no such limitation and gives as examples statements in the specification indicating that the flexible element exerts radial compression on the inner wall of the valve in both the compressed and uncompressed positions:

The seal in the decompressed state... bears against the wall structure near the opening to seal the opening... A fluid tight seal is maintained between the seal section and the wall structure as the seal is moved into the compressed state. The seal section bears against the wall structure...

Col. 3:38-48. However ICU must rip this excerpt from its context in order to retrieve the desired meaning. Immediately before this portion, the specification states "the third feature is that the resilient seal is adapted to be moved into a compressed state upon insertion of the tip of the medial [sic] implement into the opening and returns to a decompressed state upon removal of the tip." Col. 3:35-38. It is clear from this statement that the source of the compression is the insertion of the medical implement into the opening of the valve. The direction of that compression is axial, that is, it moves along the axis of the valve. See Random House Unabridged Dictionary 145 (2d ed. 1987) (defining axial as "situated in or on an axis"). The compression referred to in the excerpt cited by ICU is the force applied by flexible element against the inner wall of the valve while it under axial compression from the medical implement. If, on the other hand, ICU is claiming that the statement that the flexible element "bears against the wall structure" in the "decompressed state" demonstrates non-axial compression, then ICU refutes its own argument. As discussed more thoroughly below, it cannot be the case that the flexible element is experiencing any compression from the medical implement in the "uncompressed position."

In using the terms "compressed," "uncompressed" and "decompressed" the patent repeatedly, consistently and exclusively refers to axial compression. For example, the claim discusses the wall of the flexible element as "flexing to accommodate axial compression." Col. 16:11-12. The specification states that "[a] two-way valve eliminating dead space is used which includes a seal which, upon being compressed by the medical implement, is pierced to open the valve and reseals upon being decompressed... ." Col. 1:22-26 (emphasis added). ICU has failed to offer any statement in intrinsic evidence that contradicts this meaning. As such, this Court finds that the terms "compressed position" and "uncompressed position" refer only to axial compression.

Accordingly, the term "compressed position" is construed as the position of the flexible element when it is under axial compression from a medical implement 5 and opens the valve.

--- Footnotes ---
5 The addition of "from a medical implement" is described under the Court's construction of "uncompressed position."

The terms "compressed state" and "decompressed state" appear in the asserted claims in the '866, '862, and '592 Patents. ICU contends that a compressed state is created upon insertion of the medical implement's delivery end into the opening of the valve's internal cavity. (D.I. 118, at 12.) Conversely, it contends that a decompressed state is created upon the removal of the medical implement from the valve's internal cavity. (D.I. 118, at 13.) Essentially, the crux of ICU's contention is that the states of compression and decompression referred to in the patents-in-suit are "about what happens when you push a medical implement in, and take it out," rather than abstract notions about the existence or absence of some compression. (D.I. 232, at 7:7-12.) RyMed contends that compressed and decompressed states refer to the condition of the seal when under axial compression and when under no axial compression, respectively. (D.I. 116, at 9.) RyMed opposes ICU's contention that compressed and decompressed states are to be understood in relation to the insertion or removal of a medical implement. (D.I. 116, at 9-10.) Specifically, RyMed argues that constructing the claim terms according to ICU's proposal improperly rewrites the claim language to allow for relative or partial states of compression. (D.I. 165, at 5-6.)

The Court concludes that ICU's proposed construction is more consistent with both the literal claim language and the Common Specification. The patent repeatedly and clearly explains that the resilient seal is compressed upon insertion of the medical implement, and decompressed upon its removal. See '866 Patent, col. 15: 41-46 ("a resilient seal which is adapted to be moved distally in the cavity into a compressed state upon insertion of the delivery end of the medical implement . . ., said seal . . . returning to a decompressed state upon removal of said delivery end"); '862 Patent, col. 15:37-43 ("a resilient seal . . . adapted to be moved distally in the cavity into a compressed state upon insertion of the delivery end of the medical implement . . ., said seal . . . returning to a decompressed state upon removal of said delivery end"); '592 Patent, col. 15: 49-53 ("a resilient seal which is adapted to be moved into a compressed state upon insertion of the of the [sic] medical implement into said opening to open the valve and returns to a decompressed state upon removal of said tip to close said valve"). RyMed's proposed construction ignores the integral role of the medical implement in what is claimed about the seal's condition.

Additionally, the Common Specification provides clear support for this interpretation. See Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1379-80 (Fed. Cir. 2001)(stating that the specification should be read, "if possible, in a manner that renders the patent internally consistent"). The claim term "compressed state" is consistently described by reference to the behavior of the seal when a medical implement is inserted into the cavity. See '866 Patent, col. 3, 37-39 ("In the compressed state, the seal section is pushed by the delivery end of the medical implement away from the opening and into the cavity."); id. at col. 1, 17-19 (the valve includes a "seal which, upon being compressed by the medical implement, is pierced to open the valve and reseals upon being decompressed").
RyMed's argument that ICU’s construction allows for relative states of compression is not persuasive. In Alaris, Judge Pfaelzer stated that "[b]oth the concept of the medical implement as the source of the compression and the concept of the valve being opened as a result of the compression are already included in the applicable claim language and thus do not need to be included in the construction of compression." Alaris, 2006 U.S. Dist. LEXIS 96077, at *16. However, concerns over relative or partial compression being read into the claim language are precisely why "compressed state" and "decompressed state" must be construed with reference to the source of the compression, as well as to the condition of the seal. See Braun, 344 F. Supp. 2d, at 671-72 (noting that the claim term "uncompressed" in the '673 Patent clearly referred to a lack of compression, but that the relevant question was what source of compression was being referenced). Thus, in light of the claim language and Common Specification, the Court concludes a "compressed state" means the state of the seal when a medical implement causes axial compression; a "decompressed state" means the state of the seal when a medical implement is not causing axial compression. Whether any compression exists in the valve in the abstract, not in relation to the medical implement, is outside the scope of the claim.

795

a. "Two mold parts"

Turn-Key argues that this limitation must be construed to require that the two mold parts are a first mold part and a second mold part including all of their respective components. It asserts that these components can include mold plates, cavity inserts, alignment components, screws, heating and cooling assemblies, ejector assemblies, pins, blades, guide assemblies, etc. Pl's Opening Brief at 5. Conversely, Defendants argue that the two mold parts referred to are "not just any parts, but the two mating halves of an injection mold" and that though the mold "may have other components . . . these should not be confused with the two mold halves to which this claim term is intended to refer." Crest's Responsive Brief at 11. The parties thus appear to agree that the phrase "mold comprises two parts" signifies the mating halves of a mold and that the mold parts themselves may contain individual components. Crest's Responsive Brief at 11; Pl's Opening Brief at 5. The dispute is whether the phrase refers to the mold halves as wholes or whether it includes specific auxiliary parts.

The Court agrees with Defendants that though the mold halves can possess component parts, the "mold comprises two parts" language should be interpreted as "referring to the two mating halves of the mold as wholes, and not to their individual components." Crest's Responsive Brief at 11. This interpretation comports with the ordinary and customary meaning of the phrase which solely refers to "two parts" and the specification does not show that Sorenson, as patentee, intended to define the phrase in his own terms rather than by the terms' common, customary meaning. See Vitronics, 90 F.3d at 1584-85.

796

"[C]omprising" means including but not limited to.

797

B. "comprising"

AB/Sciex and Micromass dispute the construction of terms in the 736 patent's two independent claims, 1 and 14, for purposes of this Markman proceeding. Claims 1 and 14 both use the term "comprising" in their prefatory statements, before the claims go on to enumerate further claim limitations. AB/Sciex suggests that the court should define "comprising" as "including, but not limited to." Micromass does not disagree with AB/Sciex's proposed construction and admits that the term "comprising" permits the inclusion of additional elements beyond those recited, but argues that the court's construction of the term should not be used by AB/Sciex to evade the primary requirement of the term "comprising" -- that the invention must include all enumerated claim limitations.
It is well-established that "comprising" is a term of art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim.” Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997); see also Phillips Petroleum Co. v. Huntsman Polymers Corp., 157 F.3d 866, 874 (Fed. Cir. 1998) (“The use of "comprising" and "which comprises" in the composition and process claims generally would mean that the claims require the presence of [the listed element], but that additional elements or process steps may be present."), Regents of Univ. of California v. Eli Lilly & Co., 119 F.3d 1559, 1572 (Fed. Cir. 1997) (“The word 'comprising,' as UC argues and as is well-established, permits inclusion of other moieties.”); Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271 (Fed. Cir. 1986) (“In every case, the court has held that the open term 'comprising' does not exclude additional unrecited elements, or steps . . .”). Thus, "comprising" can neither narrow nor broaden the meaning of the claim limitations subsequently recited. It simply requires the presence of the enumerated claim limitations enumerated without prohibiting other unrecited elements, structures, or steps from being present in the invention. Because the court finds that AB/Sciex's construction of "including, but not limited to" is consistent with this well-understood construction of the term, the court hereby adopts that construction.

Contrary to the findings rendered by the district court, JSC argues here that claims 11, 12, 17, and 21 of the 280 patent do indeed disclose a device limited to three layers, with the outer layers in direct physical contact with an interior rigid layer. Independent claims 11 and 21 of the 280 patent state as follows:

11. A multiple-ply material comprising:
   a first layer of anti-static material;
   a second layer of anti-static material;
   a third layer of relatively rigid, electrically conducive material sandwiched between and contacting said first and second layers; and

   wherein said first and second layers have a surface resistivity of between 10<9> and 10<14> ohms per square inch and said third layer has a surface resistivity of less than 10<5> ohms per square inch.

21. A multiply-ply paperboard comprising:
   a first layer of anti-static material;
   a second layer of anti-static material;
   a third layer of high-carbon content paperboard sandwiched between and contacting said first and second layers; and

   wherein said first and second layers have a surface resistivity of between 10<9> and 10<14> ohms per square inch and said third layer of high-carbon content paperboard has a surface resistivity of less than 10<5> ohms per square inch.

(J.A. 508) (emphasis added). As more fully discussed below, neither this language nor the language of any of the other claims at issue limits the claimed invention to a three-layer structure, let alone one that must have the exterior layers in direct physical contact with the interior layer.

A. The 280 Patent is not Limited to a Three-Layer Structure

JSC contends that the 280 patent covers a three-layer device only, because that patent's Figure 7 "shows a three-layered laminated structure which utilizes a low density molten polyethylene material as a laminate in order to attach the low density polyethylene antistatic layers to the inner conductive layer." (Appellant's Br. at 33.) This argument is self-refuting, however, because the polyethylene that JSC describes is itself a layer that bonds the anti-static layers to the conductive layer. Additionally, because the claims here contain the language "comprising," the presence of additional layers in the
accused device does not remove that device from the scope of the 280 patent claims. See Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501, 42 U.S.P.Q.2d (BNA) 1608, 1613 (Fed. Cir. 1997) ("Comprising" is a term of art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim.). We therefore concur with the district court's construction that the claims are not limited to three layers and can include an additional layer or layers.

5. "The upper surface [of the flexible plate] having at least one concave portion"

The term at issue here is "concave," and the parties agree that the plain and ordinary meaning of "concave" is "hollowed or rounded inward like the inside of a bowl." They also agree that the plain and ordinary meaning of this term should apply. Akeva asserts, in addition, that this definition only applies when the surface is "viewed from the perspective where the surface is visible," which means that the upper surface of the plate must be viewed from above. The court sees no reason to deviate from the term's ordinary meaning. Neither the claims nor the specification contain any requirement regarding how the flexible plate should be viewed, and the court will not read additional requirements into the term. Akeva argues that adidas' expert views the flexible plate from below, but the court has not considered any expert testimony regarding claim construction. adidas makes note of the absence of any disclosure of a concave upper surface in the '300 Patent's specification, which discusses only convex or arched flexible regions or plates. The failure of the specification to discuss a particular embodiment is not enough to exclude that embodiment from the scope of the claims if the claims would otherwise encompass it. See CCS Fitness, 288 F.3d at 1368 ("[Defendant] cannot use the intrinsic evidence's silence to narrow the ordinary meaning of an unambiguous claim term.").

The term "concave" should be construed as "hollowed or rounded inward like the inside of a bowl."

The defendants argue that the term "conductive elastomeric seal" is indefinite because an "elastomeric seal" is a rubber, which cannot be conductive. Defendants contend that the resistance of elastomeric materials can vary enormously depending on attributes such as the compression forces applied to them. 11 The defendants argue that the '516 patent does not provide any standard for measuring the degree of conductivity and is, therefore, indefinite under Federal Circuit law. See Star Scientific, Inc. v. R.J. Reynolds Tobacco Co., 537 F.3d 1357, 1372 (Fed. Cir. 2008); see also Halliburton Energy Servs., Inc. v. M-I L.L.C., 514 F.3d 1244, 1255-56 (Fed. Cir. 2008) (finding the term "fragile gel" indefinite because it was ambiguous as to the requisite degree of the fragileness of the gel and failed to place any limit on the scope of what was invented beyond the prior art).

11 Defendants cite to an unrelated patent on conductivity of certain classes of elastomers. See U.S. Patent No. 3,806,471.

Plaintiff argues that a person with ordinary skill in the art would understand that an elastomeric seal is conductive if, as recited in the claim itself, it "provide[s] an electrical path." '516 patent, cl. 7, 10. Plaintiff contends that the claim is not so "insolubly ambiguous" that one skilled in the art cannot practice the invention because he or she cannot "understand the bounds of the claim when read in light of the specification." See Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001) (claims are indefinite "only if reasonable efforts at claim construction prove futile"). Indeed, as Volkswagen points out, a claim construction of this term is possible if the Court looks to extrinsic evidence to find some structural guidance. The McGraw-Hill Dictionary of Scientific and Technical Terms defines "conductive elastomer" as "a rubberlike silicone material in which suspended metal particles conduct electricity."

The Court does not find this term to be indefinite. Firstly, the Court finds that "the components of the term have well-
recognized meanings, which allow the reader to infer the meaning of the entire phrase with reasonable confidence."

Bancorp Services, L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1374 (Fed. Cir. 2004). Moreover, a person of ordinary
skill in the art of the patent would understand how much conductivity a rubber seal would need in order to "provide an
electrical path" for signals such as those being transmitted from the sensor. '516 patent, col. 11, ll. 35-37. The embodiments
disclosed in the specification detail the circuits that may be used to generate the signal that needs to be transmitted.
Similarly, the use of a wheel as an antenna helps identify frequencies that may be used to transmit the signal. Additionally,
the use of the elastomeric seal as a seal that would effectively prevent air from escaping from the tire indicates the amount
of pressure or compression forces that the seal would be subjected to. Given this detail, a skilled person would easily
understand the characteristics of the current that would need to be conducted through the seal, and would thereby
understand the metes and bounds of the claim. See Exxon Research, 265 F.3d at 1375 ("If the meaning of the claim is
discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will
disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds."); Miles Labs., Inc. v.
Shandon Inc., 997 F.2d 870, 875 (Fed. Cir. 1993) (refusing to find a claim indefinite where "the patent disclosed adequate
information to enable a skilled artisan to make and use the claimed invention").

Based on the extrinsic evidence forwarded by the defendants, the Court construes the term to mean "a seal consisting of a
rubberlike silicone (or plastic) material which is conductive."

GO BACK

801

C. "A Conductive Member Leading to Said Electrical Plane"

Claim 1 recites that a portion of the electrically conductive path extends through the fuel injection system component and "a
conductive member leading to said electrical plane."

Honeywell says that "conductive member" means "any electrically conductive part or component--whether or not part of the
fuel injection system--that forms at least part of the electrically conductive path that leads directly or indirectly to the
electrical plane." Honeywell says that "electrical plane" means "any electrically conductive mass that can be maintained at a
common electrical potential, including, without limitation, the body of an automotive vehicle."

Defendants say that "conductive member" means "an electrically conductive bracket directly attached to, or molded as a
part of, the fuel filter housing." Defendants say that "electrical plane" means "an electrically conductive mass of the motor
vehicle that is maintained at a predetermined electrical potential."

There are essentially two disagreements between the parties: (1) whether the "conductive member" can be any kind of
electrically conductive part or whether it must be an electrically conductive "bracket," and (2) whether the "conductive
member" may be physically separate from the housing or whether it must be attached to or molded as a part of the housing.
Defendants say that their interpretation, which is narrower than the ordinary meaning of the words, is warranted based on
limiting language in the specification and prosecution history.

Referring to the sole figure in the '879 patent, the specification provides:

The housing 12 is secured to the metal vehicle body, a portion of which is indicated at 38, by a bracket 40. The bracket 40
may be either a separate metallic member attached to the housing 12 or molded as a part of the housing 12 from the same
material used for the housing 12.

'879 patent, col. 2, ll. 14-19. The specification later states that the electrostatic charge build-up in the fuel cavity of the filter
"will be discharged through the electrically conductive path in bracket 40 to the body 38" to prevent arcing. Id., col. 3, ll.
41-47. The bracket 40 is the sole embodiment of a "conductive member" disclosed in the specification. However, the
specification does not specifically state that a bracket is the only possible embodiment, nor does it state that the "conductive
member" must be attached to the housing or molded as a part of the housing in every embodiment. The only requirement is
that the "conductive member" allow for an electrically conductive path from the filter housing to the electrical plane.

The prosecution history also does not support defendants' narrow interpretation. Defendants point to the following statement
in the applicant's March 9, 1998 amendment during reexamination:

Japanese Patent Document No. 63-54859 ("JP '859") was cited because it shows a fuel filter and includes structure for mounting the fuel filter to a vehicle. In more detail, the JP '859 document discloses a fuel filter 8 having a particular shape that conforms to a corner area of a vehicle to which it is mounted. Further, this reference teaches using a mounted portion 24 that is integrally formed with the case body 10 to mount the filter to the vehicle. This is done to avoid the necessity of using a bracket to mount the filter to the vehicle.

In any event, the JP '859 document is primarily concerned with the size and the shape of the fuel filter (and surrounding areas) disclosed therein, and is silent regarding materials of which the fuel filter or any other component of a fuel injection system is made. Patenpees thus respectfully submit that JP '859 neither teaches nor suggests a bracket made of an electrically conductive material.

Defendants say that in distinguishing JP-54859, the applicant effectively required a conductive bracket that is directly attached to or molded as a part of the fuel filter housing. The applicant's statement, however, does not represent a clear disavowal of claim scope, especially considering that the applicant was responding to a rejection based on JP-77878, not JP-54859.

Neither the specification nor the prosecution history overcome the broad ordinary meaning of the term. "A conductive member leading to said electrical plane" is interpreted as follows:

Any electrically conductive part or component--whether or not part of the fuel injection system--that forms at least part of the electrically conductive path that leads directly or indirectly to the electrical plane, which is any electrically conductive mass that can be maintained at a common electrical potential, including, without limitation, the body of an automotive vehicle.

The next disputed term in Claim 25, "discharge conduit," comes into play in the manufacturing process after the mixing chamber: the contents of the mixing chamber are discharged into it and then an aqueous foam is inserted into it through an inlet, "such that the foam is mildly agitated to thereby minimize destruction of the foam while uniformly dispersing the foam in the aqueous gypsum dispersion." Next, "the resultant dispersion from the discharge conduit" is discharged and deposited "onto a moving cover sheet." (635 Patent Claim 25.) In the court's view, both sides' proposed constructions of the term "discharge conduit" includes redundant terms. Plaintiff's construction again focuses on the involvement of a powered moving agitator. Defendants' construction downplays the purpose of the discharge conduit and seeks to incorporate Defendants' proposed construction of "mixing chamber" as something that the discharge conduit is not.

Defendants contend that the construction must make clear that the discharge conduit is not a mixing chamber because the
The court concludes both party's proposed constructions fail because they attempt to weigh down the terms with much more detail than is necessary. Parts of the method that are already included in the claim need not be incorporated into the construction of claim terms. Accordingly, the court begins and ends its construction with the plain and ordinary meaning of the terms. The jury will understand the word "discharge." "Conduit" may be unfamiliar, though, so the court will construe it as "passageway or channel." Accordingly, the court adopts the following construction for "discharge conduit:" "discharge passageway or channel."

---

1. "Flexible enough to be formed or arranged." This construction is consistent with the claims as well as the specification. The parties agree in principal with this construction, diverging only with defendants' proposed additional limitation of "providing structural stability during manufacture." While the specification describes one embodiment directed to a configurable separator that provides structural stability, the court declines to import the limitations of a single preferred embodiment into this limitation. See Comark Commc'ns. v. Harris Corp., 156 F.3d 1182 (Fed. Cir. 1998).

---

2. "configured to fit"

McHugh asserts that this term does not require construction, while H&B asserts that it does. H&B contends that whether or not there is an ultimate finding of infringement of the '091 Patent depends at least partly on a determination of what "configured to fit" means. "Victory in an infringement suit requires a finding that the patent claim covers the alleged infringer's product or processes, which in turn necessitates a determination of what the claim terms mean." Markman, 517 U.S. at 374. Thus, this Court will construe the term "configured to fit."

Although McHugh asserts that this term does not require construction, to the extent that it does, McHugh argues that "configured to fit" should mean "designed to fit." H&B also agrees to this construction. Accordingly, the Court adopts both parties' proposed construction and construes the term "configured to fit" to mean: "designed to fit."
The Court adopts RTI's construction of "front end configured to operate the retraction mechanism" in Claim 25 of the 077 Patent. "Front end" undisputedly refers to the plunger's end closest to the needle. "Configured" means "to set up for operation." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 241 (10th ed. 2001). Thus, RTI's proposed construction, "the portion of the plunger closer to the injection end of the syringe that operates the retraction mechanism," mirrors the term's ordinary meaning. Nonetheless, NMT would limit the term's ordinary meaning to "a dislodgeable stopper fitted into the opening in the plunger at the end closest to the injection end of the syringe" based solely on a preferred embodiment discussed in the 077 Patent. See 077 Patent Col. 3 In. 54- Col. 5 In. 8. Nothing in the preferred embodiment indicates an intent to redefine the term and NMT cannot overcome the term's ordinary meaning simply by pointing to a preferred embodiment. Sunrace Roots Enter. Co., LTD, 336 F.3d at 1305.

The parties dispute whether a "confined area" must be sealed and whether a "seal" must be fire-proof or just firmly closed. The patentee gave an express definition for "confined area" in both patents. '965 patent, 2:63-3:3; '336 patent, 3:57-65. Although both patents do not use identical definitions, they are sufficiently similar for the Court to discern the common meaning. The '965 patent defines "confined area" to mean "an area of combustible material that is located at a site having normally limited ventilation and limited access in which combustion by-products can be confined and can pose a threat to personnel attempting to extinguish a fire at the site as well as providing additional combustible material to feed the fire and make extinguishing of such a fire, other than letting the fire burn itself out, even more difficult if not impossible." '965 patent, 2:63-3:3. The '336 patent simplifies the definition: "a site having normally [limited] ventilation and limited access for extinguishing a fire." '336 patent, 3:57-65 2 While it may appear at first glance that the Court is choosing between two different explicit definitions, the second definition is merely a simpler clarification of the first. "Confined area" has the same scope in both patents and will be construed consistently. See Omega Eng'g., Inc. v. Raytek Corp., 334 F.3d at 1334. The Court construes "confined area of a coal mine" to mean "a site in a coal mine having normally limited ventilation and limited access for extinguishing a fire."

2 The '336 specification uses the word "linked" rather than "limited." The context of this sentence and the corresponding sentence in the '965 specification make clear to the Court that the intended word was "limited."

I.

Manchak is the named inventor and owner of the '003 patent, entitled "Method of Transforming Sludge into Ecologically Acceptable Solid Material." Claims 1 and 2 recite a method for treating sludge with calcium oxide (commonly known as limestone or "quick lime"):

1. A method of transforming aqueous organic material containing sludge that may include virus and odor forming bacteria and toxic soluble compounds that are converted to substantially insoluble compounds in an alkaline environment into a solid, friable, and substantially odor free reaction product, said method comprising the steps of:

   a. sequentially moving said sludge from a source thereof at a first rate;

   b. sequentially moving calcium oxide from a source thereof at a second rate, with said second rate so related to said first rate that when sludge and calcium oxide are mixed an exothermic reaction is initiated in which said sludge and calcium oxide react with the evolution of steam to form a solid, friable, substantially odor free reaction product that has a pH of at least 12 and in which bacteria and virus initially present in said sludge are deactivated by said pH and the heat of said exothermic reaction, and said soluble toxic compounds initially present in said sludge are transformed to substantially water
insoluble compounds due to the high pH of the mixture of said sludge and calcium oxide as they transform to said reaction product;

c. providing an elongate confined space that has first and second ends;

d. directing said sludge and calcium oxide at said first and second rates into said first end of said confined space;

e. concurrently mixing and moving the mixture of said sludge and calcium oxide in said confined space from said first end towards said second end thereof, with the rate of longitudinal movement of said mixture in said confined space being such that said exothermic reaction has transformed said mixture to said reaction product by the time said reaction product has reached said second end;

f. withdrawing said steam from said confined space; and

g. sequentially removing said reaction product from said second end of said confined space.

2. A method as defined in claim 1 in which said mixture is concurrently mixed and moved longitudinally in said confined space by rotating a number of longitudinally spaced, transversely and angularly disposed rigid surfaces within the confines of said confined space.

(Emphasis added.)

Briefly summarized, sludge and calcium oxide simultaneously enter one end of an apparatus through two different openings and at two different rates. They are then mixed in the "confined space" of the apparatus to initiate an exothermic reaction. The reaction product exits the apparatus through a third opening at the opposite end, and the steam created by the reaction is withdrawn from the apparatus.

Sevenson, an environmental remediation firm, used the "Maectite process" in cleaning up the Marathon Battery Site in upstate New York. In the Maectite process, sludge is poured into a hopper covered by a screen to keep out branches and rocks. The hopper funnels the sludge onto a conveyor belt that in turn leads to a weigh belt. The weigh belt weighs the sludge and then dumps it into a second hopper. Lime is then poured into the second hopper at a rate dependent upon the weight of the sludge. The second hopper leads to a final conveyor belt, which feeds the sludge into an enclosed box-like structure called a "pugmill." Inside the pugmill, a series of intertwined rotating paddles mix the sludge with the calcium oxide and advance the mixture towards an opening on the other end. Notably, the pugmill has a safety screen on top that allows the steam formed by the exothermic reaction to freely escape. The pugmill forces the mixture out the second end for transport away from the site by truck or railcar.

In November 1995, Manchak brought a patent infringement suit in the United States District Court for the District of Delaware against six defendants. When ordered to select one defendant, Manchak chose Sevenson. The district court issued its claim construction opinion on May 1, 1997. On June 19, 1997, a jury found that Sevenson had literally infringed '003 claims 1, 2, 13, and 14 and awarded damages of $975,000. Because it found literal infringement, the jury skipped the questions of infringement by equivalents as the district court had instructed. 1

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
1 The jury also found the '003 patent to be enforceable and not invalid, i.e., not anticipated, obvious, or not enabled. In January 1998, after the jury had reached its verdict but before the district court had ruled on the parties' post-trial motions, the Patent and Trademark Office ordered the reexamination of the '003 patent. On April 7, 1999, the examiner issued a Notice of Intent to Issue Reexamination Certificate, thereby confirming the patentability of the claimed invention. Sevenson does not appeal the jury's findings regarding enforceability or validity.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

After the verdict, Sevenson renewed its motion for judgment as a matter of law of no literal infringement. On February 26, 1998, the district court granted Sevenson's motion with respect to claims 13 and 14, but denied it with respect to claims 1
and 2. The district court also invoked Rule 50(b) of the Federal Rules of Civil Procedure to find, in the alternative, that Sevenson had infringed claims 1 and 2 under the doctrine of equivalents. On June 26, 1998, after realizing that Manchak had never actually moved post-trial for judgment of infringement as a matter of law, the district court re-labeled its finding of infringement by equivalents as arising under Rule 49(a). The district court also declared the case to be "exceptional," and awarded Manchak $ 18,990.55 in attorney fees. This court has jurisdiction over this appeal under 28 U.S.C. § 1295(a)(1) (1994).

II.

A district court's construction of disputed claim terms is a question of law subject to plenary review on appeal. See Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). This court owes no deference to a jury verdict based on an improper claim construction, especially where the correct construction of the claims is dispositive on the issue of infringement. See Strattec Security Corp. v. General Automotive Specialty Co., 126 F.3d 1411, 1419, 44 U.S.P.Q.2D (BNA) 1030, 1036 (Fed. Cir. 1997).

In its May 1, 1997 claim construction opinion, the district court construed the term "confined space" in claims 1 and 2 as:

An elongate space that must confine the reaction product of calcium oxide and sludge. However, steam produced as a result of the reaction between calcium oxide and water in the sludge need not be so confined.

Sevenson contends that the district court erroneously construed "confined space" as only confining the reaction product of calcium oxide and sludge. Sevenson argues that the claims themselves, the written description, and the prosecution history establish that the "confined space" must confine steam. Because the pugmills that Sevenson used in its Maectite process indisputably lack a steam-confining top, Sevenson maintains that it cannot literally infringe upon claims 1 and 2 of the '003 patent. We agree.

The plain language of the claims themselves demonstrates that the "confined space" must also confine steam. Nothing in claim 1 suggests that "confined space" be narrowly construed as confining only reaction product of calcium oxide and sludge, but not steam. "Without an express intent to impart a novel meaning to claim terms, an inventor's claims take on their ordinary meaning." York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996). The step of "withdrawing said steam from confined space" in claim 1 also would make little sense if the steam were not confined in the space to begin with.

The district court's definition of "confined space" further conflicts with claims 5 and 7, which recite:

5. The method as defined in claim 1 in which said confined space is of such depth that a longitudinally extending space is provided in said confined space into which said steam can accumulate, and said longitudinally extending confined space in communication with a passage through which said steam may flow to the exterior of said confined space.

6. The method as defined in claim 5 which includes the further step of:

h. blowing a stream of air across said passage and substantially normal thereto to withdraw said steam from said longitudinally extending space.

7. The method as defined in claim 6 which includes the further step of:

i. directing the mixture of air and steam through a spray of water to remove foreign particled material from said steam prior to said air and uncondensed steam being discharged to the ambient atmosphere.

(Emphasis added.) Claim 5 requires that the "confined space" be of sufficient depth to allow steam to accumulate and provides a "passage" through which steam may "flow" to the exterior. These limitations presuppose a steam-confining top, but the only structure in claim 5 that can provide this top is the "elongate confined space" limitation of claim 1. Claim 5 does not otherwise add any new structure that would force steam to accumulate in, rather than passively rise out of, "said confined space." Claim 6 blows the steam out of the confined space via the passage provided in claim 5 to "withdraw" it. Claim 7 further recites the "discharge" of accumulated steam to the "ambient atmosphere" after washing away particulate
matter with water. This limitation would also make little sense unless the "said confined space" of claim 1 already prevented the steam from entering the "ambient atmosphere."

The written description tends to confirm this interpretation. It mentions the term "confined" in only one other context, i.e., "sumps are covered with plastic sheet or other impervious sheet to confine the smell." '003 patent, col. 7, ll. 36-37 (emphasis added). Since an inventor is presumed to have intended a consistent meaning for a term used in different portions of the written description, Manchak's illustration of a plastic sheet as "confining" gases implies that the "confined space" should also "confine" steam.

Finally, the prosecution history also tends to reinforce our interpretation of "confined space" as also confining steam. During the prosecution of the '003 patent, the examiner cited U.S. Patent No. 3,476,873 to Liljegren ("the '873 patent"). The '873 patent teaches the treatment of sewage with lime involving the pre-treatment of the sewage in "one or more sedimentation and/or flotation pools." '873 patent, col. 2, ll. 38-39. To distinguish claim 1 over the '873 patent, Manchak explained that "applicant requires no sedimentation and/or flotation pools" and, more significantly, advised that "during the reaction steam is formed in the confined space and removed therefrom." (Emphasis added.) Logically, steam cannot be "formed in the confined space" if the "confined space" does not also confine steam. Moreover, unless confined, steam would hardly need to be "removed therefrom."

The district court's unusual construction of "confined space" primarily resulted from its oversight of two sound principles of patent law. First, the district court held that independent claim 1 could not read on any process for allowing steam to accumulate in the elongate space, since the accumulation of steam in such space was a limitation appearing only in dependent claim 5. As this court has previously recognized, however, "it is axiomatic that dependent claims cannot be found infringed unless the claims from which they depend have been found to have been infringed." Wahpeton Canvas Co. v. Frontier, Inc., 870 F.2d 1546, 1553, 10 U.S.P.Q.2D (BNA) 1201, 1208 (Fed. Cir. 1989). The district court also improperly refused to consider the embodiment depicted in Figure 14 and described in columns 8 through 10 to aid its construction of "confined space," since it incorrectly assumed that the written description required more limitations than set forth in claim 1. The district court seemingly ignored this court's repeated statement that "claims must be read in view of the specification, of which they are a part." Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 U.S.P.Q.2D (BNA) 1321, 1326 (Fed. Cir. 1998) (en banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996).

Manchak advances several arguments to defend the district court's interpretation of "confined space." First, Manchak notes that dependent claim 5 requires that steam accumulate in the "longitudinally extending space" created by adding depth to the "confined space." Manchak argues that if the "confined space" of claim 1 also confines steam, dependent claim 5 would be superfluous. Under the doctrine of claim differentiation, a claim should not ordinarily be construed in such a manner that would render a related dependent claim superfluous. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998).

As we noted in Comark, however, "doctrine of claim differentiation is not a hard and fast rule of construction." Id., 156 F.3d at 1187, 48 U.S.P.Q.2D (BNA) at 1005. Rather, the doctrine is inapplicable where one or more added limitations distinguishes the allegedly superfluous dependent claim from its parent independent claim. See Mantech Envtl. Corp. v. Hudson Envtl. Servs., 152 F.3d 1368, 1374, 47 U.S.P.Q.2D (BNA) 1732, 1739 (Fed. Cir. 1998). Here, claims 5, 6, and 7 are distinguishable from claim 1 by their respective additions of a passage and increased depth to create a "longitudinally extending space," blowing step (h), and directing and steam-discharging step (i).

Manchak also advances the well-known principle that "claims .are not to be interpreted by adding limitations appearing only in the specification. . . . Although the specification may well indicate that certain embodiments are preferred, particular embodiments appearing in [the] specification will not be read into the claims when the claim language is broader than such embodiments." Electro Med. Sys. S.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054, 32 U.S.P.Q.2D (BNA) 1017, 1021 (Fed. Cir. 1994) (citations omitted). Manchak argues that interpreting the "confined space" limitation as also confining steam would improperly incorporate the limitations of the preferred embodiment depicted in Figure 14 into claim 1.

We reject Manchak's characterization of our interpretation as erroneously reading limitations from the written description into the claim. Though columns 8 through 10 and Figure 14 of the '003 patent provide the only support for the method recited in claims 1 and 2, they nowhere describe a "confined space" as confining the reaction product, but not steam. As Sevenson properly notes, accepting Manchak's expansive construction of "confined space" would yield the anomaly of a
specification that nowhere describes or depicts a single embodiment illustrating such breadth of interpretation. See Laitram Corp. v. Morehouse Indus., 143 F.3d 1456, 1463, 46 U.S.P.Q.2d (BNA) 1609, 1614 (Fed. Cir. 1993) (viewing it as relevant that nothing in the written description suggests the rejected construction). Furthermore, "confined space" is a limitation contained in claim 1, not a feature shown only in the specification. Thus, while the meaning of "confined space" must be gleaned from the claims and the written description, our construction does not import the term from the specification into claim 1, since it is already there.

2. "the surface of said hollow plug being conformable to irregularities in the tissue or muscle wall defining the defect upon insertion of said hollow plug into the defect, said hollow plug being extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect."

The parties dispute the meaning of the claim limitation "the surface of said hollow plug being conformable to irregularities in the tissue or muscle wall defining the defect upon insertion of said hollow plug into the defect, said hollow plug being extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect."

Bard argues that this limitation should be construed to mean "and whose surface is capable of conforming to irregularities in the shape of the defect or hole when it is inserted into the hole, and which is extremely pliable, so that localized portions of the plug are able to adapt to irregularities in the shape of the defect or hole."

Defendant argue that the phrase "surface of said hollow plug being conformable" requires pre-formed pleats which render the plug "extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect."

a. means-plus-function claims

Defendant's proposed construction is based, in part, on an argument that claim 20 is written in means-plus-function language. Claims may be drafted in functional terms, as permitted by 35 U.S.C. § 112 P 6, which provides:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

A claim may invoke 35 U.S.C. § 112 P 6 even though it does not recite the words "means" or "means for." 35 U.S.C. section 112 paragraph 6 governs only claim elements that do not recite sufficient structural limitations. See Al-Site Corp. v. VSI International Inc., 174 F.3d 1308, 1318-19 (Fed. Cir. 1999). When it is apparent that the element invokes purely functional terms, without the additional recital of a specific structure or material for performing that function, the claim element may be a means-plus-function element despite the lack of express means-plus-function language. See id.; see also Mas-Hamilton, 156 F.3d at 1214 (construing "lever moving element" in means-plus-function format).

b. U.S. Surgical's position

U.S. Surgical contends that claim 20 should be limited to a pleated implant. U.S. Surgical argues that claim 20, by itself, does not disclose any structure, material, or acts that would enable one skilled in the art to make a hollow plug that would perform all the claimed functions. Claim 20 recites that the implant should be "extremely pliable." U.S. Surgical asserts that
this is a functional limitation, and that a person of ordinary skill in the art would have to consult the specification to determine what structures to use to make an "extremely pliable" implant. U.S. Surgical argues that it is necessary to invoke 35 U.S.C. § 112 P 6 and construe the claim in light of the structures discussed in the specification. See Al-Site, 174 at 1318-19. U.S. Surgical contends that the specification repeatedly states that the use of pleats enhances the flexibility and pliability of the implant.

U.S. Surgical argues that the specification only discloses the use of a pleated structure, and that it would be inappropriate to broaden the scope of the claims beyond the scope of the invention. See Wang Laboratories, Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). In Wang, Wang sued America Online and Netscape Communications for infringement of a 1984 patent directed to a system for providing users with textual and graphical information from computer-controlled databases via interactive two-way communications over a telephone network. The issue for claim construction and summary judgment was whether the claim term "frames of information" covered both character-based and bit-mapped-based protocols, or whether the term should have been limited to character-based protocols. The preferred embodiment of the invention was directed to character-based protocol systems, although the specification acknowledged that bit-mapped protocols were part of the prior art. The Federal Circuit found that a person of ordinary skill in the art would understand the specification to refer only to character-based systems, and affirmed the trial court's construction that limited the claims to character-based systems.

U.S. Surgical argues that this case is analogous to Wang. U.S. Surgical argues that the specification of the '432 patent is directed only to a pleated implant. U.S. Surgical asserts that to construe claim 20 to cover unpleated implants would grant coverage to embodiments not disclosed by the patent.

U.S. Surgical argues that the prosecution history demonstrates that claim 20 should be construed in means-plus-function format. U.S. Surgical contends that during the reexamination proceedings, the examiner specifically suggested putting claim 20 in means-plus-function format, such that the suggested "means for conforming" language would refer to the portion of the specification discussing pleats. U.S. Surgical asserts that after Bard amended its claims, the examiner granted the claims under the belief that the claims set forth a "means for conforming," as stated in his Notice of Intent to Issue Reexamination Certificate. U.S. Surgical argues that the examiner would not have granted the claim had he not interpreted the claim to be in means-plus-function format.

U.S. Surgical argues that, regardless if claim 20 is construed in means-plus-function format, the prosecution history nevertheless limits the claim's construction to a plug which has pre-formed pleats. U.S. Surgical contends that Bard distinguished its invention from Trabucco through reference to its "integrially formed pleats," and that the examiner would not have allowed the claims but for this statement.

U.S. Surgical argues, moreover, that statements made by Bard during the prosecution of Canadian and European counterpart patents of the '432 patent demonstrate that the scope of claim 20 should be limited to a pleated implant. After the Canadian examiner rejected all the claims in the application on the grounds that a plug "having a pleated surface is known and described in the prior art cited," Bard argued that the prior art devices "do not have a pleated surface and are, therefore, unable to completely fill the opening formed by an irregularly shaped defect." Bard amended its claims by substituting verbatim the claims of the United States '432 patent. U.S. Surgical argues that this amendment constitutes an admission by Bard that claim 20 of the '432 patent is limited to a plug with a pre-formed pleated surface.

U.S. Surgical further states that the European examiner rejected the only independent claim of Bard's application on the grounds that the prior art disclosed pleated plugs. In response to the rejection, Bard stated that its plug "is preferably formed by hot molding, which indicates beyond a doubt that the pleats are permanent and are inherent in the plug." According to U.S. Surgical, this statement is an admission that the invention of the '432 patent includes a pre-formed pleated surface.

c. Bard's position

Bard argues that, under the ordinary meaning of the words used in claim 20, the claim should not be construed to refer to pleats. Claim 20 refers to a structure that is "conformable" and "extremely pliable." Bard asserts that the ordinary meaning of the terms "conformable" and "extremely pliable" should control. Bard contends that additional structural limitations may be read into a claim only when the language of the claim invites reference to the remainder of the specification or the prosecution history. See Johnson Worldwide Associates, Inc. v. Zebco Corp., 175 F.3d 985, 989-90 (Fed. Cir. 1999).
In Johnson Worldwide, the patentee sought to enforce its claims to a steering control used with trolling motors. The patent at issue claimed a "heading lock coupled to a trolling motor." The defendant, Zebco, argued that statements made by the patentee during the prosecution history served to limit this claim to a directional indicator "physically attached" to the trolling motor. The Federal Circuit stated that there is a "heavy presumption" against importing additional limitations into claim language. See id. at 989. There are two situations, the court stated, in which a claim term should be accorded other than its ordinary and accustomed meaning. The first arises if the patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term. Id. at 990. The second is where the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used. Id. The court found that the claim language was sufficiently clear that there was no need to import additional limitations from the specification and the prosecution history.

In this case, Bard contends that the limitations "conformable" and "extremely pliable" are sufficiently clear that it would be improper to import additional limitations from the specification and the prosecution history. Plaintiffs insist that neither term should be construed to refer to pleats, but rather that these are structural terms whose plain meaning should control.

Bard notes that the original patent application included a number of claims specifically reciting pleats, and other claims, including claim 20, that did not recite the use of pleats. Plaintiffs assert that the specification provides a written description of an embodiment of the invention that is not limited to pleats. The specification states: "in another embodiment of the invention, a filler body is positioned in a mesh cone and packs the implant when the plug is compressed by placement in the narrow hernia opening, providing the bulkiness believed to be essential for non-recurrate repair of abdominal wall hernias." Plaintiffs argue that this embodiment is not limited to pleats, and that it provides support for a construction of claim 20 without reference to pleats.

Plaintiffs further contend that the prosecution history demonstrates that Bard never intended to refer to pleats in claim 20. When the examiner inserted a pleat limitation into claim 5, the examiner did not require the addition of language into claim 20 to refer to pleats. In the reexamination proceedings, after the examiner suggested adding a "means for conforming" limitation to claim 20, Bard declined to adopt this language, and instead added the limitation "said hollow plug being extremely pliable . . . ." This additional language, plaintiffs contend, is a structural limitation that does not refer to pleats, and that does not invoke 35 U.S.C. § 112 P 6. Plaintiffs assert that claim 20 was allowed, not because it disclosed pleats, nor because it was limited to a plug that did not kink or buckle, but rather because it defined a plug whose extreme pliability allowed it to conform to a defect to a degree not achieved by the prior art. This reason for allowance is entirely consistent with the plain language of claim 20, plaintiffs state.

Moreover, Bard contends that it would be improper to invoke 35 U.S.C. § 112 P 6 to construe claim 20. Bard argues that it never intended to draft the claim in means-plus-function language. See Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1582 (Fed. Cir. 1996) (declining to construe claim in means-plus-function format when there was no evidence that the patentee intended to claim its invention in that fashion). Plaintiffs argue that claim 20 does not contain the words "means" or "means for," and so a presumption should apply that the claim is not written in means-plus-function language. Plaintiffs contend that the use of adjectives like "conformable" and "extremely pliable" to limit the structure is insufficient to trigger 35 U.S.C. § 112 P 6. See Personalized Media, 161 F.3d at 705 ("An adjectival qualification . . . placed upon otherwise definite structure . . . does not make the sufficiency of that structure any less sufficient for purposes of 35 U.S.C. § 112, P 6. Instead, it further narrows the scope of those structures covered by the claim and makes the term more definite."); see also Al-Site, 174 F.3d at 1317-19 (reversing trial court's determination that the claim limitation "attaching portion attachable to a portion of said frame of said pair of eyeglasses" was a means-plus-function element, because the limitation is not written in traditional means-plus-function format and because the claim supplies structural, not functional, terms).

Plaintiffs argue, moreover, that it would be improper under the doctrine of claim differentiation to construe claim 20 in means-plus-function format, because, under such a claim interpretation, the distinction between claims 19 and 20 disappears. Under the doctrine of claim differentiation, it is presumed that different words used in different claims result in a difference in meaning and scope for each of the claims. Clearstream Waterwater Systems, Inc. v. Hydro-Action, Inc., 206 F.3d 1440, 1446 (Fed. Cir. 2000). This doctrine cannot be used to make a claim broader than what is contained in the written description, but it prevents the narrowing of broad claims by reading into them the limitations of narrower claims. Id. The doctrine of claim differentiation is a guide to claim construction, not a rigid rule. IMS Technology, Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1432 (Fed. Cir. 2000).
Bard argues that the court should not interpret claim 20 in light of the statements it made during the prosecution of counterpart patents in Canada and Europe, as these statements were made in different factual and legal contexts. Bard contends that, in the Canadian application, it overcame the examiner's rejection by stating that "the flexible nature of the plug further allows it to compress radially upon insertion into the defect." And, Bard contends that the European application is irrelevant to the present proceedings, because the examiner had required Bard to use a single independent claim, and Bard complied with this requirement by choosing to claim only a pleated structure.

d. the court's construction

Two competing principles of claim construction are at issue in this case. One principle, advanced by plaintiffs, is that the court should not import additional limitations from the specification or the prosecution history unless the language of the claims, themselves, invites such analysis. See Johnson Worldwide, 175 F.3d at 989-90. As discussed above, Johnson Worldwide teaches that it is proper to introduce additional limitations into the plain meaning of claim terms only when the patentee is acting as its own lexicographer, or when the claim terms chosen by the patentee deprive the claim of clarity and provide no means for determining the scope of the claims. Id.

On the other hand, patent claims should not be construed to cover embodiments that are not supported by the specification. See Wang, 197 F.3d at 1383. Although it is generally improper to limit the scope of the claims to a preferred embodiment, see Eckchian v. Home Depot, Inc., 104 F.3d 1299, 1303 (Fed. Cir. 1997), claims should not be construed to encompass embodiments beyond those that are described and enabled in the specification. See Wang, 197 F.3d at 1382; see also Modine Manufacturing Co. v. International Trade Commission, 75 F.3d 1545, 1551 (Fed. Cir. 1996) ("When the preferred embodiment is described in the specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment."). To determine whether the claims encompass art that is not supported by the specification, it is proper to look to the specification and the prosecution history to determine the scope of the invention. See Wang, 197 F.3d at 1383 ("Whether an invention is fairly claimed more broadly than the 'preferred embodiment' in the specification is a question specific to the content of the specification, the context in which the embodiment is described, the prosecution history, and if appropriate, the prior art, for claims should be construed, when feasible, to sustain their validity.").

The crux of the present dispute is whether the specification describes an unpleated implant which is "extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect." Plaintiffs note that the specification states that "in another embodiment of the invention, a filler body is positioned in a mesh cone and packs the implant when the plug is compressed by placement in the narrow hernia opening, providing the bulkiness believed to be essential for non-recurrent repair of abdominal wall hernias." Although the quoted embodiment is not limited to a pleated implant, this embodiment does not describe that the implant should be "extremely pliable." The specification does use the term "extremely pliable," as it states on two occasions that "the pleated surface is extremely pliable." While the specification describes plugs that are extremely pliable, it does so only in the context of pleated plugs. Thus, the specification does not provide support for an unpleated plug that is "extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect."

Bard amended claim 20 to include the limitation "extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect" in order to distinguish the present invention from Trabucco. Bard amended claim 20 in this fashion after the examiner had rejected claim 20 in light of Trabucco, and after the examiner suggested adding the claim term "means for conforming." In support of his suggestion, the examiner referred to Col. 4, lines 44-48 of the specification, which specifies pleats as the structure that renders the implant "extremely pliable." After Bard made its final amendment to claim 20, the examiner appeared satisfied that Bard had added a "means for conforming" limitation, as he stated in his Notice of Intent to Issue Reexamination Certificate that "claims 19 and 20 set forth a means for conforming which renders the hollow plug extremely pliable."

Bard argues that the added limitation, "said hollow plug being extremely pliable," is a structural limitation that, by itself, served to distinguish the claimed invention from Trabucco. However, as noted above, the specification does not describe how to make a plug that is extremely pliable, other than to say that the plug should be pleated. There is no basis to conclude that the term "extremely pliable" is a distinct structural limitation that is supported by the specification. The court finds that it is unlikely that the examiner found the "extremely pliable" language to be a structural limitation that distinguished Bard's invention from Trabucco.
The court finds that the best reading of the prosecution history is that the examiner found Bard's "extremely pliable" limitation to represent a "means for conforming." The court finds that the examiner would not have allowed claim 20 but for his conclusion that the claim sets forth "a means for conforming which renders the hollow plug extremely pliable such that localized portions can adapt to irregularities in the tissue of muscle wall defect," as he stated in his Notice of Intent to Issue Reexamination Certificate. Because the examiner accompanied his suggested amendment with a reference to Col. 4, lines 44-48 of the specification, which recites pleats as rendering the plug "extremely pliable," the court finds that the "means for conforming" refers to pleats.

Although claim 20 is not written in traditional means-plus-function format, the court finds that the claim language is sufficiently lacking in structural elements that it is proper to invoke 35 U.S.C. § 112 P 6. As described above, the term "extremely pliable" is not a structural term that is supported by the specification. When this term is disregarded, claim 20 has no additional structure beyond that of claim 19, which the parties acknowledge is written in functional language.

The court does not find that the doctrine of claim differentiation, as advocated by plaintiffs, bars interpretation of claim 20 in means-plus-function format. It appears that, when claim 20 is read in a means-plus-function format, claims 19 and 20 refer to the same structure. While claim differentiation is a useful canon of claim construction, the court finds that the language of the claims and the prosecution history provide adequate justification for interpreting claim 20 under 35 U.S.C. § 112 P 6.

The court recognizes that the Federal Circuit has cautioned against reading examiners' statements into the scope of claims. See Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1556 (Fed. Cir. 1997), abrogated on other grounds, Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 1454-55 (Fed. Cir. 1998). In Eastman Kodak, the patent examiner during a Reexamination Proceedings Interview Summary wrote that a set of conditions recited in a crystallization procedure referred to "further crystallization" as opposed to "initial crystallization." The Federal Circuit affirmed the trial court's decision to exclude the "further crystallization" limitation from the claims, as to do so would improperly use prosecution history statements to vary the meaning of the claims. The present case is distinguishable from Eastman Kodak because the examiner's statements in this case were made in his Notice of Intent to Issue Reexamination Certificate, wherein he gave his interpretation as to why claim 20 was allowable. There is no indication in Eastman Kodak that the examiner's remarks were determinative of the meaning of the disputed claim.

Because the court is satisfied that the prosecution history of the '432 patent in the United States demonstrates that claim 20 should be limited to a pleated structure, the court will not consider the arguments raised by U.S. Surgical concerning Bard's foreign patent filings.

The court finds that the claim term "surface of said hollow plug being conformable" requires pre-formed pleats which render the plug "extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect."

II. Ordinary and Customary Meaning

Because we conclude that the district court's claim construction must be affirmed under either methodology offered by the parties, we begin by consulting the ordinary and customary meaning of the claim terms as requested by Bard.

Bard argues that the ordinary and customary meanings of the terms "conformable" and "pliable" do not require pleating. Bard proffers general-usage dictionary definitions for the terms "conformable" and "pliable." One representative definition of the term "conformable" is "corresponding; similar." American Heritage Collegiate Dictionary 292 (3d ed. 1993). A definition from the same dictionary for the term "pliable" is "easily bent," with synonyms including "flexible" and "supple." Id. at 1050-51.

Bard's dictionary definitions are largely unhelpful. First, even under the cases Bard cites, the ordinary and customary meaning of a term does not govern if the intrinsic record contains clear lexicography or disavowal of claim scope. Tex.
Digital Sys., Inc., 308 F.3d at 1204. Because we conclude below that the intrinsic record demonstrates that the plug in claim 20 must be pleated, the ordinary and customary definitions of "conformable" and "pliable" are not controlling. Second, because claim scope in this case turns most directly on the term "plug," the proffered dictionary definitions of "conformable" and "pliable" are largely inapposite. Finally, we question the need to consult a dictionary to determine the meaning of such well-known terms. Courts, including the Texas Digital Systems court, regularly forgo detailed dictionary analyses if the term is as commonplace as "conformable" or "pliable." See, e.g., Tex. Digital Sys., Inc., 308 F.3d at 1207 (determining the ordinary meaning of "controlling the durations" without referring to a dictionary). Indeed, Bard itself "submits that merely rephrasing or paraphrasing the plain language of a claim by substituting synonyms does not represent genuine claim construction."

III. Specification of the '432 patent

U.S. Surgical contends that the plug in claim 20 must be pleated because, in various ways and places, the specification defines the claimed plug as including pleats. In two places, the patent describes in general terms what it deems to be the invention. In both places, the patent unequivocally defines the claimed plug as having pleats. First, the Summary of the Invention begins by stating that "the present invention is an implantable prosthesis." '432 patent, col. 1, ll. 36. In the next paragraph, before the embodiments of the invention are described, the patent states that "the implant includes a pleated surface." Id. at col. 1, ll. 51-52 (emphasis added). Second, the Abstract describes "an implantable prosthesis including a conical mesh plug having a pleated surface which conforms to the contours of the defect being repaired." Id., Abstract (emphasis added).

--- Footnotes ---

3 Despite the suggestion to the contrary in the concurrence, this opinion's use of the term "define" is not intended to invoke the theory that the inventors acted as lexicographers and redefined words differently from their ordinary meaning in the art. Instead, we use the term merely to denote that "the specification makes clear at various points that the claimed invention is narrower than the claim language might imply" based on a reading of the specification as a whole. Alloc, Inc. v. ITC, 342 F.3d 1361, 1370 (Fed. Cir. 2003), cert. denied, 541 U.S. 1063, 124 S. Ct. 2390, 158 L. Ed. 2d 963 (2004). The term takes on similar meaning when applied in this opinion to the prosecution history.

--- End Footnotes ---

Bard claims that a statement in the specification is not "determinative of claim construction merely because it appears in the 'Summary of the Invention' section." Although a statement's location is not "determinative," the location can signal the likelihood that the statement will support a limiting definition of a claim term. Statements that describe the invention as a whole, rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term. See Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1347 (Fed. Cir. 1998) (relying on "global comments made to distinguish the applicants' 'claimed invention' from the prior art" during the prosecution of the patent in construing a claim term). Statements that describe the invention as a whole are more likely to be found in certain sections of the specification, such as the Summary of the Invention. See Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1348 (Fed. Cir.) ("Those statements, some of which are found in the 'Summary of the Invention' portion of the specification, are not limited to describing a preferred embodiment, but more broadly describe the overall inventions of all three patents."). cert. denied, ___ U.S. ___, 543 U.S. 821, 124 S. Ct. 91, 160 L. Ed. 2d 31, 2004 WL 2058375 (2004). Accordingly, other things being equal, certain sections of the specification are more likely to contain statements that support a limiting definition of a claim term than other sections, although what import to give language from the specification must, of course, be determined on a case-by-case basis. In this case, the plug claimed by the '432 patent is defined globally as requiring a pleated surface, which limits claim 20.

Bard further contends that these statements do not limit claim 20 to pleated plugs because the statements are merely "passing references" and relies for this argument on Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898 (Fed. Cir.), petition for cert. filed, ___ U.S. ___, 2004 WL 1553522 (July 1, 2004). Liebel-Flarsheim involved patents related to powered fluid injectors used in medical procedures. Id. at 900. The trial court construed the claims as requiring the use of a "pressure jacket," reasoning that the term "syringe receiving opening" was ambiguous and that each of the two embodiments in the specification disclosed the syringe receiving opening being located at the front end of a pressure jacket. Id. at 904. This court rejected the trial court's reasoning for several reasons, the first of which was that "the specification does not define
'opening' restrictively, nor is there anything in the specification that supports the district court's conclusion that the term is ambiguous." Id. at 905.

Contrary to Bard's characterization, the holding of Liebel-Flarsheim did not depend on the number of times the term "pressure jacket" was used or on details of preferred embodiments. Instead, the Liebel-Flarsheim court rejected the trial court's reasoning because, inter alia, the specification did not clearly define the term in question, even implicitly. In this case, however, the specification explicitly defines the inventive plug as "having" or "including a pleated surface." See '432 patent, Abstract (first quotation); id. at col. 1, II. 52 (second quotation). Accordingly, Liebel-Flarsheim provides no support for Bard's position.

Bard finally contends that these statements do not define the terms "conformable" and "pliable" as requiring pleating. Even if true, this argument is irrelevant because the statements define the words "implant" or "plug." In the Summary of the Invention, the phrase "includes a pleated surface" modifies the word "implant." See '432 patent, col. 1, II. 51-55 ("The implant includes a pleated surface which increases the pliability of the implant"). In the Abstract, the phrase "having a pleated surface" modifies the word "plug." See id., Abstract (describing "an implantable prosthesis including a conical mesh plug having a pleated surface which conforms to the contours of the defect being repaired"). Accordingly, whether or not the patent describes pleating as the only way to achieve conformability or pliability is irrelevant because the patent requires the "implant" or "plug" to have a pleated surface.

This point can also be made from another perspective. Claim 20 covers a specific structure, namely the surface of a mesh plug. Whether or not the patent states that pleating is the only structure that could achieve certain effects, such as conformability or pliability, is irrelevant because the patent defines the claimed structure as including pleats. In other words, because the language requiring pleating applies to the structure, not to the effects produced by the structure, Bard's contention that the patent does not state that pleats are the only way to achieve conformability and pliability is simply beside the point.

Both parties also point to the preferred embodiments. Under our precedent, a patentee's choice of embodiments can shed light on the intended scope of the claim, but a patent claim term is not limited merely because the embodiments in the specification all contain a particular feature. See Liebel-Flarsheim, 358 F.3d at 907-08. On the other hand, a construction that excludes a preferred embodiment "is rarely, if ever, correct." Vitronics Corp., 90 F.3d at 1583.

Bard points to language in the specification that does not use the term "pleated" to argue that a construction in which the plug in claim 20 must have a pleated surface would exclude a preferred embodiment. That language states in pertinent part, "In another embodiment of the invention, a filler body is positioned in a mesh cone and packs the implant when the plug is compressed by placement in the narrow hernia opening, providing the bulkiness believed to be essential for non-recurrent repair of abdominal wall hernias." '432 patent, col. 2, II. 3-8 (emphasis added). Bard contends that construing claim 20 to require a pleated plug would improperly exclude this preferred embodiment, which describes a "mesh cone" without mentioning pleating.

We find this argument unpersuasive for two reasons. First, the "embodiment" to which Bard refers is merely a description of one aspect of the claimed implant, namely the filler body. That the patent does not explicitly mention the pleated structure of the plug's outer surface is unsurprising given the focus in that paragraph on the filler body, which is contained inside the surface of the plug. Second, because the patent globally defined the plug as having a pleated surface, the term "pleated" need not be repeated each time a term describing some other aspect of the plug is used. Accordingly, the failure to recite the term "pleated" before "mesh plug" does not mean that the patent discloses an embodiment with a non-pleated plug.

U.S. Surgical argues that the plug in claim 20 must be pleated because neither the embodiments nor the drawings describe a non-pleated plug. It is true that many of the descriptions of the plug in the specification explicitly require pleating and are strikingly similar to the language employed in claim 20. For example, the language of claim 20 --"said hollow plug being extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities in the tissue or muscle wall defect"--can be compared with the following language describing a preferred embodiment --"The pleated conical plug is extremely pliable, allowing localized portions of the implant to adapt to the irregular contour 40 of the defect." '432 Reexamination Certificate, col. 2, II. 22-24 (first quotation); '432 patent, col. 4, II. 45-48 (second quotation). The only significant difference between these two quotations is an explicit description of pleating. Similarly close comparisons can be made between other descriptions of preferred embodiments and the disputed terms in claim 20. Id. at col. 1, I. 66 to col. 2, I.
Accordingly, the specification demonstrates that Bard clearly defined the terms "implant" and "plug" in claim 20 as requiring a pleated surface. Statements of general applicability clearly define the claimed plug as "having" or "including a pleated surface." See '432 patent, Abstract (first quotation); id. at col. 1, ll. 52 (second quotation). Further, statements describing preferred embodiments of the surface of the plug universally describe a "pleated conical plug." E.g., '432 patent, col. 4, ll. 45-48 (located in the Description of the Preferred Embodiments).

Although the statements in the specification suffice by themselves to demonstrate that the plug in claim 20 must be pleated, we also consider the prosecution history of the '432 patent, which confirms the analysis of the specification.

III. Prosecution History of the '432 patent

A. Initial Examination

The prosecution history of the '432 patent equally supports our conclusion that the plug in claim 20 requires a pleated surface. We begin with the initial examination.

On February 5, 1993, Bard filed a patent application with respect to the present invention by Drs. Rutkow and Robbins. The examiner rejected a number of the claims in the initial application that matured into the '432 patent, including claim 20 (application claim 21), on a variety of grounds. In response, Bard's attorney conducted an interview with the examiner and, thereafter, submitted an amendment and accompanying remarks. Of the amendments and arguments made by Bard, three merit discussion because they explicitly or implicitly address pleating.

First, the examiner rejected claim 20 (application claim 21) based on U.S. Patent No. 5,147,374 ("Fernandez"). Fernandez disclosed a device used in hernia repair in which (1) surgical mesh was rolled into a tight cylinder, (2) one end of the cylinder was slit to produce flaps, (3) the non-slit portion of the cylinder was inserted into the hernia defect, and (4) the flaps along with a flat sheet of surgical mesh were stapled to tissue adjacent to the hernia defect. To overcome Fernandez, Bard argued that "the implant disclosed in Fernandez does not contain pleats, is not conformable to an irregular shaped defect, is not compressible into a reduced configuration which approximates the shape of the defect upon insertion therein and does not contain a filler body or freely moveable mesh petals as is claimed." (Emphasis added.)

Second, to overcome the examiner's rejection based on the indefiniteness of the claim language on compressibility, Bard argued that "the claims do not recite that the surgical mesh fabric is compressible but, rather, that the implant formed from such material is compressible from a first configuration which is larger than the defect into a second configuration which approximates the shape of the defect." (Emphasis added.)

Third, in the interview, Bard demonstrated the difference in pliability and flexibility of the claimed device as compared to prior art devices. Bard later described this interview, arguing:

The claimed device easily assumed the shape of the irregular opening while the stiffer prior art devices left gaps around the boundary of the opening. It was also pointed out to the Examiner that the Fernandez plug does not contain pleats as is found in the preferred embodiment of the claimed device and as is expressly required by certain of the pending claims. It was further explained to the Examiner that it is the texturing of the implant which permits the claimed plug to conform to irregularities in the shape of the defect without kinking or buckling.
Pleating is implicated in each of the responses to the examiner's rejections described above. In distinguishing Fernandez and describing the interview, Bard explicitly relied on pleating as a material distinction over the prior art. Further, Bard argued that compressibility is based on the configuration of the mesh surface, not the nature of the mesh fabric itself. The emphasis on the configuration of the mesh implicates pleating. Such an implication is also supported by Bard's argument that "it is the texturing of the implant which permits the claimed plug to conform to irregularities in the shape of the defect."

Although pleating is explicitly or implicitly described by each of these arguments, limiting claim 20 to require pleating based solely upon amendments and arguments made during the initial examination would likely be improper. Most importantly, because pleating is described in alternative arguments and many claims contain an explicit pleating limitation, the pleating arguments do not necessarily apply to claim 20. For example, Bard argued, "It was also pointed out to the Examiner that the Fernandez plug does not contain pleats as is found in the preferred embodiment of the claimed device and as is expressly required by certain of the pending claims." (Emphasis added.)

B. Reexamination

Having determined that amendments and arguments made during the initial examination suggest a close connection between pleating and claim 20 but do not necessarily require the plug in claim 20 be pleated, we now turn to the reexamination. Bard requested that the '432 patent be reexamined because of certain art that was submitted to the examiner but not considered during the initial examination. 5

Footnotes

The reexamination focused on the latter of two articles authored by Ermanno E. Trabucco. See Ermanno E. Trabucco, A New Preperitoneal Plug Technic for Recurrent Groin Hernioplasty (undated manuscript) ("Trabucco"). In the request for reexamination, Bard described two ways in which the claimed device was distinguishable from Trabucco. First, Bard distinguished Trabucco by noting that the plug "disclosed in Trabucco I and II does not include a pleated surface." Second, the Trabucco plug "is stiff as compared to the flexible plug claimed in the '432 patent." Like arguments made during the initial examination, this argument describing pleating does not necessarily apply to and limit claim 20. Bard distinguished Trabucco using two alternative arguments, only one of which explicitly required pleating, and the reexamination initially involved all claims in the '432 patent.

The examiner allowed all device claims that expressly included pleating and rejected claims 19 and 20, which were the only device claims that did not expressly include pleating. The rejection of claims 19 and 20 was based on the examiner's determination that the Trabucco plug was radially compressible, flexible, and conformable.

In responding to the examiner's rejection, Bard clearly distinguished the plug claimed in claims 19 and 20 from Trabucco's plug on the basis of its plug having pleats. Bard began the response by addressing conformability, contending that it was demonstrated in the interview that the Trabucco plug was not radially compressible to the same degree as the claimed device. Next, in addressing flexibility and pliability, Bard stated:

As explained in the specification of the reexamination application, the surface of the inventive plug is pleated with [sic] enhances the flexibility and pliability of the implant, allowing the prosthesis to conform to irregularities in the shape of the hernia without kinking.

(Emphases added.) In the final argument, Bard again addressed conformability, arguing that the claimed device conforms "simply with insertion into the defect," whereas the Trabucco plug does not so conform. U.S. Surgical contends, and we
agree, that the statement "the surface of the inventive plug is pleated" is an unequivocal statement constituting a clear
disclaimer of scope in claim 20. In the initial examination and early stages of the reexamination, alternative arguments
based on pleating could not conclusively demonstrate that the plug in claim 20 must be pleated because other claims were at
issue and those other claims expressly required pleating. But the only claims at issue when Bard stated that "the surface of
the inventive plug is pleated" were claims 19 and 20, which were virtually indistinguishable from one another and neither of
which expressly required pleating. Bard counters that the statement "the surface of the inventive plug is pleated" referred
only to the pleated preferred embodiment demonstrated to the examiner during the interview and contends, therefore, that
the statement does not limit claim 20. Bard's argument is unpersuasive because the statement "the surface of the inventive
plug is pleated" referred to the claimed plug in general, not merely to the embodiment demonstrated during the interview.
This can be seen by the context of the statement, which was preceded by the words "as explained in the specification" and
was located in a different paragraph from the discussion of the interview. Additionally, the statement uses the term "the
inventive plug," whereas the discussion of the interview in the preceding paragraph describes "a plug embodying the
claimed invention." Bard further argues that the statement "the surface of the inventive plug is pleated" is merely an
inaccurate statement cannot override the claim language itself, which controls the bounds of the claim."). Bard, however,
provides no evidence demonstrating that its statement was inaccurate or otherwise a mistake. Further, the context of this
argument suggests that it was intentionally made to overcome a rejection by the examiner.

The examiner maintained the rejection of claims 19 and 20 but suggested that they would be allowed if specific means-plus-
function language were inserted at the end of both claims. The examiner cited language from the specification that described
a "pleated conical plug" in making this suggestion. In response, Bard stated that "in accordance with the Examiner's
suggestion, claims 19 and 20 have been amended to clearly distinguish the arrangement shown in the Trabucco article," but
Bard failed to add the specific means-plus-function language required by the examiner to claim 20. The examiner then
allowed claims 19 and 20, describing both as means-plus-function claims.

It is unclear what import, if any, to draw from Bard's failure to follow the examiner's suggestion for claim 20 as it did for
claim 19. Although Bard did not add the term "pleated" or explicit means-plus-function language to claim 20, they did adopt
language substantially identical to the language suggested by the examiner, which language implicitly required pleating.

C. Conclusion as to the Prosecution History

In examining the prosecution history, we note Bard made a number of arguments distinguishing the prior art on the basis
that the prior art did not disclose a pleated plug. Many of these arguments are not necessarily applicable to claim 20 because
the arguments related to claims in addition to claims 19 and 20 and were offered in the alternative with other arguments that
did not address pleating. But in the only response in which claims 19 and 20 alone were considered, Bard made a clear
statement to the examiner that "the surface of the inventive plug is pleated." This statement, when combined with the rest of
the prosecution history, demonstrates that Bard therein clearly defined the plug of claim 20 as having pleats. Accordingly,
the prosecution history provides an independent ground for construing claim 20 as requiring a plug with a pleated surface.

IV. Conclusion as to Claim Construction and Infringement

As described in detail above, Bard clearly defined the plug in claim 20 as having pleats in both the specification and the
prosecution history. Accordingly, we affirm the district court's claim construction requiring "pre-formed pleats." Claim
construction order, 102 F. Supp. 2d at 217. Because an analysis of the intrinsic record suffices to support this construction,
we do not consider, in the alternative, whether the district court properly construed claim 20 as containing means-plus-
function limitations requiring pre-formed pleats even though claim 20 did not include the words "means for" or similar
language. 6 We thus need not decide whether the presumption against such a conclusion is overcome by determining
whether claim 20, drawn to structure, fails to describe specific structure. We merely note that the district court's opinion
contains extensive and careful reasoning to support such a construction.

--- Footnotes ---

6 U.S. Surgical raises a number of additional arguments that need not be reached. These include whether claim 20 included
a "kinking and buckling" limitation and whether statements applicants made during the prosecution of foreign patent
applications limited the claims of the ‘432 patent.
Lastly, the parties dispute the term "conformable part" that is found in claims 1 through 5, 6, 9, 12, and 18 of the 848 Patent. At oral argument, Plaintiff stated that claims 3, 4, 5, and 12 of the 848 Patent were not going to be pursued. Accordingly, only claims 1, 2, 6, 9, and 18 need be addressed.

Claims 1 and 2 of the 848 Patent state, in pertinent part, "said body having at least a part that is conformable to a surface on the article … wherein the conformable part of the body is made from material that can be reconfigured into a plurality of different shapes and maintains itself in the plurality of different shapes, wherein the conformable part … comprises thermal setting rubber".

Claim 6 of the 848 Patent includes, in pertinent part, "the conformable part of the body is made from a material that can be reconfigured into a plurality of different shapes and maintains itself in the plurality of different shapes independently of the article to which the security apparatus is to be connected and without any external force applied to the body".

Claim 9 of the 848 Patent states, in pertinent part, "said body having at least a part comprising thermal setting rubber that is conformable to a surface on the article to which the security apparatus is attached".

Claim 18 of 848 Patent contains similar language: "the conformable part of the body is made from a material that can be reconfigured into a plurality of different shapes and maintains itself in the plurality of different shapes independently of the article to which the security apparatus is to be connected".

The written description of the 848 Patent draws an analogy of these limitations to putty, which retains different shapes so "there is little tendency of the body to peel off". The written description distinguishes the thermal setting rubber of the patented device to conventional plastic flexible material which, "while reconfigurable, tends to resume its undeformed shape".

During the prosecution of the 848 Patent, the "conformable part" was distinguished from the suction cup found in the previously issued Norrad Patent by reason that the conformable part can be placed in different shapes but does not spring back into an undeformed state once a conforming part is released or the conformable part is separated from an article to which it had been applied.

The 848 Patent does not explicitly define "conformable part". "Conformable" is defined as "corresponding in form". Webster's Third International Dictionary 477 (3d ed 1986).

Plaintiff argues that "conformable part" can/should be construed separately for each of the claims in which it is found. However, it proffers only one construction, stating that, "in most of the claims", conformable part should be defined as a material "that can be deformed under the application of a modest force and changed from an initial starting shape and maintained in shapes different than the starting shape with the part separated from an article". Defendant argues that the term should be construed to mean "a material that can be molded into different shapes and retains those shapes on its own".

The plain language of the above claims demonstrates that Plaintiff used the term "conformable part" consistently throughout the Patent and that it should be construed consistently throughout all of the claims of the Patent. See Rexnord, 274 F.3d at 1342. All of the claims, except for claim 9, state that the material can be reconfigured into different shapes and that the material maintains itself in those different shapes. Claims 6 and 18 also state that the material maintains its different shapes independent of the article to which it is attached. The written description of the Patent, in which the above-described limitations draw an analogy to putty, which retains different shapes so "there is little tendency of the body to peel off", and distinguishes the thermal setting rubber of the patented device to conventional plastic flexible material which, "while reconfigurable, tends to resume its undeformed shape", further supports a construction requiring the material to maintain its configured state independent of the article to which it had been attached. Furthermore, the prosecution history supports such a construction.
Based on the above, the conformable part of the 848 Patent is construed to mean "a material that can be reconfigured into a plurality of different shapes and maintains itself in the plurality of different shapes independent of the article to which it is attached".

"A Conical Beam of Light"

The "source of light" limitation of claim 2 reads: "a source of light mounted within said housing for directing a conical beam of light downwardly through said opening along said side of said vehicle below said window so as to be visible from in front of and from behind said vehicle." Ford argues that the term "a conical beam of light" should be construed as "all light from the source that passes through the housing opening." Ford claims that this construction is consistent with Krippelz's use of the term "beam of light" in the '903 patent because the patent "teaches that all of the light from the 'source of light' is part of the 'beam of light.'" Unfortunately, I see no such limitation in the patent that all of the light from the "source of light" is part of the "beam of light." While the "source of light" does generate a "beam of light," there is no provision explicitly teaching that the "source of light" cannot produce any other light (i.e., non-beam light), and I should not impose negative limitations on a claim that are not explicitly provided in the claim. See Omega Eng'g., Inc. v. Raytek Corp., 334 F.3d 1314, 1322 (Fed. Cir. 2003) ("When construing the functional statement in a means-plus-function limitation, we must take great care not to impermissibly limit the function by adopting a function different from that explicitly recited in the claim.") (quoting Generation II Orthotics, Inc. v. Med. Tech., Inc., 263 F.3d 1356, 1364-65 (Fed. Cir. 2001)).

2 In its reply brief, Ford offers a "slight" modification, proposing that the term be construed as "the real-world beam light from the source of light that actually passes through a lensless housing opening." However, because Ford in the same breath "reserves its right to seek review of the Court's Orders on appeal," I will fully explain my rejection of Ford's initial proposal before offering my final construction, which adopts a portion of Ford's revised proposal.

Furthermore, the description of the term "light beam" by the Board of Patent Appeals and Interferences ("the Board") during reexamination does not support Ford's proposed construction. The key phrase from the Board's description is that light must have some "defined sweep range" in order to be a beam, but there is no limitation in the patent that the "source of light" may produce some additional light outside of this "defined sweep range."

3 I treat the terms "light beam" and "beam of light" synonymously.

Moreover, I reject Ford's argument that Krippelz is estopped from arguing that claim 2's "source of light" produces "non-beam light" based on the Board's holding that Krippelz is estopped from claiming that "a similar source, using an incandescent bulb, or other light source generating light which is not a 'beam,' infringes the instant claimed invention." There is a difference between a light source that exclusively generates non-beam light (one which Krippelz is estopped from arguing infringes its patent) and a light source that generates both beam and non-beam light (one which Krippelz may argue infringes its patent).

Finally, I reject Ford's argument that adopting the distinction between beam and non-beam light would invalidate Krippelz's patent. Ford claims that patent would be invalid because it would fail to meet the statutory written description requirement of 35 U.S.C. § 112 because neither the claim specification nor the prosecution history contains a "disclosure of how anyone would determine which light rays are critical 'beam light' and which the irrelevant 'non-beam light.'" (emphasis added). However, the relevant inquiry under the written description requirement is that the patent specification "must clearly allow
persons of ordinary skill in the art to recognize that [the inventor] invented what is claimed." Gentry Gallery v. Berkline Corp., 134 F.3d 1473, 1479 (Fed. Cir. 1998) (emphasis added). The claim specification here does indeed allow a person of ordinary skill in the art to determine the nature of the light generated by the "source of light," although it does not explicitly disclose precisely how one goes about doing so. As noted by the Board, beam light must have some "defined sweep range," and by inference, it must be possible to measure this "defined sweep range" and thus distinguish between non-beam and beam light.

Accordingly, the term "a conical beam of light" will be construed as "a conical light beam from the source of light that actually passes through a lensless housing opening." 4

4 I am confused as to what Ford's proposed "real world" term adds to this construction with the inclusion of its proposed term "actually passes through." Aside from the allure of some possible, but non-existent, connection to a long-running reality-based TV show, I see no need for this additional term.

1. "conical incident surface" and "conical exit surface"

There is, in many ways, more agreement than disagreement regarding the meaning of the terms "conical incident surface" and "conical exit surface." Both parties, for example, understand "incident surface" to denote the surface that light strikes and "exit surface" to denote the surface that light departs; in addition, both parties read "conical" to connote some type of cone shape, and the two seem to agree that such surfaces emit ring-shaped light patterns. All that the parties actually dispute is whether the phrase "conical . . . surface" mandates that the surface resemble a complete cone or, by contrast, that the surface resemble a cone in part. As it is used in the claim language, the word "conical" is plainly adjectival; it modifies and qualifies the kind of surface the light strikes. Basic semantics suggests that "conical" means cone-like, much like "pyramidal" means pyramid-like and "spherical" means sphere-like, and it also suggests that "conical [] surface" means nothing more than a surface with cone-like attributes. Simpler and more congruent with the claim text than either of the parties' somewhat diffuse definitions, a construction of "conical [] surface" to mean a surface with cone-like attributes is buttressed by the specifications' discussion of cone-shaped surfaces, see '336 Patent at 32:12-57, and of "incident" surfaces generally. Id. at 6:31-33; 13:35-39; 14:31-35; 40:5-12; see also id. at figs. 17-20; 31-33. The court thus construes "conical incident surface" to mean "a surface with cone-like attributes that light strikes." In the same manner and to the same effect, the court construes "conical exit surface" to mean "a surface with cone-like attributes from which light departs."

5. The term "connectable" should be interpreted as follows: "capable of being connected together; it does not require that the hanging means be removable."

13. "Connected to"

The term "connected to" appears in Claim 5 of the '477 Patent to describe the relation of the flexible tubes with the elongate members. See '477 Patent col. 10 ll. 10-11 ("one or more sterilized flexible tubes connected to said back of each of said one or more elongate members"). Here again, Gore argues that no construction is necessary. Millipore initially contended that this term should be construed as "joined or linked together" without requiring that there be contact between the two objects.
I agree with Millipore that the term "connected to" should be construed as "joined or linked together." See Webster's Third New International Dictionary at 480 (2002). However, because being "joined or linked together" in this setting specifically requires that there be contact between the tubes and the elongate members, I find, as Millipore now concedes, the remaining dimension to Millipore's initial construction irrelevant and therefore reject it.

d. Connected To

Claim 16 states "an eccentric weight portion connected to said cylindrical gear portion at a position radially outward of the axis of said cylindrical gear portion." '964 Patent, col. 11, ll 13-15. APE contends that the common and ordinary meaning of "connected to" is "joined together, united or linked." J&G construes the term to mean "formed of one-piece and specifically excludes bolting as the '964 patent teaches that prior art having bolted counterweights are not sufficiently durable and the '964 patent does not provide any other methods of 'connected to' other than casting from one-piece." Doc. 27 at 25.

APE first argues that other claims in the patent, 1, 6, 11, use the term "connected to" in the plain and ordinary sense of "separate items... that are joined together." Doc. 26, at 16. J&G agrees, but points out that the use of "connected to" in this sense is not disputed in those claims and, further, in each of the three instances, the term "connected to" is modified by the adverb "operatively," which is not used in claim 16. J&G argues that, although the use of a term in one claim may shed light on its meaning in another claim, the terms must be used in a similar context. This is not the case in the '964 patent. J&G again argues that "connected to" in claim 16 cannot mean a two-piece assembly because "in the Reexamination of the '964 Patent, patentee argued away from a two-piece counterweight having an eccentric weight portion that attached to a cylindrical gear portion. Exhibit A, at 6." Doc. 27 at 27. The Court has rejected this argument as not persuasive. Cf. pages 23-24 of this Memorandum on Claim Construction.

In addition J&G argues that APE "disavowed a bolted, two-piece assembly in the specification and cannot now claim that 'connected to' includes what was previously disavowed. Cf. '964 Patent, col. 1, ll. 41-45." Doc. 27 at 27. The cited language of the patent is found in the "Background of the Invention" section of the patent. After describing the prior art as including "a vibratory assembly with counterweights having a solid eccentric weight bolted to a portion of a cylindrical gear," the cited language reads, "These bolted counterweights are not sufficiently durable, because the bolts have a very undesirable tendency to break under the large stress loads generated during rotation counterweights." '964 Patent, col. 1, ll 39-45. As pointed out before, at page 20-21 of this opinion, the Background of the Invention section distinguishes the vibratory devices known in the industry and points out the disadvantages of both two-piece and one-piece vibratory devices. '964 Patent, col. 1, ll 39-51, Doc. 26, Exhibit A, at 6. Although J&G argues that the characterization of bolted counterweights as "not sufficiently durable," expresses exclusion of bolted counterweights, the statement is an expression of a problem to be solved and does not state or imply an express disavowal of two-piece assemblies. A specification disclaimer that operates to surrender subject matter from the scope of a claim must demonstrate an "intent to deviate from the ordinary and accustomed meaning of a claim term by including in the specification expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, 299 F.3d at 1325. It is interesting to note that all five of the previous opinions on the disputed term "connected to" rejected the argument J&G makes here that the term excludes "bolting." cf. footnote 4 above. All four opinions accept APE's construction of the term "connected to," as meaning "joined together, united or linked." This Court makes the same construction. The term "connected to" is construed to mean "joined together, united or linked."

The phrase "connected to" appears in asserted claims 1, 6, 11, and 16. The parties agree that the phrase generally means "joined together, united or linked" (Joint Disputed Claim Terms Chart), and the court finds this to be the ordinary meaning of the phrase. Geoquip, however, wishes the definition also to indicate that the phrase specifically excludes bolting as the '964 patent teaches that prior art having bolted counterweights are not sufficiently durable and the '964 patent does not...
provide any other methods of 'connected to' other than casting from one-piece." Id. Thus, in order to resolve the dispute between the parties, the court must examine whether the patentee has made a clear and unmistakable disavowal of bolted counterweights. See Phillips, 415 F.3d at 1316.

The court begins its analysis by looking to the claims themselves. Claim 1 describes the counterweight and then indicates that there is "at least one driving means operatively connected to said counterweight and adapted to rotate said counterweight about its rotational axis." '964 Patent, col. 9, ll. 51-53. Similarly, claims 6 and 11 describe a driving means as being "operatively connected to" the counterweight. Id. at col. 10, ll. 28-31, 64-66. Claim 16, however, uses the phrase "connected to" in a different manner, describing the counterweight as having "an eccentric weight portion connected to said cylindrical gear portion at a position radially outward of the axis of said cylindrical gear portion." Id. at col. 11, ll. 13-15. As opposed to the description in claim 19, in which the eccentric weight portion is integral with the cylindrical gear portion, claim 16 contemplates a two-piece counterweight in which the pieces are joined together in some manner. There is no mention in the claims, however, of excluding bolting as a means of connection. There is also no indication that the phrase "connected to" means something different in claim 16 than elsewhere in the '964 Patent. Because the claims do not define "connected to" explicitly, the court examines the specification for further guidance.

Geoquip argues that the patentee disclaimed bolting as a method of connecting the eccentric weight portion to the cylindrical gear portion, based upon the patentee's criticism of the prior art:

The prior art includes a vibratory assembly with counterweights having a solid eccentric weight bolted to a portion of a cylindrical gear. These bolted counterweights are not sufficiently durable, because the bolts have a very undesirable tendency to break under the large stress loads generated during rotation [of the] counterweights.

Id. at col. 1, ll. 39-45. APE responds that this statement was not a disclaimer of bolting, but rather a general discussion of the problems in the prior art. Indeed, in the rest of the paragraph, the patentee goes on to discuss problems that arose from certain one-piece, cast counterweights as well. See id. at ll. 45-51 ("These solid, cast counterweights, however, do not have sufficient mass to generate large enough vibratory forces to efficiently drive or pull piles."). As the preferred embodiment of the '964 Patent takes the form of a one-piece, cast counterweight, id. at col. 5, ll. 51-53, that embodiment is obviously not being disavowed.

Thus, the court finds that the discussion of bolting in the prior art does not provide a clear disavowal of that means of connecting the eccentric weight portion to the cylindrical gear portion. See Ventana Med. Sys., Inc. v. Biogenex Labs., Inc., 473 F.3d 1173, 1180 (Fed. Cir. 2006) (finding no disavowal of certain dispensing methods when discussion of prior art included the dispensing method of the preferred embodiment in addition to the those methods allegedly disavowed).

Because the court finds no reason to exclude bolting from the definition of "connected to," the court construes that phrase to mean simply "joined together, united or linked," as the parties agree, without the caveat suggested by Geoquip.

(4) connected to

This term appears in claims 1, 6, 11, and 16. However, in claims 1, 6, and 11 the term is used in the phrase "operatively connected to" to describe the drive assembly external to the counterweight. That is, the vibratory assembly is described in claim 1 as comprising, in addition to the counterweight, "at least one driving means operatively connected to said counterweight and adapted to rotate said counterweight about its rotational axis." '964 patent, col 9 lines 51-53. Claims 6 and 11 use similar language. '964 patent, col 10 lines 28-31, 64-66. The parties have not addressed this "operationally connected to" language in their briefs and arguments. It appears that their dispute revolves around the term "connected to" as it appears in claim 16, reciting "an eccentric gear portion connected to said cylindrical gear portion at a position radially outward of the axis of said cylindrical gear portion . . . " '964 patent, col. 11 lines 13-15.

The dispute surrounding this term, as with the term above, has been resolved by the Court's construction of the term "integral." Independent claim 16, and the following dependent claims, recite an invention in which the eccentric gear portion projects "radially outward" from the cylindrical gear portion. The "connected to" term, used in place of "integral" as found in disputed independent claims 1, 6, and 11, describes a counterweight in which the eccentric gear portion and the
cylindrical gear portion are separate and discrete, with no overlapping area.

Plaintiffs propose that the Court adopt the construction "joined together, united or linked." Joint Disputed Claim Terms Chart, Dkt. # 29-2, p. 8. Defendants propose the same language, with the addition that "connected to" specifically excludes bolting, based on the patentee's recitation of prior art which included bolting. The Court finds no basis for including the additional language, and construes the term "connected to" to mean "joined together, united or linked."

5. "connected to"

This phrase appears in asserted claims 1, 6 and 11. APE contends that the phrase should be construed to mean "joined together, united or linked. In this instance, the eccentric weight portion is joined with the cylindrical gear portion at a point radially outward of the axis of the cylindrical gear portion. 'Connected to' can mean that the two portions are separate pieces joined together so long as that connection is at a position radially outward of the axis." Bay contends that the phrase should be construed to mean "formed of one-piece and specifically excludes bolting as the '964 patent teaches that prior art having bolted counterweights are not sufficiently durable and the '964 patent does not provide any other methods of "connected to" other than casting from one-piece."

The court begins its analysis by first turning to the claims themselves. The phrase "connected to" is first introduced in claim 1, which provides: "A vibratory assembly for imparting a vibratory force to a pile, comprising: . . . at least one driving means operatively connected to said counterweight and adapted to rotate said counterweight about its rotational axis." Substantially similar language appears in claims 6 and 11. Claim 16 provides: "A cylindrical gear portion having a plurality of gear teeth around its circumference, said cylindrical gear portion being made of a first metal; an eccentric weight portion connected to said cylindrical gear portion at a position radially outward of the axis of said cylindrical gear portion . . . . " While the phrase "connected to" does not appear in claim 19, the court nonetheless finds that the language of this claim illuminates the meaning of this phrase. Claim 19, which depends from claim 16, provides: "The counterweight assembly of claim 16 wherein said eccentric weight portion is integral with said cylindrical gear portion, said first metal is cast steel, and said second metal is a tungsten."

As discussed above, because claim 19 would be superfluous if the phrase "connected to" meant the same thing as the term "integral," and because the presence of the limitation "integral" in claim 19 gives rise to a presumption that this limitation is not present in claim 16, the court, as noted above, construes the phrase "connected to" have a different meaning than the term "integral." However, because the claim language does not clearly define the phrase, the court turns to the specification for added insight.

The specification states that:

The counterweight 40 has a center bore 106 that extends fully through the gear portion 41 and the eccentric weight portion 43 . . . The center bore 106 has an inner diameter that is slightly larger than the outer diameter of the shaft 82, such that the center bore securely receives the shaft. The eccentric weight portion 43 has two threaded bores 108 that communicate with and are transversely oriented relative to the center bore 106. The threaded bores 108 are adapted to receive conventional threaded lock fasteners to lock the shaft 82 within the center bore 106, thereby securely connecting the counterweight 40 to the shaft for rotation with the shaft.

The specification further states: "At least one motor is operatively coupled to the counterweight and is adapted to rotate the counterweight to cause the vibratory forces." '964 Patent, col. 2, lines 39-42. In addition, the specification states that: "When the drive motor 42 is activated, the drive motor turns its shaft . . . causing the counterweight 40 to rotate on the shaft 82 . . . . " '964 Patent, col. 7, lines 25-31.

In this case, neither the claim language nor the specification expressly define or describe the phrase "connected to." Nor does the specification indicate explicitly or implicitly that the patentee intended to import a novel or specialized meaning to
the phrase "connected to" or the term "connected." Ordinarily, therefore, "connected" means "conjoined; fastened or linked together." Oxford English Dictionary (2d ed. 1989). In addition, the specification indicates that the word coupled is used interchangeably with "connected to" insofar as the specification uses coupled, rather than the phrase "connected to," as used in the claim language, to describe the relationship between the drive motor and the counterweight. The patent discloses no novel or specialized meaning of the word "coupled." Ordinarily, therefore, coupled means "tied, joined, linked, or associated together in pairs." Oxford English Dictionary (2d ed. 1989). Thus, while the word "coupled" appears in the specification, not in the claims, the court finds that it is meant to have the same meaning as "connected to."

Moreover, as the specification describes, and figure 4 illustrates, the shaft and counterweight are separate pieces or parts and the shaft is securely connected to the counterweight by threaded lock fasteners for rotation with the shaft upon the activation of the drive motor. The court construes this language to mean that "connected to" conveys the joining, uniting or linking of two separate pieces or parts.

Finally, to the extent that Bay asks the court to construe the term "connected to" to exclude bolting on the basis that the "'964 patent teaches that prior art having bolted counterweights are not sufficiently durable and the '964 patent does not provide any other methods of "connected to" other than casting from one-piece[,"] the court declines to do so. The court need not reach this issue to construe the phrase "connected to." Therefore, the court declines to adopt either party's proposed construction of the phrase "connected to." Instead, the court construes the phrase "connected to" to mean: "joined together, united or linked."

2. "a body connectable to the underwater cable"

This phrase is used in claim 13 of the '992 Patent. WG seeks to construe this term as "a device attached externally to the underwater cable." In support of this construction, WG offers largely the same argument as was made with respect to the previous claim term. Ion asserts that this phrase needs no construction. Ion argues that this claim need no construction.

The Court notes that the term "connectable" contains a different connotation from the word "mountable." Whereas, with the previous phrase, the plain and ordinary meaning of the claim terms connoted an external connection of some kind, the term "connectable" does not invoke the same relationship between two objects. At first glance, therefore, the Court must be suspect of WG's proposal, which seeks to construe this phrase and the previous phrase in an identical manner. As Ion correctly points out, such a construction would be contrary to presumption of claim differentiation, which counsels that identical construction of two claim terms that use different words is inappropriate. Seachange Int'l, Inc. v. C-COR, Inc., 413 F.3d 1361, 1368 (Fed. Cir. 2005) ("[D]ifferent words or phrases used in separate claims are presumed to indicate that the claim have different meanings and scope.")

Nonetheless, the Court is faced with a situation in which an externally connected body is the only device that is disclosed and described in the specification. Moreover, unlike several of the claims within the Bittleson and Zajac Patents, the claim terms here do not offer any reason to believe that the scope of this phrase should be construed more broadly than what the specification describes. In other words, "[n]o other structure is illustrated or described" and "[n]o other broader concept [is] described as embodying the applicant's invention." Toro, 199 F.3d at 1301. The '992 Patent appears to teach only a device wherein the body is attached externally to the underwater cable. Moreover, that the '992 Patent also teaches inductive coupling as part of the inventive system would also suggest that a body attached externally to the streamers which receives power though inductive coupling is a critical element of the patented device. The intrinsic evidence in the '992 Patent, therefore, offers no other interpretation for the term "connectable" other than the external connection for which WG advocates.

The Court declines, however, to adopt WG's construction wholesale, as it once again equates the term "body" with "device," which, in light of WG's own admission that a portion of Ion's invention that effectuates inductive coupling is located underneath the skin of the streamer, is improper. Accordingly, the Court will construe this term as "a body attached externally to the underwater cable." Although the Court recognizes that this construction is identical to that of the previous phrase, such identical constructions are proper in this case in light of the specification and the patent claims. See Nystrom v.
TREX Co., 424 F.3d 1136, 1143 (Fed. Cir. 2005) (holding that "[d]ifferent terms or phrases in separate claims may be construed to cover the same subject matter where the written description . . . indicate[s] that such a reading of the terms or phrases is proper").

With regard to the substance of the district court's claim construction, Searfoss argues that the district court erred in not giving the term "connecting" its ordinary meaning, as shown in general usage dictionaries, which encompasses both direct and indirect connections, and instead improperly limited its construction to direct connections. 2 Searfoss cites to several general usage, non-technical dictionaries, which it argues support a definition of "connecting" to encompass both direct and indirect connections. See Webster's Third New International Dictionary (1986) (defining "connect" as "to join, fasten or link together usually by means of something intervening"); see also Oxford English Dictionary (2d ed. 1989). According to Searfoss, neither the district court nor Pioneer has pointed to anything in the specification to overcome the "heavy presumption" of the "ordinary meaning" of "connect," and the proper construction must encompass both direct and indirect connections.

We disagree. The district court clearly acknowledged the competing general dictionary definitions of "connect," including direct and indirect connections. Markman Order at 7 ("Indeed, the court need not look to the dictionary at all, inasmuch as the court is familiar with the competing definitions advocated by the parties. The court need only decide which meaning, whether it be a direct connection or a tangential connection, is described in claim 3."). In construing the claim, however, the district court did not, and indeed must not, stop with the dictionary definitions offered by Searfoss. Instead, the district court did as it must, and consulted the written description. Bell Communications Research, Inc. v. Vitalink Communications, Corp., 55 F.3d 615, 619 (Fed. Cir. 1995) ("It is equally 'fundamental that claims are to be construed in light of the specifications and both are to be read in view of ascertaining the invention.'") (quoting United States v. Adams, 383 U.S. 39, 49, 15 L. Ed. 2d 572, 86 S. Ct. 708, 174 Ct. Cl. 1293 (1966)). The district court found that, as used in claim 3, the term "connecting" refers to a "direct pivotal connection between the tension bail and the extension assembly" because the patent referred to the term "connecting" as synonymous with "attaching." We agree. Throughout the specification we find references to direct connections between the legs of the tension bail and the legs of the extension assembly; and indeed, every pertinent figure depicts a direct connection between the legs of the tension bail and those of the extension assembly. See '955 patent, col. 3, ll. 39-44, col. 6, ll. 39-55, figs. 1, 5-8. Moreover, we agree with the district court that a construction of the word "connect" to include "indirect" and non-rigid connections (such that the canvas cover itself could be the connection between the tension bail and the extension leg assembly) is problematic because it would lead to a reading of the claim such that the cover (as the actuation means) is exerting a downward force upon itself. We hold that the district court was correct in interpreting "connecting" as used in this patent to include only direct, rigid, pivotal connections.

2. Connection segment

. Plaintiff's proposed construction: A portion of the face guard configured to engage a connector that secures the face guard to a helmet.
. Defendant's proposed construction: Wire member, projecting from the main body of a face guard, that extends rearwardly in order to be attached to the side of a helmet.

The dispute with respect to this term is similar to that for "receivers extending outwardly." Defendant argues that the claim requires the term "connection segment" to mean something more than just vertical members connecting to the connector, namely a "wire member, projecting from the main body of a face guard, that extends rearwardly in order to be attached to the side of a helmet." Defendant asserts that it is the projection that holds the two vertical members of the faceguard.

Claim 23 states that a "connection segment" has two substantially vertical members that are configured to engage the connector. Because this term is similar to the term "receivers extending outwardly" in claim 14, the two definitions should be consistent, as defendant asserts. However, plaintiff is correct when it argues that the claim specifically leaves out any reference to projecting or extending rearwardly. The specification also does not say that these members have to project or extend rearward. Therefore, I conclude that the term "connection segment" as used in claims 23 and 25 of the '151 patent means members of the face guard made of wire or other material that engage the connector on the helmet.

vi. "second end including a connector"

180s urges construing "second end including a connector" as "an end having or coupled to a connector." Gordini urges construing the term as a "second extremity forming one piece of a jack for establishing an electrical communications connection."

I adopt the following construction of "second end including a connector": "a second end having or coupled to something that establishes an electrical communications connection." 180s' construction of "second end including" as an "end having or coupled to" is consistent with the plain meaning of the phrase and the specification. However, 180s construction is incomplete; this term construction must clarify that the "connector" is an "electrical communications connection." The plain meaning of "connector" does not necessarily implicate electrical communication, so an ordinary fact finder would be easily misled into believing the "connector" lacks such a meaning. Yet the specification is unambiguous that "connector" in fact facilitates an "electrical communication connection," and 180s does not point to any claim language or specification language disclaiming such an understanding. Consequently, although "jack" may inappropriately limit the term "connector," defining "connector" as "something that establishes an electrical communications connection" is consistent with the specification. (See, e.g., Pls.' Mem., Ex. B. at col. 4, l. 59 - col. 5, l. 8 ("The connector 450 can be either a male or female connector and is configured to be coupled to another wire as illustrated, for example, by the wire W in FIG. 2. Note that connector 450 is illustrated as a female connector in FIG. 2 and as a male connector in FIG. 9.").)

1. "Connector."

The court shall apply the ordinary definition of the word "connector." The word connect means "to bind or fasten together; join or unite; link[.]

B. "A First Connector . . . Being Removable and Interchangeable . . . Defining a Parallel Flow Configuration"

The following chart contains both parties' interpretations of the disputed term "a first connector . . . being removable and interchangeable . . . defining a parallel flow configuration." Patent at Col. 19:57-62; 20:55, 61.

</table>

The parties dispute three main aspects of the definition of this term: (1) whether the connector needs to connect "by itself" the first and second fluid treatment modules to create parallel flow or whether other structures may (or even must) be involved in the connection; (2) whether the connector needs to be a one-piece structure or can consist of a structure with more than one piece; and (3) whether, in order to constitute parallel flow under the patent, the flow from each of the fluid treatment modules must recombine or whether it may remain separate. 1

--- Footnotes ---

1 In their moving papers, Everpure also disputed two other minor parts of Selecto's definition, but it did not address--and essentially acceded--to Selecto's arguments on these points at the hearing and in the supplemental briefing. See Supplemental Briefing at 5 n.4. Namely, Everpure disputed whether "removable and interchangeable," should be interpreted to mean can "be installed in the same connection location as the second connector without changing the spatial relationship of the fluid ports on the first head relative to the fluid ports on the second head," as Selecto contends. The specification supports Selecto's definition. See Patent, Col. 14: 5-8 ("Additional plumbing and other fixtures need not be removed or installed in order to change between configurations by virtue (at least in part) upon the common module and port locations in both configurations." (emphasis added)). The specification also supports Selecto's use of the phrase "releasably fluidly connect" to describe the connection, since the specification uses that exact phrase. Patent, Col. 8: 26-39.

--- End Footnotes ---

1. Must the connector "by itself" connect the first and second fluid treatment modules?

Selecto argues that because the claim indicates that the first connector "defines" a parallel configuration, the connector must "by itself" connect the first and second fluid treatment modules. Selecto relies upon the Agilent and C.R. Bard cases to support its position as to the significance of the patent's use of the word "defining." Agilent Technologies, Inc. v.
Affymetrix, Inc., 567 F.3d 1366, 1375-77 (Fed. Cir. 2009); C.R. Bard, Inc. v. Medtronic, Inc., 140 F. Supp. 2d 346, 348 (D. Del. 2001). Both cases dealt with the interpretation of the word "defining." In Agilent, the Federal Circuit held that it was error for the district court to interpret the claim "a first substrateand a second substrate having inner surfaces that define a closed chamber therebetween, said chamber adapted to retain a quantity of fluid" to mean "an enclosed cavity, or some other enclosure or system of enclosures, which is capable of being sealed or set apart from its surroundings to retain a quantity of fluid." Agilent, 567 F.3d at 1375-77. Instead, the court found that the claim meant "an enclosed cavity defined by the inner surfaces of the first and second substrates, from which there is no egress of fluid." Id. In reaching its holding, the court reasoned,

The claim itself recites a closed chamber "define[d]" by "a first substrate and a second substrate having inner surfaces." Thus, the claim requires that the chamber be bounded by two discrete substrates. The chamber is not a nebulous space that could ambiguously span a "system of enclosures." Instead, it is an enclosure explicitly defined by two surfaces.

Id. at 1376. The C.R. Bard case also makes clear that "defining" cannot mean merely "allowing." The Federal Circuit's decision in C.R. Bard was unpublished but is quoted in a subsequent district court opinion. C.R. Bard, 140 F. Supp. 2d at 348. The district court notes that the Federal Circuit held that its interpretation of "a housing defining a substantially toroidal flow path" to mean "that the housing (although not necessarily toroidal in shape) must determine with precision a fluid flow path having the shape of a substantially closed curve which rotates about, but does not intersect or contain, an axis in its own plane" was erroneous. C.R. Bard, 140 F. Supp. 2d at 348. The Federal Circuit construed "the housing" limitation as requiring that the housing itself be toroidally shaped." C.R. Bard, Inc. v. Medtronic, Inc., 250 F.3d 760, at * 3 (Fed. Cir. 2000) (unpublished table disposition). Everpure tries to distinguish these cases, arguing that they are limited to their facts, but the phrasing of the claim terms here is strikingly similar to that in those cases.

In short, Federal Circuit decisions support the proposition that "defining" should mean more than "allowing." Selecto asserts that these cases suggest that here the first connector must "by itself" connect the first and second treatment modules in a parallel configuration. As Everpure pointed out in its moving papers and at the hearing, a connector between the modules cannot "by itself" create system of parallel flow since other portions of the system (such as plugs 136g and 136b on the outside of the modules in Fig. 2A) will be required to complete the system. See Transcript at 101:15-102:2 (testimony of Mr. Cartwright that a connector does not need to constitute parallel flow by itself). However, as Selecto argued at the hearing, a skilled artisan refers to the connection between two modules when describing a flow system, not extraneous plugs. See Transcript at 76:18-77:13 (testimony of Mr. Tadlock describing connectors 3A/3B and 3O/3P as defining a parallel flow configuration based on their connection between the modules alone). Moreover, this problem can be accounted for by clarifying that the connector "by itself (notwithstanding any plugs necessary to close the system)" establishes parallel flow.

2. Must the connector be a one-piece structure?

Even though the Patent indicates that the connector must by itself establish parallel flow, that does not necessarily mean that the connector must be a one-piece structure, as Selecto argues. 2 See Selecto's Post-Hearing Brief at 1. The specification does not speak directly on this point. 3 It does provide illustrations of embodiments of connectors--Figs. 3A-3P--several of which are multi-piece structures. See, e.g., Figs. 3J and 3L. Likewise, both experts testified at the hearing that certain of the connectors described in the specification are not one-piece structures. Transcript at 101:3-14, 72:2-7. However, the issue is not whether the generic connectors mentioned in the specification are one-piece structures. The issue is whether the claimed "first connector . . . defining a parallel flow configuration," Patent at Col. 19: 57-61, is a one-piece structure. "[T]he claims of the patent need not encompass all disclosed embodiments." TIP Systems, LLC v. Phillips & Brooks/Gladwin, Inc., 529 F.3d 1364, 1373 (Fed. Cir. 2008). However, a court should avoid excluding disclosed embodiments in the absence of clear intrinsic evidence to support their exclusion. See Verizon Services Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1305 (Fed. Cir. 2007) ("We normally do not interpret claim terms in a way that excludes disclosed examples in the specification.").

--- Footnotes ---

2 Selecto tries to extend its argument about the meaning of "defining" beyond the context of whether the connector must "by itself" create a parallel flow system into the question of whether the connector may be a multi-piece structure. Selecto offers no support for the proposition that a multi-piece structure cannot "define" parallel flow.
3 To support its position that the connector need not be a one-piece structure, Everpure cites to text in the specification, which states, "Although both fluid lines need not necessarily be defined in the same body or part . . . , a single connector element 136a can simplify assembly and disassembly while also reducing the number of parts of the system . . . ." Patent at Col. 8:48-53. However, this statement is referring to the advantages of a particular embodiment of a connector (136a) over a multi-piece system. It does not speak to whether the claimed first connector must be a one-piece structure.

Here, the Patent discloses several connectors, including Figs. 3J and 3L, which both Mr. Tadlock and Mr. Cartwright agree are multi-piece structures. Transcript at 101:3-14; 72:2-7. The only possible textual basis for finding that the connector must be a single-piece structure is that the claim itself refers to "a first connector and a second connector, each being removable and interchangeable." Patent at Col. 19:56-58 (emphasis added). But this statement only implies that the connector must be a single structure, not that it necessarily needs to be a one-piece structure. In the absence of clear evidence that the claimed connector must be a one-piece structure, the Court declines to exclude these illustrated embodiments.

Thus, the Court finds that the first connector may be a "one-piece or multi-piece structure."

3. Must the fluid output from each fluid treatment module recombine in order to constitute parallel flow?

Everpure argues, relying on the testimony of its expert, Mr. Cartwright, that streams that have been separated need not be recombined to create parallel flow. He testified at the hearing that a system containing multiple fluid treatment modules must be configured in either parallel or series--no other configurations are possible. Transcript at 87:22-88:5. He testified that anybody skilled in the art would consider Figure 6 in the specification--which illustrates a configuration in which the fluid flows through both fluid treatment modules concurrently but does not recombine-- to be an example of parallel flow. Id. at 102:12-103:15.

However, extrinsic evidence may not be employed to contradict intrinsic evidence, including the specification. See Vitronics, 90 F.3d at 1584 n.6; Phillips, 415 F.3d at 1318. Moreover, "the specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs." Phillips, 415 F.3d at 1316. Here, in the portion of the patent that describes flow, each of the figures described--except for Figure 6--is referred to as an example of either "parallel" flow or "series" flow. See Patent at Col. 11:49-13:3. The section of the patent describing the flow through Figure 6 characterizes Figure 6's flow as neither "parallel" flow nor "series" flow, but instead as "yet another example of the various manners in which the system can be configured by virtue of the modular nature of the assemblies." Patent at Col. 12:56-58. This is the only passage in the discussion of flow where a given figure's flow is not described as either "parallel" or "series." See Patent at Col. 12:29 (describing Figure 2A as a system in which the assemblies are connected in parallel); 12:30 (describing Figure 4 as a system in which the assemblies are connected in series); 12:52-54 (describing Fig. 5 as a system in which the assemblies are connected in series). The specification clearly contemplates Figure 6 as illustrating neither parallel nor series flow, but something else entirely. The distinguishing feature between Figures 2A (parallel flow) and 6 is that the separated flow streams do not recombine in Figure 6. Tadlock Reply Decl. P 4. As the specification and Mr. Tadlock's testimony establish, the Patent contemplates parallel flow to require a re-combination of the separated fluid streams.

4. Conclusion

For these reasons, the Court interprets "a first connector . . . being removable and interchangeable . . . defining a parallel flow configuration" to mean

a one-piece or multi-piece structure that can: (a) physically, releasably, and fluidly couple a pair of fluid ports on the first fluid treatment module to a corresponding pair of fluid ports on the second fluid treatment module, (b) be installed in the same connection location as the second connector without changing the spatial relationship of the fluid ports on the first head relative to the fluid ports on the second head, and (c) by itself (notwithstanding any plugs necessary to close the system) physically and fluidly connect the first and second fluid treatment modules such that the stream of fluid entering the system is split into two distinct streams with one of the streams passing through only one of the fluid treatment modules, the other stream passing through only the other fluid treatment module, and the two streams recombining into one output stream.

The following chart contains both parties' interpretations of the disputed term "a second connector . . . being removable and interchangeable . . . defining a series flow configuration." Patent at Col. 19:57-62; 20:43, 49.

<table>
<thead>
<tr>
<th>Everpure's Interpretation</th>
<th>Selecto's Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>One or more structures that are capable of connecting one component of a fluid treatment system to another component of a fluid treatment system, (b) may be removed from the fluid ports and interchanged with other connectors and (c) when connected between first and second fluid treatment modules, the first connector allows the feed stream entering the system to first pass into the cartridge of the one of the fluid treatment modules and the outlet flow of the cartridge of that fluid treatment module to then pass into the cartridge of the other fluid treatment module.</td>
<td>a one-piece structure that can: (a) physically, releasably, and fluidly couple a pair of fluid ports on the first fluid treatment module to a corresponding pair of fluid ports on the second fluid treatment module, (b) be installed in the same connection location as the first connector without changing the spatial relationship of the fluid ports on the first head relative to the fluid ports on the second head, and (c) by itself physically and fluidly connect the first and second fluid treatment modules such that the entire stream of fluid passes first through one of the fluid treatment modules and upon exiting this treatment module the entire stream passes through the other fluid treatment module.</td>
</tr>
</tbody>
</table>

The parties' disputes over the definition of the second connector are identical to their first two disputes with respect to the definition of the first connector in section B, supra. The parties agree on the substance of what series flow means, although they phrase their interpretations slightly differently. Figure 4 exemplifies how the patent defines series flow configuration. See Patent at Col. 12:7-29. For the same reasons set forth above in the discussion of the first connector in section B, the Court construes "a second connector . . . being removable and interchangeable . . . defining a series flow configuration" to mean

a one-piece or multi-piece structure that can: (a) physically, releasably, and fluidly couple a pair of fluid ports on the first fluid treatment module to a corresponding pair of fluid ports on the second fluid treatment module or plug one or more of these ports, 5 (b) be installed in the same connection location as the first connector without changing the spatial relationship of the fluid ports on the first head relative to the fluid ports on the second head, and (c) by itself (notwithstanding any plugs necessary to close the system) physically and fluidly connect the first and second fluid treatment modules such that the stream of fluid entering the system passes first through one of the fluid treatment modules and upon exiting this treatment module the stream passes through the other fluid treatment module.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 At the hearing, the Court proposed a hybrid of the two parties' definitions of series flow, which both sides agreed to. See Everpure's Supplemental Brief at 6 n.5; Selecto Supplemental Brief (not disputing the Court's proposed definition of series flow).

5 The addition of the phrase "or plug one or more of these ports" is necessary to describe a series flow configuration like
Figure 4, where two of the ports are plugged.

6 The Court deleted the modifier "entire" preceding "stream" in Selecto's definition because, as Mr. Cartwright explained in his Reply Declaration at PP 19-20, certain types of filters that the specification teaches may be employed in the cartridges (e.g., hollow fiber filters and reverse osmosis filters), Patent at Col. 7:48-60, do not allow for the entire stream of fluid to pass into the next cartridge.

826 b. "consisting essentially of"

Callicrate originally argued that the phrase "consisting essentially of" should be distilled to mean "having at least the following elements." During oral argument at the Markman hearing, however, Callicrate retreated from the position and proposed that the phrase instead be construed as, "having only the following material elements but may also include additional nonmaterial items." NAIC proposes the following interpretation: "having only the following essential items." NAIC suggests that the phrase must be interpreted as limiting the scope of the claim to include only the enumerated crucial elements, particularly limiting the claim to include only devices that contain one grommet. NAIC's reference to devices that contain one grommet refers to the phrase "connection means" and will be discussed infra, when the Court construes that phrase.

Claim Language

In patent parlance, the transitional phrase "consisting essentially of" has a special meaning. 30 "Consisting essentially of" is a transition phrase commonly used to signal a partially open claim in a patent. 31 "Typically, consisting essentially of precedes a list of ingredients in a composition claim or a series of steps in a process claim." By using the term "consisting essentially of," the drafter signals that the invention necessarily includes the listed ingredients and is open to unlisted ingredients that do not materially affect the basic and novel properties of the invention. 32 A "consisting essentially of" claim therefore occupies a middle ground between closed claims that are written in a "consisting of" format and fully open claims that are drafted in a "comprising" format. 33 Thus, the claim language supports the interpretation proposed by Callicrate at the Markman hearing.

phrases in patent claims, it is highly unlikely that the examiner approved claim 34 with the phrase "consisting essentially of," if the examiner intended for the claim to be construed in a closed format. Moreover, Callicrate's amendment is consistent with the Examiner's suggestion that claim 34 be amended to include the term "consisting," as the Examiner did not specify whether he was referring to the partially open phrase "consisting essentially of," or the closed phrase "consisting of." The prosecution history, like the claim language, therefore supports Callicrate's proposed interpretation. As such, the Court will construe the phrase "consisting essentially of," to connote "having only the following material elements, but may also include additional nonmaterial items," according to its plain and ordinary meaning.

--- Footnotes ---

34 See Boeing Co. v. United States, 57 Fed. Cl. 22, 28 (Fed. Cl. 2003) (characterizing defendant's attempt to give the usually open-ended "consisting essentially of the closed-ended meaning ordinarily ascribed to "consisting of" as "linguistic legerdemain").

7. Consists of (Claim 15)

The term "consists of" in Claim 15 presents an interesting construction challenge. Both parties agree that it is a term of art used in a patent to limit the claimed invention to those elements specifically listed in the claim. However, they disagree on what the term limits. Plaintiffs argue that "consists of" only refers to "a mixture" while the broader term "containing" refers to the particular ingredients of the mixture. Defendant contends that "consists of" belongs with the entire phrase, "a mixture containing a major portion of silica together with a minor portion of titanium dioxide," limiting the ingredients of the mixture to only silica and titanium dioxide.

80 Plaintiffs' Markman hearing arguments.

81 Defendant's Brief on Claim Construction, Docket Entry No. 23, p. 18; Defendant's Markman hearing arguments.

--- End Footnotes ---

Case law dictates that "consists of" or "consisting of" at the beginning of a claim means "the claimed invention contains only what is expressly set forth in the claim." Norian Corp. v. Stryker Corp., 363 F.3d 1321, 1331 (Fed. Cir. 2004) (interpreting a claim with "consisting of" in its introductory phrase). When inserted in a particular element of a claim, the phrase limits the invention to that which follows the words "consisting of." See Vehicular Techs. Corp. v. Titan Wheel Int'l Inc., 212 F.3d 1377, 1383 (Fed. Cir. 2000) (interpreting a phrase within a claim limitation).

In the 547 patent, claim 15 begins, "A heat-insulating double casing pipe to be especially used in offshore oil pipelines, characterized in that..." 82 The claim continues, "characterized further in that said microporous material consists of a mixture containing a major portion of silica together with a minor portion of titanium dioxide." 83 Immediately, the claim language asserts itself. The claim literally states that the insulation material consists of a mixture, not that the insulation material consists of silica and titanium dioxide or even that the mixture consists of silica and titanium dioxide. According to the claim, the mixture "contains" silica and titanium dioxide. "Mixture" and "contains" are both open-ended terms, not subject to an inference of restriction. See Mars, Inc. v. H.J. Heinz Co., 377 F.3d 1369, 1375 (Fed. Cir. 2004). On the other hand, reading "consists of" as applying only to "a mixture" fails to impose any real consequence on the patentee for his selection of words. Arguably, either interpretation is consistent with case law.

--- Footnotes ---

82 547 patent at 10:23-24.
Other language in the claim begins to clarify this ambiguity. In a subsequent "characterized further in that" limitation, the claim teaches that "the portion of titanium dioxide present in said material is comprised between 30 and 35% by wt. for a silica content of 60 to 70% by wt." Before addressing how the language helps to clarify the previous limitation, the court notes that this particular limitation neither contains the words "consists of" nor, because of its separate and distinct structure, is bound by those words. Moreover, this limitation refers back to "said material," rather than to "said mixture." Certainly, therefore, no proper reading of the claim would permit the conflation of this limitation with the previous one to further narrow the claim.

That said, the percentages taught in the limitation can shed some light on the prior claim language. Simple math reveals that the patentee left open the possibility that a very small percentage of the material might be something other than silica or titanium dioxide. When the uppermost percentage of silica is added to the lowermost percentage of titanium dioxide, the total is only ninety-five percent. If silica and titanium dioxide were intended as the only possible components of the microporous material, the patentee would not have disclosed sixty percent silica content without teaching a corresponding amount of titanium dioxide that, in combination, would total one hundred percent. Therefore, although the claim requires silica and titanium dioxide in percentages within the range provided, it does not eliminate the presence of a small percentage of other ingredients.

This conclusion is further supported by the specification, which favorably mentions contemporaneously manufactured microporous materials "wherein the proportion of titanium dioxide exceeds 20% by weight based on total weight, up to 30 to 35% by weight of silica, disregarding minor portions of other mineral oxides which represent all combined at least 5% by weight."

The court recommends that the phrase "consists of a mixture containing a major portion of silica together with a minor portion of titanium dioxide" does not require that the ingredients of the mixture be limited only to those ingredients listed in the claim.

Chaffin narrows the third phrase to be construed from "in constant fluid communication with substantially the entire contained chlorine supply" to "in constant fluid communication," and argues that this latter means that the end of the tube that is in such communication "allow[s] liquid or gas access at all times." Dkt. No. 21 at 10. Cecil's argues, by contrast, that the entire phrase means "able to continuously draw chlorine from substantially the entire contained chlorine supply regardless of the duration period of continuous sewage effluent recirculation." Dkt. No. 22 at 38. The key point of differentiation between the two constructions, then, appears to be the additional phrase in Cecil's' construction: "regardless of the duration period of continuous sewage effluent recirculation." That is, there appears to be little distinction between the
phrases "has access at all times" and "able to continuously draw." The question, then, is whether the Court ought to construe the term to include Cecil's additional limitation.

Cecil's "regardless of the duration period" language is at worst a limitation not called for by the patent's claims and at best a mere repetition of the concept that access is allowed "constant[ly]" or "at all times" or "continuously." The Court, then, construes "in constant fluid communication with substantially the entire contained chlorine supply" to mean "allowing liquid or gas access at all times to substantially the entire contained chlorine supply."

4. "in continuous communication with substantially the entire amount of chlorine supply"

The phrase "in continuous communication with substantially the entire amount of chlorine supply" is quite similar to the phrase discussed immediately above. Cecil's draws on this similarity to propose that it means exactly the same thing that Cecil's proposed "in constant fluid communication with substantially the entire contained chlorine supply" meant. Chaffin's proposition for this term differs little from his proposition for the above term as well.

In light of the recognized parallels between this phrase and the one discussed in Section 3 supra, the Court construes this phrase in an analogous way to the construction of the above phrase: "allowing access at all times to substantially the entire amount of chlorine supply."

b. Constant Thickness

The second disputed issue is the meaning of "constant thickness" in the rearfoot portion of Plaintiff's claim. Defendant argues that "constant thickness" means a uniform thickness and, therefore, it does not include a rearfoot portion of "varying thickness." Defendant Marathon Shoe Company's Opposition to Plaintiff's Cross Motion for Partial Summary Judgment of Infringement (Docket No. 51) at 2-3. Plaintiff claims that darker shading in figures 9-14 of his patent actually show a thicker edge around the entire rear portion of the sole. Because the Court assumes that Dr. Talarico did not intend to exclude a preferred embodiment of his own invention by the terms in Claim 1, the language in the specification describing the optional heel lift must be read in connection with the patent's description of a rear or heel portion of the sole of "constant thickness." Plaintiff argues that the term "constant thickness means "only that the rearfoot portion of the sole must not change the angular relationship of the heel with the ground" and "that the rearfoot portion of the sole is not angled to provide any compensation in that area." Plaintiff's Opp. to Defendant's Motion for Summary Judgment and Cross-Motion for Partial Summary Judgment of Infringement ("Plaintiff's Opp.") (Docket No. 34) at 9. The Court finds that the terminology "constant thickness" does not necessarily exclude a sole that is not entirely flat under the rearfoot.

The Court queries whether a contoured cup so distinguishes the angular relationships, however, as to remove it from the terms of Claim 1 of the 882 patent. Defendant urges the Court to construe the term "constant thickness" as excluding a "contoured-cup" edge around the heel. Plaintiff argues that his patent covers this type of "cupped" heel, and points to illustrations in his own patent to support this. Plaintiff alleges that his own drawings of a preferred embodiment include shading evidencing a slight cup shape. Plaintiff claims that the depictions in Figures 9-14 actually portray a rearfoot sole portion with edges of a higher or thicker depth than the middle portion of the heel. Plaintiff cites to 37 C.F.R. § 1.84(m), which states: "Shading is used to indicate the surface or shape of spherical, cylindrical, and conical elements of an object." Additionally, 37 C.F.R. § 1.84(l) provides that "lines and strokes [including shading] of different thicknesses may be used in the same drawing where different thicknesses have a different meaning." The Court construes the terms "constant thickness" to have their ordinary meaning of uniform thickness. "Constant thickness" read in the context of the remainder of the patent does not necessarily exclude a cupped shape edge. Plaintiff's statement, "that the rearfoot portion of the sole is not angled to provide any compensation" is not necessarily inconsistent with a tapering around the edge of the heel portion because, since the heel of a foot is rounded, a tapered edge would not necessarily affect the compensation or the angular relationship of the foot to the ground, but might simply enable the insole to be effectively placed into a shoe.
II

Cartner argues that the district court improperly construed the pertinent limitation because it discounted both the specification and prosecution history, instead relying heavily on the dictionary definitions of "constantly" and "operative." Accordingly, the district court's construction, which requires the "flow control orifice" to slow fluid flow even when there is no fluid flow in the third fluid line, is inconsistent with the '284 patent's specification. Cartner also contends that the prosecution history provides a clear definition of "said control orifice being constantly operative" that is inconsistent with the district court's construction.

Alamo responds that the district court, by relying on the plain meaning of claims 5 and 12, arrived at the correct construction. In addition, Alamo contends that the district court's construction properly "gives meaning to all the terms of the claims." Appellees' Br. 30. According to Alamo, this is so because the district court's construction requires the continuous slowing of fluid when the first valve is open or closed and, thus, takes into account the word "even" in the claim language. In addition, Alamo argues that the district court did not ignore the prosecution history, but instead found it unclear and "not explanatory." Under those circumstances, Alamo argues, the court was correct to discount the prosecution history.

III

We agree with Cartner. First, we think the district court's construction of "said flow control orifice being constantly operative" is contrary to the '284 patent's specification. The specification discloses that the "flow control orifice" is located in the third fluid line and "regulates the rate at which hydraulic fluid flowing through the third hydraulic fluid line 40 can reenter the first fluid line 14." '284 patent col.4 ll.15-30; fig.1. The "flow control orifice" can only regulate fluid flow when the third fluid line 40 contains fluid. However, regardless of whether the first control valve is open or closed, there are times when the third fluid line 40 does not contain fluid--namely, when the relief valve 42 is in the closed position, thereby preventing fluid from flowing into the third fluid line 40. Id. fig.1. Until relief valve 42 is in the open position, it prohibits fluid flow in the third fluid line 40. Significantly, both parties agreed to the construction of "as regulated by a relief valve" in the third fluid line to mean the "[r]elief valve controls whether and how much fluid may flow." Claim Construction, 2008 U.S. Dist. LEXIS 40797, 2008 WL 2169005, at *7 (emphasis added). In other words, because the relief valve controls whether fluid may flow into the third fluid line, there are instances when there is no fluid flow in the third fluid line. Thus, because the third fluid line does not always contain fluid, the district court's requirement that the flow control orifice continually slow fluid "when the first control valve is in the open or closed position" (regardless of whether there is fluid flow in the third fluid line) is contrary to the '284 patent's specification.

Of particular importance to the proper claim construction in this case is the prosecution history of the '284 patent. See, e.g., Mangosoft v. Oracle Corp., 525 F.3d 1327, 1332-33 (Fed. Cir. 2008) (finding further support for the proper construction in the prosecution history). Contrary to the district court's conclusion, the statements and amendments in the prosecution history are highly explanatory about the proper construction of "said flow control orifice being constantly operative." Specifically, the claims that would become claims 5 and 12 initially did not include the language "constantly operative" to describe the claimed "flow control orifice." In due course, the examiner rejected those claims in view of U.S. Patent No. 4,194,365 granted to Stoufflet et al. ("Stoufflet"). Stoufflet shows a "flow control orifice" (called an "adjustable constriction 53") located in a two-position "solenoid valve 48." Thus, the "adjustable constriction" in Stoufflet is only placed in the third fluid line, and therefore is only "operative," when the solenoid valve 48 is activated. See Stoufflet col.3 ll.54-67; fig.1. In other words, Stoufflet's "flow control orifice" (i.e., "adjustable constriction 53") is not permanently in the fluid line, but instead must be switched into the fluid line at certain operation times. Contrastingly, the "flow control orifice" of claims 5 and 12 in the '284 patent is permanently located in the third fluid line and does not need to be switched into that line at certain times. See '284 patent fig.1 item 44 (disclosing that flow control orifice 44 is not located in relief valve 42). Cartner's prosecuting attorney added the "constantly operative" limitation to reflect this difference, arguing that Stoufflet failed to teach a "flow control orifice, which is constantly operative, rather than being solenoid controlled." Thus, Cartner's prosecuting attorney did not add the term "constantly operative" to indicate that the "flow control orifice" "continuously slows fluid," as concluded by the district court. Rather, "constantly operative" was added during prosecution to explicitly describe the difference between the claims and the prior art--namely, that the "flow control orifice" was not located in a solenoid valve. Accordingly, the district court's construction of "constantly operative" is inconsistent with the meaning it
was given during prosecution.

For the foregoing reasons, we hold that the district court erred in its construction of the limitation "said flow control orifice being constantly operative" in claims 5 and 12. Taking into account the claim language, the specification, and the prosecution history as explained above, we construe "said flow control orifice being constantly operative" to mean "the flow control orifice continuously slows fluid flow when there is fluid flow in the third fluid line, whether the first control valve is in the open or closed position." Because we have revised the district court's claim construction, we vacate its judgment of invalidity of claims 5 and 12 pursuant to § 112. We therefore remand the case to the district court for further proceedings consistent with the claim construction we have set forth above.

Small Clearance Position

The parties dispute the meaning of the terms "small clearance position" and "contact." Claim 1 provides in relevant part:

Each segment of said seal ring including . . . an outer ring portion disposed within said seal ring groove for both axial and radial movement therein and having a pair of shoulders, extending axially in opposite directions for making radial contact respectively with said pair of spaced apart shoulders on said casing and thereby limiting said small clearance position . . . .

TurboCare does not dispute that the small clearance position limitation requires contact between the inward facing surface of the outer ring portion of the seal ring segment and the outward facing surface of the casing shoulders. It does dispute, however, the meaning of the term "contact." The district court construed that term as meaning direct contact, i.e. touching. In addition, the district court seemed to indicate that certain types of indirect contact such as indirect contact through "solely passive pads or buffers . . . to adjust the degree of clearance or compensate for wear and tear" would also constitute "contact" as that term is used in the claims of the '311 patent. TurboCare asserts that all indirect contact is "contact" within the meaning of the claims.

TurboCare points to language in the specification in which Brandon referred to "direct contact" between the neck of the seal segment and the casing. '311 patent, col. 2, ll. 62-64. TurboCare argues that this language implies that when Brandon used the term "contact" alone, he must have meant something other than direct contact. The language to which TurboCare directs us, however, is found in a discussion of the pressure seal that is formed between the neck of the seal segment and the casing as a result of axial fluid pressure. The use of the term "direct contact" to denote a pressure seal does not suggest that when the term "contact" is used elsewhere in the patent it must encompass objects that are in indirect contact, i.e., objects that do not touch one another but have other objects interposed between them. In the absence of a special definition of the term "contact" in the specification, that term should be given its ordinary and accustomed meaning. The district court properly construed the term, according to its ordinary meaning, to mean "touching." Whether so-called "indirect contact" could give rise to infringement is an issue of equivalency.

"contact" and "conductive" terms

The parties dispute the construction of various terms related to the conductive portion of the housing and the wheel, and the contact between the two. MHL argues that the term "contact" is a commonly used word in the electrical field and needs no construction. MHL contends that in the context of the '516 claim language and patent specification, "contact" merely refers to an electrical contact that allows a signal to be conducted from a conductive portion of the housing to the conductive wheel. MHL points to dependant claim 4 that recites a "conductive elastomeric seal" that is capable of providing an electrical path between the housing and the wheel. See '516 patent, cl. 4. Therefore, MHL argues, the claims strongly support the inclusion of indirect contact.
Defendants also cite to the claim language in response. Claims 1, 7 and 10 recite the "elongate portion being sized to allow . . . contact the conductive wheel to allow transmission of the signal using the conductive wheel." See, e.g., id. at cl. 1. Defendants argue that if the applicants intended to claim an indirect electrical connection that did not require "touching," the size of the elongate portion would be irrelevant. Defendants further argue that dependent claim 4 does not require an elastomeric seal to be "squeezed between" the housing and the conductive wheel. To the contrary, they contend that Figure 7 shows that the seal does not need to come between the two or prevent the housing from directly touching the wheel. Defendants direct the Court to the dictionary definition of "contact" to generally mean "touching." See, e.g., THE AMERICAN HERITAGE COLLEGE DICTIONARY, 299-300 (3d ed. 1993) ("contact" means "[a] coming together or touching, as of objects or surfaces"); THE NEW SHORTER OXFORD ENGLISH DICTIONARY, Vol. 1, 491 (1993) (defining "contact" as "[t]he state or condition of touching; an instance of touching").

Volkswagen argues that the description of various structures in the specification disclosed by the applicants as establishing electrical conductivity implies direct metal-to-metal contact between housing and wheel. For example, Volkswagen points to the patentee's disclosure of a "whisker connector 172" in Figure 4 to provide electrical conductivity between housing and the wheel rim in one. See id. at Fig. 4, col. 10, ll. 14-18. Moreover, Volkswagen argues, the applicants have used the term "contact" synonymously with a direct contact throughout the specification. See, e.g., id., col. 9, ll. 59-61; col. 8, ll. 53-55.

The Court is not persuaded by the defendants' arguments. The Court agrees that in absence of any conflicting disclosure in the specification, the ordinary meaning of the term "contact" would be "touching." See TurboCare Div. of Demag Delaval Turbomach. Corp. v. General Electric Co., 264 F.3d 1111, 1124 (Fed. Cir. 2001) (construing the ordinary meaning of the term "contact" as "touching"). However, the Court finds that the inventors here clearly anticipated and disclosed the use of a seal that would "prevent air within the tire from escaping." A person of ordinary skill in the art would indeed appreciate the need for a seal between the housing and the wheel. Similarly, the use of a protective coating on a metal wheel designed to guard against road conditions would not be novel to such a person. Further, the Court finds that the manner in which the housing contacts the wheel is not an essential element of the invention. As both sides argue, the focus of the invention is to be able to use the wheel as an antenna for transmission of the tire pressure signal. Cf. On Demand Machine v. Ingram Indus., 442 F.3d 1331, 1340 (Fed. Cir. 2006) (holding that the focus of a patent guides the determination of the scope of the invention claimed). The Court finds it unnecessary, therefore, to limit the manner in which a contact may be made between the housing and the wheel. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (stating that claims are to be given their broadest meaning unless there is a clear disclaimer or disavowal).

The Court defines "contact" as "touching, either directly, or through a conductive seal."

Claim differentiation "refers to the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim." Curtiss-Wright Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006). However, claim construction positions based on claim differentiation are rebuttable, taking a secondary role if an alternate construction is dictated by the written description or prosecution history. See Regents of the Univ. of Cal. v. Dakocytomation Cal., Inc., 517 F.3d 1364, 1375 (Fed. Cir. 2008). After reviewing the claim language, specification and prosecution history, the Court concludes that the term "does not contact" should be construed as AUO proposes, according to its plain meaning without the additional temperature and thermal contraction and expansion limitations from claim 9 that inform LGD's proposed claim construction. Claim 9
depends on claim 1 and adds the limitations that "when the frame is disposed in the second position, a first gap is formed between the first supporting portion and the first constraining portion, and the first gap is an allowance for film expansion or contraction due to temperature variation; when the frame is disposed in the first position, a second gap is formed between the second supporting portion and the second constraining portion, and the second gap is an allowance for film expansion or contraction due to temperature variation." '157 patent, col. 9, ll. 16-20. During prosecution of the application for the '157 patent, the Examiner did not require the applicant to combine the elements of claims 1 and 9 into a single claim, and instead determined that claim 1 was separately patentable without any of the limitations of claim 9. AUO-10 at AUO-LGD 0001333, 0001452, 0001487-88; Tr. 1202:21-1203:6 (Smith-Gillespie). LGD points out that the embodiments of the '157 patent refer to thermal considerations, however limitations from the specification should not be read into claims. Claim 1 has no limitation relating to thermal expansion or contraction, and the Court is persuaded that, consistent with the doctrine of claim differentiation, claim 1 should not be read in a manner so as to incorporate the limitations of claim 9.

834

5. Contact Surfaces-Substantial Separation

The next term for interpretation is "contact surfaces" and "substantial separation" in claims 1 and 65 of the '486 patent. Unilin contends that "contact surfaces" and "substantial separation" as used in claims 1 and 65 of the '486 patent should be construed as "a surface on a locking element that comes into contact with a corresponding surface on an opposing locking element that prevents a sustained separation visible to the unaided eye of the user from a normal height viewing a flooring made up of joined panels." (Unilin Open. Br. 16-18.) Alloc maintains that "contact surfaces" should be interpreted as meaning "surfaces that abut one another when the panels are in their coupled position and prevent separation of the coupled panels in the horizontal direction away from each other at the joined edges." (Alloc Initial Mem. 12.)

A representative use of the terms appear in claim 1 as follows: "cooperative contact surfaces arranged to be engaged when adjacent identical ones of said panel are coupled together with their coupling parts cooperatively engaged to prevent substantial separation of two coupled identical ones of said floor panels at said upper side edges in a direction perpendicular to the edges of the panel sides and parallel to the undersides of the coupled floor panels." ('486 patent, 14:5-12)(emphasis added.)

The '486 patent specification provides background for the interpretation of the terms indicating that one of the "aims" of the invention is "a floor covering whereby the subsequent development of gaps is excluded or at least counteracted in an optimum manner, whereby also the possibility of the penetration dirt and humidity is minimalized." ('486 patent, 2:8-12.) In part, the invention consists "of hard floor panels which, at least at the edges of the two opposite sides, are provided with coupling parts, cooperating which [sic] each other . . . wherein the coupling parts are provided with integrated mechanical locking elements which prevent the drifting apart of two coupled floor panels into a direction perpendicular to the related edges and parallel to the underside of the coupled floor panels." ('486 patent, 2:14-22.)

The first portion of Unilin's proposed definition which states "a surface on a locking element that comes into contact with a corresponding surface on an opposing locking element that prevents a sustained separation," is largely consistent with the language of the claims and the patent specification. (Both Unilin and Alloc's proposed definitions use "surface" which is part of the phrases which they have asked the Court to define -- so apparently that term is understood by the parties and does not need interpretation. Indeed, "surface" is defined as "exterior or boundary of an object." See Jt. App. Ex. 4 1187. An attempt to substitute that term might make interpretation of the patent claims more difficult.)

But, what does Unilin mean by a "sustained" separation? And, is that synonymous with a "substantial" separation? Alloc's proposed definition omits the concept reflected by the word "substantial." The definition of "substantial" includes "significantly large." (Jt. App. Ex. 4 1176.) The definition of "substantial" is consistent with the specification and appropriately supplements the definition and, in the context of the patent claims and specification, is a more appropriate choice than "sustained."

Unilin also asserts that the term be interpreted to require that the contact surfaces lack separation visible to the "unaided eye of the user from a normal height viewing a flooring made up of joined panels." But, it has not demonstrated the basis for its contention. And, query, whose "normal height?" Is it the normal height of a person skilled in the art at the time of the
Alloc suggests that the language should also include that the separation prevented is that of "of the coupled panels in the horizontal direction away from each other at the joined edges." However, both claims 1 and 65 describe the directions in which separation is prevented so such descriptive language proposed by Alloc is superfluous.

Thus, the Court concludes "contact surfaces" and "substantial separation" as used in claims 1 and 65 of the '486 means "a surface on a locking element that comes into contact with a corresponding surface on an opposing locking element that prevents a significantly large separation."

B. "Sandwiched Between and Contacting" Includes Electrical Contact

JSC further argues that "sandwiched between and contacting" as used in claims 11 and 21 can only be interpreted as requiring direct physical contact between the exterior anti-static layers and the inner conductive layer. (Appellant's Br. at 35.) To support this assertion, JSC refers us to an amendment purporting to distinguish the claimed invention from the prior art. But nothing in the cited amendment indicates this contact must be direct physical contact, and JSC provides no additional evidence to support its contention. Meanwhile, Bradford's expert, Dr. Fowler, averred that:

"based on my experience (both teaching and industrial), the term 'contacting' in the claims of the 280 patent, as it would be understood by persons in the field of ESD [electrostatic discharge] materials considering the subject matter of the 280 patent, relates to the ability of an electrical charge to be transmitted through the [antistatic layer and the polyurethane layer] to [the interior conductive layer], so that there is an electrical contact between the layers. In other words, [the anti-static layer and the polyurethane layer] are in electrical contact with [the inner conductive layer]. . . . In all embodiments, regardless of whether there is direct or indirect physical contact, there is electrical contact.

(J.A. 177) (emphasis added). Nowhere in its brief does JSC attack this explanation. Accordingly, we likewise concur with the district court's construction that "contacting" as used in the 280 patent means electrical contact and direct or indirect physical contact.

5. "Contacting Relationship"

The bringing step calls for bringing "said corresponding contact surfaces of said electrically conductive terminals into contacting relationship with said corresponding contact surfaces of said conductor elements." Thomson argues that "contacting relationship" means "physical contact;" Innovatron argues that the term is one of art, meaning "a position favorable for correct alignment and electrical contact." The Commission held:

"We agree with the ALJ's construction that a contacting relationship is not established at the instant of physical contact, but instead when the card terminals and card reader elements reach a position favorable for making contact, that is, when they are roughly centered with regard to each other.

ITC at 6. The Commission further opined, "we agree that one of ordinary skill in the art would understand the bringing step to end with a position that allows a good chance of electrical contact." ITC at 7.

This Court is to interpret "contacting relationship" as one skilled in the art in 1978 would have understood the term. If the meaning were "physical contact" that meaning would be expressed far more readily by the phrase bringing the surfaces on the terminals "into contact" with the surfaces on the elements rather than "into contacting relationship." The term "relationship" adds a limitation. The Court holds that one skilled in the art would understand "contacting relationship" to mean that the terminals and elements are positioned favorably for good electrical contact."
2. Claim 16

The jury instruction is erroneous as to claim 16. Claim 16 requires only that the "housing contain[] a surface . . . which reflects light." '690 patent, col. 10, ll. 16-18 (emphasis added). The ordinary meaning of "contain" is "to have within." Webster's Third New Int'l Dict., 490-491 (1966). Thus, claim 16 does not require the reflecting surface to be located "on the inside wall of the housing cover."

However, to warrant a new trial, Ecolab must show that the erroneous jury instruction was in fact prejudicial. When the error in a jury instruction "could not have changed the result, the erroneous instruction is harmless." Environ Prods., Inc. v. Furon Co., 215 F.3d 1261, 1266-67, 55 USPQ2d 1038, 1043 (Fed. Cir. 2000) (citing 11 Charles Alan Wright & Arthur R. Miller, Federal Practice and Procedure § 2886, at 467-70 (2d ed. 1995) ("Errors in instructions are routinely ignored if . . . the error could not have changed the result."); Weinar v. Rollform Inc., 744 F.2d 797, 808, 223 USPQ 369, 376 (Fed. Cir. 1984) ("[A] reversal . . . is not available to an appellant who merely establishes error in instructions . . . . Where the procedural error was 'harmless,' i.e., where the evidence in support of the verdict was so overwhelming that the same verdict would necessarily be reached absent the error, or the error was cured by an instruction, a new trial would be mere waste and affirmance of the judgment is required."), cert. denied, 470 U.S. 1084, 85 L. Ed. 2d 143, 105 S. Ct. 1844 (1985).

This requires us to examine whether there was sufficient evidence at trial to support a finding of infringement under a correct instruction. We must therefore determine whether Ecolab presented sufficient evidence to support a finding that the Insect Inn IV trap "contains" at least one "surface . . . which reflects light" as required by claim 16. Ecolab argues that six surfaces qualify: (1) the shiny black plate located directly beneath the light source; (2) the portion of the white paper supporting the adhesive layer that is not hidden by the reflecting plate; (3) the Mylar strip behind the light source; (4) the support posts for the bulb; (5) the outer surface of the light bulb; and (6) the black matte inner wall of the housing cover. To determine whether any of these surfaces might qualify as a "surface . . . which reflects light" we consider the limitations of claim 16.

C. "An Ion Conductive Electrolyte Contained Within An Electrolyte Chamber Formed in Said Third Frame Member"

Defendants seek construction of the claim limitation "an ion conductive electrolyte contained within an electrolyte chamber formed in said third frame member." Defendants rely on The American College Dictionary (1964) to define the words "contain" and "within." The word "contain" is defined as "to have within itself; hold within fixed limits." The word "within" is defined as "in the compass or limits of; not beyond . . . ." Thus, defendants propose the phrase "contained within" means "within fixed limits and not beyond." Therefore, defendants contend the claim limitation means "the ion conductive electrolyte is within the fixed limits of an electrolyte chamber formed in the third frame member and not beyond." Defendants assert the patent specification is consistent with their definition because the embodiments show the electrolyte within fixed limits of, and not extending beyond, the third frame member. Moreover, defendants assert nothing in the prosecution history contradicts their proposed construction.

Dicon argues the meaning of the phrase "contained within" is clear to one of ordinary skill in the art and does not require a dictionary definition. Dicon asserts defendants' use of extrinsic evidence to interpret a term that is clear from the intrinsic evidence must be rejected and the phrase "contained within" should be given its ordinary and customary meaning. Further, Dicon contends defendants' attempt to make claim 1 read as if it were a "consisting of" claim that excludes other features, as opposed to a "comprising" claim that allows other features to be added, is erroneous. Dicon argues the preamble language quoted by defendants does not read "wholly contained within" and defendants are improperly placing limitations on the ordinary language of the claim.
Defendants' construction of "an ion conductive electrolyte contained within an electrolyte chamber formed in said third frame member" as meaning "the ion conductive electrolyte is within the fixed limits of an electrolyte chamber formed in the third frame member and not beyond," is sound. Nothing in the intrinsic evidence is inconsistent with defendants' proposed construction of the ordinary and customary meaning of the claim terms. Dictionary definitions may be used to assess the ordinary and customary meaning of claim terms. Tex. Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). Dicon does not argue defendants' definitions are incorrect. Instead, Dicon contends the meanings of the limitations are clear and do not need any definition. Nevertheless, the court construes "an ion conductive electrolyte contained within an electrolyte chamber formed in said third frame member" as meaning "the ion conductive electrolyte is within the fixed limits of an electrolyte chamber formed in the third frame member and not beyond."

b. "beverage container capture system . . ."; "container holder . . ."

* * *

The prosecution amendment of these phrases are similar to that of the previous phrases--"beverage container capture system" in claim 35 serves as the antecedent basis for "beverage container capture means" in claims 46, 47, 57, 58, 60, and 61 of the '930 patent, and "container holder" in claim 35 serves as the antecedent basis for "container holder means" in step (e) of claims 35, 41, 46, 57, and 58. Like the preceding phrases, however, these phrases are sufficiently descriptive. See '930 Patent, cl. 35, steps c-e (indicating that the "beverage container capture system" is operatively connected to a transporter and a controller; it is further capable of responding to a signal from the controller, capturing a beverage container from the container holder, and carrying it through the vend selection space to the delivery port); col. 28, ll. 42-47 (indicating that a "container holder" is a physical structure located in the internal cavity that physically forms at least one boundary of the vend selection space and is configured to hold a queue of beverage containers in an upright standing manner). The specification also provides a number of examples of the "beverage container capture system" and the "container holder." See '930 Patent, col. 9, ll. 40-49; col. 11, ll. 42-44; col. 14, ll. 30-39.

For these reasons, the court concludes that the terms are not subject to § 112, P 6.

III

Honeywell's infringement claim turns on the construction of claim 1 of the '501 patent. JVC argues that because the claim language requires that the mask be "contiguous" to the transparent member and that the transparent member be "contiguous" to the chip, claim 1 reads only on devices having a mask-transparent member-chip sequence. Honeywell, on the other hand, contends that neither the term "contiguous" nor anything else in the patent dictates that the elements must be arranged in that order.

This seemingly straightforward issue of claim construction is made difficult by the fact that the patent is so poorly drafted that it does not give a readily discernible answer to what would seem to be a basic question regarding the structure of the claimed invention. The district court struggled with the issue, as have we, and while we cannot fault the district court's efforts to make sense of the patent language, we conclude on the basis of all the evidence available to us that the district court's claim construction was too narrow.

A

Claim 1 recites that the transparent member containing the lenslets is "placed contiguous the chip," and that the opaque member having a plurality of transparent portions (i.e., the mask) is "placed contiguous the transparent member." The district court construed that language to require the mask to be placed on top of the transparent member and the transparent
member to be placed on top of the chip. In large part, the court premised that conclusion on its view that the term "contiguous" implied the absence of intervening structure. Thus, according to the district court, if the mask were positioned between the transparent member and the chip, the transparent member and the chip would not be "contiguous." From the court's remark that the transparent member would not be contiguous to the chip even if "the circuit chip is in contact with or next to the transparent member at the points of the holes," it appears that the court would regard the transparent member and the chip as not contiguous in such a structure, even if the two were touching.

Honeywell argues that the district court's claim construction is too restrictive. Honeywell correctly notes that claim 1 does not expressly require any particular ordering of elements, i.e., the claim does not explicitly require that the mask be on top of the transparent member and that the transparent member be on top of the chip. Honeywell further contends that the use of the term "contiguous" in claim 1 does not implicitly require that ordering of elements. In fact, as Honeywell interprets the term "contiguous," there need not even be contact between the elements in question. Rather, Honeywell argues, one element is contiguous to another if the two elements are simply near one another. In Honeywell's view, then, claim 1 reads on a device in which the mask is positioned between the transparent member and the chip, as long as there is close proximity between the mask and the transparent member, and between the transparent member and the chip.

Honeywell's proposed construction of "contiguous" is based on a definition of the term appearing in the prosecution history of the application that matured into the '501 patent. The definition offered by the inventor was as follows: "in actual contact; touching; also, near, though not in contact; neighboring, adjoining; near in succession." The inventor further explained that two elements would be "contiguous" if they were placed "in actual contact" or if they were "near, though not in contact."

The district court erred in not according more weight to the inventor's definition. It is well settled that a patentee may define a claim term either in the written description of the patent or, as in the present case, in the prosecution history. Mycogen Plant Science v. Monsanto Co., 243 F.3d 1316, 1327, 58 U.S.P.Q.2D (BNA) 1030, 1039 (Fed. Cir. 2001). Frequently, a definition offered during prosecution is made in response to a rejection, and is entered in conjunction with a narrowing amendment. See, e.g., Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1677 (Fed. Cir. 1995). Such a definition limits the scope of the claim, preventing the patentee from later recapturing what was previously surrendered. Although the inventor's definition does not have a narrowing effect, it is nonetheless relevant in indicating the meaning that the inventor ascribed to the term. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996) ("The record before the Patent and Trademark Office is often of critical significance in determining the meaning of the claims."); E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1438, 7 U.S.P.Q.2D (BNA) 1129, 1135 (Fed. Cir. 1988) (prosecution history "must be examined to ascertain the true meaning of what the inventor intended to convey in the claims").

The definition of "contiguous" set forth in the prosecution history--"in actual contact" or "near, though not in contact"--is taken from a standard English dictionary. Although the definition is broad--the most common meaning of "contiguous" connotes actual contact, not general proximity--that fact is not disqualifying, because the inventor made clear that he intended to invoke the broadest meaning of the term "contiguous," not just the most common meaning. We therefore conclude that the term "contiguous," as used in claim 1, does not require actual contact between elements that are described as "contiguous," and that the use of that term in claim 1 does not necessarily confine the scope of the claim to devices in which the elements are positioned in the mask-transparent member-chip order.

Admittedly, accepting Honeywell's definition of "contiguous" does not wholly resolve the issue of infringement, particularly with respect to the problem of intervening structure. The court rejected defining "contiguous" as "near" because it would "lead to the conclusion that the letter 'A' is contiguous the letter 'C'"--a proposition that the district court found untenable. The court then offered a second hypothetical to illustrate what it regarded as the limits imposed by the term "contiguous": "For example, if one makes a sandwich placing a piece of cheese between the bread and the bologna, the bread and the bologna are not contiguous regardless of whether the cheese is American or Swiss."

Because the structure of the accused device is not entirely clear from the record on appeal, we are unsure whether the "Swiss cheese" problem will be implicated in the determination of infringement on remand. We feel compelled, however, to offer some guidance on this issue, particularly since the district court focused on it so prominently.

To take the easiest case first, we think it evident that the bread and the bologna in the district court's example would be contiguous if they were touching through the holes in the Swiss cheese. It also seems obvious that the bread and the bologna
would not be contiguous if American cheese instead of Swiss cheese separated them so that the cheese intervened between the bologna and the bread at all points. We therefore reject what seems to be the broadest implication of Honeywell's argument—that two elements can be considered contiguous if they are near one another even if they are separated by an intervening structure at every point. The absence of intervening structure is inherent even in the broad definition of "contiguous." See, e.g., Webster's Third International Dictionary 492 (1966) ("contiguous" defined as "next or adjoining with nothing similar intervening . . . immediately preceding or following in time or sequence: without intervening interval or item"). The district court, however, seemed to be principally concerned with the thornier question whether the bread and the bologna are contiguous if they are not touching but there is nothing between them at the places where there are holes in the Swiss cheese. Under the definition of "contiguous" offered by Honeywell, we believe the answer to that question depends on whether, in context, it can be said that the bread and the bologna are "near" one another. That is, the question whether the two are contiguous depends in part on the thickness of the layer of Swiss cheese. Under Honeywell's definition of "contiguous" as "near, though not in contact," the bread and the bologna would be contiguous at the points where the holes in the Swiss cheese were located if the bread and the bologna were close to one another at those points.

By analogy, the transparent member would be contiguous to the circuit chip within the meaning of Honeywell's definition if the transparent member extended through the holes in the mask to touch or almost touch the circuit chip. On remand, then, the district court must determine whether there is some point at which the transparent member and the chip are not separated by some intervening structure, and whether the distance between the transparent member and the chip at that point is sufficiently small, in the context of the structure as a whole, to satisfy the requirements of contiguity recited in claim 1.

B

The district court's claim construction was heavily influenced by its interpretation of the written description of the '501 patent. The court interpreted the written description to require the claimed invention to solve both problems identified in the prior art: the exposed surface area problem and the surface imperfections problem. Because both problems are solved by the mask-transparent member-chip structure, but not by the transparent member-mask-chip structure, the district court concluded that the written description dictated that the claim must be construed to cover only the mask-transparent member-chip structure. In reaching that conclusion, the district court placed particular importance on the following sentence from the written description: "While the mask 30 could be placed adjacent the circuit board 10 and under the lenslet member 20 to likewise mask out the circuit areas on the chip 10, this arrangement would not help the problem of imperfections in the surface of member 20 causing scattering of light to strike other detectors." '501 patent, col. 2, l. 65 to col. 3, l. 2. The court found that this passage constituted a "clear case of disclaimer of subject matter," analogizing to SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337, 58 U.S.P.Q.2D (BNA) 1059 (Fed. Cir. 2001).

In SciMed, which involved patents on a type of medical catheter used in angioplasty, the common specification of the patents at issue stated that the catheters of "all embodiments of the present invention contemplated and disclosed herein" employed a coaxial lumen. Id. at 1343, 58 U.S.P.Q.2D (BNA) at 1065. We held that the "broad and unequivocal" language of the specification defined SciMed's invention in a way that excluded lumens that were not coaxial. Id. at 1344, 58 U.S.P.Q.2D (BNA) at 1065.

There is no similar disclaimer of subject matter in the '501 patent. The language in the '501 patent on which the district court relied is far less explicit than the "all embodiments" language in the patents at issue in SciMed. Moreover, the language in claim 1 of the '501 patent makes reasonably clear that the inventor did not intend to limit the scope of the claim to structures that would solve both of the prior art problems identified in the background section of the written description of the '501 patent.

Claim 1 recites that the opaque member is "placed contiguous the transparent member so as to permit radiation through the lenslets to reach the detector areas and to prevent radiation through the transparent member from reaching the circuit area." That language expressly requires that the opaque member must be positioned to solve the exposed circuit area problem. The claim does not, however, state that the opaque member must be positioned to prevent radiation from reaching the detector areas except through the lenslets. Thus, claim 1 does not require that the opaque member be situated to solve the surface imperfections problem.

That omission is significant. The fact that the patentee chose to include language in claim 1 relating to only one of the two cited prior art problems is persuasive evidence that the claim does not require the solution of both problems. Instead, the
natural implication is that embodiments within the scope of claim 1 must solve only the recited problem of radiation reaching exposed circuit areas. We therefore reject JVC's argument that the term "contiguous" must be construed in a manner that would lead to the solution of both prior art problems discussed in the written description, when claim 1 requires the solution of only one of those problems.

That conclusion is reinforced by the context of the sentence on which JVC relies. The sentence in the written description immediately following the purported disclaimer states:

It is therefore seen that I have provided a means for overcoming the problem of light passing through areas of a lenslet array in such a way as to be received by the circuit apparatus on an auto focus module thus overcoming the problem of spuriously generated signals.

'501 patent, col. 3, ll. 3-7.

That sentence is plainly intended to serve as a general characterization of the invention. Significantly, the sentence refers only to the exposed circuit area problem, i.e., the problem of light being "received by circuit apparatus," which can lead to "spuriously generated signals." There is no suggestion in that characterization that the invention must also solve the surface imperfections problem. We therefore conclude that the description of the mask-transparent member-chip structure, when considered in context, is not a disclaimer of subject matter, but simply an explanation of why the "mask on top" structure is a preferred embodiment of the invention. Such a description of a preferred embodiment does not, of course, limit the scope of the claims. See Electro Med. Sys. SA v. Cooper Life Sciences, 34 F.3d 1048, 1054, 32 U.S.P.Q.2D (BNA) 1017, 1021 (Fed. Cir. 1994).

Two other portions of the written description provide further support for Honeywell's argument that the invention of claim 1 is not required to solve both cited prior art problems. Like the language of claim 1, the Abstract mentions only the exposed circuit area problem. It states that the mask is positioned to "permit[] radiation to pass through the lenslets and be focused on the detector areas but prevent[] light from passing through transparent areas adjacent the lenslets and striking the circuit areas." The fact that the Abstract mentions only the exposed circuit area problem supports the argument that claim 1 should not be read as requiring a structure that will solve both that problem and the surface imperfections problem.

The Summary of the Invention, although not free from ambiguity, also contains language that supports Honeywell's proposed construction of the claim language. The Summary consists of a single sentence, which reads as follows:

The apparatus of the present invention utilizes a light aperture or masking means placed in the area adjacent the lenslets or adjacent the detector areas of the circuit chip which mask is opaque to light except in the areas of the aperture and thus prevents light from passing through the translucent member except through the lenslets and thus prevents light from reaching the circuit areas of the chip other than the detectors.

'501 patent, col. 1, ll. 47-54.

The first portion of that sentence, which states that the mask may be placed either "in the area adjacent the lenslets or adjacent the detector areas of the chip," is squarely contrary to JVC's argument that claim 1 requires the mask to be adjacent to the lenslets but not adjacent to the circuit chip, and it buttresses Honeywell's argument that the mask could either be placed above the lenslets and the chip or between the lenslets and the chip.

To be sure, the persuasive force of the Summary is undercut somewhat by the fact that the sentence contains an internal inconsistency. The second portion of the sentence states that the positioning of the mask "prevents light from passing through the transparent member." That would happen only if the mask were placed above the lenslets. Thus, while the first portion of the sentence suggests that the mask may be placed adjacent to the detector areas underneath the lenslets, the second portion describes a condition that would apply only if the mask were placed above the lenslets.

In light of the inconsistency between the two portions of the sentence quoted above, it appears that the Summary of the Invention was not well thought out. For that reason, we do not attach conclusive weight to the description of the invention that appears in the first portion of the Summary. Nonetheless, the first portion of the sentence so plainly contemplates placement of the mask either next to the lenslets or next to the detector areas of the chip that it is difficult to imagine that the
author of that passage could have intended claim 1 to be as narrow as JVC suggests.

C

JVC also contends that during the prosecution of the patent the inventor made a representation that the mask-transparent member-chip order was required by the claims. JVC argues that in view of that admission it would be improper to read the claims as broadly as Honeywell urges. As we read the prosecution history, however, there was no such admission.

When the application that matured into the '501 patent was filed, the inventor submitted several references, including a published Japanese patent application. Although the inventor stated that his invention "solves a somewhat different problem in a somewhat different way," he nevertheless indicated an intent to swear behind the Japanese reference. To that end, the inventor submitted affidavits from himself and two others describing the activity that predated the effective date of the Japanese reference.

The examiner found the affidavits insufficient to swear behind the Japanese reference. Specifically, the examiner complained that the affidavits and the accompanying exhibits did not show that the mask was placed contiguous to the transparent member and that the transparent member was placed contiguous to the circuit chip, as required by claim 1. The inventor responded by arguing that the affidavits did show that he had reduced to practice a device having "the proper positioning as required by the claims."

JVC contends that the statement by the inventor requires a construction of claim 1 in which the mask is situated above the lenslets. We disagree. The prosecution history contains no representation by the inventor that claim 1 requires a particular ordering of elements. Instead, the inventor made a much different representation--that an embodiment of the invention having a mask-transparent member-chip structural order satisfies the requirement of claim 1 that both the mask and the transparent member, and the transparent member and the chip be "placed contiguous" to one another.

The inventor was arguing that he had reduced to practice an embodiment of his invention that was within the scope of claim 1 prior to the effective date of the Japanese reference. In making that argument, the inventor took issue with the examiner's contention that the affidavits the inventor submitted did not demonstrate that the mask was contiguous to the transparent member and that the transparent member was contiguous to the circuit chip. In response, the inventor stated that in the embodiment of the invention referenced by his affidavits, the mask and the lenslets were contiguous because the mask was placed "on a lenslet and detector assembly." Similarly, the inventor stated that the lenslets and the chip were contiguous because the lenslets and detectors were referred to as "an assembly."

In making the latter point, the inventor recited the dictionary definition of "contiguous" referred to above and concluded that "placing the mask on the lenslet and detector assembly assures that these elements are either 'in actual contact' or are 'near, though not in contact.'" The inventor thus contended that his earlier embodiment of the invention had elements that were contiguous within the meaning of that term as used in the '501 patent. However, arguing that a particular embodiment satisfies the definition of "contiguous" is quite different from arguing that "contiguous" is limited to the order of elements found in that embodiment. When the inventor stated that he had demonstrated that the elements of the invention were "mounted as required by the claims," he was explaining that his assembly satisfied the requirement of contiguity; he was not arguing that the claims required that the elements of the claimed device be arranged in a specific order. For that reason, the prosecution history does not limit the express definition of the term offered by the inventor.

In sum, we conclude that the district court's claim construction was unduly restrictive. There are several possible structures that permit the transparent member to be contiguous to the chip and the mask to be contiguous to the transparent member even though the mask is not located on top of the transparent member. Although we decline Honeywell's invitation to decide that the broader claim construction that we adopt dictates a finding of infringement by JVC's imaging chips, Honeywell is entitled to an opportunity to show that JVC's chips infringe under this construction. We therefore reverse the judgment of non-infringement and remand for further proceedings on that issue.

GO BACK

841

D. "Continuous"
Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs claim that "continuous" means "uninterrupted," while Gore contends that "continuous" means "endless."

In the context of the '418's specifications, based on the concentric series of parallel channels that appears in the '418 patent's specifications, the term "endless" accurately describes each channel because within each channel, there is no beginning or ending point. Additionally, "endless" is consistent with a plain and ordinary understanding of the word "continuous." See Pl. Claim Constr. Mem., Ex. H, Random House Dictionary of the English Language Second Edition, at 440 (defining "continuous" as "uninterrupted in time; without cessation"). Although "uninterrupted" is also an accepted meaning of "continuous," the term "uninterrupted" implies a temporal component. See id. With respect to descriptions of spacial dimensions, such as the descriptions of the parallel channels on a sheet, the term "endless" is more appropriate than the temporal term "uninterrupted." Accordingly, the Court determines that "continuous" means "endless."

D. "Continuous"

Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs claim that "continuous" means "uninterrupted," while Gore contends that "continuous" means "endless" because the preferred embodiment shows the channels to be in concentric hexagons, meaning that the channels are without beginning or end.

Gore's proposed narrow construction is inappropriate when looking at the claims and specifications of the entire patent. For example, claim 10 specifically claims the "sheet in claim 1 wherein the channels and ridges are straight." U.S. Patent 6,921,418 at 10:20-21. The claim 10 language concerning straight channels is instructive as to the meaning of the term "continuous" within claim 1. See Phillips, 415 F.3d at 1314. ("Other claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term."). There is no way for a "straight" channel to be without beginning or end on a finite surface; as such, construing "continuous" to mean "endless" is unworkable if meaning is to be given to the language in the claims of the '418 patent.

The language of claim 10 shows that the inventor contemplated more than just channels formed into concentric hexagons without a beginning or end and to ignore this would be a manifest error in construing the language of the claims. A better construction for "continuous" is "uninterrupted," proposed by Ledergeber, because it would make sense to one skilled in the art whether the channels are straight, concentric, or in some other form. Therefore, the Court construes the term "continuous" to mean "uninterrupted."

Plaintiff proposes the following construction for "continuous air flow generator" in Claim 1 of the '662 Patent:

The word "continuous" in the term "continuous air flow generator" refers to dynamic adjustments being made so that there will be a continuous or consistent baseline pressure based on the user selected amount. The continuous air flow generator is used to supply air pressure to the system to compensate for leaks in the system and repeated inhalation and exhalation of the user. Together with the pressure compensation feedback system, about which the Court will instruct you in a moment, the continuous air flow generator provides continuous, or dynamic, adjustments so that the user selected pressure can be continuously maintained.

To support such a construction, Plaintiff points to the specification and the prosecution history. Specifically, Plaintiff asserts that the specification and prosecution history discuss dynamic adjustments that are made in the device to maintain a user-
selected level of pressure in the air bladder. Plaintiff also contends that the term "continuous air flow generator" is synonymous with "positive air flow generator."

Defendant contends that "continuous air flow generator" must be construed as a generator that produces continuous or non-stop air flow.

In the context of the '662 Patent, the Court rejects Defendant's proposed construction because it disregards the specification language that describes the continuous air flow generator as one that provides dynamic adjustments to maintain a user-selected air pressure. The specification and the prosecution history point to such a construction.

First, the Summary of the Invention equates the continuous air flow generator with a "positive air flow generator" and provides that such mechanism compensates for leakage:

The present invention includes a positive air flow generator operably connected with the oscillatory air flow generator. The positive air flow generator compensates for any leakage in the system, including the hoses and bladder. Also, the positive air flow generator, in connection with a feedback system, maintains the desired peak pressure delivered by the bladder, independent of variations in the bladder and the patient.

( '662, c. 2, ll: 24-36.) Further, the specification provides:

Although diaphragm 19 approximates a perfect system in terms of displacement of air into and out of bladder 2 on each stroke, remaining parts of the closed system are less perfect. For example, bladder 2 typically leaks air at a variable rate that is difficult to model. The amount of air leakage is influenced by many factors, including variations in production of the bladder, age, use, and other factors.

Also, tubes 3 and the various connections within the system may leak. Additionally, the air pressure delivered to bladder 2 must be varied due to the repeated inhalation and expiration of the user during treatment, and also due to the size of the particular user. Therefore, positive air pressure generator 16 is used to supply positive air pressure to the system to compensate for the above-identified variables.

( '662, c. 5, ll: 226-40.) The specification also provides:

Positive air flow generator 16 and pressure-compensation feedback system 50 provide several advantages. First, positive air flow generator 16 dynamically adjusts the peak pressure in air chamber 17 to provide a consistent peak pressure based on the user selected peak pressure, independent of leaks in the system, size of the user, condition of the bladder, and the repeated inhalation and expiration of the user. Maintaining a constant peak pressure provides for increased efficacy of treatment.

( '662, c. 6, ll: 1-9.)

The prosecution history provides additional support for an interpretation of the term "continuous air flow generator" that encompasses dynamic adjustments. Specifically, the prosecution history's differentiation from the '263 Patent is instructive:

Applicants respectfully submit that claim 1, as amended, is patentable over Warwick, et al. (U.S. Patent No. 4,838,263). Claim 1 as amended, includes limitations not found in Warwick et al. First, Warwick does not disclose a "continuous air flow generator . . .". Warwick et al. only discloses a storage tank 130 for use in reinflating the vest during the expiration cycle of a breath when the user actuates switch 162 (column 6, lines 12-26). Storage tank 130 does not provide, and is not capable of providing, a continuous, baseline pressure as does the continuous air flow generator of the present claimed invention. As stated in the specification of the present application as originally filed, air flow generator 16 dynamically adjusts the pressure in air chamber 17 to provide a consistent pressure based on the user selected pressure, independent of leaks in the system, size of the user, condition of the bladder, and the repeated inhalation and expiration of the user. Maintaining the pressure also provides for increased efficacy of treatment. (See page 11, lines 3-11 of the specification.) The storage tank 130 of Warwick et al. does not perform this function and, consequently, does not provide the advantages of the present claimed invention.

- 1284 -

Thus, the Court finds that the specification and the prosecution history determine the construction of the term "continuous air flow generator" in this claim. In so holding, the Court acknowledges Defendant's contention that the term "positive air flow generator" in the claim was modified and renamed "continuous air flow generator" during the prosecution of the patent. See Response to First Office Action for '662 Patent at 4-5. It appears to the Court that this amendment was made to clarify the connection between the positive air flow generator and the associated feedback and control means and, thus, to distinguish the invention from prior art. See id. Thus, in the context of the '662 Patent, the terms "continuous air flow generator" and "positive air flow generator" are used somewhat synonymously. The continuous air flow generator is a positive air flow generator that is connected to a feedback and control system to provide dynamic adjustments in order to maintain a user-selected air pressure.

Therefore, the Court construes the term "continuous air flow generator" to mean a mechanism that is used to supply and maintain a user-selected air pressure in the air chamber, thus compensating for leaks in the system and for repeated inhalation and exhalation of the user. Together with the pressure compensation feedback system, the continuous air flow generator provides dynamic adjustments in order to maintain such a user-selected air pressure.

C. Contiguous Beam

<tbody>
<tr>
<td>Said array of light emitting diodes focused/configured to form a contiguous beam</td>
<td>the array of light emitting diodes is designed to form a single beam that projects from the array forward and has no dark areas</td>
</tr>
</tbody>
</table>

The next disputed term in claim 1, "said array of light emitting diodes focused to form a contiguous beam," describes the purpose and arrangement of the LEDs in the patented invention. A substantially similar term, "said array of light emitting diodes configured to form a contiguous beam of light," appears in claim 12. The construction of both of these terms turns on the meaning of "contiguous beam," which the court presumes maintains the same meaning in both claims. See Paragon Solutions, LLC v. Timex Corp., 566 F.3d 1075, 1087 (Fed. Cir. 2009)(holding identical terms to have the same meaning when appearing elsewhere in the patent).

Essentially, the parties' constructions differ in how they would require the light emitted from the various LEDs to overlap. Plaintiffs' construction as "create[ing] a pool of light that illuminates objects," would require only that the light overlap at a single point, namely, the point at which a hypothetical object is in the wearer's view. Plaintiffs' construction would render the location of the light source or sources under the patent irrelevant; their proposed language would seem to encompass any arrangement of LEDs so long as the separate beams of each were directed to eventually converge at some point.

Neither the language of the claim, the context of the specification, nor the prosecution history supports Plaintiffs' reading. In allowing the '831 patent, the patent examiner found the production of a "contiguous beam" to be a novel achievement as compared to the prior art. (Notice of Allowability, Apx. 2, 113.) The Johnson patent, which involves distal light sources that are "separately mounted" such that their "axes converge at an acute angle . . . setting the focal point of the lamps at a predetermined location out from . . . the wearer's eyes," did not achieve a "contiguous beam" in the eyes of the patent...
examiner. (Id.) Yet, Plaintiff's proffered construction of "contiguous beam" would seemingly embrace even the separate distal headlamps of the preexisting Johnson patent. The court does not read the '831 patent to endow the term "contiguous beam" with the capacious meaning urged by Plaintiffs.

Defendant construes "contiguous beam" to require that light from adjacent LEDs join to form "a single beam" with "no dark areas." Though Defendant's reference to "no dark areas" is unnecessary surplusage, the court concludes that Defendant's construction is closer to the way a person of ordinary skill in the art would understand the term "contiguous beam.

The ordinary meaning of "contiguous" connotes objects that are "touching along a boundary or connected throughout in an unbroken sequence." WEBSTER COLLEGIATE DICTIONARY at 250 (10th ed. 1997). Specifically when describing two angles, "contiguous" means "having the vertex and one side in common." Id. at 250 ("of angles: ADJACENT 2"); Id. at 15. This ordinary meaning appears to be the usage employed in the patent. The patent specification describes each individual LED as "emitting a cone of light that spreads out at angles to about 20 degrees to each side of a central axis of the cone." (831 Patent, Col. 4, ll. 3-5). "If there are at least two LEDs aligned, then the LEDs can emit light fanned out to about 40 degrees from each other and maintain a beam with a continuous pool of light." (Id. Col. 4, ll. 5-8). The specification describes an LED array in which angled cones of light fully share one common side and appear, therefore, to create a single, unbroken beam of light. Thus, the specification's reference to a "continuous pool of light" describes a wholly continuous light along the entire length of the beam, rather than, as Plaintiffs would suggest, a single overlap of light at some distant point.

The patent describes an arrangement, by which multiple LEDs are "focused" and "configured" to form "a contiguous beam." This is one instance that necessitates a departure from the general rule of patent construction that a noun preceeded by the article "a" or "an" may refer to either the singular or plural form of the noun. See Tivo Inc. v. Echostar Comm. Corp., 516 F.3d 1290, 1303 (Fed Cir. 2008)(holding that the a patent's reference to two "components" combined into a "stream" clearly evidenced the singular form of the word "stream"). The language of the claim here refers to a single beam.

This interpretation is bolstered by consideration of the various embodiments of the patent. All depict a tight LED grouping, which (when the beam is depicted) is shown to project a single beam of light. While limiting a patent to a preferred embodiment is improper, the embodiments taken as a whole may be an important indication of how a person of ordinary skill in the art would understand the claims. See Phillips, 415 F.3d at 1323-24. In the court's view, the most illustrative example of a "contiguous beam" is found in Figure 22, which depicts a single, unbroken, conical beam of light emanating from a tight grouping of LEDs on the brim of the headgear. (831 patent, Fig. 22.) This depiction of a single, continuous, unbroken beam is reinforced by descriptive language in the specification:

The light emitting diodes can be aligned relative to each other in such a way as to project a beam of light. The beam of light can be contiguous, non-segmented or in a substantially conical shape either fanned out or oval shaped and the like. The beam has no dark areas. The LEDs can be parallel to each other or aligned such that the light emitted forms a contiguous pool of light that washes the objects that are illuminated by the beam.

(831 patent, Col. 3-4, ll. 61-1.) The specification clearly refers to a single beam, described as containing "no dark areas" and forming a "contiguous pool of light." Though the specification contemplates a beam with either an oval or fanned out shape, in both cases it describes a unified, continuous beam. The modification of "contiguous" with the related term "non-segmented" is also telling, as it suggests that the patent's use of "contiguous" is consistent with the term's ordinary meaning of "connected throughout in unbroken sequence" and, specifically with regard to angles, "having a vertex and one side in common."

Accordingly, the court adopts the following construction of "Said array of light emitting diodes focused/configured to form a contiguous beam": "The array of light emitting diodes is arranged to project what appears to be single, unbroken beam of light."
The parties propose the following constructions for "continuous retainer member surrounding the inner head," which is present in claim 43. Dkt. No. 114.

RTI
A nonretractable part of the retraction mechanism that encircles the inner head of the needle holder, and retains the retraction mechanism

BD
A nonretractable part of the retraction mechanism, separate from the needle holder, that encircles the inner head of the needle holder, and retains the retraction mechanism by frictional force with the wall of the syringe

RTI and BD proffer the same arguments as those discussed above in connection with the term "retainer member." Dkt. Nos. 111 at 13-14. Once again, the dispute between the parties is two-fold: (1) whether the holding force must be a frictional force, and (2) whether the needle holder and retainer member must be separate parts.

For the reasons stated above, this Court finds that the invention operates through the use of a clamping or frictional force and that there is no requirement that two components be separate parts. Accordingly, the Court finds that the term "continuous retainer member surrounding the inner head" means "a non-retractable part of the retraction mechanism that encircles the inner head of the needle holder and uses some clamping or frictional force to keep the needle in the projecting position until released."

The district court also erred in its construction of the term "continuous." The accepted meaning of "continuous" is: "marked by uninterrupted extension in space, time, or sequence." Webster's Ninth New Collegiate Dictionary at 284. Relying on this definition, the trial court construed "continuous slice" to mean a length of flattened food product without any interruptions. Schreiber Foods, 92 F. Supp. 2d at 860. The problem arises, however, in defining an interruption. To define "interruptions," the trial court again overemphasized the specification. 3 Specifically, the district court determined that "any creasing or cross-sealing across the width of the web of film and product, which pushes out some of the food product from that cleated or cross-sealed zone even if a thin layer of food product remains [] creates an interruption that results in separate or discontinuous slices or ribbons." Schreiber Foods, 92 F. Supp. 2d at 864 (emphasis added). This emphasis on "interruptions" impermissibly imported the limitation of "without any creases" into the term "continuous." The specification does not preclude any creases in a "continuous slice." Accordingly, this court reverses the district court's construction of the term "continuous."

5. What is the Proper Construction for the Phrase "continuous webbing structure" in the '311 Patent?

Claims 1 and 94 of the '311 patent contain the phrase "substantially continuous webbing structure." KXI contends this phrase means a thin, substantially continuous film or web which has the purpose to create a self-supporting structure for the
primary materials. KXI further contends the web is continuous but not solid, and it may have a large volume of voids or pores filled with air or gases.

Culligan contends this phrase is indefinite, as the specification offers no meaningful definition of the phrase. If the phrase is not indefinite, then Culligan contends an additional element must be added to the definition of the claim: that material compositions characterized as such are readily converted into fibers by the application of stress. In support of this element, Culligan cites the '311 patent's specification at column 5, lines 33-41 which reads:

an additional feature of the products formed by this process is that they can be 'fiberized.' The web matrix portion of the resulting structure, when formed from most common crystalline polymers can be converted to a matrix of fibers holding the primary particles in 'pockets.' This can be achieved through the application of even a mild shear.

Culligan also cites column 7, lines 27-36, which reads:

[continuous web matrix] materials have the unique characteristic that the binder within these structures, when a crystalline polymer, can be converted to a dense matrix of fibers by the application of stress to the structure. Such stress can be the result of pulling, cutting, or compressing the [continuous web matrix] structure.

According to Culligan, this is the only means offered by the patent specification "for anyone to determine whether or not they have a [continuous web matrix] structure as opposed to something else. . . ." According to KXI, it "does not dispute that the examination of fibers after the application of shear is one test that can be performed to determine if an article includes a continuous web matrix." KXI argues, though, this is not the only test, and alleges this test is particularly difficult to perform on end products using carbon primary particles ("testing for the formation of fibers is extremely subtle because the testing itself can destroy the structure."). Also, KXI argues, this test may not be accurate because only a portion of the binder need be converted to meet the claim limitations.

The court will not address Culligan's indefiniteness argument at this time, as this goes to the validity of the claim, and not how it should be construed. The court agrees in part with Culligan. The court finds that the specification defines "continuous webbing structure" as material compositions that can be converted into fibers. The court, however, finds that the term "readily" proposed by Culligan in its definition is an extraneous limitation. Accordingly, the court construes "continuous webbing structure" to mean a thin, substantially continuous film or 'web' which may have a large volume of pores or voids, and which has the purpose to create a self-supporting structure for the primary materials, and which is convertible into fibers.

2. The term "continuously heating" in claim 1 is construed as: "heating without interruption." 3 Plaintiff argues that this term did not require construction or, in the alternative, that the term be construed as "[a] process step in which the product pieces are heated as the product pieces are being carried in a continuous manner along a path of travel by a conveyor or other carrying system." Dkt. # 49, at 1. Defendant argues that the term should be construed as "[h]eating the product at a constant heating temperature." Dkt. # 51, at 16. By its plain meaning, this term refers to the manner and duration of heating, rather than the temperature at which products are heated. This is consistent with the language of the dependent claims, for example where "products are continuously heated . . . by continuously conducting said already cooked food products through an interior of a heating apparatus . . . ." '299 Patent, col. 12, Ins. 10-12. The specifications clearly contemplate applications in which the products are conducted through a heating or cooling apparatus. Further, the specifications focus primarily on the temperature of the products, rather than the temperature of the heating or cooling apparatus. Defendant argues that plaintiff described "continuously heating" as "heating at a constant temperature" during prosecution of the patent. Dkt. # 51, at 16. Plaintiff distinguished prior art, the Cygnarowicz-Provost (Provost) publication, by stating that "the pasteurization process in [Provost] does not take place at a constant temperature," Dkt. # 51-5, at 15, and the Provost procedure "was not a continuous process and . . . did not involve either steady state conditions or the use of a constant treatment temperature," Dkt. # 51-8, at 14. The Court finds that use of the term constant temperature to distinguish prior art in the prosecution history of the '299 Patent was not an unequivocal disclaimer of a meaning that does not require a constant temperature. Therefore, the claim need not be narrowed to include the requirement of a constant temperature. See Chimie,
3. The term "continuously cooling" in claim 1 is construed as: "cooling without interruption." For the same reasons as 2, supra, this construction is consistent with the plain language of the claim and patent specifications.

849

H. "a control for activating said global positioning system for transmitting the position of said cellphone to the remotely located telephone or the Internet"

Minerva argues that the meaning of "a control for activating said global positioning system for transmitting the position of said cellphone to the remotely located telephone or the Internet" is self-evident and requires no construction. The defendants contend that the limitation at issue is a means-plus-function limitation, which lacks corresponding structure in the specification, so the claim is indefinite. The absence of the word "means" gives rise to a presumption that the claim term is not governed by 35 U.S.C. § 112, P 6. Personalized Media Commc'ns, LLC v. Int'l Trade Comm'n, 161 F.3d 696, 703-04 (Fed. Cir. 1998) (internal citations omitted). The Federal Circuit has held, however, that "a limitation lacking the term 'means' may overcome the presumption against means-plus-function treatment if it is shown that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Mass. Inst. of Tech. v. Abacus Software, 462 F.3d 1344, 1353 (Fed. Cir. 2006) (internal quotations omitted). The defendants allege that the term "control" does not recite sufficiently definite structure. They cite Biomedino, LLC v. Waters Technologies Corp., 490 F.3d 946 (Fed. Cir. 2007), which holds that "control" is "not a structure or material capable of performing the identified function." Id. at 950.

The plaintiff counters that the defendants have not overcome the presumption against means-plus-function treatment. Minerva argues that the Biomedino case is inapposite because the term at issue was "control means," not merely "control," so there was a presumption of a means-plus-function limitation. Id. (emphasis added). Therefore, according to Minerva, Biomedino merely holds that the recitation of a "control" is insufficient to overcome the presumption of means-plus-function when the term contained the word "means." Finally, Minerva argues that one of skill in the art would recognize that a control, in this context, is a button, switch, or similar device.

Read in the context of the written description, a control is a button or other mechanically-activated device. Therefore, the court construes the term "a control for activating said global positioning system for transmitting the position of said cellphone to the remotely located telephone or the Internet" to mean "a button or switch for activating said global positioning system for transmitting the position of said cellphone to the remotely located telephone or the Internet."

850

A. "Control Structure"

The claim term "control structure" appears in both the '946 and '685 patents. As an initial matter, the Court will address defendant's argument that the claim term, as used in both patents, should be construed a means-plus function limitation under 35 U.S.C. §112, P 6.

Paragraph 6 of 35 U.S.C. § 112 states that "[a]n element in a claim for combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such a claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." Federal Circuit law states that:

"[A] claim limitation that actually uses the word 'means' invokes a rebuttable presumption that § 112 P 6 applies. By contrast, a claim term that does not use 'means' will trigger the rebuttable presumption that § 112 P 6 does not apply." The
use of the term "means" is "central to the analysis," because the term "means," particularly as used in the phrase "means for," is "part of the classic template for functional claim elements," and has come to be closely associated with means-plus-function claiming.

Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (internal citations omitted). The presumption that a limitation lacking the term 'means' is not subject to section 112 P 6 can be overcome if it is demonstrated that 'the claim term fails to 'recite sufficiently definite structure' or else recites 'function without reciting sufficient structure for performing that function.' Lighting World, 382 F.3d at 1358, citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002) (quoting Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000)). Federal Circuit "cases make clear, however, that the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, 382 F.3d at 1358.

In the instant case, the claim term "control structure" does not contain the word "means." Therefore, the term triggers the rebuttable presumption that § 112, P 6, does not apply. The term does not recite a function. Moreover, claim 1 recites sufficiently, definite structure by stating that "a control structure" comprises "a travel bar . . . and a spring . . . ." (Doc. # 1-2, '946 patent, col. 9, lines 61-65). Claim 26 also recites sufficiently, definite structure by stating that "the control structure comprising a travel bar" and that "the control structure further comprising an actuating lever . . . and a spring . . . ." (Doc. # 1-2, '946 patent, col. 12, lines 17, 21). As such, defendant has not rebutted the presumption that § 112, P 6, does not apply. Based on the foregoing, the Court does not construe the claim term "control structure" as a means-plus-function limitation, and will next address the parties' proposed construction of the term in the context of both the '946 and '685 patents.

2. "Control Structure" in the '946 Patent

Plaintiff requests that the Court construe the claim term "control structure" in the '946 patent as "an arrangement of one or more part(s) and element(s) which govern the movement of hinge plates." (Doc. # 26-2, at 5). In support of its proposed construction, plaintiff primarily relies on dictionary definitions. (Doc. # 26-2, at 5-6; # 51, at 4-5).

Plaintiff contends that the patentee did not act as his own lexicographer because "[a] cursory review of the patent shows that the specification contains no clear, deliberate, and precise definition of the term control structure." (Doc. # 31, at 23) (emphasis in original). Plaintiff also argues that "[a] claim term should take on its ordinary and accustomed meaning' unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of [the] claim scope." (Doc. # 31, at 23) (citing Teleflex, Inc., v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324 (Fed. Cir. 2002)). Plaintiff also argues that "[d]efendant should not be permitted to read descriptions of the preferred embodiment into the claims as limitations." (Doc. # 31, at 24) (citing CCS Fitness, 288 F.3d at 1366). Plaintiff next argues that defendant's proposed construction would not encompass the prior art. (Doc. # 31, at 24-25).

Finally, plaintiff refers the Court to the doctrine of claim differentiation, which states "that [t]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." (Doc. # 31, at 25) (citing Halliburton Energy Services, Inc. v. M-I LLC, 514 F.3d 1244, 1252 n.3 (Fed. Cir. 2008)). Plaintiff asserts that defendant's proposed construction violates the doctrine of claim differentiation by improperly incorporating the limitations of claims 10 and 14 of the '946 patent. Claim 10 states that the "control structure further comprises a connecting link pivotally connecting the travel bar to the hinge plates . . . ." (Doc. # 1-2, '946 patent, col. 10, lines 26-28). Claim 14 states that "the control structure further comprises an actuating lever pivotally mounted on the elongate plate . . . ." (Doc. # 1-2, '946 patent, col. 10, lines 43-44).

Defendant urges the Court to construe the claim term "control structure" in the '946 patent as "a control structure supported by the elongate plate . . . . The control structure includes a single actuating lever at one end of the mechanism, a travel bar, and two connecting links." 2 (Doc. # 26-2, at 5). Defendant argues "the patentee chose to be his own lexicographer with respect to the term 'control structure.'" (Doc. # 26-2, at 8). Defendant notes that, in Johnson WorldWide Associates, Inc. v. Zebeco Corp., 175 F.3d 985, 990 (Fed. Cir. 1999), the Federal Circuit held that "[w]hen a patentee chooses to be his or her own lexicographer, that definition must be applied to the claim." (Doc. # 26-2, at 8). Defendant refers the Court to the '946 patent specification, which states that "[t]he control structure 66 includes a single actuating lever 68 at one end of the mechanism, a travel bar 70, and two connecting links 72 which are supported by the elongate plate 32 and are movable relative to the elongate plate." (Doc. # 1-2, '946 patent, col. 4, lines 5-9). Defendant claims that the patentee, acting as a
Defendant also contends that "claim 1 requires including the only disclosed structures that correspond to the function of 'control structure,' being an 'actuating lever' and 'connecting links,' so that claim 1 does not exceed the breadth of the supporting disclosure. Otherwise, the claims of the '946 patent containing the term 'control structure' would be invalid." (Doc. # 26-2, at 9-10) (internal citations omitted). Finally, defendant argues that its proposed construction of the term "control structure" is "consistent with 35 U.S.C. §112, P 2, which requires that the claims of a patent 'particularly point out and distinctly claim the subject matter which the applicant regards as his invention.'" (Doc. # 26-2, at 10).

In the instant case, defendant suggests that the Court construe "control structure" to include "a single actuating lever at one end of the mechanism, a travel bar, and two connecting links." Independent claim 1 does not include the "a single actuating lever" or "two connecting links." Therefore, defendant's proposed construction improperly includes the limiting language of dependent claims 10 and 14 of the '946 patent to create "presumption that the limitation[s] in question [are] not present in the independent claim." Halliburton, 514 F.3d at 1252 n.3, citing Phillips, 415 F.3d 1303. "That presumption is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the dependent claim should be read into the independent claim." SunRace Roots Enter. Co., Ltd. v. SRAM Corp., 336 F.3d 1298, 1303 (Fed. Cir. 2003). However, "the presumption . . . is 'not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history.'" Regents of Univ. of Cal. v. Dakocytomation Cal., Inc., 517 F.3d 1364, 1375 (Fed. Cir. 2008) (citing Seachange Int'l, Inc. v. C-COR, Inc., 413 F.3d 1361, 1369 (Fed. Cir. 2005)); see also ICU Med., Inc. v. Alaris Med. Sys., Inc., No. 2008-1077, 558 F.3d 1368, 2009 U.S. App. LEXIS 5271, 2009 WL 635630, at *4 (Fed. Cir. Mar. 13, 2009).

The Court rejects plaintiff's argument that defendant's proposed construction of the term "control structure" violates the doctrine of claim differentiation. As stated above, "[u]nder the doctrine of claim differentiation, 'the presence of a dependent claim that adds a particular limitation gives to a presumption that the limitation in question is not present in the independent claim.'" Halliburton, 514 F.3d at 1252 n.3, citing Phillips, 415 F.3d 1303. Therefore, defendant's proposed construction improperly includes the limiting language of dependent claims 10 and 14 of the '946 patent to create "presumption that the limitation[s] in question [are] not present in the independent claim [1]." The written description, however, overcomes this presumption because the '946 patent specification states that "[t]he control structure 66 includes a single actuating lever 68 at one end of the mechanism, a travel bar 70, and two connecting links 72 which are supported by the elongate plate 32 and are movable relative to the elongate plate." (Doc. # 1-2, '946 patent, col. 4, lines 6-9). Therefore, the Court finds that term "control structure" in the '946 patent means "control structure including a single lever at one end of the mechanism, a travel bar, and two connecting links."}

Plaintiff urges the Court to construe the claim term "control structure" as "an arrangement of one or more part(s) and element(s) which govern the movement of hinge plates." (Doc. # 51, at 2). Plaintiff again provides dictionary definitions to support its proposed construction. Plaintiff also contends that the '685 patent specification contains no definition of the term "control structure," and that "[d]efendant should not be permitted to read the[] descriptions of an embodiment into the
claims as limitations.” (Doc. # 55, at 23). Moreover, plaintiff asserts that “[d]efendant's proposed construction of the term control structure does not comport with the representation that the patentee made to the patent office within the specification of the ’685 patent.” Id. Plaintiff also argues that defendant's proposed construction includes the term "intermediate connector," which violates the doctrine of claim differentiation. Plaintiff contends that the term improperly incorporates the limiting language from dependent claims 12 and 14 of the ’685 patent.

Defendant requests that the Court construes the term "control structure" in the ’685 patent as:

[A] control structure supported by the housing and moveable relative to the housing between a first position and a second position for use in controlling the pivoting motion of the hinge plates, the control structure including an actuator and a hinge pin pivotally connecting the actuator to the housing for movement relative to the housing to cause movement of the control structure between said first and second positions; and . . . the control structure further comprising a travel bar operatively connected to the lever such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the position in which the control structure locks the hinge plates in the closed position to the second position in which the hinge plates are free to pivot to the open position. The control structure includes the actuating lever, an intermediate connector, an elongate travel bar, and either:

(a) at least one connecting link; or

(b) an opening arm, a closing arm and three blocking elements; or

(c) and opening arm and three angled blocking elements.

(Doc. # 51, at 2-3). 3 Defendant claims that the structures outlined in subsections (a) through (c) are "three alternative sets of structure for performing the[] functions" of the control structure. (Doc. # 51, at 7). Defendant asserts that the patentee, acting as his own lexicographer, explicitly described the three, separate descriptions of the term "control structure."

--- Footnotes ---

3 Because the Court does not construe the claim term "control structure" as a means-plus-function limitation, the Court will only consider defendant's alternative, proposed construction. (Doc. # 51, at 3 n.2).

--- End Footnotes ---

Defendant's proposed construction partially violates the doctrine of claim differentiation. Independent claim 1 of the ’685 patent does not mention "intermediate connector," but dependent claims 12 and 14 includes such language. Incorporation of the phrase into the independent claim 1 invokes the presumption that the limiting language "is not present in the independent claim." Halliburton, 514 F.3d at 1252 n.3. The ’685 patent specification states that "[t]he control structure 37 includes the actuating lever 15, an intermediate connector 39, an elongate travel bar 41, and three connecting links 43 . . . ." (Doc. # 51-2, ’685 patent, col. 5, lines 20-22). However, in the Office Action dated December 13, 2007, the patent examiner referenced U.S. Patent No. 2,004,570 (the ’570 patent) and rejected claim 1 of the ’685 patent because it described "control structure" as "the control structure including an actuator and a hinge pin" as was disclosed in the ’570 patent. (Doc. # 55-7, at 1, 6). Had the patentee understood "control structure" to include the phrase "intermediate connector," then the patent examiner would not have referenced the ’570 patent, because the ’570 patent description of "control structure" did not contain the term "an intermediate connector." Therefore, despite the written description, the ’685 patent prosecution history suggests that "control structure" does not contain the phrase "intermediate connector." As such, the Court believes that defendant has not overcome the heavy burden invoked by the doctrine of claim differentiation, and will not read the limiting language into the term "control structure" in the ’685 patent.

The Court also rejects defendant's attempt to define "control structure" in light of the three embodiments disclosed in the ’685 patent specification. Federal Circuit law states that:

Although claims must be read in light of the specification of which they are a part, it is improper to read limitations from the written description into a claim. Moreover, "although the specification may well indicate that certain embodiments are preferred, particular embodiments appearing in the specification will not be read into the claims when the claim language is
broader than such embodiments."

Tate Access Floors, Inc. v. Maxcess Technologies, Inc., 222 F.3d 958, 966 (Fed. Cir. 2000). In the instant case, the first embodiment of the '685 patent specification states that "[t]he control structure 37 includes the actuating lever 15, an intermediate connector 39, an elongate travel bar 41, and three connecting links 43 . . . ." (Doc. # 51-2, '685 patent, col. 5, lines 20-22). The fourth embodiment describes a "[c]ontrol structure 337 [that] include[s] three blocking elements, . . . a closing arm 330 and an opening arm 332." (Doc. # 51-2, '685 patent, col. 10, lines 49-55). The sixth embodiment refers to the mechanism disclosed in the fourth embodiment. (Doc. # 51-2, '685 patent, col. 13, lines 33-34). As such, the sixth embodiment modifies the actuator to include "a flat opening arm" and "angled surfaces of the blocking elements [that] face the lever." (Doc. # 51-2, '685 patent, col. 13, line 51, col. 14, lines 19-20). The language in claim 1, however, only refers to "control structure" as "the control structure including an actuator and hinge pin . . . and a spring . . . and . . . further comprising a travel bar . . . ." (Doc. # 51-2, '685 patent, col. 16, lines 35-36, 40, 44-45). Thus, the claim language is broader than the preferred embodiments. As such, the Court will not read the limiting language disclosed in the embodiments into claim 1 of the '685 patent. Therefore, the Court finds that "control structure" in the '685 patent means "the control structure including a hinge pin, a spring, and a travel bar."

851

A. "Control Structure"

The claim term "control structure" appears in both the '946 and '685 patents. As an initial matter, the Court will address defendant's argument that the claim term, as used in both patents, should be construed a means-plus-function limitation under 35 U.S.C. § 112, ¶ 6.

Paragraph 6 of 35 U.S.C. § 112 states that "[a]n element in a claim for combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such a claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." Federal Circuit law states that:

"[A] claim limitation that actually uses the word 'means' invokes a rebuttable presumption that § 112, ¶ 6 applies. By contrast, a claim term that does not use 'means' will trigger the rebuttable presumption that § 112, ¶ 6 does not apply." The use of the term "means" is "central to the analysis," because the term "means," particularly as used in the phrase "means for," is "part of the classic template for functional claim elements," and has come to be closely associated with means-plus-function claiming.

Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (internal citations omitted). "The presumption that a limitation lacking the term 'means' is not subject to section 112, ¶ 6 can be overcome if it is demonstrated that 'the claim term fails to 'recite sufficiently definite structure' or else recites 'function without reciting sufficient structure for performing that function.'" Lighting World, 382 F.3d at 1358, citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002) (quoting Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000)). The Federal Circuit "cases make clear, however, that the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, 382 F.3d at 1358.

In the instant case, the claim term "control structure" does not contain the word "means." Therefore, the term triggers the rebuttable presumption that § 112, ¶ 6 does not apply. The term does not recite a function. Moreover, claim 1 recites sufficiently, definite structure by stating that "a control structure comprising a travel bar . . . and a spring . . . ." (Doc. # 1-2, '946 patent, col. 9, lines 61-65). Claim 26 also recites sufficiently, definite structure by stating that "the control structure comprising a travel bar" and that "the control structure further comprising an actuating lever . . . and a spring . . . ." (Doc. # 1-2, '946 patent, col. 12, lines 17, 21). As such, defendant has not rebutted the presumption that § 112, ¶ 6, does not apply. Based on the foregoing, the Court does not construe the claim term "control structure" as a means-plus-function limitation, and will next address the parties' proposed construction of the term in the context of both the '946 and '685 patents.

2. "Control Structure" in the '946 Patent
Plaintiff requests that the Court construe the claim term "control structure" in the '946 patent as "an arrangement of one or more part(s) and element(s) which govern the movement of hinge plates." (Doc. # 26-2, at 5). In support of its proposed construction, plaintiff primarily relies on dictionary definitions. (Doc. # 26-2, at 5-6; # 51, at 4-5).

Plaintiff contends that the patentee did not act as his own lexicographer because "[a] cursory review of the patent shows that the specification contains no clear, deliberate, and precise definition of the term control structure." (Doc. # 31, at 23) (emphasis in original). Plaintiff also argues that "[a] claim term should take on its ordinary and accustomed meaning unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of [the] claim scope." (Doc. # 31, at 23) (citing Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324 (Fed. Cir. 2002)). Plaintiff also argues that "[d]efendant should not be permitted to read descriptions of the preferred embodiment into the claims as limitations." (Doc. # 31, at 24) (citing CCS Fitness, 288 F.3d at 1366). Plaintiff next argues that defendant's proposed construction would not encompass the prior art. (Doc. # 31, at 24-25).

Finally, plaintiff refers the Court to the doctrine of claim differentiation, which states "that '[t]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim."’ (Doc. # 31, at 25) (citing Halliburton Energy Services, Inc. v. M-I LLC, 514 F.3d 1244, 1252 n.3 (Fed. Cir. 2008)). Plaintiff asserts that defendant's proposed construction violates the doctrine of claim differentiation by improperly incorporating the limitations of claims 10 and 14 of the '946 patent. Claim 10 states that the "control structure further comprises a connecting link pivotally connecting the travel bar to the hinge plates . . . ." (Doc. # 1-2, '946 patent, col. 10, lines 26-28). Claim 14 states that "the control structure further comprises an actuating lever pivotally mounted on the elongate plate . . . ." (Doc. # 1-2, '946 patent, col. 10, lines 43-44).

Defendant urges the Court to construe the claim term "control structure" in the '946 patent as "a control structure supported by the elongate plate . . . . The control structure includes a single actuating lever at one end of the mechanism, a travel bar, and two connecting links." 1 (Doc. # 26-2, at 5). Defendant argues "the patentee chose to be his own lexicographer with respect to the term 'control structure.'" (Doc. # 26-2, at 8). Defendant notes that, in Johnson WorldWide Associates, Inc. v. Zebco Corp., 175 F.3d 985, 990 (Fed. Cir. 1999), the Federal Circuit held that "[w]hen a patentee chooses to be his or her own lexicographer, that definition must be applied to the claim." (Doc. # 26-2, at 8). Defendant refers the Court to a description of preferred embodiment in the '946 patent specification, which states that "[t]he control structure 66 includes a single actuating lever 68 at one end of the mechanism, a travel bar 70, and two connecting links 72 which are supported by the elongate plate 32 and are movable relative to the elongate plate." (Doc. # 1-2, '946 patent, col. 4, lines 5-9). Defendant claims that the patentee, acting as a lexicographer, described the "control structure" as a "unique control structure." See (Doc. # 1-2, '946 patent, col. 4, line 1). Defendant also refers the Court to the '946 patent prosecution history, whereby the patentee states that the mechanism includes a "unique structure." (Doc. # 26-4, at 11-12; # 26-5, at 25).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 Because the Court does not construe the claim term "control structure" as a means-plus-function limitation, the Court will only consider defendant's alternative, proposed construction. (Doc. # 26-2, at 5 n.1).

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Defendant also contends that "claim 1 requires including the only disclosed structures that correspond to the function of 'control structure,' being an 'actuating lever' and 'connecting links,' so that claim 1 does not exceed the breadth of the supporting disclosure. Otherwise, the claims of the '946 patent containing the term 'control structure' would be invalid." (Doc. # 26-2, at 9-10) (internal citations omitted). Finally, defendant argues that its proposed construction of the term "control structure" is "consistent with 35 U.S.C. § 112, P 2, which requires that the claims of a patent particularly point out and distinctly claim the subject matter which the applicant regards as his invention." (Doc. # 26-2, at 10).

As stated above, "[u]nder the doctrine of claim differentiation, 'the presence of a dependent claim that adds a particular limitation gives to a presumption that the limitation in question is not present in the independent claim." Halliburton, 514 F.3d at 1252 n.3 (citing Phillips, 415 F.3d 1303). "That presumption is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the
Defendant requests that the Court construes the term "control structure" in the '685 patent as:

limiting language from dependent claims 12 and 14 of the '685 patent. "connector," which violates the doctrine of claim differentiation. Plaintiff contends that the term improperly incorporates the element(s) which govern the movement of hinge plates. (Doc. # 51, at 2). Plaintiff again provides dictionary definitions to

In the instant case, defendant suggests that the Court construe "control structure" to include "a single actuating lever at one end of the mechanism, a travel bar, and two connecting links." Independent claim 1 does not include the phrases "a single actuating lever" or "two connecting links." Thus, defendant's proposed construction improperly includes the limiting language of dependent claims 10 and 14 of the '946 patent, which gives rise to the "presumption that the limitation[s] in question [are] not present in . . . independent claim [1]." Halliburton, 514 F.3d at 1252 n.3 (citation omitted). The Court also rejects defendant's attempt to define "control structure" in light of the description of one preferred embodiment in the '946 patent specification. Federal Circuit law states that:

Although claims must be read in light of the specification of which they are a part, it is improper to read limitations from the written description into a claim. Moreover, "although the specification may well indicate that certain embodiments are preferred, particular embodiments appearing in the specification will not be read into the claims when the claim language is broader than such embodiments."

Tate Access Floors, Inc. v. Maxcress Technologies, Inc., 222 F.3d 958, 966 (Fed. Cir. 2000). As discussed above, a description of one preferred embodiment states that "control structure" includes two connecting links; the '946 patent claim language, however, repeatedly refers to "control structure" as only "a control structure . . . comprising a travel bar . . . hinge plates . . . a spring[]" (Doc. # 1-2, '946 patent, col. 9, lines 57-65, col. 11, lines 19-29, col. 12, lines 21-29). Therefore, the claim language is broader than the preferred embodiment in the '946 patent specification. Without more, the Court will not read the description of the preferred embodiment into the broad claim language. See MBO Labs., Inc. v. Becton, Dickinson &Co., 474 F.3d 1323, 1333 (Fed. Cir. 2007) (holding that "to import limitations onto [a] claim from the specification . . . is fraught with 'danger.'"), citing Phillips, 415 F.3d 1303, 1323 ("although [patent] specifications often describe [] very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments.") (citation omitted). Cf., ICU Med., 558 F.3d at 1375 (affirming the district court's claims construction that imported a written description in the patent specification, which "repeatedly and uniformly" narrowed the broad claim language). Therefore, the Court finds that term "control structure" in the '946 patent means "control structure including a travel bar, hinge plates, and a spring."

3. "Control Structure" in the '685 Patent

As with the '946 patent, defendant urges the Court to construe the claim term "control structure" in the '685 patent as a means-plus-function limitation. Since the claim term "control structure" in the '685 patent does not contain the word "means," the claim term invokes the rebuttable presumption that § 112, P 6, does not apply. Claim 1 recites sufficiently, definite structure by stating that "a control structure" includes "an actuator and a hinge pin . . . and a spring . . . ." (Doc. # 51-2, '685 patent, col. 16, lines 35-40). Claim 13 also states that "control structure" includes "a lever having a head, a hinge pin . . . and a travel bar . . . ." (Doc. # 1-2, '946 patent, col. 18, lines 27-31). Thus, the Court does not construe the claim term as a means-plus-function limitation, and will next address the parties' proposed construction of the claim term within the context of the '685 patent.

Plaintiff urges the Court to construe the claim term "control structure" as "an arrangement of one or more part(s) and element(s) which govern the movement of hinge plates." (Doc. # 51, at 2). Plaintiff again provides dictionary definitions to support its proposed construction. Plaintiff also contends that the '685 patent specification contains no definition of the term "control structure," and that "[d]efendant should not be permitted to read the [] descriptions of an embodiment into the claims as limitations." (Doc. # 55, at 23). Moreover, plaintiff asserts that "[d]efendant's proposed construction of the term control structure does not comport with the representation that the patentee made to the patent office within the specification of the '685 patent." Id. Plaintiff also argues that defendant's proposed construction includes the term "intermediate connector," which violates the doctrine of claim differentiation. Plaintiff contends that the term improperly incorporates the limiting language from dependent claims 12 and 14 of the '685 patent.

Defendant requests that the Court construes the term "control structure" in the '685 patent as:
A control structure supported by the housing and moveable relative to the housing between a first position and a second position for use in controlling the pivoting motion of the hinge plates, the control structure including an actuator and a hinge pin pivotally connecting the actuator to the housing for movement relative to the housing to cause movement of the control structure between said first and second positions; and . . . the control structure further comprising a travel bar operatively connected to the lever such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the position in which the control structure locks the hinge plates in the closed position to the second position in which the hinge plates are free to pivot to the open position. The control structure includes the actuating lever, an intermediate connector, an elongate travel bar, and either:

(a) at least one connecting link; or

(b) an opening arm, a closing arm and three blocking elements; or

(c) and opening arm and three angled blocking elements.

(Doc. # 51, at 2-3). 2 Defendant claims that the structures outlined in subsections (a) through (c) are "three alternative sets of structure for performing the [] functions" of the control structure. (Doc. # 51, at 7). Defendant asserts that the patentee, acting as his own lexicographer, explicitly described the three, separate descriptions of the term "control structure."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Because the Court does not construe the claim term "control structure" as a means-plus-function limitation, the Court will only consider defendant's alternative, proposed construction. (Doc. # 51, at 3 n.2).

- - - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Defendant's proposed construction partially violates the doctrine of claim differentiation. Independent claim 1 of the '685 patent does not mention "intermediate connector," but dependent claims 12 and 14 includes such language. Incorporation of the phrase into the independent claim 1 invokes the presumption that the limiting language "is not present in the independent claim." Halliburton, 514 F.3d at 1252 n.3. The '685 patent specification states that "[t]he control structure 37 includes the actuating lever 15, an intermediate connector 39, an elongate travel bar 41, and three connecting links 43 . . . ." (Doc. # 51-2, '685 patent, col. 5, lines 20-22). However, in the Office Action dated December 13, 2007, the patent examiner referenced U.S. Patent No. 2,004,570 (the '570 patent) and rejected claim 1 of the '685 patent because it described "control structure" as "the control structure including an actuator and a hinge pin" as was disclosed in the '570 patent. (Doc. # 55-7, at 1, 6). Had the patentee understood "control structure" to include the phrase "intermediate connector," then the patent examiner would not have referenced the '570 patent, because the '570 patent description of "control structure" did not contain the term "an intermediate connector." Therefore, despite the written description, the '685 patent prosecution history suggests that "control structure" does not contain the phrase "intermediate connector." As such, the Court believes that defendant has not overcome the heavy burden invoked by the doctrine of claim differentiation, and will not read the limiting language into the term "control structure" in the '685 patent.

The Court also rejects defendant's attempt to define "control structure" in light of the three embodiments disclosed in the '685 patent specification. As stated above, states that, "although the specification may well indicate that certain embodiments are preferred, particular embodiments appearing in the specification will not be read into the claims when the claim language is broader than such embodiments." Tate Access Floors, 222 F.3d 958. In the instant case, the first embodiment of the '685 patent specification states that "[t]he control structure 37 includes the actuating lever 15, an intermediate connector 39, an elongate travel bar 41, and three connecting links 43 . . . ." (Doc. # 51-2, '685 patent, col. 5, lines 20-22). The fourth embodiment describes a "[c]ontrol structure 337 [that] include[s] three blocking elements, . . . a closing arm 330 and an opening arm 332." (Doc. # 51-2, '685 patent, col. 10, lines 49-55). The sixth embodiment refers to the mechanism disclosed in the fourth embodiment. (Doc. # 51-2, '685 patent, col. 13, lines 33-34). As such, the sixth embodiment modifies the actuator to include "a flat opening arm" and "angled surfaces of the blocking elements [that] face the lever." (Doc. # 51-2, '685 patent, col. 13, line 51, col. 14, lines 19-20). The language in claim 1, however, only refers to "control structure" as "the control structure including an actuator and hinge pin . . . and a spring . . . and . . . further comprising a travel bar . . . ." (Doc. # 51-2, '685 patent, col. 16, lines 35-36, 40, 44-45). Thus, the claim language is broader.
than the preferred embodiments. As such, the Court will not read the limiting language disclosed in the embodiments into claim 1 of the '685 patent. Therefore, the Court finds that "control structure" in the '685 patent means "the control structure including a hinge pin, a spring, and a travel bar."

GO BACK

852

7. control volume ('062 patent, claims 1, 16)

This term appears in independent claims 1 and 16 of the '062 patent. The '062 patent "relates to fluid flow control devices and, more specifically, to regulating pump pressures. In particular, the invention provides a method and apparatus for increasing the fluid flow rate in a fluid flow control device while maintaining desired pressure levels." '062 patent, 1:6-10.

Claim 1 recites

A method for regulating pressure at a distal end of a fluid line, the method comprising:

- providing a fluid control system, the fluid control system having at least one liquid volume in valved communication with the distal end, a control volume in pressure communication with the liquid volume, means for measuring pressure in the control volume, and means for adjusting the pressure in the control volume;

- calibrating the means for measuring the pressure;

- establishing communication between the liquid volume and the distal end;

- measuring a pressure of the control volume; and

- adjusting the pressure in the control volume in accordance with the measured pressure.

Claim 16 recites

A method for regulating pressure at the distal end of a fluid line, the method comprising:

- providing a fluid flow control system, the fluid flow control system having at least one liquid volume in valved communication with the distal end, a control volume in pressure communication with the liquid volume, a pressure traducer in communication with the control volume, and a pressure adjuster in communication with the control volume;

- calibrating the pressure traducer;

- establishing communication between the liquid volume and the distal end;

- measuring a pressure of the control volume; and

- adjusting the pressure in the control volume in accordance with the measured pressure.

The parties dispute whether "control volume" simply refers to a "volume" of gas or liquid that "regulates" or "guides" the flow control system; or whether "control volume" more specifically refers to that portion of the "pump chamber" that contains the pressurizing fluid, and which is separated (in that pump chamber) from the "liquid volume" by the "membrane."

Plaintiffs propose that "control volume" means "a volume of gas or liquid used in regulating and guiding the fluid flow control system. " Plaintiffs also accept Fresenius' expert's definition of "control volume," which is "a region in space which is mathematically defined with the purpose of analyzing the region." Fresenius proposes that "control volume" means "the portion of the pump chamber that contains the pressurizing fluid and is separated from the liquid volume by the membrane."
The claims and specification of the '062 patent do not explicitly define "control volume" to have a special meaning, but instead use "control volume" to refer broadly to a volume of fluid (gas or liquid, as the parties agree) used in regulating and guiding operation of the claimed device.

For example, Claim 1 recites "[a] method for regulating pressure at a distal end of a fluid line, the method comprising . . .," and includes the step of "measuring a pressure of the control volume," and then, to control the liquid flow control device, requires "adjusting the pressure in the control volume in accordance with the measured pressure." Id., 7:1-3.

In certain preferred embodiments, pressure measurements are taken at the control volume and used in calculations that form the basis for system adjustments - that is, to regulate and guide the fluid flow control system. The specification states that a "control volume" can be used to identify pressure correlations and calculate pressure values, which values the processor then uses to control the fluid flow control device:

The fluid flow control device preferably includes a control volume for each liquid volume, a transducer for each control volume, and a processor for reading and storing pressure values, computing and identifying a correlation between pressure values, and calculating pressure values based on identified correlations. The processor may estimate the elevation differential based upon the pressure values, and/or regulate fluid pump pressures.

Id., 2:8-15; see also id., 5:51-56 ("In process 514, the pressure transducer 315 measures the pressure in the second control volume 311, and the relative elevation is estimated in process 515 based on the pressure in the second control volume and the calibration constants generated during calibration"). In other words, the "pressure in the second 'control volume'" is used to estimate the relative elevation between the fluid control device and the distal end of the fluid line.

Fresenius' proposed construction ignores distinctions made by the claims and specifications. Fresenius argues that the claimed "control volume" must be "a portion of the pump chamber." However, this proposal is directly contradicted by the patent, as the specification clearly indicates that the control volume need not be a portion of the pump chamber. See id., 6:38-43 ("separate pumps, control volumes, and liquid volumes may be provided and . . . the liquid volumes and control volumes may be located at a different point from the pumps along the fluid pathway to the distal end of the fluid line"); id., 2:23-24 (in one preferred embodiment, "the liquid volume and the control volume themselves are parts of a pump").

Similarly, Fresenius defines "control volume" as containing "the pressurizing fluid" (e.g., only a gas or a liquid). However, the specification states that while pressurizing "may occur" through the use of a gas or a liquid, it may also occur through "other methods known in the art, such as pumps, pistons, pressurized reservoirs, valves, and vents." Id., 3:35-38. A construction that excludes embodiments of the invention described in the specification "is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583. Fresenius offers no such highly persuasive support here.

Fresenius' proposal that the control volume must be "separated from the liquid volume by the membrane" is also contradicted by the patent. For example, claim 2, which depends from claim 1, requires that "the liquid volume includes a flexible membrane that separates the liquid volume from the control volume." Under the doctrine of claim differentiation, the requirement that the control volume is separated from the liquid volume by a flexible membrane cannot be read into claim 1, because it is a limitation that is recited in claim 2. See, e.g., Phillips, 415 F.3d at 1314-15 ("the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim"); Liebel-Flarsheim, 358 F.3d at 910 ("where the limitation that is sought to be 'read into' an independent claim already appears in a dependent claim, the doctrine of claim differentiation is at its strongest").

"Control volume" means "a volume of gas or liquid used in regulating and guiding the fluid flow control system."

9. "Controlled Flow"

The term "controlled flow" is construed to mean, "Regulated and directed forward continuous movement."
The phrase appears in claim 16 of the '207 patent:

(i) heating said core in said laminator, in the presence of minimum first ram pressure, to a temperature which causes controlled flow of said plastic which makes up said first and second plastic core sheets; (ii) applying a second pressure uniformly across said core for encapsulating said at least one electronic element within said controlled flow.

'207 patent, col. 8:22-28. The specification states that "A heat cycle is applied to the core sheets in the laminator thus liquefying or partially liquefying the sheets." '207 patent, col. 2:34-36. The specification further describes that the purpose of the "controlled flow" is to enclose the electronic element, "Once the heat cycle has been applied to the book as is set forth above, the ram pressure of laminator is increased to facilitate the flow of the plastic core sheets so that the one or more electronic elements are encapsulated thereby…” '207 patent, col. 4:48-52.

The meaning of the phrase "controlled flow" would appear to be self-evident. When a liquid "flows" it moves forward continuously. "Controlled" indicates some degree of restraint (Plaintiff's proposed term) or regulation or direction (my preferred term).

Defendant claims the phrase means that "the first and second plastic core sheets' at least partially liquefy so as to fully enclose the 'electronic element' at the ram pressure and heat applied to the 'core sheets' and allow the outer surfaces of the finished card before dye sublimation printing to assume a smoothness of approximately .0005 inches or better." (Def. Br. at 41.)

According to Defendant, "flow" is a technical term. (Id.) McGraw Hill defines "flow" to mean "the forward continuous movement of fluid, such as gases, vapors, or liquids, through closed or open channels or conduits." Defendant cites the language of the specifications quoted above as supporting the premise that the electronic element is fully encapsulated by the first and second plastic core sheets, which at least partially liquefy in order to "flow" and surround the electronic element. (Def. Br. at 42.) Defendant also notes that Leighton stresses in the '207 specification that his invention lies in producing a contactless card with a sufficiently smooth and regular surface to receive dye sublimation printing, and that this smoothness cannot be achieved unless the core plastic sheets at least partially liquefy and flow. (Id.)

I agree with Defendant to the extent that plastic, in the state we normally encounter it, would not "flow." And we know from the specifications and claims discussed above that the lamination process at issue here involves heating the plastic core sheets. So I do agree that the plastic core sheets only "flow" because they have been heated, intentionally, during lamination. However, Defendant's proposed definition of "controlled flow" attempts to introduce into the definition of that phrase concepts that are not even found in the claims -- a transparent effort to limit the meaning of this phrase to one disclosed embodiment. That is not the proper function of claim construction.

a. "controlling inflation of the airbag when deployment of the airbag is not suppressed"

Plaintiff argues that the court should construe this claim as "controlling inflation of the airbag by adjusting operation of the airbag." (Chart at 22.) In response, Defendant argues that Plaintiff's claim is indefinite because Claim 19 incorporates the method of Claim 14, which only includes "suppressing deployment" and does not contemplate any deployment. (Id.)

Paragraph 2 of 35 U.S.C. § 112 requires that a patent claim "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112 P 2. "A determination that a patent claim is invalid for failure to meet the definiteness requirement . . . is a conclusion 'that is drawn from the court's performance of its duty as the construer of patent claims [and] therefore, like claim construction, is a question of law.'" Bancorp Servs., L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1371 (Fed. Cir. 2004) (quoting Atmel Corp. v. Info. Storage Devices, Inc., 198 F.3d 1374, 1378 (Fed. Cir. 1999)). "The terms used in the claims bear a presumption that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." Honeywell Int'l, Inc. v. Int'l Trad Comm'n, 341 F.3d 1332, 1338 (Fed. Cir. 2003) (citing CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002)). A claim is presumed valid, and a court will only find a claim in definite if the "claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Honeywell, 341 F.3d at 1338-1339 (quoting Exxon
Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001)).

Claim 14 states: "A method for controlling a deployable component in a vehicle, comprising the steps of . . . controlling the component . . . the step of controlling the component comprising the step of suppressing deployment of the component." (Chart at 19.) Claim 19 of the '516 Patent is: "The method of claim 14, wherein the component is an airbag, the step of controlling the component comprising the step of controlling inflation of the airbag when deployment of the airbag is not suppressed." (Chart at 21-22.)

Defendants are correct in noting the patent contradiction in Plaintiff's claim. Claim 14 includes the method of suppressing deployment of a component. Claim 19 incorporates this method, including suppressing deployment of the component," but Claim 19 itself describes a method for "controlling inflation of the airbag when deployment of the airbag is not suppressed" (emphasis added). Under Plaintiff's own construction, Claim 19 simultaneously requires the suppression and non-suppression of the same component. There is no reconciling this contradiction, and indeed, Plaintiff appears to have dropped this claim because Plaintiff offers no argument in opposition or to clarify the interpretation to avoid this finding. The court will therefore find this claim indefinite pursuant to § 112, P 2.

E. "Controlling the Operation of Said Heater"

The parties also dispute the proper construction of the term "controlling the operation of said heater" in the claims of the '585 Patent. TSI argues that no further construction is necessary. Defendants assert that the Court should construe the term to mean causing the heater to run a pre-programmed heater operation sequence to regulate the temperature of the element at or near a single, predetermined temperature above the element's Curie temperature. Defendants do not explain why this term is ambiguous in the context of the claims; nor do they point to any disclaimer or disavowal of claim scope. Thus, defendants rely solely on Microsoft in their attempt to add limitations to the scope of the claims.

The full claim language reads: "controlling the operation of said heater in response to information received from said tag." Defendants argue that since control is limited to responses from the tag, then the scope of the patent cannot include control by using actual temperature information. Rather, control can only be exercised from information identifying the object to be heated, thereby compelling the selection of a pre-programmed sequence relating to a pre-determined temperature.

The Court rejects defendants' proposed construction. Defendants cite only a single excerpt to the specification in support of this argument, but that excerpt does not contain any description of the invention with the limitation urged by defendants. Moreover, the Court has already rejected defendants' attempt to impose a claims limitation prohibiting the use of temperature information in the control process. See supra Part III.C. Defendants have not identified sufficient language in the specification to support importation of these limitations into the claims of the patent. Accordingly, the Court rejects defendants' proposed construction of this term and concludes that no further construction of the term is warranted.

A. Cool the Skin (Claims 1, 19)

Term | Court's Construction
--- | ---
cool the skin surface in said | remove heat from the skin surface in
skin region to a selected depth | said skin region to a selected depth

The parties disagree as to whether the word "cool" means simply removing heat or instead indicates cooling or precooling that reduces the skin temperature below the pre-treatment level. The claims expressly contemplate optical radiation treatment with "at most minimal heating" of the skin while the cooling occurs, '844 Patent col.15 l.66 to col.16 l.11, col.17 ll.44-47, so the word "cool" necessarily has the more general meaning of removing heat rather than defendant's limited construction. The specification supports this interpretation because it references cooling below the pre-treatment level and the related concept of precooling only in the context of preferred embodiments. See, e.g., '844 Patent col.2 ll.35-43, col.5
The court therefore adopts plaintiff's construction of "cool" as "removing heat." Defendant also argues that "selected depth" should be construed to mean "a predetermined depth," but the court can discern no difference between the two phrases and finds that no further construction is needed.

(11) "said arms and said first and second magnetic members cooperating to stably support said auxiliary spectacle frame on said primary spectacle frame" (claim 12)

Plaintiffs contend that the term "cooperating" means "to work or act together toward a common end or purpose." JS, Exh. B at 21. Plaintiffs also contend that "stably" means "resistant to sudden change in position or condition." Id. "Support" is defined by Plaintiffs to mean "to maintain in position so as to keep from falling, sinking or slipping." Id. at 22.

Conversely, Defendant construes the entire phrase in question to mean:

the arms extending from the auxiliary spectacle frame must contact and be supported on the upper side of the side portion extensions of the primary spectacle frame and the magnets on the rear side of the extensions of the primary frame are positioned directly below although not in contact with the magnets on the arms of the auxiliary frame to cooperate in holding the arms in place on the extensions to allow the auxiliary spectacle frame to be supported by the primary spectacle frame.

JS, Exh. D at 2.

Defendant seeks to read into the instant phrase the limitation that the arms must contact and be supported on the upper side of the extensions of the primary frame; and that the primary frame magnetic members must be positioned directly below, although not in contact with the auxiliary frame magnetic members. Def.'s Opposition at 11:4-18. Defendant argues that its construction should be adopted because it is supported by "[t]he only figure in the '545 Patent [-Figure 7-] illustrating the relationship between the arms and the extension". Id. at 11:19-20. The Court rejects Defendant's argument because "the number of embodiments disclosed in the specification is not determinative of the meaning of disputed claim terms." Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). The fact that Figure 7 shows a particular embodiment does not, in and of itself, limit the entire patent to such embodiment. See Laitram Corp., 863 F.2d at 865.

Defendant further argues that its construction should be adopted under the "recapture doctrine" 16 because the patentee added the requirement that the arms must contact and be supported on the upper side of the extension during prosecution of the original '207 Patent to secure allowance of claim 1. Def.'s Opposition at 12:1-12. Claim 1, as originally submitted to the PTO, required that the arms be "engaged with and supported on said upper portion" of the primary frame. Koo Decl., Exh. D at 34-35. The only amendment to claim 1 made during the prosecution was by an Examiner's clarifying amendment which added the word "side" between "upper" and "portion." Id. at 49.

16 Under the recapture doctrine, claims in a reissue patent "that are broader than the original patent's claims in a manner directly pertinent to the subject matter surrendered during prosecution [of the original patent] are impermissible." Pannu v. Storz Instruments, Inc., 258 F.3d 1366, 1370-71 (Fed. Cir. 2001).

Additionally, and as is evident from the claims of the '545 Patent (the reissue patent), that same limiting language appears only in claim 1 and not in claims 12, 16 or 24. To this end, claim 12 of the '545 Patent simply requires that the arms and the magnetic members "cooperat[e] to stably support" the auxiliary frame on the primary frame. Koo Decl., Exh. B at 15, 11. 5-7.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1301

Based on the above, the Court construes the phrase "said arms and said first and second magnetic members cooperating to stably support said auxiliary spectacle frame on said primary spectacle frame" in claim 12 to mean said arms and said first and second magnetic members working together to maintain in position said auxiliary spectacle frame on said primary spectacle frame by resisting sudden change of position. See Webster's, Nicodema Decl., Exh. 5 at 126, defining "cooperate" as "to work or act together toward a common end or purpose"; id. at 153, defining "stable" as "resisting sudden change of position or condition"; id. at 155, defining "support" as "to maintain in position so as to keep from falling, sinking or slipping."

858

The district court then construed the term "core member" to require "a fairly rigid core member with an annular band or ring at its base that can fit into the band or ring of the outer housing." Id. The district court looked to Hemphill's statements during prosecution of the 720 patent to determine that the purpose of the "annular band" is "to keep sticky fingers off the fibers," and to possess "an outer diameter which is at least equal to the inner diameter" of the band attached to the outer housing, "so that the two can fit thereby allowing the core to be secured within the band by a suitable adhesive." Id. The specification described the core member as "fairly rigid," and secured to the outer housing. Id. We find that the district court properly construed the term "core member."

859

2. "Expansion strut pair corners" and "corners" of "expansion strut pairs."

Consistent with the claim language and its ordinary meaning 14 and the specification, 15 this court construes "corners" to mean "a place where two surfaces meet to form an angle."

14 D.I. 230, Ex. 5 at 452 (defining "corner" as "the place at which two converging lines or surfaces meet" and "the space between two converging lines or surfaces near their intersection; angle"); D.I. 233, Ex. 11 at 507 (defining "corner" as "the point or place where converging lines, edges or sides meet: ANGLE . . .").

15 '021 patent, col. 11, ll. 66-67 - col. 12, ll. 11.

860

c. "Correct Combination" (Claim 3)

82. The claim term "correct combination" defines the function of the lever moving element moving means and defines when the moving element is activated. Thus, the term defines and limits the function of a particular claim element. This term should be construed to have the same meaning as defined above for "combination", and refers to a particular type of combination which will cause the lock to open. Thus, "correct combination", as used in the '656 patent claims, means the
C. "Compressed State/Position" and "Decompressed State/Position"

The terms "compressed state" or "compressed position" and "decompressed state" or "decompressed position" appear in different forms in all four patents in suit. The Common Specification and the earlier issued '866 and '862 patents use the term "state," whereas the more recently issued '592 and '509 patents contain claims that employ the term "position." Although the parties have agreed that "state" and "position" should be construed consistently with one another, Alaris emphasizes "state" and ICU emphasizes "position" in their respective proposed constructions. The patents also use the terms "uncompressed" and "decompressed," apparently interchangeably, and the court will treat these words as synonymous for purposes of claim construction.

The parties disagree on the precise claim language to be construed. Alaris urges the court to construe the term "into a compressed state" as "from a state (i.e. condition) of no axial compression to a state of axial compression" and the term "returning to a decompressed state" as "returning to a state (i.e. condition) of no axial compression." ICU urges the court to construe the term "compressed position" as "the position of the seal when it is under axial compression from a medical implement and opens the valve" and the term "decompressed position" as the position of the seal when it is not under axial compression from a medical implement and closes the valve." Because the words "into a" and "returning to a" from the claim language are not technical or obscure in their meaning, the court will follow ICU's lead and restrict its construction to "compressed position/state" and "decompressed position/state."

As noted above, although the parties agree that "state" and "position" should be construed similarly, they disagree over which word better captures the proper manner of viewing the role of axial compression in the claim language. Alaris, in focusing on the word "state," attempts to define compression in terms of the condition of the seal, i.e., either under axial compression or not. ICU, in focusing on the word "position," highlights the actual position of the seal and attempts to incorporate into the definitions the source of the compression, i.e. a medical implement, and the status of the valve, i.e. open or closed. A plain reading of the claim language itself makes clear that there is no need to import the source and valve status limitations into the construction of these terms, because they are already present in the claim language itself. For example, claim 1 of the '862 patent requires a seal that moves distally "into a compressed state upon insertion of the delivery end of the medical implement … and returning to a decompressed state upon removal of said delivery end from said opening…” Claim 1 goes on to describe the device in terms of "pushing said delivery end into the cavity to compress said seal sufficiently to allow the fluid to flow from said medical implement through [the] valve to the patient." Id. at 15:38-43 and 15:54-56. Both the concept of the medical implement as the source of compression and the concept of the valve being opened as a result of the compression are already included in the applicable claim language and thus do not need to be included in the construction of compression; indeed, to do so would render certain portions of the claim language superfluous or redundant.

Furthermore, the "into a" and "returning to a" language preceding the respective terms under construction make clear that what is at issue in the use of the terms "compressed state/position" and "decompressed state/position" in the claim language is best understood as referring to the condition of the Seal, irrespective of the source or purpose of the compression. As Judge Stotler concluded in the July 2004 Order,

… to move into an axially compressed state the claimed seal must first start in a state in which it is not axially compressed. Logically, the claim language describing the seal as "returning to an axially decompressed state" must then mean that the seal returns to the original state of no compression from which it moved initially."

July 2004 Order at Sec. III, P27. Nothing in this claim language discloses or suggests any intermediate condition of relative or partial compression.

Every claim term must have an antecedent basis in the specification. See Tandon, 831 F.2d at 1024; Lockwood, 107 F.3d at 1572. Here, the antecedent basis in the Common Specification for both "state" and "position" is "state," and the use of the term in the Common Specification confirms that the terms in question are best understood as referring to the condition of
the seal. As an example, the Summary of the Invention mirrors the claim language in describing the seal as moving "into a compressed state upon insertion of the tip of the medical implement into the opening and returns to a decompressed state upon removal of the tip." Id. at 3:32-35. The Common Specification further states that "[the application of pressure on the syringe … creates pressure on [the] seal cap," thereby suggesting that the seal was not initially under any pressure at all. Id. at 9:1-3: The Common Specification thus supports a straightforward reading of the claim language that suggests that "Compressed state/position" and "decompressed state/compression" are best understood in terms of the presence or absence of axial compression.

The proper construction of "compressed state/position" is thus "a state (i.e. condition) of axial compression," and the proper construction of "decompressed state/position" is thus "a state (i.e. condition) of no axial compression."

D. Whether the TFN and PFN Actively Compress Fractures by Means of a Bone Screw

The '406 patent claims a method of treating intertrochanteric fractures that includes the step of "compressing the fracture using the bone screw." (Column 8:17-20.) The court has interpreted this phrase to mean "squeezing together the fractured bone fragments by means of a screw." In the summary judgment order, the court concluded that this claim would cover "a compression method in which a screw is inserted into the area of a fracture without changing the position of any bone fragments, and a doctor rotates a nut around the screw to squeeze bone fragments together." (Order at 16.) At trial, Synthes requested reconsideration of this conclusion. Smith & Nephew claims that the method of using the TFN and PFN to treat intertrochanteric fractures violates claim 1(e) of the '406 patent.

At trial, Synthes reasserted the argument that it had made in favor of summary judgment: that the TFN and PFN do not practice this claim because compression does not occur simply by rotating the screw but instead requires the use of specially-designed, additional instruments. In support, Synthes points to the Recon Nail, the invention produced and sold by Smith & Nephew under the '406 patent. The only way for a surgeon using the Recon Nail to actively squeeze the bone fragments together ("active compression") is by continuing to tighten the lag screw inserted into the femoral head after the shoulder of the screw abuts the lateral cortex of the femur. (Tr. 365:23-366:23; TX 33.) The '406 specification discloses a similar method: "A hexagonally-shaped inset 52 in the head portion permits insertion of a suitable tool for compression of lag screw 50…. A hexagonal screwdriver or any suitable tool can be used to compress lag screw 50, 250 to a desired degree." (Column 5:18-21, 7:14-16.) Once the head-portion of the screw contacts the lateral cortex of the femur, additional turning of the screw will cause the threads to draw the opposed fracture surfaces together. (Tr. 810:11-813:8, 815:23-816:21, 3086:2-3087:8.)

A patent claim will not necessarily be limited to a preferred embodiment or the particular product sold under the patent. See, e.g., Nazomi Communications, Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1369 (Fed. Cir. 2005). Nevertheless, the embodiments cited by Synthes demonstrate that the method of active compression claimed in the '406 patent is not as narrow as Synthes argues. The embodiments rely on more than the screw itself to achieve the active compression claimed by the patent, each citing the need for "a suitable tool" to turn the screw. (Column 5:18-21, 7:14-16.) The Recon Nail and the TFN and PFN, therefore, require more equipment than "just the screw" to achieve active compression. Synthes' distinction appears to be that the Recon Nail and the '406 specification anticipate active compression by rotating the screw and the TFN and PFN employ the screw 14 only as an anchoring means.

14 The court, above, has found that the Helical Blade is a "screw" under the '406 and '663 patents.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

When using the TFN device, a surgeon may compress a fracture by twisting the Buttress/Compression Nut (TX 9) around the Blade Guide Sleeve (TX 7), which is abutted against the handle of the Helical Blade Inserter (TX 11), which is in turn abutted against the coupling screw connected to the Helical Blade. All of these items must move in order to achieve active interfragmentary compression using the TFN. (Tr. 1669:17-1670:3, 1766:21-1768:24.) The PFN uses a similar mechanism.
to actively compress bone fragments. That these mechanisms have more physical components than those used by the Recon Nail or a traditional compression hip screw system does not mean that they avoid the claimed step of "compressing the fracture using the bone screw." A compression mechanism in which a screw plays an indispensable role compresses the fracture "by means of a screw." This mechanism may use only an intramedullary rod, a screw, and a screwdriver, or it may, like the TFN and PFN, be more complex. Thus, using the TFN and PFN to actively compress intertrochanteric fractures practices the claimed method of "compressing the fracture using the bone screw."

**Construction of "compression locked"**

Although, in the briefs, the parties asked for claim construction of the entire phrase "such that advancement of semi-spherical head against said retaining portion causes said head of said screw to be compression locked thereagainst," the focus of the dispute is on the meaning of "compression locked." The parties appear to agree that compression locking is the process by which the retaining portion, or socket, and the head of the bone screw become locked into a position relative to each other: something happens whereby the screw head is in contact with the retaining portion and can no longer move relative to it. The dispute appears to center on the nature of the forces at work, as well as the role of the retaining portion. Medtronic contends that compression locking requires application of an inward radial force to squeeze and crush the retaining portion around the screw head; the volume of the retaining portion is decreased. Fastenetix contends that compression simply refers to pressure, and that the claim is not limited to inward radial pressure, since there could also be downward axial pressure at work (the screw head pressing downward onto the retaining portion), nor is reduction of the volume of the retaining portion required.

From the start, Medtronic appears to be taking an extreme position, and one that disregards the obvious. Rather than contending that compression locking occurs in part through the application of inward radial force, Medtronic's extreme position is that locking occurs only through the application of inward radial force which crushes the socket against the screw head. This is seen in categorical statements such as this one, made after describing compression by inwardly directed radial force: "No other type of locking is contemplated, described, or enabled by the '089 patent." (Defs.' Br. 31.)

This extreme position disregards the obvious other process involved in locking described in the patent: that process in which downward axial force on the screw head presses it against the retaining portion. As will be seen in the discussion that follows, claim 12 clearly expresses that such a process is at least involved in compression locking. In view of this, Medtronic's categorical rejection of this kind of locking seems plainly contrary to the words in the claim.

Medtronic first contends that the surrounding claim language which describes characteristics of the retaining portion supports its proposed construction. It points to the fact that claim 12 specifies that the retaining portion has "a slot formed therein, said slot rendering a volume of said retaining portion to be adjustable." (‘665 Patent, col 11, ll. 29-31.) Medtronic does not explain, however, how this limits the process of compression locking. Medtronic next notes that the retaining portion is "shaped to seat in said retaining surface of said bottom chamber." (‘665 Patent, col 11, ll. 32-33.) Again, however, Medtronic does not explain how this characteristic limits the process of compression locking. Rather, it skips to the conclusion: "Thus, claim 12 requires that the 'compression lock' occur as the result of the shape of the retaining portion and the shape of the bottom chamber of the axial bore." (Defs.' Br. 22.) This conclusion does not appear to be logically grounded in the two antecedent observations about the structure of the retaining portion. The fact that the retaining portion is shaped so as to have adjustable volume, and to be seated in the bottom of the chamber, does not obviously limit the nature of the locking force or process. Conspicuously absent from Medtronic's position is any expert support for its proposition: if, given the structural characteristics of the retaining portion stated in the claim, one of ordinary skill in the art would understand that the locking could only occur due to the application of inward radial force producing volume reduction of the retaining portion, why has Medtronic offered no supporting affidavit from an expert? 7

---

7 Medtronic did submit the rebuttal declaration of Robert E. Guldberg, Ph.D. with its responsive brief. The Court notes that Dr. Guldberg, in discussing "compression locked," merely parroted the legal arguments offered by Medtronic. (Guldberg Dec. PP 21-22.) Dr. Guldberg provided no technical or scientific analysis to support the proposition that locking can occur.
only due to the application of inward radial force producing volume reduction of the retaining portion.

Medtronic's position is also unpersuasive because it is inconsistent both with itself and with the plain language of the claim. Medtronic argues that the compression locking occurs because of "advancement of the semi-spherical head," and that this "must mean movement of the screw head toward the bottom of the axial bore." (Defs.' Br. 22.) If compression locking occurs following axial movement of the screw head toward the bottom, does that not describe the operation of axial force? Given that the claim expressly states that advancement of the semi-spherical head against the retaining portion causes the screw to be compression locked, how could compression locking exclude the operation of axial force? Medtronic's proposed "inward radial force" limitation is contradicted by the claim language describing how the device comes to lock the screw head, which is by the head's advancement against the retaining portion.

Claim 12 has much other language relevant to understanding compression locking. In addition to the language about the "advancement of the head" just discussed, the claim contains this detailed language about the locking process:

wherein said semi-spherical head portion is freely rotational within said retaining portion prior to being compressed onto said retaining portion, and

whereby when the rod is in said channel, downward movement of said top locking nut onto the rod results in a force upon said cap portion causing forcible advancement of the semi-spherical head of said screw thereby locking said screw, said coupling assembly and said body relative to one another.

('665 Patent, col 11, ll. 43-51.) Thus, in direct conflict with Medtronic's position, the claim clearly states that the head is "freely rotational . . . prior to being compressed onto said retaining portion." This is a clear statement that locking of the head (cessation of being freely rotational) proceeds from compression of the head onto the retaining portion -- the application of axial force to the head. The claim then repeats this even more clearly: "causing forcible advancement of the semi-spherical head of said screw thereby locking said screw, said coupling assembly and said body relative to one another." The patentee has clearly and repeatedly stated, within the claim itself, that application of axial force to the screw head causes it to lock against the retaining portion. Medtronic's position cannot be reconciled with this intrinsic evidence.

Moreover, Medtronic contends that, in compression locking, it is the retaining portion, or socket, that is compressed around the head of the screw. (Defs.' Br. 23.) Thus, in Medtronic's view, "compression" must involve the application of inward radial force to squeeze the socket portion against the screw head. This is contradicted by another use of "compressed" in the claim: "said semi-spherical head portion is freely rotational within said retaining portion prior to being compressed onto said retaining portion." ('665 Patent, col 11, ll. 43-45.) This shows that the applicants understood that the screw head could be compressed onto the retaining portion. Thus, if "compression" is limited in meaning to the application of inward radial force squeezing the socket portion against the screw head, the phrase just quoted becomes incomprehensible. This problem does not occur if one adopts the interpretation of Fastenetix: to compress is to apply pressure.

8 In its responsive brief, Medtronic defines "compression locking" as "inward forces reduce the volume of the socket by virtue of the slots until it locks the screw." (Defs.' Resp. Br. 14.)

9 This is supported by the use of "compression" in two other claims. Both claim 1 and claim 7 speak of "downward compression of a rod in said channel." ('665 Patent, col 9, ll. 24-25; col 10, l. 41.) Again, if compression is redefined as the application of inward radial force to squeeze, this claim language becomes incoherent. On the other hand, if compression is understood as simply the application of pressure, as Fastenetix contends, these phrases make sense. Similarly, the '665 patent abstract uses "compressed" to refer to both inward radial and downward axial pressure: the socket is said to be "radially compressed," but the cap is "compressed toward the socket portion," which can only involve downward axial force.

In its responsive brief, Medtronic responds to this argument about the two uses of "compression" in the patent. (Defs.' Resp. Br. 14.) Medtronic's reply is that this is irrelevant because the term in dispute is "compression locked." This comment itself
is ambiguous, and no further explanation is given. If the principle at work here is redefinition by implication, this Court does not perceive how the varied uses of forms of "compress" in the patent are irrelevant to understanding what the applicants meant by "compression locked."

Any proposed construction of "compression locked" in claim 12 must be evaluated in the light of the applicants' use of the same phrase in claim 18, which states, in relevant part:

wherein when a rod is placed in said channel, advancement of said locking nut produces a downward force on the rod translating into a downward movement of at least said cap portion and said screw causing deformation of said outer surface of said retaining portion within said nesting surface resulting in a locking force applied by said retaining portion against said semi-spherical head causing said screw to be compression locked within said body.

('665 Patent, col 12, ll. 36-44.) "Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims." Phillips, 415 F.3d at 1314. The use of this term in claim 18 thus gives important information about the meaning of "compression locked" in claim 12. In claim 18, deformation of the outer surface of the retaining portion causes a "locking force" to be applied by the retaining portion against the screw head, which causes the screw to be "compression locked." This is inconsistent with Medtronic's view of compression locking as requiring volume reduction of the retaining portion. In claim 18, compression locking occurs as a result of the application of force by the retaining portion against the head. The drafter has distinguished the deformation of the retaining portion from the application of locking force by it: they are separate concepts. For Medtronic to succeed with its argument, it must show that the applicants redefined "locking" so that it involves crushing of the retaining portion. 10 The language in claim 18 shows that the patentees did not redefine locking to include crushing of the retaining portion, but kept the concepts distinct and separate.

10 As will be discussed in the next paragraph, Medtronic contends that "compression locked" and "locking" have the same meaning. See, e.g., Defs.' Br. 31 ("The word 'locking' is used in one and only one context -- compression or crush locking the socket portion around the head of the screw.")

The parties have presented terms from three claims for construction. Each claim has a term which refers to locking: "compression locked" in claim 12, "locking contact" in claim 21, and "locking" in claim 27. Medtronic does not differentiate these terms. Rather, it contends that they all mean the same thing: "locking by the application of inward radial forces to crush the coupling element around the screw head." 11 (Defs.' Resp. Br. 25.) The failure to differentiate the terms creates significant problems in Medtronic's position.

11 This sentence is given as the construction of "locking" in claim 27, but Medtronic uses the same concepts to construe the locking terms in the other two claims. Compare to the quote in the preceding footnote, which comes from the construction of "locking contact" in claim 21; the definitions are essentially the same.

First, by making "compression locking" equivalent to "locking," this makes the word "compression" in claim 12 into meaningless surplusage. This strongly suggests that this construction must be wrong, since it is clear that the applicants did not use "compression" as a meaningless word.

Second, Medtronic overlooks the major difference in the use of "locking" in claim 27. In claim 12, the screw head and the socket portion are "compression locked." In claim 21, the screw head is moved into "locking contact" with the socket portion. Claim 27, however, refers to "locking the angle of the screw," not locking the screw head. Under Medtronic's
construction, this means that inward radial forces are applied to compress the socket around an angle, which makes no sense. This shows that "locking" cannot have been redefined by implication in the way that Medtronic contends. 12 Rather, given that the applicants wrote of locking a screw as well as locking an angle, it seems most likely that "locking" was not redefined so as to give it the specialized and unusual meaning Medtronic proposes.

12 Similarly, in describing the preferred embodiment, the specification states that the locking nut has a central post which provides "a central seating pressure point for locking the rod in the channel." (089 Patent, col 5, ll. 4-5.) This does not make sense if "locking" has been redefined by implication as Medtronic contends.

This view finds further support from the use of the phrase "locking nut," which appears in the specification of both patents as well as in claim 18 of the '665 patent. Claim 18 states that advancement of the locking nut produces a downward force on the rod. ('665 Patent, col 12, ll. 36-38.) This results in "a locking force applied by" the socket to the screw head "causing said screw to be compression locked." ('665 Patent, col 12, ll. 41-44.) Quite simply, if "locking" and "locked" have been redefined even just as applying inward radial forces -- setting aside the action of reducing the volume of the socket -- claim 18 becomes fully incoherent. Medtronic's proposed constructions regarding locking cannot be correct.

Furthermore, as Fastenetix notes, the patentees wrote other claims which clearly expressed the concept of crush locking. For example, both claims 1 and 7 in the '665 patent state that pressure on the socket portion "causes the forceable advancement of the socket portion into the tapered lower chamber portion of the axial bore, and locks the screw, coupling element and body relative to one another." ('665 Patent, col. 9, ll. 24-30; col. 10, ll. 42-47.) This claim language clearly expresses that the locking is produced by forcing the socket down against the tapered axial bore, implying the compression of the volume of the socket portion and the use of inward radial forces to crush lock the screw head. The applicants clearly expressed a locking process centered on the crushing action of inward radial forces in claims 1 and 7, but chose very different language to describe the locking in claim 12, which describes only the forcible advancement of the screw head, not of the socket portion. This supports the view that the applicant understood the locking process in claim 12 to involve the application of downward axial force on the screw head.

Medtronic also makes its "only one way" and "enablement" arguments -- the patent only enables one way to compression lock. As already established, this Court rejects these arguments. Medtronic does not point to language in the specification which constitutes a clear redefinition by implication. Moreover, even if Medtronic was correct and the specification did only describe locking through the use of inward radial force, claim 12 itself clearly states that forcible advancement of the screw head locks the screw, and so axial force must be a possible cause of compression locking.

Last, Medtronic contends that the "file history" supports its position. (Defs.' Br. 23.) Plaintiff points to this examiner's statement in the office action dated July 25, 2001: "the limitations 'expandable' and 'expansion' are unclear since it seems apparent that the retaining portion is instead compressed or contracted during use." (Gleason Dec. Ex. 8 at 2.) Again, even if this Court were to consider this statement as possibly relevant under an acquiescence theory, even though it was not made in regard to claim 12, and not made by the applicant, this statement does not have the meaning that Medtronic asserts. The examiner's thought that the retaining portion is compressed during use does not speak directly to the forces involved in compression locking and, at most, indicates that the examiner believed that, at some point during use of the device, the retaining portion was compressed. There is no way to know whether the examiner believed that this occurred during the compression locking, or at some earlier point. There is no reason to infer from this statement that the examiner understood locking to be limited to the application of inward radial force to crush lock the retaining portion around the screw head. This does not remotely resemble the clear and unambiguous disclaimer required by the Federal Circuit to serve as the basis for a finding of a claim limitation from the prosecution history. Nor does this appear to be the kind of binding acquiescence discussed above in TorPharm. There is no legal basis to find a claim limitation in this piece of prosecution history.

Fastenetix contends that the ordinary meaning of "compression locking" is the locking of two elements through the application of pressure. Medtronic seeks to limit this process to locking of the retaining portion and the screw head by inward radial force involving squeezing of the retaining portion around the screw head. This Court finds that Medtronic's construction is inconsistent with the plain language of claim 12 and finds no basis to limit "compression locking" as
Medtronic proposes.

864

1. Claim Construction: "Compression Mechanism"

Both independent claims in the '615 patent contain a claim limitation that requires the presence of a "compression mechanism along a longitudinal axis of said mount" or "a compressive mechanism between said foot and said head." 24 Plaintiff defines "compression mechanism" as "any structure that can be used to generate a compressive force within the pole." 25 Defendant defines "compression mechanism" as "any mechanism that can be compressed to adjust the fit of a mounted curtain and released to pin the adjusted curtain in place." 26 As discussed in the section on infringement, below, the allegedly infringing device falls within the scope of one definition but not the other. The court must therefore undertake claim construction to determine the proper definition of "compression mechanism."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

25 Id. at 8-9.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The court adopts Defendant's definition. The '615 patent claims, abstract, figures, summary of the invention, detailed description of preferred embodiments, and prosecution history conclusively show that a "compression mechanism" is any mechanism that produces action equivalent to a spring, by itself compressing a sufficient distance to aid in installing and adjusting the curtain while concomitantly generating an outward force when compressed to stabilize the curtain mount.

First, the plain meaning of the claims supports Defendant's construction. A "compression mechanism" is a mechanism that compresses or causes compression. Plaintiff reads "compression mechanism" as including ratchet and clamp devices, as well as bottle jack-type cylinders. 27 It is problematic to label a jack or ratchet-type device as a compression mechanism, since the jack or ratchet device functions (creates a force) by expanding and not compressing. Furthermore, Plaintiff introduces no evidence to suggest that jack or ratchet devices are commonly referred to as compression mechanisms. Plaintiff argues that a ratchet is a compression mechanism because the ratchet lengthens "the point where it creates a compressive force within the pole to hold the pole in place." 28 But that compression of the pole at that point is imperceptible. In contrast, a spring itself compresses.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Second, the '615 patent abstract supports Defendant's construction. The patent Abstract describes "a spring-loaded curtain mount" including a "compression mechanism disposed between the proximal end of the mount and the head." 29 Further, the Abstract explains, "[d]uring installation . . . the length of the pole is adjusted such that the combined length of the pole and mount is slightly longer than the distance between the floor and ceiling. . . . The curtain and mount are raised to the ceiling and the mount and pole are compressed [generating a] compressive force [that] secure[s] the mount in place." 30 Figure 7E of the patent shows the device operating in this fashion, and Figures 4A and 6 also depict a device capable of being compressed. The Summary of the Invention echoes the Abstract, describing "a spring-loaded curtain mount [and]
adjustable pole, [where] the length of the pole is adjusted such that the combined length of the pole and mount is slightly longer than the distance between the floor and ceiling.” 31 In this way, the Abstract describes a "compression mechanism" that itself compresses to pin the curtain in place. In contrast, ratchet and clamp, screw, and jack-type devices do not operate in this fashion, but rather extend the pole to create a force that secure the device in place.

Furthermore, the '615 patent's Detailed Description of Preferred Embodiments describes "a compression mechanism, for example a spring," that "generates a force" "as the spring in the curtain mount compresses." 32 The patent refers to a "compressed spring," "longitudinal compression," a pole that "compress[es] the spring," a "spring in compression," and a "combined length of the curtain mount and pole [that] is sized slightly larger than the floor to ceiling distance . . . ." 33 The patent states that "[c]ompression mechanisms include springs, pneumatic devices and hydraulic devices," and depicts a pneumatic or hydraulic compression mechanism in Figure 9A. 34 Significantly, pneumatic and hydraulic mechanisms are depicted as operating exactly like springs -- only the internal components of the mechanism's cylinder change, while the mechanism's action remains constant. 35

Nowhere does the '615 patent indicate that a "compression mechanism" might include a ratchet, screw, or jack-type device. 36 Nowhere does the '615 patent's prosecution history suggest that a "compression mechanism" encompasses devices that operate like ratchets. Instead, the prosecution history demonstrates that the terms "compression mechanism" underwent successive revisions and added limitations, including the limitation in Claim 1 that "said compression mechanism [is] biased to urge said head away from said interface." 37 Whereas a spring is predisposed to resist compression and thereby urge the head of the pole upwards, a ratchet mechanism requires ratcheting to accomplish the same result.

36 Plaintiff's expert notes that hydraulic or pneumatic mechanisms operate like ratchet mechanisms in that "extending the pole 2-3 inches past the height of the ceiling would drive the head of the device through the ceiling" just like Defendant's ratchet and clamp mechanism. Slocum Decl. at P 13. This evidence fails to support Plaintiff's case for three reasons. First, the above assertion is unsupported by analysis and appears unconvincing to the court at least in regard to the pneumatic mechanism. Second, even accepting Slocum's analysis on this point, in context it at most establishes that Plaintiff erred in assuming that a hydraulic piston could provide the same action as a spring, but it does not change the clearly indicated definition of a "compression mechanism." Third, because the patent claims are not ambiguous after consulting intrinsic evidence, it is improper to rely on extrinsic evidence. Phillips, 415 F.3d at 1318 (stating that reliance on extrinsic evidence is proper only when claims are still ambiguous after consulting intrinsic evidence). This final reason alone precludes reliance.
on Plaintiff's expert.

In sum, the '615 patent claims, abstract, figures, summary of the invention, detailed description of preferred embodiments, and prosecution history show that a "compression mechanism" is a mechanism that provides the same action as a spring; i.e., the mechanism itself is sufficiently compressible to easily allow users to adjust the placement of the curtain mount, and when compressed generates an outward force.

Plaintiff was ultimately responsible for drafting the claims, and was obligated to communicate to the public a "full, clear, concise, and exact" description of the invention. 38 The court will not extend the scope of the claims to include devices not disclosed or contemplated in Plaintiff's specification. Plaintiff's broad construction of compression mechanism is rejected.

Finally, Medtronic argues that the district court failed to properly construe the "compression member" limitation as a means-plus-function limitation, and that under a proper construction, all three accused devices do not infringe. Relying on Mas-Hamilton Group v. Lagard, Inc., 156 F.3d 1206, 1213 (Fed. Cir. 1998), Medtronic argues on cross-appeal that "compression member" is properly construed as a means-plus-function limitation despite the absence of the term "means" and that when the claims are so construed, none of the accused structures infringe. Specifically, Medtronic argues that claim 1 of the '678 patent identifies "compression member" only in terms of function, not structure, and that no credible extrinsic evidence demonstrates that the term has a well-understood structural meaning in the relevant art.

DePuy counters that the absence of the term "means" creates a presumption that "compression member" is not a means-plus-function limitation, that all testifying engineers recognized that the term "compression member" referred to a well-known class of structures, that claim 1 itself imposes certain constraints on the structure of the compression member, and thus the district court's construction was correct.

"Means-plus-function claiming applies only to purely functional limitations that do not provide the structure that performs the recited function." Phillips, 415 F.3d at 1311 (citing Watts v. XL Sys. Inc., 232 F.3d 877, 880-81 (Fed. Cir. 2000)). "[A] claim term that does not use 'means' will trigger the rebuttable presumption that [35 U.S.C.] § 112 P6 does not apply." CCS Fitness v. Brunswick Corp, 288 F.3d 1359, 1369 (Fed. Cir. 2002). This presumption can be rebutted "by showing that the claim element recite[s] a function without reciting sufficient structure for performing that function." Watts, 232 F.3d at 880.

"Our cases make clear, however, that the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004).

Here, the "compression member" limitation does not use the term "means," and the presumption against means-plus-function treatment is not overcome. The claims and the specification unmistakably establish that "compression member" refers to particular structure. The claim language demonstrates that the compression member must fit inside the cylindrical opening and be of sufficient size to exert a force on the screw head, which implies structure. '678 patent, col. 4, ll. 22-24. The specification likewise makes clear that the term "compression member" refers to a particular cylindrical insert and is not simply a general reference to any structure that will perform a particular function. See id., col. 2, l. 58-col. 3, l. 16, col. 3, l. 44-col. 4, l. 6. The prosecution history, while in evidence, provides no further guidance one way or the other. However, dictionary definitions and experts on both sides confirm that "compression member" is an expression that was understood by persons of ordinary skill in the art to describe a kind of structure. See Lighting World, 382 F.3d at 1358 ("The task of
determining whether the limitation in question should be regarded as a means-plus-function limitation . . . is a question on which evidence from experts may be relevant.

Moreover, Mas-Hamilton is not applicable here. In that case, no other claim terms attributed structural significance to the elements at issue, and there was no evidence that the term at issue had an understood structural meaning in the art. Mas-Hamilton, 156 F.3d at 1213-15 ("[W]e do not see that the remaining terms in the claim limitation . . . provide any structure necessary to remove this limitation from the ambit of section 112, P6."); id. at 1215 ("The district court determined that there was no evidence that a 'movable link member' has a well-understood structural meaning in the art."). That is not the case here. Instead, the overall impression of the claims and specification of the '678 patent is that "compression member" implied structure to one of ordinary skill in the art. This is shown by the intrinsic record and confirmed by the extrinsic evidence. Accordingly, we reject Medtronic's argument that the district court erred in not construing "compression member" as a means-plus-function limitation and in not finding non-infringement of all three models on that basis.

866

Compressive Strength of the Formation

Claims in the '930 and '631 Patents contain the terms "compressive strength" of the formation, "failure of the formation," and related terms. Baker Hughes contends "compressive strength" means "the confined, constrained, in situ, unconstrained or unconfined compressive strength." It does not construe "failure of the formation." ReedHycalog contends "compressive strength" means "the confined (in situ) compressive strength" and contends "failure of the formation" means "crush or indent any portion of (i.e. exceed the in situ compressive strength of) the particular subterranean formation."

The claim language in the '930 and '631 Patents only requires "compressive strength" and does not specify whether that strength is the confined or unconfined compressive strength. E.g. '930 Patent col. 15:47-48 ("so as to maintain a unit load on the formation below a compressive strength thereof"). The '930 and '631 Patents are directed towards subterranean drilling. See '930 Patent Abstract; '631 Patent Abstract. A person of ordinary skill in the art would determine the relevant compressive strength of the formation is the formation's compressive strength when in contact with the drill bit--in the borehole. This is the in situ compressive strength.

ReedHycalog's "failure of the formation" construction is accurate and will help the jury. The '930 and '631 Patents equate "substantially indent the formation" and "fail the formation." '930 Patent col. 3:5-8; '631 Patent col. 3:39-40. A drill bit will also fail the formation when it crushes the formation. Thus, the compressive strength and failure of the formation terms are construed accordingly.

22 Ref. No. 24 of Appendix B contains the disputed terms and their constructions.

867

82. The second additional limitation of claim 24 describes "a compressor." Although the specification, indicates that "a standard, oil-lubricated, high pressure compressor" could be used in the invention, ('845 patent, col. 4, lines 52-53), the use of such a compressor is predicated on using the nitrogen gas component to inert the crankcase of the compressor. ('845 patent, col. 4, lines 42-52.) However, claim 24 contains no limitation requiring the use of the nitrogen gas component in such a manner. Accordingly, the court construes "a compressor" in this limitation as follows: a compressor, either oil-free or oil-lubricated, capable of compressing and delivering air at least at 3000 p.s.i.g.
"Comprised of"

The district court found that the meaning of "comprised of" has not been clearly resolved in patent-specific precedent, and therefore the court held that the "ordinary and customary meaning" should be used. The court ruled that "comprised of" does not have the same open-ended meaning as "comprising," which also appears in claim 1, and that "comprised of" should be construed as a closed-end term that excludes the presence of all elements beyond those presented in the "comprised of" clause. Thus the court defined "comprised of" as "a limiting description of composition," reasoning that "[t]his construction preserves the distinction between 'comprised of' and 'comprising,' the latter of which in fact is a patent term of art when used in a transitional phrase . . . ."

We conclude that this ruling is not correct. Although "comprised of" is not used as regularly as "comprising," and "comprised of" is sometimes used other than as a "transition phrase," nonetheless it partakes of long-standing recognition as an open-ended term. See generally 3 Chisum on Patents § 8.06[1][b], at 8-180-82 (2007) (claims usually are structured with a preamble, a "transition phrase," and the elements or steps that are necessary to the right to exclude). The usual and generally consistent meaning of "comprised of," when it is used as a transition phrase, is, like "comprising," that the ensuing elements or steps are not limiting. The conventional usage of "comprising" generally also applies to "comprised of."

Alliance argues that several judicial decisions have used "comprised of" to mean "consists of." However, these rare usages do not remove from "comprised of" its conventional meaning when used as a transition term. The only patent case that illustrates this casual usage appears to be Glaxo Grp. Ltd. v. Apotex, Inc., 376 F.3d 1339, 1343 (Fed. Cir. 2004), where the invention was a "highly pure amorphous form of CA [cefuroxime]," and the opinion described the accused product as "an amorphous co-precipitate comprised of 90% CA, 9% sorbitol, and 1% zinc chloride by mass." This usage of "comprised of" was not as a claim transition term, but was the court's description of the defendant's product; there was no issue of whether "comprised of" was a limiting term in patent claim style. Similarly, in Aro Mfg. Co. v. Convertible Top Replacement Co., 365 U.S. 336, 346, 81 S. Ct. 599, 5 L. Ed. 2d 592, 1961 Dec. Comm'r Pat. 635 (1961) the Court stated: "The decisions of this Court require the conclusion that reconstruction of a patented entity, comprised of unpatented elements, is limited to such a true reconstruction of the entity . . . ."; this linguistic usage is not concerned with claim drafting; and, if anything, it is open-ended and non-limiting.

The other cases to which Alliance directs us are not patent cases, and the usage is simply as descriptive text. An example is Admiral Fin. Corp. v. United States, 329 F.3d 1372, 1377 (Fed. Cir. 2003), where the court wrote that "Admiral . . . seek[s] total restitution in the amount of $14,395,075, comprised of $11,072,075, representing capital contributions to Haven, and $3,323,000, representing the amount that Admiral claims it saved the government." Similarly in Nissho Iwai Am. Corp. v. United States, 982 F.2d 505, 506 n.1 (Fed. Cir. 1992) the court explained that: "The parties estimated that the cars would be comprised of 57.45% Japanese-made components and 42.55% American-made components." These cases raise no issue of the conventional patent claim meaning of "comprised of."

In the patent claim context the term "comprising" is well understood to mean "including but not limited to." In Vivid Techs., Inc. v. Am. Sci. & Eng'g, Inc., 200 F.3d 795, 811 (Fed. Cir. 1999) the court explained that patent claims "use the signal 'comprising,' which is generally understood to signify that the claims do not exclude the presence in the accused device or method of factors in addition to those explicitly recited." In Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999) the court explained that "the terms 'comprise' and 'consist' have different meanings; . . . 'comprising' . . . is inclusive or open-ended and does not exclude additional, unrecited elements or method steps . . . . From these definitions it is clear that 'comprise' is broader than 'consist.'" Similarly, our predecessor court explained that this usage of "comprising" also embraces "comprises" and "which comprises." Application of James F. Hunter, 288 F.2d 930, 48 C.C.P.A. 887, 1961 Dec. Comm'r Pat. 289 (CCPA 1961) (the term "comprises" does not limit the claim to the steps that are listed).

The contrast, in patent lexicography, is with "consisting of," not with variations of "comprises." It is equally well understood in patent usage that "consisting of" is closed-ended and conveys limitation and exclusion. See Norian Corp. v. Stryker Corp., 363 F.3d 1321, 1331 (Fed. Cir. 2004) ("consisting of" is a term of patent convention meaning that the claimed invention contains only what is expressly set forth in the claim . . . [however] it does not limit aspects unrelated to the
invention"); In re Gray, 53 F.2d 520, 19 C.C.P.A. 745, 1932 Dec. Comm'r Pat. 85 (CCPA 1931) (the use of the claim term "consists" is limited to the claim's enumerated alloy metals without other elements, unlike the term "comprising" which permits the inclusion of other metals than those claimed). Robert A. Faber, Landis on Mechanics of Patent Claim Drafting § 2:5, 2-15 (5th ed. 2006) also elaborates that "[o]ther words, less often used, have been given the same meaning in patent claim interpretation as 'comprising': 'including,' 'having,' 'containing,' and even 'wherein.'"

District court cases illustrate this routine construction of "comprised of" in the same way as "comprising," as meaning "including but not limited to." E.g., SKW Americas v. Euclid Chem. Co., 231 F. Supp. 2d 626, 637 (N.D. Ohio 2002) ("Because the hydraulic cement mix is 'comprised of' the four elements listed . . . it may include other elements as well."); B.F. Goodrich Flight Sys., Inc. v. Insight Instruments Corp., 22 USPQ2d 1832, 1840, 1992 WL 193112, at *9 (S.D. Ohio Feb. 25, 1992) ("Use of the term 'comprised' renders this claim an 'open' claim which will read on devices which merely add additional elements or steps."); aff'd, 991 F.2d 810 (Fed. Cir. 1993) (Table); Univ. of Fla. Research Found., Inc. v. Orthovita, Inc., No. 1:96-CV-82-MMP, 1998 U.S. Dist. LEXIS 22648, 1998 WL 34007129 (N.D. Fla. Apr. 20, 1998) ("comprised of" is broader than "consisting essentially of" when used in patent claims).

These cases reflect the general understanding and usage of "comprised of" in patent convention as having the same meaning as "comprising." For patent claims the distinction between "comprising" and "consisting" is established, along with the meaning of "comprised of" as related to "comprising," not "consisting of." Correctly construed, "comprised of" does not of itself exclude the possible presence of additional elements or steps.

Applying an incorrect construction of "comprised of," the district court ruled that "unique authorized information . . . comprised of machine-readable code elements coded according to a detectable series" is limited to coding by a detectable series, and that since the Alliance code systems include a "secret" series along with a detectable series, the limit imposed by "comprised of" bars infringement. On the correct construction of "comprised of," this reasoning does not support the court's ruling as to "secret" series. However, as we shall discuss, the prior art and prosecution history served to limit the scope of "unique authorized information" to a "detectable series" and to exclude a series that included "secret" information.

As to DDI's second argument, we acknowledge that the term "comprising" raises a presumption that the list of elements is nonexclusive. See Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997). However, "'comprising' is not a weasel word with which to abrogate claim limitations." Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1380 (Fed. Cir. 1998). "Comprising" appears at the beginning of the claim-"comprising the steps of"-and indicates here that an infringing process could practice other steps in addition to the ones mentioned. Those six enumerated steps must, however, all be practiced as recited in the claim for a process to infringe. The presumption raised by the term "comprising" does not reach into each of the six steps to render every word and phrase therein open-ended-especially where, as here, the patentee has narrowly defined the claim term it now seeks to have broadened. The district court's limitation of the claim scope to exclude processes that produce some irregularly shaped particles is correct.
Federal Circuit found the construction "clear" and "not ambiguous." See id. at 1371-73 (citing, inter alia, Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001) and Abbott Labs. v. Baxter Pharm. Prods., Inc., 334 F.3d 1274, 1280 (Fed. Cir. 2003)). Gillette found that the "language of the claims depending from claim 1 also support reading comprising' and group of' as open terms." Id. at 1373 (discussing the difference between "the span" and "a span" in claim 2 of the 777 Patent).

Next, the Federal Circuit construed the terms "first, second, and third" to be "terms to distinguish different elements of the claim, not terms supplying a numerical limit." Gillette, 405 F.3d at 1373. This construction was based on the Federal Circuit finding that the language of Claim 1 (a) provided different definitions in terms of location and exposure for the "first, second, and third" blades, (b) did not follow a consecutive order, and (c) used the open-ended terms "comprising" and "group of." Id. at 1372-74. "The specification provides further support for interpreting claim 1 to encompass razors with more than three blades" by the use of the phrase "plurality of blades" and the absence of disavowals of claim scope. Id. at 1373-74. In addition, the admissions of Schick in the "prosecution of patents related to the 777 patent also support reading claim 1 as an open claim." Id. at 1373.

Schick contends that new evidence and the intervening en banc decision of Phillips require reinstatement of this Court's original claim construction.

a. New Evidence

i. Gillette's statements in prosecuting counterparts to the 777 Patent in Australia and Malaysia

Schick submits that Gillette made multiple admissions that its invention is limited to three-bladed razors in the prosecution of Australian and Malaysian counterparts to the 777 Patent. (Defs.' Markman Br. 3-5.) Specifically, in prosecuting the Australian counterpart, Gillette submitted on October 2, 1997 that:

With respect the essence of the present invention, as recited in claim 1 (the sole independent claim), is not any multiple (more than 2)-bladed razor but only a 3-bladed razor with a specific relation of blade geometry (exposure and span). . . . Referring now to paragraph 4 of the Action, in the first place the cited U.S. Patent 3,786,563 is not relevant because it is concerned with a two-bladed razor whereas the present invention is limited to a three-bladed razor.

(Id. Ex. 2 10-11.) In prosecuting the Malaysian counterpart, Gillette submitted in almost identical language on June 24, 1999 that:

It should be respectfully pointed out to the Examiner that the essence of the present invention, as recited in claim 1 (the sole independent claim), is not any multiple (more than 2) -- bladed razor but only a 3-bladed razor with a specific relation of blade geometry (exposure and span). . . . Cited references US-A-3786563 and US-A-4146958 are not relevant because they each concern a two-bladed razor, whereas the present invention is limited to a three-bladed razor.

(Harris Summ. J. & Markman Decl. Ex. 1 GIL-Q 43492-93.)

Schick contends that these also blatant admissions are critical to construing the terms "first, second, and third" in this case because the Federal Circuit expressly relied on Schick's admission, regarding a related patent in front of the European Patent Office ("the EPO"), that an open interpretation of "comprising" would not exclude an arrangement with four or more blades. (Id.) Gillette agrees that it made the statements cited by Schick but disputes their relevance based on the different procedural and patent contexts in which they were made. (See Pls.' Opp'n to Defs.' Markman Br. 4-10.)

While Gillette's statements are admissions and relevant to what a person of ordinary skill in the art would understand the terms "first, second, and third" to mean, this new evidence does not necessarily alter the Federal Circuit's construction. Schick's admission to the EPO was not integral to the Federal Circuit's reasoning in Gillette. Two members of the Federal Circuit construed the terms "first, second, and third" based on their view of the language of Claim 1. The reference to Schick's admission in a three-sentence paragraph in the opinion merely provided the cherry on the top. Therefore, Gillette's admissions have only tangential significance.

Extrinsic evidence is "less significant than the intrinsic record in determining the legally operative meaning of claim
language," Phillips, 415 F.3d at 1317-19 (discussing the reasons as well for treating extrinsic evidence with less weight), and has "no bearing" on claim construction if it "conflicts with the intrinsic record," Cross Med. Prods., Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293, 1304 (Fed. Cir. 2005) (citing Phillips, 415 F.3d at 1318). While the Federal Circuit has occasionally used statements made in front of foreign patent offices regarding related patents to determine what a person of ordinary skill in the art understands terms to mean, it has never made them a part of the intrinsic record for claim construction purposes. See Phillips, 415 F.3d at 1317 (defining intrinsic prosecution history to include "the complete record of the proceedings before the PTO and . . . the prior art cited during the examination of the patent" and extrinsic evidence to include "all evidence external to the patent and prosecution history" (quotations and citations omitted)); Gillette, 405 F.3d at 1374 (referencing statements made regarding related patent in front of foreign patent offices but not characterizing them as intrinsic prosecution history of patent at issue); C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 870 n.6 (Fed. Cir. 2004) (leaving the question unresolved of whether statements applicants made during the prosecution of foreign patent applications may limit claims when intrinsic record suffices to support the claim construction); Tanabe Seiyaku Co., Ltd. v. U.S. Int'l Trade Comm'n, 109 F.3d 726, 733 (Fed. Cir. 1997) ("In evaluating infringement under the doctrine of equivalents, representation[s] to foreign patent offices should be considered . . . when [they] comprise relevant evidence." (citation omitted)). Indeed, the rationales underlying according extrinsic evidence with less weight in comparison to intrinsic evidence seem to apply to such statements not only because the patent language may differ, as is the case here, but also because the patent regimes differ. Phillips, 415 F.3d at 1319 (noting that extrinsic evidence "is unlikely to result in a reliable interpretation of patent claim scope unless considered in the context of the intrinsic evidence").

Therefore, Gillette's admissions, while relevant, do not necessarily alter the Federal Circuit's construction of the terms "first, second, and third" in Gillette.

ii. Clerical error of the Patent & Trademark Office ("the PTO")

Schick also submits that the Federal Circuit analyzed sua sponte the difference between the use of "the span" and "a span" in a dependent claim "evidently without considering a critical aspect of the record." (Defs.' Opp'n to Pls.' Markman Br. 10.) Claim 2 of the 777 Patent ("Claim 2"), which depends on Claim 1, recites:

A safety razor blade unit according to claim 1, wherein the span between the first blade edge and the guard is substantially smaller than a span between the edges of the first and second blades and the span between the edges of the second and third blades.

777 Patent col.4 11.16-20 (emphasis added). The Federal Circuit found that this language "also support[s] reading comprising' and group of' as open terms" because:

The patent drafter's use of "a span" between the first and second blades recognizes that more than one such span may exist. On the other hand, the drafter's use of "the span" to identify the span between the guard and first blade recognizes that only one such span is possible.

Gillette, 405 F.3d at 1373. 2 The dissenting opinion pointed out that the patent drafter would have used "spans" instead of "a span" to indicate plurality. See Gillette, 405 F.3d at 1376-77 (Archer, J., dissenting).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 The Gillette decision made no mention of the drafter's use of "the span" between the second and third blades in the same sentence.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Schick contends that the difference between "a" and "the" in the 777 Patent is due only to the failure of the PTO clerk to properly enter an amendment to the patent application. (Defs.' Opp'n to Pls.' Markman Br. 10-11.) Indeed, the amendment cited by Schick requests that "the span" be changed to "a span" in four different claims. (See Harris Summ. J. Decl. Ex. 16 at G 0000101-06.) Gillette responds that the Federal Circuit's reasoning has continued vitality because "the span" remains in Claim 2. (Pls.' Reply to Defs.' Opp'n to Pls.' Markman Br. 6-7.)
Again, similar to Gillette's admissions, the Federal Circuit's misplaced reliance on a typographical error does cut support away from its conclusion that the terms "comprising" and "group of" are presumptively open-ended, but it does not eviscerate the core rationale of the two-member majority. Gillette found the "clear language" of Claim 1 to be "not ambiguous." Id. at 1371-73 (citing, inter alia, Crystal Semiconductor, 246 F.3d at 1347, and Abbott Labs., 334 F.3d at 1280). The discussion of definite and indefinite articles in claims depending on Claim 1 merely added support. Id. (noting that the language "also support[s] reading comprising' and group of' as open terms").

b. New Law

Schick submits that the Federal Circuit's subsequent en banc Phillips decision supersedes the reasoning in Gillette. Specifically, Schick contends that "the linchpin of the panel's majority decision was its observation that the 777 Patent contains no explicit disclaimer' or disavowal' of razors with more than three blades, and that this "approach to claim construction -- the view that a claim term encompasses any meaning not expressly defined away or disavowed in the patent -- plainly does not survive Phillips." (Defs. Opp'n to Pls.' Markman Br. 4.) Schick's argument fails.

Schick misinterprets Phillips in applying it to Gillette. Gillette stated that "words or expressions of manifest exclusion' or explicit' disclaimers in the specification are necessary to disavow claim scope." Id. at 1374 (citations omitted). The Federal Circuit did not reject this approach in Phillips. Indeed, as noted by Gillette, both Phillips and subsequent Federal Circuit decisions affirmed the doctrine. See Phillips, 415 F.3d at 1316 ("The specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor." (citation omitted); see, e.g., NTP, Inc. v. Research in Motion, Ltd., 418 F.3d 1282 (Fed. Cir. 2005) (finding that the "required words or expressions of manifest exclusion or restriction representing a clear disavowal of claim scope are not present in these passages from the prosecution history" after Phillips), rehe'g and rehe'g en banc denied (Oct. 7, 2005). Rather, Phillips overturned the approach of Texas Digital, where claim terms are construed to encompass all dictionary definitions consistent with the intrinsic record unless the specification contains a sufficiently specific alternative definition or disavowal. Phillips, 415 F.3d at 1319-20; Nystrom v. Trex Co., Inc., 424 F.3d 1136, 1144-45 (Fed. Cir. 2005).

Schick is correct, however, in emphasizing that Phillips reaffirmed the primacy of the specification in construing claim terms: "claims must be read in view of the specification, of which they are a part," and "the specification is always highly relevant to the claim construction analysis. Usually it is dispositive; it is the single best guide to the meaning of a disputed term." 415 F.3d at 1315 (citations omitted). In all of the post-Phillips cases cited by Schick, the Federal Circuit used the specification to interpret the meaning of a term where the meaning could not be conclusively discerned from the claim language. See Nystrom, 424 F.3d at 1143-44 (examining the specification and prosecution history to construe the term "board" when the claims established only a presumption that the term was not limited to wood); Network Commerce, Inc. v. Microsoft Corp., 422 F.3d 1353, 1359-61 (Fed. Cir. 2005) (examining the specification to construe the term "download component" when "the claim language is not clear as to what other programs are to be used with the download component" and when the parties agreed that the term "does not have a specialized meaning in the relevant art"); AquaTex Indus., Inc. v. Techniche Solutions, 419 F.3d 1374, 1380-82 (Fed. Cir. 2005) (examining the written description, prosecution history, and extrinsic evidence of record when the claims "offer little guidance as to the underlying composition of fiberfill batting material' apart from the functions it must be capable of performing").

Schick is also correct in emphasizing that the broad constructions of the terms at issue in those post-Phillips cases were rejected because the Federal Circuit panels unanimously found that the narrower meanings were contained consistently throughout the specifications. See Nystrom, 424 F.3d at 1143-44 (Fed. Cir. 2005) (construing the term "board" to be limited to wood material where "throughout the written description, Nystrom consistently used the term board' to describe wood decking material cut from a log"); Network Commerce, 422 F.3d at 1360-61 (construing the term "download program" to include a boot program that interacts with the computer operating system directly where "the specification repeatedly states that the download file contains the boot program" and "describes no programs mediating between the boot program and the operating system"); AquaTex, 419 F.3d at 1381 (Fed. Cir. 2005) (construing the term "fiberfill batting material" to be limited to purely synthetic fiber where the written description provides guidance only to materials "entirely of synthetic materials").

These latter arguments are persuasive, but Schick is preaching to the choir. While I respectfully disagree with the two-member majority in Gillette, I am bound by the construction of its opinion that the plain meaning of the claim language encompasses more than three blades. Perhaps based on a fuller record with the new evidence cutting away the support of the
U.S. Surgical claims the lockout in its open linear cutters is not in the staple cartridge, but rather in the "disposable loading unit" ("DLU"), which they contend is distinguishable from Ethicon's staple cartridge. Ethicon insists that the U.S. Surgical's disposable loading unit is actually a staple cartridge. Ethicon makes a very convincing argument that U.S. Surgical's DLU functions in a manner which in common parlance could be characterized as a cartridge. It is intended to be inserted and removed from a larger instrument, much like a cartridge for a VCR or a ball point pen. However, in the context of a patent, an inventor is his own lexicographer. United States v. Telelectronics, Inc., 857 F.2d 778, 781-82 (Fed. Cir. 1988). The meaning of any individual term in a claim is defined by the context of the patent itself. The Court must ascertain the meaning of words in a claim by interpreting the words "with regard to the other claims, the specification, and the prosecution history." Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044, 1056 (Fed. Cir. 1988). Therefore, our inquiry is not simply whether U.S. Surgical's DLU functions as a cartridge in the ordinary layman's understanding of the term, but rather whether the U.S. Surgical's DLU reads on Ethicon's cartridge as defined in the Fox Reissue Patent. In our Order denying Ethicon's Motion for a Preliminary Injunction, we conducted an extensive discussion of this issue. Ethicon Endo-Surgery v. U.S. Surgical Corp., 855 F. Supp. at 1509-13. Having once again considered the matter in great depth, we are satisfied that our original interpretation of Claim 6 was correct. In our original holding, we relied primarily upon the language of claim itself, applying the same general rules of construction as any other written instrument. See Merrill v. Yeomans, 94 U.S. 568, 571, 24 L. Ed. 235 (1877) (patent interpretation requires the use of "well-settled rules of construing all instruments").

Claim 6 states:

6. In a staple cartridge insertable within a surgical stapler and containing staples and comprising [1] an elongated body including one or more longitudinal slots for slidably receiving one or more longitudinal pusher bars comprising a firing mechanism of said surgical stapler, and [2] a plurality of drivers engageable by said pusher bars for ejecting the staples from the cartridge, said staple cartridge releasably fastened to a said [sic] surgical stapler, the improvement comprising [3] a lockout mechanism connected to said longitudinal slots for preventing said pusher bars from passing more than one time through said longitudinal slots.

United States Patent No. Re. 34,519 (the "Fox Reissue Patent"), Column 5, Lines 47-58 (emphasis supplied). As our emphasis indicates, the elements of the staple cartridge listed in Claim 6 in addition to the staples themselves are (1) an elongated body, (2) a plurality of drivers and (3) a lockout mechanism. The elongated body is further described as "including one or more longitudinal slots." The slots are designed "for slidably receiving one or more longitudinal pusher bars" which comprise the "firing mechanism of said surgical stapler." In practice, the staple works by inserting the pusher bars in the longitudinal slots, displacing the drivers, which in turn push the staples through the tissue. The staples then contact an anvil which causes them to bend and seal.

The issue as Ethicon frames it is whether U.S. Surgical's DLU is really the Fox Reissue Patent's "cartridge" with additions. If so then the U.S. Surgical lockout device, located in the DLU would be located in the cartridge and would therefore read on the Fox Reissue Patent. U.S. Surgical contends that the cartridge of the Fox Reissue Patent is analogous to the "cartridge assembly" in their device. The cartridge assembly is a part of their DLU which contains the staples, drivers and which receives the pusher bars. U.S. Surgical's cartridge assembly does not contain a lockout mechanism, but rather it is located at the opposite end of the DLU. We are satisfied that U.S. Surgical's construction of "staple cartridge" is correct.

First, the wording of Claim 6 describes the staple cartridge as comprising longitudinal slots for receiving longitudinal pusher bars. These pusher bars are the firing mechanism for engaging the drivers and thus ejecting the staples. This description by our reading depicts the pusher bars as separate entities from the staple cartridge. Ethicon argues that since Claim 6 uses the patent term of art "comprising," we should conclude that the staple cartridge is not limited to the elements delineated in the claim. See Berenter v. Quigg, 737 F. Supp. 5, 6-7 (D.D.C. 1988) ("The word 'comprising' means the recited elements are only a part of the device; therefore, the claim is open.") However, the term of art simply indicates that elements
not enumerated may be included in the category as "comprised." We agree with Ethicon that its staple cartridge can be comprised of more than slots, but we interpret the language

comprising [1] an elongated body including one or more longitudinal slots for slidably receiving one or more longitudinal pusher bars comprising a firing mechanism of said surgical stapler
to indicate that the pusher bars are outside the staple cartridge. When elements are specifically described in a claim as separate and distinct, it would be inconsistent to assume that the author intended the one to be included in the other.

This reading is also consistent with the historical development of the U.S. Surgical device. The 1970's version of that device came with the package of disposable parts including a separate anvil, staple cartridge and cam bar-knife assembly. The package was labeled a "disposable loading unit." The surgeon would assemble these parts manually. Later U.S. Surgical combined the staple cartridge and cam bar-knife assembly elements into a DLU. However, they have retained the language "cartridge" or "staple cartridge" to refer to the plastic piece which contains the staples, staple drivers and slots for receiving the cam bars. This staple cartridge remains a distinct sub-element of the DLU.

In our previous decision, we found additional evidence of this in the specification of the Fox Reissue Patent. See Ziggity Systems, Inc. v. Val Watering Systems, 769 F. Supp. 752, 784 (E.D. Pa. 1990) (holding that a court can turn to the specifications and drawings in order to aid it in understanding the scope and meaning of the language employed in the claims). The inventor is allowed considerable latitude in the use of terminology, but words must be used in the same way in both the claims and the specification. United States v. Telelectronics, Inc., 857 F.2d at 781-82. Our limited reading of the meaning of cartridge in the Fox Reissue Patent is reinforced by the language of the specification:

[A] typical surgical stapler will have an upper jaw, firing means, a lower jaw . . . and a staple cartridge which fits within the lower jaw. . . The firing means will generally comprise a pusher bar or firing wedge . . The firing means will also contain a knife which generally will be placed between the firing wedges. . . When the firing wedge travels through the staple cartridge, and its activating drivers, it will come into contact with a lockout mechanism.

United States Patent No. Re. 34,519 (the "Fox Reissue Patent"), Column 2, Lines 45-54, Column 3, lines 2-5 (reference numbers omitted). Here again the staple cartridge is described as distinct from the pusher bar(s). The pusher bars travel through the staple cartridge. Our reading of Claim 6 leads us to conclude that in the context of the Fox Reissue Patent, the term staple cartridge has a specific meaning and that it does not include the firing means or pusher bar(s).

We are satisfied that our reading of Claim 6 is required by the language of the claim itself, as interpreted in the context of the remainder of the patent, in particular the specification. However, at the August hearing Ethicon presented cogent challenges to our reading. Ethicon's technical expert Dr. Collins testified that to one knowledgeable in the art, the staple cartridge in the Fox Patent was the same as U.S. Surgical's DLU. Dr. Collins demonstrated that some of U.S. Surgical's early patents seem to use the terms "cartridge" and "DLU" interchangeably. See for example United States Patents No. 4,520,817 & 4,127,227 ("Green '817 & '227"). Additionally, these Green patents apparently allow for the inclusion of pusher bars in the cartridge. Mr. Green himself in his deposition testimony seems to use the terms "DLU" and "cartridge" interchangeably.

U.S. Surgical responds to Dr. Collins testimony by making a distinction between the generic term cartridge, which admittedly describes its DLU and the more precise term "staple cartridge" as used in the Fox Patent. This is in line with our initial finding that the generic meaning of "cartridge" is not determinative of the same term used in the disputed patents. We have already concluded that both terms "staple cartridge" in Fox Patent and "DLU" in the Tompkins Patent are more restrictive than "cartridge" in the generic sense.

Finally, Dr. Collins raises a credible issue from the Fox prosecution history. Dr. Collins demonstrated how the PTO rejected claims in the original Fox Patent application citing as prior art the Noiles '077 Patent, which contains a lockout off the cartridge. Dr. Collins testified that since the examiner cited this patent as prior art, then he must have determined that Fox allowed a lockout outside the cartridge. U.S. Surgical's expert Mr. Nusbaum, who worked in the patent office for 17 years, agreed that some statements of the PTO in the Fox Reissue Patent prosecution history were inconsistent with U.S. Surgical's position. However, he was able to explain how the prosecution history taken as a whole supported the interpretation that the Fox Reissue Patent described a lockout mechanism in a staple cartridge.
In the process of our in-depth analysis of the Fox Reissue Patent prosecution history, inconsistencies were demonstrated by both Parties. If anything we gained an appreciation for the complex and difficult job of the patent examiner. It became evident that the patent application process involves a series of interactions between the applicant and the patent office. We came to realize that it is impossible to reconcile all the implications and inferences which could be made, based on the actions taken by the PTO in the extensive Fox Reissue Patent prosecution history. This rather unusual prosecution history includes: the original application and approval, a request for reexamination, the PTO's denial of that request, the PTO sua sponte reconsideration and subsequent reexamination, the reissue proceedings and subsequent reissue, as well as several interference actions. This realization reassured us that fundamentally it is the actual language of the patent itself which should be our primary focus. Additionally, the prosecution history, taken as a whole, strongly supports our reading.

As we noted above, the implications which could be drawn from the Fox Reissue Patent prosecution history are at times difficult to reconcile, but one statement of the PTO seems particularly clear. The PTO, upon reexamination, reconfirmed all twelve of the original Fox Patent claims, in a document dated July 7, 1991. This document, cited by both sides says in pertinent part:

The claims are confirmed because the prior art of record do not disclose or suggest a surgical staple cartridge comprising a lockout mechanism connected to longitudinal slots of the cartridge in the manner set forth in claim 6 wherein the lockout mechanism prevents the pusher bars from passing more than once through the longitudinal slots.

All of the references cited by the patent owner, with the exception of the Poirer reference and Auto Suture booklet, disclose devices having a lockout mechanism that allow its pusher bars to pass more than one time through the longitudinal slots. The devices shown by Poirier and the Auto Suture booklet do not have a lockout mechanism in the cartridge.

Notice of Intent to Issue Reexamination Certificate, United States Patent No. 4,892,244, July 7, 1991, Defendant's Memorandum in Opposition, Exhibit 14, Document 11. Our reading of this statement is that the PTO distinguished Fox from the prior art for two reasons: because the lockout is in a cartridge and because it prevents multiple firing.

The transition of claim 24 reads:

comprising the step of:

The parties agree that this is interpreted as the "method including but not limited to the following steps performable in any order unless inherently demanded by the nature of the step."

The parties disagree as to whether the order of the steps is fixed by the claim. Generally, steps are not fixed in the order presented unless the steps of the method actually require an order. Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1342 (Fed. Cir. 2000). When the method steps, however, implicitly require that they be performed in the order as laid out in the claim, that order becomes fixed. Id. Defendants claim that since it only makes sense that step (f) be performed after step (e), this fixes the order of the steps to the way they are listed in the claim. Plaintiff claims that the steps may occur in any order. It is not absolutely necessary that (e) (collapsing and removing) be performed before (f) (severing edges). In fact, one could envision a situation where the surgeon may sever the edges of the expended layer in order to facilitate the removal process. Therefore, the court interprets this claim as not requiring steps (e) and (f) to be performed in the stated order.

B. "comprising the steps of: seating …; suspending …; and driving …."

Plaintiff argues that each of the three steps in this method claim (seating, suspending, and driving) require specialized construction as step-for-function elements under 35 U.S.C. § 112 P 6. 15 The analysis of such elements is similar to that
applied to means-plus-function elements, and would be limited by the detail provided in the specification. Defendants contend that these elements require no construction at all.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

15 35 U.S.C. § 112 P 6 states: "An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." (emphasis added).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - 

Determining whether a claim invokes the step-for-function application of § 112 ¶ 6 has been explained by the Federal Circuit accordingly:

Method claims necessarily recite the steps of the method, and the preamble words that "the method comprises the steps of" do not automatically convert each ensuing step into the form of § 112 P6. Nor does the preamble usage "steps of" create a presumption that each ensuing step is in step-plus-function form; to the contrary, the absence of the signal "step for" creates the contrary presumption.

Cardiac Pacemakers, Inc. v. St. Jude Medical, Inc., 381 F.3d 1371, 1382 (Fed. Cir. 2004). Accordingly, this Court determines that the inclusion of the phrase "comprising the steps of" does not convert the elements of this method claim into steps-for-function. Thus, the steps of the method (seating, suspending, and driving) are construed the same as any other claim element. The Court finds that these words are readily understood and, therefore, no construction is required.

GO BACK

The term "a method . . . comprising the steps" is found only in the method claims of the patents-in-suit. This term constitutes the preamble and transitional phrase of the method claims. Claim 1 of the 779 Patent claims: "A method of manufacturing a smooth garment seam between first and second garment components comprising the steps" (a) through (g). 779 Patent at 6:26-28 (emphasis added). Claim 1 of the 615 Patent claims: "A method of manufacturing a pucker free garment seam between first and second garment components comprising the steps" (a) through (g). 615 Patent at 6:28-30 (emphasis added).

Taltech originally asked the Court to construe "a method . . . comprising the steps" to mean that "elements (a)-(g) of these method claims may be performed in any order consistent with the language and logic of the respective method claim and consistent with the Taltech 779 and 615 patent specifications." In its supplemental brief, Taltech altered its proposed construction as follows:

Elements of the method claims may be performed in any order consistent with the language and logic of the respective method claim and consistent with the patent specification, provided that claim 1 of the 779 Patent recites a method requiring that steps (c), (d) and (f) be performed after step (b), and that step (g) be performed after step (e). Claim 1 of the 615 Patent recites a method requiring that step (d) be performed after step (c), step (e) be performed after step (d), step (f) be performed after step (e), and step (g) be performed after step (e). 7

Taltech relies on the claims, on the specifications, on the opinion of Taltech's expert, Mr. Nienke, on U.S. Bodle Patent No. 2,120,458 (Taltech's Markman Ex. 8) (the "Bodle Patent"), and on the video shown as part of Taltech's tutorial (Taltech's Markman Ex. 7).

7 The Court distributed a document entitled "The Court's Preliminary Construction of Claims Prior to Markman Hearing" to the parties prior to the Markman hearing to focus the parties' arguments. The Court's preliminary construction of claims was not binding on the parties and was not meant to be reviewed on appeal. The Court advised that any opinions contained therein were tentative and subject to change. Taltech altered its proposed construction of "a method . . . comprising the steps" in response to the Court's preliminary construction of the term. See Taltech's Supplemental Brief, docket no. 137, at
Esquel asks the Court to construe "a method . . . comprising the steps" to mean that the elements (a)-(g) of these method claims be performed in a particular order. Esquel proposes the following constructions for the two patents-in-suit:

Claim 1 of the 779 Patent recites a method requiring that step (b) be performed after step (a), step (c) be performed after step (b), step (d) be performed after step (b), step (e) be performed after step (b), step (f) be performed after step (e), and step (g) be performed after step (e).

Claim 1 of the 615 Patent recites a method requiring that step (b) be performed after step (a), step (c) be performed after step (b), step (d) be performed after step (c), step (e) be performed after step (d), step (f) be performed after step (e), and step (g) be performed after step (e).

Esquel relies on the claims, on the specifications, and on the prosecution history of the 779 Patent.

"Unless the steps of a method [claim] actually recite an order, the steps are not ordinarily construed to require one." Interactive Gift, 256 F.3d at 1342. To determine if the steps of a method claim that do not otherwise recite an order must nonetheless be performed in the order in which they are written, a court should first "look to the claim language to determine if, as a matter of logic or grammar, they must be performed in the order written." Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369 (Fed. Cir. 2003) (citing Interactive Gift, 256 F.3d at 1342-43). For example, if the second step requires the presence of a structure that is formed in the first step, then the claim language itself shows that the steps must be performed in a particular order. See Loral Fairchild Corp. v. Sony Corp., 181 F.3d 1313, 1321 (Fed. Cir. 1999); but see Kemin Foods, L.C. v. Pigmentos Vegetales del Centro, 301 F. Supp. 2d 970, 993 (S.D. Iowa 2004) (not requiring steps (a) and (b) to be performed in the order listed even though step (b) refers to "said homogeneous liquid" formed in step (a), because one skilled in the art would understand steps (a) and (b) to be interchangeable). A particular order might also be required if each subsequent step referenced something logically indicating that the prior step had been performed. See Mantech Envtl. Corp. v. Hudson Envtl. Servs., Inc., 152 F.3d 1368, 1375-76 (Fed. Cir. 1998). If the claim language does not indicate a particular order, then a court should look to the specification to determine whether it "directly or implicitly requires such a narrow construction." See Interactive Gift, 256 F.3d at 1343. "If not, the sequence in which such steps are written is not a requirement." Altiris, 318 F.3d at 1370.

In the present case, the claims do not recite an order. Thus, the presumption is that no order is required. Under Altiris and Interactive Gift, the presumption may be overcome if the logic or grammar of the claim language requires a particular order, or if the specifications directly or implicitly require a particular order. See Altiris, 318 F.3d at 1369-70; Interactive Gift, 256 F.3d at 1343. The Court may look to expert testimony to determine whether the presumption is overcome because "the expert testimony serves the permissible purposes of aiding our understanding of the technology and in helping us view the patent through the eyes of the skilled artisan." Altiris, 318 F.3d at 1371 (considering expert testimony that it is technologically possible to achieve the invention's purpose by performing the steps in any order). Although Taltech's expert, Mr. Nienke, did not disclose an opinion on the term "a method . . . comprising the steps" in his expert report, see docket no. 85, Ex. J (part 1), the Court will consider his opinion in construing this term because Esquel has taken the opportunity to question Mr. Nienke regarding this term in a deposition on December 7, 2005. See Nienke Rebuttal Dep. (Esquel's Markman Ex. 2 -- complete transcript).

The first area of dispute between the parties is whether step (b) must come after step (a) in Claim 1 of the 779 Patent. These steps involve "placing" the first and second garment components and the bonding element into position to form a seam. The claim language, as read by a person of ordinary skill in the art, does not require a particular order. Mr. Nienke testifies on behalf of Taltech that he "absolutely" knows that steps (a) and (b) "can be reversed because the bonding element typically comes from a reel or a supply so that it's continuous and the bonding element is present typically under the foot before the garment components are introduced." Nienke Rebuttal Dep. at 30:23-31:13, 31:21-32:12, 47:15-23 (Taltech's Markman Ex. 13 -- highlighted deposition transcript); see also Nienke Rebuttal Decl., docket no. 110, P 5 (Taltech's Markman Ex. 11) (explaining how the bonding element can be present (i.e., step (b)) before the garment components are brought together (i.e., step (a)). Contrary to Esquel's argument, Mr. Nienke's testimony is not merely conclusory because he explains how step (b) may be performed prior to, or at the same time as, step (a) given how the bonding element comes from a reel and is typically under the foot before the garment components are introduced. Nienke Rebuttal Dep. at 31:21-32:12 (Taltech's Markman Ex. 13). Mr. Nienke's testimony is unrebutted. Furthermore, the specification of the 779 Patent implicitly requires
no particular order to steps (a) and (b) because the description of the seam manufacturing process in the specification begins with the sewing of the first stitch, not with the placement of the garment components and bonding element. 779 Patent at 4:4-7 ("After the bonding element 32, first garment component 20, and second garment component 22 are positioned as shown in [Figure] 3a, a first stitch 38 is sewn along the seam line defined by the first and second garment components."); Fig. 3a (showing first step with the garment components and the bonding element in place and the first stitch sewn). This specification implies that the timing of the positioning of the bonding element and the garment components together is unimportant. The Court concludes that the patent does not require step (b) in Claim 1 of the 779 Patent to come after step (a).

Similarly, the parties dispute whether steps (a), (b) and (c) in Claim 1 of the 615 Patent need to be performed in any particular order. These steps involve "providing" the first and second garment components and bonding element in positions relative to each other. Again, as with steps (a) and (b) of the 779 Patent, the claim language, as read by a person of ordinary skill in the art, does not require a particular order. Mr. Nienke testifies that steps (a) and (b) in Claim 1 of the 615 Patent can occur simultaneously and that step (c) can occur before, after, or simultaneously with either of steps (a) and (b). Nienke Rebuttal Decl., docket no. 110, P 6 (Taltech's Markman Ex. 11). He further testifies that the order of these steps does not affect the ultimate structure and folding described in the claim. Id. This testimony is analogous to the testimony in Altiris that it was technologically possible to achieve the invention's purpose by performing the setting' step before, during, or after the booting normally' step. See 318 F.3d at 1371. Mr. Nienke's testimony is unrebutted. Furthermore, as with steps (a) and (b) in Claim 1 of the 779 Patent, the specification of the 615 Patent begins its description of the seam manufacturing process with the sewing of the first stitch, thus indicating that the timing of the positioning of the bonding element and the garment components together is unimportant. 615 Patent at 4:5-8; Fig. 3a. The Court concludes that steps (a), (b) and (c) in Claim 1 of the 615 Patent do not need to be performed in any particular order.

Both parties agree that the first and second garment components and the bonding element must be in position before the first stitch is sewn. Thus, step (c) must come after steps (a) and (b) in Claim 1 of the 779 Patent, and step (d) must come after steps (a), (b) and (c) in Claim 1 of the 615 Patent.

Both parties also agree that the folding of the first garment component over the bonding element must occur after the bonding element is in place; thus step (d) must come after step (b) in Claim 1 of the 779 Patent, and step (e) must come after step (c) in Claim 1 of the 615 Patent. In Claim 1 of the 615 Patent, step (e) must also come after step (d) because step (e) requires the presence of the first set stitch introduced in step (d). 8

8 The parties agree that step (e) must come after step (d) in Claim 1 of the 615 Patent.

The next area of dispute is whether step (e) must come after step (b) in Claim 1 of the 779 Patent. 9 Step (e) involves the folding of a portion of the second garment component such that the lower surface of the second garment component abuts the lower surface of the bonding element. Mr. Nienke has testified that step (e) can occur before, after, or simultaneously with the "placing" of the bonding element in step (b). Nienke Rebuttal Decl., docket no. 110, P 7 (Taltech's Markman Ex. 11); Nienke Rebuttal Dep. at 51:4-13 (Taltech's Markman Ex. 13). The Court does not rely on Mr. Nienke's testimony given Taltech's clearly stated position that "in claim 1 of the 779 Patent, the logic and language of the claim indicates that step (d) occurs after step (b). . . . " Taltech's Supplemental Brief, docket no. 137, at 7. If step (d) must come after step (b), then step (e) must come after step (b) because step (d) involves the folding of the first garment component over the bonding element, and step (e) involves the folding of the second garment component over the bonding element. Both steps (d) and (e) require the presence of the bonding element. The Court concludes that the logic and the grammar in Claim 1 of the 779 Patent require step (e) to come after step (b).

9 Claim 18 of the 779 Patent makes it clear that step (e) may come before step (c). 779 Patent at 7:66-8:2 ("step (e) is performed prior to step (c)").

The next area of dispute is whether step (f) must come after step (c) or after step (b) in Claim 1 of the 779 Patent. In step (b), the bonding element is introduced. In step (c), the first stitch is sewn. In step (f), the second stitch is sewn. Esquel argues that step (f) must be performed after step (c). The Court agrees because the Court construes "first" and "second" stitch to be temporally limited to that order (see construction of "first stitch" and "second stitch," above). The Court concludes that step (f) must come after step (c) in Claim 1 of the 779 Patent.
Both parties agree that steps (f) and (g) must be performed after step (e) in Claim 1 of the 615 Patent and that step (g) must be performed after step (e) in Claim 1 of the 779 Patent. Indeed, the folding that takes place in step (e) must occur prior to these other steps.

This construction, which requires that certain steps be performed in a particular order, is consistent with the specifications' reference to the "progressive manufacturing steps" shown in Figures 3a-3c. 779 Patent at 3:36-37; 615 Patent at 3:37-38. The Court does not, however, impose the strict limitations imposed by the words "after" and "next" from the description of the preferred embodiment shown in Figures 3a-3c. 779 Patent at 4:4-25; 615 Patent at 4:5-26. For example, this preferred embodiment requires the first garment component to be folded over the bonding element (i.e., step (d)) after the first stitch is sewn (i.e., step (c)). Neither party proposed a construction requiring that step (d) come after step (c). To so require would be to improperly limit the claims by the preferred embodiment.

The prosecution history of the 779 Patent shows that Taltech distinguished the prior art (i.e., the Benstock patent) by stating that this invention prevents seam puckering during subsequent laundering "due to the novel sequence of steps and novel positioning of garment components and sewing with respect to a bonding element." 779 Prosecution History, March 11, 1996, Amendment Filed Under 37 C.F.R. § 1.115, docket no. 85, Ex. D (part 2) at 15 (emphasis added). Taltech's reference to the "novel sequence of steps" is not an "explicit argument" requiring that the steps be performed in the exact order as listed in the claims. See Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378-79 (Fed. Cir. 1998) ("[E]xplicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations . . ."). This statement in the prosecution history is insufficient to overcome the presumption that no order is required.

Accordingly, the Court construes the term "a method . . . comprising the steps" as follows:

Claim 1 of the 779 Patent recites a method requiring that step (c) be performed after steps (a) and (b), that steps (d) and (e) be performed after step (b), that step (f) be performed after step (c), and that step (g) be performed after step (e).

Claim 1 of the 615 Patent recites a method requiring that step (d) be performed after steps (a), (b) and (c), that step (e) be performed after step (d), and that steps (f) and (g) be performed after step (e).

The '885 patent claims at issue include independent claims one and four. Claim one recites:

1. Apparatus for control of a dangerous prisoner to prevent unpredictable dangerous actions by said dangerous prisoner while in social context situations while nevertheless concealing such apparatus from public view, comprising:

   incapacitant delivery means,

   torso mounting means comprising a belt of sufficient extent to encircle a prisoner's torso and means for securing said incapacitant delivery means in contact with said prisoner's torso,

   said mounting means being adapted for concealment beneath garments ordinarily worn by ordinary persons in said social context to prevent said prisoner from being marked by observers in said social context as a person under restraint,

   said incapacitant delivery means being powered to deliver an incapacitating electrical shock to said prisoner,

   said mounting means further including means for receiving a remotely activated signal, and

   means in said mounting means responsive to said signal for delivering said incapacitating electrical shock to said prisoner.

(emphasis added). Claim four provides:

4. Nonobvious prisoner control apparatus for operation by a controlling authority located remotely from a prisoner, while
said prisoner is in clothing both appropriate to a public situation, and permitting normal functions of movement by said prisoner comprising:

- means concealable beneath said appropriate clothing of said prisoner to[ ] be controlled, securely banded around said prisoner[']s torso, for delivery of a nonlethal disabling electrical impulse to said prisoner,

- means connected to said electrical impulse delivery means for receiving a signal, including means for activating said electrical impulse delivery means upon receipt of said signal, and

- means, operable by said controlling authority, for generating and transmitting said signal for activating said electrical impulse delivery means to disable said prisoner.

(emphasis added).

Stun-Tech presented two primary arguments as to why its stun belts did not infringe these claims, both focusing on the concealability limitations. First, Stun-Tech argued that combination of the radio receiver and stun package in a single pouch produce a noticeable bulge when worn under clothing. Therefore, Stun-Tech urged, they are not "adapted for concealment" or "concealable" as required by the '885 patent claims. Second, Stun-Tech argued that the claim language about concealability created a hybrid apparatus and method of use claim which requires concealment in actual use. Stun-Tech asserted that its belts are primarily used in open prisoner transport situations often in combination with handcuffs and shackles - far from a concealment situation. Because of this allegedly non-infringing use, Stun-Tech sought to avoid direct infringement.

The district court did not agree with either of Stun-Tech's contentions. The district court rejected Stun-Tech's proposed "hybrid" claim interpretation, instead construing both claims solely as apparatus claims. According to the district court, Stun-Tech provided "absolutely no citation to authority [for its argument] that the R-E-A-C-T belts cannot infringe on the '885 patent because they are designed to be worn outside of the clothing." The district court added that "Stun-Tech's own characterization of how its product ought to be used cannot change the fact that the product otherwise infringes every element of the claims."

The district court then construed the concealability limitations to require only that the stun belts "when worn under clothing ordinarily worn by a defendant in social situations, [not] be noticeable, observable, or discernible as a prisoner control apparatus." The district court stated that "the apparatus must be concealable 'beneath garments ordinarily worn by ordinary persons in said social context to prevent said prisoner from being marked by observers in said social context as a person under restraint."

The district court continued: "This objective can be achieved by concealing the nature of the device while it is not necessary to conceal the very existence of the device." Based on this claim interpretation, the district court found that even though the accused devices produced a noticeable bulge under a prisoner's clothing, this did not avoid infringement of the '885 patent. The district court therefore granted RACC's motion for summary judgment. Stun-Tech appeals both the district court's claim interpretation and its grant of summary judgment of infringement.

II.

On appeal, Stun-Tech asserts that the district court erred in its claim interpretation. Stun-Tech argues that claims one and four should be construed as hybrid apparatus and method of use claims. Stun-Tech further contends that these claims, when properly construed, cannot be infringed unless the accused device is used according to method of use limitations in the claims. Stun-Tech cites In re Benson, 57 C.C.P.A. 797, 418 F.2d 1251, 164 U.S.P.Q. (BNA) 22 (CCPA 1969), In re Swinehart, 58 C.C.P.A. 1027, 439 F.2d 210, 169 U.S.P.Q. (BNA) 226 (CCPA 1971), and ZMI Corp. v. Cardiac Resuscitator
Corp., 844 F.2d 1576, 6 U.S.P.Q.2d (BNA) 1557 (Fed. Cir. 1988) in support of its unique hybrid claim argument. These cases, however, do not authorize this court to transform an apparatus claim into a hybrid apparatus and method of use claim. Rather, these cases merely acknowledge that an apparatus claim may include functional limitations. Similarly, in Intel Corp. v. U.S. International Trade Commission, 946 F.2d 821, 832, 20 U.S.P.Q.2d (BNA) 1161, 1171 (Fed. Cir. 1991), this court interpreted functional language in an apparatus claim as requiring that an accused apparatus possess the capability of performing the recited function. This court has never determined that functional language in a claim converts an apparatus claim into a method of use or hybrid claim.

Although claims one and four of the '885 patent contain recitations about concealability, the prosecution history demonstrates that this language does not make these claims method of use claims. Specifically, the prosecution history shows that the Examiner initially rejected all of the application's claims based on U.S. Patent No. 4,089,195 (Lai), which discloses a stun device in handcuffs. In response, RACC attempted to establish patentability of its claims over Lai based solely on intended use:

> By contrast the applicants' device can be worn comfortably by the prisoner without restriction of the prisoner's freedom of movement and without the need for the prisoner's restraint becoming noticeable to even the closest observer.

The Examiner rejected RACC's argument, however, and again rejected the claims based on Lai, noting that the concealability of the apparatus did not change the fact that the claims did not recite any structure different from Lai. Accordingly, RACC then amended its claims to recite structural differences from Lai, namely, a belt of sufficient length to fasten around the torso. With the addition of this structural limitation, the Examiner allowed the claims. This prosecution history shows that RACC was unable to distinguish its invention from the prior art based solely on intended use. Only by adding the structural limitation requiring torso mounting did RACC successfully overcome the prior art. Accordingly, the district court correctly decided that the functional language in claims one and four does not convert them into method of use or hybrid claims.

The claims do, however, recite concealability as a necessary limitation. Claim 1 recites a mounting means "adapted for concealment" while claim 4 recites a "means concealable beneath said appropriate clothing." This functional language limits the scope of these claims to devices that have the capability of being concealed. See Intel Corp., 946 F.2d at 832 (Regarding patent claims to an EPROM, "the accused device, to be infringing, need only be capable of operating in the page mode. . . . Actual page mode operation in the accused device is not required."). The district court therefore also correctly construed claims one and four as requiring the capability of being concealed although not requiring concealment in actual use.

Furthermore, the district court correctly construed the apparatus claims to cover an apparatus not "noticeable, observable, or discernible as a prisoner control apparatus." The specification, the prosecution history, and, most importantly, the claims themselves support this reading. The language of claim one is particularly telling. Claim one recites "mounting means . . . adapted for concealment . . . to prevent said prisoner from being marked by observers in said social context as a person under restraint." '885 patent, col. 9, ll. 1-5 (emphasis added). Thus, this language emphasizes a mounting means adapted for concealment in a courtroom setting. The specification of the '885 patent further clarifies that this language provides "means for control of dangerous prisoners in public trial without the stigma of visible restraints so as to enable the restrained accused to appear as a normal, ordinary member of society." Id. at col. 3, ll. 15-19. Furthermore, during prosecution of the '885 patent, RACC stated that its belt would allow a prisoner's freedom of movement, "without the need for the prisoner's restraint becoming noticeable to even the closest observer." (emphasis added). These defining statements support the district court's conclusion that the concealment limitations specify an apparatus not "noticeable, observable, or discernible as a prisoner control apparatus." The district court correctly determined that these claims require only that an ordinary observer would not identify the apparatus as a prisoner control device when worn under ordinary clothing. The district court therefore appropriately concluded that the noticeable bulge under the clothing when the accused device is secured to a prisoner's torso does not remove the accused device from the proper scope of the claims.

GO BACK

876

2. Claim 36
Claim 36 relates to a method of preparing foamed gypsum board having a hard edge or edges. In the LNA Method, the edge streams are on the paper before the core stream. When the core stream is deposited on the paper, it is allowed to spread to reach the edge streams on each side of the paper. Defendants contend this is different from claim 36, which they contend provides that the core stream is deposited first and that, when the edge streams are deposited onto the paper, they are immediately next to the core stream. Defendants focus on the element of claim 36 that provides: "depositing the edge streams onto the cover sheet contiguous to one or both edges of the deposited core stream." Focusing on "deposited" being in the past tense, defendants contend this should be construed as meaning the core stream is deposited on the paper first. Defendants also contend that this element should be read as requiring that the edge stream be deposited onto the paper immediately contiguous to the core stream. USG contends that the use of "concurrently" in the preamble and the lack of any express statement of an order is consistent with the stated steps of the process having no particular order. It also contends that having the core and edge streams be contiguous at any step of the process is sufficient.

The use of "concurrently" in the preamble cannot be read as meaning that all steps in the process occur at the same time or in no particular order. It is clear that the mixing and agitating of the gypsum and water must occur before foam is added. It is also clear that the core and edge streams must be separated before the foam is added to only the core stream. Also, the second cover sheet cannot be added over the two streams until after they are deposited on the lower cover sheet. The reference to "continuously and concurrently" should be read as a reference to a plant line, where all the steps are continually run at the same time on the line as a whole, but can occur at different points of the line in a particular order as the materials move (stream) down the line. Claim 36 does not number each step of the process. However, the language used, basic grammar, understanding, or logic, and the understanding of wallboard production that a person skilled in the art would have indicate certain steps must be taken in a particular order. See Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369-71 (Fed. Cir. 2003); Taltech Ltd. v. Esquel Enterprises Ltd., 410 F. Supp. 2d 977, 998-99 (W.D. Wash. 2006). In appropriate situations, the specification may be considered in construing whether a claim requires a particular order. Altiris, 318 F.3d at 1370.

As previously indicated, stating that a second cover sheet is applied over deposited streams necessarily means that the streams must first be on the face paper and a person skilled in the art would also know that this is how wallboard is manufactured. Stating that foam is added to the core stream, necessarily means that the core stream has previously been separated out of the aqueous dispersion. Since the core stream comes from the aqueous dispersion and the aqueous dispersion is described as being created from mixed and agitated calcined gypsum and water, it is also evident that the gypsum and water must be mixed before the core stream is separated out. Logically, since the foam is added to the core stream, adding of the foam also must occur subsequent to the mixing and agitation that created the aqueous dispersion. It is also noteworthy that each step that clearly must occur after another step is recited in order in claim 36. The question is whether any of the language supports that the core stream must be deposited before the edge stream.

In claim 36, the step of depositing the edge stream(s) is recited after the depositing of the core stream. This provides some support for reading claim 36 as providing that the core stream is deposited first. As defendants emphasize, stating that the method involves depositing the edge stream(s) when the core stream is deposited plainly provides that the core stream has already been previously deposited. USG contends that "deposited" is simply being used as a descriptive term to distinguish a core stream that has already had foam added from the core stream before being mixed with foam. The plain language of claim 36, however, is that the core stream is deposited first. USG does not point to any language in the specification supporting that the plain language of claim 36 should not be given its ordinary meaning.

Claim 36 is construed as providing that the core stream is to be deposited prior to the edge stream. Since the LNA Method deposits the edge stream prior to the core stream, there is no literal infringement.
A steam cooking utensil comprising:

[A] a base;

[B] a boiling water reservoir defined by the base;

[C] a heater, mounted in the base to heat liquid in the boiling water reservoir;

[D] thermostat means, mounted in the base and coupled to the heater, for switching off the heater when all the liquid in the boiling water reservoir has evaporated therefrom;

[E] a condensate trough, defined by the base and thermally insulated from the heater; and

[F] a food tray comprising an imperforate surface and a drainage surface, said food tray supported above the reservoir and trough such that said imperforate surface is aligned with the boiling water reservoir, said drainage surface is aligned with the condensate trough, and water flows from the imperforate surface to the drainage surface into the condensate trough, said reservoir, trough and tray cooperating substantially to prevent the flow of water from the imperforate surface into the reservoir.

Claim 2:

The invention of claim 1 wherein the food tray comprises a surface shaped to facilitate radial drainage to the drainage surface and into the condensate trough.

Claim 3:

The invention in claim 1 wherein the food tray defines a central baffle, vertically aligned with the heater, said baffle operative to direct heated water back to the vicinity of the heater in order to accelerate steam formation.

Claim 6:

The invention of claim 1 wherein the imperforate surface defines a multiplicity of raised surfaces effective to facilitate radial drainage through the drainage surface into the condensate trough.

Claim 31:

A steam cooking utensil comprising:

[A] means for defining a boiling water reservoir;

[B] a heater mounted adjacent a central portion of the reservoir to heat water contained in the reservoir;

[C] means for supporting food to be steamed above the reservoir, said supporting means defining an imperforate surface above the heater; and

[D] a baffle which extends downwardly from the supporting surface over the heater, said baffle shaped to define a partially enclosed region of the supporting surface in alignment with the heater;

[E] said baffle effective to impede the outward flow of water, heated by the heater and splashed by the heater against the partially enclosed region, radially away from the partially enclosed region.

Claims 1 and 31 are independent claims. Claims 2, 3 and 6 are dependent claims, being dependent upon Claim 1.

B. Markman Hearing
On November 18, 1997, this Court held a Markman hearing. See Markman v. Westview Instruments, 52 F.3d 967 (Fed. Cir. 1995) aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). Markman sets forth a two-step process for resolving patent infringement claims. The first step requires that claim construction (determination of the meaning and scope of the claims) is an issue of law for the district judge to decide. 52 F.3d at 979. The second step is that of the jury looking at the claims and the court-determined definitions in order to determine whether an infringement of the patent took place.

Prior to the Markman hearing, this Court required the parties to brief the type of evidence to be heard at a Markman hearing, to identify any disputed language in the claims, the type of evidence used to resolve any disputes and to offer proposed definitions of the claims. The proposed definitions of both parties greatly assisted this Court during the claim construction phase.

Both Rival and Sunbeam agreed with that only "intrinsic" evidence should be used to construe the disputed claims. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Intrinsic evidence is made up of (1) the claims, 5 (2) the patent specification, and (3) the prosecution history. 6 Markman, 52 F.3d at 979. However, the claims should always be the first place a court looks to determine the scope of the claim. Vitronics, 90 F.3d at 1576.

5 The words in a claim should be given their ordinary and customary meaning. Vitronics, 90 F.3d at 1576.

6 Both parties were also required, prior to the Markman hearing to submit the prosecution history (or file wrapper) on each of their patents.

Extrinsic evidence is anything external to the patent, i.e. expert testimony, dictionaries, technical treatises and articles. Markman, 52 F.3d at 980. Even the plaintiff's product is extrinsic evidence. SRI Int'l v. Matsushita Elec. Corp. of America, 775 F.2d 1107, 1118 (Fed. Cir. 1985). Extrinsic evidence is only to be relied upon to resolve any ambiguity in a disputed claim term. CVI/Beta Ventures, Inc. v. Tura L.P., 112 F.3d 1146, 1153 (Fed. Cir. 1997); Vitronics, 90 F.3d at 1583.

The theory behind the admission of intrinsic evidence, and the exclusion of extrinsic evidence, has been explained by the Federal Circuit 7 in the following manner:

competitors are entitled to review the public record, apply established rules of claim construction, ascertain the scope of the patentee's claimed invention and, thus, design around the claimed invention . . . . Allowing the public record to be altered or changed by extrinsic evidence . . . would make this right meaningless.

Vitronics, 90 F.3d at 1583.

Even though both parties agreed that only intrinsic evidence should be used to determine the claim construction, both parties attempted to influence this Court through the use of extrinsic evidence. Defendant Sunbeam used plaintiff Rival's product in the hearing and attempted to enter into evidence Sunbeam's products. During argument before this Court, Rival referred the court to dictionary definitions and expert testimony. However, this Court did not use any of this extrinsic evidence to determine the claim construction. In fact, this Court did not go beyond the actual claim language and patents in order to construe the disputed claims in the following manner:

1. "[A] boiling water reservoir defined by the base": a receptacle that holds boiling water. The water may be at one time
fresh, non-boiling water, but the water must actually come to a boil in the reservoir. To be defined by the base, the base must create or form the outline of the shape of the boiling water reservoir.

2. "Thermostat means . . . for switching off the heater when all the liquid in the boiling water reservoir has evaporated therefrom" : a thermostat that automatically switches off the heater when all of the water in the reservoir has boiled dry.

3. "[A] condensate trough, defined by the base": a receptacle for collecting condensate. To be defined by the base, the base must create or form the outline of the shape of the condensate trough.

8 These claim constructions will be hereinafter referred to as the "Markman definitions."

Dispute

878

Claim 1, with emphasis added, is representative of the asserted claims and reads as follows:

1. A capacitive displacement sensor, comprising a vessel having a wall including at least two adjacent conductive wall segments,

   means for electrically insulating said wall segments from each other,

   a dielectric coating on the interior of at least one but not all of said wall segments, the interior of at least one conductive wall segment being exposed,

   a conductive liquid-like medium contained inside said vessel covering a variable part of at least one wall segment with said dielectric coating and at least one wall segment without said dielectric coating, and electronic means electrically connected to at least one wall segment with said coating and at least one wall segment without said coating for producing an output related to the capacitance between said liquid-like medium and said one wall segment with said dielectric coating,

   whereby displacement of said vessel causes relative movement between said vessel and said liquid-like medium and a concomitant detectable change in the capacitance between said liquid-like medium and the wall segment with the dielectric coating.

Eckhian filed suit against Lucas alleging that the Lucas "Accustar" inclinometers infringe every claim of the '140 patent. The accused device uses a vessel partially filled with liquid and has a thin film coating on an interior wall. Lucas denied infringement, claiming that the liquid in the accused device acts as a dielectric across which an electric field is generated and that, in any event, its liquid is not sufficiently conductive to be covered by the claims of the patent.

On Lucas's motion for summary judgment, the district court construed the claim term "conductive liquid-like medium" as requiring a conductivity similar to the examples contained in the specification, which exceed the conductivity level of the liquid in the accused device. The court held that in light of its claim construction and based upon prosecution history estoppel, the accused device did not infringe the patent, literally or under the doctrine of equivalents.

Discussion

We review a district court's grant of summary judgment de novo. Conroy v. Reebok Int'l, Ltd., 14 F.3d 1570, 1575, 29 U.S.P.Q.2d (BNA) 1373, 1377 (Fed. Cir. 1994). Summary judgment is appropriate when no genuine issue as to any material fact exists and the moving party is entitled to judgment as a matter of law. Fed. R. Civ. P. 56(c). On summary judgment, the evidence must be viewed in the light most favorable to the party opposing the motion, Poller v. Columbia Broad. Sys., Inc., 368 U.S. 464, 473, 7 L. Ed. 2d 458, 82 S. Ct. 486 (1962), with doubts resolved in favor of the nonmovant, Cantor v. Detroit Edison Co., 428 U.S. 579, 582, 49 L. Ed. 2d 1141, 96 S. Ct. 3110 (1976); Transmatic, Inc. v. Gulton

1330
Determining whether a patent claim has been infringed requires a two-step analysis: "First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device or process." Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1576, 27 U.S.P.Q.2D (BNA) 1836, 1839 (Fed. Cir. 1993). Claim construction is a question of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 983-84, 34 U.S.P.Q.2D (BNA) 1321, 1333 (Fed. Cir. 1995) (in banc); aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384, 38 U.S.P.Q.2D (BNA) 1461 (1996). In construing the claims, the court looks to the patent itself, the prosecution history, and, if necessary, extrinsic evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996).

Application of a properly construed claim to an accused device is a question of fact. On appeal from a grant of summary judgment of noninfringement, we must determine whether, on the patentee's version of the facts, the district court correctly concluded that the patentee had failed to show that a reasonable jury could find infringement. See Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986); Conroy, 14 F.3d at 1575, 29 U.S.P.Q.2D (BNA) at 1377 ("The moving party . . . may discharge its burden by showing the district court that there is an absence of evidence to support the nonmoving party's case.").

In construing the claims of the '140 patent, the district court declined to adopt Ekchian's proposed definition of "conductive" as "the slightest ability to carry a current" because it concluded that such an interpretation would render the limitation meaningless, essentially reading the term "conductive" right out of the claims. Because Ekchian's proposal would "include virtually all liquids (and, indeed, all materials) on the planet," the district court sought a narrower definition that would render the term meaningful. The court concluded that, as a matter of law, the claimed conductive liquid-like medium did not extend to the liquid in the accused device. In particular, it determined that the liquid in the accused device "is vastly less conductive" than the preferred liquid mentioned in the patent specification and that the two liquids appear to be used for different purposes, the invention employing a liquid as a capacitor plate and the accused device employing a liquid as a dielectric.

Ekchian argues that the district court erred in its claim construction by reading the conductivity of the preferred embodiment into the claims. Ekchian contends that the patent does not impart any special meaning to the term "conductive" and therefore that the term's ordinary meaning to those skilled in the art should control. Lucas, on the other hand, contends that the district court properly interpreted the claim in light of the specification and that the patent defines "conductive liquid-like medium" as being limited to liquids having a conductivity equal to or greater than the examples listed in the specification. To support its proposition, Lucas relies on the following sentence in the specification which states, "Accordingly, the label 'conductive liquid-like medium' used herein shall refer to materials of whatever kind whether liquid or not, meeting the foregoing requirements of flowability, conformity, horizontal surface retention and conductivity." '140 patent, col. 5, line 66 - col. 6, line 2.

Lucas argues that the examples of conductive liquids in the specification are the only "foregoing requirements of . . . conductivity" disclosed in the patent and therefore must be read as limiting the claim term. We do not agree. Contrary to the assertion by Lucas, the expression "the foregoing requirements" also refers to the enumerated requirements immediately preceding the quotation, which include, "in addition, all points beneath the horizontal upper surface of the liquid medium must be conductive, preferably but not necessarily uniformly conductive." '140 patent, col. 5, lines 60-63. The statement thus is not a reference only to the stated examples, as Lucas asserts.

More importantly, Lucas identifies nothing further to support its contention that the term "conductive" is limited to the conductivity levels inherent in the disclosed examples. While examples disclosed in the preferred embodiment may aid in the proper interpretation of a claim term, the scope of a claim is not necessarily limited by such examples. See Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 U.S.P.Q.2D (BNA) 1289, 1299 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."); Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563, 231 U.S.P.Q. (BNA) 833, 835 (Fed. Cir. 1986) ("This court has cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification."). We therefore conclude that the term is not so limited.

Because the specification does not use the term "conductive" in a special or unique way, its ordinary meaning to one skilled
in the art controls. See Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580, 36 U.S.P.Q.2d (BNA) 1162, 1165 (Fed. Cir. 1995) ("The words of a claim will be given their ordinary meaning to one of skill in the art unless the inventor appeared to use them differently."); cf. Texas Instruments, Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558, 1564, 39 U.S.P.Q.2d (BNA) 1492, 1497 (Fed. Cir. 1996) ("Although the dictionary broadly defines 'conductor' as any substance that conducts an electrical charge, the patent itself belies such a broad construction.").

Ekchian contends that those skilled in the art would recognize that the term "conductive liquid-like medium" in the context of the claimed invention refers to any material that is sufficiently more conductive than the dielectric so that a capacitor is formed. We agree. There is nothing in the patent specification that suggests that Ekchian intended to limit the meaning of that term to a specific range of conductivity. This does not mean that the claim term "conductive" is meaningless or superfluous. Both Lucas and Ekchian agree that the term "conductive" ordinarily means the ability to transport electric charge. Furthermore, it is undisputed that the specification and prosecution history both state that the liquid must act as a capacitor plate, which must necessarily store electric charge. Therefore, one skilled in the art of capacitor design would recognize that the term "conductive" modifies "liquid-like medium" in the claims to indicate that the liquid must act as a capacitor plate, i.e., that it must be sufficiently more conductive than the dielectric material so that it stores electric charge. Accordingly, we hold that the district court erred in its claim construction by incorrectly limiting the degree of conductivity permitted by the term "conductive liquid-like medium." Within the context of this patent, "conductive liquid-like medium" means a medium sufficiently conductive to perform its function as a variable capacitor plate.

Both parties dispute the meaning of the term "conduit." Plaintiff construes the term to mean any device or apparatus providing a channel or flow path for fluids including the contaminant vapors. Defendants argue that the "conduit" is a single channel, generally a pipe, placed in the shaft in a generally vertical position.

The Court construes the term "conduit" by looking at the claim language, the ordinary meaning of the term 'conduit", and the specification. The claim provides for "a conduit", hence the Court agrees with the Defendants that the claim language provides for only one "conduit." The ordinary meaning of the term "conduit" is "... 1: a natural or artificial channel through which water or other fluid passes or is conveyed ..." WEBSTER'S THIRD NEW INTERNATIONAL UNABRIDGED DICTIONARY ((c) 1961, 1993) at 474. In the specification, the Court finds that Plaintiff has explicitly provided in the '407 patent that his invention can be practiced without the use of a pipe as a conduit, and that the shaft itself can act as the conduit. '407 Patent, Column 4, Lines 14-18. From the ordinary meaning of the term and the limitation in the specification, the Court concludes that the term "conduit" means a channel through which the contaminant vapors are conveyed; the conduit may be a pipe in the shaft or the shaft itself.

The Court refuses to add the limitation that the "conduit" has to be vertical. This limitation is not found in the ordinary meaning of the term, neither is it explicitly provided for in the specification. However, as the conduit may be a pipe in the shaft or the shaft itself, it follows that the orientation of the conduit must be consistent with the shaft. Thus, one end must be open to the air while the other end is located to a point below the surface, in the contaminated area.

Finally, Claim 1 of the '227 patent describes a "conduit which connects said first interior channel to said second interior channel and allows said electrical means to pass therethrough." (App. To Def.'s Markman Br. Ex. B at Col. 4, L.L. 41-44) (emphasis added). Lampi defines "conduit" as a connecting passage which connects the area which contains the tube with the area which contains electrical components and allows the wiring to pass from the first area to the second area. APP, on the other hand, contends that "conduit" means a separate structure designed and used exclusively for enclosing and loosely holding wires passing from the unobstructed tubular sleeve which has two closed ends for enclosing the ends of the fluorescent tube (i.e. the first interior channel) to the unobstructed tubular sleeve containing the wiring for the fluorescent lamp. (i.e. the second interior channel).
In brief, the ordinary and customary meaning of conduit is a connecting passage which permits something (here wiring) to get from one place to another. Even after examining the briefs and the relevant prior art, we are uncertain as to what APP means by a "separate structure." Nor did counsel for APP explain this limitation at the hearing. In any event, there is no indication in the claims, specification, or prosecution history that the patentee claimed an entirely different structure as a means of connecting the two channels. On the contrary, it is clear that the patentee merely claimed a passage for connecting one channel to another. We accordingly adopt Lampi's definition of "conduit."

CONCLUSION

For all of the foregoing reasons, we interpret the disputed terms as follows:

"Comprising" means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim. More specifically, "comprising" denotes an open claim such that infringement may not be avoided merely by adding additional elements so long as the recited claims are present.

"Half-shells" mean two equal or corresponding parts forming a hard or firm outer covering into which the housing of the fluorescent lamp is divided.

"Identical" means the same or exactly alike.

"First interior channel" means an interior sleeve where the fluorescent tube is contained.

"Second interior channel" means an interior sleeve where the electrical components are contained.

"Conduit" means a connecting passage which connects the area containing the tube (first interior channel) with the area containing the electrical components (second interior channel) and allows the wiring to pass from the first channel to the second channel.

2. "Refrigerated source liquid conduit line"

For "refrigerated source liquid conduit line," Foodie offers a proposed construction of "at least one channel through which the source liquid is conveyed from the refrigeration unit," while Jamba Juice offers "a channel (or pipe) through which a refrigerated source liquid is conveyed." The only difference between the parties' proposals reflects the only dispute the Court must decide, namely whether the "remotely located refrigeration unit" must be connected to the "customer service station" through a "refrigerated source liquid conduit line."

Jamba Juice argues that the specification does not say that the refrigerated source liquid conduit lines are connected to the remotely located refrigeration unit. Instead, Jamba Juice contends the specification calls for the refrigerated source liquid conduit lines to be connected to the source liquid inside refrigerated liquid containers, not the unit itself. In support of its assertions, Jamba Juice offers the following lines from the specification: (1) "[a] most common form of containerized distribution provides such liquids to the retailer in pressurized steel, or similarly constructed metal tanks. In this instance, once connecting the refrigerated source liquid to refrigerated transport lines..." '448 patent col. 4 ll. 3-10, and (2) "[r]efrigerated source liquids such as juices, yogurt, etc. are refrigerated and stored in such remote facility until such time as they are needed." '448 patent col. 5 ll. 53-56. Foodie responds that the patent very clearly calls for a connection of the customer service station and the remote refrigeration unit via the refrigerated conduit lines, and offers the following as support: "[u]pon determining the consumer's refrigerated source liquid requirement(s), a [customer service station] beverage tapping mechanism 2.55 is engaged and such designated refrigerated source liquids are pumped or propelled, via refrigerated conduit lines 2.30 from the remote walk-in refrigerator 2.10 to the [customer service station]." '448 patent col. 6 ll. 3-8.

Both parties point to embodiments in the patent to support their contentions. Jamba Juice argues that embodiments four and
five show the refrigerated tanks connected to the conduit lines sitting beneath the counter, not connected to a refrigeration unit. '448 patent figs. 4-5. Foodie counters that in order to save space, which is the purpose of the patent, the conduit lines must connect the remote refrigeration unit and a customer service station, and claims that Figure 2 shows this to be the preferred embodiment. See '448 patent fig. 2. In response to Foodie's preferred embodiment argument, Jamba Juice claims that even if connection directly to the remote refrigeration unit was the preferred embodiment in the patent, there is no requirement that the Court limit the claim to the preferred embodiments. Only if the patentee expresses clear disavowal of any other configuration should the Court limit the claims only to the preferred embodiment. Conoco, Inc. v. Energy & Envtl. Int'l, L.C., 460 F.3d 1349, 1357-58 (Fed. Cir. 2006).

Finally, while Foodie claims the invention would not work if the conduit lines did not connect the source liquid in the refrigeration unit to a customer service station, Jamba Juice argues the patent does not mandate such an interpretation, and that the source liquid could be removed from the refrigeration unit and still connected to a customer service station without frustrating the purpose of the patent. Jamba Juice argues that the patent itself states "while this invention has been described in reference to illustrative embodiments, this description is not to be construed in a limiting sense," and that there are no manifest words of exclusion that should limit the patent solely to Foodie's proposed interpretation that the remote refrigeration unit is connected to a customer service station via the conduit lines in question. See '448 patent col. 7 ll. 18-20.

What the dispute amounts to is that certain embodiments in the patent show the refrigerated tanks inside the remotely located refrigeration unit. Foodie is essentially arguing for a narrower construction, saying that since the tanks are inside the refrigeration unit in Fig. 2, the conduit lines must therefore connect the refrigeration unit to a customer service station. Jamba Juice is arguing for a broader interpretation whereby a connection between the refrigeration unit and customer service station is not specifically required by the claims. In resolving this dispute, the Court begins, as it must, with the words of the claim. See Teleflex, 299 F.3d at 1324. Claims "must be read in view of the specification, of which they are a part." Markman, 52 F.3d at 968. After considering all of the arguments of the parties, the Court finds Jamba Juice's construction more persuasive.

The claims do not discuss the refrigerated source liquid conduit lines connecting the remote refrigeration unit and a customer service station. The only reference in the claims to any sort of connection to a customer service station refers to a connection between the source liquid and the consumer service station beverage tapping mechanism: "comprising … a customer service station including … at least one refrigerated source liquid conduit line, the refrigerated source liquid conduit line connecting said refrigerated source liquid and said consumer service station beverage tapping mechanism." '448 patent col. 8 ll. 11-15. While, as Foodie points out, the specification does discuss pumping refrigerated liquids via refrigerated conduit lines, that is not what the patent claims. The claims of the patent establish and limit the patentee's right to exclude, by describing the outer boundaries of the invention. CIAS, Inc. v. Alliance Gaming Corp., 460 F.3d 1349, 1357-58 (Fed. Cir. 2007). Here, the claims do not establish any boundary excluding the possibility that a customer service station might be connected to the source liquid in tanks outside the refrigeration unit, and the Court finds nothing in the specification which would limit the invention in such a manner. The Federal Circuit has cautioned against confining the claims to even specific embodiments. See Phillips, 415 F.3d at 1323. Particular embodiments appearing in the written description are not be used to limit claim language that has broader effect. Foodie's interpretation improperly limits the claims.

Therefore, the Court's construction leaves open the possibility that the conduit lines might convey source liquid from tanks outside the refrigeration unit. The Court finds that a "refrigerated source liquid conduit line" is "a channel through which a refrigerated source liquid is conveyed."

Cone, Nose, Flank, and Shoulder Region

Claims in the '249, '715, and '631 Patents contain the terms "cone" or "cone region," "nose" or "nose region," "flank" or "flank region," and "shoulder region." The parties dispute whether these regions extend around the circumference of the drill bit face or are limited to the blades of the drill bit face. The parties further dispute the construction of these regions with respect to each other.

Whether the Regions Extend Around the Circumference of the Drill Bit Face

- 1334 -
Baker Hughes contends "cone," or "cone region," means "the area or region extending around the entire circumference on the drill bit face and which is located radially closest to the centerline or longitudinal axis of the drill bit body (and which is shaped more or less like an inverted cone)." Baker Hughes proposes similar constructions for the other claim terms and contends these regions extend around the entire circumference of the bit face.

ReedHycalog contends "cone," or "cone region," means the "region, defined by the blades of the bit, radially between the nose and the center longitudinal axis of the bit." ReedHycalog proposes similar constructions for the other claim terms and claims these regions are defined by the drill bit blades and do not extend around the entire circumference of the bit face.

The specifications of the '249, '715, and '631 Patents support a construction that limits the "cone," "nose," "flank," and "shoulder" regions to the blades. The '249 and '715 Patents refer to the "cone," "nose," "flank," and "shoulder" regions as being regions within the bit profile. '249 Patent col. 5:66-col. 6:1; '715 Patent col. 9:34-39. As the blades define the bit profile, and each of these regions are located in the bit profile, the blades likewise define the "cone," "nose," "flank," and "shoulder" regions.

Second, figures in the '249, '715, and '631 Patents confirm that these regions are limited to the area defined by the drill bit blades. Fig. 10 of the '249 and '715 Patents, displayed in Appendix C and annotated, shows the "cone," "nose," "flank," and "shoulder" regions along the bit profile. Fig. 13 of the '715 Patent, a quarter-sectional side view of the three-region embodiment of the claimed drill bit, similarly shows the disputed regions along the bit profile. '715 Patent Fig. 13. Figs. 14A and 14B of the '631 Patent, reproduced in Appendix C and annotated, show the "cone," "nose," "flank," and "shoulder" regions on the blades of the drill bit. While Fig. 14C of the '631 Patent, annotated and shown in Appendix C, tends to support Baker Hughes's contention that the "cone region" extends circumferentially around the drill bit, the above intrinsic evidence more clearly shows that this region, in addition to the "nose," "flank," and "shoulder" regions, is limited to the drill bit blades. Thus, the Court construes these terms to only extend on the blades of the drill bit.

Radial Location of Each Region With Regard to Other Regions

Baker Hughes and ReedHycalog additionally dispute the definition of each region on the drill bit in relation to the other regions. In short, Baker Hughes defines "cone" as "... located radially closest to the centerline or longitudinal axis of the drill bit body ..." and subsequently defines "nose" as the area or region radially between the cone and the "flank," which includes the leading most point on the drill bit body. Similarly, Baker Hughes defines "flank" as the area or region radially between the "nose" and the "shoulder" or "gage," and "shoulder region" as the area or region radially between the "flank" and the "gage," although in a given drill bit, the "flank" and "shoulder" regions may be the same part of the bit.

ReedHycalog's constructions are similar, except that ReedHycalog starts with the "nose," which it construes as "extending radially and proximately about the leading-most point." ReedHycalog defines "cone" as the region radially between the "nose" and the longitudinal axis of the drill bit body, "flank" as the area or region radially between the "nose" and the "shoulder region," and the "shoulder region" as radially proximate the "gage."

The '715 Patent, in the Brief Summary of the Invention, describes "cone region" as the "radially innermost portion." '715 Patent, col. 3:14-15, 39-40. Similarly, the '631 Patent, in the Brief Summary of the Invention, describes the "cone" as "the region of the bit proximate the centerline of the bit." '631 Patent, col. 5:37-43. The patents do not disclose any area or region radially between the "cone" and the "nose."

The Court adopts a modified construction of "cone" and "cone region" to comport with the specifications. Thus, "cone," or "cone region," means "radially innermost region, defined by the blades of the bit, located radially between the nose and the center longitudinal axis of the bit, labeled 230 in Fig. 10 of the '249 and '715 Patents."

Footnotes

6 Ref. No. 5 of Appendix B contains the disputed terms and their construction.
3. Language in Dispute: "conical tapered tip" and "a truncated cone" 5

5 The parties have agreed that the ruling on claim 12 will be the same as the ruling on claim 19's construction. Thus, the word "cone" is equivalent to the word "conical" for purposes of this Markman decision. The language in dispute in claim 19 is: "...the distal end portion of said tube defining a truncated cone..."

Does "smooth conical tapered tip" mean (1) a shape with a circular base tapering to a point as in either a centered (right circular) cone or an off-center (oblique circular) cone or (2) a shape tapering evenly on all sides as in a right circular cone?

Does "cone" mean (1) a shape with a circular base tapering to a point as in either a centered (right circular) cone or an off-center (oblique circular) cone or (2) a shape tapering evenly on all sides as in a right circular cone?

Answer: Both "smooth conical tapered tip" and "cone" mean a shape with a circular base tapering to a point as in either a centered (right circular) cone or an off-center (oblique circular) cone.

a). Claim Language

The parties do not dispute that the limitation in this claim covers an ordinary centered (right circular) cone. Where they do not agree is whether the claim limitations also cover an off-center (oblique circular) cone. A right circular cone, or a centered cone, is a cone in which the apex is aligned with the center of the circle (i.e., an ice cream cone shape). In an oblique circular cone, or an off-center cone, the apex is above the circle, but not directly above the center of the circle. The Court holds the term "cone" includes both a right circular cone and an oblique circular cone. The claim language is helpful because in claim 12, it refers only to a "smooth conical tapered tip," whereas in claim 13, it specifies a type of cone when it states "said conical tip is substantially aligned with the axis of said cylindrical tube." Under the doctrine of claim differentiation, these two claims must mean different things. Thus, under claim 12, the cone may be either a right circular cone or an oblique circular cone and claim 13 is limited to only a right circular cone.

b). Written Description

The specification also supports construction of this claim as not limited to right circular cones. The specification states that in accordance with the invention:

the distal end portion of the tube 11 has a conical tip generally designated 20 which smoothly merges with the cylindrical body of the tube11. Preferably the apex of the conical tip 20 is centered on the axis of the cylindrical body of the tube 11 thus serving as a guidance point to uniformly distribute the frictional resistance encountered by the conical tip when the tube is inserted into the body cavity...Since the frictional resistance is uniformly distributed and the conical tip smoothly merges with the body of the tube 11, insertion trauma and kinking are minimized. ( '968 patent, col. 3, lines 47-54; 62-64). (Emphasis added).

In order for the frictional resistance to be uniformly distributed, the conical tip must be a right circular cone and not an oblique circular cone. The use of the term "preferably" indicates that the centered cone is Dr. Mahurkar's preferred configuration, but that he also contemplates other types of cones. Because claim 12 does not explicitly recite that the apex of the conical tip is centered on the axis of the cylindrical tube, claim 12 is not limited to this preferred approach. Had Dr. Mahurkar intended to limit claim 12 to right circular cones, he would simply have included the "centered apex" language of claim 13 within claim 12. See Rodime PLC v. Seagate Technology, Inc., 174 F.3d 1294, 1305 (Fed. Cir. 1999)("Had [the patentee] intended or desired to claim thermal compensation as a function of the positioning means in the asserted claims, it could have done it explicitly as in claim 11").
It is agreed that all of the figures in the '968 patent depict right circular cones, not oblique circular cones. Arrow claims that "conical" must be limited to the described preferred embodiment because "no other embodiment of a tip shape is shown or described in the '968 patent." (Def. Br., at p. 22). Arrow is wrong about the law. A claim term can be limited to the described preferred embodiment only when the specification clearly and unambiguously so limits that term. See e.g., Johnson Worldwide Associates, 175 F.3d at 991. And, "just as the preferred embodiment itself does not limit claim terms—, mere inferences drawn from the description of an embodiment of the invention cannot serve to limit claim terms." Id. at 992. 6

6 Arrow also suggests that the word "cone" is limited to the right circular cone shown in the figures because the '968 patent claims priority from a design application. This argument is contrary to well established law. In Vas-Cath, Inc. v. Mahurkar, 935 F.2d 1555, 1565 (Fed. Cir. 1991), the Federal Circuit held that Dr. Mahurkar's claims in a utility patent may claim priority from a design application (which shows only figures) so long as the figures in the design application satisfy the written description and enablement requirements of 35 U.S.C. § 112, P 1. It is black letter law that a specification (or drawing) need not describe every possible embodiment covered by the claim to satisfy the written description requirement. See, e.g., Johnson Worldwide Assoc., 175 F.3d at 993. See also Lampi Corp. v. Am. Power Prods., Inc., 228 F.3d 1365, 1378 (Fed. Cir. 2001). Thus, whether the drawings in the design application showed off-center cones in addition to right circular cones is immaterial.

c). Prosecution History

Arrow also seeks to support its narrow construction with passages from the prosecution history contending that Dr. Mahurkar was forced to distinguish a prior art oblique circular cone by limiting his claims to a right circular cone. During prosecution of the '968 patent, Dr. Mahurkar distinguished the Edelman structure. Arrow incorrectly characterizes Edelman's tip as an oblique circular cone. It is not. First, the Edelman tip has a rounded blunt end, not an apex. Second, one entire side of the Edelman tip is flat, and the base, therefore, is not a circle. The Edelman tip structure is perhaps best described as a "beak" or a "nose," not as a circular cone. The prosecution history statements cited by Arrow, therefore, do not support Arrow's argument.

Perhaps more importantly, the actual grounds upon which Dr. Mahurkar distinguished Edelman was that Edelman lacked the claimed smooth conical tip, not just that it lacked a conical tip. Regarding Edelman, Dr. Mahurkar described why his invention differed from Edelman's structure:

The Edelman et al. patent 4,403,983 shows a septum-type dual-lumen catheter in which the septum is inserted as a separate piece; the outer wall of one of the two lumens formed by the insertion of the septum is tapered toward the septum, and the other is cut off "normal to both the septum and the tube axis" (column 2, lines 59-60), thereby forming a sharply stepped tip which would also seem to produce high insertion trauma….None of these septum-type catheters has applicant's smooth conical tapered tip which smoothly merges with the surface of the cylindrical tube …. (Def. Ex. 2 at NSHN 128765-66.) This passage clearly shows that Dr. Mahurkar's primary concern with the Edelman structure was the sharp step between the tube and the tip. Dr. Mahurkar's claims distinguished this structure by reciting a smooth conical tapered tip that smoothly merges with the tube.

Dr. Mahurkar's statements during the prosecution history, therefore, never limited the word "cone" to right circular cones, and do not constitute a clear and deliberate surrender of claim scope. See Northern Telecom Ltd. v. Samsung Electronics Co., Ltd., 215 F.3d 1281, 1294-95 (Fed. Cir. 2000)("We cannot conclude that [the defendant] has demonstrated that the patentees -- with reasonable clarity and deliberation [citation omitted] - defined 'plasma etching' as excluding ion bombardment.").

d). Dictionary Definition

Medical dictionaries also support Plaintiffs' contention that "conical" is not limited to a centered (right circular) cone. Cone is defined as "a solid figure or body with a circular base tapering to a point." (Dorland's Illustrated Medical Dictionary,
Twenty-Sixth Edition). Cone is defined as "a solid figure or body having a circular base and tapering to a point, …" (Miller-Keane Encyclopedia & Dictionary of Medicine, Nursing & Allied Health (5th Ed. 1992)). Cone is defined as "a figure or anatomic structure tapering to a point from a circular base." (Melloni’s Illustrated Medical Dictionary (2nd Ed. 1985)).

4. Construction of "an analyte sensor configured and arranged to determine the concentration of the analyte from 500 nL or less of body fluid"

The parties next seek to construe the phrase "an analyte sensor configured and arranged to determine the concentration of the analyte from 500 nL or less of body fluid" found in Claim 16 of the '164 patent as follows:

A method for determining a concentration of an analyte in a body fluid of a patient, comprising the steps of: creating an unassisted flow of a body fluid from the patient; transporting a portion of the body fluid into an analyte sensor configured and arranged to determine the concentration of the analyte from 500 nL or less of body fluid…

Plaintiffs argue for the construction "a device to detect the presence and/or measure the concentration of an analyte that is constructed and disposed to determine the concentration of the analyte from 500 nL or less of body fluid" and Defendant for the construction "a coulometric sensor where the electrodes are separated by no more than .2 mm and the mediator is immobilized (i.e. entrapped or chemically bound) to the surface of the working electrode."

Defendant first contends that Claim 16 expresses a means plus function claim, and as such, is limited to the structures and materials disclosed in the specification for performing the invention pursuant to 35 U.S.C. § 112 P 6. It is not necessary to include the word "means" in the language of a means-plus-function claim. Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed.Cir.2004). However, a claim which does not include the word "means" raises a rebuttable presumption that the claim does not recite a means plus function element. Id. Defendant contends that the language at issue states a means-plus-function element because the claim does not convey a well-defined structure for an analyte sensor that is "configured and arranged to determine the concentration of the analyte from 500 nL or less of body fluid." The Court finds this argument unavailing. The contested language recites a step in Plaintiffs’ method claim; and the terminology "configured and arranged" states a limitation requiring the presence of an analyte sensor which has been designed for the purpose of determining the concentration of analytes in volumes less than 500 nL. Defendant points to nothing in the record indicating that Plaintiffs intended this language to recite a means-plus-function element within their process claim. Accordingly, the Court finds that Defendant has failed to overcome the presumption created by the absence of the "means for" language.

Defendant next contends that the invention is limited to only those analyte sensors which use the process of coulometry 8 to determine the concentration of analytes. 9 Defendant argue that the specification frames the invention within the context of the coulometric technique and that Plaintiffs specifically disclaimed other analytical methods during the patent application process. Defendant cites a portion of the prosecution history in which Plaintiffs distinguished the invention from the prior art before the PTO examiner, stating:

Claim 133- 142 were rejected… as being unpatentable over [prior art] Niwa,… The claim 133, and claims 134-147 by dependency on claim 133, are directed to a method for determining the concentration of an analyte in a sample by coulometry…. Niwa is cited as teaching the determination of the concentration of an analyte by amperometric methods… The examiner notes that this reference fails to teach the determination of an analyte by coulometry…. The advantages provided by a coulometric measurement as compared with other electrochemical methods are described in the specification…. these advantages include temperature independence… and a much smaller sample size. Mehta Declaration, Exh. 5, Plaintiffs Amendment Application to USPTO, Dec. 16, 1998,4-6.

Footnotes

8 Coulometry is a method for indirectly determining the concentration of a substance in a solution by submitting the substance to an electrolysis reaction, and then measuring the amount of electricity released during the reaction.
As its name suggests, "analyte" is the generic term for any substance which is to be analyzed.

Defendant asserts that these concessions were directed toward Claim 16, and that Plaintiffs limited the scope of Claim 16 in making these statements. However, there is no indication that this discussion was directed toward Claim 16, which is the claim at issue here. Rather, it appears that the portion of the prosecution history cited by Defendant was actually directed toward other claims which specifically include a coulometry limitation in the claim language. For example, Claim 1 recites, "[a] method for determining a concentration of an analyte in body fluid, comprising the steps of: collecting a sample of body fluid of about 500 nL…. and determining the concentration of the analyte in the sample using a coulometric technique." (164 Patent, Claim 1)(emphasis added). Plaintiffs explicitly limit the method in Claim 1 to the use of the coulometric process. By contrast, the method recited in Claim 16 does not identify any specific process for determining the concentration of an analyte.

Defendant's argument is undermined by the fact that Plaintiffs do identify specific techniques for determining analyte concentration in Claims 33,34, and 35, which are dependent upon Claim 16. Plaintiffs limit the methods claimed there to coulometry, amperometry, and optics, respectively. Under the doctrine of claim differentiation, "[t]here is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims." Tandon Corp. v. U.S. Intern. Trade Com'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). "To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Id. Applying the doctrine of claim differentiation, the fact that Plaintiffs identify specific processes in Claims 33, 34, and 35, which are all dependent on Claim 16, implies that no such limitation exists in Claim 16.

Therefore, Defendant's contention that Claim 16 includes a coulometry limitation is belied by the limitations expressed in dependent Claims 34 and 35, which specifically identify alternative processes to coulometry.

The '164 patent states Claims 33 and 34 as follows, "33. The method of claim 26, wherein determining the concentration of the analyte comprises determining the concentration of the analyte using a coulometric technique. 34. The method of claim 26, wherein determining the concentration of the analyte comprises determining the concentration of the analyte using an amperometry." Claim 26 in turn is dependent on claim 16, as follows, "26. The method of claim 16, wherein the analyte sensor is an electrochemical sensor.

12 Defendant also contends that the specification "disparages" non-coulometric methods such as amperometry and that Plaintiffs disavow amounts to a disclaimer of such methods. For this proposition, Defendant cites Honeywell Intern., Inc. v. ITT Industries, Inc., 452 F.3d 1312 (Fed. Cir. 2006). The Honeywell court stated that where "the written description has gone beyond expressing the patentee's preference for one material over another…. repeated derogatory statements concerning one type of material are the equivalent of disavowal of that subject matter from the scope of the patent's claims," Id. at 1318. Defendant argues that Plaintiffs' repeated affirmations, within the specification, of the superiority of the coulometric technique amounts to a disavowal of non-coulometric techniques. The Court finds this argument unavailing. Defendant misconstrues the scope of Plaintiffs' statements. While the specification clearly states a preference for the coulometric technique, it does not disavow non-coulometric techniques. To the contrary, the patent specifically claims...
several non-coulometric techniques. (See Claims 34 and 35). It would make little sense to find that Plaintiffs disclaimed a technique that they claim in the same patent. Accordingly, the Court finds Honeywell distinguishable on this basis.

Defendant also argues that Claim 16 should be limited to sensors with electrodes located within 0.2 mm of each other and containing immobilized mediators. In support of this argument, Defendant cites the preferred embodiment portion of the specification in which Plaintiffs state, "(t)ypically, the thickness of the sample chamber [should be] less than about 0.2 mm." (164 Patent, 10:50-54). The preferred embodiment section also states, "More preferably, the redox mediators of the present invention are bound or otherwise immobilized on the working electrode to prevent undesirable leaching of the mediator into the sample. A diffusing or leachable (i.e., releasable) redox mediator is not desirable when the working and counter electrodes are close together (i.e., when the electrodes are separated by less than about 1 mm), because a large background signal is typically produced as the unbound mediator shuttles electrons between the working and counter electrodes, rather than between the analyte and the working electrode. This and other problems have hindered the development of low resistance cells and increased the minimum sample size required for determination of analyte concentration." (164 Patent, 6:26-40). The Court finds this argument unpersuasive. It is improper to read a limitation from the preferred embodiment into the claims. Liebel-Flarsheim at 905. Defendant's proposed reading would improperly impose limitations from the preferred embodiment. In light of the above analysis and the plain and ordinary meaning of the terms, the Court construes the disputed phrase to mean, "a device designed to measure the concentration of an analyte given a sample of 500 nL or less of body fluid."

10. Claim 17 - "configured for being manipulated into an erected position for containing a product placed therein during shipment and for subsequently being manipulated into a collapsed position for reducing the size of the container for return"

Bradford proposes that this term means "having a structure, design, arrangement, or shape that can be folded into an erected position for containing a product placed therein during shipment and for subsequently being folded into a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position." Defendants propose that this term means "having a structure, design, arrangement, or shape that can be manipulated into an erected position for containing a product placed therein during shipment and for subsequently being manipulated into a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position." Again, the difference between the parties' proposed definitions is Bradford's use of "folded" and Defendants' use of "manipulated".

For the reasons stated in Part IV A.3, this term should not be limited to "folded." The plain language of the claim uses the word "manipulated" and the Court sees no reason that "folded" should be substituted for "manipulated". "Manipulate" means "to treat, work, or operate with the hands or by mechanical means." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 1376 (1971). "Manipulate" is certainly a broad enough term to encompass "folding" and accurately captures the erecting and collapsing operation of the container.

Finally, the Court observes that in Bradford's definition, the phrase "folded into an erected position" is illogical. Typically, objects are not folded into erect positions. For instance, to erect a card table, the legs are unfolded. Similarly, to erect a lawn chair, the legs are unfolded. These objects are folded in order to collapse them. Bradford's proposed definition, therefore, does not accurately define the erecting operation. Conversely, "manipulated" is a term which accurately describes both the erecting operation and the collapsing operation. Therefore, Bradford's definition is rejected.

Accordingly, the Court holds that "configured for being manipulated into an erected position for containing a product placed therein during shipment and for subsequently being manipulated into a collapsed position for reducing the size of the container for return" means "having a structure, design, arrangement, or shape that can be manipulated into an erected position for containing a product placed therein during shipment and for subsequently being manipulated into a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position."
3. Claim 1 - "configured for being moveable between an erected position for containing a product placed in the container and a collapsed position for reducing the size of the container for return"

Bradford proposes that the above term, which for ease of reference the Court will refer to as "configured for being moveable" means "having a structure, design, arrangement, or shape that can be folded between an erected position for containing a product placed in the container and a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position." (emphasis added). Defendants on the other hand, propose that "configured for being moveable" means "having a structure, design, arrangement, or shape that can be moved between an erected position for containing a product placed in the container and a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position." (emphasis added). Thus, the dispute over this term is between "folded" and "moved".

In support of its definition, Bradford relies principally on the specification and argues that each of the drawings therein depicts a folding operation to transform the container from an erect position to a collapsed position. In contending that "configured for being moveable" is not limited to folding operations, Defendants also rely on the specification. Defendants highlight Figure 5A in support of their argument. Figure 5A shows an alternative embodiment of the invention in which the container is collapsed by means of telescoping legs. The Court agrees with Defendants.

Contrary to Bradford's argument, and as Defendants correctly observe, the embodiments in the specification do not all depict folding operations to collapse the container. To fold, in common usage, means "to lay one part over another part of" or "to reduce the length or bulk of by doubling over or lapping over." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 882 (1971). "Moveable", on the other hand, means among other definitions, "capable of being moved: not fixed: not stationary: not fixed to one position or location." Id. at 1479 (emphasis added). As can be seen, although Defendants propose using "moved" in their definition, they essentially propose giving "moveable" its ordinary meaning.

Bradford does not contend that "moveable" has a special meaning to those skilled in the art of collapsible container invention. Therefore, the Court sees no reason to ascribe to "moveable" any other than its ordinary dictionary meaning. And, indeed, the term "moveable" best captures the essence of the invention -- the container is not fixed in one position or location. Rather, the container is capable of assuming two positions, erected and collapsed. Moreover, "moveable" is broad enough to include "fold" or "folded" within its scope. In the context of the embodiments disclosed in the specification, folding is but one method of changing the position of the container from erected to collapsed. Obviously, employing telescoping legs is another. In any event, it seems clear that Bradford's proposed definition selectively imports a limitation from the specification into the claims. Accordingly, Bradford's proposed definition of "configured for being moveable" is rejected.

The Court holds that "configured for being moveable means "having a structure, design, arrangement, or shape that can be moved between an erected position for containing a product placed in the container and a collapsed position for reducing the size of the container so the container can be sent back while in the collapsed position."

19. The '622 patent - Element [e]

72. Element [e] defines the "angulated portion" as including an outer surface, a second threaded bore "extending therein" having an axis forming a fixed angle with the axis of the first through bore and adapted to receive a fastening means for securing the dental prosthesis.

73. The phrase "an outer surface configured for receiving and supporting the dental prosthesis" is presumptively not a means plus function element because it does not use the phrase "means for." Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996). Further, the phrase "configured for" has not been treated as a means-plus-function element.
by the Federal Circuit. For example, in National Presto Industries, Inc. v. The West Bend Company, 76 F.3d 1185, 1189 (Fed. Cir. 1996), the Court did not treat the phrase "retention chamber which is configured for reception within the retention compartment" as a means-plus-function element. In this case, the angulated portion is defined in terms of its structural features, since the "outer surface" and second threaded bore at an angle to the first threaded bore both define structure.

74. When this claim element is read as a whole, it is clear that the part of the outer surface which is configured for receiving and supporting the dental prosthesis is the part which defines the second threaded through bore, which receives the screw which fastens the dental prosthesis to the abutment.

888

ii. a bridge configured to connect two retaining mechanisms and hold them together

Plaintiffs construe the phrase "a bridge configured to connect two retaining mechanisms and hold them together" as "the middle section of eyeglasses, designed to connect the rims, pins, screws or other mechanisms for supporting the lenses." Defendant interprets the same phrase to mean "middle section of eyeglasses, designed to connect rims."

In light of the court's constructions of the terms "bridge" and "retaining mechanism," the court construes the above phrase as "the middle part of the eyeglasses spanning the nose designed to connect the rims."

889

With this language as our framework, the Court now turns to the disputed claim language. Claim 1 is representative of the independent claims that Stryker alleges Pioneer to have infringed. The relevant portion of the language of claim 1 is that which relates to Stryker's locking cap. It provides, "what is claimed is: 1. A device for securing a spinal rod to the spine comprising … b) a locking cap including a first portion configured to engage an interior surface of the head portion and a second portion having an elongated recess configured to engage an exterior surface of a spinal rod received by the channel … , the first portion of the locking cap being mechanically joined and configured to rotate relative to the second portion of the locking cap."

The language in dispute, as highlighted above, is "a first portion configured to engage an interior surface of the head portion." Specifically, the dispute concerns the proper interpretation of "configured to engage" as used in this context. Stryker offers no interpretation of the disputed claim language beyond asserting that the words should be given their "plain and ordinary meaning." Although the ordinary meaning of a claim term "is the meaning that the term would have to person of ordinary skill in the art," Phillips, 415 F.3d 1312-13, Stryker provides no interpretation as to how the disputed terms would be understood by someone skilled in the art. Rather, it simply concludes that every claim element in the '565 patent is present in Pioneer's pedicle screw system. With specific reference to the locking cap, it asserts that Pioneer's locking cap, like the one disclosed in the '565 patent, includes a first portion (with arcuate engagement flanges) configured to engage an interior surface of the head portion (i.e. arcuate engagement slots), and thus literally infringes the '565 patent.

Pioneer argues, in contrast, that, in light of the patent's specification, the claim language "a first portion configured to engage an interior surface of the head portion" must be construed to mean a first portion configured to cammingly engage an interior surface of the head portion. In support of this construction, Pioneer points out, as instructed by Phillips, that claims must be interpreted "not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." 415 F.3d at 1313. Pioneer argues that "the '565 patent's specification discloses only one approach for providing the force to lock the [spinal] rod in place." (Pl.'s Opp'n Def's Mot. Summ. J. Infringement at 3.) "Every one of the '565 patent's disclosed locking caps, in every embodiment," Pioneer notes, "requires inclined arcuate engagement flanges that rotate in inclined arcuate engagement slots within the head portion to create [a] downward, camming, force on the rod located in the head portion." (Pl.'s Supp. Mem. Re. Phillips v. AWH Corp. at 6.) The following description of the engagement between the arcuate engagement flanges on the upper portion of the locking cap with the inside of the head portion is representative of the descriptions of this engagement throughout the specification:
The flanged portion 64 of locking cap 20 is defined … by two diametrically opposed arcuate engagement flanges 82 and 84 which are dimensioned and configured for operative engagement with two complementary diametrically opposed arcuate engagement slots 86 and 88 defined in the interior surfaces of the opposed side walls 30 and 32 of head portion 22.

Engagement flanges 82 and 84 define ramped camming surfaces 92 and 94, respectively. Camming surfaces 92 and 94 are of opposite angular inclination with respect to one another. More particularly, each engagement flange has a low side … and a high side … whereby the low sides of the two flanges are diametrically opposed from one another as are the high sides. Actually, the camming surfaces of the flanges are mirror images of one another.

The arcuate engagement slots 86 and 88 in head portion 22 of fastener 14 have inclined surfaces which mate with the ramped camming surfaces 92 and 94 of flanges 82 and 84.

('565 Patent col. 6, l. 45 to col. 7, l. 1.) The patent's specification further provides:

Care must be taken to ensure that the upper portion 220a of locking cap 220 is positioned in such a manner so that the low sides of the flanges … are aligned with the high sides of the engagement channels …, or the flanges will not cammingly engage the channels upon rotation of the upper portion 220a of the locking cap 220 relative to the head portion 222.

Once the upper portion 220a of locking cap 220 has been properly oriented with respect to head portion 222 …, it is rotated … relative to the lower portion 220b of locking cap 220 …. Thereupon, the arcuate engagement flanges 284, 286 of upper portion 220 cammingly engage the corresponding engagement slots 284.

('565 Patent col. 11, ll. 15-30.) In light of this specification language, Pioneer concludes, the claim language "a first portion configured to engage an interior surface of the head portion" must be interpreted as requiring a first portion configured to cammingly engage an interior surface of the head portion (through the mating of inclined arcuate engagement flanges with inclined arcuate engagement slots), which produces the downward locking force needed to secure a spinal rod in place.

In interpreting claims, as instructed by Phillips, a court is to give the words of the claims their ordinary meaning as understood by a person of ordinary skill in the art. Phillips, 415 at 1312-13. The Phillips court also noted that "in some cases, the ordinary meaning of claim language … may be readily apparent …, and claim construction in such cases involves little more than the application of the widely accepted [i.e. general purpose dictionary] meaning of commonly understood words." Id. at 1313. Stryker appears to maintain that this is such a case. Although Stryker asserts that it is not proffering a dictionary definition of the phrase "configured to engage," (see Defs.' Resp. Re. Phillips v. AWH Corp. at 3), it must be advancing such an interpretation in maintaining this claim for literal infringement. This is so because the flanges on Pioneer's and Stryker's locking caps engage with the heads in their pedicle screw systems in different ways. Stryker's inclined flanges) as evidenced by the specification, cammingly engage inclined slots in the head portion, thus creating the force necessary to secure the rod, whereas Pioneer's flanges, which are not inclined, are merely pressed against the slots in the head portion of its system as the lower surface of Pioneer's upper cap cammingly engages the top surface of the saddle. For Stryker to successfully prosecute its infringement claim, then, it must be advancing an interpretation of "configured to engage" that is broader than "designed to cammingly engage." Its interpretation of "a locking cap including a first portion configured to engage an interior surface of the head portion" must be "a locking cap with a first portion 'designed to mesh or interlock' with engagement slots in the head portion" since, with such an interpretation, Pioneer's system would literally infringe the '565 patent, as its locking cap includes a first portion "designed to mesh or interlock" with engagement slots in a head portion.

Stryker's "dictionary definition," however, cannot serve as the definitive definition of the disputed claim language in this case. For one, this is not a case where the ordinary meaning of the disputed claim language as understood by a person of skill in the art is so readily apparent that the "claim construction involves little more than the application of the widely accepted meaning of" the disputed terms. It is true, of course, that the Court is not unacquainted with the words "configure" or "engage," in the sense that a lay judge could recite their dictionary definitions. Detached from their context, however, these words can be defined only very generally. For instance, Webster defines "configure" as "1. to shape according to some model, and 2. to arrange in a certain form, figure, or shape: give a configuration to." Webster's Third New International Dictionary 476 (1971). Similarly, Oxford English Dictionary defines "configure" as "to fashion according to something else as a model, and . . . to put together in a certain form or figure." Oxford English Dictionary, available at http://www.oed.com.
Webster defines "engage" as "to be or become in gear: interlock and interact," and by Oxford English Dictionary as "to interlock with, fit into a corresponding part." Webster's Third New International Dictionary 751 (1971); Oxford English Dictionary, available at http://www.oed.com. From the dictionary definition, then, the most one can say is that the phrase "a locking cap including a first portion configured to engage an interior surface of the head portion" means that the cap's first portion is shaped or arranged in a certain way to interlock or fit with the interior surface of the head portion. The way in which the locking cap is shaped or arranged to interlock or fit with the head portion, is, of course, indiscernible from the dictionary definition. Thus, in view of the fact that the ordinary meaning of the disputed terms is not readily apparent, the Court must look to the specification to properly construe the claims.

--- Footnotes ---

2 The Court notes that the phrase "configured to engage" is used twice in claim 1. (‘565 Patent claim 1) "a locking cap including a first portion configured to engage an interior surface of the head portion and a second portion having an elongated recess configured to engage an exterior surface of a spinal rod . . . .) The Phillips court noted that in construing a claim, "the context in which a term is used . . . can be highly instructive." 415 F.3d at 1314. For instance, the court explained, "because terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims." Id. In Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1356 (Fed. Cir. 1999), the court interpreted the term "discharge rate," which was used twice in the same claim, to mean the same thing in both usages, because identical language, which illuminated the phrase's meaning, was associated with the phrase in both usages. In this case, the phrase "configured to engage" is not used in the same way: the first usage relates to the engagement between the upper portion of the locking cap and an interior surface of the head portion while the second usage relates to the engagement between the lower portion of the locking cap and the spinal rod. There is no indication from the words of the claims that they should be interpreted to refer to the same form of engagement. Moreover, in light of the specification, a person of ordinary skill would not interpret the phrase to refer to the same type of engagement in both instances.

--- End Footnotes ---

Not only must the Court look to the patent's specification because the ordinary meaning of the terms is not readily apparent, but also because, as instructed by Phillips, "the person of ordinary skill in the art is deemed to read the claim . . . in the context of the entire patent, including the specification." 415 F.3d at 1313. Reading the disputed claim language in the context of the specification, the Court concludes that the phrase "a locking cap including a first portion configured to engage an interior surface of the head portion" requires a locking cap with a first portion configured to cammingly engage an interior surface of the head portion. The ‘565 patent's specification envisions a number of different approaches and embodiments for teaching a person skilled in the art to make and use the invention. For instance, the specification explicitly recognizes that the disclosure is not limited to the particular fasteners shown in the embodiment, but rather envisions that any component designed for attachment to a spinal rod could be used. (‘565 Patent col. 5, ll. 27-35.) Moreover, the specification also envisioned the following: both a one-piece and two-piece locking cap, (id. figs. 9 and 12(b)), a one-piece locking cap with transverse recesses on the bottom and one with a flat bottom surface, (id. col. 6, ll. 25-30), different tooling methods for rotation of the locking cap, (id. col. 6, ll. 37-40), and arcuate engagement flanges with and without radially inwardly directed tapers. (Id. col. 8, ll. 30-34.) The patent's specification, however, discloses one and only one approach for generating the force necessary to secure a spinal rod in place. That is, consistently throughout the specification, the embodiments contain a locking cap including an upper portion with inclined arcuate engagement flanges designed to cammingly engage inclined arcuate engagement slots in the head portion.

Stryker argues that an interpretation of the claim that requires a camming engagement between the first portion of a locking cap and the interior surface of a head portion would improperly "narrow the scope of the asserted claims to the embodiment disclosed in the specification of the '565 patent." (Defs.' Resp. Re. Phillips v. AWH Corp. at 3.) To avoid improperly limiting a claim's scope to an embodiment in the specification, the Federal Circuit has instructed that courts should "focus . . . on . . . how a person of ordinary skill in the art would understand the claim terms." Phillips, 415 F.3d at 1323. The Court concludes that not only would a person of ordinary skill in the art consult the specification to aid in determining the meaning of the disputed terms, but such a person would also conclude that the claims require a locking cap with a first portion configured to cammingly engage an interior surface of a head portion, for "there is nothing in the context [of the specification] to indicate that the patentee contemplated any alternative" for a locking cap other than the one disclosed. Snow v. Lake Shore & Mich. S. Ry. Co., 121 U.S. 617, 629-30, 30 L. Ed. 1004, 7 S.Ct. 1343, 1350-51, 1887 Dec. Comm'r Pat. 354 (1887).
Phillips, 415 F.3d at 1323 ("To avoid importing limitations from the specification into the claims," a court should read the specification with an eye towards "whether the patentee is setting out specific examples" to teach a person of ordinary skill in the art to make and use the invention, "or whether the patentee instead intends for the claims and the embodiments in the specification to be . . . coextensive."). Moreover, Stryker "is not entitled to a claim construction divorced from the context of the written description." Nystrom v. Trex Co., 424 F.3d 1136, 2005 U.S. App. LEXIS 19748, 2005 WL 2218632, at *7 (Fed. Cir. 2005). In this case, the written description consistently describes a device where the camming force necessary to secure a rod into place is generated by the engagement of inclined arcuate engagement flanges with inclined arcuate engagement slots in the inside surface of a head portion.

Stryker also asserts that the phrase "a first portion configured to engage an interior surface of [a] head portion" cannot be interpreted as requiring a camming engagement because it did not disavow the full scope of the claim terms' ordinary and customary meanings. Requiring a disavowal in the specification to construe a claim term more narrowly (or simply differently) than its dictionary definition "improperly restricts the role of the specification in claim construction." Phillips, 415 F.3d at 1320. As the Phillips court explained, "assigning such a limited role to the specification, and in particular requiring that any definition of claim language in the specification be express, is inconsistent with our rulings that the specification is 'the single best guide to the meaning of a disputed term.'" Id. at 1321 (citation omitted). Rather, a specification may not only expressly define a claim term, but it may also "define claim terms by implication such that the meaning may be found in or ascertained by a reading of the patent documents." Idento Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004). In other words, "what Phillips now counsels is that in the absence of something in the written description . . . to provide . . . notice to the public . . . that the inventor intended a disputed term to cover more than the ordinary and customary definition as [revealed by the context of the intrinsic record, it is improper to read the term to encompass a broader definition simply because it maybe found in a dictionary." Nystrom, 424 F.3d 1136, 2005 U.S. App. LEXIS 19748, 2005 WL 2218632, at *7 (emphasis added). In this case, the Court will not read "configured to engage" in "a first portion configured to engage an interior surface of [a] head portion" to encompass the breadth of its dictionary definition where the phrase's meaning as revealed by the context of the intrinsic evidence demonstrates that the phrase must be interpreted as requiring a camming engagement between the first portion of the locking cap and the interior surface of the head portion.

Finally, the Court addresses Stryker's argument that Phillips, despite its extensive discussion of the importance of the specification in claim construction, supports its position that the disputed terms should not be read as requiring a "camming engagement." In Phillips, the dispute was over the meaning of the term "baffles." 415 F.3d at 1324. Both parties, stipulating to a dictionary definition, agreed that "the term 'baffles' refers to objects that check, impede, or obstruct the flow of something." Id. The dispute concerned whether "baffles," as used in the claims, must be disposed at angles other than 90 degrees. Although the specification contained no disclosure of baffles disposed at right angles, but rather only at acute or obtuse angles, Stryker notes, the court concluded that the definition of baffles did not exclude baffles disposed at right angles. Id. at 1327. Similarily, Stryker asserts, the Court should not limit the disputed phrase "configured to engage" as requiring a camming engagement simply because that is the only embodiment disclosed in the specification.

The Phillips court reached its conclusion that baffles as used in the claim did not exclude those disposed at 90 degree angles not because it advanced a dictionary interpretation of the disputed term above that revealed in the patent's intrinsic evidence. Rather, it reached its conclusion upon reading the disputed language in the context of the entire patent. That is, applying the doctrine of claim differentiation, the court noted that since the dependent claims provided specific functions, such as baffles "disposed at angles for deflecting projectiles," to avoid rendering the independent claim redundant, it construed the independent claim as not requiring baffles disposed at acute or obtuse angles. Id. at 1324-25. In this case, however, the doctrine of claim differentiation is not applicable, as no other claims reference how "a first portion [is to be] configured to engage an interior surface of [a] head portion." Rather, in this case, the disputed claim language is ambiguous, and it is not made clear by reference to the remaining claims. Recognizing that "the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventors actually invented and intended to envelop with the claim," id. at 1316, this Court consulted the remainder of the specification. Id. at 1316. Upon review of the specification, the Court concludes that it demonstrates that a "locking cap including a first portion configured to engage an interior surface of [a] head portion" requires a camming engagement between the first portion of the locking cap and the interior surface of the head portion.
III. "configured to nest"

Claim 1 of the '783 Patent provides:

said center link tang portions configured to nest between the sprocket teeth . . . .

The parties agree a "tang portion" consists of a portion of a saw-chain link that in some manner engages with a nose-sprocket gullet as the saw chain rotates.

Defendants contend "tang portions configured to nest between the sprocket teeth" should be construed to mean "[t]he tangs are symmetric with respect to an axis bisecting a line between the rivets on the center links and are shaped and sized to contact the entire radiused portion of the gullets." As noted, however, the Court already has determined Claim 1 does not necessarily require a radiused shape for the gullet.

Moreover, Defendants' proposed construction would largely render redundant the next disputed term, "bottom tang portion mated for engagement with the rounded bottoms in said gullets." Here the disputed term refers to tang portions configured to nest between sprocket teeth. In addition to seeking a construction of the relationship between the tang portions and the sprocket teeth, Defendants' construe the term to mean that the tang portions "are shaped and sized to contact the entire radiused portion of the gullets." The manner in which the tang portion engages the gullet bottom is more directly addressed by the fourth disputed term, however, which provides "bottom tang portion mated for engagement with the rounded bottoms in said gullets."

The Federal Circuit has cautioned against construing a claim in a manner that renders another limitation meaningless or superfluous. For example, in Primos, Inc. v. Hunter's Specialties, Inc., the court held the terms "engaging" and "sealing," both recited in a claim, could not mean the same thing without impermissibly rendering one of the terms superfluous. 451 F.3d 841, 848 (Fed. Cir. 2006). If the Court were to construe the disputed term ("tang portions configured to nest between the sprocket teeth") in a manner that included a construction of how a tang bottom interacts with the rounded bottom of a gullet, the Court could render the fourth disputed term meaningless. Thus, the Court concludes the proper construction here should be limited to defining how the tang portion must relate to the sprocket teeth.

Plaintiffs contend the term "tang portions configured to nest between the sprocket teeth" should be construed to mean "[t]he tangs are sized to be closely received such that they fit between the sprocket teeth." Again, this definition is more faithful to the specification than Defendants' proposed definition. The specification describes prior technology as follows:

The drive tang engages the nose sprocket in wedge-like fashion, i.e. the tang contacts the sprocket at two points along the upper portion of the gullet, i.e., at the sides of the adjacent sprocket teeth.

'783 Patent col.1 ll.47-51. This "wedge-like" contact can cause fatigue at the bottom of a gullet formation and result in cracking. '783 Patent col.5 ll.3-6. The '783 Patent, however, is designed so that the nose sprocket

receives the drive tang portion of the saw chain substantially along the entire semi-circular gullet formation 70 resulting in substantially compressive forces applied to the sprocket 47. Similarly, tangential forces, such as force vectors 62 illustrated in FIG. 1, result in tensile forces upon the conventional sprocket 80. In contrast, the close nesting of the drive tang portions 42 within the gullet formation 70 of the nose sprocket assembly 16 substantially reduces the effect of tangential force vectors by delivering such tangential force primarily as compressive forces.

'783 Patent col.5 ll.8-19. Thus, rather than the drive tang contacting the gullet in a wedge-like manner, the nose sprocket closely receives the drive tang "substantially along the entire semi-circular gullet formation" to produce compressive force on the sprocket. Accordingly, "nesting" is intended to distinguish a mere two-point, wedging contact in which the sprocket teeth are driven apart in favor of a close receiving of the drive tang and resulting compressive forces toward the bottom of the gullet.
For these reasons, the term "tang portions configured to nest between the sprocket teeth" is construed to mean "[t]he tangs are sized to be closely received such that they fit between the sprocket teeth."

</tbody>
</table>

The phrases "the inner and outer spatial volumes are configured to provide a minimum prescribed absorbed dose" and "configuring the inner and outer spatial volumes to provide a minimum prescribed absorbed dose" are not indefinite for essentially the same reasons given in the previous section. As Cytyc again appears to be attempting to impermissibly broaden its claims to capture any therapeutic effect, despite the clear limitation provided by the patentee's definition of "brachytherapy," the court also cannot adopt Cytyc's proposed construction. No construction of the disputed language is necessary in light of the court's construction of other terms in the patent.

Similarly, considering claim 7 in its entirety and the intrinsic evidence of record, we conclude that claim 7 requires a susceptor that resides proximally adjacent to the surface of a food item throughout the entire cooking process and conforms to almost the entire surface of the food item.

892

Claim 7 requires "$[a susceptor] conforming generally to the shape of said food item and residing in a proximal relation thereto." The "conforming generally to the shape of said food item" phrase must be construed as generally enveloping the food item to take the shape of the food item's exterior, conforming to almost the entire surface of the food item. The specification leads to that construction. Where the surface topology of a food item makes it difficult to dispose a susceptor adjacent to the entire surface of the food item, such as in the case of onion rings and certain forms of potatoes, the susceptor may generally envelop the surface of the food item.

893

3. THE CLAIM LANGUAGE AND UNDISPUTED PHYSICAL CHARACTERISTICS OF THE HUNT-WESSION BAG.
The "Orville Redenbacher" bag comprises two rectangular sides dimensioned 11 1/2" X 6". The sides are folded into three sections: two ends measuring 3 1/2" X 6" and the middle, measuring 4 1/2" X 6". The 6 1/2" X 5 3/4" susceptor is laminated between the bag's inner and outer layers of paper. It resides in one side of the middle section. Prior to cooking, the slurry of popcorn kernels, oil and seasonings form a cake which rests atop the susceptor. Although photographs submitted by General Mills suggest otherwise, the court accepts its contention that approximately 0.9 inches of the susceptor rests atop the cake by virtue of extending slightly into the upward-angled end panels.

Because the patentee must demonstrate infringement with respect to each limitation of the claims, each limitation is a material one. Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1389 (Fed. Cir. 1992). Claim 1 requires a "flexible" *wrapping material* which "conforms generally" to the shape of the food item. General Mills asserts that whether the Hunt-Wesson bag meets this description is a question of fact not susceptible of summary resolution. This argument is inconsistent with the ordinary meaning of these terms.

"Wrapper" is a synonym for "wrapping". Unsurprisingly, it means "that in which something is wrapped". Several examples are given, including: a tobacco leaf used for covering cigars; the paper cover of a book; a paper wrapped around a newspaper or magazine, or an article of clothing worn wrapped around the body. Webster's New Collegiate Dictionary (1977 ed.). These examples share an obvious similarity in that what is used for a wrapper "hugs", or envelops the material completely. Moreover, each is essentially formless without the support of the thing wrapped. This common sense reading of the term "wrapper" is, in this context, bolstered by the claim's requirement that the material "conform[] generally" to the food item. Each of the examples given above "conforms generally" to whatever is wrapped. Although a wrapper may not be in actual contact with every point of the item, its own shape is defined by the item, whose "shape, qualities or contour" it assumes. Id.

At a minimum, these limitations require that the shape of the putative "wrapping material" be dictated by the shape of the item. The physical description of the Hunt-Wesson bag is not in dispute. The photographic evidence submitted by General Mills conclusively establishes that the bag is not formless without the cake contained within. The shape of the bag is not dictated by the popcorn. Indeed, it is the mass of popcorn which is essentially formless; its shape is determined by the semi-rigid bag. Under General Mills' theory of permissible constructions of "wrapping material", almost anything which contained the food item would qualify, even a cardboard box with a susceptor on the bottom.

This view is further confirmed by the specification, and prosecution history of the '420 patent. In distinguishing the Tanizaki dish, Brastad noted that the prior art did not include a flexible susceptor which permitted the food to be "wrapped for direct heat transfer". Exh. 6 to the Decl. of James, at 34. It is clear that the flexibility of the susceptor must contribute to the ability of the device to directly impart heat from the converted microwaves. Therefore, the susceptor, consistent with the claim language, must be in a "close proximal relation" with the surface of the food item. Because a principal aim of the '420 is to provide browning precisely where previous attempts could not, the court interprets the claim as requiring that the entire food surface be subject to direct heat transfer.

3 The word "proximal" means "close". Regardless of whether the term "close proximal" means "really close" or is merely redundant, it clearly encompasses something stronger than "in the neighborhood".

Putting to one side the interesting technical question whether it is actually possible completely to wrap the surfaces of popcorn kernels grouped such as this, it is undisputed that the Hunt-Wesson bag only contains a susceptor on one side of the slurry. Even assuming General Mills' contention regarding the slight overlap of the susceptor, much of the top surface of the slurry is not subject to direct heat transfer from the susceptor. This is not to say that the topmost kernels are not hotter than they would be absent a susceptor. Rather, they are not hotter because of the direct transfer of heat from the susceptor. Any increase in temperature of the top surface at most represents indirect transfer as heat is transmitted upwards from kernel to kernel.

Finally, as detailed above, popcorn is not browned and crispened in the sense contemplated by the claim language. Given
the court's construction of the claim language, and the uncontested physical characteristics of the Hunt-Wesson bag, there are no material issues of fact precluding summary judgment of literal non-infringement.

2. "A Movable Member" Limitation

218. Based on the specification and prosecution history of the '275 patent, the phrase "a movable member to which a stylus is connectable" as used in claims 1 and 4 of the '275 patent, and as the phrase would be understood by those skilled in the pertinent art, must be construed to mean a rigid connection between the stylus and a movable member. Even Dr. Duffie agreed that the connection must be rigid. Tr 644-45.

219. According to claim 1, the movable member is in turn supportable at a plurality of spaced-apart locations or, with respect to claim 4, at three spaced apart locations. It is the engagement of the "convergent surfaces" at the spaced-apart locations which positively define the rest position for the movable member and therefore also for the rigidly connected stylus. Tr 637, 643-45, 1305-08. See PP 38, 41, 43, 48, 53-61 supra.

C. Term 6: "connected in series"

The Court construes the term "connected in series," which appears in claims 1, 9, 15, and 24 of the '325 patent and claims 1 and 9 of the '664 patent, to mean:

Connected in a sequential arrangement.

This is the construction proposed by Toro, Toro Opening Br. at 23, and it is consistent with the patent claims and written descriptions.

Textron argues that this term "means that the pressurized fluid is directed without branching from the wheel drive motors for the front wheels to the wheel drive motor for the rear wheel." Textron Opening Br. at 18 (emphasis added). The Court rejects Textron's proposed construction because it improperly adds the phrase "without branching" to the claim language.

The Court disagrees with Textron that the prosecution history mandates that the term "connected in series" be construed to incorporate the further qualification "without branching." Textron relies on Toro's statement, made in distinguishing the claimed invention over a prior-art reference that was the basis for the PTO's initial rejection of Toro's patent application, that the prior-art reference does not have "the claimed serial/parallel connection in which all of the flow from the source is directed without branching through at least one serially connected drive motor . . . ." JA 0086. This reference to "branching" -- made in the context of distinguishing a prior-art reference featuring an all-parallel-drive system -- does not require the narrow claim construction advocated by Textron.

It is apparent from the '325 and '664 patents and their prosecution history that the "connected in series" limitation describes the relationship between the motors on two different ends of a vehicle and the fluid source that supplies the motors. As long as the motors and the fluid source are connected serially -- i.e., "in a sequential arrangement" -- with respect to each other, it is immaterial whether objects other than motors might be found on "branches" of the drive circuit.

A rear motor, for instance, is "connected in series" relative to the front motors and to the fluid source if the fluid flows in sequence (though not necessarily without detours) from the source, to the rear motor, and then to the front motors. Even if the fluid flow passes through a "branch" between the source and the rear motor (say, to pass through a valve or gauge of some kind), or between the rear motor and the front motors, the motors remain "connected in series" within the meaning of the claim language as long as the fluid does not flow in parallel to the rear and front motors.
C. Claim 12

NMT challenges the district court's construction of Claim 12, arguing that the requirement that the collar be connected "directly" to the occluder improperly narrowed the claim. We agree with NMT that the district court erred by requiring this restriction.

As an initial matter, the '235 patent's specification demonstrates that the patentees actually used the word "directly" when they meant to describe a direct connection. For example, the specification describes Fig. 5e, below, as follows:

"In FIG. 5e, loops 82, 84 connected to individual occluder elements 12, 14 or 42, 44 are connected by means of an interconnecting link 86 to form, generally, a three link chain for interconnecting the individual occluder elements." '235 patent col.7 ll.33-37 (emphasis added). Contrast the specification's description of Fig. 5i: "Unlike the interconnection of FIG. 5h, the interconnection of FIG. 5i has replaced the pin with a second connecting rod 132 that connects directly to an occluder element." Id. col.8 ll.15-18 (emphasis added). The description of Fig. 5k uses basically identical language to describe a similar embodiment.

The specification therefore demonstrates that the patentees used the word "directly" when they meant to specifically point out that a connection was direct. Reading these claims in the context of the specification's usage of language, see Phillips v. AWH Corp., 415 F.3d 1303, 1315-17 (Fed. Cir. 2005) (en banc), there is no reason on the face of the patent to limit Claim 12 to embodiments that connect "directly."

Cardia argues that the claims should nevertheless be limited because the patentees disclaimed indirectly-connected embodiments during prosecution. See Phillips, 415 F.3d at 1317 ("[T]he prosecution history can often inform the meaning of the claim language by demonstrating . . . whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be.") However, we have "declined to apply the doctrine of prosecution disclaimer where the alleged disavowal of claim scope is ambiguous." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003).

Here, Cardia points out that what ultimately became Claim 12 of the '235 patent began prosecution reading simply "The device of claim 1 wherein the connector comprises a ball and collar assembly." The Examiner objected to this claim on indefiniteness grounds, because "it [was] unclear how the ball is interrelated with the collar, and how this assembly as a whole is connected to the occluders." After two amendments, the patentees were able to surmount the indefiniteness rejection by adding more detail about how the ball, collar, and occluders were interrelated. The Examiner did not object on definiteness grounds to a claim reading:

"The device of claim 1, wherein the connector means comprises a ball and collar [sic] assembly, said assembly comprises a collar connected to one of the first and second occluders with an aperture and a pin with a ball fitting connected to the other of the first and second occluders on at least one end thereof wherein a diameter of said ball fitting is larger that [sic] a diameter of the aperture in the collar." (emphasis added). Ultimately, this claim was rewritten into independent form and further amended to issue as Claim 12.

The issue here is whether these amendments amount to an unambiguous surrender of indirect connection. They do not. While the patentees added considerably more detail about the relationship between the ball, collar, and occluders, the amendments here do not refer at all to whether those relationships are direct in nature or if the connections are made through intermediate parts. As noted above, the term "connected" as used in the specification--the same specification which was before the Examiner at the time of these amendments--does not necessarily imply direct connection. When the patentees added limitations to their claim more specifically describing the organization of their invention's connected parts, they did
not somehow implicitly add other limitations about the specific nature of those connections.

Accordingly, the prosecution history provides no unambiguous basis to vary from the meaning of the claims as read in light of the specification. The correct construction of Claim 12 does not require "direct" connection between the enumerated parts: Since the district court relied on an incorrect claim construction, its summary judgment of noninfringement as to Claim 12 must be vacated.

2. "Connected to"

This phrase appears in asserted claims 1, 6, 11 and 16. APE argues that the proper meaning of the phrase should be:

. . . joined together, united, or linked. In this instance, the eccentric weight portion is joined with the cylindrical gear portion at a point radially outward of the axis of the cylindrical gear portion. 'Connected to' can mean that the two portions are separate pieces joined together so long as that connection is at a position radially outward of the axis.

See Joint Disputed Claim Terms Chart (Doc. No. 37), at 7. ECA proposes a definition of:

joined together, united or linked, but specifically excluding bolting as the '964 [P]atent teaches that prior art having bolted counterweights are not sufficiently durable. While the '964 [P]atent does not disclose any other ways to effect the condition of being 'connected to,' one of ordinary skill in the art likely would have known of other methods to effect the condition of being 'connected to,' such as welding or brazing.

See ECA's Proposed Claim Construction, Doc. No. 41 at 2. 5 The Northern District of California has construed "connected to" to mean simply "joined together, united or linked." Bay, 632 F. Supp. 2d 956, 2009 WL 1684611, at *17.

5 As the name of the document implies, ECA submitted proposed claim construction language along with APE in the Joint Disputed Claim Terms Chart. See Doc. No. 37. However, during oral argument before this Court on June 23, 2009, ECA argued proposed construction that did not appear in the joint document. ECA filed updated proposed claim construction language (i.e., the document entitled "ECA's Proposed Claim Construction") on July 21, 2009. As such, this Report and Recommendation does not consider ECA's proposed claim construction language from the joint document.

As required under the rules of claim construction, this Court first looks to the language of the claims themselves in order to discern the meaning of the phrase to a person having skill in the art. The phrase "connected to" appears first in claim 1, which recites, inter alia: "[a] vibratory assembly for imparting a vibratory force to a pile, comprising . . . at least one driving means operatively connected to said counterweight and adapted to rotate said counterweight about its rotational axis." '964 Patent, col. 9, 11. 33-53. The term is used in substantially the same manner in claims 6 and 11: as a description of the manner in which a driving mechanism is joined to the counterweight.

Claim 16 deviates from the above trend, reciting " . . . [a] cylindrical gear portion having a plurality of gear teeth around its circumference, said cylindrical gear portion being made of a first metal; an eccentric weight portion connected to said cylindrical gear portion at a position radially outward of the axis of said cylindrical gear portion . . . " '964 Patent, col. 11, 11. 10-15. This usage of the phrase "connected to" is the first and only time the phrase appears to describe the joining of the eccentric weight portion of the counterweight with the cylindrical gear portion of the counterweight. Furthermore, unlike the prior uses of phrase, it is unmodified by the term "operatively." However, despite these differences, and without arguments to the contrary by the parties, this Court presumes that the phrase "connected to" has the same meaning in claim 16 as it does in the other claims in which it is used. Given that there is no explicit definition of the phrase in the claims, the Court next turns to the specification for guidance.
The specification uses the term "connecting" to describe the joining of the counterweight to the shaft for rotation. Specifically:

[the eccentric weight portion 43 has two threaded bores 108 that communicate with and are transversely oriented relative to the center bore 106. The threaded bores 108 are adapted to receive conventional threaded lock fasteners to lock the shaft 82 within the center bore 106, thereby securely connecting the counterweight 40 to the shaft for rotation with the shaft.]

'964 Patent, col. 5, 11. 43-50. The specification also describes that "[a]t least one motor is operatively coupled to the counterweight," '964 Patent, col. 2, 11. 39-40. While this implies that "coupled" is synonymous with "connected to," the definition of the phrase, as it would be understood by someone having skill in the art, is still unclear.

At this point in the analysis, Judge Hamilton turned to the Oxford English Dictionary (2d ed. 1989) in order to construe the phrase, reasoning that "neither the claim language nor the specification expressly define or describe the phrase . . . [n]or does the specification indicate explicitly or implicitly that the patentee intended to import a novel or specialized meaning." Bay, 632 F. Supp. 2d 956, 2009 WL 1684611, at *11. While any use of extrinsic evidence is disfavored, it is still acceptable under case law so long as the extrinsic evidence is not contradicted by any intrinsic evidence. See Phillips, 415 F.3d at 1318-19. Judge Hamilton noted that the Oxford Dictionary gives "connected" the ordinary meaning of "conjoined; fastened or linked together," and the term "coupled," which is used in the specification in a manner that appears to be synonymous with "connected to," has the ordinary meaning of "tied, joined, linked, or associated together in pairs." 6 Bay, 632 F. Supp. 2d 956, 2009 WL 1684611, at *11.

6 The Northern District of California's opinion in Bay did provide pinpoint cites for the words "connected" or "coupled.". However, this Court notes that their definitions are exactly the same in another edition of the Oxford English Dictionary. See The Compact Edition of the Oxford English Dictionary, 520, 581 (1987).

Judge Hamilton determined that, in light of these definitions, the drawings of the invention in the patent, and the description of the invention in the specification, the phrase "connected to" indicated "joined together, united or linked." Bay, 632 F. Supp. 2d 956, 2009 WL 1684611, at *11-*12. As this definition is not contradicted by any intrinsic evidence, and both parties to the instant litigation have incorporated it as part of their proposed claim construction language, this Court accepts it as part of its construction of the term "connected to."

However, this Court's construction of this disputed phrase is not yet complete. ECA argues that any definition of "connected to" must exclude bolting as a method for "connecting" parts of the claimed device. ECA reads this limitation from the specification, pointing to the following wording in, column 1, lines 39-51, of the '964 Patent:

The prior art includes a vibratory assembly with counterweights having a solid eccentric weight bolted to a portion of a cylindrical gear. These bolted weights are not sufficiently durable, because the bolts have a very undesirable tendency to break under the large stress loads generated during rotation counterweights [sic]. Another prior art vibratory assembly avoids this breaking problem by using a cast, one-piece, solid counterweight having an eccentric weight portion that is integral with a cylindrical gear portion. These solid, cast counterweights, however, do not have sufficient mass to generate large enough vibratory forces to efficiently drive [sic] or pull piles.

See also Doc. No. 37 at 7. ECA argues that the identification of this problem with the prior art in the specification of the '964 Patent acts as a clear disavowal of the use of bolting as a method of connection for the claimed invention. See ECA's Resp. to APE's Opening Claim Construction Br. (Doc. No. 33), at 25-26.

APE responds that this statement, which comes early in the specification, merely acts as an identification of problems that existed in the prior art, and not as a disavowal of a specific method of connecting parts of the claimed invention. By APE's reasoning, the right to exclude under the '964 Patent extends to embodiments of the counterweight in which the gear and eccentric weight portions are connected to each other by bolting.
How to treat a limitation of the prior art that is stated in the specification of a patent is not a trivial issue. On one hand the rules of patent drafting encourage an inventor to state such problems in order to show the examiner, and the person having skill in the art, how the new invention is novel or useful. See M.P.E.P § 608.01(c) (Rev. 7, July 2008) (stating that "[w]here applicable, the problems involved in the prior art or other information disclosed which are solved by the applicant's invention should be indicated"). In contrast, a disclaimer of prior art that leads a person having skill in the applicable art to believe that the inventor had limited the scope of his or her patent protection could lead to such a limitation being read into the language of the claims. See Phillips, 415 F.3d at 1315-16.

Fortunately, the Court of Appeals for the Federal Circuit has provided some guidance on this issue. In Ventana Medical Systems, Inc. v. BioGenex Laboratories, Inc., Ventana owned patents relating to automated methods and apparatus for staining slides. See 473 F.3d 1173, 1176 (Fed. Cir. 2006). BioGenex argued that statements made in the "BACKGROUND ART" section of Ventana's patent that described the limitations of a number of prior art staining devices limited the scope of Ventana's patent protection from including the methods used by the named prior art. Id. at 1180 (emphasis in original). The court of appeals, noting that, under its standard in Phillips, 415 F.3d at 1316, language used in the specification could act as a disavowal of claim scope by the inventor in certain cases, rejected this argument. Ventana, 473 F.3d at 1180. That court decided instead that, in cases where general statements are used to identify limitations in the prior art, such statements, without more, "will not be interpreted to disclaim every feature of every prior art device discussed in the "BACKGROUND ART" section of the patent." Id. at 1181 (emphasis in the original). 7

Applying this precedent to the issue before this Court, it can be seen from the specification of the '964 Patent that several incarnations of prior art, and their shortcomings, are mentioned in the "BACKGROUND OF THE INVENTION" section. See '964 Patent, col. 1, 11. 39-68, col. 2, 11. 1-17. This prior art includes inventions that are connected by bolting as well as by casting, which is the method of "connecting" used in the preferred embodiment of the '964 Patent. The statements in this section are also general in nature. As such, this Court will not apply ECA's proposed limitation excluding bolting as a method of connecting parts of the '964 Patent.

Thus, for the reasons stated above, it is respectfully recommended that the phrase "connected to" be construed to mean: "joined together, united or linked."

--- Footnotes ---

7 Additionally, the Federal Circuit noted that the method used in Ventana's preferred embodiment had also been identified in its "BACKGROUND ART" section as having problems in its prior-art form. Ventana, 473 F.3d at 1180 (emphasis in original). This provided further indication to that court that BioGenex's argument was without merit. See id.

--- End Footnotes ---

A. Claim Construction

Hearth's motion seeks an interpretation of the following limitations in Claim 1:

1) "...and one of said remaining walls having a horizontal exhaust pipe connected thereto for insertion through said outside wall of the space to be heated."

2) "the wall having said horizontal exhaust pipe connected thereto comprising an inner plenum, a middle plenum and an outer plenum."

3) "Said horizontal exhaust pipe being connected to said inner plenum of said wall having said horizontal exhaust pipe connected thereto..."

The primary disagreement between the parties involves the proper meaning of the phrase "horizontal exhaust pipe." Although both parties concur that the pipe must be horizontal at the point at which it traverses the exterior wall, only FMI
asserts that it must also be horizontal at the point at which it is connected to the fireplace.

As stated previously, the Court may look to the claim language, specification, and prosecution history in an effort to divine the proper meaning of a claim. Several observations about the claim language itself suggest that FMI is correct in its interpretation of Claim 1. The phrase "horizontal exhaust pipe" must be given its ordinary meaning. Nothing in the claims, specification, or prosecution history suggests otherwise. In short, "horizontal" means "horizontal;" it does not mean "horizontal and vertical," "angled," or even "substantially horizontal."

In addition, Hearth contends that "connected to" does not mean "directly connected to." Hearth makes this assertion in an effort to circumvent the Court's construction of "horizontal." In other words, if a horizontal pipe may be "connected" to the fireplace through a secondary piece of vertical pipe, then the Court's construction of "horizontal" is irrelevant from Hearth's perspective. Hearth's construction of "connected to" is untenable. A wall with a pipe "connected thereto" implies that there is no intermediate link between the wall and the pipe. This construction of "connected to" applies equally to the phrase "said horizontal exhaust pipe being connected to said inner plenum of said wall…".

The contentious language of Claim 1 is therefore construed as follows: 5 "horizontal exhaust pipe" means the exhaust pipe which is horizontal both at the point at which it exits the building and the point at which it is connected to the fireplace; "connected to" means directly connected to without the presence of an intermediate link. This construction of Claim 1 largely comports with the specification. The descriptions and diagrams emphasize a horizontal exhaust pipe connected to an inner plenum.

5 FMI also urges the Court to interpret the limitation in Claim 1 as a requirement that the wall connected to the horizontal exhaust pipe be vertical or substantially vertical. In support of its contention, FMI relies on a theory involving the antecedent basis for "said remaining walls." FMI contends that "one of said remaining walls" can only refer back to the "said … vertical walls" phrase which immediately preceded it. Although the Court finds FMI's antecedent basis theory marginally persuasive, the patent examiner did not consider the imperfect antecedent basis to be problematic. Consequently, this Court will not adopt FMI's restrictive construction of "said remaining walls." 6 All descriptions and diagrams with the exception of Figure 5 depict a horizontal exhaust pipe connected to the inner plenum of a vertical wall. Although Hearth urges the Court to determine whether Figure 5 is within the purview of the '322 patent, FMI correctly points out that such a ruling would constitute an advisory opinion. See A.B. Dick Co. v. Burroughs Corp., 713 F.2d 700, 704 (Fed. Cir. 1983); DF & R Corp. v. American Int'l Pac. Indus. Corp., 830 F. Supp. 500, 509 (D. Minn. 1993). There is no justiciable issue involving Figure 5 directly before the Court at this time. The critical issue is whether Claim 1 or 14 reads on the DVF series based on the language of the claims as construed by the Court.

Our initial understanding of the meaning of Claim 6 was reinforced by the last four lines:

"the improvement comprising a lockout mechanism connected to said longitudinal slots for preventing said pusher bars from passing more than one time through said longitudinal slots."

Patent No. Re. 34,519 (Fox Reissue Patent) Column 5, Lines 55-58 (emphasis added). Claim 6 recites a lockout mechanism "connected to said longitudinal slots." In our earlier order, we interpreted this to mean directly connected to the slots. As we have noted the lockout device in the U.S. Surgical cutter never touches either the longitudinal slots or the pusher bars, but rather attaches to the cam bar retainer. Ethicon argues for a different interpretation of "connected." Ethicon asserts that the U.S. Surgical lockout is connected to its longitudinal slots, since one of the walls of its longitudinal slots is defined by a metal sheet which if followed beyond the longitudinal slots will eventually connect with the hooking clip. However, by this logic every piece of a linear stapler is eventually connected to every other piece. In order to give substantive meaning to the
assertion in the Fox Patent that the lockout is connected to the longitudinal slots, we must understand this to mean directly or operably connected. Since the longitudinal slots are part of the Fox Patent's cartridge, this reading of the term connected would require that the claimed lockout be part of the cartridge. Therefore, we interpreted these last four lines of Claim 6 to reinforce our reading of that entire claim. Claim 6 of the Fox Patent describes a lockout in a staple cartridge, directly and operably connected to the longitudinal slots. The allegedly infringing device of U.S. Surgical is a lockout which is outside the cartridge and which is not connected to the longitudinal slots.

At our August hearing, Ethicon presented a host of examples of the use of the expressions "connects," "connection," and "connecting." See for example U.S. Surgical's Patent No. 4,488,523 ("Schichman") and Patent No. 5,071,052 ("Rodak"). Ethicon apparently chose these examples to demonstrate that two elements of a mechanical device which were relatively far apart could be considered connected to each other. We find these arguments unconvincing. In each of the cases cited by Ethicon, the connection was described because that connection had some functional relevance to the operation of the device. For example, in the Schichman Patent we see this language:

It is true that the flexible shaft in Schichman is long and connects elements relatively distant from each other, but the functional import of the connection is obvious and the actual connection is direct. In order to give this same meaning to "connected to" in the Fox Reissue Patent, we must understand "connected to" to mean that the lockout is directly and functionally connected to the longitudinal slots. Such a reading would exclude the relationship between the slots and the lockout practiced by U.S. Surgical.

The term "connected to" was not casually chosen by Fox. That language was supplied in response to an objection by the PTO that the applicant must be more specific in terms of the location of the lockout, and how it functioned. Therefore, we can be assured that a technical and not a generic meaning should be attached to that language.

The phrasing ("connected to a source of water") used to describe the relationship between the first inlet port (24) and the source of water is also used to describe the relationship between the second inlet port (26) and the atomizing nozzle (40) ("a one-piece atomizing nozzle . . . connected to said second inlet port"). The connection between the second inlet port and the atomizing nozzle, as shown in figure 4, is direct, with the surfaces of the second inlet port and the atomizing nozzle in physical contact with each other.

Because the patent uses the same term ("connected to") to describe the relationship between the first inlet port and the source of water, the defendants argue that there must also be a direct connection between such source and the first inlet port, as there is between the second inlet port and the atomizing nozzle.

I disagree: there is nothing in the phrase "connected to" that, in ordinary usage, requires the two connected items to be joined physically or adjacent to each other. Two items often are located some distance from one another, and yet are connected by means of a line, pipe, or other medium. Indeed, when talking about a liquid, such as water, there would be relatively few instances where the point of its use for mechanical purposes is in direct contact with its source, without intermediate transmission by pipe or similar means. Faucets are far more commonplace than waterwheels.

To read the patent in the manner argued by the defendants would lead to the nonsensical requirement that the method and apparatus could be used primarily, if not only, in sub-marine applications, where water flowed directly into the first inlet port.

Replacement of the term "in communication with" with the term "connected to" clarifies the application's terms, rather than limiting its scope.
The fact, moreover, that the applicant continued to use the term "in communication with" in the specification does not compel adoption of the defendants' reading of the term "connected to.". In each instance, the terms are used with their ordinary meanings, no confusion or ambiguity arises, and the meanings are clear to all, including those skilled in the art.

Support for my interpretation of the term "connected to" is found in Ethicon Endo-Surgery, Inc. v. U.S. Surgical Corp., 93 F.3d 1572, 1575 (Fed.Cir. 1996). That case involved a surgical stapler, in which a "lockout mechanism [is] connected to ... longitudinal slots for preventing . . . pusher bars from passing more than one time through said longitudinal slots," so that only one staple would be ejected at a time. The allegedly infringing device employed a "cam bar retainer," which was not located at the point of ejection, to prevent multiple ejection of staples.

The patent holder argued that "connected to," as used in the patent, could "be read broadly to include two distant elements which are 'connected' by intervening elements." Id. at 1578. The Federal Circuit rejected this contention, stating:

the entire phrase "connected to said longitudinal slots" must be read narrowly. First, in what meaningful sense is it possible to "connect" the restraining member, which is a physical item, with the longitudinal slots, which are hollow passageways, unless "connected to" is understood to mean that the restraining member operatively interacts with the longitudinal slots by blocking them? Second, [the patentee's] argument proves too much. If, as [the plaintiff] argues, "connected to" should be read broadly to include elements which are connected directly or indirectly, then this language would read on a lockout mechanism located anywhere in the surgical stapler, and the "connected to" limitation would be meaninglessly empty.

Id.

Although "connected to" in Ethicon was interpreted to mean proximate, or in direct contact with, the court made clear that the phrase "connected to" did not always convey such a limited meaning: "We acknowledge that the term "connected to" could, in other contexts, be broadly construed." Id.

This is such a case. Whereas in Ethicon, the patented device could only function if the referenced components were in contact, in this case the method and apparatus will work only if "connected to a source of water" allows the water to be piped into the inlet port from some distance from the port. Cf. Hay & Forage Industries v. New Holland North America, Inc., 25 F. Supp. 2d 1170, 1177 (D. Kan. 1998) (phrase "connected to" did not denote an inflexible connection; the definition of connected as [joined or fastened together]; . . . cannot preclude all relative movement.); United States v. LaBerge, 267 F. Supp. 686, 690-91 (D. Md. 1967) (shed located about 190 feet from a house was "connected to" the house, as that term was used in a statute prohibiting distillation of spirits in any dwelling house or in any shed, yard, or inclosure connected with such dwelling house).

I conclude, accordingly, that the term "connected to," as used in Claims 1 and 7, does not require the source of the water to be proximate, or in direct contact with, the first inlet port. Instead, the water source can be located elsewhere, with the source and the inlet port being connected by an intermediate means of transmission.

Michaels argues that the phrase "connected to and aligned with the length of the gun barrel cleaning device" should be allowed its ordinary meaning and simply refers to a brush attached to the cleaning device, with its length in line with the rest of the cleaning device. There is no requirement that the brush be enclosed within a sheath. Col 5, lines 17-52; Col 9, lines 18-21; Col 9, line 66 to Col 10, line 5; Fig. 4, elements 14, 32, and 36; see also Fig 1 (elements 26 and 28 are connected to and aligned with sheath 12); Fig. 4 (elements 26 and 28 are connected to and aligned with the cable 30 via connectors 32, 34); Figs. 10 and 10A (elements 26, 28, and 48 are connected to and aligned with sheath 12).

In contrast, Clean Gun construes this phrase to mean that the brush must be encased within a length of the tubular sheath, instead of being connected to the device by hard metal parts exposed outside the sheath or by other twisted or crimped connections. Abstract; Figs. 5-10A; Col 2, line 62 to Col 3, line 1-25; Col 4, lines 30-33; Col 4, line 63 to Col 4, line 7; Col
For the reasons discussed above, this court finds no reason to adopt Clean Gun's proposed construction. Accordingly, the phrase "connected to and aligned with the length of the gun barrel cleaning device" must be afforded its ordinary meaning, that is, the cleaning section is coupled to the pull cord and extends longitudinally in alignment with the rest of the gun barrel cleaning device.

902

a. "Connected to" Claims

We begin with asserted claims 4, 13, 16, 18, and 22, each of which require "supporting members connected to and projecting from the hanger bar that slidably guide the retainer bar." In arguing over the construction of these claims, the parties focus on the meaning of the phrase "connected to." According to defendants, "because the [Plaintiff's Patent] specification does not specifically mention the words connected to, case law supports assigning to the words connected to their ordinary meaning to those persons skilled in the art at the time of the [Plaintiff's Patent]." (Memorandum in Support of Defendants' Motion, at 9). Unfortunately, the defendants provide no support for their factual assertion nor, having apparently attended the Fermat School of Law, do they bother to cite any of the case law to which they refer. (Id.). The gist of defendants' argument, however, is that because the pins of its device are fixed to the retainer bar and are not fixed to the hanger bar, they are not connected to the hanger bar, as required by the asserted claims.

Plaintiff submits that "connected to" means "in physical contact with . . . and cannot be separated without physical modification" or "linked together." (Plaintiff's Opposition to Defendants' Motion, at 12). It explains that the pins in defendants' device are, then "connected to" the hanger bars because they are "in physical contact" or "linked." (Id.). Plaintiff also contends that because the term "fixed" is used throughout the Plaintiff's Patent specification, the term "connected to" must be interpreted more broadly.

The court in Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576 (Fed. Cir. 1996) detailed the applicable rules of claim construction as follows:

- the court should look first to intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history.

  First, we look to the words of the claims themselves, both asserted and nonasserted, to defined the scope of the patented invention. Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history.

  Thus, second, it is always necessary to review the specification to determine whether the inventor has used any terms inconsistent with their ordinary meaning. The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. . . . the specification contains a written description of the invention which must be clear and compete enough to enable those of ordinary skill in the art to make and use it. Thus, the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.

  Third, the court may also consider the prosecution history of the patent, if in evidence.

  In most situations, an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term. In such circumstances, it is improper to rely on extrinsic evidence. . . . The claims, specification, and file history, rather than extrinsic evidence, constitute the public record of the patentee's claim, a record on which the public is entitled to rely.

Vitronics, 90 F.3d at 1582-83.

The words of the claim with which we begin here are:
A plurality of supporting members connected to and projecting from the hanger bar that slidably glide and support the retainer bar...

and:

a plurality of supporting bar members connected to and projecting from a hanger bar through the aperture in the retainer bar, said supporting members slidably gliding and supporting the retainer bar...

The ordinary and customary meaning of the disputed term, "connected to" is "joined or linked together." Webster's Third New International Dictionary, at 480 (1986). Obviously, as the parties' arguments demonstrate, this can range from "connected" as are two links of chain, to "connected" as are two blocks of wood by glue. It is, as plaintiff suggests, a very broad term. Our application of the rules of construction, however, leads us to the conclusion that plaintiff is not entitled to its entire scope.

The claims themselves suggest, if not mandate, that the pins or supporting members be affixed to the hanger bar, as opposed to the retainer bar -- they are claimed to be "connected to and projecting from the hanger bar." It would be something of a stretch to say that defendants' device has supporting members or pins connected to and projecting from the hanger bar; they are, more accurately, connected to and projecting from the retainer bar. Resolving doubt in plaintiff's favor, however, we are hesitant to find the claim language dispositive on this question, as the examiner did allow it to be broadly drawn.

The specification (emphasis added) is more instructive. The disclosure of the invention states that:

the retainer bar includes a plurality, typically a pair, of supporting members fixed to and extending from the hanger bar...

The best mode of carrying out the invention (emphasis added) is said to be as follows:

the retainer bar is provided with apertures to accommodate a pair of vertical supporting members that are fixed to the hanger bar. The supporting members each include a guide pin fixed to the hanger bar. The pin is rigidly fixed substantially perpendicular to the hanger bar by means of a . . . screw or bolt that passes through hanger bar apertures and threads into internal threads of the pin.

It is clear from this language that Plaintiff's Patent describes a device wherein the pins or supporting members are affixed -- like blocks of wood with glue rather than links of chain 2 -- to the hanger bar, as opposed to the retainer bar. This is a narrower sense of "connected to" than one might arguably take from the claim language, but this is the sense we must take in our construction of Plaintiff's Patent, reading the claims in view of the specification. Vitronics, 90 F.3d at 1582. "When there is an equal choice between a broader and a narrower meaning of a claim, and there is an enabling disclosure that indicates the [patentee] is at least entitled to a claim having a narrower meaning . . . the notice function of the claim is best served by adopting the narrower meaning." Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996). The claims and specification are dispositive in this case, meaning that consideration of the intrinsic evidence the parties have submitted would be inappropriate. Vitronics, 90 F.3d at 1584.

2 We leave mustache and toenail analogies to the parties.

The claims thus construed, we can say as a matter of law that defendants' device does not infringe on Plaintiff's Patent. The claims as construed are totally missing from the defendants' device. The device's supporting members or pins are affixed to the retainer bar, not the hanger bar as required by Plaintiff's Patent. To put it another way, in Plaintiff's Patent, the hanger bar and supporting members can be said to be a rigid assembly with respect to the moving retainer bar. In defendants' device, the retainer bar and supporting members can be said to be a rigid assembly and the moving part with respect to the hanger bar. Accordingly, we must find that the defendants are entitled to summary judgment on the question of literal infringement, and that the plaintiff's motion for summary judgment on this question must be denied.
1. "Connected to" Claims

Plaintiff's patent, in claims 4, 6, 7, 13, 16, 18, 22, 23, and 24, requires the presence of "supporting members connected to and projecting from the hanger bar that slidably guide the retainer bar." The parties' interpretations of that claim differ. Defendants move, and plaintiffs cross-move, for summary judgment on the issue of literal infringement.

Defendants maintain that, because the supporting members [pins] of its device are affixed to the retainer bar, rather than to the hanger bar, they are not "connected to" the hanger bar. Defendants assert that "connected to" means "fixed or secured to." (Mem. in Supp. of Defs.' Mot. for Summ. J. at 10.)

Plaintiff contends that the supporting members are indeed connected to the hanger bar, asserting that "connected to" means that the pins and the hanger bar are "in physical contact with [each other] . . . and cannot be separated without physical modification" or, that they are "connected to" one another because they are "linked together." (Pl.'s Opp'n to Defs.' Mot. at 12).

The parties' asserted meanings of "connected to" range from indirect to direct connections between objects. The Court's task is to construe the meaning of the disputed term. In Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576 (Fed. Cir. 1996), the court laid out the applicable rules of claim construction:

the court should look first to intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. . . .

First, we look to the words of claims themselves, both asserted and nonasserted, to define the scope of the patented invention. Although the words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history. . . .

Thus, second, it is always necessary to review the specification to determine whether the inventor has used any terms inconsistent with their ordinary meaning.

Id. at 1582 (citations omitted).

Plaintiff's claim requires not only that the supporting members be "connected to" the hanger bar, but also that they "project from" the hanger bar. The term "connected to," therefore, has been modified, and must be interpreted in conjunction with the limitation that the members also "project from" the hanger bar. Looking at the specification, the Court finds no special definition of "connected to," "projecting from," or "connected to and projecting from" that would mandate attributing unusual meanings to the terms. Therefore, the Court construes the terms according to their ordinary meanings. The ordinary meaning of "connected" is "joined or linked together." Webster's Ninth New Collegiate Dictionary 278. The ordinary meaning of "project," with regard to concrete objects rather than ideas, is "to throw or cast forward: thrust" or "to cause to protrude." Id. at 940. Synonyms for "projecting" include "jutting," "protruding," and "protuberant." Webster's New World Thesaurus 591.

While the term "connected" would permit an indirect relation between objects, the necessity that the supporting members also "project from" the hanger bar compels a more direct relation. We agree with Magistrate Judge Bobrick that the language mandates that the pins be affixed to the hanger bar. For example, a hat and the head on which it rests are "connected," but one would not ordinarily state merely because of that connection that one's head projected from the hat, rather than from one's neck. Rather, a protruding object, such as a pin, ordinarily projects from something to which it is affixed, not necessarily from something to which it is merely somehow connected. One might argue that a pin that has been stuck into a pin cushion projects from the cushion. In that example, however, there is only one object from which the pin could project. Where, as here, the pin is situated between two bars, it would be more accurate to differentiate the relation of the pin to the two bars by stating that it projects from the bar to which it is affixed. In the accused device, the supporting
members are affixed (by screws) to and project from the retainer bar, and the supporting members and the retainer bar move as one object -- a rigid assembly -- in relation to the hanger bar, which remains static. Plaintiff's patented claims, on the other hand, disclose a device in which the supporting members are affixed to the hanger bar, those two pieces constituting a rigid assembly that remains static in relation to the moving retainer bar. In a way, the accused device and plaintiff's claimed invention are mirror images.

This Court finds no ambiguity in the language of plaintiff's claim. Plaintiff has assigned no special meanings in his specification to the disputed terms. Therefore, this Court, as a matter of law, construes the patented claim that the supporting members are connected to and project from the hanger bar to mean that the supporting members must be affixed to the hanger bar. The supporting members of the accused device are affixed to the retainer bar. Thus, this Court finds no literal infringement of plaintiff's "connected to" claims.

Defendants' motion for summary judgment on the issue of literal infringement is granted. Plaintiff's cross-motion is denied.

**A. Construction of the '304 Patent Limitation**

As noted, in the '304 patent, claims 1, 9 and 15 each require a "plurality of annular shell rings" each ring being "non-jointed along its circumference" and "connected to form a generally cylindrical drum shell."

In construing the elements in plaintiff's independent claims, the words must be given "their ordinary and accustomed meaning, unless it appears from the specification or the file history that they were used differently." Carroll Touch, 15 F.3d at 1577. Reference to a dictionary to determine the ordinary and accustomed meaning of a word is appropriate. Miles Labs, Inc. v. Shandon, Inc., 997 F.2d 870, 876 (Fed. Cir. 1993), cert. denied, 510 U.S. 1100, 127 L. Ed. 2d 232, 114 S. Ct. 943 (1994). Webster's Dictionary defines plurality as "the state of being plural," or "the state of being numerous," or "a large number or quantity," or a "multitude." Webster's Third New International Dictionary 1745 (1986). Webster's defines "connected" as "joined" or "linked together." Id. at 480.

Nothing in the '304 patent's specification points to a definition of "plurality" different from Webster's. Indeed, the specification always refers in the plural to the rings which comprise the drum shell. For example, in defining the sounding ring, the specification states that "one or more of such rings function as sounding rings which have a greater outer radius than the other shell rings." (Lovelett Aff., Ex. A, col. 3, lines 21-23) (emphasis added). Therefore, each of plaintiff's independent claims -- 1, 9 and 15 -- requires a "multitude of" or "numerous" annular shell rings. The '304 patent does, however, define "connected." "Pins are positioned axially into adjacent rings to precisely position the rings relative to one another," and "pins . . . are embedded into adjacent rings to radially align and maintain the relative ring positions." (Lovelett Aff., Ex. A, col. 3, lines 17-19; col. 4, lines 19-22) Accordingly, "connected" in the '304 patent means linked together with the use of pins embedded in the rings. Finally, the term "drum shell," as used in the '304 patent, includes both the stacking and the sounding rings. (Id. col. 3, Line 62 - col. 4, Line 6)

**Claim 10**

Claim 10 requires "connecting a detachable tip to the handpiece . . . the tip comprising an irrigation tube . . . and a suction tube for aspirating irrigation fluid from the irrigation site . . . aspirating spent irrigation fluid from the irrigation site through the suction tube of the tip and directing the aspirated irrigation fluid along a path that is disposed exteriorly of the handpiece . . ." 452 Patent, Col. 8: 31-32, 33-34, 40-43 (emphasis added). As noted above, it is clear from the patent, that in order for the aspirated fluid to be disposed of externally of the handpiece, the tip must include a bypass path. Claim 10 states that the tip includes a suction tube that aspirates irrigation fluid along a path that is disposed "exteriorly of the handpiece." The Court reads this claim consistent with the entire patent and concludes that a person of ordinary skill in the art would understand that in order for the tip to dispose of the aspirated fluid "exteriorly of the handpiece" the tip must
contain a fluid bypass path. Consequently, the Court finds that the language in claim 10 must be read in a manner consistent with the language in claims 9 and 30 and that a person of ordinary skill in the art would conclude that the language of claim 10 requires that the tip include a bypass path.

**GO BACK**

906

The first element in claim 17 that requires construction is the phrase "connecting a plurality of intraluminal grafts." To "connect" means to join or fasten together. Webster's II New College Dictionary (1995) at 239. A "plurality" means at least two. Webster's at 849. "Intraluminal" means within the inner open space of a tubular organ such as a blood vessel or other body passageway. Webster's at 581, 650. A "graft" is a structure that is "implanted . . . surgically . . . to compensate for a defect" in a body organ or tissue. Webster's at 483. Therefore, an "intraluminal graft" is a structure designed for use within the lumen of a body passageway to compensate for a defect in said passageway. (PX 1/API 1: '417 patent, col. 1, lns. 28-32; col. 6, lns. 23-54; col. 9, lns. 6-13) Neither the specification nor the claim language require that the intraluminal grafts be of any particular length; the court concludes, however, that each such "graft" must be functional, as would be expected in a method claim such as claim 17.

**GO BACK**

907

Claim 17 - '417 patent

The first element in claim 17 that requires interpretation 4 is the phrase "connecting a plurality of intraluminal grafts." To "connect" means "to join, fasten, or link together usually by means of something intervening . . . ." Webster's at 480. A "plurality" refers to the state of being "plural," which relates to or consists of or contains more than one. Id. at 1745. "Intraluminal" means being within the lumen, or the cavity or passageway of a tubular organ such as a blood vessel. Id. at 1185, 1345. A "graft" is a structure that is "implanted . . . surgically . . . to compensate for a defect" in a body organ or tissue. Webster's II New College Dictionary 483 (1995). 5 Therefore, an "intraluminal graft" is a structure designed for use within a body passageway to compensate for a defect in said passageway. ('417 patent, col. 1, Ins. 28-35; col. 6, Ins. 23-54; col. 9, Ins. 6-13) The court continues to hold that each such "graft" must be functional; i.e., once it has "expanded and deformed," it must be capable of "serving to prevent a body passageway from collapsing . . . ." ('417 patent, col. 8, Ins. 60-63)

--- Footnotes ---

4 The court preliminarily construed disputed claim language for purposes of resolving motions for injunctive relief. To some extent, therefore, the following analysis may be repetitive of the court's July 17, 1998 memorandum opinion. (D.I. 284)

5 The court has relied more substantially in this opinion on Webster's Third New International Dictionary for definitions simply because it is the version purchased for and easily available to the court.

--- End Footnotes ---

908

3. "connecting device" -- The parties are in disagreement about what kinds of "things" can be considered a "connecting device" as understood in Claim 2 and about whether the "connecting device" must be construed as a separate element from the rivet that mates with the pocket. As to the first issue, I agree with Amesbury that the term "connecting device" should not be limited to "retractable tabs", also referred to as "resilient tabs," as suggested by Caldwell in its written submissions. 17 Claim 2 describes a window balance comprising a "connecting device for attaching the balance shoe within the U-shaped channel of the window balance" without including any specifics about the "connecting device". This wording contrasts with the specific description set out in Claim 1 (which is not at issue here) that defines a "connecting device" as one "comprising one or more resilient
tabs for attaching the balance shoe within the U-shaped channel of the window balance, wherein the one or more resilient tabs extend at least partially through a corresponding number of the plurality of openings in the U-shaped channel.” In addition, there are three claims that are dependent on Claim 2 that limit the scope of the “connecting device” in those claims. Claim 3 refers to “the window balance system of claim 2 wherein the connecting device comprises a rivet”; Claim 4 refers to “the window balance system of claim 2 wherein the connecting device comprises a screw”; and Claim 5 refers to “the window balance system of claim 2 wherein the connecting device comprises a resilient tab”. Given this important overlap, I turn again to the doctrine of claim differentiation.

17 At the hearing, Caldwell proposed the following definition on page 33 of its handout:

A pair of retractable tabs or a screw used for attaching the balance shoe in the channel, separate from the pocket that mates with a rivet.

As discussed above, “the doctrine of claim differentiation create [s] a presumption that each claim in a patent has a different scope.” Free Motion Fitness, 423 F.3d at 1351 quoting Comark, 156 F.3d at 1187. "The difference in meaning and scope between claims is presumed to be significant to the extent that the absence of such difference in meaning and scope would make a claim superfluous.” Id. quoting Tandon Corp., 831 F.2d at 1023. Caldwell misunderstands the law in stating that “since the dependent claim specifically limits the connecting device' to a screw, the independent claim 2 presumptively does not encompass that structure.” See id. (holding that the "dependent claims limiting the claim to a single cable confirm that the independent claims may encompass more than one cable")

Here, Claims 3-5 incorporate Claim 2 and limit "connecting device" to three different types of fastening devices -- rivet (Claim 3), screw (Claim 4), and resilient tabs (Claim 5). Consequently, these specific references support Amesbury's construction that "connecting device" in Claim 2 ought to be given the broader meaning described in the specification. The specification explains that the "connecting device" can include one or more retractable tabs for engaging the right U-shaped channel" [368 Patent, col. 2, 11. 35-36] or "other connecting devices such as a screw." [368 Patent, col. 5, 11. 31-32.]

In addition, since Claim 1 specifically defines the connecting device as one comprising "one or more resilient tabs . . ., [which] extend at least partially through a corresponding number of the plurality of openings in the U-shaped channel" and Claim 2 does not specify any limits, the term in Claim 2 should be given the broad meaning suggested by the specification. Caldwell also incorrectly argues that "connecting device" should be limited to resilient tabs because dependent claims 3 and 4 are invalid for lack of enablement. As a basis for this argument, Caldwell cites to Pandrol USA, LP v. Airboss Ry. Products, Inc., 320 F.3d 1354 (Fed. Cir. 2003) and Toro Co. v. White Consol. Indus., 199 F.3d 1295 (Fed. Cir. 1999) without pin cites for the proposition that because "the patent drawings do not contain a picture of those claimed structures as required by 37 CFR § 1.83(a) 18, . . . those claims are not enabled." In doing so, Caldwell misinterprets Pandrol and Toro, the later of which actually stands for the proposition that a claim may be limited to the embodiment depicted if that is the only embodiment and "no other structure is illustrated or described." Toro, 199 F.3d at 1301. "It is well established that the preferred embodiment does not limit broader claims that are supported by the written description." Id.

18 37 C.F.R. § 1.83 Content of drawing. (a) The drawing in a nonprovisional application must show every feature of the invention specified in the claims. However, conventional features disclosed in the description and claims, where their detailed illustration is not essential for a proper understanding of the invention, should be illustrated in the drawing in the form of a graphical drawing symbol or a labeled representation (e.g., a labeled rectangular box). In addition, tables and sequence listings that are included in the specification are, except for applications filed under 35 U.S.C. 371, not permitted to be included in the drawings.

The enablement requirement in 35 U.S.C. § 112, P 1, “provides in pertinent part that the specification shall describe the manner and process of making and using [the invention], in such clear and concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use [the invention].” AK Steel Corp. v. Sollac and Ugine, 344 F.3d 1234, 1243-44 (Fed. Cir. 2003) quoting 35 U.S.C. § 112, P 1. “The enablement requirement is satisfied when one skilled in the art, after reading the specification, could practice the ["full scope of the"] claimed invention without undue experimentation.” Id. at 1244 quoting In re Wands, 858 F.2d 731, 736-37 (Fed. Cir. 1988). The requirement for drawings, on the other hand, is set out in 35 U.S.C. § 113, which provides that:
The applicant shall furnish a drawing where necessary for the understanding of the subject matter sought to be patented. When the nature of such subject matter admits of illustration by a drawing and the applicant has not furnished such a drawing, the Director may require its submission within a time period of not less than two months from the sending of a notice thereof. Drawings submitted after the filing date of the application may not be used (i) to overcome any insufficiency of the specification due to lack of an enabling disclosure or otherwise inadequate disclosure therein, or (ii) to supplement the original disclosure thereof for the purpose of interpretation of the scope of any claim.

35 U.S.C. § 113. Consequently, it appears to me, that drawings in a patent may help overcome any insufficiency of the specification due to lack of an enabling disclosure, but they are not to be scrutinized for proper "enablement" or depiction of every "claimed structure" under 35 U.S.C. § 112, P 1 as suggested by Caldwell. Although 37 CFR § 1.83(a) of the PTO rules require that applications include drawings that "show every feature of the invention specified in the claims", I will not limit my construction of "connecting device" to retractable or resilient tabs because Claims 3 and 4 are not "enabled". "The fact that the drawings are limited to a particular embodiment does not similarly limit the scope of the claims. Rather, [the patentee] is entitled to the full breadth of claim scope supported by the words of the claims and the written description." TI Group, 375 F.3d at 1138 citing Anchor, 340 F.3d at 1306-07 ("The mere fact that the patent drawings depict a particular embodiment of the patent does not operate to limit the claims to that specific configuration.") Here, it is clear that the written description supports a broader meaning of the claimed term "connecting device" than the depicted embodiment, which uses retractable or resilient tabs. Thus, Caldwell has failed to convince me that 37 C.F.R. § 1.83(a) requires me to find that the other embodiments are not sufficiently "enabled."

As to the second issue, I am inclined to disagree with Caldwell that the "connecting device" must be a separate and distinct component of the window balance assembly from the fastener (rivet) that mates with the frame "pocket".

Claim 2 describes a window balance comprising a "connecting device for attaching the balance shoe within the U-shaped channel of the window balance" in addition to a balance shoe comprising a frame "wherein the second end of the frame of the balance shoe further forms a pocket positioned in the second end of the frame adapted to mate with a rivet." [368 Patent, col. 8, 11. 59-62.] This compares with Claim 1 where the frame of the balance does not have a pocket and the connecting device is specifically described as "one or more resilient tabs [that] extend at least partially through a corresponding number of the plurality of openings in the U-shaped channel." [368 Patent, col. 8, 11. 44-46.] It is clear that in "one embodiment of a method for securing the snap lock balance shoe within a rigid U-shaped channel with multiple openings" depicted in Figures 6A-6D shown below, [368 Patent, col. 6, 34-36], the fastener (the rivet) and the connecting device (resilient tabs) are different structures. The specification explains that under this method:

The first step, shown in FIG. 6A, is to place a fastener 635, such as a rivet, in one of the pairs of openings in the rigid U-shaped channel. The next step, as depicted in FIG. 6B, is to slide the snap lock balance shoe into the rigid U-shaped channel such that the fastener is received in the connection pocket of the snap lock balance shoe. As shown in FIG. 6C, the snap lock balance shoe is then rotated down so that the front frame surface is aligned with a bottom wall of the rigid U-shaped channel. FIG. 6D shows the last step of attaching the snap lock balance shoe within the rigid U-shaped channel. In this step, the connecting device 212 of the snap lock balance shoe snaps into one of the pairs of openings located on the rigid U-shaped channel. [368 Patent, col. 6, 40-53.]

Furthermore, in Figures 3A and 3B shown below, the patent depicts the connecting device 212 as "a pair of retractable tabs that snaps into the rigid U-shaped channel", [368 Patent, col. 5, 11. 29-31], and a connection pocket 213 that is sized to receive a "fastener located in the inverted window balance [that] can be used to further secure the connection between the snap lock balance shoe and the inverted window balance." [368 Patent, col. 5, 11. 34-36.] This suggests that the rivet (635 in Figs. 6A-6D) is only supposed to help the separate and distinct component called the connecting device secure the balance shoe.

[SEE FIGURE 6A IN ORIGINAL]  
[SEE FIGURE 6B IN ORIGINAL]  
[SEE FIGURE 6C IN ORIGINAL]  
[SEE FIGURE 6D IN ORIGINAL]  

[SEE FIGURE 3A IN ORIGINAL]  
[SEE FIGURE 3B IN ORIGINAL]
However, Figs. 3A and 3B only depict one embodiment of the snap lock balance shoe and Figs. 6A-6D only depict "one embodiment of a method for securing the snap lock balance shoe within the rigid U-shaped channel with multiple openings." [638 Patent, col. 6, 11. 34-36.] The patent also explains that in "some [other] embodiments, the snap lock balance shoe is attached to the rigid U-shaped channel with the fastener 635. In other embodiments, the snap lock balance shoe is attached to the rigid U-shaped channel without the fastener 635." [368 Patent, col. 6, 54-61.] The latter alternative embodiment appears to be captured by Claim 1 since that claim omits the "pocket" from the description of the balance shoe's frame. The former alternative embodiment appears to describe a balance shoe consisting of a pocket "adapted to mate with a rivet", wherein the rivet (the fastener) acts as the "connecting device for attaching the balance shoe within the U-shaped channel of the window balance." [368 Patent, col. 8, 11. 62, 66-67.]

Since the function of the "connecting device" is to "attach[] the snap lock balance shoe directly within an inverted window balance", [368 Patent, col. 5, 11. 19-21], Claim 2 ought to be construed to include the possibility that the rivet could serve as the "connecting device" when it locks into the frame "pocket" shaped to mate with it. Furthermore, the specification explains that the "connecting device can be integral with the frame", suggesting that as just described, the connecting device may not be integral to the frame and may be a "screw", [368 Patent, col. 5, 1. 32], or the rivet in addition to or instead of resilient tabs. As a result, I will not construe "connecting device" in Claim 2 as a structure necessarily distinct from the rivet that mates with the pocket.

Construction -- A device, such as a rivet, screw, or resilient tabs, that connects the balance shoe to the U-shaped channel of the inverted window balance.

ACS argues that the district court erred in its claim construction. It asserts that none of the asserted patents ascribe any significance to the orientation of the claimed connecting elements in relation to each other or to the stent's longitudinal axis. ACS notes that the phrase "generally parallel" appears nowhere in the specification, and only appears in some of the asserted claims, specifically independent claim 12, and dependent claims 13-15, 17, 18, and 20 of the '154 patent and dependent claim 2 of the '158 patent. ACS points out that only the drawings of the asserted patents show the connecting
elements generally parallel both to each other and the stent's longitudinal axis, and it contends that such a limitation, that only appears in the drawings, should not be read into the claims. ACS also contends that the district court gave too much weight to statements made during the prosecution of the '986 application because the '986 application specifically claimed "generally parallel connecting elements."

Scimed responds that the district court's claim construction was proper. Scimed argues that the only embodiments disclosed in the asserted patents depict the connecting elements in parallel alignment both with each other and with the stent's longitudinal axis. Scimed also argues that the asserted patents emphasize the longitudinal orientation of the connecting elements and the fact that this orientation prevents shortening and deformation of the stent upon expansion. In light of these teachings in the specification, Scimed asserts, the district court properly limited the described connecting elements to connecting elements that are generally parallel both to each other and to the stent's longitudinal axis. Scimed also argues that the inventors expressly disclaimed non-parallel connecting elements during prosecution by indicating that the "invention," not just the claims in the '986 application, was distinguishable from the Palmaz '417 patent because the Palmaz '417 patent disclosed connectors that were not parallel to the stent's longitudinal axis and therefore deformed upon expansion.

We agree with ACS that the district court erred in construing "connecting elements" and the similar terms "interconnected," "connecting members," and "struts for connecting" by requiring the stent's connecting elements to be generally parallel both to each other and to the stent's longitudinal axis. We reach this conclusion based on the intrinsic evidence of record--the claims, the specification, and the prosecution history, Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1576 (Fed. Cir. 1996).

We begin our analysis with the claim language. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 U.S.P.Q.2d (BNA) 1161, 1165 (Fed. Cir. 1999) ("The starting point for any claim construction must be the claims themselves."). In that regard, none of the claims presently under discussion require the recited "connecting elements," "interconnected" members, "connecting members," or "struts for connecting," to be "generally parallel" both to each other and to the stent's longitudinal axis. For example, independent claim 1 of the '154 patent simply recites "a plurality of connecting elements." '154 patent, col. 8, l. 43. The claim continues, indicating that the connecting elements are "configured to interconnect only said cylindrical elements that are adjacent to each other . . . ." Id., col. 8, ll. 44-46. The claim has no other express structural limitations on the claimed connecting elements. In contrast, independent claim 12 of the '154 patent, which is discussed in Part III below, recites "a plurality of generally parallel connecting elements . . . ." Id., col. 9, l. 28 (emphasis added). Claim 12's language includes an express limitation on the described connecting elements, that they be generally parallel. Based on the claim language alone, the term "connecting elements," and the terms "interconnected," "connecting members," and "struts for connecting," are not limited to those connectors that parallel each other and the stent's longitudinal axis.

The specification further supports not requiring the connecting elements described in the asserted claims to be generally parallel both to each other and to the stent's longitudinal axis. "Claims must be read in view of the specification, of which they are a part." Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2d (BNA) 1321, 1329 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 38 U.S.P.Q.2d (BNA) 1461, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). However, "while it is true that claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims . . . ." Sjoland v. Musland, 847 F.2d 1573, 1581, 6 U.S.P.Q.2d (BNA) 2020, 2027 (Fed. Cir. 1988). Here, the specification does not require the connecting elements be parallel to each other and to the stent's longitudinal axis. Scimed admits that the phrase "generally parallel" only appears in the patents in suit when it is used in a particular claim. At the same time, the specifications of the asserted patents do not discuss the orientation of the connecting elements in relation to each other or to the longitudinal axis of the described stent. Looking at the '154 patent for example, the specification's only discussion of the connecting elements' orientation states that the connecting elements are "disposed between adjacent cylindrical elements," '154 patent, col. 4, ll. 25-26, and that this adjacent placement "prevents shortening of the stent during the expansion thereof," id. at col. 5, ll. 50-51. See also id. at col. 3, ll. 1-4 (noting that the connecting elements should be joined at "either the peaks or the valleys of the undulating structure of the cylindrical elements . . . . In this manner there is no shortening of the stent upon expansion."). The specification's only other discussion of the connecting elements' orientation indicates that it is preferred to place them "on one side of the cylindrical element 12 . . . . to achieve maximum flexibility for a stent." Id. at col. 5, ll. 34-37. Contrary to Scimed's assertions, none of the specifications of the asserted patents teach that the connecting elements must be parallel both to each other and to the stent's longitudinal axis in order to prevent the shortening of the stent when the stent is expanded. As noted
above, the specifications teach that it is the attachment of the connecting elements to either the peaks or the valleys of the cylindrical elements, as demonstrated in Figures 3 and 4 of the '154 patent, not the parallel placement of the connecting elements, that prevents shortening upon the stent's expansion.

Scimed correctly notes that all of the drawings in the asserted patents depict the connecting elements in parallel alignment both with each other and the stent's longitudinal axis. However, this fact, by itself, does not support adding such a limitation to the claims. See Johnson Worldwide Assocs., Inc. v. Zebeco Corp., 175 F.3d 985, 992, 50 U.S.P.Q.2D (BNA) 1607, 1612 (Fed. Cir. 1999) (noting that "mere inferences drawn from the description of an embodiment of the invention cannot limit claim terms"). Without a "generally parallel" limitation in the claim or a discussion in the specification about the claimed connecting elements being generally parallel both to each other and to the stent's longitudinal axis, the drawings' depiction of the connecting elements in parallel relationship both with each other and the stent's longitudinal axis can not support the conclusion that such a limitation exists. Since nothing in the specification assigns significance to the fact that the drawings align the connecting elements parallel both to each other and to the stent's longitudinal axis, we will not allow this aspect of the drawings to be imported into the claims as a limitation. See, e.g., Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1367-69, 53 U.S.P.Q.2D (BNA) 1814, 1818-19 (Fed. Cir. 2000) (indicating that the claim term "protecting back panel" was limited to a "relatively stiff" panel because, in addition to other intrinsic evidence, the specification's text described the back panel in the patent's drawings as being "constructed of a relatively stiff material"); Torco Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1300-02, 53 U.S.P.Q.2D (BNA) 1065, 1069-70 (Fed. Cir. 1999) (construing the claim term "including" to mean "part of" and "permanently attached" because, in addition to the patent's drawings, the specification's text stressed that the claimed vacuum/blower's flow restriction ring was part of and attached to the invention's air inlet cover); Wang Labs., Inc. v. Am. Online, Inc., 197 F.3d 1377, 1382-83, 53 U.S.P.Q.2D (BNA) 1161, 1164-65 (Fed. Cir. 1999) (noting that the claims were limited to a character-based protocol because of the express teachings of such a protocol in both the patent's specification and the drawings). In this case, the specifications only discuss the orientation of the connecting elements in relation to the cylindrical elements, not to other connecting elements or the stent's longitudinal axis. Therefore, although the drawings show the connecting elements parallel both to each other and to the stent's longitudinal axis, the drawings do not require limiting the claimed connecting elements to a configuration in which they are in parallel alignment both with each other and with the stent's longitudinal axis.

Finally, we note that the prosecution history supports a claim construction that does not require that the recited "connecting elements" be generally parallel both to each other and to the stent's longitudinal axis. The prosecution history "is often of critical significance in determining the meaning of the claims;" Vitronics, 90 F.3d at 1582-83, 39 U.S.P.Q.2D (BNA) at 1577, since it may be used to determine the scope and meaning of the claims, Alpex Computer Corp. v. Nintendo Co., 102 F.3d 1214, 1220, 40 U.S.P.Q.2D (BNA) 1667, 1671 (Fed. Cir. 1996).

The prosecution history does not support the district court's claim construction. In prosecuting the '986 application, the inventors argued that, in contrast to the Palmaz '417 patent's non-parallel connecting members, "the independent claims of the present invention recite a plurality of generally parallel connecting elements." However, when making this argument, the inventors were referring to the specific language in the '986 application's claims, language that recited "a plurality of generally parallel connecting elements," to distinguish the '986 application from the Palmaz '417 patent. As discussed below in Part III, this language appears in other asserted claims of the '154 patent, specifically claims 12-15, 17, 18, and 20. The inventors explicitly limited their arguments to the '986 application's claims that recite "generally parallel connecting elements," not to claims that only recite "connecting elements." Therefore, the arguments do not apply to the invention's connecting elements in general, but only to connecting elements that are described, in the claims, as "generally parallel."

Scimed, however, points to statements that the inventors made that allegedly applied to their invention in general and that, therefore, were not exclusive to the '986 application's claim language. In distinguishing the Palmaz '417 patent, the inventors stated:

Moreover, Applicants' invention is superior to the stent disclosed in the Palmaz patent from a functional standpoint. As is clearly shown in Figs. 7 and 10 of the '417 Palmaz patent, due to its construction, upon expansion, the stent will substantially shorten as the slotted members of the stent body expand. Further, connecting members 100 and 102 deform upon expansion, as depicted in Figure 10, which adds to the shortening of the stent. . . .

The problem of stent shortening as taught by Palmaz has been solved by Applicants' invention due to its novel structure. The connecting elements of Applicants' invention are configured to "interconnect only said cylindrical elements that are

- 1366 -
adjacent to each other." Accordingly, as Applicants' stent is expanded from its first configuration to a larger configuration, the stent will not appreciably shorten . . . .

We reject Scimed's argument. Even if these statements could apply to the claims that are now at issue, the inventors argued that their invention's structure was superior to the Palmaz '417 patent because the Palmaz '417 patent allowed substantial shortening upon expansion while "the connecting elements of the inventors' invention are configured to 'interconnect only said cylindrical elements that are adjacent to each other.' Accordingly, as the inventors' stent is expanded from its first configuration to a larger configuration, the stent will not appreciably shorten." The inventors thus argued that their invention was superior to the Palmaz '417 patent because it configured the connecting elements to join adjacent cylindrical elements. The inventors did not argue that their invention was superior because its connecting elements were parallel to the stent's longitudinal axis. Finally, even if parts of the '986 application's prosecution history could be viewed as applying to asserted claims that do not explicitly describe "generally parallel connecting elements," the prosecution history does not support the district court's claim construction. As discussed below in Part III, nowhere in the prosecution history did the inventors indicate that their invention, in general, required that the connecting elements be parallel to each other and to the stent's longitudinal axis.

The district court erred in construing the claim terms "connecting elements," "interconnected," "connecting members," and "struts for connecting" as requiring connecting members to run parallel both to each other and to the longitudinal axis of the stent. The court's grant of summary judgment of no literal infringement or infringement under the doctrine of equivalents with respect to claims 11 and 12 of the '955 patent, claims 1-4, 9, and 23 of the '154 patent, claims 1-4 of the '721 patent, and claims 1, 2, 5, 6, 9, and 11-13 of the '158 patent was based on this incorrect construction, Adv. Cardiovascular IV, slip op. at 11-12. We therefore vacate the district court's grant of summary judgment with regard to those claims, and remand for further proceedings.

2. "Connecting elements" limitation

The court construed "connecting elements" to mean "segments of a stent that extend between adjacent cylindrical elements, connecting them together." 16 (D.I. 639 at 1884:3-7) Medtronic asserts that it is entitled to JMOL of non-infringement of the '154 patent because no reasonable juror could have found that its stents have "connecting elements" required by the claims. (D.I. 654 at 16-19) Medtronic introduced evidence at trial that its stents are formed by welding the crowns of individual segments together with a laser in a process known as "autogenous laser fusion," which does not add any new material to the crowns. 17 (e.g., D.I. 634 at 788:20-793:10) ACS's expert, Dr. Jerome Segal, M.D. ("Segal"), an interventional cardiologist, agreed that Medtronic's fusion welding process does not add any new material. (D.I. 633 at 596:11-18) Because it was unrefuted that Medtronic's fusion welds are not a discrete component, Medtronic argues, there was no evidence that the welds "extend between adjacent cylindrical elements" under the court's definition. (D.I. 654 at 19)

16 The court also gave this same definition to the terms "connecting members," "interconnecting elements," and "struts for connecting." (D.I. 639 at 1884:3-7)

17 Photographs of the welds were introduced into evidence. (D.I. 634 at 793:11-796:9; DTX-149A; DTX-150A)
C. "a connecting loop at the free end of said elongate member"

Defendants suggest a construction of this term to require that the loop be "secured to and extending from the outermost end of the elongate member," and points to a statement made by Plaintiff during prosecution as support: "Neither of the main references shows or suggest a connecting loop at the free end of an elongate, pliable member, from which a toy object is suspended via a connecting line." (Def's Ex. B at 40-41.) Since the claim already includes the limitation "at the free end of said elongate member" -- the language actually employed in the prosecution history--the Court finds no need to construe the term as limiting the connecting loop only to one placed at the "outermost end of the elongate member." Defendants' contention that the prior art references disclosed an assortment of loops may be true, but Plaintiff did not rely on his connecting loop to distinguish from these references, except as mentioned above, and the claim is limited as such. Thus, the term will not be construed with the limitation Defendants suggest.

3. "connecting said adjacent panels at a first pivot axis, and at least one center hinge assembly connecting said adjacent panels at a second pivot axis offset from said first pivot axis" -- Claim 1

Amarr's proposed construction is: "the pivot axis of at least one center hinge is located vertically below the pivot axis of the end hinges when the adjacent panels are in the vertical, or closed, position." Amarr's Opening Brief at 11.

The thrust of Amarr's proposed construction of this claim term is that it contends that "offset" should be read to mean "located vertically below." Amarr contends that this limitation is found in the specification and therefore limits the meaning of the term "offset" to mean "located vertically below." Wayne-Dalton not only disagrees, but notes that Amarr's proposed construction reads into Claim 1 an element of dependent Claim 3, rendering Claim 3 "superfluous and redundant," which is not permitted. Transcript at 134; see also Wayne-Dalton's Response Brief at 10.

This dispute points up one of the stickier areas of claims construction law:

On the one hand, claims "must be read in view of the specification, of which they are a part." Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L.Ed. 2d 577, 116 S. Ct. 1384 (1996). On the other hand, it is improper to read a limitation from the specification into the claims. . . . "The problem is to interpret claims 'in view of the specification' without unnecessarily importing limitations from the specification into the claims." E-Pass Techs., Inc. v. 3COM Corp., 343 F.3d 1364, 1369 (Fed. Cir. 2003); accord Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204-05 (Fed. Cir. 2002).

In Acumed LLC v. Stryker Corp., 483 F.3d 800 (Fed. Cir. 2007), the court faced a similar situation, in which the party seeking construction argued that the language "transverse holes" in a claim should be construed as holes "perpendicular" to the nail shaft, because every description of the transverse holes in the patent contemplated a perpendicular hole and because the figure depicting the nail reflected a perpendicular hole. Id. at 807. The Federal Circuit declined to so limit the claim.
language, however, declaring that "[t]he plain meaning of Claim 1 covers more than the particular embodiment shown in the figures." Id. The court explained that:

The intrinsic evidence of the specification therefore suggests that the patentees knew how to restrict their claim coverage to holes passing through at right angles. They could have used the word "perpendicular," as they did in discussing their preferred embodiment. Instead, they chose a different term that implies a broader scope.

Id.

Similarly, here, the 872 Patent reflects that the patentee knew how to restrict the claim coverage to a pivot axis that is "offset vertically below" rather than merely "offset," because the more restrictive language is used in the specification, in description of the preferred embodiment and in Claim 3, which is dependent on Claim 1. Amarr has cited to nothing, however, tending to persuade the Court to abandon the general principle that "Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.' Teleflex[, Inc. v. Ficosa N. Am. Corp.], 299 F.3d [1313] at 1327 [Fed. Cir. 2002]." Liebel-Flarsheim Co., 358 F.3d at 906; see also Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005) (stating that the Federal Circuit has "expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment."). Under this precedent, Amarr's argument fails.

The referenced language will be accorded its ordinary and customary meaning to one skilled in the art and the proposed limitation on the language will not be added.

914

1. "connecting segment"

In the August 2005 Markman Order, the Court construed "connecting segment" to mean "a distinct portion of the device, capable of detaching the distal tip from the guidewire." (August 2005 Markman Order at 7.) This Order modifies that definition.

The phrase "connecting segment" is a coined phrase. The Court looks to the specification for a clear statement of the meaning of coined phrases. Vitronics Corp., 90 F3d at 1582.

In the written description and in various claims of the patents-in-suit, the inventors use the words "segment" and "portion" interchangeably to indicate discreet parts of their invention. For example, with respect to an embodiment of the "guidewire," the written description states that it has a "core wire," (a phrase which will be considered later in this Order) which has a distal "portion" which is a stainless steel "segment:"

The distal portion is an exposed stainless steel segment.

The stainless steel segment comprises a coil connected at its proximate end to the core wire and connected at its distal end to the tip portion of the guidewire.

('136 Patent, Col. 4:63-69.) As a further example, in describing the tip, the written description uses the words "portion" and "segment" interchangeably:

The tip portion is a long and substantially pliable segment and is comprised of a material not susceptible to electrolytic disintegration within blood.

('136 Patent, Col. 5:8-10.)

With respect to the subject phrase, "connecting segment," the written description provides:
The step of electrolytically detaching the distal tip from the guidewire comprises the step of electrolytically disintegrating at least one portion of a connecting segment extending between the guidewire and the distal tip.

The step of electrolytically disintegrating the connecting segment comprises the step of electrolytically corroding away at least a portion of a coil segment.

(‘136 Patent, Col. 4:25-32.)

The Court finds that a person of ordinary skill would understand that the "connecting segment" is a distinct segment of the guidewire which functions to connect other portions or segments. It would also be clear to one of skill in the art reading the patent documents that another function of the connecting segment is to perform the function of "detaching." In the plain language of Claim 5, the distal tip is detached from the guidewire by electrolytically disintegrating at least one portion of the connecting segment. Thus, the construction of "connecting segment" must be one which includes the "detaching" function. Before giving a construction to this part of the subject phrase, the Court considers the other disputed phrase.

2. "extending between said guidewire and said distal tip"

With respect to the "connecting segment," the parties dispute the proper construction of the phrase "extending between said guidewire and said distal tip" as it is used in Claim 5. The dispute is whether the phrase should be construed to mean "located between" or whether it should be construed to include both "located between and connecting spatially."

It is clear from the language of the Claim that the phrase "extending between" is a limitation on the relationship among three components: the "connecting segment;" the "guidewire" and the "distal tip."

One of ordinary skill in the art would understand the phrase "extending between" to be composed of non-technical words which have ordinary and customary meanings. The phrase "extending between" uses the common preposition, "located between," meaning "in or through the space that separates two things." See Webster's New Twentieth Century Dictionary, 177 (2d ed. 1983). A common definition of "extending" is "stretched out." Id., 649. The Court finds that one of ordinary skill in the art would understand the phrase "extending between" to mean that the connecting segment is not only "between" the guidewire and the distal tip but that it also "extends" from the guidewire to the distal tip. In other words, a person of ordinary skill in the art would conclude that the connecting segment is attached at one of its ends to the guidewire and at its other end to the distal tip. This construction of the claim language is supported by a statement in the written description, describing an embodiment with these connections:

The stainless steel segment comprises a coil connected at its proximate end to the core wire and connected at its distal end to the tip portion of the guidewire.

(‘136 Patent, Col. 4:65-68.)

The Court construes "connecting segment" as it is used in Claim 5 to mean:

A segment of the guidewire that is attached at one of its ends to the core wire and is attached at its other end to the distal tip. The connecting segment is capable of being operated on to detach the distal tip from the remainder of the guidewire.

6 The same definition applies to the phrase as it is used in Claims 5 and 14 of the ‘578 patent, which provides: "The method of claim 11 where said step of electrolytically detaching said distal tip of said wire electrolytically disintegrates a connecting coupling between said wire and said distal tip to effect separation."

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

6 The same definition applies to the phrase as it is used in Claims 5 and 14 of the ‘578 patent, which provides: "The method of claim 11 where said step of electrolytically detaching said distal tip of said wire electrolytically disintegrates a connecting coupling between said wire and said distal tip to effect separation."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
3. Claim 6

The parties have submitted the following phrase in Claim 6 of the '194 Patent for construction by the court: for construction by the court (phrase for construction is underlined; phrase already construed in Claim 1 is italicized):

A method of making a wheel support assembly adapted to bolt to an axle of a vehicle for supporting a tire, said method comprising the steps of:

a. providing an outer annular rim having an outer annular surface configured to support a tire;

b. providing a single piece of sheet metal and stamp forming from the sheet metal as a single integrally formed unit a plurality of spoke arrangements, each of which is formed to include

i. at least two elongated spokes respectively including inner ends and outer ends and

ii. a cross-bar connecting together the inner ends of the spokes and configured to bolt to said axle for connecting the inner ends of said spokes to said axle, whereby to serve as part of a hub of said wheel support assembly, said plurality of spoke arrangements serving as the only spoke arrangements making up said wheel support arrangement and said single integrally formed unit serving as the only strength imparting structure between said rim and the hub; and

c. connecting the outer ends of said spokes to said rim.

The parties differ in their proposed construction of Claim 6(c). Plaintiff asserts that Claim 6(c) "is a function and must be analyzed under 35 U.S.C. 112 (6), using a step plus function analysis." (Pl.'s Br. at 29-30.) As a result, Plaintiff further states that Claim 6(c) is "limited to the connecting means disclosed in the specification: short flanges plus welding." (Id.)

Defendants, on the other hand, contend that Claim 6(c) is not a step-plus function but, instead, "[t]he 'connecting' in claim 6 is an act or step involved in effectuating the purpose described in the preamble, namely the making of a wheel support assembly." (Defs.' Reply at 12.)

The Claim 6 preamble sets forth a method of making a wheel support assembly, comprising a number of steps, but does not use the "step for" language that signals the claim drafter's intent to invoke section 112, paragraph 6. Masco Corp. v. United States, 303 F.3d 1316, 1326 (Fed. Cir. 2002); Utica Enters., Inc. v. Fed. Broach and Mach. Co., 109 F. App'x 403, 409 (Fed. Cir. 2004). Because Claim 6 uses the term "step of" instead, there is no presumption that the Claim 6 limitation is a step-plus function. Masco Corp., 303 F.3d at 1328. Indeed, "[w]here the claim drafter has not signaled his intent to invoke § 112, paragraph 6 by using the 'steps for' language, we are unwilling to resort to that provision to constrain the scope of coverage of a claim limitation without a showing that the limitation contains nothing that can be construed as an act." Id. at 1327; see also Utica, 109 F. App'x at 409; O. I. Corp., 115 F.3d at 1583. "In general terms, the 'underlying function' of a method claim element corresponds to what that element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish. 'Acts,' on the other hand, correspond to how the function is accomplished." Seal-Flex, Inc. v. Athletic Track & Court Constr. 172 F.3d 836, 849-50 (Fed. Cir. 1999).

The disputed language, "connecting the outer ends of said spokes to said rim," merely claims a step by reciting and performing an act, not a function, necessary to complete the method of making a wheel support assembly. "Connect," according to the Oxford Dictionary's definition, means "join (one thing with another)," "join (two things)," and also "be joined or joinable." The Oxford Dictionary and Thesaurus 296 (Am. ed. 1996). "Connecting the outer ends of said spokes to said rim" should therefore be interpreted to describe not a function, but an act of joining the outer ends of the spokes to the rim, which is a step involved in the making of a wheel assembly. Because Claim 6(c) can be construed to contain an act, it is not a step-plus function claim subject to the requirements of § 112, paragraph 6.
3. Connection Means as Means-Plus-Function Format (claims 5 and 7)

The issue here is whether the term "connection means" is a means-plus-function limitation under 35 U.S.C. § 112, P 6. As noted above, both claims 5 and 7 state that the "connection means interconnect[s] said crank arms on said right and left hydraulic pumps." According to Toro, use of the term "connection means" does not create a presumption that this is a § 112, P 6 element because the term is not followed by the word "for." See, e.g., Personalized Media Communications, LLC v. International Trade Comm'n, 161 F.3d 696, 703 (Fed. Cir. 1998) (quoting Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996) ("Use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' (particularly as used in the phrase 'means for') generally invokes [§ 112, P 6] and that the use of a different formulation does not."). Rather, Toro claims that the term "connection means" in the '961 patent 1) recites structure (the "connection," i.e., the linkage), and 2) describes the location (the crank arms on the right and left hydraulic pumps) and the extent of the structure (movable in a first and then a second direction).

As support, Toro depends on a disposable training pants case in which the patent claimed a "perforation means extending from the leg band means to the waist band means through the outer impermeable layer means for tearing the outer impermeable layer means for removing the training brief in case of an accident by the user." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 526 (Fed. Cir. 1996). The court found that while the patent drafter "was clearly enamored of the word 'means'," the claim language did not create a means-plus-function element. Id. at 531. The court said that "an element with such a detailed recitation of its structure, as opposed to its function, cannot meet the requirements of [§ 112, P 6]." Id.

Toro maintains that its "connection means" -- like the perforation, leg band, waist band, and outer impermeable layer means of the disposable training pants case -- describes the structural character of the element as well as its location and extent. The plain meaning of the word "connection" means a joining together. In the mechanical arts, Toro says, that joining together "is accomplished by linkages which may include a shaft, rod or arm, or a combination of mechanical links." Toro's Markman Brief at 22. In claims 5 and 7, the crank arms secured to the shafts of the hydraulic pumps "are connected together by a common shaft or rod including available linkage components." Id. The linkage is indicated by use of term "means" in the claims. Thus, Toro contends that "connection means" should be construed "to cover a linkage between a speed control lever and a crank arm on each hydraulic pump which enables the input and output rates of both pumps to be changed by the same amount so that the drive wheels will be driven at the same rotational rate." Id.

Scag, however, contends that Toro has failed to rebut the presumption that its use of the term "connection means" creates a § 112, P 6 element since the connection means claims fail to recite any structure to interconnect the crank arms. Scag says that Toro's use of "connect" is therefore functional rather than structural since the claims themselves contain no structural language to override the presumption that § 112, P 6 applies. To construe the claims as Toro suggests, Scag says, would require the court to remove the term "means" and substitute the term "linkage," an impermissible rewriting of the claims.

I conclude that Toro's suggested reading of the term would require the court to infuse structure into the claims where no definite structure exists. Nothing prevented Toro from using the term "linkage" instead of the term "means" when writing the claims. Nothing prevented Toro from explicitly defining the structure with the function of "joining together" the crank shafts on the hydraulic pumps. The "perforation means" discussed in the Cole case is not analogous to the "connection means" in this case because the disposable training pants had an obvious, definite structure to perform the function of tearing the impermeable layer: the holes punched through the material forming the impermeable layer. Here, Toro can point to no such single, definite structure, only to some sort of functional "connection." In stating that the crank shafts could be connected by numerous types of "linkages," such as "a shaft, rod or arm, or a combination of mechanical links," Toro's Markman Brief at 22, Toro in effect attempts to cover any structure that will perform the function of connecting. I therefore find that the term "connection means" is to be construed as means-plus-function element governed by 35 U.S.C. § 112, P 6. 
Having either potentially or actually dodged one '172 Patent bullet by causing one layer of naturally-waterproof fabric to become non-water-impervious, Dometic must find a way to keep its customers dry while at the same time it keeps itself out of harm's way in the form of the '172 Patent's claims. To accomplish that, Dometic blithely abandons its insistence on looking at the intrinsic evidence of the patent itself by fabricating a distinction that is found only in its own mindset, not in the patent. Dometic Mem. 9-10 raises the straw man of "series" versus "parallel" types of awnings, urging in the Memorandum's ensuing discussion that the '172 Patent claims are directed only to the former type.

But that contention, which rests on Dometic's characterization of the invention as an "awning connection," amounts to reading something either into or out of the actual claims of the '172 Patent. Those claims clearly specify that the invention is a device connecting a metal awning cover to the recreational vehicle. That plain meaning of the '172 Patent's language appears to require no artificial gloss of the type contended for by Dometic's asserted division into "parallel" and "series" awnings.

This Court sees no need as part of the threshold Markman procedure to provide a construction other than the normal reading of the term "connector." It is however worth adding, in light of Dometic's arguments, that this Court does not expect to prevent the factfinding jury from considering the possibility that because of the stitching that Dometic has employed to create an integrated construction that will keep any water from penetrating that construction, Dometic's accused device may still be viewed as constituting a water-impervious strip (comprising the combined layers of fabric) that is connected to the recreational vehicle at one end and to the metal awning cover at the other.

III. The requirement for a "connector"
A. Claim Interpretation

Claims 4 and 21-24 of the '709 reissue patent and all of the claims of the '397 patent specify a "connector" for the lamp assembly. Claim 21 of the '709 reissue patent is representative in pertinent part: "A lighting system comprising . . . a submersible connector electrically coupled between said lamp assembly and said electrical lighting elements. . ." '709 reissue patent, col. 9, lines 6-8. Claim 1 of the '397 patent states in part: "A lighting assembly comprising . . . a lamp assembly . . ., said lamp assembly including a submersible connector on said socket enclosure and having electrical connector leads into said enclosure. . ." '397 patent, col. 5, lines 44-52. Finally, claim 2 of the '397 patent is representative in pertinent part: "A lighting assembly comprising . . . a submersible connector electrically coupleable between said lamp assembly and said electrical lighting elements; . . ." '397 patent, col. 5, line 64 - col. 6, lines 8-10.

Defendant's motion contends that the term "connector" is not limited to a plug-type connector capable of quickly connecting or disconnecting two things, but describes any type of connector including one intended to permanently connect two things together. Defendant argues that the term "connector" is used in several different places in the written description portion of the patents in suit. 12 According to Defendant, the only discussion of a "connector" in connection with the detailed description of the lamp assembly illustrated in the drawings of the patents does not include any description of the connector 64 as being a plug-type connector that enables a quick connect or disconnect of the lamp assembly 40 from the connector so that the lamp assembly might be removed from the housing. 13 Additionally, the inventor of Plaintiff's fixtures in question stated that "the term 'connector' is applied in the present context to either permanently or impermanently joined electrical conductors." Tyson Decl., p.2 Therefore, Defendant asserts that the term "connector" as used in Plaintiff's claims is not limited to a plug-type connector capable of so-called quick connect or disconnect, but includes any connectors whether they join things together permanently or impermanently.

Footnotes

12 "A method of creating such a wicking barrier includes the soldering of a portion of a stranded electrical connector and potting the soldered portion in the creation of the barrier.

"A wicking barrier is alternatively contemplated employing a bare, conductive metal strip held in a harness and submerged in potting material. Attachment elements may be mutually spaced on the strip to receive connectors in a displaced
arrangement." '709 reissue patent, col. 2, lines 8-17.

13 "At the bottom end of the socket enclosure 42, a submersible connector 64 is mounted through the wall. An electrical conductor 66 is associated with the submersible connector 64, extending to submersible connector leads 68. Socket leads 70 extend from the socket 60 and are electrically coupled with the leads 68. Solidified solder beads 72 join the paired leads with the leads not otherwise electrically coupled. By using a solder bead as the sole coupling between leads, water cannot pass through the stranded electrical connector from the socket 60 to the connector 64 of vice versa. Potting material 74 is then hardened in place about the leads and the solder beads 72 to provide a complete barrier to the passage of moisture along the electrical conductor 66 inwardly of the insulation. Outwardly of the insulation, the submersible connector 64 prevents such transmission of moisture in association with the potting material 74." '709 reissue patent, col. 3, line 62 - col. 4, line 11.

Plaintiff challenges Defendant's interpretation on the grounds that the term "submersible connector" has specific meaning in the industry, a meaning that is known to those of ordinary skill in the art of electrical components for lighting fixtures. Therefore, the term "submersible connector" needs no further clarification. It appears that Plaintiff's dispute is to Defendant's contention that the term "connector" also encompasses a cord seal such as item 36 shown in Figure 2 of Plaintiff's patents. 14 As such, the Court does not believe that Plaintiff raises any challenge to the position that the term "connector" can be used to describe any connector that may join things together permanently or impermanently. The Court thus determines that Plaintiff has not sufficiently disputed Defendant's interpretation that the term "connector" as used in the patents in suit is any type of connector, whether intended to permanently or impermanently connect two things together.

14 As to this issue, both parties rely on the deposition testimony of inventor Glenn Tyson. Defendant, citing Tyson's deposition, asserts that Tyson himself identified the cord seal as an example of a connector. However, Plaintiff notes that a corrected transcript conforms the cited portion of the deposition to testimony given later in the same deposition. It does not appear, for the interpretation Defendant is advancing, that the issue of the cord seal must be decided.

The first term requiring construction is "connector assembly." Pandora's construction, "any device which can be used to connect two elements together," is more persuasive. (Pandora's Brief at 15.) Chamilia's construction adds a term, "end cap," which does not even appear in the '507 patent. 6 The prosecution history, specifically the November 18, 2004 Preliminary Amendment that deleted the term "hook component" and broadened it by stating "a connector assembly for reversibly coupling the first end and second end of the strand," supports Pandora's construction, as does the ordinary meaning of "connector assembly," which one of ordinary skill in the art would understand to mean any device that can be used to connect two elements together. (Altobelli Dec. at P 10.) 7 Chamilia's construction, first advanced at the Markman hearing, adds a requirement ("threaded end caps") that is not supported by the claims, specifications, or prosecution history of the '507 patent.

6 Chamilia proposes that "connector assembly" be construed as "[e]lements attached to the end of the strand that enable the strand to be connected to form a loop. Threaded end caps are part of the connector assembly."

7 Nothing in Mr. Brown's declaration or deposition testimony contradicts this understanding. (See, e.g., Brown Dep. at 43-44.)
Claim 1 of the ‘460 patent recites:

A lighting fixture for fluorescent lighting comprising:

a) a plurality of support members, each having a mounting surface for receiving a fluorescent lamp;

b) a socket for receiving a fluorescent lamp mounted on said mounting surface;

c) a connector assembly for connecting each pair of adjacent support members, said connector assembly being pivotally connected to said pair of adjacent support members; and

d) said plurality of support members being movable relative to each other to form the lighting fixture into the desired shape.

‘460 patent, col. 4, ll. 27-39 (emphasis added). Because the "connector assembly" limitation does not contain the term "means," we begin with the presumption that section 112 P 6 does not apply to that limitation. The district court held that Birchwood successfully rebutted that presumption, but we disagree.

In an effort to rebut the presumption that section 112 P 6 does not apply, Birchwood introduced the declaration of Dr. Andrew Wortman. Dr. Wortman declared that the term "connector" encompasses "at least a single infinity of possible devices" and that the term "would not provide [him] or others of ordinary skill in the lighting fixture art with sufficient structural information to put [him] on notice as to what device or component would read on the claim element." Dr. Wortman's declaration, however, does not address the central issue in determining whether section 112 P 6 applies. Implicit in Dr. Wortman's statement is the premise that in order to be regarded as structural for purposes of section 112 P 6, a claim limitation must identify a specific structure and not use a generic term that includes a wide variety of structures. The district court adopted that view explicitly when it held that the claim language "connector assembly being pivotally connected to said pair of adjacent support members" was not structural because "it would cover every conceivable structure that could connect two elements and pivot."

That approach is unduly restrictive. In considering whether a claim term recites sufficient structure to avoid application of section 112 P 6, we have not required the claim term to denote a specific structure. Instead, we have held that it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function. See Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996); see also Apex, 325 F.3d at 1372; CCS Fitness, 288 F.3d at 1369; Watts, 232 F.3d at 880; Personalized Media Commun., 161 F.3d at 704.

In Greenberg, for example, we held that the trial court erred when it characterized the claim phrase "detent mechanism" as a means-plus-function limitation. The district court in Greenberg based its decision that section 112 P 6 applied on the following observations: (1) detent mechanism "did not describe a particular structure but described any structure that performed a detent function," 91 F.3d at 1583; (2) the proffered definitions for detent mechanism were expressed in functional terms, id.; and (3) the written description twice used the term "detent means" when referring to the specific structure disclosed and at other times used "detent mechanism," leading the district court to conclude that "mechanism" was synonymous with "means." In rejecting that evidence as insufficient to establish that the claim was subject to section 112 P 6, we explained that "the fact that a particular mechanism . . . is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of section 112(6)." Id. We noted that the definitions made "clear that the noun 'detent' denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms." Moreover, we rejected the claim that because a term does not bring to mind a particular structure, it invokes section 112 P 6. Specifically, we said, "It is true that the term 'detent' does not call to mind a single well-defined structure, but the same could be said of other commonplace structural terms such as 'clamp' or 'container.'" Id.

We have made the same point in other recent cases dealing with the question whether particular broad claim language
should be considered functional for purposes of section 112 P 6 even though it is not in the traditional "means for" format. In those cases, based on the same analysis, we have rejected arguments that broad terms such as "digital detector" (Personalized Media Communications), "eyeglass hanger member" (Al-Site Corp.), "reciprocating member" (CCS Fitness), and "sealingly connected" joints (Watts) trigger section 112 P 6.

Thus, while it is true that the term "connector assembly" does not bring to mind a particular structure, that point is not dispositive. What is important is whether the term is one that is understood to describe structure, as opposed to a term that is simply a nonce word or a verbal construct that is not recognized as the name of structure and is simply a substitute for the term "means for." The court in Personalized Media Communications drew the pertinent distinction in holding that the term "detector," although broad, is still structural for purposes of section 112 P 6 because it "is not a generic structural term such as 'means,' 'element,' or 'device'; nor is it a coined term lacking a clear meaning such as 'widget' or 'ram-a-fram.'" 161 F.3d at 704.

In Greenberg and subsequent cases, we have looked to the dictionary to determine if a disputed term has achieved recognition as a noun denoting structure, even if the noun is derived from the function performed. See Greenberg, 91 F.3d at 1583 ("Dictionary definitions make clear that the noun 'detent' denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms."); Linear Tech. Corp., 371 F.3d at 1371 (technical dictionary makes clear that "circuit" is structural); CCS Fitness, 288 F.3d at 1369 (dictionary definitions consulted to determine that an artisan of ordinary skill would understand the term in question to have an ordinary meaning); Personalized Media Commun., 161 F.3d at 704 (same). Dictionary definitions in this case disclose that the term "connector" has a reasonably well-understood meaning as a name for structure, even though the structure is defined in terms of the function it performs. "Connector" is defined by Webster's Third New International Dictionary 481 (1993), as "something that connects." "Connect" is defined as "to join, fasten, or link together usu. by means of something intervening." Id. at 480; see also Random House Dictionary of the English Language 311 (1966) ("connector" defined as "one who or that which connects; . . . any of various devices for connecting one object to another.") Thus, in the context of claim 1, the term "connector assembly" means a unit that joins, fastens, or links each pair of adjacent support members. The fact that more than one structure may be described by that term, or even that the term may encompass a multitude of structures, does not make the term "connector assembly" any less a name for structure.

In addition to the fact that the word "connector" has a generally understood meaning as demonstrated by the dictionary definitions of the terms, it is clear that the parties in this case have used that term to denote structure. The written description of the '460 patent, for example, uses the term "connector assembly" as the name for structure. The patent recites:

The plurality of support and mounting sections 12a to 12h is connected in series to form the fluorescent lighting fixture track 20, wherein each pair of adjacent support members 12 is joined together by a connector assembly 22.

As shown in detail in FIGS. 1 and 2, each connector assembly 22 has a left and right hinge pin 24a and 24b that are hingedly or pivotally connected to hole openings 26 formed in the upper and lower surface walls 30 and 32 of the connector assembly 22, respectively. The hinge pins 24a and 24b of each connector assembly 22 are also pivotally attached to the adjacent ends of each support member 12 at hole openings 34. However, the first and last support members 12 of lighting fixture track 20 has [sic] the connector assembly 22 attached only to one of the ends of support member 12.

'460 patent, col. 2, ll. 38-53 (emphases added). As Lighting World's expert pointed out, the same thing is true of Birchwood's patent application on the invention corresponding to the Sydney model lamp fixtures. That application uses the term "connector" more than 40 times, and the context makes it clear that the term is used not in a purely functional manner designed to invoke section 112 P 6, but as a description of structure that is generally understood to persons of skill in the art. While the terms "connector" and "connector assembly" are certainly broad, and may in the end include any structure that performs the role of connecting, the same could be said of numerous other terms, such as "clamp," or "clip," or even "support member," another term that is used in the '460 patent. Those terms are routinely treated as structural by patent practitioners and courts, and we conclude that there is no reason to treat the term "connector assembly" any differently for purposes of section 112 P 6. The consequence of defining the term "connector assembly" free of the constraints of section 112 P 6 may be to render the claim more vulnerable to attack for invalidity, but that is a risk that a claim drafter assumes by choosing broad structural terms rather than choosing to claim in means-plus-function format under section 112 P 6.

In light of the principles discussed above, it is not surprising that we have seldom held that a limitation not using the term
"means" must be considered to be in means-plus-function form. In fact, we have identified only one published opinion since Greenberg in which we have done so, and that case provides a useful illustration of how unusual the circumstances must be to overcome the presumption that a limitation lacking the word "means" is not in means-plus-function form.

The exceptional case is Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206 (Fed. Cir. 1998). In that case, we held that the terms "lever moving element" and "movable link member" recited in a patent to a high security combination lock were in means-plus-function form. Id. at 1213-15. In addressing "lever moving element," the court stated, "While true that 'many devices take their names from the functions they perform,' the 'substantially non-resilient lever moving element' of claim 3 is not one of them." Id. at 1213 (quoting Greenberg, 91 F.3d at 1583). The only term in "lever moving element" that could denote structure is "element." Although the term "element" may be recognized as structural in some fields of art, the Mas-Hamilton court noted that the patentee had not directed the court "to any evidence demonstrating that the district court erred in determining that the term 'lever moving element' lacks a reasonably well understood meaning" in the relevant art. Id. at 1214.

The court in Mas-Hamilton also upheld the district court's ruling that there was no evidence that the term "movable link member" had a well-understood meaning in the art. Accordingly, the court held that the limitation reciting a "movable link member for holding the lever out of engagement with the cam surface before entry of a combination and for releasing the lever after entry of the combination" was in means-plus-function format. The court stated:

We note that the subsequent functional language requires two functions: (1) "for holding the lever out of engagement with the cam surface before entry of a combination," and (2) "for releasing the lever after entry of the combination." Such language is precisely what was intended by the statutory phrase in section 112, ¶6 requiring that means-plus-function limitations provide "a specified function." Further, we do not see that the remaining terms in the claim limitation other than those defining the two functions, i.e., "a movable link member," provide any structure as necessary to remove this limitation from the ambit of section 112, ¶6.

Id. at 1215 (citation omitted). Based on the entire record, the court concluded that the term "movable link member," like the term "lever moving element," was not a recognized term that identified structure, but was simply a way of describing any device that performed the recited functions. The prosecution record in Mas-Hamilton showed that the patentee had used the terms "member," "element," and "means" interchangeably, and in the patent itself the patentee described the "lever moving element" and the "movable link member" as the "means . . . for moving the lever," and the "means . . . for releasably maintaining the pivotable lever in a position substantially disengaged." U.S. Patent No. 5,307,656, col. 2, ll. 24-27. Thus, the court found that the terms "element" and "member," as used in the disputed claims, were mere proxies for the term "means for" and held that the presumption flowing from the absence of the term "means for" was overcome.

Unlike in Mas-Hamilton, in this case the pertinent patents and dictionaries indicate that the term "connector assembly" refers to a device that takes its name from the function it performs. The term "connector assembly" is therefore more like the "detent mechanism" of Greenberg than the "lever moving element" or "movable link member" of Mas-Hamilton.

On this record, Birchwood has not demonstrated that section 112 ¶6 should apply to the "connector assembly" limitation. The only evidence supporting Birchwood's position is the Wortman declaration, which as we have noted is based on an unduly restrictive standard that would require all structural terms to describe a particular device and would presumably treat general structural terms as functional in nature. Because the intrinsic record and dictionaries reflect that the terms "connector" and "connector assembly" are used as the names for structure, we conclude that the "connector assembly" limitation in claim 1 of the '460 patent is not in means-plus-function form. Accordingly, we vacate the district court's ruling that Birchwood's product does not literally infringe the '460 patent, and we remand the literal infringement issue to the district court for reconsideration in view of the proper claim construction.
with and without loss or damage). Given that the claim was drafted so that the connector could both fixedly and releasably fasten, or link together" which imply both permanent and non-permanent connections (or connections that can be separated of being released, Plaintiff does not offer anything to support the contention that a person of ordinary skill in the art would language of the claim that requires the connector to both fixedly and releasably engage. While some connectors are capable On the other hand, Plaintiff contends that "connector" should be defined as "anything that connects," but ignores the term "a device for detachably connecting," which is anything that connects, the second connector being capable of being releasably and fixedly engaged with the first connector."

The relevant dictionary definition of "connector" is "2: something that connects: as a: a flexible tube for connecting the ends of tubes b: a railroad coupling c: (1): a device for detachably connecting flexible electrical conductors together . . ." Webster's Third New International Dictionary 481 (1993). In turn, "connect" is defined as "1: to join, fasten, or link together usually by means of something intervening." Id. at 480. The examples of connectors provided in the dictionary definition, as well as those offered by Plaintiff, all describe a connector that can be later released. Indeed, one of the definitions included - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

17 Because MDTech argues that claim 2 covers only the reusable embodiment of the invention, it only identifies structures that correspond to the structures of Fig. 1, not Fig. 5. Put another way, it argues that no structure in Fig. 5 performs the recited function.

The first question the Court must resolve is whether the use of the term "connector" recites sufficient structure for performing the recited function to overcome the presumption that the drafter intended to invoke Section 112, P 6, a presumption triggered by the use of the word "means". See Rodime, 174 F.3d at 1302. MDTech argues that a person of ordinary skill in the art would not have understood "connector" to perform both the functions of releasably and fixedly engaging; specifically, MDTech contends that "connector" is commonly understood as only performing the function of engaging or joining, not releasing. According to MDTech, absent evidence that the patentee intended to act as his own lexicographer and define connector as also performing a releasable function, the term "connector" does not recite sufficient structure to perform the recited functions and this clause must be given a means-plus-function limitation.

Plaintiff argues that the term "connector" is commonly understood as a structure that is inherently capable of releasably and fixedly engaging another mating connector. Plaintiff gives examples in the field of medicine that include mechanical connectors (for fluid transfer), electrical connectors (for monitoring vital signs), and computer connectors (for imaging equipment). Plaintiff contends that, in those examples, the connectors are capable of being removed or released after they have been fixedly engaged with the other connector.

The problem with both of the parties' positions regarding this term is that they are too extreme. MDTech essentially argues that no connectors are capable of being released after they engage another connector (i.e., that all connectors form permanent connections), and Plaintiff argues that all connectors are capable of being released. If the Court accepted MDTech's proposed construction, then this claim would be limited only to the precise structure in Fig. 1 - the quarter turn male thread on the spring guide - that performs this function in that one embodiment. That construction is too narrow. While it is true that some connectors may form a permanent connection and cannot be released, there are many aside from the screw-in cannula mount depicted in Fig. 1 that are capable of being released. For example, at the Markman hearing, the Court suggested that a hooking mechanism would operate as a connector that both fixedly engages and is releasable. (Tr. at 104.) MDTech's construction is improperly limiting.

On the other hand, Plaintiff contends that connector should be defined as "anything that connects," but ignores the language of the claim that requires the connector to both fixedly and releasably engage. While some connectors are capable of being released, Plaintiff does not offer anything to support the contention that a person of ordinary skill in the art would have understood that all connectors are capable of being released. The definition of "connector" includes the words "join, fasten, or link together" which imply both permanent and non-permanent connections (or connections that can be separated with and without loss or damage). Given that the claim was drafted so that the connector could both fixedly and releasably
engage, this term must be construed to reflect the language chosen by the drafter.

For the foregoing reasons, the Court first concludes that "second connector means" recites sufficient structure to perform the stated functions, thereby rebutting the means-plus-function presumption. In addition, however, the Court does not accept Plaintiff's proposed construction of "connector" as "anything that connects." The claim describes a connector that is capable of being released after engaging, and the Court's construction must take into consideration this language chosen by the drafter. In determining how to construe the limitation of being "releasably" engaged, the Court looks to the previous term because the patentee used the same term in the specification -"detachably" - in describing how the cannula mount connects to the spring guide as he did in describing how the stylet connects to the spring guide (or inner support rod, see infra, n. 13). Because the specification describes the cannula mount as being "detachably affixed" to the spring guide, it appears the patentee wrote the claim term "releasably engaging" with a similar meaning in mind. For the reasons stated in the previous term, the Court interprets the term "releasably" as requiring separation without loss or damage.

Accordingly, the Court construes this term to mean "the biopsy actuator comprising a second connector, which is anything that can connect and be released without loss or damage, the second connector being capable of being releasably and fixedly engaged with the first connector." 18

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

18 Once again, the Court acknowledges that this construction of claim 2 may exclude coverage of the single use embodiment, but concludes that such a construction is not improper for that reason alone.

II

A

In his challenge to the district court's construction of the '798 patent, Dr. Baran advocates a definition for the terms "detachable" and "releasably" that does not include the "without loss or damage" condition. Dr. Baran objects to that condition because it excludes the single-use embodiment from the asserted patent claim and therefore precludes his infringement claim against the BioPince, which is a single-use device.

As an initial matter, we accept Dr. Baran's assertion that the '798 patent "never discloses a stylet that is joined to a cannula." The specification indicates that the stylet 60 is attached to a support rod 14, and that the cannula 66 is attached to a spring guide 18. The full needle is then assembled by placing a coil spring "coaxially" onto the stylet and placing the cannula "telescopically" over the stylet and coil spring. The cannula remains an independent component that slides freely over the stylet.

[SEE FIG. 1 IN ORIGINAL]

The fact that the stylet is not attached to the cannula, however, is not favorable to Dr. Baran. If anything, it lends further credence to the district court's construction of "detachable" as meaning "separation without loss or damage," because the stylet and cannula as described in the specification are readily separable without loss or damage.

Of greater significance is the different language used by the patentee to distinguish the single-use embodiment from the reusable embodiment. In describing the reusable embodiment, the patent states that "the stylet 60 is received and detachably engaged within the clevis 46 of the spring guide 18. The thread 74 on the inner surface 72 of the collar 62 is engaged with the thread 56 on the spring guide 18 to secure the cannula mount 58 to the spring guide." '798 patent, col. 7, ll. 42-46. Figure 1 shows that the stylet is inserted into a notched recess on the support rod from which it can be easily removed, 1 and that the cannula is screwed onto the spring guide from which it too can be easily removed.
1 Although the specification states that the stylet is inserted into the clevis of the "spring guide," Figure 1 clearly shows that the clevis is located on the support rod.

By contrast, in describing the single-use embodiment, the patent states that the assembly of the device is "quite similar" except that "the stylet 262 is adhesively bonded within the recess 246, and the base 262 of the cannula mount 258 is similarly secured within the bore 255a." '798 patent, col. 10, ll. 22-27. Figure 5, which corresponds to the single-use embodiment, shows that the clevis is absent from the support rod, and that the screw threads are absent from the spring guide. Instead, the stylet and the cannula are glued permanently into the support rod and the spring guide, respectively.

[SEE FIG. 5 IN ORIGINAL]

The patentee used the term "detachably" in the specification to draw a direct contrast between the removable components of the reusable embodiment and the adhesively bonded components of the single-use embodiment. That usage effectively concedes that adhesively bonded components--including the single-use embodiment--are not "detachable" components within the meaning of the patent. We agree with the district court that "[t]his distinction suggests that the patentee intended 'detachable' to mean capable of removal or separation without breaking or causing damage through the necessary use of undue force." Baran v. Med. Device Techs., Inc., 519 F. Supp. 2d 698, 724 (N.D. Ohio 2007); see also K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1365 (Fed. Cir. 1999) ("Screws, unlike rivets and [adhesive] laminates, are meant to be unscrewed, that is, to be removed. A rivet or a laminate, to the contrary, is meant to remain permanent, unremovable unless one is bent on breaking the permanent structure apart."). Incorporating the "without loss or damage" condition into the claim construction has the additional advantage of comporting with the plain meaning of "detachable," as expressed by the several dictionary definitions cited by the district court.

We also agree with the district court that the terms "releasably" and "detachable" have the same meaning in the '798 patent. Dr. Baran argues that the use of different terms implies that they have different meanings, see CAE Screenplates Inc. v. Heinrich GmbH, 224 F.3d 1308, 1317 (Fed. Cir. 2000), but that implication is overcome where, as here, the evidence indicates that the patentee used the two terms interchangeably. See Tehrani v. Hamilton Med., Inc., 331 F.3d 1355, 1361 (Fed. Cir. 2003).

In a final attempt to bring the single-use embodiment within the scope of the asserted claim, Dr. Baran argues that the district court's claim construction improperly excluded a preferred embodiment and ignored the Summary of the Invention. There is no force to either of those arguments. It is not necessary that each claim read on every embodiment. In this instance, while claim 2 reads on only the reusable embodiment, a different claim of the '798 patent (claim 18) reads on both the single-use and the reusable embodiments,. See Helmsderfer v. Bobrick Washroom Equip., Inc., 527 F.3d 1379, 1383 (Fed. Cir. 2008) ("It is often the case that different claims are directed to and cover different disclosed embodiments."); Intamin Ltd. v. Magnetar Techs., Corp., 483 F.3d 1328, 1336-37 (Fed. Cir. 2007) ("[A] claim need not cover all embodiments."). As for the excerpt from the Summary of the Invention, it simply repeats verbatim the claim language that the "stylet means is . . . detachable from the cannula" and that the "second connector . . . releasably and fixedly engages the first connector." '798 patent, col. 3, ll. 50-60. The fact that those claim terms were used in the Summary does not mean that they must be read to encompass all the embodiments of the invention.

Because we do not disturb the district court's construction of "releasably," or the related constructions of "first connector means" and "second connector means," Dr. Baran's stipulation of noninfringement of the '798 patent remains effective.

7. "said proximal end having a first connector means secured thereto"

Like the preceding term, the dispute in interpreting this term concerns the phrase "first connector means." Plaintiff's proposed construction for "first connector means" mirrors his proposed construction for "second connector means" -
"anything that connects" - such that the entire term should be construed to mean, "said proximal end having a first connector, which is anything that connects, secured thereto." In its claim construction brief, MDTech originally proposed the construction, "the proximal end of the cutting cannula includes a first means to connect." At the Markman hearing, however, MDTech changed its proposed construction to defining this term as having a means-plus-function claim limitation under Section 112, ¶6. (Tr. at 107.) According to counsel for MDTech, the change occurred in order maintain consistency with MDTech's position that the phrase "second connector means" also constituted a means-plus-function claim and that the first connector means "would inevitably be that which communicates with the structure that is called for in the second connector means." (Id.) The structure MDTech identifies as correlating to the function of the "first connector means" is the cannula mount 58, which contains a female quarter turn thread 74 that interacts with the male quarter turn thread on the spring guide (the second connector means, according to MDTech).

For the reasons stated in connection with preceding term, the Court does not find that this is a means-plus-function clause, but it also does not find that "first connector means" can be defined simply as "anything that connects" because the first connector necessarily interacts with the second connector, which must be capable of being released. Therefore, the Court construes this disputed term as "said proximal end having a first connector, which is anything that can connect and be released without loss or damage, secured thereto."

1. Claim 1

Claim 1 of the patent states:

A variable torch apparatus comprising:

- a torch portion having a fuel canister and wick element, said torch portion constructed of a segment of copper pipe which has been capped and sealed;

- a vertical support portion constructed of a length of copper pipe and attached to said torch portion by a copper pipe reducer element; and

- a base portion connected to said vertical support portion, said base portion constructed of copper pipe material.

'371 Patent col.4 11.11-19. Both parties state this claim creates three parts for the invention: a torch portion, a vertical support portion, and a base portion. As the following discussion shows, these three parts can be manipulated into a variety of configurations: table-top torches, lawn torches, torches with one or multiple torch portions, and torches of various heights. Thus, "all . . . variations . . . result from the combination of the three basic components," id. col.3 1.46, col.4 11.1-2, and this makes the torch a variable torch apparatus.

One of the first disagreements is over the meaning of "copper pipe." While both parties state that pipe is a "hollow body," Gardendance argues that the meaning should be limited to cylindrical pipe. Such a limitation is unreasonable because although all the patent's figures use cylindrical pipe, none of the claims limit "pipe" to only cylindrical pipe. Moreover, the specification states that those "skilled in the art" of coppersmithing can make modifications without departing from the "spirit and scope" of this invention. Id. col.4 11.3-7. Thus, the specification shows the claim terms should be construed so that a slightly modified apparatus still falls under the claim terms. Changing the shape of the pipe is a minor change.

The torch portion has a fuel canister, or "a container for holding combustible matter" and a wick element, or "a bundle of fibers, or a loosely twisted or braided cord, tape, or tube" that draws up fuel. (Def.'s Markman Br. at 9, 12.) There is some confusion over what is "capped and sealed" in the torch portion. Gardendance proffers three possible interpretations. Gardendance's preferred interpretation is not clear from its argument. Woodstock only asserts that "the 'copper pipe' has been closed off and covered." (Id. at 14.)

The difference in the terms appears to be that "seal" is a more complete "closing off." The specific arrangement of what is capped and what is sealed, however, comes from the specification.

The copper pipe that forms the torch portion has a pipe fitting on the bottom with a plug in it, and "this creates a vessel or fuel canister." '317 Patent col.2 1.61. The bottom has a "cap," and this is where the "seal" is because a seal, or a complete closing off, prevents fuel from leaking. The top of the pipe has "a standard one and one-fourth inch copper cap" that has a hole drilled for a wick. Id. col.2 11.63-64. The cap can be friction fit or soldered, with the first option being the preferred method. In either case, there remains a hole in the top for a wick. This hole can allow fuel to evaporate. Thus, the top of the tank is not completely closed off; the top is merely capped. Thus, the torch portion is capped and sealed on the bottom so that fuel does not leak, and the top is only capped.

The vertical portion is copper pipe and connects to the torch portion by a copper pipe reducer element. A copper pipe reducer element is "a part that connects two hollow copper bodies of different sizes." (Def.’s Markman Br. at 13.) Thus, the vertical portion and torch portion are not of the same diameter pipe. The parties disagree over how the copper pipe reducer element is actually formed and the meaning of "connects."

The best interpretation of the '371 Patent is that the copper pipe reducer element does not have to be a separate piece. Woodstock argues that the copper pipe reducer element "need not be a separate and distinct item, but may simply be an integrated part of the 'torch portion' or an integrated part of the 'vertical support portion.'" (Id.) Gardendance argues the interpretation should clearly spell out that the copper pipe reducer element is a separate piece.

The best interpretation is that the element does not have to be a separate piece; the element can be one with another part of the torch, or it may be a separate element. Nothing in the claim states that the copper pipe reducer element is a separate piece from the torch portion. Also, the specification states that "it is obvious that modifications and changes . . . may be made by those skilled in the art" of coppersmithing "without departing from the spirit and scope of the invention." '371 Patent col.4 11.4-7. Thus, the specification shows that the claim terms should be construed to allow minor modifications that do not otherwise depart from the spirit and scope of this patent. Someone versed in coppersmithing, even if it takes as much time as Gardendance suggests in its brief, could make the torch portion and copper pipe reducing element into one unit and otherwise still construct the torch covered by this patent. When those two pieces are actually one piece, that torch retains its variable nature in that a user could still create a variety of torch units, including lawn and table-top units, and units with one, two, or more torches. One has a variable torch even if the two elements are actually one element. Making the torch unit and copper pipe reducing element into one is within the claim terms, and the copper pipe reducing element may or may not be a separate piece.

The parties also disagree over the term "connects," which appears in the third paragraph of Claim 1. The base portion, which neither party disputes is made of copper pipe, is "connected to [the] vertical portion." Id. col.4 1.18. The proffered definition is that "connects" means "to associate," which Gardendance suggests "is a definition meant in an intangible[] sense and not in a physical sense." (Pls.' Response Ct.'s Req. Final C1. Interpretation Submissions at 14.) While Gardendance's argument is not entirely clear, the argument seems to be that Woodstock wants "connect" to mean "associate" so that the Gardendance torch will more clearly infringe the '371 Patent.

The best interpretation is that "connects" means that the base part and the vertical portion join or associate together. The base portion may be in one of two configurations, which are discussed below at Claim 4. See infra Section II.B.4. The base may be a separate element or simply the end of the vertical portion (meaning it is one with the vertical portion, as the reducing element may be). In either case, the base portion connects to the vertical portion in that the separate element or the end of the vertical portion both join or associate with the vertical portion.
matter which the applicant regards as his invention.

If the limits of a patent are not adequately defined, a zone of uncertainty is created which would discourage invention. Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1396, 134 L. Ed. 2d 577 (1996). If it is shown by clear and convincing evidence that claims are indefinite, they may be held invalid as a matter of law. Morton International, Inc. v. Cardinal Chem. Co., 5 F.3d 1464, 1470 (Fed. Cir. 1993). Whether a claim is invalid for indefiniteness requires a determination of whether those skilled in the art would understand what is claimed when the claim is read in light of the specifications. Id.; Orthokinetics, Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1576 (Fed. Cir. 1986). Claims must "reasonably apprise those skilled in the art" as to their scope and be "as precise as the subject matter permits." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir. 1985).

If the Court were to accept Semmler's arguments regarding the meaning of the terms "whenever the engine is overrunning" and "considerable fuel saving," the patent would be invalid for indefiniteness. As the Court noted in its Memorandum Opinion and Order of September 30, 1996, p. 11:

"Semmler's position is that overrunning as used in his patent occurs when the speed of the engine exceeds a pre-determined speed established by any fixed relationship between engine speed and throttle position. Under this definition, overrunning would be a hypothetical construct divorced from any consideration of engine load or demand. This definition would eliminate the necessity for using the word "overrunning," as the condition it defines would be completely described by simply stating that a fuel cut occurs whenever the engine speed exceeds the speed determined by the fixed relationship. Indeed, this is how Semmler originally expressed his claim. Under this definition Semmler would be free to select any fixed relationship between engine speed and throttle position and call it overrunning. In this way, he could confine overrunning to any condition of load or demand he might choose." (Emphasis in original)

If the Court were to adopt Semmler's definition of overrunning, those skilled in the art would not understand what is claimed in his patent.

The limiting language "considerable fuel saving" is problematic. The Court has construed the phrase to mean a fuel-saving that one skilled in the art in 1976 would have considered large, substantial or important. Even when construed in this manner, this claim fails to satisfy the definiteness requirement of 35 U.S.C. § 112. The difficulty in ascribing definiteness to this claim is demonstrated by the fact that Semmler's experts, who are highly skilled in the art, have taken the position that fuel savings of one percent, or even less, fall within the definition of "considerable". See p. 37 infra.

The Court concludes that the expression "considerable fuel saving" in the Semmler patent is like the term "partially soluble" in Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448 (Fed. Cir. 1985), and the expression "about" in Amgen, Inc. v. Chugai Pharmaceutical Co., Ltd., 927 F.2d 1200 (Fed. Cir. 1991). The term "considerable fuel saving" does not reasonably apprise those skilled in the art as to the scope of Semmler's claim, nor is it as precise as the subject matter permits. Semmler could have measured the fuel savings obtained by his device and expressed the limitation in terms of a percentage or range of percentages. The Court finds that this limitation of the Semmler patent does not satisfy the definiteness requirement of 35 U.S.C. § 112, and that Claims 1, 5 and 17 of the Semmler patent are invalid for indefiniteness.
well recognized meaning as a "middle ground" transitional phrase. Momentus agrees that the phrase "consisting essentially of" is a transitional phrase, but argues it is a phrase defined by law and needs no construction by the Court.

The transitional phrase "consisting essentially of" is commonly used to signal a partially open claim in a patent. PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351, 1354 (Fed. Cir. 1998).

Typically, 'consisting essentially of' precedes a list of ingredients in a composition claim or a series of steps in a process claim. By using the term 'consisting essentially of,' the drafter signals that the invention necessarily includes the listed ingredients and is open to unlisted ingredients that do not materially affect the basic and novel properties of the invention. A 'consisting essentially of' claim occupies a middle ground between closed claims that are written in a 'consisting of' format and fully open claims that are drafted in a 'comprising' format.

In the present case, Claim 1, as submitted in the original application, did not contain the phrase "consisting essentially of"; rather, it contained the term "comprising".

1. A golf swing trainer comprising a golf grip fixed about one end of a length of solid round stock having center of gravity substantially centered at a midpoint thereof.

Catalano's proposed amended Claim 1 read as follows:

1. A golf swing trainer comprising a golf grip fixed about one end of a length of sold [sic] round stock, said trainer having a center of gravity substantially centered at a midpoint [there] of a longitudinal axis of said stock.

However, the examiner proposed substantial modifications to Claim 1. He replaced the term "comprising" with the phrase "consisting essentially of." "Sold [sic] round stock" was changed to "round stock which is solid throughout it [sic] length and crosssection." 4 In a telephone interview on March 6, 1996, Catalano consented to the examiner's amendments.

- - - - - - - - - - - Footnotes - - - - - - - - - - -

4 The examiner also added the following to the end of Claim 1 and eliminated Claims 11 and 12:

length of round stock, and the weight of said round stock being heavier than a typical golf club so that repeated swings of the trainer establishes a muscle memory of the path of the swing, breaking down the incorrect muscle memory and building the correct muscle memory of the path of the swing.

- - - - - - - - - - - End Footnotes - - - - - - - - - - -

The examiner unambiguously replaced the "open" transitional term - comprising -- with the "middle ground" transitional phrase - consisting essentially of. Therefore, the claim includes all listed elements and those unlisted elements that do not materially affect the basic and novel properties of the invention. PPG Indus., 156 F.3d at 1354. The "included" elements are a golf grip which (1) is fixed about one end of a length of round stock which is solid throughout its length and cross-section; (2) has a center of gravity substantially centered at a midpoint of a longitudinal axis of said length of round stock; and (3) the weight of said round stock being heavier than a typical golf club.

The trainer, therefore, is open to unlisted elements that do not materially affect its basic and novel properties. Id. The novel properties of the trainer, stated in the summary and restated in the descriptions, are a homogeneously weighted shaft with a center of gravity closely positioned to the center of gravity of an actual golf club. These novel properties cause the break down of incorrect muscle memory and simultaneously develop the muscle memory appropriate to the correct golf swing. Therefore, anything added to the trainer which alters those novel features would fall outside the scope of the invention.
During the prosecution of the patent, Momentus made a central concession regarding what fell outside the scope of the invention. The prosecution history must be viewed in light of the fact Momentus was defending all claims because its application was rejected in its entirety. Therefore, concessions made during the prosecution must be considered in conjunction and not in isolation.

One reason the application was rejected was because the examiner found the device was anticipated by or made obvious over the Wallo Weighted Practice Golf Club, U.S. Patent No. 3,231,281. To fully grasp what transpired later with regard to defining the '407 patent, it is necessary to review the details of the prior art. The Wallo patent, issued to Edward Wallo on January 25, 1966, reads, in pertinent part, as follows:

This invention relates to … a golf club designed specifically for practice swinging only.

It is the principal object of the present invention to provide a practice golf club constructed in such manner as to provide effective and proper toning and strengthening of the body muscles while simultaneously and automatically guiding the body movements into proper coordination.

The overall length of the practice golf club may be varied as desired, it being preferred that the length correspond approximately with the standard length of a long iron or medium wood, for example about 40". However, it is important that the total weight of the club be from three to five times the weight of a standard golf club in order to derive the proper benefit from its use. The standard medium wood club being approximately 14 ounces in total weight, the practice club of this invention therefore should have a total weight of at least about three pounds and preferably not exceeding five pounds.

Moreover, a substantial proportion of this total weight must be distributed substantially uniformly throughout the length of the shaft, with the remainder contained in the head. The shaft should constitute at least 75%, and preferably about 90%, of the total club weight. This provides the head with sufficient weight for proper feel. This weight distribution distinguishes markedly from the weight distribution in a conventional golf club, wherein approximately 75% of the total weight is concentrated in the head and the remainder in the shaft.

In the event the shaft and head are made of lighter material, such as aluminum piping, the proper weight may be provided by filling the hollow shaft and head with a material of appropriate density, such as sand, lead, synthetic resin, and the like, as indicated at 20 in Fig. 3.

In the use of the practice golf club of the present invention, the conventional stance and grip is taken. Because of the substantially increased weight of the club, a firmer grip is required for controlling the club. This contributes materially to the strengthening of the hands. Further, the excessive weight forces the back swing to be taken much slower than normal, thereby tending to correct the common fault of a fast and jerky backswing.

It will be apparent to those skilled in the art that various modifications may be made in the details of construction described hereinafter. For example, the practice club may be constructed from a conventional golf club by appropriate weighting of the shaft and head so as to provide from three to five pounds total weight with at least 75% of the weight distributed through the shaft. These and other modifications may be made, as desired, without departing from the spirit of this invention and the scope of the appended claim.

Having now described my invention and the manner in which it may be used, what I claim as new and desire to secure by Letters Patent is:

A practice golf club comprising:
(e) the total weight of the practice golf club being from about three to about five pounds, and the shaft thereof constituting about seventy-five to ninety percent of said total weight, the overall length of such club corresponding to that of a standard full swing golf club, …

(emphasis added).

To save its claim from rejection and to distinguish its device over the Wallo device, Momentus made the following argument:

The Examiner has rejected claims 1-12 under 35 U.S.C., Section 102 as anticipated by, or under 35 U.S.C., Section 103 as obvious over, Wallo. In Wallo, from 75 to 90% of the weight of the trainer is in the shaft, resulting in from 10 to 25% of the weight being in the head of the trainer (col 2, lines 18-24). The shaft is hollow (col 2, lines 25-40). The overall weight of the trainer is such as to require a firmer grip, to strengthen the hands and to slow the swing (col 2, lines 41-49). The down swing is resisted by the “excessive weight of the club” (col. 2, lines 58-59). The trainer causes “toning and strengthening of the muscles by swinging the excessive weight” (col. 2, lines 69-70). Unlike Wallo, applicant's trainer has a solid shaft, uses no club head and substantially 100% of the trainer weight is non club head weight. A hollow device having 10-25% club head weight cannot meet the requirement in applicant's claims that the center of gravity of the trainer be substantially at the center of a solid round stock. Furthermore, as explained above, and as set forth in greater detail in claim 11 and in even greater detail in claim 12 of the present application, the claimed weighting of applicant's device is related to changing the memory and not the strength of the muscles involved in the swing and to changing the path of the swing due to balance rather than changing the speed of the swing due to weight. Applicant therefore submits that applicant's present invention is neither anticipated by Wallo, which does not disclose the structure claimed by applicant, nor obvious over Wallo, which teaches an entirely different concept of golf swing training and is not applicable to the principles taught by applicant.

(emphasis added).

Defendants assert that the prosecution history shows Momentus conceded that a device having 10-25 percent club head weight cannot meet the requirements of its claims. Momentus denies this assertion stating the Defendants ignore that the statements were made to specifically distinguish its device from a hollow device. Momentus further argues the claim was allowed without a percentage limitation and one cannot be read into the claim.

Momentus overlooks the fact that the examiner initially rejected Momentus' application indicating the device was anticipated by or made obvious over the Wallo device despite the fact the Wallo device was hollow. That is, taken alone, Momentus' solid shaft design did not distinguish it from the Wallo device because a solid shaft was anticipated by the Wallo patent, which provided, "In the event the shaft and head are made of lighter material, such as aluminum piping, the proper weight may be provided by filling the hollow shaft and head with a material of appropriate density, such as sand, lead, synthetic resin, and the like." (Wallo Patent) (emphasis added). Moreover, Momentus had to distinguish other features as novel over Wallo, for instance, the weighted shaft which was common to both the Momentus device and the Wallo device.

As the above highlighted language from the prosecution history demonstrates, Momentus defended the novelty of its weighted design by clarifying that Wallo was 75-90 percent shaft weight with 10-25 percent club head weight, whereas, its own device normally had no club head and substantially 100 percent of the trainer weight was nonclubhead weight. 5 Momentus distinguished that was the combined characteristics of being solid and weighted and having no club head, which made its device novel over Wallo. Although Momentus suggests that independently each characteristic distinguishes the Momentus device from the Wallo device, that is not what the prosecution history reveals. Rather, the characteristics must be read in conjunction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 Certainly Claim 9 contemplates the additional attachment of a club head at the end of the trainer, but the addition of a club head does not address the issue of added weight and the alteration of the center of gravity along the shaft. The device begins with a homogeneous shaft, for which the center of gravity would be precisely at the midpoint on the shaft. To this is added a
light weight grip at one end and normally a protective tip at the other, leaving the center of gravity essentially unchanged. At
some point the addition of weight at the distal end of the club would materially alter the essential features of the trainer. In
the absence of the prosecution history, specifically defining the point of departure would be an elusive task. In the presence
of the prosecution history, however, the specificity is provided by the patent applicant. See following discussion.

The specifications and the prosecution history repeatedly state that the novel feature of the Momentus trainer is the center
of gravity which is substantially at the center of the solid round shaft. To save its claim from rejection in view of prior art,
Momentus conceded that modifications which altered this defined center of gravity would fall outside the scope of its
claimed invention. Momentus cannot now gratuitously deny those concessions in order to broaden the scope of its
invention. Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1220 (Fed. Cir. 1995) ("[A] concession made or position
taken to establish patentability in view of prior art on which the examiner has relied, is a substantive position on the
technology for which a patent is sought, and will generally generate an estoppel."); Southwall Tech., Inc., 54 F.3d at 1576
("Claims may not be construed one way in order to obtain their allowance and in a different way against accused
infringers.").

Therefore, as discussed above, during the prosecution of its claim, Momentus conceded that the center of gravity of a device
with a club head weight of 10-25 percent would not be substantially centered at a midpoint of the shaft and therefore cannot
meet the requirements of Momentus' claims. Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304, 1313 (Fed. Cir. 2002)
("Thus, the prosecution history limits even clear claim language so as to exclude any interpretation that was surrendered
during prosecution, but only where the accused infringer can demonstrate that the patentee surrendered that interpretation
"'with reasonable clarity and deliberateness.'"') (quoting Pall Corp. v. PTI Techs. Inc., 259 F.3d 1383, 1393 (quoting N.
Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1294-95 (Fed. Cir. 2000)), vacated on other grounds by PTI Techs.,
Inc. v. Pall Corp., 535 U.S. 1109, 122 S. Ct. 2324, 153 L. Ed. 2d 152 (2002))). The Court finds on this record the patentee
did deliberately and clearly provided the basis for this interpretation.

In construing the phrase "consisting essentially of" in Claim 1, the Court considers the fact that the examiner insisted on a
middle ground transitional phrase rather than an open transitional term. Therefore, the examiner intended that the Claim
would be open only to elements which "do not materially affect the basic and novel properties of the invention." PPG
Indus., 156 F.3d at 1354. The novel property of the Momentus trainer is that its center of gravity is substantially centered at
the midpoint of its solid round shaft, therefore, any element which materially affects this feature would fall outside the
scope of the patent. For the reasons stated, the Court must construe the phrase "consisting essentially of" in Claim 1 as
excluding any element, if added to the device would constitute more than 10 percent club head weight, because such an
element would materially alter the novel property of the invention.

CLAIM 9

Claim 9 reads, "A trainer according to claim 1 further comprising a golf club head fixed to another end of said length of
stock." 6

There is no dispute that Claim 9 is dependent on Claim 1 and includes all the limitations of Claim 1 as well as the
limitations of Claim 9. Consequently, the construction of Claim 9 is subordinate to the construction of Claim 1.

Plaintiff argues that Claim 9 clearly anticipates a golf swing trainer with a club head, and therefore a device with a club
head would not be outside the scope of Momentus' patent claims. 7 Defendants argue that despite the fact Claim 9
anticipates a club head, in prosecuting the patent, Momentus provided notice as to how much weight a club head, if added to
the end of the shaft, would take the device outside the scope of the claims. That is, a golf swing trainer having 10 percent or
more club head weight would be outside the scope of the patent claims. Defendants assert that to hold otherwise would run
afoul of the "fair notice" function of claiming.
The '407 specifications clarify the preferred parameters of a club head:

Some golfers have difficulty psychologically in associating their swing trainer swing to their actual golf club swing. To overcome this psychological difficulty, one preferred embodiment of the swing trainer may incorporate a clubhead 27 at the end of the shaft 11 as is shown in Fig. 11. However, the addition of the clubhead 27 tends to alter the center of gravity 17 of the trainer in more than a negligible amount. It is therefore desirable that the clubhead 27 be kept as light as possible. Furthermore, if a 1/2 inch stock is used for the shaft 11, the clubhead end of the shaft must be adapted to fit a standard d" golf club head connector or, in the alternative, a d inch stock could be used and the grip end of the shaft 11 adapted to accommodate the standard grip 13.

Thus, the club head included in Claim 9 is anticipated to provide only a cosmetic function, with essentially no impact on the center of gravity along the shaft, and no alteration of the novel weighting feature.

The prosecution history also shows that Momentus conceded certain limitations regarding the addition of a club head in defending its claims.

Claims 1, 11 and 12 have been amended so as to clarify that the midpoint is a position along the longitudinal axis of the stock and to further clarify that the relationship of the golf grip to the stock is such that the center of gravity of the trainer is substantially located at the longitudinal midpoint of the stock. Applicant respectfully submits that a structural configuration in which a solid piece of round stock fitted with a golf grip at one end with the components being so interrelated as to result in the center of gravity of the combined arrangement being substantially centered at the longitudinal midpoint of the solid round stock is critical to the operation of applicant's trainer and is the heart of applicant's claims. Claims 2 through 7 are specific limitations on this relationship. Specific options include the soft tip of claim 8, the club head of claim 9 and the indicia of claim 10. Claim 11 is intended to further define the relationship of the components of the invention defined in claim 1 in that the weight of the length of stock of the trainer is sufficiently heavier than conventional clubs used in actual play as to result in a new muscle memory related to the golf swing path. That is, and as is stated in some of the references cited by the Examiner, presently known weighted clubs are weighted so as to strengthen the muscles of the golfer and thus enable him to better manipulate or control the path of the swing. Applicant's device is not based on such manipulated control of the swing due to any increased strength or muscle development in the user, but rather is based on the structural balance of the trainer, that is the center of gravity of the trainer being substantially centered at the longitudinal midpoint of a sold [sic] round stock which is of sufficient weight in relation to the conventional golf club so as to cause the user's body parts to move in an appropriate golf swing path.

Momentus argues that substantially centered does not mean that the center of gravity is exactly at the center of the longitudinal midpoint. Momentus further argues the Defendants are trying to read a limitation into the claim that is not present. The Court disagrees.

Although Claim 9 provides for the addition of a club head on its device, as discussed above, any addition including a club head which alters the novel property of Momentus' trainer will fall outside the scope of the '407 patent.

Therefore, consistent with the construction of Claim 1, the Court construes Claim 9 to be limited by Claim 1 in that a club head comprising more than 10 percent of the weight of the device would affect the basic and novel property of the invention being its center of gravity substantially centered about the midpoint of the shaft and would fall outside the scope of the '407 patent.

GO BACK
BACKGROUND

Gentry owns the '244 patent, which is directed to a unit of a sectional sofa in which two independent reclining seats ("recliners") face in the same direction. Sectional sofas are typically organized in an L-shape with "arms" at the exposed ends of the linear sections. According to the patent specification, because recliners usually have had adjustment controls on their arms, sectional sofas were able to contain two recliners only if they were located at the exposed ends of the linear sections. Due to the typical L-shaped configuration of sectional sofas, the recliners therefore faced in different directions. See '244 patent; col. 1, ll. 15-19. Such an arrangement was "not usually comfortable when the occupants are watching television because one or both occupants must turn their heads to watch the same [television] set. Furthermore, the separation of the two reclining seats at opposite ends of a sectional sofa is not comfortable or conducive to intimate conversation." Id. at col. 1, ll. 19-25.

The invention of the patent solved this supposed dilemma by, inter alia, placing a "console" between two recliners which face in the same direction. This console "accommodates the controls for both reclining seats," thus eliminating the need to position each recliner at an exposed end of a linear section. Id. at col. 1, ll. 36-37. Accordingly, both recliners can then be located on the same linear section allowing two people to recline while watching television and facing in the same direction. Claim 1, which is the broadest claim of the patent, reads in relevant part:

A sectional sofa comprising:

- a pair of reclining seats disposed in parallel relationship with one another in a double reclining seat sectional sofa section being without an arm at one end . . .,
- each of said reclining seats having a backrest and seat cushions and movable between upright and reclined positions . . .,
- a fixed console disposed in the double reclining seat sofa section between the pair of reclining seats and with the console and reclining seats together comprising a unitary structure,
- said console including an armrest portion for each of the reclining seats; said arm rests remaining fixed when the reclining seats move from one to another of their positions,
- and a pair of control means, one for each reclining seat; mounted on the double reclining seat sofa section . . .

Id. at col. 4, line 68 to col. 5, ll. 1-27 (emphasis added to most relevant claim language). Claims 9, 10, 12-15, and 19-21 are directed to a sectional sofa in which the control means are specifically located on the console.

In 1991, Gentry filed suit in the District Court for the District of Massachusetts alleging that Berkline infringed the patent by manufacturing and selling sectional sofas having two recliners facing in the same direction. In the allegedly infringing sofas, the recliners were separated by a seat which has a back cushion that may be pivoted down onto the seat, so that the seat back may serve as a tabletop between the recliners. In response to Gentry's complaint, Berkline moved and was granted a transfer to the District Court for the District of Massachusetts of its earlier-filed action in the United States District Court for the Middle District of North Carolina seeking a declaration that the patent was invalid and not infringed. After that declaratory judgment action was consolidated with Gentry's infringement suit, Berkline added a counterclaim asserting that the patent was unenforceable because of inequitable conduct. The district court granted Berkline's motion for summary judgment of non-infringement, but denied its motions for summary judgment of invalidity and unenforceability. In construing the language "fixed console," the court relied on, inter alia, a statement made by the inventor named in the patent, James Sproule, in a Petition to Make Special (PTMS). See 37 C.F.R. § 1.102 (1997). Sproule had attempted to distinguish his invention from a prior art reference by arguing that that reference, U.S. Patent 3,877,747 to Brennan et al. ("Brennan"), "shows a complete center seat with a tray in its back." Gentry I, 30 U.S.P.Q.2D (BNA) at 1137. Based on Sproule's argument, the court concluded that, as a matter of law, Berkline's sofas "contain[] a drop-down tray identical to the one employed by the Brennan product" and therefore did not have a "fixed console" and did not literally infringe the patent. Id. The court held that Gentry was also "precluded from recovery" under the doctrine of equivalents. Id. at 1138.

Gentry then requested that final judgment be entered so that it could immediately appeal the non-infringement decision. Berkline requested that its invalidity and unenforceability counterclaims proceed to trial on the authority of Cardinal
Chemical Co. v. Morton International, Inc., 508 U.S. 83, 26 U.S.P.Q.2D (BNA) 1721, 124 L. Ed. 2d 1, 113 S. Ct. 1967 (1993). The court agreed with Berkline, stating "that further proceedings will be necessary on the issues of invalidity and inequitable conduct." After a bench trial, the court held that the patent was not invalid under 35 U.S.C. §§ 102 or 103 (1994), and that the claims in which the location of the controls is not limited to the console (claims 1-8, 11, and 16-18) are not invalid under 35 U.S.C. § 112, P 1 (1994). See Gentry II, 939 F. Supp. at 101-06, 41 U.S.P.Q.2D (BNA) at 1348-52. The court also held that Berkline had failed to prove that the patent was obtained by inequitable conduct and in so ruling noted that "the evidence at trial was not even close." Id. at 101, 41 U.S.P.Q.2D (BNA) at 1347. The court denied Gentry's motion for the attorney fees it had incurred in overcoming Berkline's allegation of inequitable conduct. The court expressed "sympathy for Gentry, especially in view of Berkline's insistence on pressing the case after prevailing on the infringement issue," but nonetheless concluded that "these circumstances do not permit consideration of an award of fees."

Gentry appeals from the decision of non-infringement and the court's refusal to award attorney fees. Berkline cross-appeals from the decision that the claims are not invalid under §§ 103 or 112. We have jurisdiction pursuant to 28 U.S.C. § 1295(a) (1) (1994).

DISCUSSION

A. Infringement

Gentry argues that the district court erred in construing the claim terms "fixed" and "console" in granting summary judgment of non-infringement. Gentry asserts that the term "fixed" merely requires that the sofa section be rigidly secured to the adjoining recliners and that the term "console" refers to any sofa section that separates two recliners and can function as a tabletop. Accordingly, Gentry argues that on the undisputed facts it, not Berkline, is entitled to summary judgment on the issue of infringement. Berkline argues that summary judgment was properly granted because the term "fixed" requires that no part of the console be movable, while Berkline's sofa has a center seat back that can pivot. Berkline also argues that Gentry effectively defined a center seat with a retractable seat back as not a "console" when it distinguished the Brennan reference in the PTMS. On the basis of Berkline's second argument, we agree that it is entitled to judgment as a matter of law that it does not infringe the '244 patent.

We review a district court's grant of summary judgment de novo. See Conroy v. Reebok Int'l, Ltd., 14 F.3d 1570, 1575, 29 U.S.P.Q.2D (BNA) 1373, 1377 (Fed. Cir. 1994). Summary judgment is appropriate when there is no genuine issue as to any material fact and the moving party is entitled to judgment as a matter of law. See Fed. R. Civ. P. 56(c); Johnston v. IVAC Corp., 885 F.2d 1574, 1576-77, 12 U.S.P.Q.2D (BNA) 1382, 1383 (Fed. Cir. 1989). A determination of infringement requires a two-step analysis. "First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device or process." Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1576, 27 U.S.P.Q.2D (BNA) 1836, 1839 (Fed. Cir. 1993).

Because there is no dispute concerning the structure of the accused device, our infringement analysis involves only claim construction, a question of law which we review de novo. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979-81, 34 U.S.P.Q.2D (BNA) 1321, 1329-31 (Fed. Cir. 1995) (in banc), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 38 U.S.P.Q.2D (BNA) 1461, 134 L. Ed. 2d 577 (1996). The proper construction of claims is based upon the claim language, the written description portion of the specification, the prosecution history, and if necessary to aid the court's understanding of the patent, extrinsic evidence. See id. Our present analysis of infringement under the doctrine of equivalents involves prosecution history estoppel, also a question of law which we review de novo. See Southwall Techs. Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579, 34 U.S.P.Q.2D (BNA) 1673, 1679 (Fed. Cir. 1995).

We agree with Gentry that the term "fixed" requires only that the console be rigidly secured to its two adjacent recliners. The term "fixed" and the explanatory clause "with the console and reclining seats together comprising a unitary structure" were added during prosecution to overcome a rejection based on a sectional sofa in which the seats were not rigidly attached. Thus, because the term "console" clearly refers to the complete section between the recliners, the term "fixed" merely requires that the console be rigidly attached to the recliners. Moreover, Berkline's interpretation of the term "fixed" unnecessarily excludes from the claim Sproule's preferred embodiment, in which the console can be opened by pivoting its lid. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1578 (Fed. Cir. 1996) (noting that a claim interpretation that excludes the preferred embodiment "is rarely, if ever, correct"). Accordingly, as there is no dispute that Berkline's center seat and recliners form a unitary structure, we conclude that the "fixed" limitation is met
by Berkline's sofas.

However, Berkline's sofas do not have a "console." The prosecution history indicates that the term "console" is not met by a sofa section having a seat back that folds down to serve as a table top, as in Brennan's seat or Berkline's sofas. As noted by the district court, Sproule's PTMS distinguished the Brennan reference in the following passage: 1

Even if one were to apply the disclosure of reclining vehicle seats such as Brennan . . . to furniture, one would not produce the pair of reclining seats joined by a center console as taught by [Applicant]. The tray units of Brennan . . . while disposed between tandem reclining vehicle seats, are freestanding retractable structures that are not, per se, consoles nor do they join the pair of reclining seats as taught by Applicant. Rather Brennan shows a complete center seat with a tray unit in its back.

Gentry I, 30 U.S.P.Q.2D (BNA) at 1137 (emphasis added). This statement unambiguously indicates that the tray units in Brennan are not "consoles" as that term is used in the patent, regardless of the term's ordinary meaning or the way in which Gentry now urges us to interpret it. The relevant feature of Berkline's sofas, viz., a center seat back that may be folded down to provide a table top between the adjacent recliners, is indistinguishable from the comparable feature in Brennan, a fold-down tray table. In the PTMS, that feature was distinguished from the claimed "console." Thus, we conclude that Berkline's sofas do not contain the claimed "console." See Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1304, 41 U.S.P.Q.2D (BNA) 1364, 1368 (Fed. Cir. 1997) ("Since, by distinguishing the claimed invention over the prior art, an applicant is indicating what the claims do not cover, he is by implication surrendering such protection."). The claims are therefore not literally infringed. Similarly, the argument advanced in the PTMS precludes recovery under the doctrine of equivalents because of prosecution history estoppel. Arguments made by an applicant in a PTMS can create an estoppel, and thus preclude a finding of infringement under the doctrine of equivalents. See 104 F.3d at 1303-04, 41 U.S.P.Q.2D (BNA) at 1368 (Fed. Cir. 1997) (regarding arguments made by an applicant in an Information Disclosure Statement). Accordingly, we affirm the judgment that Berkline does not infringe the patent.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 Gentry asserts that Sproule distinguished the Brennan reference on several other grounds. Such an observation is not relevant to our analysis of the prosecution history, for even if Brennan was distinguished on multiple grounds, any of those grounds may indicate the proper construction of particular claim terms and provide independent bases for prosecution history estoppel.

GO BACK

928

1. "heater is constructed and arranged to add heat to the fluid while the fluid is disposed within the tank"

Claim 5 of the '110 patent recites a system for cleaning hydrocarbons from a part "wherein the heater is constructed and arranged to add heat to the fluid while the fluid is disposed within the tank." '110 patent, col. 8, ll. 52-54. Plaintiff argues the phrase should be construed to mean "an apparatus that heats or provides heat and that is assembled and ordered to make the fluid that is in the tank warmer." Defendant contends this element should be construed as "an electric heating element that extends from the control panel into the depths of the tank, which is constructed and arranged to add heat to the fluid while the fluid is disposed within the tank." In essence, Defendant seeks to limit this element to the specific heater disclosed in the specification.

The specification explains that it is beneficial to maintain the cleaning fluid at a certain temperature in order to maintain viability of the microorganisms and to facilitate biodegradation. See id., col. 7, ll. 45-47 ("The cleaning fluid 72 is preferably maintained in a temperature range which supports the lives of the particular microorganisms employed within the parts washer 10."). Thus, the specification discusses the use of a heater and thermostat in order to maintain an optimal temperature range. See generally id., col. 7, ll. 36-56. With respect to the heater itself, the specification teaches that "the heater 76 is acceptably in the form of an electric heating element that extends from the control panel 30 into the depths of the tank cavity 44." Id. col. 4, ll. 32-34.
The claim language requires only that the heater warm the fluid while it is in the tank; it does not require that any particular kind of structure be employed to do so. Nor does the specification suggest that a particular kind of heater is required to heat the fluid. Though the specification reveals a heater in the form of an electric heating element extending from the control panel, it is clearly disclosed in the context of explaining a preferred embodiment. It is apparent from the claims and the specification that the Applicant did not intend to limit his claims narrowly to the specific heater discussed in the specification, and thus it is entitled to all forms of heaters which "add heat to the fluid while the fluid is disposed within the tank." See Phillips, 415 F.3d at 1323 ("Much of the time, upon reading the specification in . . . context, it will become clear whether the patentee is setting out specific examples of the invention . . ., or whether the patentee intends for the claims and the embodiments to be strictly coextensive.")

The Court construes "the heater is constructed and arranged to add heat to the fluid while the fluid is disposed within the tank" as "the heater warms the cleaning fluid while the cleaning fluid is in the tank."

6. "Consumer service station beverage tapping mechanism"

The parties agreed that the definition of "consumer service station beverage tapping mechanism" should at its base be "a mechanism located in the customer service station through which refrigerated source liquids are dispensed." However, Foodie wanted the word "operatively" included in the definition out of concern that if it was not included, embodiments where part of the operation is done outside the station(s) and part of it is in the station(s) might be precluded, which Foodie believes is inconsistent with the specification. At the Markman hearing, Foodie noted they could "live without" operatively being included in the definition, and the inclusion of "operatively" would seem to confuse the definition more than it would clarify the term. Accordingly, the Court adopts the parties' agreement, without the term "operatively," as the Court's construction.

Claim 31 continues:

said wall means including an expandable cover in contact with the layer of skin and subcutaneous tissue when the device is implanted,

The parties agree that the wall means includes a portion that is capable of increasing in size or area. The parties disagree as to how "contact" should be construed. The specification only discusses the device as being implanted "beneath the skin and subcutaneous tissue", col. 2, line 9; col. 3, lines 11-23, of the port "facing" the skin, col. 4, line 60, and of the base "paralleling and facing away from the overlying soft tissue" col. 4, lines 56-58. There is no discussion of how the cover "contacts" the skin and subcutaneous tissue, but it is impossible for the cover to be in direct contact with both the skin and the tissue. The word "contact" in this context is most clearly understood as used in place of "facing."

The court finds this limitation means "a portion of the wall means that can be increased in size which would face the layer of skin and subcutaneous tissue when implanted."

contacting

Plaintiff argues that the term contacting is unambiguous and requires no definition. Defendants propose the same definition to the term "contacting" as they proposed for the term "into engagement with" for Claim 1, Issue 5, i.e., "physically attached and retained by."
Defendants defend this definition by citing the same prosecution history previously cited. (See Pfl. Ex. A at 58.) Again, there is no citation to the patent language or patent specification by either party.

The Court finds the term "contacting" to be unambiguous and easily comprehensible by the finder of fact. It therefore declines to define such term.

Inverness contends that the proper construction of the term "contacting," as that term is used in independent claims 1, 14, and 59 of the Campbell patent, is "directly applying the sample and tracer to the binder." Its argument in favor of this construction is twofold. First, Inverness argues, with the support of its expert, Dr. Gunter, that the claims of the Campbell patent teach only the direct application of sample and tracer to the binder to create a "spot assay." Second, Inverness argues that because "lateral-flow" technology of the Rosenstein patent and the Inverness products was not developed at the time the Campbell patent issued in 1987, the term "contacting" should not include this later developed technology.

Dr. Gunter contends that the Campbell patent discloses only a "spot assay" and that therefore "[a] person of ordinary skill in the art would understand that the proper way to interpret "contacting" is that the user must directly apply the sample and tracer to the 'spot' of binder." He draws support for this conclusion from the patent's specification, and states, "after a thorough review of the Campbell patent, it is my opinion that the specification is directed to and only discloses 'spot' assays . . . ." Similarly, he states that "the specification describes that in use, the sample must be directly applied to the 'spot' of binder. . . . The specification also explains that the tracer is in a solution which is also directly applied to the 'spot' of binder." Dr. Gunter also finds support for his interpretation of "contacting" in the only figure of the Campbell patent, which depicts three spots of binder on a rectangular solid support, and in Example III of the patent, which teaches the user to pipet both urine and the tracer directly onto the spot of binder. According to Dr. Gunter, it is clear from the patent's examples and specification "that if the user does not directly apply the sample and tracer to the 'spot,' the assay would not work."

Inverness also finds support for his conclusion that "contacting" must mean "directly contacting" from the prosecution history of the Rosenstein patent. As set forth above, during the prosecution history of the Rosenstein patent, BD repeatedly acknowledged that the Campbell patent does not disclose the transfer of the tracer and sample to the binder across the solid support by capillary action.

Last, in support of Dr. Gunter's construction of the term "contacting," Inverness argues that any other construction that might result in the inclusion of its one-step lateral flow assays within the bounds of the Campbell patent is untenable. According to Inverness, because lateral flow assays were unknown at the time the Campbell patent issued, the term "contacting" must be construed to prevent its application to this later-developed technology. Inverness finds support for this argument in this court's opinion in IPPV Enters., LLC, v. Echostar Communications Corp., 106 F. Supp. 2d 595, 605 (D. Del. 2000). In IPPV Enters., the plaintiff's patent was addressed to encrypting television program signals. At the time of the invention, the television industry was broadcasting its signals in analog form. The patent exclusively discussed the encrypting of analog television signals. Subsequently, the industry began commercial broadcasts of digital signals. The defendants operated a direct broadcast satellite subscriber television service that transmitted encrypted video signals in a digital format. In response to plaintiff's infringement claim, defendants argued that because the patent exclusively discusses the encryption of analog television signals, the court should construe the phrase "television program signal" in the claim at issue as meaning "analog television program signal." The court agreed with defendants, but noted that this construction would not preclude plaintiff's claim that defendants infringed under the doctrine of equivalents. Id. at 605-06. In identifying its construction, the court relied upon two principles of claim construction: that the literal meaning of a claim is fixed at its issuance, see Al-Site Corp. v. VSI Int'l, Inc., 174 F.3d 1308, 1320 (Fed. Cir. 1999), and that broadly written claims may, in certain instances, be construed to limit their scope to the technologies disclosed in the patent specification, see Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). IPPV Enters., 106 F. Supp. 2d at 605. Inverness contends that the same principles are relevant here and that therefore the meaning of "contacting" must be limited to cover spot assays, because only spot assays are revealed in the patent specification and the lateral-flow technology was not yet developed when the Campbell patent issued.
BD responds by arguing that the plain meaning of "contacting" is not limited to Dr. Gunter's suggested interpretation of "directly contacting." According to BD, the court must begin with meaning of the term "contacting" as it was known to those skilled in the art at the time the patent issued. BD contends that because the term "contacting" has no specialized meaning and has not changed since the Campbell patent issued, it should be interpreted consistently with its plain meaning. BD suggests that "contacting" is defined as "the coming together or touching of two objects or surfaces." American Heritage Dictionary of the English Language, 287 (Houghton Mifflin 1981).

Furthermore, BD notes that Inverness's suggested interpretation violates the rule of claim construction that the specification should not be used to import limitations into the claim language. According to BD, the Campbell patent's disclosure of only alleged "spot assays" cannot limit the breadth of the plain language of its claims or alter the meaning of "contacting." See Markman, 52 F.3d at 980 ("The written description part of the specification itself does not delimit the right to exclude. That is the function and purpose of claims.").

In evaluating the meaning of the term "contacting," as used in claims 1, 14, and 59 of the Campbell patent, the court must begin with the plain meaning of the claims. Vitronics, 90 F.3d at 1582. Inverness has not suggested that "contacting" had a specialized meaning to those with skill in the art at the time the Campbell patent was issued. Nor has it suggested that elsewhere in the Campbell patent the patentee assigned a particular meaning to the term "contacting." Thus the court adopts the definition proffered by BD, "the coming together or touching of two objects or surfaces" as its plain meaning.

Inverness's arguments that the term contacting has a more limited definition find their root in two places: the specification of the Campbell patent and BD's statements about the Campbell patent while prosecuting its application for the Rosenstein patent. Beginning with the Campbell patent, Dr. Gunter's report finds no support for his definition of the term in the patent claims themselves, but instead looks to the written description of the patent, a figure included with that description, and the examples given of how to employ the invention. The uses of the patent specification to define the terms of the patent claims is limited. If the claims are clear, the patent specification can only be used to determine whether a deviation from the claims is required, such as when the specification uses a term in other than its plain and ordinary meaning. Interactive Gift Express, 256 F.3d at 1331. If the claims are unclear, then the patent specification can be used more liberally to aid the court in resolving ambiguities and identifying a claim construction that properly delimits the bounds of the patentee's invention. Renishaw PLC, 158 F.3d at 1250. Inverness has not explained why the uses of the term "contacting" in claims 1, 14, and 59 are unclear or ambiguous on their face. Thus, there is no reason to use the patent specification to explain the claims and the claim language should be accorded its plain meaning.

Even were the court to find that the claim terms are ambiguous and employ the patent specification to resolve that ambiguity, Dr. Gunter's suggested definition of contacting still lacks support. Patent specifications cannot be used to import into the patent claims a limitation suggested only by the specification or the preferred embodiment of the invention. Intervet Am., 887 F.2d at 1053. In this case, Inverness is attempting to use the fact that the patent specification's written description, figure, and examples all disclose that a user should directly contact the sample and tracer to the binder. Because doing so would have the effect of diminishing or limiting the plain meaning of the claims, the court refuses to import into its claim construction a limitation purported to be required by the patent's specification.

Inverness also finds support for its definition of "contacting" in BD's statements to the PTO during the Rosenstein patent that a person of ordinary skill in the art at the time of the Campbell patent would not have known of using capillarity through the solid support to bring the analyte, tracer, and binder into contact. However, statements made during the prosecution history of another patent are extrinsic evidence. Such statements would only be intrinsic evidence if the patentee used those statements in the prosecution of the contested patent. See Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1332 (Fed. Cir. 1999). "Relying on extrinsic evidence to construe a claim is 'proper only when the claim language remains genuinely ambiguous after consideration of the intrinsic evidence.'" Interactive Gift Express, 256 F.3d at 1332 (citation omitted). This court finds that the claim language is not genuinely ambiguous and thus resort to extrinsic evidence to construe the term "contacting" is unwarranted.

--- Footnotes ---

1 While the court acknowledges that the position currently taken by BD on the meaning of the claims of the Campbell patent may be inconsistent with its position during the Rosenstein prosecution, and that such inconsistency might be
relevant to other relief for Inverness, it does not change the meaning of the terms the court is asked to construe for purposes of this summary judgment motion.

Furthermore, Inverness's reliance on this court's opinion in IPPV Enters. is misplaced. While it is true that the literal meaning of a claim is fixed upon the issuance of the patent, Al-Site Corp., 174 F.3d at 1320, IPPV Enters., 106 F. Supp. 2d at 605, the important distinction here is the nature of the disputed term. Inverness disputes the meaning of the term "contacting." In IPPV Enters., the parties disputed the term "television program signal." While it was asserted that the meaning of the latter had changed over time due to technological progress, the meaning of the former has not. While technological progress in the field of immunoassays may have been significant, it has not altered the meaning of the term "contacting" and therefore has not restrained the types of contacting covered by the Campbell patent.

Inverness also relies on the statement in IPPV Enters, that broadly written claims may be construed to limit their scope to the technologies disclosed in the patent specification. IPPV Enters., 106 F. Supp. 2d at 605 (citing Wang Labs., 197 F.3d at 1383). 2 The court in IPPV Enters. employed this principle to construe the phrase "television program signal" as meaning "analog television program signal." Inverness argues this case is analogous because the patent specification in this case discloses only "spot assays" and lateral-flow technology had not been developed at the time. While it may be true that lateral-flow technology is not disclosed in the specification of the Campbell patent, the court's primary inquiry is into the scope of the claims themselves. Markman, 52 F.3d at 980 ("The written description part of the specification itself does not delimit the right to exclude. That is the function and purpose of claims."). Because the court has concluded that the meaning of the term "contacting" is clear, the court need not resort to the claim specification unless it contains some indication that the claims do not use the term "contacting" in its ordinary sense. Interactive Gift Express, 256 F.3d at 1331.

Thus, the court finds that the term "contacting," as used in claims 1, 14, and 59 of the Campbell patent means "the coming together or touching of two objects or surfaces." The term does not require a user of the Campbell patent to directly apply the solution of analyte and the tracer to a spot of binder; it only requires that those components come together or touch.
of contact arms, although we hold that claim 9 can also encompass a contactor with a single contact arm.

The language of claim 9 does not mandate that the spring and the contact arms be connected to each other; indeed, it provides only that the "contactor [has] a spring . . . and at least one contact. . . ." '900 Patent col.11 1.36-40. Furthermore, the Summary does not actually preclude the spring and the contact arms from being separate, as it provides that "the electrical contact may be connected with one end of the spring for electrical connection with the first terminal of the battery." '900 Patent col.2 1.6-8 (emphasis added). Perimeter's reliance on the written description as well as the drawings is misplaced.

Furthermore, the doctrine of claim differentiation supports a reading of claim 9 whereby the spring and contact arms are separate. The doctrine of claim differentiation stems from "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Seachange Int'l, Inc. v. C-Cor Inc., 413 F.3d 1361, 1368 (Fed. Cir. 2005) (quoting Karlin Tech. Inc. v. Surgical Dynamics, Inc, 177 F.3d 968, 971-72 (Fed. Cir. 1999)). Here, claim 21 provides for "a contact connected with one end of the spring," '900 Patent col. 13 1.12-13, while claim 9 makes no reference to the spring and contact arms being connected. Although claim 21 is an independent claim, under claim differentiation "there is still a presumption that two independent claims have [a] different scope when different words or phrases are used in those claims." Seachange Int'l, Inc., 413 F.3d at 1369 (citing Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1365-69 (Fed. Cir. 2000)). Thus, claim 21 is presumed to have a narrower scope than claim 9. 11

"The doctrine of claim differentiation is not a hard and fast rule of construction," and therefore "claims that are written in different words may ultimately cover substantially the same subject matter." Id. (citations omitted). The presumption created by the doctrine, however, can only be overcome "by a contrary construction dictated by the written description or prosecution history." Id. (citing Kraft Foods Inc., 203 F.3d at 1368). Here, the language from the Summary quoted above hardly suggests, let alone dictates, that the contact arms and the spring be connected.

In light of the foregoing, the Court finds that claim 9 does not mandate that the spring and the contact arms be connected.

Invisible Fence includes "or equivalent thereof" in its proposed construction of "a contactor," explaining that this phrase was added to preserve a potential argument under the doctrine of equivalents. The Court, however, is not to consider the doctrine of equivalents when construing claims, because whether the claim includes an equivalent is a question of infringement rather than an issue of claim construction. See Dayco Prods., Inc. v. Total Containment, Inc., 258 F.3d 1317, 1327 (Fed. Cir. 2001) ("We do not reach the issue of the infringement under the doctrine of equivalents, because that issue must be addressed first under a proper claim construction."); Microsoft Corp. v. Multi-Tech Sys., Inc., 2002 U.S. Dist. LEXIS 15960, Nos. Civ. 00-1412ADMRLE, Civ. 00-1627ADMRLE, 2002 WL 1949755, at *4 (D. Minn. Aug. 16, 2002) (declining to address any issues related to the doctrine of equivalents because it is an infringement issue); Jackson v. Thomson Consumer Elecs., Inc., 39 F. Supp. 2d 995, 1003, 1008 (S.D. Ind. 2001) (articulating that the doctrine of equivalents analysis "is a fact question not at issue in claim construction"). Thus, the Court declines including "or equivalent thereof" in its construction of "a contactor." 12

12 Also included in Perimeter's proposed construction of "a contactor" is the notion that the contactor is an "electrically-conductive component." (Joint Statement 3.) Neither of the parties discuss this specific construction, ostensibly because the contactor must be an electrically-conductive component if it is to make electrical connection with the first terminal of the battery. Therefore, we will include this definition in our construction of "a contactor."
6. Claim 7 - "to contain"

Claim 7 depends from claim 1 and adds to the invention a catalytic combustion flask "to contain" a combustible liquid. Plaintiffs argue that the present invention, as recited in claim 1, is a catalytic combustion burner and that claim 7 adds a flask designed to hold the catalytic combustion burner, the flask being present "to contain a combustible liquid." However, Plaintiffs contend that the combustible liquid is not itself a part of the present invention. Defendants, on the other hand, propose that claim 7 should be construed to require a flask containing a combustible liquid.

Because this claim includes all of the limitations of claim 1, the Court finds that the "combustible liquid" is a required limitation of this claim as well. Further, the ordinary language of the claim itself requires "a wick (4) dipping into said liquid. . . See '061 patent, claim 7. As Defendants posit, if the liquid is not there, how can the wick be "dipping" into the liquid? The claim language not only states "a wick (4) to dip;" the claim clearly states "a wick dipping into said liquid." Id. This additional language demonstrating the active tense of the verb "dipping" into the liquid further supports Defendants' position that the liquid is part of the claim.

Thus, as it did in claim 1, the Court finds that the "liquid" referenced in claim 7 is itself part of the claimed invention and is, therefore, a required limitation of the claim.

A. Container/Canister

The meaning of the term "container" or "canister" is disputed by the parties. Microfil asserts that the term "container" should be limited to a "unitary structure" as embodied in Figure 3 of the AutoMed patents. (Def. Resp. SJ for Infr. 7). Microfil's proposed claim construction for the term "container," however, is entirely wrong. Looking at the intrinsic evidence, the patentee clearly did not limit the container to one specific design. In fact, the written specification explicitly states that the "canister may be of any suitable design that allows dispensing of countable oral solid drugs." ('927 Patent Col. 6 L. 15-24). The specification further states that "canister 130 is preferably an assembly of components . . . ." (Id.). Accordingly, because the patentee used language that did not limit the term "container" to a specific "unitary structure," a container as defined in the AutoMed patents shall include any suitable design that allows dispensing of countable oral solid drugs.

3. "Container" and "Canister"

As an alternative basis for affirmance, Microfil challenges the district court's construction of "container" and "canister," as "any suitable design that allows dispensing of countable oral solid drugs." Claim Construction Opinion, 2005 U.S. Dist. LEXIS 26032, slip op. at 17. Microfil contends that these terms, which the parties agree are synonymous, should be limited to a unitary structure. AutoMed counters that nothing in the intrinsic record compels this narrow construction. Having considered the claims, the written description, and the figures of the '927 and '671 patents, we agree with the district court's refusal to read in this additional limitation. See '927 patent, col.6 ll.15-17 ("The canister may be of any suitable design that allows dispensing of countable oral solid drugs within an automated drug dispensing system."); '671 patent, col.6 ll.17-19 (same). We accordingly affirm the district court's construction of these terms.
9. Container

Defendants' Proposed Construction: A "container" is a receptacle for holding items.
Plaintiff's Proposed Construction: Leave undefined.
The Court's Claim Construction: A "container" is a receptacle for holding items.

MPT does not dispute Defendants' definition of container. Instead, it claims that it would confuse the jury to provide a definition for this non-technical term. However, the Court perceives no harm in providing this definition to the jury and adopts Defendants' definition.

The critical claim in this matter is Claim 1. Claim 1 provides that the invention has a "main body portion" that "contains" an "FM transmitter" and "power/charging circuitry." '085 Patent col.6 ll.1-6. "Contains" is the critical word in this claim, and nothing in the claim terms defines "contains." Furthermore, "contains" does not appear to be a technical term, and common-use dictionaries might illuminate possible relevant meanings for this everyday, commonly understood word. "Contain" means "to keep within limits," "to have within," and to "enclose, bound." Merriam-Webster Online Dictionary, http://www.m-w.com/dictionary/contains (last visited May 17, 2006); accord Webster's Seventh New Collegiate Dictionary 180 (1970). In light of these definitions, Claim 1 describes a product in which the FM transmitter and the power supply/charging assembly are "enclosed," "bound," or "kept within" the same housing unit.

This definition does not conflict with the other relevant evidence. The patent's entire content reflects that the invention has the FM transmitter and power supply/charging assembly within one unit. The patent's other language states that "[t]he present invention provides an integrated FM transmitter and power supply/charging assembly for an MP3 player." '085 Patent col.2 ll.64-66 (emphasis added). "Integrated" shows that this invention's critical feature is that the FM transmitter and the power supply/charging assembly are housed within one unit. Such language is consistent with Claim 1's "contains."

This construction is also consistent with the prosecution history. In his "Reasons for Allowance," the patent examiner stated he approved the '085 Patent because the patent application described, unlike other patent applications, a product that contained the FM transmitter and power supply/charging assembly within one main body. Thus, that single unit allowed not only "FM transmission . . . of audio content when played by the MP3 player in the docking cavity," but also the "transmission of electrical power through the modular docking unit . . . for charging of a battery of the MP3 player and/or powering of the MP3 player, as specified in the claim." (Birdwell Decl. Ex. 16 at 4.) Thus, in communicating his reasons for allowing the patent, the patent examiner focused on the single, integrated unit having two separate functions. In light of this evidence, Claim 1's plain language as illuminated by dictionaries, and the patent's entire content, the '085 Patent protects an invention where one module houses, contains, or holds within itself two separate functions: a fully functioning FM transmitter and power supply/charging assembly.

2. "Contaminated Underground Areas"

Plaintiff claims that the phrase "contaminated underground areas" means subterranean area of ground soil. He claims that as numerous references have been made in the specification to soil and soil conditions, the purpose and application of the invention is for removal of volatile contaminants from soil. Defendants argue that the phrase is self-explanatory. They argue there is the requirement for the underground areas to be contaminated. They further argue that the phrase "underground areas" cannot be limited to soil, as the specification contains numerous references to the "contaminated area" without limiting the reference to "soil."

The Court finds that the phrase "contaminated underground area" is unambiguous. In the claim, this phrase is not limited to "soil." Also, the claim unambiguously limits the underground area with the term "contaminated." Thus, the plain language of the claim leads to the Court to conclude that the underground areas are not limited to soil, and that such areas must be
contaminated. The specification does not alter this result. Plaintiff makes various references to soil and soil conditions, yet he does not clearly indicate that the underground areas are limited to "soil" or "soil conditions."

4) "Said visor being adjustably rotated into contiguous relation with said sheet rear surface"

This phrase means that the vehicle visor is rotated so that it contacts the rear surface of the sunshade. When in operation, the visor is "contiguous" in that it lies flat against the rear surface of the sunshade, touching the sunshade.

"Continually"

The district court properly construed the term "continually" to mean "at all times, after the manufacturing process of the balloon is completed when the balloon is not inflated." C.R. Bard, Inc. v. Boston Scientific Corp., No. 95-CV-215, slip op. at 2. However, BSC argues that the term "continually" should be construed to require that the tension from the wire exist prior to the completion of manufacture. BSC quotes claim 1 in support of its argument: "the balloon being mounted on the catheter in a manner that when the balloon is not inflated, the wire will apply continually a longitudinal tension . . . ." '246 patent, col. 6, ll. 43-45. BSC misinterprets "being mounted" as the action of mounting the balloon onto the catheter. However, as is common and accepted in patent practice, the plain claim language uses "being" in a static manner, as in "in a state of being." Thus, the claim merely refers to the balloon at any point after it has been mounted, not during the act of mounting. This reasoning alone causes BSC's proposed interpretation of "continually" to fail.

Once the catheter is completely assembled, the term "continually" as well as all other terms in the claim apply. To require that any apparatus claim term apply before completion of manufacture would be incongruous because the claim covers the apparatus and not the method of manufacturing the apparatus. As long as the accused device contained each claim limitation or its equivalent during its existence, the device infringed, and whether it infringed or did not infringe prior to the completion of a time in its existence labeled as "manufacture" is irrelevant. See Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 622-23, 34 U.S.P.Q.2D (BNA) 1816, 1822 (Fed. Cir. 1995) (stating that part-time infringement is still infringement).

The foundation of BSC's proposed claim construction is logically flawed. Any apparatus which is a composite of other apparatuses must be assembled at some point during its existence. In this case, the catheter apparatus is not complete until it has been fully assembled. The claim terms would not apply to a partially assembled apparatus, as BSC contends. Infringement of an apparatus claim is based on whether the accused device includes each claim limitation or its equivalent.

3. continually detecting the instantaneous flow rate

This phrase is found in Claims 3 and 24 of the '802 Patent and Claims 9, 44, and 53 of the '193 Patent.

Phrase: continually detecting the instantaneous flow rate

Construction: Without interruption, creating a signal corresponding to the flow rate at a particular point of time.

Reasoning: At its core, there is little dispute between the parties as to the meaning of this phrase. Both parties agree that the computer circuitry detects the instantaneous flow rate by creating a signal corresponding to the instantaneous flow rate. The real dispute between the parties is over the meaning of "flow rate", which we have already construed above.
B. A Continuous Piece of Fabric

The parties also dispute the meaning of "a continuous piece of fabric," which is contained in claims 4, 9 and 16. The issue is whether a combined "back piece" and "nursing flap" must be made of one piece of fabric or may be made of two or more pieces of fabric sewn together to form a continuous piece of fabric. Claim 16, which is the same as claims 4 and 9, states that: "a nursing garment in accordance with claim 13, wherein said back piece back and internal nursing flap are one continuous piece of fabric." Plaintiff contends that the construction should be read as: "the back piece and the nursing flap are sewn together to form a continuous piece of fabric," while Defendants' proposed construction is: "the back piece and internal nursing flap are a single continuous piece of fabric."

Plaintiff submits that this is a dependent claim, and that claims 4, 9 and 16 add a feature -- that the separate pieces be sewn together -- to form one continuous piece of fabric. According to Plaintiff, the back piece and internal nursing flap are separate pieces of fabric and the continuity is achieved by sewing the two pieces together. Plaintiff contends that normally one continuous piece of fabric is sewn or joined together and not cut from only a single piece of fabric. Defendants, however, contend that claims 4, 9 and 16 require the back piece and internal nursing flap to be formed from the same, single bolt of fabric. Defendants claim that to construe the term otherwise is to ignore the plan meaning of the term "one continuous."

In the specification, Plaintiff explains that in the alternate embodiment where the back piece is joined to the internal nursing flap, they are described as separate fabric panels. In figure 4, they are also shown as separate panels, however, both share a common reference numeral "8" which Plaintiff claims means the two panels could be sewn together as joined components. Defendants contend that construing a continuous piece of fabric conflicts with the specification, which states "for additional support, internal nursing flaps 8A and the back pieces of fabric 8B may alternatively be constructed using one piece of fabric extending around the torso, in the same manner that the elastic chest band extends around the torso." '029 Patent, col. 3, ln 24-8. Defendants argue that one piece simply means one piece and the drawings reflect only one piece of fabric and not two sewn together.

The Court agrees with Plaintiff's construction of "a continuous piece of fabric" to mean that "the back piece and the nursing flap are sewn together to form a continuous piece of fabric." Based on the plain meaning of the term as well as the specification, a continuous piece of fabric requires at least one seam to join it together. It is not necessary that the two components -- a back piece and the nursing flap - be cut from the same bolt of fabric. Rather, this can be accomplished by sewing or joining together the two parts to combine as a continuous piece of fabric.

Continuous source of illumination

The phrase "continuous source of illumination" appears in the '823 and '302 patents. Gekko's proposed construction is "illumination with an uninterrupted source of current." Gekko contends that for illumination to be continuous, the source of current must be uninterrupted. Gekko offers no intrinsic evidence to support its construction; it only offers its expert's assertion that "[Gekko's definition] is consistent with the specification of the '823 and '310 patent specification."

An expert's conclusory allegations are entirely unhelpful to the Court. Phillips, 415 F.3d at 1317. Because neither Gekko nor its expert offers any supporting evidence to show how its construction is consistent with the specifications, the assertion is conclusory and unhelpful.

Gekko's proposed construction would render the '823 patent's Claim 1 incompatible with dependent Claim 2. Although Claim 2 is not asserted, it is helpful in construing this phrase. See Phillips, 415 F.3d at 1314 (usage of a term in one claim can often illuminate the meaning of the same term in other claims). Claim 2 is dependant upon Claim 1, which requires the light elements' illumination level to be controlled using pulse width modulation ("PWM"). '823 patent, Col. 31:2-17. Neither
parties disputes that PWM involves interrupting the power current. Claim 2 requires the light elements to provide a "continuous source of illumination." Id. at Col. 31:18-20. Applying Gekko's construction of "uninterrupted current" would render Claim 1 incompatible with Claim 2.

Gekko's construction focuses on the power source for the illumination, but the intrinsic evidence does not support this view. The proper focus is the visible effect not the power source. The specification discusses controlling visible effects, such as "strobing," "dimming," "pulsation," and "pattern generation." See id. at Cols. 19:7-52; 20:36-38. In one embodiment, the specification teaches "the lighting assembly 4600 can provide continuous light or, if applicable, various lighting effects." Id. at Col. 22:40-44. The positioning of continuous light as an alternative to "various lighting effects" further supports that the specification focuses on the effect as perceived by the eye and not on the power source.

The specification does not prescribe a special meaning for "continuous source of illumination." As Gekko stated in its moving papers, one skilled in the art of photography lighting would readily understand this phrase. Also, a lay juror would have no problem understanding what "continuous source of illumination" means. Therefore, the Court does not construe this term.

---

11. **Continuously**

Again, Vision Advancement argues that this term, found in Claim 1 of the '461 patent, should be given its plain and ordinary meaning and does not require construction. Vistakon proposes a construction of, "The lens surface has no discontinuities in progressivity." Vistakon supports its argument by pointing to the prosecution history and the examiner's disallowance of claim language allowing correction power to change "substantially continuously." The Court disagrees with Vistakon. The Examiner rejected the use of "substantially" because of the "inherent vagueness" of that word. Vistakon's Br., Ex. R at VIST029104. That does not provide an explicit basis to graft onto the term a requirement of "no discontinuities in progressivity." Without such a clear showing, the Court finds no need to construe this term.

---

7. **"Continuously Curved" (230 Patent, Claims 1, 7, 13)**

"Continuously curved" is construed as "rounded without interruption in the longitudinal direction."

---

"**Contoured**: A surface shaped to fit the outline or form of something.

---

2. **"contoured to complement"**

Schindler asserts that "contoured to complement" should mean "configured so as to mutually complete so that there is no gap in between." Otis proposes: "shaped to guide engagement of the tension member with the sheave."

Schindler makes three arguments in support of its interpretation. First, it cites a dictionary definition of complement as "one of two mutually completing parts." Second, Schindler relies on the figures in the patent depicting a completely engaged
tension member and sheave. Third, Schindler argues that a gap between the engagement surface and the sheave would go against a stated purpose of the invention (i.e., reduce pressure on the tension member by increasing traction forces between the tension member and sheave).

This Court disagrees with Schindler, and finds the "no gap" limitation proposed by Schindler to be inappropriate. First, the dictionary definition Schindler relies upon is inapposite, because as noted above in Section III.H.1, the entire engagement surface of the tension member need not come into contact with the sheave. Therefore, even if the tension member surface and sheave surface were a precise fit (i.e., contoured to be perfectly complementary), they still might not be in full contact at all times. Next, as previously noted, strict reliance on the figures contained in the patent is improper. See MBO Labs, Inc., 474 F.3d at 1333; Kara Technologies, 582 F.3d 1341, 2009 U.S. App. LEXIS 21120, at *13. Finally, Schindler's assertion that the existence of any gap between the tension member and sheave would reduce overall friction is not accurate. For example, if a belt was contoured in a wave pattern (such as the belt contained in Figure 5) it may have more surface contact with a similarly contoured sheave than a comparable flat-surfaced belt and flat-surfaced sheave-even if there were slight gaps between the contoured belt and sheave in particular locations. For these reasons, the Court does not find Schindler's arguments in support of its construction of "contoured to complement" to be compelling.

Otis' suggests that the Court construe "contoured to complement" to mean "shaped to guide engagement of the tension member with the sheave." This functional description of the contours of the tension member is appropriate, as it "tells us something about the structural requirements" of the claim. K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1363 (Fed. Cir. 1999) (noting that where a functional purpose requires a certain structure, the statement of function can serve as a claim limitation).

The Court will adopt Otis' construction, and interpret "contoured to complement" to mean "shaped to guide engagement of the tension member with the sheave."

IMS contends that the district court erred when, based on the preambles of claims 1 and 7, it limited those claims to a "control system for machine tools rather than an entire machine tool apparatus." To the extent that the district court's claim interpretation precludes a finding of infringement by a machine tool apparatus that includes the claimed control-related limitations, we agree that the district court improperly limited the claims.

"[A] claim preamble has the import that the claim as a whole suggests for it." Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620, 34 U.S.P.Q.2D (BNA) 1816, 1820 (Fed. Cir. 1995). If the preamble adds no limitations to those in the body of the claim, the preamble is not itself a claim limitation and is irrelevant to proper construction of the claim. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 U.S.P.Q.2D (BNA) 1161, 1165-66 (Fed. Cir. 1999). That is the case here. The phrase "control apparatus" in the preamble merely gives a descriptive name to the set of limitations in the body of the claim that completely set forth the invention. Its use does not limit the claims, as Haas contends, to a control apparatus that is separate from the machine tool. The claim is infringed by any apparatus encompassing all of the limitations in the body of the claim. Such an infringing apparatus may be a machine tool apparatus that includes the claimed control features or a control apparatus that is separate from and communicates with a machine tool apparatus.

The prosecution history is consistent with this interpretation. In a restriction requirement, the PTO recognized that the claimed invention, a machine tool control, was part of a machine tool. In sum, the applicant's choice to elect claims directed to machine tool control rather than machine control structure does not limit the scope of the claims to a control apparatus that is separate from the machine tool itself.
7. "control button" or "first [or second] control button that enables a first [or second] player to activate or deactivate the first beam emitting device"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendants' Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>A &quot;control button&quot; is a structure that can control the operation of a device. In the context of the patent-in-suit, the &quot;control button&quot; controls the operation of a beam emitting device (for example, a laser)</td>
<td>The phrase &quot;first [or second] control button that enables a first [or second] player to activate and deactivate the first beam emitting device&quot; is a control button means, that is permanently mounted to the raised periphery surrounding the game board adjacent to the first [or second] beam emitting device, which is likewise permanently mounted to the game board, for enabling a first [or second] player to activate and deactivate the first beam emitting device</td>
</tr>
</tbody>
</table>

a. Innoventions' Proposed Construction

Innovention insists that its invention does not require a raised periphery surrounding the game board, which means that the claims do not require that the "control buttons" be permanently mounted to such a structure. Innovention asserts that Claim 13 specifically locates the "control buttons" on the "game board" but that the claims themselves imply that claims 1, 15, and 25 require no such further limitation. Finally, Innovention contends that the defendants' reliance on the prosecution history is misplaced because Innovention did not raise any distinction as to the location of the "control buttons."

b. Defendants' Proposed Construction

The defendants contend that Innovention's proposed construction fails to account for the plain language of the term, the specification, and explicit statements made to distinguish the invention from prior art. The defendants point out that the claims themselves do not recite the location of the control button; instead, the claims specify only the function that the control button performs. However, the defendants insist that, when read in their entirety, the language of the claims clarifies the location of the control button. 14 The plain meaning of the claims, say defendants, is also supported by the specification, which states that the control buttons (designated by numerals 19 and 20) are positioned at opposite ends of the raised periphery of the game board, as shown in Figure 1. Finally, the defendants point to the prosecution history: the defendants insist that, to overcome prior art, Innovention argued that the prior art did not describe any laser control buttons on the game board.

14 The defendants say that it logically follows from the language of Claim 1, which recites that the first and second beam emitting devices are mounted to the game board and that the first and second control buttons enable players to activate and deactivate the beam emitting devices, that the control buttons must also be mounted on the game board.

c. The Court's Proposed Construction

As used in the claims, "control buttons" are used to activate and deactivate beam emitting devices -- the latter are taught by the claims as being mounted to the game board. The Court finds that an ordinary person skilled in the art of laser board games would be sufficiently apprised of the meaning of "control button" from the ordinary meaning of the term and its contextual use in the claims. Accordingly, the "control button" is simply "A structure that activates a beam emitting device."
2. Meaning Of "Control Head".

Claim 1(c) of the '904 patent discloses "a control head for operator control by a person in the vehicle." Dependent claims 6, 7, and 8 further provide that the control head is mounted inside the vehicle, includes a power on/off switch and a record/stop switch subject to operator control, and includes an LED display for displaying the date, time, and operational status of the surveillance system.

The specification of the '904 patent discusses the "control head" as being mounted in the driver's compartment of the vehicle, within "easy reach of the police officer" to facilitate operation of the system. The LED display lights indicate when the tape is nearing the end and whether the microphone is operational. The control head also is discussed as including a light indicating whether the system is on. To insure the integrity of the videotape, the control head is designed so as to prevent rewinding and erasure by recording over the video tape.

Neither plaintiffs nor defendant has introduced any prosecution history to support their proposed interpretations of "control head." The prosecution history provides that the vault which holds the video recorder is in a locked compartment of the vehicle. When read in the context of the specification, this statement confirms that the "control head" provides a means for remotely operating the video recorder.

From the patent claims, specification, and prosecution history, the court construes "control head" to mean a control panel that is located within the vehicle and is accessible to the vehicle operator, and that provides a means for remotely operating the video recorder.

3. Claim 8(f) -- "pipe path control means"

Limitation (f) of claim 8 states "pipe path control means for determining a pipe path within said piping between a pair selected from among said first and second containers, said filter unit and said first and second coupling attachments". (Dkt. entry no. 1, Ex. A, '511 patent, at col. 12, lines 11-15.) The parties agree that this language is subject to a means-plus-function analysis. (RTI Br., at 28;Defs. Br., at 29.) However, the parties disagree about the structure that corresponds to the recited function of determining a pipe path within the piping. RTI asserts that "the 'pipe path control means' recited as element (f) of claim 8 encompasses any manual or electrical system that performs the recited function of determining a pipe path within the piping between a pair of structures selected from the first and second containers, the filter unit, and the first and second attachments." (RTI Br., at 28.) In contrast, the Defendants contend that the mental process of determining a pipe path cannot be claimed, and thus, the Court must limit its interpretation of "pipe path control means" to a plurality of electrically operated valves and a microprocessor based controller for sending operating signals to those valves to select a pipe path. (Defs. Br., at 29.)

The function explicitly recited in limitation (f) of claim 8 is determining a pipe path within the piping between a pair selected from the first and second containers, the filter unit, and the first and second coupling attachments. See Versa Corp., 66 Fed.Appx. at 855. The specification contains the following statements, which reference structures corresponding to this recited function:

Selecting the pipe path selected for an appropriate cycle can be accomplished either by manually opening and closing appropriate valves as is discussed below, or electronically through a controller such as a panel controller that provides signals to the appropriate valves when a particular cycle is selected. Microprocessor controls for controlling the opening and closing solenoid operated valves are well known. (Dkt. entry no. 1, Ex. A, '511 patent, at col. 6 lines 46- 53.)

The various operation cycles and manually operated valves may be completely or partially automated, using microprocessor based controls. (Id. at col. 10, lines 46-49.)
See Omega Eng'g, Inc., 334 F.3d at 1322 (explaining that once the function is identified, the Court must determine what structures disclosed in the specification correspond to that function); Epcon Gas Sys., Inc., 279 F.3d at 1032 (explaining same). Accordingly, the specification indicates that manually or electronically operated valves are the structures that correspond to the recited function of determining a pipe path. See Linear Tech. Corp., 379 F.3d at 1322 (noting that Section 112, paragraph 6 permits a claim element to embrace alternative described structures for performing a claimed function).

The Court notes, as previously discussed, that some level of human intervention is permissible in a patent's claims as long as a human is not a claimed structure, but instead merely operates a claimed structure. See Default Proof Credit Card Sys., 412 F.3d at 1300 (stating that a human being cannot constitute a "means", and noting that it must determine what structure the human being operates to perform the recited function). Here, the '511 patent's specification describes a manual system where a human being will operate a structure such as a knob, which in turn opens or closes a valve that determines or selects a pipe path between certain structures. Therefore, construing limitation (f) of claim 8 as encompassing manual as well as electronic systems for performing the recited function does not infer that human intervention is claimed as part of the corresponding structure.

"speed control means including a control panel"

Precor urges the Court to apply a means-plus-function construction to the disputed claim element "speed control means including a control panel" found in claims 3, 4, 13, and 21. Life Fitness argues that this disputed claim element should be assigned its ordinary meaning. The Court finds that this disputed claim element should be given its ordinary meaning, and declines to adopt a further construction.

The Court recognizes that the use of the word "means" in this disputed claim element creates a presumption of means-plus-function format. However, the Court finds that the phrase "control panel" discloses sufficient structure to overcome this presumption.

The use of the phrase "control panel" in prior art bolsters Life Fitness' proposed construction. See '822 patent at column 3, lines 65-66 (Rodriguez Dec., Ex. I) ("As generally indicated at 25, a control panel is provided at the front end of exercise treadmill 1."); U.S. Patent No. 4,643,418 ("'074 patent") at column 4, lines 29-32 (Rodriguez Dec., Ex. K) ("A control panel 21 extending between and secured to arms 20b, 20c includes a timer having a settable knob 23, and adjustable speed control knob 25 and a speedometer 152."). Moreover, figures and illustrations used in prior art depict many different types of control panels. See U.S. Patent Nos. 4,792,134; 4,643,418; 4,659,074; 4,749,181 (Rodriguez Dec., Exs. Y, J, K, L).

Because the disputed claim element discloses structure of a type clearly meaningful to one of ordinary skill in the art, the Court finds that "control panel" has an ordinary meaning and that no further claim construction is required.
(d) a pressurized source of generally incompressible liquid operatively connected to said frame, said pressurized source having an output;

(e) a valve having an input and an output;

(f) a fluid conduit mechanism connected between the output of said pressurized source of generally incompressible liquid and the input of said valve;

(g) a fluid conduit connected between the output of said valve and the inputs of each of said plurality of fluid nozzles;

(h) control mechanism for controlling the operation of said valve and the movement of said frame over the turn to be treated such that the valve periodically releases high pressure jets of generally incompressible liquid from the output of the nozzles at an output pressure commensurate with the speed of the frame over the turf and the spacing of said nozzles so that said jets of liquid penetrate through the turf into the soil such that the dispersion pattern from the output of each nozzle in the soil generally coacts with the dispersion pattern of adjacent nozzles so as to lift and fracture the soil and reduce the general turf and turf subsoil density.

As will be discussed, the parties do not agree on which specific clauses are disputed in claim 17. Plaintiff alleges that (b) and (h) are in dispute, while defendant seems to argue, without explanation, that clauses (d) and (e) are in dispute. (Def.'s Mem. Opp. Summ. J. at 24.) Defendant fails to brief this claim sufficiently, and in a conclusory fashion asserts that, "for the same reasons, Deere does not infringe claim 17 of the '744 patent either." (Id. at 30.) In a footnote, defendant also indicates that clause (h) of claim 17 must be construed as a means-plus-function limitation since it recites insufficient structure. (Id. at 29.) Given this inexactitude and the court's ultimate finding of non-infringement on this claim, the court will limit its construction to clauses (b), (e) and (h) of claim 17.

Clause (b) recites "a drive mechanism connected to [the machine's] frame for moving [the machine] in a given direction, and at a controlled speed, over the turf to be treated." (Patent '744, Col. 13, Lines 31-33.) The court concludes that this is not a means-plus-function clause. This clause does not lack sufficient structure to warrant construction under a means-plus-function analysis, nor is there language signaling that § 112, P 6 should apply. An ordinary interpretation and construction of this claim therefore must include two components: (1) a drive mechanism, i.e., some form of mechanized propulsion; 6 that is (2) connected to the machine's frame for providing this propulsion. The common understanding of the word "connected" suggests: "joined, linked or incapable of being separated." See, e.g., Merriam Webster's Collegiate Dictionary 244-245 (10th ed. 1998).

Clause (e) indicates "a valve having an input and output." (Patent '744, Col. 13, Line 41.) There is also no means-plus-function language in this clause nor paucity of sufficient structure. Thus, this limitation must be construed to reflect the ordinary meaning of the language, in other words, a valve that has in and out ports.

Clause (h) does not disclose a function nor fails to disclose sufficient structure, the court also concludes that there is no means-plus-function language invoked by this clause. It must therefore be construed to recite its ordinary and unambiguous language of delineating a "control mechanism for controlling the operation of [the conduit] valve and the movement of [the device's] frame over the turf to be treated in a way that the valve periodically releases high pressure jets … from the output of the nozzles at output pressure commensurate with the speed of the frame over the turf" so as to create the lifting and fracturing coaction needed to reduce subsoil compaction. (Id., Col. 13, Line 48-60.)
The parties agree that these phrases should be given their ordinary meanings. However, Fox argues that these phrases constitute a means-plus-function element, and should be limited to the means disclosed in the specification. Such a specially claimed element is defined in 35 U.S.C. § 112, P 6:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

When a claim does not use the term "means," a rebuttable presumption arises that the element is not a means-plus-function element. CCS Fitness, 288 F.3d at 1369. Claim 16 does not use the term "means." The presumption therefore arises that these phrases are not a means-plus-function element.

Fox can rebut that presumption by showing that the phrases recite a "function without reciting sufficient structure for performing that function." Id. The presumption is strong and not easily overcome. Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). "Control" has an ordinary meaning of "a device for regulating and guiding a machine." RANDOM HOUSE COLLEGE DICTIONARY 285 (Rev. ed. 1984); see also WEBSTER'S NEW ENCYCLOPEDIA DICTIONARY 219 (1993). Within the context of the '049 Patent, the phrase "fluid circulation control unit" means "a device that regulates the circulation of fluid within the system." That many different structures may be so described does not make this a means-plus-function element. Lighting World, 382 F.3d at 1361. The phrase is also used as the name for a structure within the parent. (7:13-14; Fig. 8) Id. Fox has failed to overcome the presumption that § 112, P 6 does not apply.

The district court restricted the meaning of "controlled" to require control of the inclination of the arms "throughout the range of motion of the pivotable joint." The district court erred in so restricting the function of the "joint means" of claim 1 of the '169 patent, which literally recites merely "allowing controlled medial and lateral inclination of each rigid arm relative to the pivotable joint."

The construction of the function of the "joint means" in the present case is analogous to our construction of the "weighing means" means-plus-function limitation in Micro Chem. In that case, the recited function of the "weighing means" was "weighing different weights of" additives or "determining the weights of" additives. Micro Chem, 194 F.3d at 1258, 52 U.S.P.Q.2D (BNA) at 1263. Because the specification disclosed multiple methods of weighing, and at least one method of weighing was disclosed as being "too slow or too inaccurate" for handling additives, id. at 1255, 52 U.S.P.Q.2D (BNA) at 1261, the district court limited the function of "weighing" to include only the sequential and cumulative weighing described in the preferred embodiments of the invention, id. at 1258, 52 U.S.P.Q.2D (BNA) at 1263. Despite the fact that there were multiple methods of weighing disclosed in the specification, at least one of which was disclosed as being undesirable, this court refused to limit the function of weighing beyond its ordinary meaning. Id. at 1258, 52 U.S.P.Q.2D (BNA) at 1263. The court reasoned that to do so would impermissibly limit the claim by adopting a function different from that explicitly recited in the claim, and such an error in identification of the function could improperly alter the identification of the structure corresponding to that function. Id.

In this case, Med Tech argues that because there are different types of control, i.e., static control and dynamic control, and because the teaching of the specification implies that the "joint means" performs only dynamic control, the "control" function must be restricted to dynamic control. However, under the teachings set forth in Micro Chem, we decline to restrict the claimed function of "controlled" to either static or dynamic control. To do so would impermissibly limit the claim by
adopting a function different from that explicitly recited in the claim, and such an error in identification of the function could improperly alter the identification of the structure corresponding to that function.

Med Tech likens the term "controlled" to the term "when" at issue in Renishaw PLC v. Marposs Societa’ per Azioni, 158 F.3d 1243, 48 U.S.P.Q.2D (BNA) 1117 (Fed. Cir. 1998). Med Tech's assertion lacks merit for a number of reasons. First, in the present case, we are construing the functional statement in a means-plus-function limitation. When construing the functional statement in a means-plus-function limitation, we must take great care not to impermissibly limit the function by adopting a function different from that explicitly recited in the claim. Micro Chem, 194 F.3d at 1258, 52 U.S.P.Q.2D (BNA) at 1263.

Second, in Renishaw, this court found in the specification a clear intent of the inventor to limit the term "when" to a more specific "at the time of or immediately thereafter." The court relied on several passages in the specification indicating that the invention was aimed at making the delay between stylus contact of the workpiece and signal generation "as small as possible." Id. at 1253, 48 U.S.P.Q.2D (BNA) at 1124.

Med Tech's application of Renishaw to the facts of this case is flawed, because defining the term "when" to include instantaneous generation of the trigger signal was clearly necessary to give effect to the patentee's description of the invention as having but a singular purpose, namely producing a machine that provides very accurate, very precise probe readings by maintaining tight control over the position of the stylus. Such readings could only be obtained if the probe triggers very soon after contacting the workpiece. In the present case, although Med Tech asserts that the "whole purpose" of the claimed brace "is the dynamic application of force to an osteoarthritic knee as the knee joint is flexed and extended," we find no evidence in the record that control throughout the entire range of motion of the knee brace is the singular purpose of the invention described throughout the specification by the patentee. To the contrary, the written description specifies that the treatment of osteoarthritis entails "applying a force to the knee as the knee moves to extension," emphasizing the importance of controlling the force applied to the knee when the leg is in a fully extended, weight bearing position and suggesting that the purpose of the invention is served by control over less than the entire range of motion of the knee brace. '169 patent, col. 1, ll. 12-14 (emphasis added).

"Controlled dose"

Cytyc's proposed construction
(no construction required)

Xoft's proposed construction
(indefinite)

"To reduce or prevent necrosis in healthy tissue proximate to the expandable surface"

Cytyc's proposed construction
(no construction required)

Xoft's proposed construction
(indefinite)

"Providing a controlled dose at the outer spatial volume expandable surface to reduce or prevent necrosis in healthy tissue"

Cytyc's proposed construction
Controlling the ratio of the dose at the expandable surface of the outer spatial volume to the prescribed dose at the depth of interest in the target issue so that the dose at the expandable surface is not so high that it lethally damages cells in healthy tissue in contact with the expandable surface

Xoft argues that the patent does not reveal how one goes about controlling a dose using the device and that "reducing necrosis" is a hopelessly vague concept, making the '204 patent indefinite. Xoft, however, has presented no evidence that one skilled in the art would not be able to understand the patent and has again failed to meet its burden of proof. The court will therefore adopt Cytyc's construction proposals. "Providing a controlled dose at the outer spatial volume expandable
surface to reduce or prevent necrosis in healthy tissue" means "controlling the ratio of the dose at the expandable surface of the outer spatial volume to the prescribed dose at the depth of interest in the target issue so that the dose at the expandable surface is not so high that it lethally damages cells in healthy tissue in contact with the expandable surface."

B. Controller

The term "controller" is disputed by the parties. Microfil asserts that the term "controller" should be limited to a single device that controls the entire automated pill dispensing system. (Def. Resp. SJ for Infr. 6). AutoMed, on the other hand, asserts that the modifier "single" does not appear in the claims, the specifications, or the prosecution histories and that the term should be construed to mean a device or system that regulates a process or another device. AutoMed's construction, however, is inconsistent with the written specification. In the written specification, the patentee clearly states that a control system regulates all aspects of the automated pill dispensing device. For example, the written specification states that "the control system places a refill request with the vibratory dispenser," that the "control system assigns at least one accumulation receptacle," and that the control system controls the various processes employed by the system. ('927 Patent Col. 9 L. 48-51, Col. 10 L. 12-14, Col. 11 L. 43-46; '671 Patent Col. 9 L. 61-63, Col. 10 L. 14-16, and Col. 11 L. 44-47). Accordingly, while the patentee did not modify the term controller with the word single, the specification indicates that a single control system regulates the entire process.

1. "Controller"

The district court construed the term "controller" to mean "a single control system [that] regulates the entire process." In so doing, the district court rejected AutoMed's preferred construction of "a device or system that regulates a process or another device" as inconsistent with the specification. AutoMed Techs., Inc. v. Microfil, LLC, No. 04-CV-5596, 2005 U.S. Dist. LEXIS 26032, slip op. at 17-18 (N.D. Ill. Oct. 26, 2005) ("Claim Construction Opinion"). In applying this construction, the district court then held that "multiple controllers . . . coordinated by a master computer" could not constitute a single control system. Infringement Opinion, 2006 U.S. Dist. LEXIS 2439, slip op. at 8. In effect, the district court's application treated the "single control system" as referring to a single control device. Id. (emphasis added). AutoMed argues that the district court erred by limiting "controller" to a single control device, while Microfil urges us to adopt a definition from a technical dictionary, which defines "controller" as "[a] module or specific device which operates automatically to regulate a controlled variable or system." Charles J. Sippl, Microcomputer Dictionary 85 (2d ed. 1981). Microfil misrepresents this definition in its brief, however, by introducing the modifier "single" before "module or specific device," and by ignoring the first definition listed, which recites "[a]n element or group of elements . . . ." See id. (emphasis added). The cited dictionary
definition does not limit the term "controller" to a device as distinguished from a group, collection, or system of devices.

We agree with the district court's initial construction, with the clarification that the "controller" need not be limited to a single device, as applied by the district court and asserted by Microfil. We see no basis in the intrinsic record to warrant reading the term "controller" to be limited to a single device or to any particular hardware or software. The specifications of the '671 and '927 patents support a broad interpretation of "controller." While the specifications differ in some respects, these differences are not material to our analysis here; we rely on text common to both specifications. Moreover, "the same term or phrase should be interpreted consistently where it appears in claims of common ancestry." Epcon Gas Sys. v. Bauer Compressors, Inc., 279 F.3d 1022, 1030 (Fed. Cir. 2002). The specifications disclose at least two structures that perform control functions: a "controller 180," which apparently controls only the rate of vibration; and a "control system 80," which seems to control many aspects of the entire process. Compare, e.g., '927 patent col.8 ll.51-59, with id. col.11 ll.43-46.

Unfortunately, the specifications fall short of clarity in outlining the exact functions and details of the control system software and hardware. Even though the relationship between these structures is not entirely clear from the written description, what is unmistakable is that no single device is disclosed which performs or is capable of performing all of the functions recited in claim 1 of the '927 patent, namely, to receive a patient's prescription information and to control the entire apparatus, including the vibratory dispenser, the container transport assembly, and the vial transport assembly. See '927 patent claim 1. To the contrary, the patents describe only in general terms the control of several distinct systems and processes. E.g., '927 patent col.8 ll.1-2 (drive unit vibration); id. col.10, ll.58-62 (vial transport); id. col.11, ll.47-63 (patient entry process). With all due respect to the view expressed in the dissent, a construction of the term "controller" to be "a single module or specific device which operates automatically to regulate a controlled variable or system," as argued by Microfil, would fly in the face of the specification and would engraft onto the claims an unwarranted limitation. See Phillips v. AWH Corp., 415 F.3d 1303, 1322-23 (Fed. Cir. 2005) (en banc) (cautioning that dictionary definitions cannot be used to "contradict any definition found in or ascertained by a reading of the patent documents" (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 n.6 (Fed. Cir. 1996))). Without a clear indication from the patentee that a single device must control these varied functions, it is improper to limit the term "controller" to a single device rather than a single system. Accordingly, while we affirm the district court's initial construction of "controller" to mean a "single control system that regulates the entire process," we clarify that the controller need not be limited to a single device, nor to any particular hardware or software.

6. "controlling"

Claim 14(h) states "controlling the kinetic energy of ions entering said first rod set to maintain such kinetic energy at a relatively low value." Micromass asserts that the proper construction of "controlling" is "to exercise restraining or directing influence over," "regulate," or "to have power over." It then argues that the claim specification nowhere discloses how one might practice the method of "restraining or directing influence over" the kinetic energy of ions, other than perhaps the use of an offset voltage between 1 and 30 volts, and possibly up to 40 volts, between the inlet orifice and the first rod set. Although it does not say so, it appears that Micromass is proposing to the court a definition of "controlling" that would require the practitioner of the invention to use these voltage parameters.

AB/Sciex disagrees. It argues that the meaning of "controlling" is clear and does not require construction by the court. Moreover, Micromass's proposed construction seeks to import from the specification limitations not listed in the claim.

The court agrees. As Micromass notes, the meaning of "controlling" is well understood as "exercising restraining or directing influence over." This meaning is unambiguous and clear from the claim. The fact that the specification may recite particular voltage levels by which the control can be administered neither contradicts this construction nor introduces further clarity. Instead, Micromass is seeking to import parameters existing only in the specification to the claim limitations themselves. It may not do so. See Intervet Am., Inc., 887 F.2d at 1053.
B. Controlling a Parameter of the Light Beams

The dispute about the construction of "controlling a parameter of the light beams" centers on whether time is a parameter of the light beams. The term "parameter" is used in Claim 1 of the 272 patent as follows: "controlling a parameter of the light beams to produce spots of different sizes whereby the appearance of smoothed edges are given to the generated shapes." 272 pat., col. 6, ll. 27-30. Thus, based on the claim language, relevant parameters are any parameters that may be controlled to produce "spots of different sizes," which are used to generate shapes with "smoothed edges." Id. The plain meaning of the claim indicates that more than one parameter is disclosed. The issue is thus whether the 272 patent disclosed time as a parameter that may be controlled to produce such spots of different sizes.

The court finds that time is a parameter claimed in the 272 patent. As the Federal Circuit said:

The 272 patent teaches two methods for varying toner dot size. First, as illustrated in Figure 1 of the 272 patent, an intensity modulator 64 can be attached to the source of the light beam. The degree of exposure on the photoreceptor is determined by two factors: (1) the intensity of the beam of light; and (2) the length of time that the beam of light remains in contact with the surface of the photoreceptor (which factor is termed the pulse width).

Pitney III, 182 F.3d at 1302. The ordinary meaning of a parameter is "a typical element." Webster's II New College Dictionary (1995). The pulse width or duration for which a light beam is on is a "typical element" of a light beam just as the intensity of the beam and the diameter of a beam are typical elements of a light beam. Thus, under its ordinary meaning, time is a parameter of a light beam.

In addition, the plain meaning of the language of Claim 1 indicates that the claim is not limited to the specific parameters of intensity and duration. Claim 1 claims a method for "controlling a parameter of the light beams to produce spots of different sizes . . ." 272 pat., col. 6, ll. 27-28. Such language is inclusive. The claim provides for a method for controlling a parameter, meaning any parameter, not for controlling only specified parameters. 2 Thus, under the ordinary meaning of the claim language, time is a parameter of the light beam. The issue is whether Pitney disclaimed time as a parameter in either the specification or the prosecution history.

During oral argument on April 24, 2001, Hewlett argued that, under the recent Federal Circuit decision in Netword v. Centraal Corp, 242 F.3d 1347 (2001), the claims at issue could not be construed to include time as a parameter of a light beam. In Netword, the Federal Circuit affirmed the district court's construction of a claim term where the district court relied on the specification and the explanation of an expert witness to limit the system at which the claim at issue was directed. Id. at 1351. The Federal Circuit stated:

Netword's argument that the district court improperly limited the scope of claim 1 by importing the caching and pulling functions from the specification misperceives the role of claim construction in infringement analysis. The role is neither to limit nor to broaden the claims, but to define, as a matter of law, the invention that has been patented. The claims are always construed in light of the specification, of which they are a part. The role of the specification includes presenting a description of the technologic subject matter of the invention, while the role of claims is to point out with particularity the subject matter that is patented. The claims are directed to the invention that is described in the specification; they do not have meaning removed from the context from which they arose.
Id. at 1352 (internal citations omitted). Hewlett argues that, based on this language, time cannot be a parameter of a light beam because the specification does not describe it as such.

Unlike Netword, however, the specification in this case does not contain language that specifically limits parameters to intensity and diameter. In Netword, the specification stated that the local server database that was the issue of the claim construction "contains only certain of the Resource Aliases and their records" and that the central registry computer "maintains the entire collection of Resource Aliases in its database." Id. at 1351 (emphasis added). The 272 patent specification does not similarly specify intensity and diameter as the only parameters or indicate that time is not a parameter. Pitney does not, therefore, disclaim time as a parameter in the specification.

Further, the specification refers to the on-off gating of the modulator. 272 pat., col. 2, ll. 20-23; col. 3, ll. 10-11. The intensity modulator, used to control toner dot size, is attached to the source of the light beam and controls the degree of exposure on the photoreceptor by controlling either the intensity of the beam of light or the length of time that the beam of light remains in contact with the surface of the photoreceptor. 272 patent, Fig. 1. While not explicitly listing time, or pulse width, as a parameter of a light beam, the references to the on-off gating of the modulator in the specification indicate that Pitney did not intend to disclaim it as a parameter.

Hewlett argues that the only parameters Pitney refers to in the prosecution history prior to the reexamination are intensity and diameter and, therefore, Pitney disclaimed time as a parameter. Hewlett points to Pitney's response to the Examiner's rejection on September 23, 1981. HP Ex. K. One of the concerns raised by the Examiner was that it was unclear how one photoreceptor would distinguish between a plurality of beams and how one or both beams would be controlled. Pitney responded that "use of such plural beams is only one parameter that may be used for controlling dot sizes." Id. at 3. Pitney noted that "the size of a dot can be controlled by varying the intensity." Id. Hewlett argues that, because Pitney did not mention duration as a parameter, it cannot be considered one. There is nothing to suggest in its response that Pitney was making an exclusive list of the parameters that could be varied. It was responding to a specific concern about the use of plural beams and mentioned another parameter, intensity, that could be controlled. This response was not a disclaimer of time as a parameter.

Hewlett also argues that time cannot be considered a "parameter" of the light beams because of the Examiner's treatment during reexamination of a character rounding technique disclosed in an article by J. R. Kinghorn ("Kinghorn"). HP Ex. S. Such character rounding is accomplished by controlling the duration for which the electron beam is on. HP Ex. S at 230. Hewlett argues that, because the Examiner did not cite Kinghorn as an invalidating reference but did reference prior art that disclosed the parameters of diameter and intensity, the Examiner did not consider time a parameter of the light beams. There is no basis to assume, however, that the Examiner excluded the Kinghorn cite because she did not consider time a parameter of the light beam, as opposed to some other reason.

Hewlett finally argues that Pitney disavowed time as a parameter of the light beams in distinguishing the Spicer reference during the reexamination. Spicer discloses a system for generating dot matrix characters in a CRT display that uses a technique for "smoothing between the parts of a character in one row and the next." U.S. Patent No. 4,095,216 ("Spicer patent"), col. 3, ll. 11-12. Pitney distinguished Spicer first by noting that Spicer is "directed towards a display of alphanumeric data on TV receivers. Thus, no light beams are involved in the creation of this display." HP Ex. G at 40. Pitney further distinguished it from the 272 patent because Spicer "generates dot matrix characters in which a diagonal line in a character is formed by causing the focused scanning beam to turn on for a longer period of time." Id. at 40-41. Thus, Spicer applies "full length traces and half length traces next to each other . . . There is no change in spot size, only in the length of the trace on the CRT screen." Id. at 41. Pitney did not disavow time as a possible parameter of a light beam in distinguishing Spicer because Pitney distinguished Spicer based on the fact that Spicer does not disclose a light beam and does not disclose a means for changing spot size. In making this distinction, Pitney did not state that time was not a parameter of a light beam controlled by the method disclosed in the 272 patent.

During the reexamination of the 272 patent, Pitney made several statements in which it described time as a parameter of the light beams. Arguments made during reexamination proceedings "are relevant prosecution history when interpreting claims." E.I. Du Pont De Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1439 (Fed. Cir. 1988); accord Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1270 (Fed. Cir. 1986). These statements were made during reexamination while this litigation was pending and may, therefore, be self-serving statements, which should be "accorded
no more weight than testimony of an interested witness or argument of counsel." Moleculon, 793 F.2d at 1270. Hewlett
attempts, however, to use other statements made during the reexamination as evidence that Pitney gave up time as a
parameter. For example, as discussed above, Hewlett argues that Pitney disclaimed time as a parameter in distinguishing
the 272 patent from the Spicer patent during reexamination and that the PTO did not consider time a parameter because of its
treatment of Kinghorn. Hewlett cannot have the court examine some remarks but ignore others made during the same
proceeding.

During the reexamination proceedings, Pitney described time as a parameter when it explained that 'intensity and duration
have equivalent effects on the size of the spot on the photoconductor, as does laser beam diameter.” Affidavit of Katie
Crosby in Support of Pl. Pitney Bowes 'Mem. on Claim Constr., Dkt. No. 269 [hereinafter PB Ex.], Ex. 17 at 25. Pitney also
stated 'it can be seen that the spot size of the discharged area on the photoreceptor is a function of the exposure of that area
to the laser beam. Therefore, varying the exposure or energy (either intensity or duration) of the laser beam, will create
different size spots on the photoreceptor.” Id. at 13-14. Finally, Pitney noted that "according to the invention, if the intensity
is reduced, or its equivalent time of exposure is made shorter, a smaller spot is produced." Id. at 41. Such statements indicate
that Pitney did not disclaim time as a parameter. In addition, the statements demonstrate that, even if prior art controlled the
time that a laser was left on, the patent office reissued the patent over such prior art when Pitney specifically claimed that
time was one of the parameters that the method in Claim 1 controlled.

Because the ordinary meaning of parameter includes the pulse width and because neither the specification nor the
prosecution history demonstrate that Pitney intended to exclude pulse width as a parameter, the court concludes that the
term "controlling a parameter of the light beams" includes controlling the length of time that the beam of light remains in
contact with the photoreceptor. The parameters or typical elements of the beams that may be varied to produce spots of
different sizes to smooth the edges of generated shapes include intensity time, and beam diameter.

962

9. controlling a pressure of the flow of breathing gas delivered to a patient based on a product of . . .

This phrase is found in Claims 29 and 32 of the '517 Patent.

Phrase: controlling a pressure of the flow of breathing gas delivered to a patient based on a product of the expiratory gain
and the fluid characteristic during at least a portion of an expiratory phase of such a patient's breathing cycle, so that a
pressure of the flow of breathing gas delivered to the patient during at least a portion of the expiratory phase varies with
fluctuations of the fluid characteristic.

Construction: controlling the pressure of breathing gas delivered to a patient during at least part of the expiratory phase so
that it fluctuates in relation to the patient's flow rate, by multiplying the constant expiratory gain value by the flow rate.

Reasoning: The dispute between the parties as to the meaning of this phrase centers around whether and how the step-plus-
function limitation applies to it under 35 U.S.C. § 112, P 6. However, we can see no validity in defendant's argument on this
point. The portions of the prosecution history on which defendant relies do not even address the claims that are being
asserted in this case. For instance, defendant cites to an amendment to Claim 45, which corresponds to claim 1 in the final
published patent. That claim specifically recites a "processing means". Claims 29 and 32 are not discussed in the office
action response on which defendant relies.

Construing this claim element is straightforward after dispensing of defendant's step-plus-function argument, and
considering previous constructions that this court has given to the term "gain" and the phrase "fluid characteristic."

963

(b) controlling said supply of gas . . . based on said fluid characteristic signal and said first gain
This phrase is found in Claim 23 of the '575 Patent.

Phrase: controlling said supply of gas . . . based on said fluid characteristic signal and said first gain

Construction: The supply of gas is controlled based on the flow rate signal and a constant value that is applied to either boost or reduce the delivered pressure.

Reasoning: There is little dispute remaining regarding the proper construction of this phrase. We have previously defined fluid characteristic to mean flow rate. The first gain is simply a constant value. The patent defines gains as constant values that, when applied to other values or signals, are used to either reduce or boost pressure. '575 Patent, cl. 13, lns. 36-52; cl. 15, lns. 8-35. We reject defendant's argument that this phrase is limited to any particular formula or illustration of its concepts.

GO BACK

"Controlling the partial pressure of at least one of the vapors"

Although neither the language of the claim nor the specification of the patent sets forth any particular method for controlling the partial pressure, ASM argues that the pressure must be controlled through use of a feedback loop. ASM's expert, Martin Hammond, states that the specification shows the maintenance of a constant pressure in the reaction chamber by various feedback loop mechanisms. (Brown Decl., Ex. F (Hammond Expert Report) at 9.) Hammond points to the presence of mass flow controllers at several points in the specification. (See, e.g., '568 patent 5:19-27.) According to Hammond, one of ordinary skill in the art knows that mass flow controllers would be required to achieve the necessary precision, and that they use measurement and feedback control. (Hammond Expert Report at 9-10.) Hammond also points to the specific subatmospheric pressure of 350 Torr cited at column 5, lines 53 and 63, and the fact that the native oxide is etched within ten to twelve seconds ('568 patent 5:59-61, 6:68, 7:13). Hammond contends that one of ordinary skill in the art would recognize that such a result would require active pressure measurement and control using feedback mechanisms. (Hammond Expert Report at 10.) Hammond also argues that the specific temperature control of vaporizers set forth at column 6, lines 10-39, and the controls specified therein for the total pressure and flow rate of the inert gas through each temperature-controlled vaporizer inherently require measurement and feedback mechanisms to achieve repeatable results under dynamic conditions. (Hammond Expert Report at 10.)

All of Hammond's examples, however, are from the description of a preferred embodiment, which does not limit the language of the claims. Genus' expert, William Oldham, notes that the summary of the invention does not set forth any method of controlling the pressure but simply states that "the temperature of the substrate and/or vapor and/or the pressure of the vapor are controlled to prevent vapor from condensing on the substrate until the native oxide is removed." (568 patent 3:8-11.) Oldham states in his rebuttal expert report that "mechanisms for 'controlling' the partial pressure are not discussed in the '568 patent, because one of ordinary skill in the art would have known that there are multiple mechanisms by which such control can be obtained and that the appropriate mechanisms would depend on the design of a particular reactor and a particular process." (Brown Decl., Ex. E (Oldham Rebuttal Report at 9-10.) Oldham states that one such method for adjusting the pressure is simply to adjust the flow rate. (Id. at 10.)

As the summary of the invention and the plain language of the claim support Genus' contention that the '568 patent does not require any particular method of controlling the partial pressure, the Court rejects ASM's construction, and finds that "controlling the partial pressure" needs no construction.

GO BACK
On its face, the meaning of "controlling the temperature of the substrate" is clear. There must be a method of changing and maintaining the temperature of the substrate. ASM argues, however, that the specification clearly indicates that the substrate must be heated in a particular way.

ASM points to the following language from the specification, which is the only portion of the specification that discusses the desired temperature of the substrate:

Since native oxide can be etched with HF/H[2]O vapor and HF/HCl/H[2]O vapor before condensation of the vapor on the thermal oxide surface, condensation of the vapor on the thermal oxide is preferably controlled to increase the time available to etch the native oxide before initiation of thermal oxide etch. Temperatures and pressures are controlled to defer initiation of condensation. It has been discovered that in the HF/H[2]O vapor process of the present invention, the liquid HF/H[2]O does not condense if the wafer temperature is above about 27[degree]-28[degree] C. Accordingly, applicants' process includes provision for heating the wafer above about 27[degree]-28[degree] C. such as up to 30[degree] C. via the semiconductor substrate heater described in U.S. Pat. No. 4,778,559 or with infrared or ultraviolet energy. Alternatively, the water vapor partial pressure in the reactor can be reduced to delay condensation of water vapor on the thermal oxide.

('568 patent 7:21-38.) This language appears in the section of the specification entitled "Description of the Preferred Embodiment," however. Nothing in the specification or the prosecution history requires the substrate to be heated in any particular way. As Genus points out, it is black letter patent law that "limitations from elsewhere in the specification will not be read in where, as here, the claim terms are clear." Tate Access Floors, 279 F.3d at 1371. "References to a preferred embodiment, such as those often present in a specification, are not claim limitations." Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988). "In the course of construing the disputed claim terms, a court should not ordinarily rely on the preferred embodiments alone as representing the entire scope of the claimed invention." CCS, 288 F.3d at 1370 (emphasis added). The language ASM cites to is not a definition of the term "controlling," but simply provides examples of several ways to control the temperature of the substrate.

Accordingly, the Court adopts the plain meaning of the claim language and finds that no construction is necessary.

966

Conventional Rotary Drag Bit

Claims in the '715 Patent contain the term "conventional rotary drag bit." Baker Hughes argues this term does not need construction. ReedHycalog contends the Court should construe this term to mean "a rotary drag bit having either highly backraked cutters distributed over generally the entire face of the bit or having more aggressive cutters positioned in the cone region of the bit and relative less aggressive cutters positioned toward the gage region of the bit."

The Court agrees with Baker Hughes. The term "conventional rotary drag bit" does not require construction. 15

15 Ref. No. 17 of Appendix B contains the disputed term "conventional rotary drag bit" and its construction.
In the "Amended Joint Claim Construction Chart," Durr proposes that this phrase should be construed to mean "a device capable of moving workpieces to be painted." (Am. Joint Claim Construction Chart at 1; FANUC's Ex. 1.) Durr does not support this proposed construction with any argument in its briefs, but neither does FANUC propose an alternate construction, either in its brief or in the "Amended Joint Claim Construction Chart." The court finds this construction to be supported by the ordinary meaning of "conveying device" and consistent with the intrinsic evidence. In the absence of any substantive objection by FANUC, the court will adopt the construction proposed by FANUC.

GO BACK

Having properly put back into the claims the "at least two" limitation, we next interpret the term "conveyor." "Terms in claims are to be given their ordinary and accustomed meaning, unless it appears that the inventor used them differently." Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 USPQ 473, 477 (Fed. Cir. 1984). The term conveyor is neither ambiguous nor highly technical. More importantly, there is nothing in the claims, the specification or prosecution history that would suggest a meaning other than its ordinary meaning.

The district court properly concluded that the ordinary meaning of conveyor was applicable and correctly set forth its meaning as "an apparatus that transports articles from one place to another." 5 Nevertheless, as discussed below, the district court subsequently embraced Lantech's erroneous "conveying or moving surface" definition. The term conveyor, as used in the claims and described in the specification always refers to an operative device or structure which would ordinarily be considered a conveyor. A conveyor necessarily includes components such as belts, slider plates, and drives, in addition to a moving surface.

--- Footnotes ---

5 As defined in the American Heritage Dictionary of the English Language (1981).

--- End Footnotes ---

The claims require two or more conveyors or conveyor means and not two or more moving surfaces. There is nothing in the specification or prosecution history to suggest that a conveyor is defined as merely a moving surface. While a conveyor has a moving surface, a moving surface alone is not a conveyor.

GO BACK

Conveyor is the only disputed claim term that we must construe in order to determine Garvey's likelihood of success. 2 This term is used in claim 1 when describing the second conveying means:

(b) second conveying means for receiving products from the first conveying means, for accumulation and movement of products on and around the second conveying means and for delivery of products to the first conveying means for movement to the downstream destination, said second conveying means solely comprising a single, continuous looped path, curvilinear shaped conveyor, the conveyor path being substantially located in the same transverse plane as the first conveying means, at least one section of the second conveying means being in substantial adjacent alignment with at least one section of the first conveying means, both conveying means, at all times when in adjacent alignment, moving in the same direction.

(R. 27, Defs.' Resp., Ex. 1. U.S. Patent No. 6,575,287, col. 7, lines 7-20 (emphasis added).) The ordinary meaning of conveyor, according to Merriam-Webster's Online Dictionary, is a "mechanical apparatus for moving articles or bulk material from place to place (as by an endless moving belt or a chain of receptacles)." Merriam-Webster's Online Dictionary, at http://www.m-w.com (last visited March 18, 2005). A more technical definition of conveyor, found in the IoPP Glossary of Packaging Terminology, provides a slightly broader definition:
A horizontal, inclined, or vertical device for moving or transporting bulk materials, packages, or objects in a path predetermined by the design of the device and having points of loading and discharge fixed, or selective; included are skip hoists and vertical reciprocating and inclined reciprocating conveyors. Typical exceptions are those devices known as industrial trucks, tractors and trailers, tiering machines (truck-type), cranes, hoists, monorail cranes, power and hand shovels, power scoops, bucket drag lines, platform elevator or conveyor designed to carry passengers or the elevator operator, and highway or rail vehicles. Basically a conveyor is made up of one or more sections that transfers (via an intermittent or continuous media) such inputs (bottles, hags, caps, cartons, product, etc.), packages, cases, or pallets from one location or position to another. Each section may be driven independently at varying speeds or employ gravity as a method of transfer.

Institute of Packaging Professionals, IoPP Glossary of Packaging Terminology (Walter G. Soroka & Paul J. Zepf eds., 1998). Using these definitions, we find that the ordinary meaning of conveyor is: "a device for moving products in a path predetermined by the design of the device." We relied more on the technical definition than the ordinary definition because: (1) it provides "the full range of [conveyor's] ordinary meaning as understood by persons skilled in the relevant art," Texas Digital, 308 F.3d at 1202; (2) "device" is more appropriate than "mechanical apparatus" because some conveyors, such as gravity-powered slides, have no mechanical parts; and (3) "in a predetermined path" is more appropriate than "from place to place" because it distinguishes industrial devices such as forklifts and cranes.

2 The parties also have a small grammatical dispute: whether conveyor is modified by the preceding term "single." We find that "single" modifies "conveyor" because the indirect article "a" modifies conveyor and indicates that conveyor is a singular word. Furthermore, claim 32 uses the phrase "continuous looped path of the conveyor," which also indicates that "single" should modify "conveyor." (R. 27, Defs.' Resp., Ex. 1, U.S. Patent No. 6,575,287, col. 10, lines 37-38.)

Defendants asserted during the preliminary injunction hearing that the term conveyor should be limited by the patent's written description to conveyors that are "constructed of interlocked segments." (Col. 4, line 14.) The written description can be used to construe claim terms, but it cannot be used to limit the scope of the patent's claims. Liebel-Flarsheim, 358 F.3d at 904. Accordingly, we decline to incorporate this limitation into our construction of the term conveyor. Defendants also assert that Garvey disclaimed the use of multiple conveyors while prosecuting this patent. (R. 27, Def.'s Resp. at 11.) Garvey's disclaimer, however, has already been incorporated into the patent's claims because the second conveying means solely comprises a single conveyor. After reviewing the patent's claims, written description, and prosecution history, we accord the term conveyor the ordinary meaning provided above because this construction does not render any claim language meaningless or unamenable to construction. 3 See Prima Tek, 318 F.3d at 1148.

3 Garvey also requested that this Court construe the term conveyor as a device that moves articles from place to place in the same direction or without reversing their direction. (R. 35-2, Pl.'s Reply at 11.) There is nothing in the patent to support this construction, and Garvey provides no extrinsic evidence other than a self-serving declaration. Moreover, Garvey, while prosecuting this patent, distinguished prior art because it used "various conveyors, traveling in opposite directions." If a conveyor by definition never reverses direction, Garvey would not have specified that those conveyors "traveled in opposite directions." (R. 27, Defs.' Resp., Ex. 7, Prosecution History at 5.) Thus, we also reject Garvey's proposed construction.

a. "Conveyor Drive Means"

During claim construction, Magistrate Judge Valdez construed the term "conveyor drive means" as simply a "drive for the conveyor." Magistrate Judge Valdez concluded that this was not a means-plus-function term because the claim recites
sufficient structure for performing the recited function. Neither Goss nor the Defendants objected to this construction and it was adopted by Judge Manning. Although none of the parties raised, briefed, or argued the issue before Special Master Harmon, he nevertheless recommended that the Court overrule Judge Manning's construction of the term "conveyor drive means." Goss objects to this new construction.

As discussed above, while there is a presumption that a claim element that uses the word "means" is a means-plus-function term, that presumption can be rebutted if the claim element includes sufficient structure for the claimed function. See TriMed, Inc. v. Stryker Corp., 514 F.3d 1256, 1260 (Fed. Cir. 2008). Here, the claim language "conveyor drive" provides sufficiently definite structure to overcome the means-plus-function presumption. The structure is a "drive," that includes a "variable speed motor," or "a motor." (see U.S. Patent No. 6,082,724 col. 14 ll. 48-65; col. 19-20 ll. 25-32, 1-30.) Thus, the Court sustains Goss's objection to Special Master Harmon's recommendation to construe the term as a means-plus-function limitation and adopts Judge Manning's construction of the term.

3. "Convex Top Surface"

The district court construed "convex top surface" to mean "an upper surface with an outward curve that has a ratio of its radius of curvature to width of the board between 4:1 to 6:1." Claim Construction Order, 2002 U.S. Dist. LEXIS 27501 at *23. It noted that "the specification does not contain any indication that the term convex top surface is to be assigned a specific range of curvature." 2002 U.S. Dist. LEXIS 27501 at *21. The district court relied on statements the applicant made in the prosecution history that "the preferred [radius of curvature] ration [sic, ratio] is about 5:1." 2002 U.S. Dist. LEXIS 27501 at *22.

Nystrom argues that the district court erred by ignoring the ordinary and customary meaning of this claim term, which is "an upper surface with an outward curve," and by importing additional limitations into this claim term from the written description. He observes that claim 1 does not provide an explicit radius of curvature ratio, and that such radii measurements are recited only in dependent claims 3, 7, and 13. Nystrom also argues that the district court erred in finding that he restricted the term to a specific radius of curvature to overcome a rejection based on the Zagelmeyer reference. He thus contends it was error for the court to construe "convex top surface" to include a specific radius of curvature ratio. TREX responds that the district court properly held that Nystrom limited his claim to a particular radius of curvature in the range of 4:1 to 6:1 to distinguish the invention over the prior art Zagelmeyer reference.

The dictionary definition of the claim term "convex" is "having a surface or boundary that curves or bulges outward, as the exterior of a sphere." American Heritage Dictionary of the English Language 402 (4th ed. 2000). This is consistent with the specification of the '831 patent. See, e.g., '831 patent, col. 3, ll. 10-14 ("More importantly, the board of the invention has a slightly rounded upper surface 13 that slopes gradually off to either side of the center of the board, defining a convex surface that promotes the running off of water. This surface may have a radius of curvature R1, for example, of about 24 inches."). The district court relied on statements Nystrom made during prosecution to distinguish the Zagelmeyer reference as limiting the expression "convex top surface" to a surface with a radius of curvature in the range of 4:1 to 6:1. Claim Construction Order, 2002 U.S. Dist. LEXIS 27501 at *19-20. Nystrom stated in a supplemental amendment amending claim 16 of the issued patent (referred to as claim 19 during prosecution):

Applicant then began trying different radiuses of curvature, but some were too shallow and when the board tried it tended not to shed water. Others had too short a radius of curvature and a distinct sensation of an uneven surface. Eventually, by trying a variety of curvatures, applicant discovered that a ratio of radius of curvature to width of the board of about 5:1 produced the desired result, i.e., it shed water and did not produce and uneven sensation to someone standing on it.

Claim 19 [claim 16 in the issued patent] and the claims dependent therefrom (the remaining claims have been previously allowed), are directed to a decking board that has a particular configuration which produces specific results not achieved with any of the prior art. . . . It should be noted, however, that the ratio of the radius of curvature of a board to its width can vary within certain relatively narrow limits, e.g. from about 4:1 to about 6:1, and still meet the basic objectives of the
invention, although the preferred ratio is about 5:1. Anything much outside this range does not provide satisfactory performance and/or is not acceptable to the consumer.

Supplemental Amendment, Sept. 7, 1994, at 2-3 (emphasis added). The district court noted that Nystrom's statement that "anything much outside this range . . . is not acceptable" implied that his statements regarding the radius of curvature ratio applied to the entire patent, and was not intended to apply solely to issued claim 16.

The district court erred in its analysis of the prosecution history. Nystrom's statements were expressly directed to issued claim 16. There is no indication that Nystrom intended the term "convex top surface" in all of the pending patent claims to be limited to a specific radius of curvature ratio. The district court ignored the fact that the language of claim 16 at the time Nystrom made the disputed statements included the following claim language expressly providing for a radius of curvature ratio of approximately 5:1: "said top surface having a radius of curvature that is approximately five times as great as the width of the board, thereby defining a smoothly shaped and shallow convex top surface that sheds water . . . ." Supplemental Amendment, Sept. 7, 1994, at 1 (emphasis added).

Other statements in the prosecution history support this view. Nystrom points to the examiner's prior rejection of claims 1, 2, 5, 6, 11 and 12 under 35 U.S.C. § 102(b): "This rejection is being made over the broad claims since they fail to specify any particular degree for the curve of the board." Examiner's Action, Mar. 24, 1994, at 2. The examiner eventually allowed claims 1-14 and 18 because the "prior art failed to teach both sides of the board with a curved configuration," not because the invented board specified a particular radius of curvature ratio. Examiner's Action, Dec. 8, 1994, at 4. The prosecution history did not redefine or disclaim "convex top surface" in claim 1 to be limited to a particular radius of curvature ratio. Accordingly, we hold that the correct construction of the expression "convex top surface" as used in claim 1 is the ordinary and customary meaning of an upper surface that curves or bulges outward, as the exterior of a sphere.

2. Cooling Member

The parties also dispute the meaning of the term "cooling member" in claim 1. The patent does not define or otherwise refer to a "cooling member." Plaintiff argues that the "cooling member" limitation requires "active cooling." Defendants assert that the ordinary meaning of a "cooling member" is "a part that cools" regardless of whether it utilizes passive or active cooling.

Plaintiff states that "active cooling" involves some mechanism or system effort to dynamically cool a target. Reitman Supp. Decl. P 38. Plaintiff does not define "dynamic." According to plaintiff, an example of active cooling from the 624 patent is the flow of coolant to dissipate heat from the skin. Id. In contrast, plaintiff states that a heat sink is an example of "passive cooling" because it cools the skin surface by removing heat through the scientific properties of conduction inherent in all materials in nature. Id.

There is no specific limitation in the claim that requires "active cooling." All that claim 1 requires is a "cooling member." Although various embodiments describe the delivery of a cooling fluid, the Federal Circuit has cautioned against reading limitations from the specification into the claim. See Burke, Inc. v. Bruno Indep. Living Aids, Inc., 183 F.3d 1334, 1340 (Fed. Cir. 1999); Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1989) ("References in a preferred embodiment, such as those present in a specification, are not claim limitations."). Further, plaintiff has not offered a definition of "dynamic" nor is any definition apparent from reading the patent and other embodiments.

The Court has adopted a broad definition of surface and similarly adopts defendants' broad definition of "cooling member" as "a part that cools." The Polaris WR system literally infringes the cooling member limitation of claim 1 because the light guide and electrodes act as a heat sink to conduct heat away from the skin. See Grundfest Supp. Decl. P 30. Therefore, plaintiff has shown that defendants' Polaris WR system likely infringes claim 1 of the 624 patent.
F. "cooperating to provide a desired three dimensional and/or topographic structure"

The parties dispute the meaning of the term "cooperating to provide a desired three dimensional and/or topographic structure" as it appears in claims 37, 41, and 45 of the '748 Patent. Synovis contends that no construction is necessary, but if the Court decides to construe the term, that it should be construed as "cooperating to provide a structure that is not flat." (Joint Statement at 10.) Gore, on the other hand, asserts that the Court should construe this term as "forming an integral raised center portion." (Id.)

Synovis asserts that a jury is capable of understanding the term without further construction. Alternatively, Synovis asserts that its proposed construction is consistent with the claims and intrinsic evidence, including the file history, and that the term "not flat" encompasses the concepts of "three dimensional" and "topographic." Synovis relies on the specification, which Synovis asserts provides examples of buttress material with a structure that is three dimensional and/or topographic. Synovis further argues that the three-dimensional structure of the claimed buttress material contrasts with the prior art reference U.S. Patent No. 6,656,193, which Synovis asserts disclosed two flat circular buttress material embodiments. Synovis asserts that the examiner allowed independent claims 37 and 45 because they explicitly included limitations on the buttress material structure, specifically that the buttress material must include at least two portions that cooperate to provide a desired three-dimensional and/or topographic structure. Synovis claims that Gore's proposed construction seeks to introduce a limitation that does not exist in the claims, lacks support in the intrinsic evidence, and is an attempt to improperly limit the scope of the claim to a single preferred embodiment.

Gore contends that Synovis' proposed construction is too general and that the patent provides no support for a reinforcement wherein the three-dimensional structure is not in the central, raised region. Instead, Gore asserts that its proposed construction, "forming an integral raised center portion," is supported by Figure 3 of the patent, which Gore asserts shows the second region as having an integral raised center portion that is three-dimensional on its own. Gore asserts that this second region does not need to "cooperate" with the first region to provide a three-dimensional structure. Gore further asserts that written description and the prosecution history of the '748 Patent support its proposed construction. In particular, Gore asserts that in a January 3, 2006 Office Action, the USPTO expressly allowed the claims because the examiner concluded that "[n]one of the prior art of record . . . discloses a kit with a buttress material portion . . ., where each of the portions comprise, inter alia, a circumferential disc with an integral raised center portion." (Gore Ex. 7 P 9.) Gore further asserts that Synovis acquiesced to the inclusion of the subject matter of Paragraph 18 of the published application into all of the asserted claims. Gore maintains that Paragraph 18 makes clear that the second region provides the three-dimensional structure.

The Court first looks to the claim language, which expressly provides for "the first and second regions cooperating to provide a desired three dimensional and/or topographic structure." This language, on its face, contradicts Gore's proposed construction, which does not require the second region to cooperate with the first region to provide an integral raised center portion that is three-dimensional. Further, the specification provides examples of buttress material with three dimensional structure. The Summary of the Invention provides that buttress material portions can "retain three dimensional structure and/or topographic features (e.g., raised/indented portions, ridges) that permit them to be positioned in a secure fashion upon a restrictive stapler component, e.g., by press fit or friction fit onto the corresponding grooves, apertures, ridges and edges of the stapler device component." (See ‘748 Patent c. 3, 11: 29-35.) The specification also contains an example of a buttress material structure with a three-dimensional structure. Figures 2 and 3 both show a buttress material with a circumferential disc and an integral raised center portion. With respect to Figure 2, the specification calls the "interior circumferential regions" of the buttress material "nonplanar." (‘748 Patent c. 5, 11: 46-47.) The specification also indicates that buttress structure is defined by the shapes they are adapted to fit onto. The Detailed Description explains: "The actual buttress
portions used are defined by the shapes they are adapted to be positioned upon, which for a circular stapler are typically the staple cartridge and the anvil components." (‘748 Patent c. 7, 11: 7-10.)

In addition, differences in the language of other claims suggest that claims 37, 41, and 45 are not limited to "forming an integral raised center portion." As explained above, claim 1 of the ’748 Patent recites "a circumferential disc having an integral raised center portion," while claim 37 does not. Instead, claim 37 requires the first and second regions to cooperate to provide a three-dimensional or topographic structure.

Gore relies primarily on the prosecution history to limit the claim term. Gore's arguments are similar to those made with respect to the construction of the "second region of buttress material." The Court similarly rejects those arguments here. In addition, the Court concludes that Gore's proposed construction ("forming an integral raised center portion") is not supported by the intrinsic evidence. The Court further concludes that the term has a meaning that is readily understandable and no construction is necessary.

2. Construction of "Cooperatively Engaging"

The parties dispute the meaning of the phrase."cooperatively engaging". Plaintiff Lisle seeks to construe the phrase to mean "work together to interlock." (Pl. Br. at 11). Defendant A.J.'s proposed construction of the phrase is "the retainer and the slots of the hollow tube work at the same time so that the tabs of the c-shaped wrench disc are locked into position." (Def. Br. at 16). However, the parties agree that "the plain meaning of cooperatively is to work together and that of engage is to interlock with." (Def. Br. at 16).

Before embarking on construction of this phrase, the Court will recite the phrase in its full context in claim 1: "said tube having a retainer at one end and at least two slots for cooperatively engaging the tabs of the wrench disc". (Pl. Ex. A at col. 4, line 21-24). Lisle asserts that the disputed phrase only relates to the slots of the tube and the tabs of the disc. (Pl. Br. at 11-12). A.J.'s proposed construction, on the other hand, would relate the disputed term to the slots of the tube, the tabs of the disc, and the retainer.

Looking solely at the plain language of this segment of the claim, it seems to be a victim of grammatically imprecise drafting. Reading the claim from left to right, "at one end" could refer only to "having a retainer" and "cooperatively engaging" could refer only to the slots and the tabs. It is clear from the specifications and the drawings, though, that the phrase "at one end" modifies both "a retainer" and "at least two slots". An alternative, and more precise, way of phrasing the same portion of the claim then would be: "said tube having at one end a retainer and at least two slots for cooperatively engaging the tabs of the wrench disc." This must be what the inventor intended to convey, as the invention can only accomplish its intended purpose if the tabs, the slots, and the retainer work together. This intrepretation is consistent with part (a) of claim 1, which indicates the C-shaped wrench has "outwardly projecting tabs for cooperation with a retainer". (Pl. Ex. A at col. 4, line 19-20). The Court finds that the disputed phrase "cooperatively engaging" refers to the tabs, the slots on the tube, and the retainer to operate together.

Beyond that, the Defendant has not presented any compelling arguments that the terms themselves should mean anything beyond their plain meaning. The plain meaning of the term, again, is "work together to interlock." A.J. seeks a further construction that working together requires the parts to function simultaneously. There is a danger in relying upon dictionary definitions of words that are themselves definitions of other words. As the distance from the original term ("cooperatively") increases, the precision with which any dictionary can produce the plain or ordinary meaning of the term decreases. A.J. rightly points out that "together" ordinarily connotes simultaneity, but the Court believes that "work together" is a sufficiently precise definition of "cooperatively." It would begin to move too far from the language of the claim to impose a further definition.

A.J. also seeks a further construction of "interlock" to mean "lock into position." This again presents the risk of moving too far from the claim language in constructing the claim. The term "engage" does not necessarily suggest that the retainer, tabs, and slots must "lock into position." Moreover, "lock into position" does not offer much of an advantage over "interlock" as a definition of the "engage." To function properly, the invention Rather than drift further away from the language of the claim,
the Court constructs engage to mean "interlock."

To sum up, then, the Court finds that the disputed phrase "cooperatively engaging" refers to the tabs of the C-shaped wrench disc, the retainer, and the slots of the tube. The phrase itself is constructed to mean "work together to interlock."

2. Hub Legs Collapsible by Pivoting from Coplanar Spread Configuration to Non-coplanar Configuration

Regalo also contends that the legs of the accused device do not pivot about their pivot connection into and out of the plane defined by each hinged member of the central hub to a compact non-coplanar configuration, but, rather, the leg pairs remain in the same plane as the hinged members.

Graco responds that Regalo's hub legs in the spread/open configuration diverge radially from the hub member and are coplanar with each other. The legs in the compact or folded position are substantially parallel and non-coplanar. Thus, according to Graco, the reference in the claim to a "compact non-coplanar configuration" only refers to the change in relationship between and among the legs when they arrive at the folded position. (Graco's Reply at 7.)

Regalo counters that Plaintiff ignores the fact that Claim 1 requires each hub leg to be "pivotably coupled at one end portion" to the "hub member" and at the same time requires that all of the hub legs to "diverge radially outwardly" from the "hub member" while the legs are in a "substantially co-planar spread configuration." According to Regalo, "if the legs diverge 'radially outwardly' from the hub member AND at the same time are 'co-planar,' the hub must have a plane in common with the legs. Otherwise, the adjective 'radially' has no context or meaning." (Def.'s Reply in Supp. of Mot. for Partial Summ. J. at 4.) That being said, Regalo takes this one step further and argues, under its claim interpretation, that since "coplanar" refers to the legs having a common plane with the central hub in the spread configuration, than "non-coplanar" must refer to the legs not sharing a common plane with the central hub in the folded position. Based on the above, Regalo submits that because the hinged members of its central hub fold into the same plane as the legs, or become "coplanar" with the legs, when the playyard collapses, there can be no infringement based on the limitation in the '437 patent that the hub legs be in a "non-coplanar" position when they are collapsed (assuming "non-coplanar" refers to the position of the legs with respect to the "unitary central hub member" of the '437 patent).

Despite Regalo's arguments, a review of the claim language at issue shows that there is no requirement that the central hub be substantially coplanar with the legs in the spread configuration; rather, only the hub legs need be substantially co-planar in the spread configuration. As Graco points out, "while it may be reasonable that the plane defined by the legs in the spread configuration is within the plane defined by the hub member, there is no requirement that any part of the hub member be within the same plane as the legs." (Graco's Surreply Brief at 3) (citing '437 patent, Fig. 4, hub member (166) and hub legs (206) and (212), and Fig. 10, which shows a cross-section through hub leg (208) and the hub member in the open or spread configuration of the hub legs).

Thus, Regalo's concern that the term "radially" has no meaning unless the "coplanar" and "noncoplanar" language of Claim 1 is interpreted to include the legs with respect to the hub is unfounded. An examination of the language of Claim 1 makes clear that "radially" merely refers to how the legs diverge from the hub in the coplanar spread configuration. Moreover, the final part of the of the claim language at issue specifically refers only to the hub legs, which, upon collapsing, form "a compact non-coplanar configuration where said hub legs are substantially parallel" with no reference to the central hub. Based on the above, this Court concludes that the terms "coplanar" and "noncoplanar" refer to whether or not all of the hub legs lie in the same plane. In other words, all of the hub legs lie within the same plane, or are coplanar, when the lower frame assembly is in the spread configuration, and all of the hub legs do not lie within the same plane, or are non-coplanar, when in the collapsed position.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 During oral argument, Regalo's counsel stated that Claim 1 lacks the prepositional phrase that explains what the hub legs are "coplanar" and "non-coplanar" to. (Tr., dated 7/28/00, at 39-40.) However, an examination of the entire paragraph at issue reveals that, despite referencing the central hub when describing the position of the legs in the spread configuration,
the patentee consistently used "coplanar" and "non-coplanar" when referring to just the hub legs, and the choice not to specifically reference the central hub when describing the legs in the collapsed position indicates to this Court that the terms "coplanar" and "non-coplanar" refer to whether or not all of the legs lie in the same plane. Therefore, this Court concludes that Regalo's attempt to read into the claim language the requirement that the "coplanar" and "non-coplanar" language references the position of the legs with respect to the hub is unsupported by the patent itself.

10 Counsel for Graco convincingly makes the point that because Regalo has admitted infringement with respect to its early model playyards, which contain a unitary central hub member that is structurally the same as in the Graco playyard, it is difficult to understand how its current models do not fit the claim language and, thus, do not infringe on the '437 patent. (Tr., dated 7/28/00, at 20-22, 27-28.) Indeed, although this Court is mindful of Regalo's stated position with regard to how the bi-fold hub in its current model playyards makes the structure of the lower frame of Regalo's playyard distinguishable from that of the Graco playyard, such a distinction becomes insignificant when employing this Court's interpretation of the "coplanar" and non-coplanar" language of Claim 1 of the '437 patent as referring to whether or not all of the hub legs lie in the same plane.

3. "cords"

Otis asserts that "cords" should be defined as "load-carrying groups of strands." Schindler contends that no construction of the term is necessary. Alternatively, Schindler disputes Otis' inclusion of the "load-carrying" limitation.

The Court, again, agrees with both parties in part. "Cords" are properly defined as "groups of strands." However, the term "cords" need not contain the "load-carrying" limitation.

4 The Court, above, has already determined that the invention is limited to use as a tension member in an elevator system. See section III.A.2. Therefore, the "load-carrying" function of the cords is already implied.

2. "Core." The singular component of the golf ball that occupies the geometric center of the sphere of the golf ball.

a. Because the invention of the Sullivan patents is directed to the inner and outer cover layers, there is not much discussion in the specifications about the "core" of the golf balls. Instead, the specification simply refers to the fact that the golf balls can be produced by injection molding or compression molding the inner cover layer about wound or solid molded cores . . . . Although either solid cores or wound cores can be used in the present invention, as a result of their lower cost and superior performance, solid molded cores are preferred over wound cores.

('293 patent, col. 15, ll. 16-26)

b. Although multi-component cores were known in the art at the time the patents in suit were filed, 6 Mr. Sullivan referred to "conventional solid cores" 7 without further description. Given the common understanding of the word "core," 8 I conclude that the above construction is consistent with both the intrinsic and extrinsic evidence of record.

3. Core

The parties next dispute the interpretation of the limitation requiring the claimed blocks be free from cores. See, e.g., '713, claim 61(e) ("The block is free from cores extending through the block, either from the upper to the lower surface, or from one side to the other."). CP argues a "core," as recited in the Patent claims, is "an opening extending through the block from the upper to the lower surface." Def.'s Mem. at 3C. Anchor states that "core" ordinarily means "a central and often foundational part usually distinct from the enveloping part by a difference in nature." Pl.'s Mem. at 15 (quoting Merriam-Webster's Collegiate Dictionary).

The general understanding of "core" conveyed by dictionary definitions such as that cited above, is the central or interior part of something, such as a piece of fruit or the earth. See, e.g., Webster's Third New International Dictionary 506 (unabridged ed. 1993) (defining core in the first instance as "the central and often foundational part of a body, mass or construction …"). The meaning of "core," however, like so many words, varies depending on the context of use.

The Patents do not include an express definition of this term, but do offer indicia of the understanding of the meaning of
"core" in relation to the inventions. The '015 Patent specification, particularly, provides some insight into the usage of "core" in the context of concrete retaining wall blocks. See '015, col. 10: 2-7. In discussing the manufacturing of the blocks, "core forms" are indicated as a means of preventing the formation of portions of interior mass so as to "lighten the block." Id. at col. 10: 5. As part of the molding process, the core forms prevent mix from entering the areas of their positions, thereby creating voids in these areas in the final block. Id. Figs. 11-13, col. 8: 55-56, cols. 9-10: 65-13. The representative figures indicate multiple interior voids bounded by block mass. See id. Figs. 11-13.

--- Footnotes ---

2 Drawings in the specification may play a significant role in construing the meaning of a claim term. See CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1153 (Fed. Cir. 1997).

--- End Footnotes ---

The prosecution history of the '713 Patent provides further contextual meaning: Referencing Figures 11-13, which depict the core forms used in the molding process, these remarks explain Anchor's understanding of the industry definition of a core. "Cores, as known in the industry, are larger openings in blocks which extend at least partially through the block from bottom to top, although they can go entirely through a block …. Alternatively, cores can extend through a block from side to side." Amendment and Response of 10/29/99 at 17 (Ali Decl. Ex. C). Additional support for this interpretation is found in the prosecution history of the '015 Patent, which references and discusses U.S. Patent No. 4,909,010, issued March 20, 1990 (the "Gravier" Patent). Amendment and Verified Response at 40 (Ali Decl. Ex. D). Anchor sought to distinguish this prior art, in part on the basis of the Gravier Patent's "upwardly-opening cores." Id. Figures associated with the Gravier Patent show two large voids in the body of the block that extend through and are therefore visible through the top surface. Gravier Patent, Figs. 1, 7 (Moore Decl. Ex. 17).

These materials, along with the specification, which is the primary source of interpretive evidence, establish a particular application and meaning in the art, similar to and supported by ordinary understanding. See Vitronics, 90 F.3d at 1582, 1583. Based on the usage revealed in the intrinsic Patent records, "core" is construed as "a relatively large void of constituent mass bounded by the body of the block." As explained in the specification and prosecution history, cores lessen the weight of the block and may extend partially or fully through a block.

The claim construction dispute centers around the classification of wrapped strands as either part of the "core" or part of the "cover" within the meaning of the claims of the patent. Both independent claims require, inter alia, that the core of the yarn contain at least two strands, one of which must be fiberglass. 2 Each of World's accused yarns in dispute contains a single strand of fiberglass wrapped first by a strand of Spectra (R), an extended chain polyethylene, at a rate of just greater than four turns per inch and then by two additional strands, the type of which varies among the different World yarns, at a rate of close to eight turns per inch. Whether these yarns infringe the patent depends upon whether the strand of Spectra (R) wrapped around the fiberglass strand is part of the core or part of the cover within the meaning of the patent claims. If the Spectra (R) strand is part of the cover, then World's yarns do not meet the limitations of the claims because they contain only one strand in their core.

--- Footnotes ---

2 While differences exist between the two independent claims, both require that the core contain at least two strands. Because we conclude that a strand wrapped around a central fiberglass strand is part of the cover and that, therefore, the cores of the World yarns contain only one strand, we do not discuss the claims separately.

--- End Footnotes ---

Therefore, the inquiry before this court is whether a strand wrapped around a central fiberglass strand is a member of the core of the yarn or a member of the cover of the yarn within the meaning of the patent claims. In determining the proper construction of the claims, a court may consult both intrinsic and, where necessary, extrinsic evidence. See Vitronics Corp.
v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1576 (Fed. Cir. 1996). The court should first look to the intrinsic evidence of the record, including the claims, the specification and, if in the record, the prosecution history. See id.

In examining the intrinsic evidence, the court looks to the language of the claims, both asserted and nonasserted. See id. Because a patentee can be his own lexicographer and give words in the claim meanings other than their ordinary and customary meaning, the specification must always be examined to determine if the patentee has defined any term in a manner inconsistent with its ordinary meaning. See id.

In the present appeal, the language of the claims provides only limited guidance in distinguishing which strands are part of the core and which strands are part of the cover of any particular yarn. Both independent claims limit the scope of the claimed invention, inter alia, by defining what strands must be included in the core and in the cover. Claim 1 specifies that the core must include a strand of fiberglass and a second strand that is "substantially parallel" to the fiberglass strand. Claim 11, the only other independent claim, specifies that the core must include a strand of fiberglass and a strand formed of an extended chain polyethylene. However, the claims alone do not provide conclusive guidance on how to determine whether a strand is part of the core or part of the cover. Both independent claims describe the cover as being wrapped on the core, but, while this favors a conclusion that a strand that is wrapped around a core strand is part of the cover, it does not explicitly define all strands so wrapped as part of the cover.

The specification provides more helpful guidance in determining whether a strand wrapped around a central fiberglass strand is part of the core or part of the cover. While the specification does not provide an explicit method for identifying a core strand, the specification does provide enough information about the scope of the invention that a person of ordinary skill in the art would conclude that a strand of Spectra (R) wrapped around a central fiberglass strand is part of the cover for the purposes of the claims.

The specification states on lines 36-40 of column 5 that "the yarn, according to the principles of the present invention, may be formed on a standard hollow spindle covering machine with the coverings or wrappings being at a rate of 4-12 turns per inch, with 8 turns per inch being preferred." While this statement does not, as World argues, explicitly define any strand wrapped between 4-12 turns per inch as part of the cover, it favors the conclusion that a strand wrapped at such a rate is part of the cover. Further, the interchangeable use of the words "coverings" and "wrappings" further supports the conclusion that a strand so wrapped is considered part of the cover for the purposes of the patent.

Examination of the figures and the descriptions of those figures would also lead one skilled in the art to conclude that World's innermost wrapped Spectra (R) strand is part of the yarn's cover. Figures 1 through 5 depict yarns composed of varying numbers of strands in their respective cores and covers. Without exception, every strand depicted to be and described as "wrapped" plainly constitutes part of the cover of that particular yarn. Figures 3 and 5 are particularly illuminating. Figure 3 shows a yarn composed of two parallel strands around which three strands are wrapped. The written description of figure 3 defines the two parallel strands as the core and three wrapped strands as the cover. As the three strand cover of the yarn in figure 3 is identical to the three wrapping strands in each of World's yarns in terms of the number of wrapping strands, their respective wrapping directions and their type, the description of the innermost wrapping strand in figure 3 is highly probative of the question of the proper claim construction. The relevant strand, the innermost of the three wrapping strands in figure 3, is described as being part of the cover.

Figure 5 depicts a single strand of fiberglass wrapped by two other strands. The description of the figure defines the single strand of fiberglass as the core and the two wrapping strands as the cover. This figure and its description are notable for two reasons. First, the figure demonstrates that, for the purposes of defining the word "core" as it is used by the patentee, a single strand of fiberglass can alone comprise the core. Second, the figure and its description show that a strand wrapped around a single fiberglass strand is part of the cover. Taken together, the figures strongly suggest that an innermost wrapped strand, such as the innermost Spectra (R) strand of each of World's yarns, is considered part of the cover, as that word is used in the patent.

--- Footnotes ---

3 The yarn depicted in figure 5 is not an embodiment of the claimed invention. As originally filed, the claims included a yarn with a single strand of fiberglass for a core. However, subsequent amendments during prosecution limited the invention
to yarns with cores of at least two strands. The figure and its description, however, are still relevant for determining the meaning of the words "core" and "cover."

Kolmes can only cite a single sentence in the specification in support of his argument that the core can include wrapped strands. In describing the two strand core illustrated in figure 1, the specification states that "the strands are illustrated as being placed parallel to each other, although it is within the spirit of the present invention that the core strands may be wrapped, twisted or braided together." Based on this passage, Kolmes argues that the core can include strands that are wrapped around other strands. However, the cited passage only provides that two strands "wrapped together" are considered the core of a yarn included in the claimed invention. In other words, the core can consist of two strands wrapped about one another. Presumably, the definition of "wrapping" as being at a rate between four to twelve turns per inch distinguishes "wrapping together" from "twisting together" which would presumably have a much higher rate of turns per inch. This sentence therefore does not speak to the currently relevant situation wherein a single strand of fiberglass is wrapped by other strands but does not itself wrap about any strands. Indeed, this is the only way to read this sentence in a manner consistent with the rest of the specification.

Moreover, if this sentence were to be read to include strands wrapped around other strands and if the claims were to be interpreted such that strands wrapped around other strands could be part of the core, as Kolmes argues, then it would be impossible for a person of ordinary skill in the art to determine which strands of a given yarn are part of the core and which are part of the cover. Such a construction would be impermissible as rendering the claims invalid for indefiniteness.

Taken as a whole, the intrinsic evidence requires a claim construction that would designate a strand wrapped around a central fiberglass strand as part of the cover and not the core of the yarn. While the claims and the specification do not state this explicitly, the patent when read as a whole can only lead to this construction of the claims.

The extrinsic evidence in the form of the testimony of the inventors bolsters this conclusion. Specifically, both inventors testified to the effect that a strand wrapped around a single fiberglass strand depicted in particularly exhibits or figures was part of the cover and not the core of the yarn. Such conclusions by the inventors support a claim construction that places a Spectra (R) strand wrapped around a central fiberglass strand in the cover rather than in the core.

Kolmes argues that the district court erred in placing reliance on this extrinsic evidence and cites Vitronics. However, Vitronics only states that reliance on extrinsic evidence is improper in cases where the intrinsic evidence "unambiguously describes the scope of the patented invention." Vitronics, 90 F.3d at 1583, 39 U.S.P.Q.2D (BNA) at 1577 (emphasis added). Moreover, Vitronics was concerned with the use of extrinsic evidence to alter or contradict clear statements within the intrinsic evidence. Id. at 1583-84, 39 U.S.P.Q.2D (BNA) at 1577. In the present case, the district court only turned to the extrinsic evidence after concluding that ambiguity existed in the intrinsic evidence with regard to the proper interpretation of the claims. In addition, the testimony of the inventors is consistent with the guidance provided by the patent itself. Therefore, the district court did not err in its use of the inventors' testimony.

Both the intrinsic and the extrinsic evidence support a claim construction that a strand of Spectra (R) wrapped around a central fiberglass strand is part of the cover and not the core of the yarn. As the infringement issue turns on the legal question of claim construction, the material facts not being in dispute, we hold that World's yarn styles 331, 332, 334, and 336 do not infringe the patent as a matter of law. Therefore, the district court's denial of Kolmes's motion to hold World in contempt was proper.
from the apparatus with the core pins forcing the plastic washing machine basket to shift relative to the mold core as the cavity sidewall members are shifted away from the mold core due to the engagement of the core pins in the beveled apertures of the plastic washing machine basket.

The '809 patent, Claim 8 (emphasis added).

ii. The parties' definitions and arguments. The parties' proffered definitions of this term are shown below, with bold font indicating differences between their definitions. Also, the authority on which each party relies for its definition is shown just below that party's definition.

</tr>
</tbody>
</table>

In its initial brief, Maytag argues that Claim 8 of the '809 patent not only states that the core pins aid in ejecting the basket from the mold core, but describes how this is done. Maytag contends that this language is so clear on its face that any claim construction should closely track the language used in the claim. The precise language Maytag has chosen in its construction, Maytag contends, is consistent with this clear language and the pertinent part of the specification. On the other hand, Maytag asserts that Electrolux's use of "separating" to mean "shifting" is improper, because the two terms have different meanings. Maytag also contends that describing the washing machine basket as "separated from the mold core" is a "backdoor" approach to redefining the claim to confuse "ejection" with "removal."

In its initial brief, however, Electrolux contends that this claim limitation is directed to the use of the core pins to cause the molded product to shift and separate from the mold core when the sidewalls, where the pins are located, are shifted. Electrolux contends that Maytag attempts to collapse this claim term with the previous claim limitation, "utilizing the core pins to aid in ejecting." Indeed, Electrolux contends that Maytag's construction would make the two limitations essentially synonymous. Electrolux also contends that Maytag is importing claim limitations, such as "axial" force and "slightly," that are not found in the claim language or the file history.

In its rebuttal brief, Maytag asserts that Electrolux's construction is improper, because "shift" connotes a minor adjustment, while "separate" connotes a major adjustment and potentially even complete removal of the basket from the mold core. However, Maytag points out that the specification uses the word "separate" in the context of removing bores from guide rods. In short, Maytag contends that Electrolux's definition again improperly requires complete removal of the basket. For its part, Electrolux asserts in its rebuttal brief that, while asserting that the construction of this term should closely track the claim language, Maytag improperly imports two limitations not found in the claim: "axial force" and "slightly." However, Electrolux contends that neither importation is supported by the claim language, the specification, or the file history, and Maytag does not even offer supporting citations from such sources. Moreover, Electrolux argues that the specification makes clear that the molded product is moved to the "ejection position," so that "slightly" moving the washing machine basket is a misleading construction. Finally, Electrolux contends that nothing in the patent requires that the lifting force be an "axial" force.
In its surrebuttal brief, Maytag asserts that it is not attempting to import any limitations into the claim language. Rather, Maytag contends that its proposed construction uses "to shift or slightly move" to define "shift," so that "slightly" only modifies "move," not "shift." Maytag contends that such a definition of "shift" is what would be understood by one of ordinary skill in the art and is consistent with dictionary definitions. However, Maytag contends that it would be content to let "shift" speak for itself. Maytag also contends that Electrolux's argument about "axial force" is a red herring, because not only would one of ordinary skill in the art understand the core pins' force on the basket to be "axial," but that this term is tangential to the real dispute between the parties. Therefore, Maytag asserts that it would be willing to drop "axial" from its definition, and instead, urges the court to construe the term to mean "the core pins provide a lifting force to shift the washing machine basket about the mold core." This construction, Maytag asserts, removes all of Electrolux's concerns. In its surrebuttal, Electrolux contends that no further response is required.

iii. Analysis. Beginning with the language of the claim in which the disputed language appears, see Nystrom, 424 F.3d at 1142 (construction begins with the words of the patent); Biagro, 423 F.3d at 1302 (same), it appears to the court that there is little or nothing about this term that requires construction. The court observed, just above, in reference to the other term in Claim 8 that is "in dispute" at this time, that Claim 8 expressly states how the core pins "aid," that is, are "used to assist," in ejecting the washing machine basket from the apparatus: the core pins "force the plastic washing machine basket to shift relative to the mold core as the cavity sidewall members are shifted away from the mold core due to the engagement of the core pins in the beveled apertures of the plastic washing machine basket." The '809 patent, Claim 8. The court finds nothing inherently vague or confusing about this language. Nevertheless, the court will consider, albeit briefly, specific aspects of the parties’ constructions.

While the core pins "aid" in "ejecting the washing machine basket from the apparatus," which suggests that the washing machine basket is ultimately "separated" from the mold core, the precise portion of the claim language now at issue relates only to the extent of the "aid" provided by the core pins, which is only to "force the washing machine basket to shift relative to the mold core." Id. (emphasis added). Therefore, the court agrees with Maytag that it is inappropriate, in light of the claim language, to adopt Electrolux's use of "to separate from" as synonymous with "to shift relative to." Indeed, to the extent that guidance from a standard dictionary is helpful to determine the ordinary meaning of the word, see Free Motion Fitness, Inc., 423 F.3d at 1348 ("Phillips confirms that courts may "rely on dictionary definitions when construing claim terms" and that "dictionaries . . . are often useful to assist in understanding the commonly understood meaning of words.") (quoting Phillips, 415 F.3d at 1322, in turn quoting Vitronics Corp., 90 F.3d at 1584 n.6), "shift" means, for example, "to change the place, position, or direction of: MOVE," not "to separate." See, e.g., MERRIAM-WEBSTER’S COLLEGIATE DICTIONARY (10th ed. 1995) (definition of "shift vt). The court also finds that the plain language of the term supports Maytag's elimination of "slightly" and "axial force" from the construction of the claim, because "shift" requires no further modifier, and "axial force" is found nowhere in the patent claim or pertinent part of the specification.

The final issue is whether Maytag is correct to include a definition of the nature of the "forcing" by the core pins as "providing a lifting force." Such language concerning the force provided by the core pins does, indeed, appear in the specification. See the '809 patent, col. 6, ll. 23-26 ("During the initial lifting of stripper ring 96, each of the core pins 191 will be engaged within a respective aperture 44 of basket 2 to provide a lifting force about the entire periphery of mold core 90.") (emphasis added). However, to import this language might be improper, because it would be reading a limitation from the specification into the construction of the term, where no such limitation is actually claimed or necessary to the understanding of the claim language. See Playtex Prods., Inc., 400 F.3d at 906 ("The court must take care in its analysis, when locating in the written description the context for a disputed term, not to import a limitation from that written description. It must use the written description for enlightenment and not to read a limitation from the specification [into the construction of the term].") (citing Comark Comms., 156 F.3d at 1186-87). Consequently, the court finds "forcing" sufficient by itself.

Therefore, the court concludes that the claim term "core pins forcing the plastic washing machine basket to shift relative to the mold core" is unambiguous, so that no further construction is required.
The parties dispute the proper construction of the phrase "core wire." This phrase is neither a phrase of common use in the English language nor is it a commonly used technical term. The phrase "core wire" was coined by the inventors to describe a part of the invention.

On the face of Claim 21, the phrase was coined by the inventors to describe a segment of the guidewire. Earlier in this Order, the Court gave its modified construction of the word "guidewire." It is also clear from the language of Claim 21 that the core wire has a "distal portion," and that "coupled to" the "distal portion" of the core wire is an "elongated tip portion."

The Summary of the Invention of the '136 Patent discusses all of these portions:

The invention is also a guidewire for use in electrothrombosis and used in combination with a microcatheter comprising a core wire. The core wire has a distal portion susceptible to electrolytic disintegration in blood. A tip portion is coupled to the distal portion of the core wire.

('136 Patent, Col. 4:54-59.) This description in the Summary is significant because it is not limited to a particular embodiment. Therefore, the Court considers that unless a particular claim states otherwise, the phrase "core wire" should be construed to provide that its distal portion is susceptible to electrolytic disintegration in blood. Significantly, this excerpt from the Summary also makes it clear that the "tip portion," which is "coupled to the distal portion of the core wire," is not a part of the "core wire."

In a description of Figure 1, "stainless steel guidewire 10," "reduced diameter section 16," and "threadlike section 18," are collectively included in the definition of a "core wire" of that embodiment:

The stainless steel guidewire 10, comprised of that portion disposed within the microcatheter body, tapered section 12, reduced diameter section 16 9 and threadlike section 18, is collectively referred to as a core wire which typically is 50-300 cm. in length.

In the illustrated embodiment the portion of the core wire extending from tapered section 12 to second bonding location 22 is collectively referred to as the grinding length and may typically be between 20 and 50 cm. in length.

('136 Patent, Col. 6: 3-12.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 Figure 1 has no reduced diameter section 16. The Court assumes that the written description was intended to read, "reduced diameter section 14." This apparent mistake does not affect the Court's claim construction.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Figure 1 shows a component other than those which are listed "collectively" as the core wire, namely, stainless steel coil 26. The issue becomes whether the inventors meant the phrase "core wire" to include this additional component. Before addressing that issue, the Court considers how, if at all, the phrase "core wire" is used in descriptions of other embodiments of the invention.

With respect to the "second embodiment of the invention, illustrated by Figure 2, the written description states:

FIG. 2 illustrates in enlarged partially cross-sectional view a second embodiment of the invention. Stainless steel core 32 terminates in a conical distal portion 34. Stainless steel coil 36, shown in cross-sectional view, is soldered to distal portion 34 of guidewire 32 at bonding location 38. The opposing end of the stainless steel coil 36 is provided with a soldered, rounded platinum tip 40. In the illustrated embodiment, stainless steel core wire 32 is approximately 0.010 inch in diameter with the length of stainless steel coil 36 being approximately 8 cm. With the longitudinal length of platinum tip 40 being between 3 and 10 mm. The total length of guidewire 32 from tip 40 to the proximate end is approximately 150 cm.

The embodiment of FIG. 2 is utilized in exactly the same manner as described above in connection with FIG 1 to form a thrombic mass within an aneurysm or other vascular cavity. The embodiment of FIG. 2 is distinguished from that shown in
FIG 1 by the absence of the extension of stainless core 32 through coil 36 to tip 40. In the case of the embodiment of FIG. 2 no inner core or reinforcement is provided within stainless steel coil 36. Threadlike portion 18 is provided in the embodiment of FIG 1 to allow increased tensile strength of the guidewire. However, a degree of flexibility of the guidewire is sacrificed by the inclusion even of threadlike tip 18, so that the embodiment of FIG 2 provides a more flexible tip, at least for that portion of the microguidewire constituting the stainless steel coil 36.

("136 Patent, Col. 6:66 - 7:26.) In their description of the second embodiment, the inventors use "stainless steel core" and "stainless steel core wire" interchangeably.

The "third embodiment" of the invention, illustrated in Figure 3, does not use the phrase "core wire." However, the description of the third embodiment refers to components which have the same names and descriptions 10 as the components which are included in the definition of "core wire" in the first embodiment:

Turn now to the third embodiment of the invention as shown in FIG 3. FIG 3 shows an enlarged side view of a guidewire, generally denoted by reference numeral 42, disposed within a microcatheter 44 shown in crossectional view. Like the embodiment of FIG 1, a stainless steel coil 46 is soldered to guidewire 22 at a first bonding location 50. A thin threadlike extension 52 is then longitudinally disposed within stainless steel coil 46 to a second bonding location 54 where stainless steel guidewire 46 and threadlike portion 52 are soldered to a soft platinum coil 56. Platinum coil 56 is not prebiased, nor does it contain any internal reinforcement, but is a free and open coil similar in that respect to stainless steel coil 36 of the embodiment of FIG. 2.

("136 Patent, Col. 7:42-55.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

10 "Threadlike section 18" of the first embodiment is included in "core wire." The third embodiment discloses "thin threadlike extension 52." The Court finds that a skilled artisan would conclude that the components are the same for purposes of defining "core wire."

11 Figure 3 does not contain a drawing labeled "guidewire 22." The Court considers this reference to be an erroneous reference to guidewire 42.

12 Figure 3 does not contain a drawing labeled "guidewire 46." The Court considers this reference to be an erroneous reference to guidewire 42.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

The phrase "core wire" is used in other claims of the '136 Patent. Claim 13 discloses a guidewire comprising a "core wire" with a "distal portion" and an "elongated tip portion." Claim 14 discloses a guidewire as disclosed in Claim 13 in which the "distal portion" of the core wire is a "stainless steel segment." Claim 15 discloses a guidewire as disclosed in Claim 14 in which the "stainless steel segment" of the "distal portion" of the "core wire" is a "coil." 13

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

13 The language of Claim 14 imposes a limitation on the distal portion of the core wire. The limitation imposed by Claim 14 is that the distal portion of the core wire "is an exposed stainless steel segment." Claim 15 imposes a limitation on the stainless steel segment, namely, that the segment "is a coil." Thus, Claim 15 claims a distal portion of the core wire which is a coil. A potential ambiguity is introduced within Claim 15, however, because it also imposes the limitation that the "coil" be connected to the "core wire." If the distal portion of the core wire "is" a coil, it is arguably ambiguous to say that the coil "is connected to the core wire." It is unnecessary for a dependent claim to claim that a coil is connected to the core wire if in that dependent claim the coil is a part of the core wire. The Court has chosen to treat the arguable ambiguity as a valid claim in that it is permissible in a dependent claim to define the coil as part of the "core wire" if the dependent claim discloses connecting the coil to the core wire.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -
Accordingly, the definition of "core wire" must be broad enough to include a coil. However, in every claim, the "elongate tip portion" is excluded from the definition of "core wire." Therefore, the definition of the "core wire" must exclude the elongate tip portion.

The Court construes "core wire" as it is used in Claim 21 of the '136 Patent to mean:

The guidewire of the invention, except for the elongate distal tip.

C. "Corners"

Finally, Bridgeport challenges the district court's construction of the "corners" limitation of Claim 15. This limitation appears in the following context: "corners connecting said side edges of said sides which are adjacent one another with said sides furthermore capable of having their corners removed to increase the degree of flexing about said axis through said face member to increase the amount of flexibility." '674 patent, col. 8, ll. 31-36. The district court construed this limitation as follows:

The word corners in Claim 15 refers to the meeting place of two lines or surfaces. They are capable of being removed to increase flexing. The corners can be removed but need not be removed. The corners are removable, but there is no requirement that the corners contain cut lines, score lines, or other physical features indicating that the corners are intended to be removed.

Trial Tr., Vol. 5 at 120. Bridgeport maintains, again on the basis of an embodiment described in the specification, that "the only correct construction . . . is that the corners must be specially constructed to flex or to be cut or removed to 'increase the degree of flexing.'" Bridgeport's attempt to read in limitations from the specification, and its general assertion that the district court's construction causes validity problems and is thus erroneous, fail for the same reasons described above. We find no error in the district court's construction of this limitation.

7. Corners of the First Frame

a. The Parties' Constructions

LPL argues that the "corners of the first frame" are areas located in or near the edges of the first frame and positioned on or inside the border of the flat display panel. Tatung asserts that the corners are the area at the back surface of a flat-panel display device near the intersection of two of its side edges. ViewSonic construes the corners as places on the first frame where two of its side edges intersect.

b. The Special Master's Construction

Claims 38 and 39 recite that the fastening holes are at the corners of the first frame. In the context of the common specification, the Special Master is of the view that the corners of the first frame as they relate to the fastening elements are not at the exact place where two of its side edges intersect, as urged by ViewSonic. For example, as seen in Figure 4C of the patents, the holes 15 extend through the frame but not the edges themselves. Moreover, as discussed above regarding the term "rear mountable," the fastening elements are not necessarily on or inside the border of the flat display panel. It follows that the phrase "corners of the first frame" is also not limited to being "on or inside the border of the flat display panel," as asserted by LPL.

Accordingly, the Special Master's construction is as follows:
Superior argues that the district court erred in construing the claims of BBA's '413 patent. Superior argues that "corona means," as a means-plus-function limitation, is limited to embodiments disclosed in the specification and equivalents, and the only embodiment disclosed in the '413 patent shows the corona means within the four walls of the attenuator. Superior argues that during prosecution, the applicant distinguished prior art by limiting the position of the corona means to be "within" the slot draw attenuator at a location above the exit slot of the attenuator. Superior argues that its accused device includes an electrostatic device positioned below the exit slot of the attenuator, and thus the claims, which require that a collection surface be positioned adjacent the exit slot, fail to read on the accused device.

The district court's claim construction of August 17, 2001, addressed the arguments raised by Superior on appeal. The district court agreed that the corona means of claim 1 is a means-plus-function limitation, but found that the claim also includes further language designating location, "positioned for electrostatically charging the filaments . . . before they are deposited on said collection surface." The district court found that the language of the claim permits the corona means to be outside, albeit connected to, the attenuator. The district court addressed Superior's prosecution history argument but found that the prosecution history failed to limit the claims in the way argued by Superior.

Claim 1 recites, inter alia,

d) corona means cooperating with said attenuator and positioned for electrostatically charging the filaments so that repelling forces are induced in the filaments to more uniformly spread the filaments before they are deposited on said collection surface to form a web.

'413 patent, col. 9, ll. 32-37.

As the district court correctly concluded, the limitation "corona means" is in means plus function form, and thus is subject to the requirements of 35 U.S.C. § 112, paragraph six. See B. Braun Med., Inc. v. Abbott Lab., 124 F.3d 1419, 1424, 43 U.S.P.Q.2D (BNA) 1896, 1899 (Fed. Cir. 1997) ("Because this limitation is expressed in 'means plus function' language and because it does not recite definite structure in support of its function, it is subject to the requirements of 35 U.S.C. § 112, P 6 (1994).") Construction of such a limitation requires the court to first identify the function of the means-plus-function limitation and next identify the corresponding structure in the written description necessary to perform that function. Micro Chem., Inc. v. Great Plains Chem. Co., 194 F.3d 1250, 1258, 52 U.S.P.Q.2D (BNA) 1258, 1263 (Fed. Cir. 1999).

Superior argues that the recited function includes "for electrostatically charging the filaments . . . before they are deposited on said collection surface to form a web." We disagree. The district court correctly identified the recited function:

The "function that corresponds to the "means" in this portion of Claim 1 stems from the word "corona"; that is, the claim is properly read as if it said "means for forming a corona."

Superior's proposed construction ignores the word "positioned" in claim 1, as the district court observed. Rather than reciting the function of the corona means, the expression following the word "positioned" describes where the corona means is located and is a separate limitation not subject to section 112, paragraph 6. What the "corona means" is and where it is located are two different things.

Superior's argument that the "corona means" must be "within" the slot draw attenuator is misplaced. The "within" limitation proposed by Superior does not appear in the claim. The prosecution history shows that the applicant described a prior art reference, Japanese Pat. No. 60-94663, by noting that it "discloses applying a corona to filaments after the filaments have
exited an attenuator," but the applicant did not distinguish this reference on that basis. Instead, the applicant distinguished this reference as referring to "tube-type round attenuators and not to a slot draw attenuator," and having a different filament configuration. We can find no error in the district court's finding that the intrinsic evidence does not require that the corona means be "within" the attenuator.

Superior's argument that the claims fail to read on the accused device, due to the "adjacent" limitation, is similarly unpersuasive. Claim 1 recites, "a collection surface positioned adjacent said exit slot of said attenuator." '413 patent, col. 9, ll. 28-29. Superior's contention, that the collection surface cannot be adjacent the exit slot if the corona means is not within the attenuator, is without merit. Just because the corona means is located outside the attenuator, and connected to the attenuator, does not mean that the collection surface is precluded from being adjacent to the attenuator exit slot. Again, Superior invites us to ignore the "positioned" limitation in favor of restricting the corona means to that shown in the patent figures. Because Superior's construction reads a limitation out of the claims, we decline Superior's invitation.

We find Superior's arguments concerning claims 8, 9, and 13 to be unpersuasive for similar reasons.

GO BACK

986

5. Corona Treatment

The definition proposed by Avery for Corona treatment is: "The discharge of a high voltage field onto a surface to raise the surface energy of the surface treated." Whitlam proposed this definition: "The discharging of up to 10,000 volts of electricity from a ceramic electrode to a ground roll over which a film is passing to alter the surface of the film by raising the surface energy of a film (measured in terms of dyne level) to allow for enhanced printing." Whitlam's proposed definition corresponds almost exactly with the discussion of Corona treatment in the specifications of the patents, column 3, lines 2-8 in both patents. This part of the specification states,

"Corona treating involves discharging up to about 10,000 volts of electricity from a ceramic electrode to a ground roll over which the film is passing. This high voltage field called 'corona' alters the surface of the film. Treating the surface of the film alters the surface energy of the film (measured in terms of dyne level) and allows for enhanced printing."

This definition would limit the voltage, electrode type, and purpose of Corona treatment as used in this patent. As in the preceding four definitions it is an impermissible attempt to limit a claim by language in the specification. See e.g. Intervet America, Inc. v. Kee-Vet Laboratories, Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989). As such, the Court adopts the following definition of Corona treatment: "The discharge of a high voltage field onto a surface to raise the surface energy of the surface treated."

GO BACK

987

10. Correction power being caused to vary

This phrase is found in Claim 1 of the '461 patent. Vistakon urges a construction of, "the dioptric power varies due to the design of the surface of the lens." Vision Advancement contends that "vision correction power" has already been construed and that this phrase does not require any further construction. Further, Vision Advancement argues that the term should not be limited to the "design"of the lens, nor should it reference the physical structure of the "surface" of the lens, as correction power is an optical property. The Court finds nothing in that phrase or the specification cited by Vistakon that would require inserting the "design of the surface of the lens" into that phrase. Accordingly, the Court declines to construe this phrase.

GO BACK

988

Claim 1 of the '813 patent states:
An improved correlated set of iron-type golf clubs, each club having a head which includes a face for impacting a golf ball, a back surface, a heel portion, a toe portion and a sole, said sole having a trailing edge extending between said heel and toe portions, the improvement comprising at least a central portion of said trailing edge being indented toward said face at least 1/16 of an inch and having at least the lower portion of said back surface adjacent said indented trailing edge configured to conform to said indented trailing edge by sloping upwardly and inwardly from said indented trailing edge toward said face.

('813 patent, col. 7, line 40 to col. 8, line 6 (emphasis added).)

First, all of the '813 claims-at-issue require a "correlated set of iron-type golf clubs." ('813 patent, col. 7, lines 40-41; Id., col. 8, lines 18-19.) The '813 patent may not be infringed by individual golf clubs, it may only be infringed by a "correlated set."

Cleveland argues that the prior art cited in the '813 patent refers to U.S. Patent 3, 655, 188 ("'188") (1972) entitled "Correlated Golf Club Set," which defined a complete correlated set of iron-type golf clubs to be irons No. 1 to No. 11, 12, or 13, but commonly only Nos. 2-10 or 11. (‘188 col. 2, lines 37-41.) A "short set" was defined as consisting of irons Nos. 3, 5, 7, 9 and 11, only. ( Id. at 41-42.) Regardless of the number of clubs in the set, Cleveland argues that Karsten's '813 patent claims require that each club in the set have all the characteristic elements recited in the '813 patent claims. Cleveland asserts that it made and sold the 792 irons in Nos. 1-9 and P, D, S and L wedges and that each and every "correlated set" sold by Cleveland did not contain the elements of the '813 patent.

Karsten argues that "correlated set" means that "two or more clubs comprising a set are related to each other." (Response, p. 9.) Karsten posits that the '813 patent illustrates a correlated set of clubs by virtue of the fact that FIGS. 4-10 illustrate a 5-iron, 2-iron, and 8-iron in which the structure of the loft angles is "clearly 'related' or 'correlated.'" (Id.) This Court finds Karsten's argument problematic at best.

Karsten's argument defies common sense. In essence, Karsten submits that the claim term "correlated set" may be implicitly defined by the illustrations contained in the patent. This basic thesis is plausible. Unfortunately, Karsten's definition lacks any relationship to the number of clubs depicted in the patent's illustration. The patent depicts several clubs, yet Karsten submits two or more define a correlated set. There is no relationship between Karsten's definition of "correlated set" and the illustrated figures found in the '813 patent.

This Court finds that a "correlated set," comprises two or more clubs which contain the same design characteristics. While a single club can not constitute a correlated set, a short set, a set of wedges, or even a set comprised of a 1 and 2 iron may constitute a correlated set if all of clubs possess the same design characteristics and they are sold together as a set.

The Correlated Set

The district court ruled that a "correlated set" is a claim limitation, and "comprises two or more clubs which contain the same design characteristics [and] are sold together as a set." The court recognized the commercial usage "short set," and held that when two or more iron-type clubs are sold as a set, each iron must embody the claimed characteristics. Cleveland Golf sells its accused clubs in sets of 1-9 irons and P, D, S, and L wedges. The district court held that this is a "correlated set," and required that all of the clubs in the Cleveland set must embody all of the claim limitations in order to infringe the claim.

Karsten states that the district court erroneously interpreted the term "correlated set" to preclude infringement if the set of iron-type clubs is not completely correlated, that is, if any club does not have the claimed structure. Karsten argues that it suffices if at least two of the irons in a set of clubs have the claimed structure, however large the "set." Karsten states that the term "correlated set" was used in the specification and claims to distinguish fairway irons from putters and woods, and that the '813 invention does not require that every iron-type club that is included in a set must have the claimed structure. Karsten points out that the district court's construction would enable an infringer to avoid the claim simply by including one non-conforming club in the set.
Karsten also argues that this limitation appears only in the preamble and is irrelevant to the patentability of the claims. Karsten states that a preamble term that states an intended use does not limit the claimed device to that specific use, see Rowe v. Dror, 112 F.3d 473, 478, 42 U.S.P.Q.2d (BNA) 1550, 1553 (Fed. Cir. 1997), particularly when as here the use was not argued as relevant to patentability. The district court, however, deemed the "correlated set" a limitation of claim scope, in view of Karsten's description of the invention in the specification as relating to a correlated set of irons, and Karsten's inclusion of this term in all of the claims.

We agree with the district court that this term, appearing in every claim, does not simply refer to the prior art or to a possible use, but describes and limits the invention being claimed. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1306, 51 U.S.P.Q.2d (BNA) 1161, 1166 (Fed. Cir. 1999). The district court correctly defined the term "correlated set" in the context of the specification and the evidence of customary usage. We confirm the court's ruling that the claims require that each iron-type club in a set of at least two clubs that are sold together must embody the claimed elements.

3. "Corresponding Contact Surfaces"

The method taught by claim 1 requires a "removable article having electrically conductive terminals and [an] electric device having conductor elements, both said electrically conductive terminals and said conductor elements having corresponding contact surfaces." Col. 9, lns. 57-61. It is "plain" to Thomson -- but not to the ALJ nor the Commission -- that the term "corresponding contact surfaces" means "that all, not just a subset, of the corresponding contact surfaces of the electric device and the removable article be brought into electrical contact." Thomson's Post-Markman Reply (Proposed Order) [hereafter "Thomson's Prop. Or."]. Thomson argues that the natural reading of the plural is that the surfaces correspond in a one-to-one manner. Thomson argues for a one-to-one correspondence so that Claim 1's step (b), which calls for "testing said corresponding contact surfaces for the existence of correct alignment and electrical contact between said corresponding contact surfaces," requires that all surfaces be tested.

However, the cases Thomson cites do not support its "plain language" argument. See Texas Instruments v. United States International Trade Comm'n, 988 F.2d 1165, 1172 (Fed. Cir. 1993) (reading plural to mean all on the basis of "the specification, the drawings and TI's own witness"); see also Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1346 (Fed. Cir. 1998) (discussing term "areas" in description to interpret claim term "slice data").

Thomson also argues that during prosecution of a different claim, Moreno changed "at least one corresponding contact surface" to "corresponding contact surfaces" to overcome an indefiniteness objection.

Rejecting these arguments, the Commission held that "no language in the claim requires that all the card terminals and card reader elements be brought into contact and tested. We also agree with the ALJ that the use of the plural form indicates 'more than one' but does not necessarily mean 'all.'" In the Matter of Certain Removable Electronic Cards, Inv. No. 337-TA-396 (ITC Aug. 13, 1998) [hereafter "ITC"] at 5.

This Court finds the term "corresponding contact surfaces" ambiguous as it can mean either that the surfaces correspond one-to-one or that the surfaces on the removable article's conductive terminals correspond sufficiently to allow for electrical connection (less than one-to-one correspondence) with the surfaces on the electric device's conductor elements. Nor does Claim 1 require that the number of conductive terminals and conductive elements on which the "corresponding contact surfaces" rest match in a one-to-one fashion. Resort to the specification also does not require the limitation that Thomson would read in. Finally, the amendment during prosecution does not necessarily lead to the conclusion that all surfaces must be brought into contact. For these reasons, the term "corresponding contact surfaces" will be construed to mean "more than one contact surface, but not necessarily all contact surfaces."

GO BACK
Plaintiff proposes no definition and argues that the term is unambiguous and readily comprehensible to the finder of fact. Citing a dictionary definition of "corresponding," Defendants propose the term be construed as: "having the same or nearly the same."

No citation from the patent is provided by either party. **The Court finds that this term requires no definition and is unambiguous and readily comprehensible.**

4. Claim Construction of the Term "Corresponding"

Defendants also contend that the Contessa chair does not include the limitation of "a flexible membrane coupled to and extending between said side members and having a second bowed section corresponding to said first bowed sections of said side members." '741 Patent, col. 22, ll. 53-56 (emphasis added). Specifically, defendants argue that the specification, and in particular, Figures 1 and 20, demand that "corresponding" means that the bowed section of the membrane correspond exactly to the bow shaped side members.

Plaintiff disputes defendants' interpretation, contending that "corresponding" requires that the second bowed section--the bowed section of the membrane--generally takes the shape of the bowed shaped sections. According to plaintiff, defendants' asserted definition is wrong because the term "corresponding" in no way requires conformity or agreement without any deviation whatever.

The court agrees with plaintiff that the term "corresponding" does not require "exact" agreement such that no deviation in the shape of the second bowed section is permitted. The plain meaning of the term does not require such strict identity of shape. Rather, the individual bowed sections are required merely to correspond to one another. As a starting point, the court notes that the Merriam-Webster Dictionary defines "correspond" "to be in conformity or agreement: suit, agree: match." Webster's Third New International Dictionary of The English Language Unabridged 511 (3rd ed. 2002); see Old Town Canoe Co. v. Confluence Holdings Corp., 448 F.3d 1309, 1316 (Fed. Cir. 2006) ("reference to the dictionary was not an improper attempt to find meaning in the abstract divorced from the context of the intrinsic record but properly was a starting point in its analysis, which was centered around the intrinsic record consistent with Phillips"). In the instant case, the specification simply fails to shed even a modicum of light on the term, and the court finds the Figures referenced by defendants to be entirely unhelpful because it is impossible to determine from them whether there is or is not "exact" agreement. In other words, neither the claims themselves nor the specification provide any assistance in deciphering the meaning of the "corresponding."

Accordingly, the court finds that this situation lends itself to giving greater weight to the dictionary definition of the term. As the court in Phillips stated:

In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words . . . . In such circumstances, general purpose dictionaries may be helpful. 415 F.3d at 1314 (citations omitted).

It would be inimical to the plain meaning of the term to construe "corresponding" so narrowly without any guidance from the specification. Indeed, incorporating "exact" into the ordinary meaning of the definition would be akin to rewriting the claim. Therefore, this court finds the limitation "a second bowed section corresponding to said first bowed section" to contemplate the bowed shape portion of the membrane to maintain general agreement with the shape of the first bowed shaped section.
3. Corrugated

Habasit contends that the term "corrugated" means "formed into or having a series of either straight or rounded ridges and valleys." In defending its construction, Habasit argues that corrugated should be read in the context of the 941 patent specification and understood to identify the "corrugated portion." Habasit further contends that the term corrugated does not require that the ridges and valleys be "parallel" or "even," as Rexnord insists. (D.I. 62 at 8.) First, Habasit argues that the term "parallel" is inappropriate because, while the vertical walls of the corrugated portion are parallel, the curved walls are not. Second, Habasit contends that the term "even" is repetitive because the term "sinusoidal" in the claim requires the corrugated portion to have a regular frequency and height.

Rexnord responds that "corrugated" means "having even parallel ridges and furrows." (D.I. 57 at 18.) Since the term does not have a special meaning in the art, Rexnord refers to Webster's dictionary for its definition. Rexnord argues that its proposed dictionary definition is consistent with the specification of the 941 patent which states, "The corrugated portion forms a series of ridges and valleys . . ." (941 patent, col. 3, 1. 50-51.)

After considering the claim language, specification, and prosecution history of the 9.41 patent and the parties respective positions, the Court agrees with Habasit's interpretation of the language. Corrugated must be read in the context of the specification as "corrugated portion." Claim 1 states, "the corrugated portion has a sinusoidal shape comprising a series of regularly spaced ridges and valleys . . ." (941 patent, col. 6.) The preferred embodiment of the specification further supports this understanding. The intrinsic evidence clearly sets forth the meaning of corrugated, thus eliminating the need to consult outside dictionaries. Moreover, the Court finds that the addition of the terms "even" and "parallel" are confusing and unnecessary for the construction. Thus, the Court concludes that corrugated means "formed into or having a series of either straight or rounded ridges and valleys."

1) "counterbalance weight"

Plaintiff's proposed definition of "counterbalance weight" is "a mass that provides significant dynamic balance for the reciprocating effective mass of the piston." (Dynamic balance is "the state of having the weight (of a pulley, shaft, or the like) so distributed that there will be no vibration when running." Merriam-Webster New International Dictionary 206 (2d ed. 1958).) Defendant proposes that "counterbalance weight" be defined as "a weight that counters forces associated with movement of a piston."

The 166 patent's written description distinguishes between counter weights, which counter only the primary forces of piston reciprocation, and counterbalance weights, which counter primary and secondary forces of piston reciprocation. '166 patent, col. 1, Ins. 26-40. The innovation behind the 166 counterbalance weight system is its ability to guide the counterbalance weight to reduce the vibrations caused by piston reciprocation. The invention does this by improving the engine's dynamic balance. Defendant's proposed construction fails to capture the essential difference between counterweights and counterbalance weights as described in the patent. Therefore, I will construe the term "counterbalance weight" to mean a mass that provides significant dynamic balance by countering forces associated with the movement of a piston.

1. Counterbalanced

Momentus contends that the plain meaning of "counterbalance" is that two weights are in perfect equilibrium about an axis, as two weights would balance on a legal scale. CSI argues for a broader definition of the term. In their initial response to
Momentus's interrogatory on their definition of the term, CSI offered several dictionary definitions that alternatively offer constructions as narrow as that which Momentus seeks, and ones that are as broad as that CSI claims, which is that "counterbalance" simply means weights opposing or acting against each other. Just one example is the definition given by the American Heritage Dictionary of the English Language: "1. To act as a counteracting force, influence, or weight to; counterpoise. 2. To oppose with equal force; offset." Other dictionary definitions provided by CSI confirm that the common usage of "counterbalanced" yields two possible interpretations, a narrow one claimed by Momentus and a broad one claimed by CSI. 1

--- Footnotes ---

1 Merriam Webster's WWWebster Dictionary: 1: a weight that balance another 2: a force or influence that offsets or checks an opposing force.

Cambridge International Dictionary of English: a weight or force which balance another one.

Online Plain Text English Dictionary: To oppose with an equal weight or power; to counteract the power or effect of; to countervail; to equiponderate; to balance.

--- End Footnotes ---

The evidence strongly points to CSI's broader interpretation of the term "counterbalanced." First, there is language in the patent specification, which is the first place a court should look in interpreting claim language beyond the claim itself, which states "as appropriate, the weight at one end may be different from the weight at the opposite end." '307 Patent, col. 2: 44-46. 2 Momentus explains this language away by citing Unique Concepts, Inc. v. Brown, 939 F.2d 1448, 1562 (Fed. Cir. 1991) which held that a patentee cannot use an exception to a limitation discussed in their patent specification to get around the limitation in general. This argument, however, is badly circular. Momentus argues that the specification language that states that the weights need not be equal is an exception to the general limitation that the weights are equal. Therefore the Court should conclude the weights must be equal. Indeed, this argument assumes its conclusion, that a limitation exists which requires the equality of the weights. In fact, nearly all the intrinsic and extrinsic evidence contradicts this assumption.

--- Footnotes ---

2 Momentus claims that this specification language is used in reference to a baseball-related device that was ultimately excluded from the patent, but a reading of the paragraph in question simply does not support this.

--- End Footnotes ---

The patent specification explains that the problem the invention seeks to solve is that "additional weight on the end of the golf club shaft adversely affects the balance of the golfer. The weight tends to pull the golfer toward the weight." '307 Patent, Col. 1:8-11. Thus, the balance that the weight on the other end of the club is intended to strike is not that of a pendulum, requiring precisely equal weights, but the balance of a golfer, holding the club at an angle, which may not require equal weights.

While not at all dispositive, an impressive piece of extrinsic evidence is that Momentus itself uses the term "counterbalance" to describe its device, the Momentus Strength Trainer. Thus, Momentus argues that the Court should apply a narrower definition to CSI's '307 Patent than Momentus, presumably a practitioner skilled in the art, uses for its own product.

One other nondispositive item of extrinsic evidence weighs in favor of Momentus's interpretation. In a deposition of the inventor listed on the '307 Patent, Larry Huffman, Mr. Huffman testifies that he intended the weights in the device patented by the '307 Patent to be equal. Nevertheless, the Federal Circuit made it clear in Markman that "the subjective intent of the inventor when he used a particular term is of little or no probative weight in determining the scope of the claim (except as is documented in the prosecution history)." Momentus argues that this rule seeks only to bar the self-serving claims of an inventor in favor of the patent owner, which is not the case here; however, the Federal Circuit in Markman offered a quite separate rationale for disregarding the claims of the inventor.
Commonly the claims are drafted by the inventor's patent solicitor and they may even be drafted by the patent examiner in an examiner's amendment (subject to the approval of the inventor's solicitor). While presumably the inventor has approved any changes to the claim scope that have occurred via amendment during the prosecution process, it is not unusual for there to be a significant difference between what an inventor thinks his patented invention is and what the ultimate scope of the claims is after allowance by the PTO.

Markman at 985 (citation omitted). See also Solomon v. Kimberly-Clark Corp., 216 F.3d 1372, 1380 (Fed. Cir. 2000). Given the alienability of patents from their inventors, this rule would be skewed if it only discounted an inventor's testimony with respect to the scope of claim construction when the inventor's incentives are in favor of broad construction. Such a rule would put patent purchasers at risk that the inventors may turn up and give testimony that could narrow the scope of their claims. Moreover, such a rule would require district courts to open the claim construction process to evidence regarding an inventor's intentions. Such a step would transmogrify the claim construction process from one of legal construction, as dictated by Markman, into a broad fact-finding exercise that the Court is supposed to defer until the resolution of patent infringement and validity.

The Court interprets "counterbalanced" to mean that the weights oppose or act against each other. The Court does not infer from this term that the weights in a device patented by the '307 Patent must be equal or must balance on a fulcrum between the weights.

Claim 1 of the '516 patent reads, in relevant part:

A forming roller for use with a heated thermoplastic film as brought to this forming roll and when in contact with an outer diameter surface portion of said roller is vacuum-shaped and cooled to bring this heated film to a condition whereat said film is weldable to another film, this roller including:

* * *

(b) a central axial bore formed in this metal roller and having a precise size and with a counterbore formed in each end of the roller and substantially concentric with the axial bore;

* * *

(d) a multiplicity of fluid-conducting passageways formed longitudinally and substantially parallel to the axis of said roll, each of these passageways open at each end to a counterbore; . . . .

'516 patent at col. 5, l. 20 - col. 6, l. 15 (emphases added). Independent claim 10 was also at issue. Limitation (b) of claim 10 reads: "a central axial bore formed in this metal roller and having a precise size." '516 patent at col. 6, ll. 65-66 (emphasis added). Other than this limitation, the district court found claims 1 and 10 similar in all respects.

On May 3, 2001, the district court granted Caputo personal access to review the March 30, 2001 opinion, even though the opinion contained restricted confidential information. Based upon this review, Caputo filed a motion for reconsideration on March 6, 2002, approximately eleven months after the March 30, 2001 opinion. The court issued a second opinion on August 8, 2002 addressing various motions from both parties. The court dismissed Caputo's motion for reconsideration as untimely and denied both parties' motions for sanctions and attorney's fees. The court also reprimanded Caputo for retaining an unredacted copy of a page from Sealed Air's brief in support of its motion for summary judgment (in violation of the protective order), but nevertheless, declined to impose sanctions. Final judgment was entered on September 3, 2002. Caputo appealed to this court and we have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1).

Footnotes

1 From approximately this time until the present, Caputo has been arguing this case pro se.
DISCUSSION

Our review of a grant of summary judgment of patent infringement or noninfringement is plenary. Cole v. Kimberly-Clark Corp., 102 F.3d 524, 528, 41 USPQ2d 1001, 1004 (Fed. Cir. 1996). We first determine whether "the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law." Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311, 1316, 48 USPQ2d 1099, 1102 (Fed. Cir. 1998) (quoting Fed. R. Civ. P. 56(c)). "In determining whether there is a genuine issue of material fact, the evidence must be viewed in the light most favorable to the party opposing the motion, with doubts resolved in favor of the opponent." Chiuminatta Concrete Concepts, Inc. v. Cardinal Indus., Inc., 145 F.3d 1303, 1307, 46 USPQ2d 1752, 1755 (Fed. Cir. 1998). "Claim construction, as a purely legal issue, is subject to de novo review on appeal." Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1451, 46 USPQ2d 1169, 1171 (Fed. Cir. 1998) (en banc).

On appeal, Caputo alleges a host of errors by the district court. They can be reduced to the following: (1) Sealed Air continues to infringe the '516 patent, as evidenced by the district court's April 4, 2001 opinion; (2) the district court improperly granted trade secret status to Sealed Air's roller; (3) Sealed Air offered misleading evidence, testimony, and argument; and (4) the burden to prove that the bubble wrap produced by Sealed Air does not use Caputo's patented process shifts to Sealed Air under 35 U.S.C. § 295.

The district court properly construed limitation (b) to mean that the forming roller requires "a counterbore formed in each end of the roller and substantially concentric with the axial bore." The court noted that these counterbores provided a reservoir for fluid that passes through limitation (d). The district court construed limitation (d) to mean that "within the roller is another set of longitudinally formed water-conducting passageways that run substantially parallel to [the] axis of the roller." The district court noted that at least one purpose of these passageways was to control temperature along the roller during operation. We find both these constructions to be correct.

Zebco's second interpretive argument is that the term "coupled" in the phrase "[a] heading lock coupled to a trolling motor" found in the preamble of claim 1 is limited to a mechanical or physical coupling. We are unpersuaded. Even assuming--as did the district court and Zebco--that the language of the preamble of claim 1 constitutes limitations on the claim rather than mere description, see Bell Communications, 55 F.3d at 620, 34 U.S.P.Q.2D (BNA) at 1820 (Fed. Cir. 1995) When the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects.

As with "heading signal," Zebco (a) recognizes that the unmodified term "coupled" generically describes a connection, and does not require a mechanical or physical coupling; and (b) does not suggest that "coupled," as used in the preamble, lacks clarity. Instead, Zebco points to passages of the written description implying the relationship between elements of the
preferred embodiment, and argues that such language constitutes a special (and limited) definition of "coupled." For example, Zebco argues that the phrase "feedback means for providing a feedback signal to the control means, wherein the feedback signal is indicative of the direction of thrust," '825 patent, col. 2, lines 32-34, defines "coupled" to mean "mechanically coupled." However, just as the preferred embodiment itself does not limit claim terms, see Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120, mere inferences drawn from the description of an embodiment of the invention cannot serve to limit claim terms, e.g., Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571, 7 U.S.P.Q.2D (BNA) 1057, 1064 (Fed. Cir. 1988), as they are insufficient to require a narrower definition of a disputed term.

Zebco also identifies statements in the prosecution history which purport to indicate the true (and limited) meaning of "coupled." Specifically, Zebco points to the aforementioned June 17, 1992 amendment of the '586 application, where the applicant argued that "it is not obvious to affix a compass to a propulsion device in a matter recited by [the] claims." However, as we noted above, that statement lends no support to Zebco's position, as it was made in reference to original claims 4 and 14, each of which expressly required that the compass be fixed to the trolling motor.

Because Zebco has not shown a sufficient reason to alter the clear meaning of the term "coupled," we agree with the district court that the term is not limited to a mechanical or physical coupling.

ii. Analysis

The claim construction analysis in this case focuses on the meaning of the term "coupled" in the '818 Patent. Desert Aire argues that the term should be construed to mean "connected, either directly or indirectly." Pl.'s Resp. 5. AAON asserts that it should mean "the linking of adjacent components without intervening control valves." Def.'s Mot. 11. The precise meaning of the term is significant because the '818 Patent, depicted in Figure 1, 2 claims:

(1) a "first condenser [(No. 55)] being coupled to said compressed refrigerant outlet [(No. 65)]," (from Claim 1); and

(2) "an electroresponsive flow-throttling valve [(No. 61)] having an inlet [(No. 67)] coupled to said outlet [(No. 65)] of the compressor [(No. 62)] and to said inlet [(No. 73)] of said first condenser [(No. 55)]," (from Claim 4).

Def.'s Mot. Ex. A col. 10 11. 22-23, col. 11 ll. 30-32, Fig. 3 (emphasis added). AAON argues that a control valve positioned between the first condenser and both the compressor and flow-throttling valve in the accused devices sets them outside the claims of the '818 Patent, because the presence of such an intervening valve means the adjoining compressor, valve, and first condenser are not "coupled" to each other.

--- Footnotes ---

2 Figure 1 depicts the preferred embodiment from the '818 Patent specification. At this point the Court refers to this diagram for illustration only, and not to impose any limitation from the specification onto the claims.

--- End Footnotes ---

Both of the parties' proffered definitions are consistent with the presumed ordinary and accustomed meaning of the word "coupled" in the context of the claims, yet they are not coextensive. The first part of each parties' interpretation--Desert Aire's "connected" and AAON's "linking of adjacent components"--is indistinct from "coupled." The dispute arises over the scope of the claim term. Desert Aire broadly asserts that components coupled under the '818 Patent can be "connected . . . directly or indirectly," while AAON asserts a more narrow scope of coupled components being "link[ed] . . . without intervening control valves."

GET DRAWING SHEET 2 OF 4

Figure 1: Depiction of the Preferred Embodiment in the '818 Patent. Def.'s Mot. Ex. A.
AAON's narrow interpretation is not apparent from the context of the claims themselves. Nor does the use of the term "coupled," which appears in the '818 Patent's four claims seventeen times, invalidate Desert Aire's broader interpretation of "directly or indirectly." Def.'s Mot. Ex. A cols. 10-12. AAON argues that the claims' use of "coupled to" with the "inlet" or "outlet" of a component as the prepositional object indicates that the components are directly adjacent, or at least lack an intervening control valve; but the use of "inlet" or "outlet" of a successive component could simply indicate the direction of flow, and not exclude intervening components, so this argument fails.

Both parties often refer to the '818 Patent's specifications to support their constructions, especially the description of the preferred embodiment and its depiction in '818 Patent (Figure 1). The specification lends support to Desert Aire's construction including indirect connections of non-adjacent components. The diagram and related text indicate an intervening "manually-operable valve 72" between the "coupled" "throttling valve 61" and "second condenser 70." Def.'s Mot. Ex. A col. 6 ll. 11-14. There is also, among other components, an intervening "liquid line solenoid valve 86" between the "coupled" "[second] condenser 70" and the "expansion valve 88." Def.'s Mot. Ex. A col. 7 ll. 8-17, col. 10 ll. 36-37.

AAON refers to the specification to counter Desert Aire's construction and support its own interpretation, arguing that the intervening components in the preferred embodiment, including the manually operable and solenoid valves, do not restrict flow of the refrigerant during the normal operation of the system, and are thus not intervening control valves. AAON's assertion may be correct, but it does not serve AAON's limited scope of construction. Although the specification may be used to clarify claim terms, "[i]n examining the specification for proper context . . . this Court will not at any time import limitations from the specification into the claims." CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1231 (Fed. Cir. 2005); see also Teleflex, Inc., 299 F.3d at 1326.

Although there is no clear limit to the scope of "coupled" in the language of the claims or the specification, a reading of the prosecution history clearly shows that Desert Aire adopted a more narrow definition of the disputed term, similar to that asserted by AAON, by disclaiming a configuration with an intervening control valve in order to gain patent approval.

United States Patent Number 3,926,008 (the "Webber Patent") claims a: "condenser means including, in series with said first passageway, an aircooled [sic] condenser through which said refrigerant flows, and [a] thermostatically-controlled valve means for connecting said compressor directly to said air-cooled condenser and bypassing said first-mentioned passageway." Def.'s Mot. Ex. G col. 4 ll. 22-27. The Webber Patent's preferred embodiment is depicted in Figure 2. The specification more clearly describes "a valve 42 connected between the compressor 16 and the condenser 20 and a by-pass valve 44 connected between the compressor 16 and condenser 22." Id. col. 2 ll. 59-61.

GET DRAWING SHEET 1 OF 1

Figure 2: Depiction of the Preferred Embodiment in the Webber Patent. Def.'s Mot. Ex. G.

In rejecting Desert Aire's patent application in the July 23, 1998 office action, the patent examiner stated:

Claim 1 is rejected under 35 U.S.C. [§] 103(a)3as being unpatentable over Webber in view of Considine. 4Webber shows a refrigeration system having a first condenser 20 a second condenser 22 a solenoid on/off valve 44 having an inlet coupled to the outlet of compressor 16 and the inlet of [first condenser] 20, [valve] 44 having an outlet coupled to the outlet of [first condenser] 20 and the inlet of [second condenser] 22. Considine at 11-17 shows on-off and throttling (proportional-position) at 11-21 with the conclusion that throttling provides more stable flow. In order to achieve more stable flow it would have been obvious to provide throttle flow for [valve] 44 in Webber. Claim 1 is an "open" claim since it recites "including". Therefore the presence of valve 42 in Webber does not prevent claim 1 from being readable on Webber.

Def.'s Mot. Ex. I.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 35 U.S.C. § 103(a) provides: "A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the
AAON argues that the basis of the patent examiner's rejection was that the '818 Patent's claims read on the prior art of the Webber Patent's two-control-valve configuration. Desert Aire contends that although it "presented arguments that, based on its analysis of the Webber Patent, . . . the piping and valve configuration claimed in the '818 Patent was different than that of the Webber Patent," it "never argued that the reason its configuration was novel and patentable was because Plaintiff used a single valve." Pl.'s Resp. 11. Desert Aire is correct that its arguments to the patent examiner were not so explicitly stated, but its disclaimer is nonetheless clear from the context of the prosecution history.

Desert Aire argues that in its Amendment B--After Final ("Amendment B"), filed March 19, 1999, it offered the patent examiner "a combination of three elements" in its proposed amendment to Claim 1 that distinguished its invention from the Webber Patent's claims. Referencing the diagram in Figure 1, the appeal states that:

(1) "there is substantially unimpeded flow through conduits 65 and 73 to reheater [(first condenser)] 55;"
(2) "the outflow from condenser 55 can travel via conduits 74 and 71 to the secondary condenser 70;" and
(3) "in additional to having parallel, or shunt paths, all the liquid passing through both condensers is returned via line 80 to the evaporator."

Def.'s Mot. Ex. K at 3. Desert Aire argues that it specifically contended to the examiner that, in the Webber Patent (Figure 2), "there is no path by means of which the outlet from condenser 22 can enter the inlet of the second condenser 20." Id.

Only Desert Aire's first asserted element, that "there is substantially unimpeded flow through conduits 65 and 73 to reheater 55," could have validly distinguished its invention from the Webber Patent, as its remaining two elements were based on a confused reading of the Webber Patent that was contradicted by the patent examiner. Desert Aire first asserted to the patent examiner in its Amendment A, filed November 13, 1998, that "condenser 22" of the Webber Patent be considered the first condenser, and "condenser 20" be considered the second condenser. Pl.'s Resp. Ex. Q at 2. The patent examiner apparently rejected this confused reading of the Weber Patent in his January 19, 1999 office action, stating: "The applicants arguments are based upon different modes of reading the reference on the claim, but none of these mode [sic] is the one used by the Examiner. The arguments are therefore not considered germane to the Examiner's rejection." Def.'s Mot. Ex. J at 2. The patent examiner had previously stated in the July 23, 1998 office action that "Webber shows a refrigeration system having a first condenser 20 a second condenser 22."

There is no evidence in the record that the patent examiner reversed his interpretation, and it is consistent with the language of the Webber Patent, which states that "condenser 20" is bypassed by "clos[ing] the valve 42 and open [ing] the valve 44 to conduct refrigerant directly from the compressor 16 to and through the air-cooled condenser 22." Def.'s Ex. G col. 2 11. 59-68, col. 3 11. 1-3 (emphasis added). When "condenser 20" and "condenser 22" are correctly compared to the '818 Patent's first and second condensers, respectively, it is clear that the condensers are arranged in series so that, in both inventions: (1) refrigerant always passes from the first condenser to the second condenser; and (2) the refrigerant from both condensers is returned to the evaporator. Desert Aire's final contention that, in the Webber Patent, "there is no path by means of which the outlet from condenser 22 can enter the inlet of the second condenser 20" is inconsistent with a correct interpretation of the Webber Patent specifications. Def.'s Mot. Ex. K at 3.

As to the remaining valid distinction, there is further dispute between the parties as to the meaning of the term "substantially unimpeded flow." AAON asserts that the diagram referred to by Desert Aire in the '818 Patent specification (Figure 1) does not include any component "along conduits 64 and 73 to reheater 55." Thus in distinguishing its invention from the Webber Patent by the "substantially unimpeded flow" between the compressor and first condenser, Desert Aire disclaimed patent coverage of a structure with a control valve between the compressor and first condenser. Desert Aire counters by arguing that the term "substantially" has been determined in patent law to mean "'largely but not necessarily wholly'" and thus "the
claimed elements of the ’818 Patent could be expected to incorporate a certain degree of impedance in the indicated flow path," including an intervening control valve. Pl.'s Reply 3 (quoting LNP Eng'g Plastics, Inc. v. Miller Waste Mills, Inc., 275 F.3d 1347, 1354 (Fed. Cir. 2001)).

Desert Aire's semantic argument is not convincing when the asserted "substantiated unimpeded flow" between the compressor and first condenser is considered in the context of Desert Aire's response to the July 23, 1998 rejection by the patent examiner. The examiner concluded that, because the replacement of "on-off" valves with more stable "throttling" valves was obvious, Desert Aire's invention was otherwise readable on the two-valve configuration specified in the Webber Patent. Def.'s Mot. Ex. I. "[T]he presence of valve 42 in Webber" (the valve between the compressor and the first condenser), did "not prevent claim 1 from being readable on Webber," because Desert Aire's Claim 1 is an "open' claim"--it recites a system "including" certain elements without explicitly excluding others. Id.; see SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1284 (Fed. Cir. 2005) ("includes" is a patent law term of art that permits the presence of additional elements in a device that do not satisfy the stated claim limitations). In other words, Desert Aire claimed a "flow-throttling valve having an inlet coupled to said outlet of the compressor and to said inlet of the first condenser," but such a valve configuration was readable on the Webber Patent, despite the presence of a second valve between the compressor and first condenser in the Webber Patent, as such had not been excluded from Desert Aire's open claim. Def.'s Mot. Exs. H, I (emphasis added).

By arguing that "substantially unimpeded flow" between the "coupled" compressor and first condenser distinguished its invention from the Webber Patent, Desert Aire excluded the use of a second control valve to proportion the flow from the compressor to the first condenser from the scope of the ’818 Patent. Def.'s Mot. Ex. K at 3. Although, as Desert Aire argues, "substantially unimpeded flow" can have other meanings, there is only one use apparent in the prosecution history that distinguishes Desert Aire's single flow-throttling valve concept from the two-valve configuration in the Webber Patent. The clear distinction between "the flow through conduits 65 and 73," i.e., from the compressor (No. 62) "to reheater 55" (the first condenser) in the ’818 Patent diagram (Figure 1), and the flow from the compressor (No. 16) to the first condenser (No. 20) in the Webber Patent diagram (Figure 2) is an intervening valve controlling flow to the first condenser present in the Webber Patent. Because Desert Aire's other asserted distinctions were based on a confused reading of the Webber Patent's specifications, the valve-configuration disclaimer is the only valid distinction that would be apparent to one skilled in the art. Following the filing of Amendment B the ’818 Patent was not rejected based on any readability on the Webber Patent.

It would be reasonable then for one skilled in the art, upon reviewing the entire ’818 Patent file, to rely on Desert Aire's statements to the patent examiner in the context of the prosecution history and make the same conclusions as this Court as to the scope of the ’818 Patent's claims. The Court will not "recaptur[e] through claim construction" additional elements that were clearly "disclaimed during prosecution in order to obtain the patent." Omega Eng'g, Inc, 334 F.3d at 1323. The Court thus narrows the scope of the claim term "coupled" in the ’818 Patent and construes it to mean "connected without an intervening valve that may impede flow to the first condenser during normal operation." Such a construction, albeit cumbersome, is consistent with the claims and specifications of the ’818 Patent, as it permits the presence of intervening components and other valves that may impede flow when the system is not operating, 5 while providing the necessary limits to exclude the configuration disclaimed by Desert Aire to avoid the Webber Patent.

--- End Footnotes ---

b. "coupled"

The term "coupled" appears in claim 1. Boston Scientific proposes that the term be construed as "directly or indirectly linked." ev3 argues that "coupled" should be construed as "the filter must be directly attached to the wire and not be attached to a tube that rides on the wire." After reviewing the intrinsic evidence, and the prosecution history in particular, the Court construes "coupled" as "adjacent and directly connected to."
Evergreen alleges that Biomed's sputum collector infringes claim 1 of Evergreen's '346 patent. The disputed portion of claim 1 reads:

A specimen collecting device comprising: . . . graspable means releasably coupled to said supporting means, releasably holding said cap means in said supporting means when said supporting means is secured thereto, said graspable means being adapted to be grasped while holding said cap means as said closing means is coupled to and/or released from said container, whereby said graspable means aids in the coupling and/or releasing of said cap means.

'346 patent, col. 6, lines 36, 47-55 (emphasis added to disputed language).

Biomed argues that its device does not literally infringe claim 1 for two reasons which are dealt with seriatim.

1. Biomed contends that its device does not have "graspable means releasably coupled to said supporting means," i.e., a base stand cover. Evergreen responds that this limitation is met by the funnel lid which is "releasably coupled to the base unit via the collection tube." The Court concludes that the word "coupled" does not support Evergreen's interpretation. See ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988) (patents must be interpreted in accordance with the plain meaning of the claims). "Coupled" signifies direct contact between two objects. The specification uses the word "coupled" a multiple of times when referring to the direct contact of two objects. '346 patent, col. 3, lines 52-56; col. 4, lines 3-5, 7-10, 23-24. The other claims use the word "coupled" in the same way. See, e.g., '346 patent, col. 6, lines 66-69; col. 7, lines 22-29, 40-44. The part of Biomed's device which holds the vial cap is not, therefore, "coupled" to the base.

B. Noninfringement of the '096 and '916 Patents

Bradford argues that the district court erred in its construction of the term "coupled to" and related terms by requiring that the dunnage structure of the claimed containers be attached directly to the frame or side structures of the containers.

Bradford points out that both the '916 patent and '096 patent, by incorporation of the '119 patent, clearly disclose dunnage attached to a rail, which is attached to a side structure, and that nothing in the specification requires dunnage to be directly attached to the container frame. On the contrary, Bradford argues, given that dependent claim 10 of the '096 patent recites dunnage indirectly fixed to the frame through a rail, the doctrine of claim differentiation mandates a reading of the term "coupled to" as not limited to directly attached. ConTeyor NA and ConTeyor NV do not respond to Bradford's arguments on this issue.

We agree with Bradford that the district court erroneously construed the term "coupled to," and we hold that the term should be construed broadly so as to allow an indirect attachment. We review claim construction de novo on appeal. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). We begin a claim construction analysis by considering the language of the claims themselves. See Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) (en banc). However, "claims must be read in view of the specification, of which they are a part." Id. at 1315 (quotation marks omitted). "[A] court should also consider the patent's prosecution history, if it is in evidence. . . . Like the specification, the prosecution history provides evidence of how the [Patent Office] and the inventor understood the patent." Id. at 1317 (citations and quotation marks omitted).

Although it properly gave the term "coupled to" a broad construction in its earlier order, the district court appears to have unnecessarily narrowed it in ruling on defendants' invalidity contentions. Invalidity Opinion, 2007 U.S. Dist. LEXIS 31975, at *25 (holding that a prior art reference that showed that the dunnage structure coupled to support bars was different from the '916 patent claims, which required dunnage coupled to the frame of the container). Thereafter, the court determined that its invalidity decision mandated that the term "coupled to" be restricted to a direct attachment to the frame or side structure of the container. Noninfringement Opinion, 628 F. Supp. 2d at 762-64 (basing its noninfringement finding on the fact that in
its invalidity decision, the court had held that the "patents-in-suit do not encompass containers in which the dunnage is coupled to support bars or support rails"). Given that the accused device uses bars or rails to hold the dunnage structure, the court concluded that, under its claim construction, there was no infringement of any of the asserted claims. Id. at 764.

We agree with Bradford that the doctrine of claim differentiation supports a reading that allows an indirect coupling of the dunnage to the frame of the container. Dependent claim 10 of the '096 patent recites a dunnage structure that is coupled to rails which in turn are coupled to the side structures. In light of a dependent claim that clearly states an indirect attachment of the dunnage structure, the scope of independent claim 1 is presumed to be broader to allow for other types of indirect attachments. See Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) ("The doctrine of claim differentiation creates a presumption that each claim in a patent has a different scope.").

While the doctrine of claim differentiation, contrary to arguments regularly made in this court, is not a conclusive basis for construing claims, we find nothing in the '096 patent specification or the prosecution history that would allow us to overcome its effect here. On the contrary, the '096 patent specification clearly discloses dunnage coupled to the side structure through a rail. '096 patent fig.3; id. at col.9 ll.24-31; see also '119 patent figs.1 & 1A. Similarly, the use of words such as "operably" and "movably" in the claims suggests that the dunnage structure is not fused to the frame, but rather attached flexibly allowing for intermediate parts between the frame and the dunnage structure such that the dunnage is operable or movable. In light of such clear disclosure in the patent, the term "coupled to" is entitled to a broader scope than the district court allowed. We therefore reverse the court's revised claim construction of the term "coupled to." Because the court based its noninfringement finding solely on its revised construction of that term, we remand the question of infringement to the district court for a determination using its original and correct claim construction.

1002

2. Claim 1 - "coupled to"

Bradford proposes that "coupled to" means "linked together, connected, or joined." Defendants, on the other hand, argue that "coupled to" means "at least temporarily, linked together with." The basic dispute here is Defendants' addition of the temporal limitation "at least temporarily" to "coupled to".

Defendants contend that the temporal limitation comes from the '119 Patent, specifically Figures 10 and 11 of the specification. Figures 10 and 11 show an alternative embodiment of the invention known as a sleeve pack container. In this embodiment, a container is formed by means of a collapsible sleeve which contains dunnage structures. The sleeve fits into a peripheral groove on a pallet base. The assembly is completed by placing a cover or top on the sleeve. '119 Patent, col. 16, ll. 8-19, 43-44. To disassemble the sleeve pack, the cover is removed from the sleeve and the sleeve is lifted from the pallet base. To collapse the container, the sleeve is then folded along hinge lines on the side walls. Id. col. 16, ll. 52-55.

Admittedly, in this embodiment, the coupling between the side walls and the pallet base is only temporary. Indeed, it has to be temporary because if the side walls were permanently coupled to the pallet base, the container would not be collapsible. Nonetheless, Figures 10 and 11 do not support importing the temporal limitation proffered by Defendants to this term. The plain language of Claim 1 only requires the "side walls" to be "coupled to" the bottom. There is no temporal restriction in this claim. The embodiment in Figures 10 and 11 fulfills this requirement because the side walls connect to the pallet base via the peripheral grooves. None of the other embodiments in the specification suggest that the "side walls" are "coupled to" the bottom "at least temporarily". Hence, Defendants' definition of "coupled to" improperly imports a limitation from the specification into the claim. Therefore, Defendants' definition of "coupled to" is rejected.

The Court holds that "coupled to" means "linked together, connected, or joined."

1003

17. Coupled to/Removably coupled to/Decoupled

Synventive proposes
"coupled" means the ring holds the valve pin to the piston while allowing side-to-side (radial) motion between the valve pin and the piston. When the valve pin is "decoupled" from the piston, it is not retained by the piston. "Removably coupled" means the valve pin can be decoupled from the piston without requiring removal of the valve pin from the manifold and with the valve pin assembly remaining secured to the manifold in alignment with the piston.

Husky proposes "'coupled' means 'secured;' 'decoupled' means 'unsecured;' 'decoupling' means 'unsecuring;' 'removably coupled' and 'being removably coupled to' means 'can be unsecured from;' 'removably coupling' means 'can secure and unsecure.'"

These terms are not used in the patent claims in any specialized fashion. The ordinary meaning of "coupled" as "fastened" or "secured" adequately conveys the meaning where these terms are used throughout the patent claims. Thus "coupled to" means "fastened to" or "secured to;" "removably coupled to" means "removably fastened to" or "removably secured to;" "decoupled" means "unfastened" or "unsecured."

GO BACK

2. "[A] drive shaft coupled to" and "a drive shaft coupled at one end to a suction cup"

"[A] drive shaft coupled to" means a drive shaft linked with and "a drive shaft coupled at one end to a suction cup" means a drive shaft with an end portion linked to a suction cup.

The parties dispute whether the term "coupled," found in Claims 1 and 15, describes a connection between two distinct parts. Palmetto argues that the suction cup and drive shaft are separate features, while NPI contends that the two can exist as an integrated piece.

The court declines to read a limitation into the broad term "coupled." See Verizon Cal. Inc. v. Ronald A. Katz Tech. Licensing, L.P., 326 F. Supp. 2d 1060, 1077 (C.D. Cal 2003) ("One of ordinary skill in the art understands the term 'coupled' to connote a broad range of associations between two things."). The parties agree that the ordinary use of the term means to join or link together. It does not follow that the term necessarily implies the physical joining of two separate components. Id. at 1078; see Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 992 (Fed. Cir. 1999) (holding that "coupled" does not necessarily require a mechanical or physical coupling). Indeed, one embodiment in the specification indicates a drive shaft and suction cup "integral" molded of the same material. 420 Patent, col. 7, lines 12-18. Even so, Palmetto argues that these "few lines" from the specification contradict the clear language of the claims. Palmetto Resp. at 6-7. Thus, according to Palmetto, the inventor may have disclosed such an embodiment, but failed to claim it. The court disagrees. There is no contradiction between the specification and the claim given the broad definition of the term "coupled." The court rejects Palmetto's veiled attempt to limit the claim in such a way as to exclude one embodiment. See Vitronics, 90 F.3d at 1581 (an interpretation that would exclude an embodiment "is rarely, if ever, correct").

1005

2. "electrocardiograph module coupled to a handheld module by a cable"

Plaintiffs' construction: electrocardiograph (ECG) module that is external to and attached to the handheld module by a cable

Defendant's construction: a module that measures electrical potential difference across the chest and is attached to the handheld module by a cable

The parties' disagreement with respect to this term is whether the electrocardiograph module must be external to the handheld module. Defendant faces an uphill struggle in promoting its proposed construction. First, the claim language itself distinguishes three separate components, including a handheld module, a transducer assembly and an electrocardiograph module. This strongly suggests that they are separate from each other. However, even if this leaves some room for
interpretation, the patent specification does not. The second sentence of the abstract supports plaintiffs' construction squarely and unambiguously: "An external electrocardiograph (ECG) unit is also disclosed." '566 pat., Abstract (emphasis added). The Court of Appeals for the Federal Circuit has recognized on multiple occasions the importance of the abstract in construing the scope of a claim term. Pandrol USA, LP v. Airboss Ry. Products, Inc., 320 F.3d 1354, 1363 (Fed. Cir. 2003); SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337 (Fed. Cir. 2001). Defendant advances no argument for disregarding it in this case.

The same understanding of the invention is repeated in the Summary of the Invention. In describing the invention, the patent states that "ECG capacity is also described using a separate module to preserve weight in the handheld instrument." '566 pat., col. 2, lns. 24-26.

Defendant attempts to dismiss these references in the specification as discussions of embodiments, but its efforts are unconvincing. It argues that the description of a separate electrocardiograph unit is limited to situations where it is necessary to " preserve" the lightweight nature of the device. However, the references in the Summary of the Invention to the "separate" electrocardiograph module are made in the context of discussions of "the present invention." Therefore, this limitation may be properly applied to the invention as a whole. Verizon Services Corp., 503 F.3d at 1308; C.R. Bard, Inc., 388 F.3d at 864.

**Court's construction:** electrocardiograph (ECG) module that is external to and attached to the handheld module by a cable

**1006**

c. "a side cover is coupled to an outer side surface of said engine block"

Honda argues that this term should be construed to mean "a cover that is removably attached to a generally exterior side surface of the engine block," and Coast argues that it should be construed to mean "a cover that is removably attached to an exterior surface of the engine block, defining a plane that is generally aligned with the long axis of the cylinder head, and is not a head cover." As an alternative, Coast suggests that the term be construed to mean "a cover that is removably attached to a generally exterior side surface of the engine block, and is not a head cover."

Honda argues that the claim language does not support Coast's proposed construction, to the extent it includes the language "defining a plane that is generally aligned with the long axis of the cylinder head." Coast argues that this language is necessary because Coast's construction "leaves room for ambiguity about which 'side' is the 'side surface of the engine block.'" (Opp. Br. at 20:18-10.) However, the claim states that the side cover is "coupled to an outer side surface of said engine block on a side of the engine block opposite from said parting plane." (273 Patent at 6:48-50.) Thus, there is no ambiguity in the claim as to the location of the side surface of the engine block. Accordingly, the Court rejects this aspect of Coast's proposed construction.

The claim language also is broad enough to include a "head cover." Coast argues, however, that the inventors specifically disclaimed a broad interpretation of the claim term in order to distinguish over prior art. On August 17, 2000, the Examiner rejected proposed Claim 1 on the basis that it was anticipated by Japanese Patent No. 177441 ("JP '441"). According to the Examiner, that reference "shows a valve cover at 2 that is deemed to be at a 'side' of the engine and opposite the oblique plane. The claim must set forth more detail of the relationship between the valve drive elements, the cover, and the engine block to overcome the art of record." (Shariati Decl., Ex. L at 2.)

In response to this Office Action, the inventors amended the relevant portion of the claim to read "a side cover is coupled to an outer side surface of said engine block [which is] on a side of the engine block opposite from said parting plane, so as to define a valve operating chamber for accommodation and support of a valve operating mechanism between said side cover and said outer side surface." (Id., Ex. M at 2.) The inventors also explained that they had amended Claim 1 "to clarify that the side cover serves to support the valve operating mechanism in cooperation with the outer side surface of the engine block on the side opposite from the parting plane." (Id. at 3.)

The inventors then distinguished the prior art reference and state that "element 2 of JP '441," which the Examiner referred to as a valve cover, "is a cylinder head." (Id.) The inventors note that "[t]he applied reference teaches that engine body E is
formed of a cylinder block 1, a cylinder head 2 and a crankcase half 3 which are integrally molded. ... In the applied reference the valve operating mechanism T is disposed inside the engine body E and, more specifically, within the cylinder head 2. No separate side cover is used. The valve operating mechanism T is located on the same side as the parting plane, which is further away relative to the claimed invention." (Id. at 3-4 (emphasis added).) Finally, the inventors argue that "the side cover as recited in Claim 1 is not taught or suggested in the cited reference." (Id. at 4.) Thus, the inventors distinguished their invention from JP ’441, because that reference did not include a "separate" side cover and because its valve operating mechanism was not located on the opposite side of the parting plane.

The Court finds that no clear disclaimer exists in this case. The inventors discuss JP ’441 in the specification. In describing the invention taught by that patent, they note that it is difficult to reduce the distance between the first and second bearing portions, because the valve operating mechanism poses an obstacle due to its location. ('273 Patent at 1:28-33.) The inventors also state that in order to assemble the engine, "a portion of the valve operating mechanism is obliged to be temporarily attached to the crankshaft before coupling the first and second case halves to each other." (Id. at 1:36-39.) The inventors then note that their invention attempts to solve these problems by placing the valve operating mechanism in a space between the side cover and the outer side surface of the engine block, which is formed of a first case half, a cylinder barrel and a cylinder head. (Id. at 1:44-2:4, 2:65-67.) This arrangement also allows for the valve operating mechanism to be assembled when the side cover has been removed. (Id. at 17-20.) There is nothing in the specification that would exclude a side cover from including a head cover. In addition, the prosecution history suggests that the inventors distinguished their invention from the prior art because their invention used a "separate" side cover. Again, nothing in that statement lends support to Coast's argument that this "separate" side cover could not include a head cover.

Accordingly, the Court construes the term "a side cover is coupled to an outer side surface of said engine block" to mean: "a cover that is removably attached to a generally exterior side surface of the engine block."

D. Coupled to Said Crown

The phrase "coupled to said crown" appears in claims 2 and 13 of the patent and describes the location at which the power source is attached to the headgear. The parties do not appear to seriously dispute the meaning of "coupled." Their proffered terms, "connected" and "attached," can be used interchangeably. The court prefers "attached" because it adequately reflects the "fastening" and "link" connotated by the term "couple." MERRIAM WEBSTER COLLEGIATE DICTIONARY at 267 (10th ed. 1997).

The parties' main dispute focuses on how to construe or limit "crown." Plaintiffs contend that the word speaks for itself. Defendant offers a lengthy definition: "the generally dome-shaped portion that extends upward from the lower edge of the headgear to cover the top of the head." Independent claims 1 and 12 identify the "crown" as an integral structural component of headgear, distinct from the "brim." The specification demonstrates that the patent's references to the "brim" and "crown," maintain the same meaning in the patent that they have in ordinary usage. "][A] ball cap generally comprises a crown contoured for covering part of the user's head when worn, [and] a brim disposed exteriorly of and attached to the crown at a lower edge such that the brim extends outwardly from the crown." ('831 Patent, Col. 3, ll. 33-37.) The ordinary and undisputed meaning of the term "crown," as distinct from the brim, is apparent enough to anyone who has either worn or seen a baseball cap. There is nothing to be gained by weighing down the term with excess verbiage.

Defendant's wordy construction is apparently aimed at distinguishing the "crown" of the headgear from another structural component of many ball caps: the "sweatband." 2 There is substantial support in the patent for this distinction. The '831
The court can resolve the parties' dispute merely by distinguishing the "crown" from other structural components of headgear, further construction of the term is unnecessary. O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1361 (Fed. Cir. 2008). The court adopts the following construction for the phrase "coupled to said crown": "attached to the crown, as distinct from the brim or the sweatband, of the headgear."

1008

A. "the handle coupled to the contraceptive device by an elongate body" / "a deployment shaft having a proximal end and a distal end releasably coupled to the contraceptive device"

The claims themselves provide guidance as to the meaning of the term "couple." For example, the method in claim 5 covers an apparatus having a handle with "an actuator," where manipulation of the actuator retracts a protective sheath surrounding the contraceptive device. Similarly, in the apparatus covered by claim 14, "movement" of an "actuator mounted on the handle . . . releases the contraceptive device from the . . . deployment shaft."

This "handle" and "actuator" are easily visualized by two disclosed embodiments shown below in FIGS. 7 and 11J.
As shown in FIG. 7, the handle (denoted by 30) may contain numerous actuators (denoted by 33 and 39) that perform different actions once the contraceptive device is properly positioned within the fallopian tube. These actions may include the release of the contraceptive device from the installation apparatus or retraction of a protective sheath around the contraceptive device (col. 8:47-64). FIG. 11J shows an alternative embodiment of such a handle being held by the user, and illustrates how the actuators can moved (in this particular embodiment, the thumb rotates the actuator). To show how the handle fits in with the entire apparatus, an exemplary embodiment of the complete apparatus is shown below in FIG. 1B.

As seen in FIG. 1B above, the handle (denoted as 30) is only one component of the entire installation apparatus. On the opposite end of the apparatus is the contraceptive device (denoted by 12). Connecting the handle and contraceptive device to each other are various components, including a protective sheath (14), a release catheter (16), and a core shaft (18). Important to this order, however, is the fact that the various components are interconnected as to allow the actuators on the handle to retract the sheath (claim 5) or release the device within the fallopian tube (claim 14).

In light of this intrinsic evidence, it is clear that the term "coupled" as used in the asserted claims means something more than the components of the apparatus being simply "paired to or joined with" each other, as proposed by Conceptus. A person having ordinary skill in the relevant art at the time the patent was filed -- after reading the entire patent -- would have understood the term "coupled" as used in the asserted claims as requiring a more interactive connection. Stated differently, the components of the device must be "coupled" together in a way that allows the actuator(s) on the handle to trigger activity elsewhere on the device. This is the principal object of the invention (col. 2:32-34).

The claims themselves, however, do not limit or describe how this interactivity between components of the invention must be achieved. Nevertheless, Hologic argues that the components of the invention must be "mechanically attached" to each other using "threads, cooperating key/slots, connectors, or the like." This construction of the term "coupled" was taken directly from the description of one particular embodiment of the present invention (see col. 10:30-33).

Hologic's proposed construction, however, is too limiting. While it is true that the specification only disclosed embodiments featuring mechanical attachments between the various components of the invention, a person having ordinary skill in the relevant art at the time the patent was filed would have understood that the required interactivity between various components could have been achieved by mechanical or electronic means. For example, nothing in the claims limit the "actuators" on the handle of the apparatus from being digital (i.e., based on electronic circuitry) rather than mechanical. Pressing this button could send an electronic signal to the deployment shaft or contraceptive device, triggering the mechanical retraction of the sheath (in claim 5) or release of the device (in claim 14). Indeed, claim 14 also expressly covers an apparatus that can administer RF energy to a portion of the fallopian tube (to promote scar tissue formation). A person having ordinary skill in the relevant art at the time the patent was filed would have understood that triggering this RF energy would likely involve electronic, rather than mechanical, actuation.

In light of this analysis, this order finds that a person having ordinary skill in the relevant art at the time the patent was filed would have understood "coupled" in claims 5 and 14 to allow for the components of the apparatus to be mechanically or electronically connected to each other. Accordingly, the following constructions will govern:

The phrase "the handle coupled to the contraceptive device by an elongate body" from claim 5 will be construed as "the handle mechanically and/or electronically connected to the contraceptive device by the elongate body." Similarly, the phrase "a deployment shaft having a proximal end and a distal end releasably coupled to the contraceptive device" from claim 14 will be construed as "a deployment shaft having a proximal end and a distal end that is mechanically and/or electronically configured to attach to and detach from the contraceptive device."

GO BACK
3. "wherein the wings are coupled to the first and second actuators"

This phrase is used in claim 1 of the '992 Patent. WG seeks to construe this term as "wherein each actuator is linked to both wings." Ion seeks to construe this term as "wherein the wings are connected to the first and second actuators." WG argues that its construction is appropriate because the specification only discloses having one roll actuator and one pitch actuator, each linked to both wings. WG also points out that Ion relied on the actuator to distinguish prior art. Ion argues that WG is improperly importing a limitation from the disclosed preferred embodiments into the claim language. More precisely, Ion argues that the specification does not require that each actuator has an individually dedicated function such that it must be linked to both wings.

This Court agrees with Ion. Although WG may be correct that the preferred embodiment of this invention requires each wing to be coupled to the first and second actuators, one of which controls roll and one which controls pitch, the Court cannot hold that the scope of claim should be limited according to this embodiment. The language cited by WG from the specification is consistent with the notion that it is the preferred embodiment of Ion's Patent that one actuator is the roll actuator and the other is a pitch actuator. (See Pl. Resp. Br., Doc. No. 71, at 12.) However, nothing in the claim language or in the specification constitutes a disavowal of the possibility that each actuator may control both roll and pitch and be linked to a separate wing. Indeed, the only claim that specifically teaches one actuator controlling the roll or the pitch of both wings is claim 4. Because, however, this claim is a dependent claim, independent claim 1 and dependent claims 2 and 3 need not be read as having an identical scope as this claim. Therefore, the claim language allows for a broader interpretation than the embodiment that is disclosed in the specification. Innova/Pure Water Inc., 381 F.3d at 1117 (stating that "[p]articular embodiments appearing in the written description will not be used to limit claim language that has a broader effect"). In addition, nothing in the specification indicates that having each actuator dedicated to a separate function is a necessary or critical element of the invention's functionality. See Andersen, 474 F.3d at 1367.

Therefore, the Court will construe this phrase according to its apparent plain and ordinary meaning to a person of ordinary skill in the art, as made apparent through the parties' arguments. Both WG and Ion offer extrinsic evidence to suggest that the term "coupled," as it is used here, can be defined as "linked." Accordingly, the Court will construe this term as "wherein the wings are linked to the first and second actuators."

12 Defendants claim that the court's construction of the term "coupled to the independent poles and rebounding mat" implies that any component of the safety enclosure connected to any element that ultimately connects to the rebounding mat may be considered "indirectly" connected to the rebounding mat and thus covered by the patent. That interpretation of the claim construction is overbroad. Given the interconnected nature of the invention described in the Jumpsport patent, all the elements of the invention could conceivably be considered to be "indirectly connected" to the mat under defendants' interpretation. The plain meaning of the term "coupled . . . to the rebounding mat" does not encompass such a broad definition. The court therefore clarifies its construction of "coupled to the independent poles and rebounding mat" as: connected to the independent poles and to the rebounding mat, either directly or through a discrete coupling device that is not an element of the trampoline or enclosure.
3T moves for a summary finding of non-infringement of claim 1 of the '784 patent, which reads:

1. A system for dispensing money orders at least one retail establishment comprising:
   [a.] a money order dispenser for dispensing money orders at a retail establishment;
   [b.] a digital processor for controlling the operation of the dispenser;
   [c.] a memory associated with the digital processor for storing the transaction data and control data;
   [d.] a printer with a compartment for storing blank money order forms and coupled to the money order dispenser for receiving a blank money order form from said compartment and printing alphanumeric indicia thereon;
   [e.] a host device remotely located from the retail establishment and coupled to the money order dispenser for management and control of the dispenser system;
   [f.] a data collector remotely connected to the money order dispenser for issuing a polling command; and
   [g.] means in the data collector for receiving transaction information from the money order dispenser upon issuance of said polling command.

(Powell Aff. Ex. C, cols. 71-72.) Unlike the claims at issue in the '275 and '596 patents, claim 1 of the '784 patent does not recite any security features.

3T alleges that the printer claim element of the '784 patent should be construed to cover a physically secure "internal" printer located within the money order dispenser itself. First, 3T points to the language of the limitation, which describes the printer as "coupled to" the dispenser and having a "compartment for storing" blank money order forms. Travelers argues that the claim language does not support such a construction because the claim does not recite the terms "internal" or "physically secure."

To ascertain the ordinary and customary meaning of claim terms, the court may rely on dictionary definitions and treatises. 3M Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1370-71 (Fed. Cir. 2003). Here, the plain meaning of the claim terms supports a construction similar to 3T's argument. The definition of "coupled" is "mechanically or electrically connected." Webster's Third New International Dictionary 522 (1993). Although that definition of "coupled" may include printers physically or electrically attached to a dispenser, the definition of the verb "couple" provides greater clarity. "Couple" means "to fasten together, to connect" or "to join." Id. at 521. Furthermore, the definition of "couple" in the electrical sense applies only to electric circuits or devices. See id. According to these definitions, the coupling of a mechanical device such as a printer should consist of a mechanical connection. The court therefore construes claim 1 of the '784 patent as covering a printer that is mechanically or physically connected to the dispenser, rather than merely electrically connected.

The meaning of a "compartment for storing" money orders does not suggest a physically secure system, however. "Compartment" means "a small chamber, receptacle, or container," and the verb "store" means "to have space for, provide storage room for" or "hold." Id. at 462, 2252. These definitions do not contemplate or mention physical security. Furthermore, the claim language refers to the function of the storage compartment as simply that part of the device from which the printer receives blank money orders. There is no suggestion of security in the context of the term's use. Therefore, the court does not construe the claim as requiring a secure storage compartment as part of the printing system.

Once the parties identify a disputed claim term and the court ascertains its plain meaning to the ordinarily skilled artisan, the court then examines the written description and drawings "to confirm that the patentee's use of the disputed terms is consistent with the meaning given to it by the court." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). First, the specification language shows that a physically or mechanically connected printer was contemplated by the "compartment for storing" and "coupled to" terms in the claim element. In particular, the specification provides for an "output throat" for the storage compartment cover, "through which the printed money orders are dispensed." ('784 patent, col. 5, 11. 27-29.) Further, the printing mechanisms move "the money orders through the dispenser." (Id. 11. 29-32.) This
language describes how the printer, storage compartment and dispenser are mechanically connected.

The specification also mentions the preferred security features of the printing system including a physically or electronically locked storage compartment and fan-folded money orders. (See, e.g., id. 11. 17-23.) However, the specification text does not explicitly state that the "compartment for storing" must be physically secure. Therefore, the court's construction is not in conflict with the language of the specification.

Second, the specification drawings confirm the court's construction of the disputed terms. Figure Two depicts a dispenser with an internal printer and storage compartment. (See id. Fig. 2.) The flow chart represented in Figure Three labels the modem and journal printer as "external," but does not identify the money order printer as external. (See id. Fig. 3.) These drawings support the construction of the printer as being physically or mechanically connected to the dispenser.

The prosecution history also supports this construction. The claim was originally rejected over Foudos. The applicant then added among other things the following underlined language to overcome the patent rejection: "a printer with a compartment for storing blank money order forms and coupled to the money order dispenser for receiving a blank money order form from said compartment and printing alphanumeric indicia thereon." (Powell Aff. Ex. I at 105 (emphasis in original).) The added language clarifies that the printer itself is coupled to the dispenser and that the storage compartment contains the blank money orders until they are printed and dispensed. Therefore, the physical or mechanical connection of the printer to the dispenser is emphasized by the prosecution history.

**C. Coupling Member**

As highlighted in the joint submission of the parties at oral argument, the recitation of "coupling member" appears in the Claim 1(e) of the '456 patent: 13 "a coupling member structured and disposed to detachably couple said cutting head assembly and said positioning ring and including means for permitting movement of said cutting head assembly relative to said positioning ring along said generally arcuate path."
Again, the primary dispute between the parties with respect to this term is that defendants argue that § 112, P 6 is invoked, while plaintiff contends it is not. Defendants propose the following construction: the function should be construed as a "separate element for coupling the cutting head assembly to the positioning ring," and the corresponding structure should be comprised of: a retaining segment 92, including an aperture 94 formed therein; and a pivot segment 95 structured and disposed to be coupled to the rigid upstanding member 44 of the positioning ring 32 and to permit coupling member 90 and accordingly, the cutting head assembly 50 connected thereto, to pivotally move about post member 45. (Court Reference Sheet at 1.) Plaintiff counters with the following construction: "the term "coupling member" is a structure that detachably joins the cutting head assembly and the positioning ring." (Id. at 2.)

As with the guide terms, the defendants essentially argue that "coupling member" connotes only the most generic structure and is therefore subject to a means-plus-function analysis. Plaintiff counters that the term invokes sufficiently definitive structure to those skilled in the art to escape § 112, P 6. The dictionary definitions provided by plaintiff define coupling as "a pairing or joining," Dorland's Illustrated Medical Dictionary (25th ed. 1974), "a device that serves to connect the ends of adjacent parts or objects," Webster's Ninth New Collegiate Dictionary at 299 (1987), "something that links or connects, as a railroad coupler," The American Heritage Dictionary at 332 (Second College ed. 1985), and define member as "[a] structural unit such as a wall, column, beam, or tie, or a combination of any of these," McGraw-Hill Dictionary of Scientific and Technical Terms (5th ed. 1994). Dr. Akin, an expert for the plaintiff, defines coupling member as "a mechanism or device to join two or more elements." (Pl.'s Ex. 10, Akin Report at 7.) Dr. Slade, plaintiff's rebuttal expert, offers this definition: "a structural element that detachably couples the cutting head and the positioning ring together." (Pl.'s Ex. 11, Slade Report at 6.) Plaintiff's own proposed construction mirrors that of its experts. These definitions essentially rely on the generic shapes of a "device," "structure," "something" and "mechanism" to accomplish the function of joining, linking, or connecting. I therefore conclude that for the same reasoning which led me to conclude that the guide and drive terms invoked § 112, P 6, coupling member is also under its ambit. None of these definitions indicate that the term would call to mind for those skilled in the art a range of structures sufficient to escape a means-plus-function analysis. To hold otherwise, would be to include every conceivable device. See Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1214 (Fed. Cir. 1998).

17. Coupling in a Common Plane

The parties disagree on the proper construction of "coupling in a common plane," and request that the Court interpret the term. Alloc maintains that "coupling in a common plane" as used in claim 1 of the '486 patent is "an obvious reference" to joining the panels by shifting them in a common plane which is sometimes referred to as "snapping" them together. (Alloc Resp. Mem 10.) It asserts that the limitation is subsumed in the limitation that arises out of the file history calling for the panels to be assembled alternatively by sliding the panels toward each other laterally or by rotating the panels together. (Id.)

Unilin maintains that "coupling in a common plane" makes no reference to how the panels are coupled. (Unilin Reply Br. 3.) Rather, states Unilin, a reading of the phrase in context discloses that it describes the position of the panels in relation to each other after they are coupled. (Id.)

The phrase "coupling in a common plane" appears in claim 1 of the '486 patent as follows:

said locking means comprising a locking element in the form of a downwardly extending protrusion located on the lower side of the tongue and an upwardly facing cooperating locking recess in the lower lip, said locking recess being located at a position that is at least partially distally beyond a distal edge at which the upper lip terminates, said cooperative contact surfaces defined respectively by said protrusion and said recess, and configured, when engaged in a cooperative relationship upon coupling in a common plane of two identical ones of said panel, to meet each other at a common plane of tangency that with respect to the lower lip is inclined at an angle other than 90 [degree] relative to the common plane of the coupled
panels, said angle extending inwardly and downward from a distally outer location to a proximal inner location.

('486 patent, 14: 16-26) (emphasis added.)

Claim terms must be read in the context of the claim. Phillips, 415 F.3d at 1313. Having carefully considered the phrase "coupling in a common plane" in context as required under claim construction law, this Court concludes that the term describes the panels once they are coupled. The panels become "engaged" in a cooperative relationship once they are joined. The use of the past tense of engage, "engaged," indicates that the panels have been joined. Alloc's definition is inconsistent with the patent specification. Unilin's definition comports with the language in claim 1 of the '486 patent.

Also, comparison with the language in claims 23, 29, 38, 39 through 40, and 65 of the '486 patent shows that when "laterally shifting in the common plane," is required the limitation is explicitly stated in the claim. Alloc's interpretation would render meaningless the claim language of dependent claims 23, 29, 38 through 40. Again the doctrine of claim differentiation suggests that Alloc's interpretation is incorrect. See Liebel-Flarsheim Co., 358 F.3d at 910.

In light of the foregoing, the Court concludes that the phrase "coupling in a common plane" describes the position of the panels in relation to each other after they are coupled.

B. Claims Construction in the '415 Patent

On September 19, 2003, the Court held a hearing in accordance with Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996), to construe the disputed terms and phrases of the asserted claims. The Court's October 7, 2003 Order Following Claims Construction Hearing construed the following disputed terms in the '415 patent which are relevant to the present findings on validity and invalidity:

"implant delivery assembly"  
"an apparatus for delivery of occlusive devices, such as embolic coils that comprises three distinct components: a pusher, a coupling, and an implant"

"pusher"  
"any device or structure intended to push another device or structure"

"selectively operable coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"said coupling operable by fluid pressure so that when a sufficient amount of fluid pressure is applied to the coupling, the fluid pressure a user causes the occlusive implant to separate from the pusher"  
"the coupling is a connecting device that can be operated by selectively applying fluid pressure to the coupling to separate the implant from the pusher, and the application of the fluid pressure by the user to the coupling causes the detachment of the implant at the coupling"

"delivering fluid pressure through the pusher such that the implant detaches from the pusher"  
Plain and ordinary meaning applies, no specific construction
1. Construction of "coupling assembly"

Medtronic contends that "coupling assembly" means "a two-piece interlocking coupling element that mounts around the screw head." (Defs.' Br. 18.) Medtronic begins its argument by noting that "[t]here is no accepted plain and ordinary meaning for 'coupling assembly' in the prior art of multi-axial pedicle screws." (Id.) Medtronic then turns to the claim language and observes that the two text sections following "comprising" describe a cap portion and a retaining portion, and finds in this language two limitations: 1) the coupling assembly has two pieces; and 2) the two pieces are interlocking. As to the first point, as Plaintiff contends, "[w]hen a patent claim uses the word 'comprising' as its transitional phrase, the use of 'comprising' creates a presumption that the body of the claim is open. In the parlance of patent law, the transition 'comprising' creates a presumption that the body of the claim is open. In the parlance of patent law, the transition 'comprising' creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements." Crystal Semiconductor Corp. v. Tritech Microelectronics Intl, Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). Thus, the use of "comprising" creates a presumption that the coupling assembly is not limited to two parts, but consists of at least two parts.

As for the argument that the coupling assembly is limited to interlocking pieces, Medtronic here makes its first use of the "only one way" redefinition by implication argument: because the specification describes only one embodiment, and in this embodiment the parts are interlocking, the interlocking limitation should be read into the claim. As discussed above, there are numerous problems with this argument. Here, specifically, Medtronic invokes the principle of redefinition by implication, but does not actually explain how the words "coupling assembly" have been implicitly redefined. Moreover, astonishingly, Medtronic concedes that "the '665 patent [specification] does not use the term 'coupling assembly.'" (Defs.' Br. 19.) How the specification redefines the claim term by implication without ever actually using it is an unexplained mystery. Medtronic is merely trying to read the preferred embodiment into the claims, and calling it redefinition by implication does not make it so. Medtronic has not pointed to anything in the specification that clearly redefines the phrase "coupling assembly" so as to justify importing the proposed limitation into the claim.

Medtronic next points to statements in the specification in which the applicant says what the invention "is." This argument has a number of problems, but the first comes from the fact that Medtronic's evidence from the specification ignores the context in which these statements appear. Medtronic first points to the statement that "the present invention relates to a screw . . . via a two-piece interlocking coupling element" in the "Background of the Invention." ('665 Patent, col 1, ll. 22-26.) Now, consider the statement in context:

This invention relates generally to a polyaxial screw and coupling apparatus for use with orthopedic fixation systems. More particularly, the present invention relates to a screw for insertion into spinal bone, and a coupling element polyaxially mounted thereto, via a two-piece interlocking coupling element . . .

('665 Patent, col 1, ll. 20-26.) The fact that the first statement characterizes the invention more broadly, while the second statement characterizes it more particularly, informs the reader that the second statement has a narrower scope than the first and does not provide the definitive description of the invention. Medtronic ignores this, and proceeds to make the same mistake again, as it quotes out of context from the "Summary of the Invention." ('665 Patent, col 1, ll. 22-26.) Now, consider the statement in context:

The preceding objects of the invention are achieved by the present invention which is a polyaxial locking screw and coupling element for use with rod stabilization and immobilization systems in the spine. More particularly, the polyaxial screw and coupling element assembly of the present invention comprises a bone screw having a head which is curvate in shape, for example semi-spherical, and a two-piece interlocking coupling element mounted thereto.

('665 Patent, col 3, ll. 2-9.) Again, Medtronic ignores the fact that these statements contain the same structure: a broader statement about the invention is followed by a narrower, more detailed one. The "interlocking" description is thus preceded by the qualifying phrase "more particularly," which notifies the reader that what follows is not a general statement of the
outer bounds of the scope of the invention.

These statements, read in context, are actually significant evidence against Medtronic's position. What we find is that, as the first sentence of the two major sections preceding the description of the preferred embodiment, the sections headed "Background of the Invention" and "Summary of the Invention," the patentees have begun with a very broad statement about the invention. These statements have a scope that is very much broader than the preferred embodiment. In particular, the statement that the "invention [] is a polyaxial locking screw and coupling element for use with rod stabilization and immobilization systems in the spine" is significant evidence that the inventor did not intend to limit the scope of the invention to the preferred embodiment. (’665 Patent, col 3, ll. 2-5.)

Medtronic turns to Honeywell for legal support for its position, but this backfires. The Honeywell Court did indeed find significance in such statements about what the present invention is and stated that "the public is entitled to take the patentee at his word . . ." Honeywell, 452 F.3d at 1318. The public is indeed entitled to take the patentee at his word, but the evidence shows that the patentees' words begin with general statements about what the invention is that are very broad in scope. This is significant evidence against Medtronic's main argument in claim construction, that claim scope should be limited to the preferred embodiment. These specification statements clearly show that the patentees described the invention at different levels of generality at different points, and that their initial broad statements were followed by narrower, more particular statements. The public is very clearly on notice that the patentees have an understanding of the invention that is quite broad in scope, and that their detailed example of the invention does not define the outer limits of the territory of the invention. This, in and of itself, constitutes significant evidence against the majority of Medtronic's arguments in the present claim construction disputes.

-Footnotes-

6 Again, the first sentence of the "Summary of the Invention" states: " . . . the present invention [] is a polyaxial locking screw and coupling element for use with rod stabilization and immobilization systems in the spine." (’665 Patent, col 3, ll. 2-5.) This Court notes that this statement of what the invention is contains no limitations concerning partial slots, inward radial forces for crush locking, top-loading, or tapering of the axial bore.

-End Footnotes-

The Federal Circuit's guidance in Phillips can now be applied: "Much of the time, upon reading the specification in that context, it will become clear whether the patentee is setting out specific examples of the invention to accomplish those goals, or whether the patentee instead intends for the claims and the embodiments in the specification to be strictly coextensive." Phillips, 415 F.3d at 1323. Given what has just been described -- the express use of broad initial statements of the invention, followed by narrower statements with increasing detail -- the specification indicates that the patentees were setting out examples of the invention; they did not intend for the claims and the embodiments to be strictly coextensive. Following Phillips, the claims should not be confined to the preferred embodiment.

In its responsive brief, Medtronic contends that the "only enabled construction" of "coupling assembly" is a two-piece interlocking element. (Defs.’ Resp. Br. 8.) As discussed above, this Court rejects the "only enabled construction" approach Medtronic uses here.

Fastenetix proposes that "coupling assembly" means "a collection of parts in adjustable association," a phrase which on its face is so vague that, if this Court were to declare that Fastenetix is right, it would have succeeded only in obscuring, rather than clarifying, the meaning of "coupling assembly." Furthermore, given that "coupling assembly" is followed by a fairly lengthy description of the two parts which comprise it, this Court does not see at this point why any construction of the phrase is needed. This Court has rejected the importation of the "two-piece" and "interlocking" limitations into the construction of the phrase, and the parties have not put into focus any other specific dispute over its meaning. In the absence of a specific dispute over a specific material issue, claim construction becomes an abstract and purely advisory exercise. Should the parties find a specific, material dispute over the meaning of this phrase, they will be given the opportunity to request further claim construction.

-GO BACK
2. "detaching a coupling between said distal tip and said wire"

Claim 25 is a method claim. The parties dispute the proper construction of the phrase: "detaching a coupling between said distal tip and said wire." Specifically, the parties dispute the proper construction of the word "coupling" in the disputed phrase.

The word "coupling" is used in the specification in two different ways. In the following excerpt, "coupling" is used as a verb:

The invention comprises a core wire and a detachable elongate tip portion extending the core wire for a predetermined lineal extent. The core wire is adapted to being packed into the vascular cavity to form the occlusion in the vascular cavity and is coupled to the distal portion of the core wire. The tip portion includes a first segment for disposition into the cavity and a second segment for coupling the first portion to the core wire.

('133 Patent, Col. 5:63 - 6:1.)

Claim 29 of the '133 Patent uses the word "coupling" as a verb:

The method of claim 28 where said step of detaching said distal tip of said wire electrolytically disintegrates a connecting segment coupling said wire to said distal tip to effect separation.

In contrast, in the following excerpt, the word "coupling" is a gerund, which is used as a noun:

Depicted in FIG. 6 is an embodiment of the invention wherein such mechanical thrombosis can be achieved. Wire 10 has a tapering end portion 14 covered with a Teflon laminate 24 similar to that described in connection with the embodiment of FIG. 1. Wire 10 is attached by means of a mechanical coupling 100 to a platinum coil 102 which has a plurality of filaments or fine hairs 104 extending therefrom. In the illustrated embodiment, hairs 104 have a length as may be determined from the size of the vascular cavity in which coil 102 is to be used.

(133 Patent, Col. 9:67-10:10.)

One skilled in the relevant art would understand "coupling" as used in Claim 25 to be used as a noun. 24 The commonly understood meaning of the noun "coupling" is "a joining together; a pairing; a device for joining two railroad cars together."

See Webster's New Twentieth Century Dictionary, 419 (2d ed. 1983). Thus, a "coupling" could be a separate device, such as a sleeve which joins two separate objects on either end. Alternatively, a "coupling" could be a description of the condition of two things being joined or "coupled" to each other joint without any separate device, such as the twisting or "coupling" of two wires together. There is nothing in Claim 25 or in the specification which would lead to the conclusion that one definition should be used to the exclusion of the other.

24 Grammatically, the noun "coupling" would be the direct object of the verb detaching.
5. Coupling means

The parties dispute whether the term "coupling means" as used in claims 1, 2, 7, 9 and 16 of the '480 patent is a means-plus-function limitation. The claims' use of the word "means" raises the presumption that the limitation is means-plus-function. Plaintiff contends that the word "coupling" provides sufficient structure to overcome the presumption, placing the limitation outside the scope of § 112 P6. Plaintiff is mistaken.

All the relevant claims provide for the same element: "a coupling means for selectively connecting and disconnecting said accessory unit to said vehicle." E.g., '480 pat., col. 8, lns. 53-54; col. 9, lns. 6-7. As with "switch," "coupling" can refer to a device defined by its function. E.g., New Oxford American Dictionary 388 (2d ed. 2005) ("a device for connecting parts of machinery"). However, the remainder of the claim language does not provide any additional information about the proper structure for the coupling means, other than the function of the coupling. Moreover, "coupling" needs to be narrowed to some structure because the term standing alone could encompass too many structures that do not fall in line with the invention. For example, a screw and bolt connecting two steel plates could connect and disconnect the accessory unit to the vehicle. However, it is clear from the patent that such a coupling would fall outside the scope of the invention, which intended to use the "coupling means" as a way to connect the electrical circuits of the accessory unit to the vehicle's energy source. '480 pat., col. 3, lns. 34-35. Therefore, "coupling means" is a means-plus-function limitation.

According to the claims, a "coupling means" functions to selectively connect and disconnect the accessory unit to the vehicle. The only "coupling means" described in the specification are conventional "female and male plow plugs 60 and 78" and "female and male batter plugs 62 and 80." Id., col. 3, lns. 36-39. Figure 2 provides a visual representation of these type of plugs:

[SEE FIGURE IN ORIGINAL]

Thus, the structures clearly linked with the claimed function are conventional female and male plow plugs and female and male battery plugs and their equivalents.

Defendant contends that the specification's specific examples of female and male battery plugs and female and male plow plugs should be included in the construction. The specification lists the preferred embodiment of the battery plugs as (1) a two-pin plug for the male battery plug and a two-receptacle plug for the female battery plug and (2) a 12-pin plug for the male plow plug and a 12-receptacle plug for the female plow plug. '480 pat., col. 3, lns. 45-68 and col. 4, lns. 1-8. However, those specific versions of the different plugs are not clearly linked to the claimed function. In other words, whether the plugs have 2 pins or 100 pins, all that matters are that they are male and female and that they function to connect and disconnect the electrical circuits of the accessory unit to the vehicle. Further, even though the specification lists the male plow plug as a 12-pin plug, the figure shows only a 6-pin plug. Id., col. 3, lns. 57-68 and col. 4, lns. 1-5. The specification notes that the function of the other six pins is not explained because "they are not part of the operation of the invention." Id., col. 4, lns. 4-5. Accordingly, including the specific plugs listed in the specification would read in functions not listed explicitly in the claims.
connected to a first end of a corresponding foot link; (b) a double wheel flywheel supported for rotation about the pivot axis, each wheel being pivotally connected directly to the first end of a corresponding foot link; or (c) equivalent structures thereof." Alternatively, Fitness Quest argues that the claim should be construed as:

A pair of members, each of which: (1) is directly connected to a component defining the pivot axis; (2) is directly connected to the first end of the foot link at a single connection point defining a common axis between the member and the foot link; (3) permits rotational movement of the foot link relative to the member about the common axis; and (4) maintains a fixed distance between the common axis and the pivot axis.

Fitness Quest proposes this construction if the Court does not conclude that the claim should be construed as means-plus-function.

Pursuant to § 112 P 6, a means-plus-function claim is a claim that is "expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P 6. Unless a claim includes the phrase "means to" and then describes a function, the Court typically will not construe the claim as invoking § 112 P 6. Greenberg v. Ethicon Endo-Surgery, 91 F.3d 1580, 1584 (Fed. Cir. 1996) ("the use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' (particularly as used in the phrase 'means for') generally invokes section 112(6) and that the use of a different formulation generally does not."). Fitness Quest does not rebut this presumption.

The Court agrees with the reasoning in Judge Zilly's construction and from a prior Federal Circuit opinion that the term "member" specifically describes 'a structural unit such as a . . . beam or tie, or a combination of these' which connotes a definite structure to someone of ordinary skill in the art. CCS Fitness v. Brunswick Corp., 288 F.3d 1359, 1367 (Fed. Cir. 2002). The patent does not lose its definiteness by modifying "member" with the adjective "coupling." Rather, it specifically describes a range of devices that are structural units which couple.

The CCS Fitness opinion also counsels against Fitness Quest's alternative proposed construction, which limits the scope of the claims by requiring the coupling member to provide a direct connection between the foot links and the pivot axis. That opinion identifies a "member" as a specific term for a component that can attach different parts through a variety of structural arrangements. To the contrary, Fitness Quest's proposed construction seems like a way to limit the coupling member to bell cranks and fly wheels without specifically mentioning these types of components. The Court therefore rejects Fitness Quest's alternative proposed construction of coupling members.

The Court is not persuaded by Fitness Quest's argument from the Markman hearing that CCS Fitness and Judge Zilly's opinion relying thereon should be discounted because they are pre-Phillips decisions. First, Phillips only discounted the priority of extrinsic evidence in the scheme of claim construction, and not its validity. Second, CCS Fitness's definition of "member" has not been called into doubt by subsequent decisions and is therefore valid precedent. Finally, Fitness Quest fails to show, other than through conclusory assertions, that the term "member" does not denote a specific set of structures, as established in CCS Fitness. While the Court acknowledges Fitness Quest's argument that pre-Phillips claim construction principles are suspect, no persuasive competing theories have been offered in the instant action.

Fitness Quest's other citations are unavailing. In Mas-Hamilton Group v. LaGard, the Federal Circuit held that the claim term "lever moving element" lacked "a reasonably well understood meaning in the relevant lock art" that would "save it from application of [§ 112, P 6]." 156 F.3d 1206, 1214 (Fed. Cir. 1998). The court in that case observed that while "many devices take their names from the functions they perform," the patent holder failed to "directly to this court any evidence demonstrating that the district court erred in determining that the term. lacks a reasonably well understood meaning in the relevant lock art." Id. This opinion does not dictate the result in the instant case because "coupling" is easily understood to provide more structural information than "lever moving." 1 The disputed claim terms in the remainder of Fitness Quest's cases are equally distinguishable. Power Integrations, Inc. v. Fairchild Semiconductor Int'l, Inc., 422 F. Supp. 2d 446 (D.Del. 2006) ("soft start circuit," a "soft start" could be accomplished in numerous ways); Aspex Eyewear, Inc. v. Altair Eyewear, Inc., 386 F. Supp. 2d 526 (S.D.N.Y. 2005) ("retaining mechanisms for supporting," "supporting" provides inadequate structural guidance for an object as vague as a "mechanism"); Verizon Cal. Inc. v. Ronald A. Katz Technology Licensing, L.P., 326 F. Supp. 2d 1060 (C.D.Cal. 2003) ("credit verification structure," the function of "credit verification" could be accomplished in far too many ways to provide any meaning to the "structure" it described).
1 Indeed, during cross-examination at the Markman hearing, Fitness Quest's expert strongly implied that, to him, a "coupling member" had a specific structural meaning when he denied that a number of different arrangements (e.g., numerous levers connected by numerous pivoting joints or a pulley system) proposed by counsel for Precor could be considered a member that coupled the first lever to the last lever.

Furthermore, the proposition that the '829 patent's use of the term "coupling member" is intended to be a generic term for a set of structural units that couple the foot links to the pivot axis is also suggested in the specification, which asserts that "various mechanical arrangements may be employed to couple the foot links." Col. 4, lines 28-29. Claim 2 proposes an embodiment of claim 1 that includes bell cranks. This intrinsic evidence implies that bell cranks are only one potential embodiment of the coupling members. See Comark, 156 F.3d at 1187 (claim differentiation). Different types of coupling members other than flywheels and bell cranks are also implied in the specification, where the motion of the foot link end is described as "arcuate," which is defined as "a circular oval or other such closed, curved path of travel." If only bell cranks and flywheels were taught, then the path of travel would only need to be described as a circle.

The second major point of disagreement between the parties' constructions of this claim is the meaning of the phrase "predetermined distance." Fitness Quest argues that this phrase should be understood to mean a "fixed distance." Precor argues that this Court should employ Judge Zilly's definition, which rejected "fixed distance" and construed the phrase literally, to mean "a distance determined beforehand." 2 The Court employs Precor's proposed construction based on the doctrine of claim differentiation and because of the Court's conclusion that "arcuate" does not mean only circular.

2 Judge Zilly's actual construction for "predetermined distance" was "the amount of separation between one end of a foot link and the pivot axis before use of the claimed device; this amount of separation need not be unvarying while the machine is in use." Order at 17.

First, the doctrine of claim differentiation dictates the conclusion that the end of the foot link is not always at a fixed distance from the axis in the generic embodiment because claim 73 teaches a device "wherein said first and second coupling members couple their respective foot links to said pivot axis at a fixed distance therefrom." '829 Patent, Col. 8, lines 5-8 (emphasis added). In order for this claim to mean something different than a claim that describes the distance as pre-determined, the term "pre-determined" cannot mean "fixed." Juxtaposing these terms renders the difference obvious: Pre-determined means simply "determined beforehand" while fixed means "always the same."

Second, it is clear that if the path of the foot links can be circular or non-circular, as the Court concludes that arcuate means, the distance from the end of the foot link to the axis will not necessarily be the same. If the foot link path is circular, then the distance will be fixed and pre-determined. If the foot link path is oval or some other closed curved path of travel, then the distance will be variable and pre-determined.

The Court therefore construes this phrase as follows: "a first and a second structural unit which couples, each associated with a foot link, that attaches its associated foot link to the pivot axis at a distance from the axis that is not necessarily unvarying while the machine is in use, but is determined beforehand."

FieldTurf's Proposed Construction: "Relatively distinct, substantially continuous layer"
SCG's Proposed Construction: "Distinct, continuous, separate and uniform covering of material of a depth determined before the covering is applied across an entire area"

The Court's Claim Construction: "Relatively distinct, substantially continuous layer"

SCG argues that its construction of a "course" "is taken directly from FieldTurf's own Specification." It then makes three references to the specification. The first describes "[a] unique infill layer of two graded courses of particulate matter disposed interstitially between the upstanding ribbons upon the upper surface of the backing and at a depth less than the length of the ribbons." '689 patent, 5:10-15. The second reference is to point to Figure 1 and describe that figure as showing "a distinct, continuous, separate and uniform covering of material of a depth determined before the covering is applied across an entire covered area." In support of this description, SCG explains that "there are no breaks or gaps in the bottom course 5 or the top course 6[,]" "there are no peaks in the bottom course 5 or the top course 6[,]" and "there are no valleys in the bottom course 5 or the top course 6." The third reference to the specification notes that it contains the words "resistance to particle displacement" and uses this language to support its argument that particles that migrate to form a course after installation cannot infringe the patent.

The Court will address the third argument first. As the Court explained above, the issue of migrating particles or the time of infringement is an infringement issue, not a claim construction issue. 13

12 FieldTurf presented the claim construction of "course" as integral to each of the two courses described in the claim. Because its proffered definition for course is consistent, the Court will address "course" independently.

SCG argues that its construction of a "course" "is taken directly from FieldTurf's own Specification." It then makes three references to the specification. The first describes "[a] unique infill layer of two graded courses of particulate matter disposed interstitially between the upstanding ribbons upon the upper surface of the backing and at a depth less than the length of the ribbons." '689 patent, 5:10-15. The second reference is to point to Figure 1 and describe that figure as showing "a distinct, continuous, separate and uniform covering of material of a depth determined before the covering is applied across an entire covered area." In support of this description, SCG explains that "there are no breaks or gaps in the bottom course 5 or the top course 6[,]" "there are no peaks in the bottom course 5 or the top course 6[,]" and "there are no valleys in the bottom course 5 or the top course 6." The third reference to the specification notes that it contains the words "resistance to particle displacement" and uses this language to support its argument that particles that migrate to form a course after installation cannot infringe the patent.

The Court will address the third argument first. As the Court explained above, the issue of migrating particles or the time of infringement is an infringement issue, not a claim construction issue. 13

Moving to the second argument, the Court declines to import SCG's characterization of the drawings, unsupported by the specification, into the claims. Rather, the specification appears to disclose two courses with some level of particle movement between the courses. '689 patent, 7:44-45. As is explained in great detail earlier in the specification, the mixed bottom course may have a similar size, size distribution and shape such that there is little migration within that layer. '689 patent, 7:11-32. However, the bottom course particles may be smaller than the top course particles such that they can migrate from the top course. '689 patent, 7:63-8:9.

The first argument is the only one that references relevant specification language. However, the only portion of the proposed definition arguably supported is the concept "of a depth determined before the covering is applied across an entire covered
area." However, the "depth" reference in the specification is actually referring to the entire layer depth, not a course depth. Moreover, to the extent a depth is determined in the specification it is defined by a maximum value of less than the length of the ribbons, not a specific "depth determined before the covering is applied across an entire covered area." Finally, with respect to the layer, there is no need to include language regarding the layer depth in the claim as the claims in the patents-in-suit explicitly state that the layer depth is less than the ribbon length.

Defining what constitutes a vacuum-blower's "cover" is a critical issue. Toro defines "cover" functionally. As used in element iv of claim 16, "cover" refers to whatever is used to exclude fingers or clothing from the impeller, while permitting air flow to the impeller. The term "cover" does not imply any particular design. (Pl. Supplemental. Mem. at 2).

So construed, Toro argues that the White air inlet "cover", which includes a hinged outer lid and a removable baffle, is contemplated by claim 16 because both pieces together function as a cover. (Pl. Mem. at 12). The two-piece White cover, like the one-piece Toro cover, "perform[s] the covering function of restricting access to the air inlet." (Pl. Supplemental Mem. at 2). Toro asserts that the language of claim 16, which defines "cover" functionally, is broad enough to include both the "one-piece and two-piece [covers], and protects the full scope of the removable cover versions." (Pl. Mem. at 16-18). Thus, any cover that restricts access to the air inlet necessarily "includes means for increasing pressure." (Pl. Mem. at 18).

White rejects Toro's functional definition. White does not explicitly present its own definition. Instead, White refers to limitation vi of claim 16 to show that a "cover including a means for increasing pressure" means the '528 patent claims a removable one-piece air inlet cover with a pressure ring attached to or included as part of the cover. (Def. Mem. at 18).

White further argues that Toro has repeatedly admitted in its pleadings that the pressure increasing means described in the '528 patent are claimed as part of the air inlet cover and not as a separate removable competent. (Id. at 19).

According to the common dictionary definition, the noun "cover" means: "1: Something that protects, shelters, or guards 2: something that is placed over or about another thing ... a: LID, TOP." Webster's Third New Int'l Dictionary 524 (1986). Both the outer lid component and the baffle of the White "cover" cover the air inlet during blowing operation and are both removed from the air inlet cover during vacuuming. Both pieces lie over and conceal the air inlet cover and guard the impeller when needed and can be removed as needed. As the Second Circuit has stated, "It is not an avoidance of infringement to make any two separate pieces while in the patent they are made one integral piece or vice versa." See Hookless Fastener Co. v. G.E. Prentice Mfg., Co., 75 F.2d 264, 267 (2d Cir.), cert. denied, 295 U.S. 748, 79 L. Ed. 1693, 55 S. Ct. 826 (1935). Moreover, as Toro points out, removable covers may take many forms other than the designs at issue in this case. See (Pl. Mem. at 14).

The court has reviewed the ordinary meaning of the claim language, as well as the definitions offered by the parties. The court concludes that "cover" as used in the '528 patent includes the entire cover assembly and not only the air inlet lid as White argues. Thus, the '528 patent claims both one-piece covers and two-piece covers that include a separately removable pressure ring.

The Defendants' proposed construction is: "a removable cover that the user chooses to engage or disengage in which the cover, when engaged, completely covers the open top portion of the container (subject to the definition of 'open top portion')." Sunbeam's proposed construction is: "a removable structure adapted to mount to the end of a container to cover the end of the container to some extent." As the Defendants note, the parties agree that "cover" means "cap" and that this definition incorporates the construction of "open top portion," leaving the sole area of disagreement as the phrase "selectively covering."
1. Words of the Claim

The relevant claim language is the same as for the term "open top portion:"

A beverage container assembly for use with a blender, comprising:

- a beverage container having an open top portion and a closed bottom portion;
- a first removable cover for selectively covering said top portion of said container, said first cover adapted to be removably mountable on and off a blender and comprising an adapter portion for mounting said container on a blender; and
- a second removable cover for selectively covering said open top portion of said container, said second cover comprising a cap, and wherein said first and second covers are interchangeable on said container.

'592 Patent at 20:50-63 (emphasis added).

2. Specification and Prosecution History

The Defendants assert the following specification language as supportive of their construction:

A removable cap 198 (FIG. 2) is provided that may be screwed onto the male threads 196. The removable cap 198 may include a drinking hole, and/or may include a closure tab to avoid spillage.

* * *

The cap 198 may then be screwed onto the single serving beverage container 38, and the single serving beverage container is ready for use.

By the Defendants' reasoning, the phrase "may be screwed onto the . . . beverage container" reveals that the "selection" contemplated within the words "selectively covering" is one of whether or not to screw on the cap.

There is nothing in the prosecution history pertinent to this claim term. Although the Defendants reassert the "Flores reference," that was made respecting prior art that does not appear relevant to claim construction. Def. Memo. at 29; Sunbeam Exh. E, part 2, at SB000169-71.

3. Extrinsic Evidence

Neither party has submitted any pertinent extrinsic evidence.

4. Proper Construction of "Second removable cover for selectively covering said open top portion"

Nothing in the record reveals any greater specificity or any limitations regarding this claim term. Although the phrase "selectively covering" could be construed as a simple selection of whether or not to affix the cap, it could also refer to a selection within the cap itself of how much of the open top portion should be covered, through a device such as a "closure member."

Thus, the proper construction of the claim term is: "a cap that either allows the user to cover the drinking hole, through a mechanism such as a closure member to an extent that the user may select, including fully open and fully closed, and which may allow the user to select a degree of opening somewhere between fully open and fully closed; or a cap that may be screwed onto the beverage container by the user and which covers some or all of the open top portion."
1. "Cover layer having a Shore D hardness." This limitation requires that Shore D hardness be measured "on the ball."

a. The court recognizes, at the outset, that there is support for both parties' respective claim constructions in the intrinsic and extrinsic evidence of record. For instance, the specifications of the Sullivan patents refer to both "on the ball" and "off the ball" measurements of Shore D hardness. Notably, however, the "off the ball" measurements are called out in relation to raw materials, while the "on the ball" measurements are called out when comparing the characteristics of the finished products, in this case, actual golf balls. 2 The prosecution history is not inconsistent with this observation. 3

b. There is record evidence that, in the art, those of ordinary skill take Shore D hardness measurements "in accordance with ASTM test 2240" both "on the ball" and "off the ball." 4 In this regard, of course, it is evident that Mr. Sullivan could have specified, but failed to do so, whether he meant "on the ball" or "off the ball" measurements. However, given that claim construction is a matter both of science and of semantics, when the science (such as it is) is ambiguous, the claim construction exercise becomes more a matter of semantics, i.e., the words and grammar the patentee actually used to describe the invention.

c. In this case, the claim language refers to a "cover layer having a Shore D hardness," not the material comprising the cover layer. Therefore, I conclude that the language of the claims at issue is more consistent with a finding that Shore D hardness is measured "on the ball," since one does not have a cover layer until an actual golf ball is produced.

Acushnet argues that the determinations that the claims were not invalid were based upon a faulty interpretation of the phrase "cover layer having a Shore D hardness," which appears in each of the asserted claims. Acushnet contends that the district court's on-the-ball construction led it to improperly reject Acushnet's invalidity arguments, which in part depended on prior art disclosing the off-the-ball hardness of polyurethane materials that can be used to make golf ball covers. We review the district court's claim construction de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). We generally assign to claim terms "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc).

Acushnet argues that the district court's claim construction is erroneous because the specification notes in several places that the hardness values therein are "measured in accordance with ASTM method D-2240." '293 patent col.7 ll.21-22. 5 The ASTM D-2240 standard states that hardness should not be tested on a rounded or curved surface, which Acushnet argues precludes measuring hardness on the rounded and irregular surface of a golf ball. ASTM D-2240, at 2. Thus, Acushnet contends, a person of ordinary skill in the art would understand "cover layer having a Shore D hardness" to mean the hardness of a flat sample of the material used for the cover layer at issue, tested off the ball.

We disagree. The Sullivan patents make clear that, when read in context, the reference to ASTM D-2240 does not require hardness of the cover layer to be tested off the ball. To the contrary, the claims speak of "[a] golf ball" with a "cover layer" having a certain hardness, rather than focusing on the hardness of the material used to create the cover layer. E.g., '293 patent col.23 ll.49-60. Likewise, the specification points to the hardness of the assembled ball (rather than of the cover materials in isolation) as the relevant characteristic. E.g., id. col.5 ll.7-8 ("The hardness of the ball is the second principal property involved in the performance of a golf ball." (emphasis added)). While there are examples providing off-the-ball measurements of commercially available materials in the patent, the examples directed to golf balls as opposed to starting materials specifically disclose hardness measurements taken on intermediate and finished balls. E.g., id. col.22 l.14 (Table 8,
showing "Shore D" hardness measurements on finished balls); see also id. col.17 ll.36-37, 41 (Table 5, showing "Shore C Hardness" of "Molded Intermediate Balls" with inner cover); id. col.18 ll.52-53, 57 (Table 6A, showing "Shore C Hardness" of "Molded Finished Balls" with outer cover in place); id. col.19 ll.63, 66 (Table 6B, same). These examples confirm that hardness was to be measured on the ball. 6 Indeed, as the district court noted, there is no "cover layer" to measure until a golf ball is produced. Markman Order, 523 F. Supp. 2d 388, 2007 WL 4165415, at *1.

6 Acushnet notes that some unasserted claims also specify a flexural modulus for the cover layers, which must be measured off the ball. See, e.g., '130 patent col.24 ll.1-2. Unlike modulus, however, hardness can be measured on the ball, and as discussed above, the patent makes clear that the claims refer to on-the-ball measurement of hardness.

Moreover, here there was evidence at trial from Acushnet's own witnesses showing that those of skill in the art typically took Shore D hardness measurements on the ball. Jeff Dalton, for example--Acushnet's Vice President of Product Development--testified that the golf ball industry commonly conducted hardness tests in substantial compliance with ASTM D-2240, with the exception of the requirement that the test not be conducted on the ball: "[W]e--technical people in the golf ball industry deviate from that standard by not measuring [hardness] on the kind of test specimen that is called for in ASTM [D-2240]. We generally measure it on the ball." Trial Tr. 514:21-515:1 (emphasis added). 7 Such evidence of accepted practice within the art, when not at variance with the intrinsic evidence, is relevant to the question of how a person of skill in the pertinent field would understand a term. See Phillips, 415 F.3d at 1318 ("[E]xtrinsic evidence in the form of expert testimony can be useful to . . . establish that a particular term in the patent or the prior art has a particular meaning in the pertinent field."); see also Symantec Corp. v. Computer Assocs. Int'l, Inc., 522 F.3d 1279, 1289 n.3 (Fed. Cir. 2008). The district court did not err in holding that the phrase "cover layer having a Shore D hardness" refers to an on-the-ball hardness measurement.

7 See also Trial Tr. 344:13-14 (Acushnet Senior Vice President of Research and Development William Morgan noting that "it was our standard practice at the time to measure the Shore D hardness directly on the golf ball").
that disclosed in Schnyder could not operate on a circular container.” However, because the sliding cover was merely an embodiment of the ’658 patent, 6 this prosecution history does not restrict the type of cover described in Claim 1.

6 This fact is made apparent by Claim 5 which specifically states, "The smoking system of claim 1 wherein said cover is slidably mounted on said receptacle between a pair of guides associated with said receptacle." The fact that the sliding cover was specifically described in dependent Claim 5 means that the type of cover described in Claim 1 must be more broad. See McGill, 736 F.2d at 674.

Finally, Defendant argues that the term "cover means" contained in Claim 1 invokes a means-plus-function under 35 U.S.C. § 112, P 6. The Court agrees. As noted above, the sliding cover structure used in Claim 1 was merely an embodiment of the claim and cannot be used to limit or define the claim. There is no other indication of what particular structure is contemplated by the term "cover means" other than the fact that it lies "across said openings of said cavities" and is "movable to alternatively close or expose one or both of said cavities." While the position of the cover means is described, its meaning truly lies in the function assigned to it. Thus, it must be considered a means-plus-function element under section 112, paragraph 6.

The sixth disputed claim language states:

said cover member being removably integratable into said storage structure to improve the structural integrity of the storage structure.

Joint Statement, Table X, at 72-73. The language is clear and does not need construction. The language describes a cover member that can be integrated into the grain bin structure. Sukup argues that the phrase must be interpreted under the means plus function method. The Court disagrees. The word "means" is not used so there is no presumption. The language also describes an object, a cover member. The means plus function analysis therefore does not apply.

a. Parties' Positions

The parties propose the following constructions for "cover plate partially enclosing said fin structures," which is present in claim 2 of the ’631 Patent. Here, the dispute is whether "side walls" are required as urged by Defendants.

Plaintiff
A generally planar member positioned generally below the fin structures (relative to the top plate) which partially encloses the fin structures

Defendants
A flat member positioned on top of the fin structures having opposed side walls and a slot for directing forced air flow only into the air inlet path between said fin structures

b. Court's Construction
Again, the claim language does not support Defendants' exclusive entry argument. While the cover plate may block some of the air, there is no guarantee that the cover plate will actually prevent air from entering from any direction other than through the gaps. As urged by Plaintiff, the opening is a hole which allows air through the cover plate.

Regarding Defendants' proposed "side walls," this proposal is inconsistent with the word "plate." Notwithstanding the use of the term "plate," Defendants assert the cover plate must be "U"-shaped with side walls extending up from the base. The requirement is also inconsistent with the non-specific phrase "partially enclosing." The fact that the cover plate "partially encloses" the fin structures does not mean that side walls are mandatory. It is sufficient if the cover plate "partially encloses" the fins by sitting below them to minimize stray air escaping out the bottom (just as the "top plate" keeps air from escaping out the top). The modifier "partially" demonstrates that the claim does not require any particular extent of enclosure and not the tight seal that Defendants claim to be "essential."

Finally, Defendants suggest that the opening in the cover plate must be a "slot." To the extent Defendants assert that this term connotes a particular shape, the claim language would not support Defendants' assertion nor would the "cautionary language" of the specification which notes that the "shapes" and "dimensions" used in the described embodiments are non-essential. ('631 Patent at 7: 7).

In light of the foregoing, the Court construes "cover plate partially enclosing said fin structures" to mean "a flat member positioned to partially enclose the fin structures."

GO BACK

1028

CLAIM 9:

The parties are also disputing the meaning of the word "covered" as used in Claim 9 which states, in pertinent part, "said magnetic member is covered with a non-ferromagnetic material." Defendants argue that "covered" means a thin film layer. Plaintiff contends that the term "covered" should be interpreted as being structural in nature. Plaintiff notes that claim 10, which defendants are not accused of infringing, provides that the "magnetic member is coated with a non-ferromagnetic material." Plaintiff asserts that accepting defendants' interpretation of claim 9 would result in the words "covered" and "coated" as having the same meaning. Plaintiff contends that by allowing both claims to survive, the examiner obviously recognized that claims 9 and 10 are claiming two different things. Additionally plaintiff argues that the doctrine of claim differentiation precludes claims 9 and 10 from being interpreted to mean the same thing as it would render one of the claims superfluous. Thus, plaintiff maintains that since claim 10 refers to a layer of non-ferromagnetic material coating the magnet, claim 9 must invariably refer to a physical structure comprised of non-ferromagnetic material which covers the magnet.

The word "cover" can be used as either a noun or verb. Used as a noun it would refer to a device such as a lid or cap that is placed over or upon something else. Claim 9 uses the compound verb "is covered." The verb "cover" has the following primary meanings: "to place something upon or over, so as to protect or conceal;" "to overlay or spread with something;" and "to spread upon the surface of." The American Heritage Dictionary of the English Language, supra, at 432. Claim 10 uses the compound verb "is coated." The verb "coated" means "to cover with a layer." Id. at 363. When an object is coated with a material, the material forms a continuous film over the surface of the object. See e.g., Astra Aktiebolag v. Andrx Pharms., Inc. (In re Omeprazole Patent Litig.), 222 F.Supp.2d 423, 464 (S.D.N.Y. 2002) (quoting McGraw-Hill Dictionary of Scientific and Technical Terms, 5th ed. at 394 (1994)), aff'd sub nom. Aktiebolag v. Andrx Pharms., Inc. (In re Omeprazole Patent Litig.), 84 Fed. Appx. 76, 2003 WL 22928641 (Fed.Cir. 2003). Thus, in the context of claims 9 and 10, the terms "covered" and "coated" are used in such a manner as to render them with an identical meaning. See e.g., Leighton Technologies LLC v. Oberthur Cord Sys., S.A., 358 F.Supp.2d 361, 379 (S.D.N.Y. 2005); Yanova, Inc. v. Johnson, 2005 U.S. Dist. LEXIS 497, 2005 WL 66610, *4 (S.D.N.Y. Jan. 12, 2005); Revlon Consumer Prods. Corp. v. Estee Lauder Cos., 2003 U.S. Dist. LEXIS 13004, 2003 WL 21751833, *16 (S.D.N.Y. July 30, 2003) (citations omitted).

Such a finding runs afoil to the doctrine of claim differentiation. Under this doctrine, it is presumed to be a difference in meaning and scope when different words are used in different claims. Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1366 (Fed.Cir. 2000); Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed.Cir. 1987); "To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon, 831 F.2d at 1023. Thus, the Court should
avoid interpreting a claim in such a manner if it would make the claims read like another claim. However, claim differentiation "is not a hard and fast rule of construction," but rather it only creates a rebuttable presumption that each claim has a different scope from one another. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed.Cir. 1998); see also, ATD Corp. v. Lydall, Inc., 159 F.3d 534, 541 (Fed. Cir. 1998)(quoting Autogiro Co. of Am. v. United States, 384 F.2d 391, 404, 181 Ct. Cl. 55 (Ct.Cl. 1967) ("The presumption that separate claims have different scope is a guide, not a rigid rule."). Despite the fact that interpretations that would render a portion of the language of a claim superfluous are disfavored, "where neither the plain meaning nor the patent itself commands a difference in scope between two terms, they may be construed identically." Power Mosfet Technologies, L.L.C. v. Siemens AG, 378 F.3d 1396, 1410 (Fed.Cir. 2004). If the claim can only bear one interpretation, similarity must be tolerated. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed.Cir. 1991) (quoting Autogiro Co., 384 F.2d at 404). "Although the doctrine of claim differentiation may at times be controlling, construction of claims is not based solely upon the language of other claims; the doctrine cannot alter a definition that is otherwise clear from the claim language, description and prosecution history." O.I. Corp. v. Tekmar Co., 115 F.3d 1576, 1582 (Fed.Cir. 1997) (citation omitted). The doctrine does not permit a claim to be broadened beyond its correct scope as determined by the specification and claims as filed, as well as the prosecution history and any relevant extrinsic evidence. Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1302 (Fed.Cir. 1999); Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1480 (Fed.Cir. 1998); ATD Corp., 159 F.3d at 541; Tandon, 831 F.2d at 1024. "The words of patent claims have the meaning and scope with which they are used in the specification and prosecution history." Kinik Co. v. Int'l Trade Comm'n, 362 F.3d 1359, 1365 (Fed.Cir. 2004); see also, Toro Co., 199 F.3d at 1301 (a word in a claim should not be construed in a "lexicographic vacuum," but rather it is interpreted in the context of the specification and drawings.).

In the case at bar, the specification and prosecution history overcome any presumption arising from the doctrine of claim differentiation. The prosecution history reveals that when claim 9 was originally submitted to the PTO, it read that the magnet was "covered and/or coated with non-ferromagnetic material." Claim 9 was initially rejected because the examiner found that the use of the phrase "and/or" was too vague. Additionally, the original specification contained two references to the placement of the non-ferromagnetic material on the magnet. First, it stated that the magnet "can be coated with a non-ferromagnetic material." Further in the text it stated that the magnet "can be coated with a non-ferromagnetic material." With regard to the latter statement, the examiner deleted the words "be coated" and replaced it with the word "covered." As a result, the official specification is silent with regard to the magnet being "coated" with the non-ferromagnetic material. The specification contains the following two references to the magnet being covered with the material:

The magnetic member can be covered with a non-ferromagnetic material as illustrated in FIG. 1. In the embodiments of FIGS. 1 and 2 which include end walls, a space can be defined between the end wall and the magnetic member. The space can be either opened or filled with the non-ferromagnetic material as illustrated in each of FIGS. 1 and 2. The non-ferromagnetic material stabilizes the magnetic member.

* * *

Similar to the embodiments of FIGS 1-4, the magnetic member can be covered with a non-ferromagnetic material and a space can be defined between the magnetic member and the end walls . . . The space can be filled with the above-noted non-ferromagnetic material or can be open.

Thus, the prosecution history reveals that the applicant was using the terms "coated" and "covered" interchangeably. Additionally, despite claim 10 stating that the magnet is coated with non-ferromagnetic material, the specification makes no mention with regard to the magnet being coated with such material. Rather, the specification indicates that the magnet is covered with the material. Moreover, the specification does not provide that a tangible structure is placed over the magnet. Similarly, none of the schematic drawings depict a physical structure over the magnet. "The drawing in a nonprovisional application of the invention must show every feature of the invention specified in the claims." 37 C.F.R. 1.83(a).

Plaintiff contends that since the specification provides that the magnet is covered with non-ferromagnetic material to stabilize the magnet, a solid physical cover, as oppose to a film covering, would be necessary. There is no basis to conclude that the act of stabilizing the magnet cannot be accomplished by covering the magnet with a layer of non-ferromagnetic material in a liquid or gelatinous form which can form a protective membrane over the magnet. Additionally, the specification provides that the space between the magnet and end wall can also be filled with the non-ferromagnetic material. Such a statement further indicates that the non-ferromagnetic material is in a liquid-type state capable of being used to fill an existing open space.
To construe claim 9 as requiring a physical entity made of non-ferromagnetic material which is physically placed over the magnet would improperly broaden claim 9 beyond the specification, the drawings depicting the invention, and the prosecution history. Thus, claim 9 is construed to mean "a magnetic snap as described by claim 1 in which the magnet is covered with a film layer of non-ferromagnetic material."

4. "covering"

Agere argues that the term "covering" should be construed as "lying or spreading over." Atmel argues that the term "covering" should be construed as "directly contacting from above." The Court concludes that neither construction is appropriate and therefore will provide its own construction of the term "covering."

The Court has referred to Webster's Third New International Dictionary, which provides a number of definitions for "cover." The definition which is clearly most relevant to the instant context is: "to lie over: spread over: be placed on or often over the whole surface of." Webster's Third New International Dictionary of the English Language 524 (1986). Employing this ordinary meaning of the term "covering" in claim 1 in its entirety would allow for the possibility, but would not necessarily require, that a glue layer "covering" a dielectric and an exposed underlying material would be in direct contact with both the dielectric and the exposed underlying material. Thus, it is not clear from the face of the claim language and the ordinary meaning of the claim language whether direct contact is required.

The specification provides some guidance as to whether direct contact is necessary. The specification states: "The glue layer film may be deposited, through openings in the dielectric, directly on the silicon or on a conducting material, such as a silicide, overlying the silicon. Of course, the glue layer is also deposited on the dielectric." '335 Patent at col. 3:7-11 (emphasis added). This language indicates that the patentee contemplated that the glue layer would be in direct contact with both the dielectric and the exposed underlying material, and indicates that one of ordinary skill in the art, reading the patent, would have so understood the term "covering."

Moreover, the prosecution history reveals that the patent applicants distinguished their invention from the prior art based on the requirement that there be direct contact between the glue layer and the exposed underlying material. The patent applicants distinguished their purported invention from a prior art reference by pointing to the language in claim 1 referring to the glue layer "covering said dielectric and said exposed underlying material," and asserting that the claim language "clearly recite[s] that the aluminum layer contacts not only the insulating layer but also the underlying material." Exhibit AG 006893 from 12/05/02 Hearing. The patent applicants further asserted that in the prior art reference, which employed a thin aluminum layer to improve adhesion, "the aluminum layer touches only the insulating layer; it apparently does not contact the underlying silicon substrate." Exhibit AG 006896 from 12/05/02 Hearing. The applicants argued that "such contact is clearly recited in the applicants' own claim, rendering the applicants' claim "unobvious." Id. Thus, the patent applicants relinquished a construction of the term "covering" that would not require direct contact between the glue layer and both the dielectric and the exposed underlying material. See also Exhibit AG 006874 from 12/05/02 Hearing.

Accordingly, the term "covering" is construed as "lying over and directly contacting."
10. "[C]able covering:" means to insulate and protect the cable that is exterior to the interior support and insulated conductors disposed in the open spaces of the interior support. This construction is consistent with the specification, in which the patentee evinces its understanding that a cable covering serves to "insulate and protect" the cable. (col. 5:39-45) Figure 1A is described as "provid[ing] an example of an acceptable cable covering" including an "outer jacket, shield, drain spiral and binder . . . ." (col. 5:42-45) This exemplary language does not, however, work to further narrow this limitation to the recited components.

13 Id.

"[C]overing a majority surface area of said tool body"

This phrase is contained in independent claims of the 787 patent, 64 the 781 patent, 65 the 386 patent, 66 and the 539 patent. 67 The 787 and 781 patents claim magnet members covering a majority surface area of the tool body; the 386 and 539 patents claim magnet assemblies covering a majority surface area of the tool body. As to this phrase, the Court construes the following meaning: "covering a majority surface area of said tool body" means the actual, physical magnet (or assembly) takes up more than half of the exterior of the tool body. To put it another way, at least half of the outer surface area of the tool body contains the physical magnetic material itself rather than the undefined magnetic field created by the magnets.

64 Col. 6, line 14-15.
65 Col. 6, line 17-18.
66 Col. 5, line 62-63, col. 6, line 49-52.
67 Col. 6, line 8-9.

All four patent Abstracts, whether method or apparatus claims, contain explicit language declaring that the device contains "a plurality of magnet members... covering a majority surface area of the tool body." 68 All four summaries of the invention contain explicit language that the device contains "a plurality of magnets encircling the body of the tool and covering a surface area greater than one half of the tool body." 69 All four patents contain drawings that illustrate that more than half the tool body visibly contains magnets. The language is explicit that it is the surface area of the tool itself that is covered by magnets (or assemblies).

69 787 patent, col. 1, line 58-60; 781 patent, col. 1, line 67 through col. 2, line 2; 386 patent, col. 1, line 67 through col. 2,
The Court is not persuaded that the phrase can be expanded to include the area subjected to any magnetic field created by the magnets, as argued by Plaintiff. References in the specifications of the four patents to the magnets providing 360-degree "coverage" explicitly refer to what happens when the tool is rotated, and the magnetic field thus created, but not to the physical layout of the magnet on the tool itself. Plaintiff's argument that the phrase should be interpreted in a parallel manner to a spotlight or water sprinkler covering a yard is also unconvincing. A spotlight, when operated, provides an area with illumination coverage, and a water sprinkler, when operated, provides a lawn with water coverage. This phrase cannot be stretched to say that the spotlight or the water sprinkler itself covers a majority of the surface area of the yard.

While comparison of an accused device to a patent is not relevant to claim construction, the Court notes that it is also not persuaded by Plaintiff's argument that "more than one-half of the longitudinal length of the Bilco tool is occupied by magnets, and the magnets are arranged to provide 360-degree coverage, that is, coverage over the blue area as well as over the magnet assemblies, thereby resulting in magnets that effectively cover a majority surface area of the tool body." No amount of torturing the simple phrase "covering a majority surface area" can allow for the interpretation that placement of magnets "effectively covers" more than half the tool body when the actual magnets themselves -- and not any magnet field -- are at issue according to the claim. The language of the Abstracts, the specifications, and the claims is explicit, and cannot be expanded beyond the patent itself. In addition, the drawings accompanying the patents support this interpretation. The requirement that the language of the patent, when read as a whole, be full, clear, concise, and exact, so that inventors are protected but innovation is still permitted, demands that the plain language "covering the majority surface area of the tool body" means exactly that and no more.

The "forming" step

Claim 1 of the '361 patent states, in relevant part:

1. A method of making a pizza comprising the steps of: . . . (c) covering each food portion with an unbaked dough section of sufficient dimensions to cover said food portion thereby forming a separate closed pocket about each food portion."

Defendant says that the "forming step" of claim 1 requires pinching the dough cover pieces to the dough base, including between adjacent food portions, to form closed pockets. Plaintiff contends that pinching is not required in claim 1, but that simply covering the food portions with dough is sufficient to form the closed pockets.

The interpretation of a disputed claim term requires reference to other claims, and, unless there is "a clear indication to the contrary" a term must be interpreted consistently in all claims. Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d
1570, 1579 (Fed. Cir. 1995). Claims 3 and 4 of the '361 patent, which are dependent on claim 1, expressly describe a "forming" step that is separate from "covering," and involves pinching dough sections together, including in between food portions.

Plaintiff concedes that "forming" is a separate step from "covering" in its memorandum that claim 3 further defines "the placing step and covering step including the step of forming closed pockets" (emphasis supplied).

Plaintiff argues that interpretation of the term "forming" with reference to other claims is improper under the doctrine of claim differentiation, which requires a difference in scope among the claims. But the doctrine of claim differentiation applies only where a claim construction would render another claim superfluous. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). Where there are other differences between the claims, the element at issue may be construed to cover "the same subject matter" that is expressed differently in other claims. Tandon Corp. v. U.S. International Trade Commission, 831 F.2d 1017, 1023 (Fed. Cir. 1987).

Claim 1 recites no particular method of covering; claim 3 recites a covering step that involves folding an outside peripheral strip of the dough base over the food portions; and claim 4 recites a different covering step that involves covering food portions with an unbaked dough section separate from the dough base. Because there are differences in the recitation of the "covering" step in claims 1, 3, and 4, the "forming" step may be construed to "cover the same subject matter" in all three claims.

Although the specification says that the general method of making a pizza with pockets of enclosed food portions "may be accomplished in a number of specific ways," the only "ways" it refers to involve making the dough covers, and not the formation of the pockets. In fact, the specification discloses no method of forming a pocket other than by pinching the outside edges of the cover piece to the dough base.

Where a patent specification suggests only one meaning of a claim limitation, it may be construed no more broadly. See Gentry Gallery, Inc. v. Berkline Corp., 134 F.3d 1473, 1480 (Fed. Cir. 1998) ("claims may be no broader than the supporting disclosure, and . . . a narrow disclosure will limit claim breadth").

Plaintiff's suggestion that the forming step in claim 1 may include merely touching the two dough surfaces together to form a seal if inherently "sticky" dough is used is completely without support in the specification and thus cannot be considered in construing the claim.

The prosecution history also supports the construction of "forming" as requiring pressure placed around the pocket area. In the December 16, 1985 office action the examiner observed that the claimed method was similar to the prior art by requiring "pinching (crimping) the edges of the dough to form a filled pocket." The amendments that followed did nothing to correct that interpretation.

Plaintiff also argues that the photograph of the "forming" step in the record, number five, shows "a first pocket being formed" by merely folding the dough over without pinching. But photograph number seven shows the "completion" of the process, and the pinched edges of the pockets in that photograph are clearly visible.

The court concludes that the "forming" step is an affirmative step separate from "covering," and requires pinching dough areas to the dough base, including in between food portions. Merely draping the dough over the filling is insufficient to perform the claim.

Playtex argues that the court should construe "said thin membrane covering said opening in said passageway" to mean that "the thin membrane prevents liquid from flowing from the interior of the container through the opening to the outside (i.e., making the container spill-proof)." Plaintiffs did not respond to Playtex's argument on this issue. The phrases "said thin membrane," "said opening," and "said passageway" have antecedent basis and therefore the novelty of this claim element is
that it claims a membrane that covers the opening in the passageway. "Covering" is defined "as covers." Webster's, supra, at 525. The relevant definition of "cover," in turn, is "something that is placed over or about another thing." Id. at 524. "In" is simply "a functional word to indicate location or position." Id. at 1139. The ordinary meaning of these words does not require the court to import a limitation requiring the membrane to make the container spill proof. Certainly, this claim limitation attempts to describe a structure that has that intended function, and if the court needed to construe an ambiguity in the claim this consideration might carry some weight. Absent any such ambiguity, however, the court sees no reason to import the intended function into a structural limitation. Accordingly, the court construes this aspect of claim element 7(e) to mean said thin membrane being placed over or about the opening in the passageway.

1. "Covers"

The parties dispute the meaning of the term "covers" as it relates to a portion of the facer covering a portion of the backer, namely the edge surface. (Claims 2 and 18 of '018 Patent; claim 7 of '493 Patent.) Specifically, the parties dispute whether "covers" means "completely overlays" as Plaintiff argues or "overlays" as Defendants assert. As indicated by the parties in their proposed constructions, the only issue is whether the Court should include the word "completely" in its construction.

Plaintiff argues that the inventors describe surfaces that are less than completely covered as "partially" covered, so the inventors clearly expressed an intent for "covers" to mean completely covered. For example, in claim 3 of the '493 Patent, the overhang portion of the facer extends beyond the edge surface of the backer and wraps around the edge surface so that the facer "covers at least a portion" of the backer's opposite side. Also, the specification of the '018 Patent states that the overhang portion is folded over and wrapped around the edges of the backer "so that it covers a perpendicular side edge of the backer and a portion of the backer's opposite side." ('018 Patent, col. 6:18-22 (emphasis added).) However, as Defendants point out, the inventors also described surfaces that are completely covered as "entirely cover[ed]." (Id. col. 6:25-27.)

The claims at issue do not limit the term "covers." The specification suggests that when the term "covers" is used with regard to the opposite side of the backer, it either means partially (id. col. 6:18-22) or entirely (id. col. 6:25-27). From this, the Court cannot conclude that the term "covers" necessarily means "completely covers." The Court therefore construes the term "covers" to mean "overlays" and declines to read the word "completely" into the term.

The parties also dispute the meaning of the term "covers" as used in claim 23 of the '018 Patent, which claims that "said plurality of liner panels include a plurality of discrete said backers sharing a common said facer, so that said common facer covers said vertical posts." (Claim 23 of '018 Patent.) In other words, claim 23 claims a trailer that has more than one liner panel, each of which includes a plurality of backers sharing a common facer so that the common facer covers the vertical posts to which the liner panels are attached. Plaintiff proposes the following construction: "multiple liner panels in which each liner panel has more than one backer sharing a single facer, arranged so that the facer completely overlays more than one vertical post." Defendants, on the other hand, contend that the phrase means "a single metal facer covers all the posts such that the facer extends the entire length of the side wall inner surface and covers more than one backer." The key dispute is whether (1) the common facer covers all the vertical posts on the side wall inner surface of the trailer, or (2) the common facer only covers "more than one" post.

Claim 23 of the '018 Patent is ultimately dependent on claim 1, and it is also dependent on claims 14, 15, and 16. Claim 1 claims a trailer comprising:

- a plurality of wheels;

- a floor supported by said wheels; and

- a side wall extending vertically upward from a longitudinal side of said floor, said side wall including an exterior surface, and

- a liner panel inward of and spaced apart from said exterior surface, said liner panel including a stiff backer and a tough
facer attached to an inward side of said backer so that said facer at least partially defines a planar inner surface of said side wall, wherein said facer defines an overhang portion that extends beyond an edge of said backer.

Claims 14, 15, and 16 recite the trailer as in claim 1 with "a plurality of spaced-apart" vertical posts extending up from the floor between the exterior surface and the liner panel and "a plurality of vertically-aligned" liner panels, each pair of which is attached to a vertical post between the adjacent liner panels. Claim 23 recites that the plurality of liner panels "include a plurality of discrete said backers sharing a common said facer, so that said common facer covers said vertical posts."

Defendants argue that claim 23 claims a single common facer for each side wall because claim 23 recites one common facer that covers "said vertical posts"-which Defendants contend refers to the vertical posts that form the skeleton of one of the trailer's side walls. Defendants also point the Court to the specification, which refers to an example in which the "backers share a common facer [] so that the facer passes over the front surface of all vertical posts in the side wall." ('018 Patent, col. 8:9-13; Fig. 22.) The Court does not, however, conclude that claim 23 requires one common facer that covers an entire side wall of the trailer. First, the description of one possible embodiment in the specification cannot be read to limit claim 23 because there is no clear disavowal of claim scope. Second, referring back to claims 14, 15, and 16, there is no indication that the vertical posts referenced in claim 23 are all of the vertical posts of one of the side walls. Accordingly, the Court construes the phrase "said plurality of liner panels include a plurality of discrete said backers sharing a common said facer, so that said common facer covers said vertical posts" to mean that "at least two of the liner panels include at least two backers that share a common facer so that the common facer for the liner panel covers the vertical posts to which the liner panel is attached."

The point of contention between the Parties is the definition of the covers for the holes of the vent. To determine the scope of the claim, the Court must, therefore, define the terms and establish the elements prescribed therein. Looking first to the language of the claims, the Court notes that both Claims 1 and 6 contain the following language describing the covers:

> an array of cowls integral with and positioned on the exterior surface of the plate, each of said cowls formed of an inflexible material, each cowl for shielding one of the holes, said holes and cowls, being sized shaped, and oriented to inhibit entry of fluids through the holes and into the envelope interior while allowing generally unrestricted air circulation between the envelope interior and exterior . . . .

Defendants argue that the definition of an array of cowls cannot encompass a strip of adjacent holes with a louver or slat covering that does not create separate hoods. Plaintiff asserts that a cowl is a more general term for hood than Defendants contend and that in fact Defendants' louver hood does fall within the scope of the claim. Furthermore, Plaintiff argues that the claim language does not require that there be multiple, individual or separate cowls and holes, but that even if the Court determines the claim so indicates, Defendants' vent contains multiple, individual holes which each have their own cowl, the fact that they are adjacent to one another notwithstanding. Based on these arguments, the Court must define the terms "array" and "cowl" and the phrase "each cowl for shielding one hole."

--- Footnotes ---

2 In the instant case, Plaintiff Bickerstaff alleges infringement of claims 1, 4, 6 and 9 of the '911 Patent. Claims 1 and 6 are independent claims, while claims 4 and 9 are dependent on claims 1 and 6 respectively. Thus, if the scope of claims 1 and 6 cannot include Defendants' vent, then Plaintiff's assertion of infringement necessarily fails as to all four claims.

--- End Footnotes ---

An array is alternatively defined as "a rectangular arrangement of quantities arranged in rows and columns, as in a matrix," "an orderly, often imposing arrangement," or "an impressively large number, as of persons or objects." THE AMERICAN HERITAGE DICTIONARY 102 (3d Ed. 1996). When this language is reviewed in light of the figures attached to the specification of the patent, it becomes clear that the intended definition of an array in this context is the first definition. See Fig. 2. Given that the prosecution history provides no contrary argument, the Court finds that the term "array" as used in patent '911 refers to "a rectangular arrangement of quantities arranged in rows and columns."
Next, the Court confronts the term "cowl." Again, looking initially to the plain meaning of the term, the Court finds that, generally speaking, a cowl refers to a hood or cover some sort. Reference to the specification and the remaining claims in this case does not provide a more specific definition of the term. Indeed, such review reveals that a cowl may refer to hoods of different shapes. For instance, figure 6 presents "another embodiment of the cowl" as do claims 2, 3, 7 and 8. In addition, the prosecution history indicates that the shape of the cowl has no impact on the patentability and, thus, the scope of the claim. The Court, therefore, finds that a cowl as used in these claims refers to a hood of any shape.

3 Cowl: "1.a. The hood or hooded robe worn especially by a monk. b. A draped neckline on a woman's garment. 2. A hood-shaped covering used to increase the draft of a chimney. 3. The top portion of the front part of an automobile body, supporting the windshield and dashboard." THE AMERICAN HERITAGE DICTIONARY 433 (3d Ed. 1996).

4 Both Parties refer the Court to portions of Mr. Talbot's deposition testimony. Upon review, however, the Court concludes that, because Mr. Talbot's use of the term is inconsistent, his testimony does not aid the Court in making this determination. Furthermore, given that the intrinsic evidence provides a clear definition of the term, the Court need not make reference to extrinsic evidence, such as Mr. Talbot's testimony.

We conclude that the district court did not err in its construction of the term "cowl."

2. Claim 6, Step (b)

Claim 6, Step (b) reads: "applying cranial traction to the epidermis severed from the ungual crest to displace the distal edge of the epidermis cranially …." Defendant argues that the words "cranial" and "cranially" render this step indefinite. Although both parties agree that the definition of "cranial" is "towards the animal's head," Defendant asserts that the word can only be used to describe any action occurring above a cat's carpus, which is the group of joints in each leg of a cat that allows the cat to walk with its paws flexed. Here, Defendant argues, the word describes actions occurring below the cat's carpus; thereby rendering Step (b) insolubly ambiguous because one skilled in the relevant art would not understand in which direction to pull the incised skin. Plaintiff counters that Defendant's expert, while disagreeing with the way in which the '579 patent uses the word "cranial," had no trouble understanding its meaning. Moreover, Plaintiff notes that the word's meaning is made clear by Figure 2, which uses an arrow, labeled T, to depict the "cranial" direction in which the surgeon must pull the skin.

6 It is often analogized to the human wrist. Olsen Decl. at P 16.
Plaintiff's argument is well-taken. It is well-established that only claims "not amenable to construction" or "insolubly ambiguous" are indefinite. See Novo Indus., L.P. v. Micro Molds Corp., 350 F.3d 1348, 1353 (Fed. Cir. 2003); Honeywell Int'l, 341 F.3d at 1338. Here, Defendant's experts Dennis Olsen, DMV, although intending to disagree with Plaintiff's use of the word, ultimately demonstrated the ease with which it can be construed by noting, in his declaration, that "cranial means towards the animal's head." See Olsen Decl. at 1115. See Rosemount, Inc. v. Beckman Instruments, Inc., 727 F.2d 1540, 1547 (Fed. Cir. 1984) (finding an indefiniteness argument undermined by the defendant's "own ease in applying "close proximity" ... in its briefs here, [and] its own witness' statement that he had no trouble understanding the claims of the '525 patent ... "). In sum, the Court finds that one skilled in the art would understand the meaning of the word "cranial" when read in light of the specification. Id. 7

7 With regard to Defendant's objection to Plaintiff's use of the word "cranial" in Claim 6(c), the Court reaches the same conclusion.

3. Creases

Claim 5 describes the patented device as having "a plurality of creases formed in said member which are oriented in vertical and horizontal directions." Plaintiff suggests defining "creases" as "thin integral strips of pliable material defined by grooves or ridges in the flat rectangular shaped member about which the member is folded in use," Pl. Brief on Claim Construction (DE # 40) at 12, or as "a line, a groove, or a ridge made by folding a pliable substance." Tr. at 10. Defendants would define creases as "marking line, marks, or ridges made by slits in an outer layer of the material, folding a pliable substance, and not hinges or living hinges." Def. Claim Construction Chart (DE # 38). Defendants argue that hinges were specifically disclaimed by Plaintiff when he stated that "the use of a hinged apparatus can by no stretch of the imagination be considered equivalent to an apparatus employing creases." in order to distinguish his invention from a "Garment Folding Tray" patented in 1928. Def. Mem. in Support of Proposed Claim Construction (DE # 37) at 2. Defendants assert that living hinges must be specifically excluded from the definition because Plaintiff's patent does not include instructions for making living hinges, and because living hinges cannot cross each other in the manner shown in the patent. Id. at 15-16. Defendants' arguments go more to whether the patent is enabled for construction in plastic, rather than the definition of "crease." Accordingly, this Court will construe "crease" to mean a line, a groove, or a ridge made by folding a pliable substance and not a hinge.

15. "Creating said anatomic space" means the act of pushing tissue aside to make an accessible open working space outside the inflated balloon.

5. "crimp"

Braun construes "crimp" to mean "a portion of the needle which is sufficiently small to allow the needle to move axially along the catheter but which is greater in width than the opening." (D.I. 74 at 21) Alternatively, Braun has no objection to defining the term "crimp" as a "bulged section" or "segment of increased width." (D.I. 99 at 18) Terumo proposes that "crimp" should be given its ordinary and customary meaning and, therefore, has not provided a proposed construction. (D.I. 71 at 25) I recommend adopting Braun's original construction. 13
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

13 Initially, the primary dispute between the parties was whether the "crimp" must be manufactured through a traditional crimping process. Terumo insisted it must be, while Braun disagreed. (D.I. 71 at 26 n.13; D.I. 74 at 23) At the hearing, Terumo stated that it is no longer requesting that the Court's construction of "crimp" require that it be "something produced by crimping." (Tr. at 99; see also D.I. 97 at 16-17.)

Braun's proposed construction is derived from the specification's description of a "crimp." For example, the specification states: "The safety catheter illustrated in FIGS. 1C and 1D is the same as that illustrated in FIGS. 1A and 1B, except that the slot 60 in the needle shaft in the latter is replaced in the former by a crimp 61 whose width is greater than that of the opening 58 in the vertical arm 54." ('613 patent, col. 6 lines 58-62; see also id. col. 9 lines 18-22 ("The safety catheter illustrated in FIGS. 7D and 7E is the same as that illustrated in FIGS. 7A and 7B, except that the slot 60 in the needle shaft in the latter is replaced in the former by a crimp 61 whose width is greater than that of the opening 58 in the vertical arm 54."); id. col. 9 lines 49-53 ("The needle 16 includes a[] crimp 138 which is sufficiently small to allow the needle 16 to move axially along the catheter 24 but is greater in width than the opening 134 . . . ."); id. col. 11 lines 61-64 ("The needle 16 includes a[] crimp 138 which is sufficiently small to allow the needle 16 to move axially along the catheter 24 but is greater in width than the opening 134 . . . .") (all emphasis added).)

Terumo asserts that the ordinary meaning of "crimp" is "a structure withinwardly extending depressions and corresponding outwardly extending bulges." (D.I. 71 at 26 n.13) Braun does not disagree, but it contends that this type of "crimp" is only a preferred embodiment. On this point, Braun is correct. As the specification states:

"[T]he crimp 138 formed in the needle 16 preferably defines a pair of generally opposed, inwardly extending depressions 138b, which are disposed generally orthogonally with respect to the bulges 138a. The bulges 138a define a crimp 138 having a width, dimension W, which is small enough to facilitate movement of the needle 16 within the catheter 24, as shown in FIG. 14, and which is too large to pass through the central opening 134 formed in the end wall 126 of the needle guard 120, as discussed above.

The crimp 138 may be formed by any contemporary crimping process, such as those processes wherein two jaws of a vise or crimper come together so as to squeeze the needle 16 in a manner which forms the depressions 138b of FIG. 19, thereby consequently also forming the bulges 138a.

('613 patent, col. 13 lines 9-19) (emphased added) "[T]he use of the term 'preferably' makes clear that the language describes a preferred embodiment, not the invention as a whole." Cordis Corp. v. Medtronic A VE, Inc., 339 F.3d 1352, 1357 (Fed. Cir. 2003).

Terumo also points to the prosecution history, and complains that adopting Braun's proposal will deprive Terumo of an inequitable conduct defense that may otherwise be meritorious. In addition to Braun's invention disclosure documents, appearing to illustrate the conception of a "crimp" as early as February 1998 (Tr. at 95-96, 107), 14 the prosecution history reveals that the crimp (along with Figures 10A and 10B depicting it) has been in the specification since June 1998 -- although the word "crimp" did not appear until August 2000, when "crimp" was substituted for the prior version's "bulge" (Tr. at 94-95, 101). 15 As Braun explained: "The originally filed applications depicted and described 'crimps,' albeit calling some of them bulges. The examiner permitted without objection the subsequent substitute specification substituting the term 'crimp' for 'bulge' in certain places to describe the identical subject matter." (D.I. 74 at 23) Terumo's argument about the impact Braun's construction has on Terumo's inequitable conduct defense -- see Tr. at 100-01 ("If you go with their construction, these very legitimate defenses go away. Because if it's just a bulge section, they're able to say, well, that was in the patent from the beginning.") -- is not a persuasive basis for adopting Terumo's construction.

14 With respect to invention disclosure, Braun illustrates with various documents that the inventors apparently conceived of a "crimp" as early as February 1998. See, e.g., D.I. 99 at 17; D.I. 100 Exs. A, B & C). This was before filings within the '613 patent family tree such as U.S. Patent No. 6,117,108 ("the '108 patent"), filed in June 1998; U.S. Patent No. 6,287,278 ("the
For example, in the '278 patent application, filed in October 1998, the preferred embodiment depicted in Figure 10A was described as "[t]he needle 16 includes an increased diameter bulge 138, which is sufficiently small to allow the needle 16 to move axially along the catheter 24, but greater in width than the opening 134." (D.I. 75 Ex. E at FIG. 10A & col. 8 lines 44-48) (emphasis added) In connection with Figure 10B, the same '278 patent stated: "If an attempt is made . . . to pull the needle further to the right, as viewed in Fig. 10, out of the needle guard, the bulge 138 on the needle shaft will come into contact with the end wall 126, and since its diameter is greater than that of opening 134, the end wall 126 will at this point prevent any further axial movement of the needle out of the needle guard." (D.I. 75 Ex. E at FIG. 10B & col. 9 lines 9-15) (emphasis added) In the '630 patent, filed in August 2000, the same preferred embodiment was depicted in the same Figure 10A, but now it was described as: "[t]he needle 16 includes a crimp 138 which is sufficiently small to allow the needle 16 to move axially along the catheter 24 but is greater in width than the opening 134." (D.I. 75 Ex. F at BBM-TER0001289) (emphasis added) In connection with Figure 10B, the '630 patent stated: "If an attempt is made . . . to pull the needle further to the right, as shown in FIG. 10B, out of the needle guard, the crimp 138 on the needle shaft will come into contact with the end wall 126, and, since its width is greater than the diameter of the opening 134, the end wall 126 will at this point prevent any further axial movement of the needle out of the needle guard." (D.I. 75 Ex. F at BBM-TER0001290) (emphasis added)

Terumo also again relies on the deposition testimony of inventor Wynkoop. Again, however, this testimony is not much help to Terumo. In response to the question "do you think, for example, people in the shop, when someone says, 'We need to crimp this,' they know what that is?" Wynkoop replied, "In my shop? I would say most of them, yes." (D.I. 140 Ex. B at 130-31) As an initial matter, in the deposition question the word "crimp" is used as a verb, while in the claims it is used as a noun. Second, even assuming that everyone in Wynkoop's shop is a person having ordinary skill in the art, all that Wynkoop stated was that he would "think" (but is evidently not sure) that "most of them" (not all) would know what it means to crimp something. Finally, to the extent the Court must construe the claims in a manner that will help a jury to understand the meaning the claims have to one of ordinary skill in the art, Wynkoop's testimony provides no basis for confidence that lay jurors would know (without construction) the ordinary meaning of a "crimp." (See generally D.I. 140 Ex. B at 131 (Wynkoop explaining workers in his shop would understand "crimping" "[b]ecause of their mechanical ability and the things that we do in the shop") (emphasis added).

16 See generally Power-One, Inc. v. Artesyn Technologies, Inc., 599 F.3d 1343, 1348 (Fed. Cir. 2010) ("The [claim] terms, as construed by the court, must ensure that the jury fully understands the court's claim construction rulings and what the patentee covered by the claims.") (internal quotation marks omitted); see also D.I. 71 at 26 n. 13 (Terumo inviting Court to consider if "it would assist the jury to provide a construction [of 'crimp'] beyond the ordinary meaning"); but see Riddell, Inc. v. Schutt Sports, Inc., 2009 U.S. Dist. LEXIS 56316, 2009 WL 1444217, at *1 (W.D. Wis. May 21, 2009) (refusing to construe claim terms where the only proffered purpose of such a construction was that "construction of the limitations will assist the jury in its deliberations").

Hence, I recommend that the Court construe "crimp" to mean "a portion of the needle which is sufficiently small to allow the needle to move axially along the catheter but which is greater in width than the opening."

--- Footnotes ---

3 This term also appears in claims 19 and 37 of the '331 Patent, and claims 48, 50, 54, and 56 of the '404 Patent. (FDL's Mem. in Supp. (69), Ex. 2, '331 Patent at col. 21, lns. 54 and 57, and col. 24, lns. 62 and 65; FDL's Motion for Invalidity (originally document 24 in 1:03CV0013TC) Ex. 1, '404 Patent at col. 34, lns. 18-23, col. 25, lns. 38-33, col. 27 lns. 42-47, and col. 28, lns. 53-58.) Because the Lifetime Patents are related and all proceed from one application, the interpretation of this term will be the same for, and will be guided by, the '331 and '404 Patents as well.

4 The number given in parentheses in citations to the parties' briefs denotes the docket number for the particular brief being cited.

--- End Footnotes ---

As shown by their interpretations in Table 1, the only significant disagreement over the interpretation of cross brace member, which is part of the retaining assembly structure used to connect the table pedestals (legs) to the table, is whether it extends entirely across the mounting surface of the table top (the underside). Lifetime argues that to require the cross brace member to completely extend from side to side would effectively limit the claim to the preferred embodiment. FDL responds that if this limitation is not imposed, then the claim is anticipated by U.S. Patent No. 4,951,576 to Cobos (the "'576 Patent").

Looking first at the ordinary meaning of the claim language, "cross" means "to lie or pass across; "intersect" means "to lie or be athwart; intersect," and "to move, pass, or extend from one side or place to another." Webster's New Universal Unabridged Dictionary 479 (1996) (hereinafter "Webster's"). "Brace" is defined as "something that holds parts together or in place, as a clasp or clamp" and "anything that imparts rigidity or steadiness." Id. at 250. A "member" is "a constituent part of any structural or composite whole." Id. at 1198-99.

The specification confirms that, for at least one preferred embodiment, the cross brace member extends completely across the underside of the table, or in other words, from one side rail to the other:

In one presently preferred embodiment, each of the retaining assemblies 36a, 36b, comprise a cross-brace member having opposing ends and an intermediate body portion formed there between. … The opposing ends of the first and second cross-brace members 36a, 36b, respectively, are configured so as to be introduced and retained within corresponding retaining apertures 46 formed in opposing side rails 42, 44 of the frame 40 or, in the alternative, within opposing, interior side walls of the table top 12.

(FDL's Mem. in Opp. (69), Ex. 1, '092 Patent at col. 13, lns. 29-44; see also id. at Fig. 4 (showing cross brace members 36a and 36b extending full width of table); id. at Fig. 5 (similar); FDL's Mem. in Opp. (69), Ex. 2, '331 Patent at col. 6, lns. 19-23; FDL's Mem. in Opp. (69), Ex. 3, '404 Patent at col. 22, lns. 19-22; FDL's Mem. in Supp. (69), Ex. 2, '404 Patent at col. 22, lns. 23-27; FDL's Motion for Invalidity (originally document 24 in 1:03CV0013TC) Ex. 1, '404 Patent at col. 34, lns. 18-23, col. 25, lns. 38-33, col. 27 lns. 42-47, and col. 28, lns. 53-58.)
24 (similar.) This specification language, however, is not dispositive. The quoted language suggests that other, non-preferred embodiments would still fall within the meaning of the term if the cross brace member did not extend completely across the underside of the table.

The specification also teaches that the retaining assembly, of which the cross brace member is a part, provides support for the table:

As best shown in FIGS. 1, 2, and 3, the distal ends 28, 34 of each pivotal support brace 24, 30 are engageably secured to the retaining assembly 36 (e.g., cross brace member). … It will be appreciated by those skilled in the art that the retaining assembly 36 generally provides structural support to the center of the table top 12 of the utility table 10.

(FDL's Mem. in Opp. (69), Ex. 2, '331 Patent at col. 6, lns. 13-26.) Accordingly, the correct construction of cross brace member must include a strength component.

The specification is also helpful in deciding what particular shape or spatial arrangement is required for the cross brace member. The preferred embodiment shows that the cross brace member is a long and thin bar. (FDL's Mem. in Opp. (69), Ex. 1, '092 Patent at col. 13, Ins. 29-44; see also id. at Fig. 4 (showing cross brace members 36a and 36b as thin bars extending full width of table); id. at Fig. 5 (similar); (FDL's Mem. in Opp. (69), Ex. 2, '331 Patent at col. 6, Ins. 19-24 (similar).)

Pointing to the prosecution history, FDL contends that the '576 Patent to Cobos, which was before the examiner during the prosecution of the Lifetime Patents, bars a definition of cross brace member that includes the bracket and pin arrangement shown in the '576 Patent. To attach the table legs in such a manner to allow them to fold--the function of the cross brace member--the '576 patent uses brackets with pins to secure the support brace (and the table legs) to the underside of the table. One side of the bracket is secured to the underside of the table, and the legs or support braces are attached to the bracket with a short pin. 5

5 The '576 Patent discloses every other limitation of claim 76 of the '092 Patent. As required by claim 76 of the '092 Patent, the '576 Patent table has a table top with first and second ends, a working surface (topside) and a mounting surface (underside) that may be constructed of blow-molded plastic. (FDL's Mem. in Opp. (69), Ex. 8, '576 Patent at col. 6, Ins. 34-37, 49-60, Figs. 1-6.) The '576 Patent table also has a frame with parallel side raits and pivotally connected pedestals, or folding legs. (Id. at col. 7, Ins. 18-20, col. 8, Ins. 51-54, Figs. 3, 6, 7, 8, 11, and 14.) Lastly, the '576 Patent has support braces that pivotally connect to both the table legs and the mechanism for securing the support braces to the underside of the table. (Id. at col. col. 8, Ins. 51-54, Figs. 5, 6, and 14.)

The Federal Circuit has noted that: "it is sometimes difficult to balance a patentee's broad claim reading against an assertion that the claims at some indefinite breadth may" read on prior art. Abbott Labs. v. Baxter Pharm. Prods., Inc., 334 F.3d 1274, 1282 (Fed. Cir. 2003). Because the '576 Patent was before the examiner, however, Lifetime has "acquiesced" to the conclusion that the '576 Patent "indicate[s] the scope of the ['092 Patent] claims." Liquid Dynamics, 355 F.3d at 1367-68. "In other words," the '576 Patent helps define "what the [092 Patent] claims do not cover." Id.

Moreover, because patents are presumed valid, and when possible courts must interpret claims "to preserve their validity," the court must, if possible, give a construction to cross brace member so as to preserve its validity over the '576 Patent. Modine, 75 F.3d at 1557. Here, this obligation is heightened by the fact that the '576 Patent was before the examiner. Ultra-Tex Surfaces, Inc. v. Hill Bros. Chemical Co., 204 F.3d 1360, 1367 (Fed. Cir. 2000).

In view of the above, the court concludes that the correct construction of cross brace member is a long thin device that: (1) is longer than it is wide; (2) is used as part of the structure that connects the table legs to the table top; (3) imparts strength to the table; (4) lies transverse to, and some distance across, the underside of the table top; and (5) cannot be the bracket and pin arrangement of the '576 Patent to Cobos.
Because it includes devices that extend completely from one side of the table to the other as well as those that do not, this construction preserves the maximum breadth of the claim language without limiting it to the preferred embodiment.

1042

10. "A Cross-Cutting Cylinder"

As noted above, Claim 12, an independent claim, teaches:

A cross-cutting cylinder comprising:

a. a plurality of cutting disks with each disk having at least two circumferentially spaced teeth, with the disks arranged in a longitudinal direction of the cutting cylinder to provide a helix; and

b. a spacer located between each adjacent disk, wherein a surface of the spacer has a linear measure greater than the distance between each adjacent disk.

'780 Patent, col. 4, lines 39-47. The Court having construed most of the disputed language in Claim 12, the only part requiring construction is the term "a cross-cutting cylinder," element 12(a).

Fellowes and Michilin agree that a "cross-cutting cylinder" is a "device for cutting paper that has a generally cylindrical overall shape and cuts materials into a number of small pieces both lengthwise and widthwise." Intek submits that a "cross-cutting cylinder" is a "device for cutting that has a generally cylindrical overall shape and cuts materials into a number of small rectangular pieces." The only differences between Intek's construction and the other parties' is that Intek removes the word "paper" from its definition of what the "cutting cylinder" cuts, and substitutes the words "small rectangular pieces" for "small pieces both lengthwise and widthwise."

Fellowes correctly notes that the specifications refer to the shredder being used to shred paper. See '780 Patent, title "("PAPER SHREDDER SHAFT") (emphasis added); id. at col. 3, lines 36-38 ("The shredder cylinder of the present invention . . . creates small paper chips."); id. at col. 1, lines 4-5 ("The present invention relates to a cross cutting cylinder for shredding paper") (emphasis added). In addition, the Court finds it significant that both Fellowes and Michilin agree that a "cross-cutting cylinder" cuts paper; it is Intek, which is represented by the same counsel as Michilin, that is at odds with the other parties. As sophistry becomes a science, it is wonderful if a party can position itself on both sides of an issue at the same time. It is hard to lose that way—but in this case, lose someone must. Although the '780 Patent could be read as applying to a "cross-cut" shredder that shreds non-paper items, the Court will add the word "paper" to its construction of "cutting cylinder" because such a reading is supported by the patent language and is agreed to by Fellowes and Michilin.

Finally, although the difference between "small rectangular pieces" and "small pieces [which are cut] both lengthwise and widthwise" may be immaterial, the Court finds the latter definition to be more in line with the somewhat more ambiguous word "chips" used in the patent. See '780 Patent, col. 1, line 55 ("paper chips"); id. at col. 2, line 43 ("chips of material"); id. at col. 3, lines 37 ("small paper chips"). The Court adopts the construction proposed by Fellowes and Michilin and FINDS that a "cross-cutting cylinder" in Claim 12 is a "device for cutting paper that has a generally cylindrical overall shape and cuts materials into a number of small pieces both lengthwise and widthwise."

1043

C. Cross-Laminated Section

The parties seek a construction of the term "cross-laminated section," which appears in both the preamble and bodies of claims 1 and 21. The preambles of claims 1 and 21 recite "[a] method of injection molding a plastic product, with a cross-laminated section that includes a first plastic layer and a second plastic layer . . . ." 268 Patent, col. 8, lines 11-13; col. 10, lines 53-55 (emphasis added). The bodies of the claims recite, in step (e) of the claimed method:
(e) solidifying the flowed second plastic in the second-layer-defining-mold-cavity-section to thereby form said second plastic layer, so that the second plastic layer has a second-direction-flow-record which is positively different from said first-direction-flow-record, to thereby form said plastic product with said cross-laminated section that includes both the first plastic layer and the second plastic layer.

'268 Patent, col. 8, lines 37-45; col. 11, lines 11-19 (emphasis added).

As an initial matter, the court notes that Turn-Key has directed its arguments towards the language appearing in the preambles of claims 1 and 21, and it appears that it wishes the court to construe this preamble language. However, claim preambles do not always limit the scope of the claimed invention, and, in fact, the Federal Circuit has noted that "generally, . . . the preamble does not limit the claims." DeGeorge v. Bernier, 768 F.2d 1318, 1322 n.3 (Fed. Cir. 1985). Later cases have clarified, however, that "a claim preamble has the import that the claim as a whole suggests for it," and "when the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects." Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995). In this case, the same language that appears in the preamble also appears in the body of the claims, i.e. a "cross-laminated section that includes both the first plastic layer and the second plastic layer." Thus, even if the preamble language does not limit the '268 claim scope, this particular term does limit the claims by virtue of its inclusion in the claim body, and therefore the court will construe this term.

The claim recites a "plastic product with said cross-laminated section that includes a first plastic layer and a second plastic layer." Thus, by its own terms the claim requires that the cross-laminated section contain at least two different layers: the first plastic layer and the second plastic layer. Furthermore, the claims dictate that the first plastic layer and second plastic layer that form the cross-laminated section have flow records that are "positively different." '268 Patent, col. 8, lines 37-45. As discussed above, the court has construed "positively different" to mean definitely or certainly not alike. Therefore, the claims themselves define "cross-laminated section" as a section of the injection molded plastic product that contains both a first and a second plastic layer, where the first and second plastic layers have definitely different flow records.

As it did with respect to the meaning of "positively different," Koito argues that "cross-laminated section" requires that the flow records of the two layers intersect at 90 or substantially 90 degree angles. In making this argument, Koito raises many of the same arguments that it did with respect to its proposed construction of "positively different," including its reliance on the preferred embodiments, which show 90 degree angles between flow records in the cross-laminated section. The court rejects those arguments here for the same reasons as it did above. However, with respect to the "cross-laminated section" limitation, Koito also marshals an extensive array of technical dictionaries and treatises that define a "cross-laminate" as "a laminate in which the grain direction of some layers of material is oriented at right angles to the grain of the remaining layers." J. Shields, Adhesives Handbook 341 (3d Ed. 1985); see also A. Landrock, Adhesives Technology Handbook 21 (1985) (defining cross laminate as "[a] laminate in which some of the layers of material are oriented at right angles to the remaining layers with respect to the grain or strongest direction in tension"); McGraw-Hill Dictionary of Scientific and Technical Terms 455 (4th Ed. 1989) (defining cross-lamination as "construction of a laminated composite material so that some layers are oriented at right angles to the other layers with respect to the grain or the strongest direction in terms of tension"); T. Whelan, Polymer Technology Dictionary 93 (defining cross-laminate as "[a] laminate in which some of the layers of material are oriented approximately at right angles to other layers; used to make, for example, strong film for packaging").

Based on the breadth of technical materials Koito presents and the consistency of the definitions provided therein, it seems clear that "cross-lamination" ordinarily does refer to layers oriented at 90 degree angles to one another, and thus Koito's proposed definition of "cross-laminated section" is more consistent with the ordinary understanding of "cross-laminate" in the polymer arts than is Turn-Key's. However, a patentee is free to depart from the ordinary meaning of a term like "cross-laminated section," so long as the patentee's definition is provided in the intrinsic evidence. See Bell Atl. Network Servs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001); Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998). Here, as discussed above, the patent claims themselves define the cross-laminated section as including two layers that have "positively different" flow records, and the patent uses "positively different" to refer to angles other than 90 degrees. That the other "positively different" angles are between flow directions rather than flow records does not change the fact that the patentee clearly did not use the phrase "positively different" to refer to angles of only 90 degrees. And, because a cross-laminated section is defined as including two layers with positively
different flow records, the broad meaning of "positively different" espoused by the patentee results in an equally broad meaning of "cross-laminated section."

For the reasons discussed above, the court construes "cross-laminated section" to mean a section of the injection molded plastic product that contains both a first and a second plastic layer, where the first and second plastic layers have positively different flow records--meaning that the flow records of the two layers are definitely not alike.

F. Cross Support Structured for Support of the Person's Leg

Brike contends the term "cross support structured for support of the person's leg" means a support which contacts the leg. Brike relies on the same arguments as for the term "foot and leg support."

Invacare contends the term "cross support" should be construed to be a support that supports the leg by contacting the foot, ankle, or leg, but does not necessarily require contact with the leg. Invacare also relies on its same arguments.

For the reasons just stated, I construe "cross support structured for support of the person's leg" to mean a support that supports the leg by contacting the foot, ankle or leg, but does not necessarily require contact with the leg.

6. Claim 10: "cryogenic" and "cryogenically"

"Cryogenic" and "cryogenically" are construed to mean "pertaining to or causing the production of low temperatures."

III. "Cup Shaped"

Finally, both Claims 1 and 5 require a "cup shaped" cover and holder. ( '969 Patent Col 5, Ln. 49); ( '969 Patent Col 6, Ln. 12, 17). U.S. Can argues that the term "cup shaped" should be construed to mean "generally round; although the base can also be generally rectangular, star shaped, or another preferred shape," as is stated in the specifications for the '969 Patent. (P Resp. 11). Limited argues that the term "cup shaped" should be construed to mean "a structure formed by a generally round or circular sidewall . . . ." (D Mem. 14).

The Federal Circuit has made it clear that "claims must be read in view of the specification, of which they are a part [that] the specification 'is always highly relevant to the claim construction analysis [and that] usually, it is dispositive.'" Phillips, 415 F.3d at 1315 (quoting Markman, 52 F.3d 967 at 979, and Vitronics, 90 F.3d at 1582). The Federal Circuit has also stated that "the inventor's lexicography governs." Phillips, 415 F.3d at 1316. In the instant action, the summary of the invention states that the patent "includes a cup shaped generally circular or rectangular holder" and the specification states that the cup-shaped base is "generally round [even though] it can also be generally rectangular, star shaped, or another preferred shape." ( '969 Patent Col 1, Ln. 51-52); ( '969 Patent Col 2, Ln. 32-34). It is clear from this language in the patent that the term "cup shaped" is intended to include a hollow structure that is generally round, although it can also include hollow structures that are generally rectangular, star-shaped, or any other shape.

Limited argues that the prosecution history of the '969 Patent supports its interpretation of the term "cup shaped." Specifically, Limited argues that the original Claim 1, which was rejected by the Patent Examiner as being anticipated by United States Patent Number 6,155,451, Pietruch et al. ("Pietruch Patent"), did not include the "cup shaped" limitation. Accordingly, Limited argues that U.S. Can "is now estopped from arguing that its patent covers anything other than [round] cup shaped tins." (D Mem. 13). The Federal Circuit has stated that "the prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention and whether the inventor limited the
innovation in the course of prosecution, making the claim scope narrower than it would otherwise be." Phillips, 415 F.3d at 1317. However, Limited's interpretation of the prosecution history of the '969 Patent is misplaced. Limited correctly states that the Patent Examiner did reject Claim 1 for anticipating the Pietruch Patent. However, the Examiner did not in any way state that the rectangular shape of the prior art was the reason that the original Claim 1 was rejected. Moreover, the prosecution history shows that the original Claim 1 was also rejected for being anticipated by United States Patent Number 5,879,151, Schultz et al. ("Schultz Patent"), which discloses a round base. If U.S. Can's amendment had limited Claim 1 to holders and covers that were circular or round, as Limited contends, Claim 1 would still have been anticipated by the Schultz Patent. Accordingly, the prosecution history in this case does not support Limited's contention relating to the meaning of the term "cup shaped." Therefore, based on the above, we agree with U.S. Can and construe the term "cup shaped" to mean a hollow structure that is "generally round" or "generally rectangular, star shaped or another preferred shape."

1047

6. Claim 15 ("curved along the longitudinal axis")

Claim 15 of the '286 patent uses the term "curved along the longitudinal axis" in the following context: "An ultrasonic instrument according to claim 7, wherein the cutting surface of the cutting jaw is curved along the longitudinal axis of the instrument." '286 Patent, Claim 15 (emphasis added). Plaintiff's proposed construction of the term is: "Deviating from a straight line along the lengthwise dimension," while defendant's proposed construction is: "Curved outwardly and downwardly in the distal direction."

Defendant urges that its proposed construction is appropriate because the intrinsic evidence in the patent abstract and specifications describes a cutting jaw that "is curved outwardly and downwardly." See '286 Patent, Abstract ("The cutting jaw has a blade surface which is curved downwardly and outwardly in the distal direction with respect to the longitudinal axis . . . "), 1:65-67 ("The cutting jaw has a blade surface which is curved outwardly and downwardly along its surface and thus, curved with respect to the axis of vibration"), 4:26-28 ("Cutting jaw 58 includes a curved blade surface 59 that slopes downwardly and outwardly in the distal direction."), Figure 4. Plaintiff argues, however, that the references to "outward" and "downward" in the intrinsic evidence indicate that the patentees clearly knew how to include explicit language in the claims if they wanted to, and chose not to do so.

As noted in Phillips, the specifications are properly consulted in order to ascertain the ordinary meaning to be given to claim terms, particularly where the claim terms themselves are vague. See Phillips, 415 F.3d at 1315. However, as discussed above, courts must avoid importing limitations from the specifications into the construction of the claims. To avoiding importing limitations, "it is important to keep in mind that the purposes of the specification are to teach and enable those of skill in the art to make and use the invention and to provide the best mode for doing so." Phillips, 415 F.3d at 1323.

One of the best ways to teach a person of ordinary skill in the art how to make and use the invention is to provide an example of how to practice the invention in a particular case. Much of the time, upon reading the specification in that context, it will become clear whether the patentee is setting out specific examples of the invention to accomplish those goals, or whether the patentee instead intends for the claims and the embodiments in the specification to be strictly coextensive. . . . The manner in which the patentee uses a term within the specification and claims usually will make the distinction apparent.

Id.

In this case, while the intrinsic evidence does describe a cutting surface that is curved outwardly and downwardly, nothing in the intrinsic evidence requires that the cutting surface be so curved. Indeed, as Ethicon's counsel acknowledged at the Markman hearing, the cutting surface could be curved along the lengthwise axis "up or down," as long as it did not curve "side to side" - which curvature, the Court notes, would no longer be along the longitudinal axis, but a curve along the latitudinal axis. See Markman Tr. at 115 (emphasis added). Additionally, as Tyco argues, the intrinsic evidence demonstrates that the patentees clearly knew the appropriate terminology to use in their claims had they sought to limit their claimed invention to one with a blade surface that curved outward and downward; the patentees chose not to do so. n10 Accordingly, the Court will not import any limitations from the specification into its claim construction and will adopt plaintiff's proposed
construction: "Deviating from a straight line along the lengthwise dimension." n11

The parties also dispute whether the patent background and prosecution history are relevant and, if so, the import of these sources. Defendant argues that these sources (both of which describe blades that curve outwardly and downwardly) indicate a specific need that the patentees sought to address, by remediating past deficiencies in earlier technology. See Def. Claim Construction Br. at 19-20 & n.11, 22-23 (citing, inter alia, CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1160 (Fed. Cir. 1997) ("In construing claims, the problem the inventor was attempting to solve, as discerned from the specification and the prosecution history, is a relevant consideration."); Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1347-50 (Fed. Cir. 2004) (finding that prosecution history was relevant to the interpretation of claim terms, given that the prosecution history included statements made regarding an earlier and related patent)). Plaintiff argues that defendant's suggestion that the patent history is relevant and supports its construction is "legally and factually wrong," given that (1) the law provides that the prosecution history cannot be used to "enlarge, diminish or vary the limitations of the claims," (2) the inventions in the earlier patents differed from the '286 Patent, and (3) the patent history demonstrates that if the inventors had wanted to use the term "outwardly and downwardly," they knew how to do so. See Pl. Claim Construction Br. at 25, Pl. Reply Br. at 7.

The Court declines to consider the patent background and prosecution history, however, because the claim language and intrinsic evidence provide adequate guidance to construe the claims. Moreover, the Court agrees with plaintiff's contention that the patent history in this instance is ambiguous - it could be read as demonstrating that the inventors sought to remedy a problem by using a blade surface that curves "outwardly and downwardly," or it could be read as indicating that the patentees knew how to specify the "outward and downward" direction of the blade if they wanted to, and chose not to do so. Cf. Phillips, 415 F.3d at 1317 (noting, "because the prosecution history represents an ongoing negotiation between the [Patent & Trademark Office] and the applicant, rather than the final product of that negotiation, it often lacks the clarity of the specification and thus is less useful for claim construction purposes").

n11 At the Markman hearing, counsel for Ethicon also argued that plaintiff's proposed use of the phrase "deviating from a straight line . . . " was contrary to the claim language, which provides that the blade surface is "curved along the longitudinal axis." See Markman Tr. at 117-18 (plaintiff's language "contradicts the claim language itself where you have language that says you must curve along the axis, and then you are saying, well, it can deviate from the axis, that's just contrary to the plain language of the claims"). The Court is constrained to disagree based on the claim language. Plaintiff's proposed language - "deviating from a straight line . . . " is simply plaintiff's description of the curvature of the blade; the balance of plaintiff's proposed construction describes the nature of the curvature - "along the lengthwise dimension." Contrary to Ethicon's contention, the claim language does not provide that the blade surface exactly follows the longitudinal axis - if it did, the blade surface would not be curved at all, but would be straight - instead, the claim language provides that it is curved "along the longitudinal axis" - i.e., curved in the up or down direction.

GO BACK

II. "Curved Along the Longitudinal Axis" in the '286 Patent

Next, plaintiff contends that while the Court adopted its construction for this claim term as "deviating from a straight line along the lengthwise dimension," see Claim Construction at 26, the Court should clarify its comments regarding this claim term because "the Court's opinion may be read to suggest an apparent misinterpretation that is inconsistent with this construction and will lead to confusion in applying this term for purposes of determining infringement and validity." Tyco Motion at 2. Tyco refers to the Court's comments that the cutting surface would not curve "side to side," but only "in the up or down direction." Claim Construction at 25, 26 n.11. Tyco argues that the claim language "is not so limiting" and that by suggesting "that the curve must be in the up or down direction, the Court appears to be doing precisely what it avoided doing in rejecting Ethicon's 'outwardly and downwardly' construction - importing a limitation that is not present in the claim language." Tyco Motion at 2. Ethicon opposes Tyco's motion, arguing that "[u]nder the guise of seeking 'clarification' of [the Court's] construction, [plaintiff] seeks to change it entirely - and impermissibly - in a way that would eliminate an express limitation from the claim." Ethicon Opp. at 5.

Because reconsideration is appropriate where a need is shown to correct a clear error of law, at oral argument the Court granted Tyco's motion for the purpose of considering whether the Court's comments in its Claim Construction improperly

- 1488 -
Thus, blade curves up, down, or to one side or the other is not static and is only defined by the perspective of the user. "outward" and "downward" in the specification suggests that they knew how to articulate that curvature if they had sought the longitudinal axis. Further, as the Court noted in its Claim Construction ruling, that the inventors used the descriptions of direction with respect to the longitudinal axis" suggests that the surface could curve in other directions and still be along the Patent Abstract describing a cutting jaw with "a blade surface which is curved downwardly and outwardly in the distal curved." See Claim Construction at 23-25 (citing, inter alia, '286 Patent, Abstract, 1:65-67). Indeed, the language in the specifications into its construction of the claims, and "nothing in the intrinsic evidence requires that the cutting surface be so "outwardly and downwardly" "with respect to the longitudinal axis," the Court must avoid importing limitations from the specifications into the construction of the claim term at issue. As the Court addressed in its Claim
illustrate Tyco's characterization of the "longitudinal axis" as a line, rather than a plane. These conflicting analogies from which they deviate along this axis to from the curve." Tyco Reply [Doc. # 67] at 5 n.3. These conflicting analogies that "what [plaintiff] wants the Court to do is rewrite the claim to remove an express limitation." Ethicon Opp. at 6. As it did in the original claim construction phase, Ethicon also refers to the prosecution history of the patent to argue that the inventors intended a blade surface that "curved outwardly and downwardly" to improve on ultrasonic instrument technology by allowing the user to vary the force applied by the blade surface by adjusting the location of the tissue on the blade. Id. at 10. Ethicon cites the deposition testimony of one of the two named inventors of the patent discussing this improvement and stating he never considered a blade that curved "outward," "instead of up or down." Id. at 11 (citing deposition of Corbett Stone, Ethicon Opp. at Ex. 1 at 144:6-8, 161:21-22).

Ethicon also addresses an argument advanced by Tyco - that because the instruments are designed to rotate and be used in multiple different orientations, there is no meaningful difference between a cutting surface that curves up and down or side to side - contending that this explanation conflicts with the language of patent, which specifies a curve along the longitudinal axis. Ethicon compares the curved cutting surface described in the claim language to a road going straight, due North, ")it may go down a hill (i.e., curve downward), or it may go up a hill (i.e., curve upward), but it continues going straight North. Its surface is curved along the longitudinal axis. If its surface were the cutting surface of a cutting jaw, the cut it would make would be a straight line." Ethicon Opp. at 7. Ethicon compares a surface curving "side to side" to a road that is also going straight, due North, and then turns West, "now its surface is curving away from the longitudinal axis. If its surface were the cutting surface of a cutting jaw, the cut it would make would be a curve." Id. Tyco demonstrates an alternative illustration of "water shot under high pressure from a pipe pointing upwards. The tube of the pipe defines a longitudinal axis. As the water exits the pipe and shoots into the air, it will curve off this longitudinal axis in any number of ways (left, right, forward, backward, etc.). These curves are deviations along the longitudinal axis regardless of the direction from which they deviate along this axis to from the curve." Tyco Reply [Doc. # 67] at 5 n.3. These conflicting analogies illustrate Tyco's characterization of the "longitudinal axis" as a line, rather than a plane.

The Court agrees that Tyco's illustration is more accurate and that Ethicon's comparison and arguments would import a limitation from the specifications into the construction of the claim term at issue. As the Court addressed in its Claim Construction, although the specification describes an embodiment with a cutting jaw having a blade surface curved "outwardly and downwardly" "with respect to the longitudinal axis," the Court must avoid importing limitations from the specifications into its construction of the claims, and "nothing in the intrinsic evidence requires that the cutting surface be so curved." See Claim Construction at 23-25 (citing, inter alia, '286 Patent, Abstract, 1:65-67). Indeed, the language in the Patent Abstract describing a cutting jaw with "a blade surface which is curved downwardly and outwardly in the distal direction with respect to the longitudinal axis" suggests that the surface could curve in other directions and still be along the longitudinal axis. Further, as the Court noted in its Claim Construction ruling, that the inventors used the descriptions of "outward" and "downward" in the specification suggests that they knew how to articulate that curvature if they had sought to so limit what they were claiming. Additionally, as Tyco argues, the instrument is meant to be rotated and thus whether the blade curves up, down, or to one side or the other is not static and is only defined by the perspective of the user.

Thus, the Court withdraws its comments regarding whether the blade surface could curve "side to side" as impermissible importing a limitation from the specification into the claim language. The language of the claim provides a curve "along the
longitudinal axis," and the Court's construction - "deviating from a straight line along the lengthwise dimension" - should not be read to limit that curvature to surfaces curving only up or down. 2

2 For the same reason that it rejected Ethicon's arguments concerning patent prosecution history in its Claim Construction, the Court declines to consider the patent background and prosecution history here. See Claim Construction at 25 n.10. Additionally, the inventor testimony to which Ethicon refers could just as easily be describing a preferred embodiment as suggesting a limitation in the claim language and thus is inconclusive. Further, while Ethicon claims that a blade that curved "side to side" would not achieve the enhanced blade force advantage described in the "Background" section of the patent, as Tyco noted at oral argument the patent also states that "the curved blade surface provides better visibility at the surgical site," see '286 Patent, 4:37-38, an advantage that would be gained even if the curve was "side to side."

Claim 6 and dependent Claim 8 of the '544 Patent include the claim term "curved blade surface" in the following context: "An ultrasonic instrument according to claim 1, wherein the jaw member includes a curved blade surface," '544 Patent, Claim 6 (emphasis added), and "An ultrasonic instrument according to claim 6, wherein the curved blade surface includes a longitudinally extending cutting edge," '544 Patent, Claim 8 (emphasis added). Plaintiff's proposed construction of the Claim 6 term is: "Blade surface that has a deviation from a straight line," while defendant proposes: "Surface adapted to be used for cutting that is curved outwardly and downwardly in the distal direction."

As in the case of the '286 Patent claim term, discussed above, defendant supports its proposed construction by pointing to the specifications in the '544 Patent that describe a blade surface that is "curved outwardly and downwardly." See '544 Patent 1:67-2:2, 4:31-55, Figure 4. Nevertheless, nothing in the '544 Patent requires that the blade surface be curved outwardly and downwardly and, as discussed above, counsel for Ethicon acknowledged that the blade surface could curve upward, as well as downward. Markman Tr. at 115. Additionally, the presumption that similar claims in related patents should be construed consistently applies here, counseling for construing the '544 Patent claim term consistently with the '286 Patent claim term described above. See Omega Eng'g, 334 F.3d at 1334. Accordingly, the Court adopts plaintiff's proposed construction of the claim term.

11. "curved [curving] in a non-radial direction of the stent"

This phrase is found only in the '255 patent, specifically in claims 11-18, and 25. See Joint Statement, '255 Patent. Plaintiffs contend that "curved [curving] in a non-radial direction of the stent" should be construed to mean "curved or curving such that the [arcuate U-shape or flexure member curved portion] does not extend substantially outside the outer surface or inside the inner surface of the tubular wall." Defendants contend that the phrase should be construed to mean "curved in at least one direction other than the radial direction." The intervenor, by contrast, contends that the proposed construction should be "curving along the tubular surface." 7

7 Although the intervenor has presented a differing proposed construction, the intervenor's supporting brief does not include argument regarding the particular proposed construction at issue.
For support of their positions, plaintiffs rely on the prosecution history, while defendants base their arguments on a practical application of directional concepts to the claim language. Specifically, plaintiffs contend that the prosecution history of the '255 Patent reveals that the phrase at issue was included in order to distinguish the claimed invention from the prior art Orth patent, which was directed to a stent that had connectors projecting outside the outer surface of the tubular wall in order to keep the stent in place against the blood vessel wall. The '255 Patent, by contrast, covers flexure members that do not extend substantially outside or inside the surface of the tubular wall, and which instead stay within the curved plane of the walls. For that reason, plaintiffs assert that their proposed construction, which would construe flexure members curving "in a non-radial direction of the stent" as flexure members that do not "extend substantially outside the outer surface or inside the inner surface of the tubular wall," is consistent with the prosecution history.

Defendants, for their part, preliminarily define the three directions applicable to cylindrical stents -- the radial direction (i.e., extending away from the stent wall), the longitudinal direction (i.e., extending along the stent's length), and the circumferential direction (i.e., extending around the stent's circumference). From this premise, they argue that "curving in a non-radial direction" of a stent must be construed to mean simply that a stent's flexure members or connectors must curve in at least one non-radial direction. In other words, as long as the connectors curve in a non-radial direction (e.g., the longitudinal or circumferential direction), then the claim language is satisfied, regardless if the connector also curves in a radial direction.

Given that neither party has squarely invoked reliance on either the claim language or the specification, the court turns straight away to the prosecution history. A review of the prosecution history reveals that the '255 Patent applicants, in traversing the patent examiner's earlier prior art rejections regarding certain claims, represented to the examiner that: (a) the flexure members claimed by the patent "comprise[] a curved shape, curved in a plane of the pair of side walls"; (b) that "projecting barb 22" of figure 4A of the Orth patent "does not curve in the plane of the pair of side walls"; and (c) that "projecting barb 22" of figure 4A of the Orth patent "does not comprise a U-shape in a non-radial direction of the stent," whereas the claimed flexure member does. See Jelenchik Decl., Ex. E at AB0732126-27. Looking in turn at figure 4A of the Orth patent, and specifically at "projecting barb 22" -- labeled as element 22 on the figure -- it is apparent that element 22 projects outside the stent walls - i.e., in a radial direction. See, e.g., U.S. Patent No. 5,591,197 ("Orth Patent"), Fig. 4A; see also id. at 8:52-56 (describing "projecting barb 22" as "form[ing] radially outwardly"). 8 Comparing both Figure 4A of the Orth patent and the prosecution history to the claim language, therefore, the logical conclusion to be reached is that any outward (or inward) projection from the stent walls constitutes a curvature in a radial direction. And since the claim language covers flexure members that extend in a "non-radial direction," the claim language necessarily refers to flexure members that do not significantly project either outwardly or inwardly from the tubular walls of the stent. This is so, regardless whatever other directions in which the flexure members are curved. Defendants' proposed construction, which would cover stents with flexure members curved in both the radial and non-radial directions, cannot be reconciled with the prosecution history or the claim language.

Footnotes

8 The Orth Patent -- along with other patents referenced by the parties -- was not originally submitted for the court's consideration in connection with the present motion. At the hearing on the present matter, however, the court highlighted the parties' failure to include relevant documentation, and plaintiffs thereafter submitted the Orth Patent and other prior art references.

Accordingly, the court hereby adopts plaintiffs' proposed construction, and construes "curved [curving] in a non-radial direction of the stent" as: "curved or curving such that the [arcuate U-shape or flexure member curved portion] does not extend substantially outside the outer surface or inside the inner surface of the tubular wall."

B. Proper Construction of the Term "Curved Internal Passageway"
Donnelly argues their GMT900 power sliding rear window does not infringe upon the '769 Patent due to the absence of:

[a] block or bracket that forms a passageway that is curved in shape and that is internal to the block or bracket to guide a drive cable from an entry point into proper alignment with a cable channel.

[Def.'s Br., Doc. No. 201, p.10]. As discussed supra, Phillips instructs this Court to construe the phrase "curved internal passageway" not only through examination of the actual claim language, but within the context of the entire patent.

Both Dura and Donnelly concede in their briefs that the phrase "curved internal passageway," as used within the '769 Patent, is clear and unambiguous. 1 [See Def.'s Br., Doc. No. 201, p.8; Pl.'s Br., Doc. No. 250, p. 8]. Thus, the Court agrees with the parties, and in construing the instant claim of the '769 Patent, adopts the construction outlined by the Plaintiffs in their brief:

"[t]he plain meaning of the claim language is an internal passageway that is curved." [Pl.'s Br., Doc. No. 250, p.9].

1 In its brief, Donnelly characterizes the "curved internal passageway" as being "serpentine" in nature [See Def.'s Br., Doc. No. 201, p.8], a distinction Dura regards as unnecessarily narrowing the '769 Patent's terms [See Pl.'s Br., Doc. No. 250, p.9]. While the Court notes that Dura itself describes the required passageway as "serpentine" within the "Preferred Embodiments" section of the '769 Patent [See '769 Patent, Def.'s Ex. 1, p.MD000923 ("...A serpentine passageway 60 extends from socket 58, guiding drive cable 42. . .")], the Court holds this distinction to be one which does not make a difference in the outcome of this motion, and thus declines to resolve this dispute between the parties.

GO BACK

1052

1. "Curved shank"

The main dispute between the parties on construction relates to the claim requirement of a "curved shank," construed by the district court to mean a shank that "has a bend or deviation from a straight line without sharp corners or sharp angles." Stryker challenges that interpretation, arguing that the better reading of the term is "a nonangular continuous bend."

When construing claims, a court must begin by "look[ing] to the words of the claims themselves . . . to define the scope of the patented invention." Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)). The task of comprehending those words is not always a difficult one. "In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Id. at 1314. "[C]urved," as it is used in the '444 patent, is not a "term[] that ha[s] a particular meaning in a field of art." Id. Its ordinary meaning encompasses "curvature" made up of small discontinuities. Consider, for instance, an archway made from rectangular bricks. The bricks are at angles with respect to each other, but the overall effect is to describe an arc. It would be unreasonable to say that such an archway is not "curved." If the word "curved" is given its ordinary, lay meaning, the district court's construction is correct.

Stryker argues that "curved" is implicitly assigned a different, narrower meaning by virtue of the context in the written description in which it appears. See id. at 1316 ("[T]he specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs."). That argument is based on a particular manner of implanting the nail disclosed and touted by the written description. The '444 patent's Summary of the Invention section states that "[t]he tapered shape of the present invention permits it to be inserted into a cavity formed by a broach tool having the same shape as the nail." '444 patent col.1 ll.49-51. A broach tool is "essentially a rasp having the same profile as the hole it is intended to form." Id. col.3 ll.27-28. The patent teaches that broaching is advantageous, since, inter alia, it "generally causes less tissue damage than a rotating drill bit or reamer." Id. col.3 ll.32-33. However, "[b]roaching is only suitable for certain shapes of holes and objects" -- in particular, it is useful only for an object that "largely passes through its own envelope." Id. col.3 ll.37-40. "Objects with angled bends or small radius curves (relative to the object length) do not pass through their own envelope on insertion, and are not well suited to
The parties agree that claim 7's limitation that the arm "curves forwardly slightly" means that the arm can have a small base unit as it proceeds upwardly away from said longitudinal axis of said handle.

Stryker's argument is essentially an assertion that since the patent says broaching is desirable, the term "curved" must be construed to cover only embodiments whose curvature allows them to be inserted into a broached hole, excluding "angled bends or small radius curves." That assertion is flawed: it is an attempt to import a feature from a preferred embodiment into the claims. See Phillips, 415 F.3d at 1323 (“Although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments.”). Neither use with a broaching tool nor suitability for such use is claimed. Indeed, the application which led to the '444 patent originally included claims to the method of implanting the nail with a broaching tool, but the patentee elected to withdraw those claims from the application after the Examiner noted they were directed to a separate, distinct invention.

The fact that usability with a broaching tool is merely a feature of a preferred embodiment provides sufficient grounds for refusing to read "curved" narrowly. We also note, though, that the patent's Claim 13 (not asserted by Acumed in this case) covers "[t]he nail of claim 1 having a profile that substantially passes within its own envelope." '444 patent col.6 ll.26-27. "[T]he presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim." Liebel-Flarsheim Co v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004); see also Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225, 1234 (Fed. Cir. 2001); Comark, 156 F.3d at 1187; Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). "That presumption is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the dependent claim should be read into the independent claim." Sunrace Roots Enter. Co. v. SRAM Corp., 336 F.3d 1298, 1303 (Fed. Cir. 2003); see also Ecolab Inc. v. Paraclipse, Inc., 285 F.3d 1362, 1375-76 (Fed. Cir. 2002); Wenger Mfg., 239 F.3d at 1233 ("Claim differentiation . . . is clearly applicable when there is a dispute over whether a limitation found in a dependent claim should be read into an independent claim, and that limitation is the only meaningful difference between the two claims."). If we were to give "curved" in Claim 1 the meaning which Stryker advances, Claim 1 would cover only nails that "substantially pass[] within [their] own envelope[s]." Such a restrictive reading would render Claims 1 and 13 identical in scope. Since independent claims are presumed to have broader scope than their dependents, the presumption is that Claim 1 should not be limited in the manner Stryker urges. For the reasons discussed above, that presumption has not been rebutted.

Stryker also argues that the district court's exclusion of "sharp corners or sharp angles" renders the construction insufficiently definite, since the court did not specify precisely how "sharp" is too sharp. However, a sound claim construction need not always purge every shred of ambiguity. The resolution of some line-drawing problems -- especially easy ones like this one -- is properly left to the trier of fact. See PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351, 1355 (Fed. Cir. 1998) (“[A]fter the court has defined the claim with whatever specificity and precision is warranted by the language of the claim and the evidence bearing on the proper construction, the task of determining whether the construed claim reads on the accused product is for the finder of fact.”); Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1554 (Fed. Cir. 1996) (whether claim limitation requiring diameter of "about 0.040 inch" embodied a matter of "technologic fact"); see also Abbott Labs. v. Baxter Pharm. Prods., Inc., 471 F.3d 1363, 1368 (Fed. Cir. 2006) (where result is the same under any reasonable construction, "we need not construe [the disputed] phrase with numerical exactitude."). Here, the accused product has a rounded-off six-degree angle in its shaft. A reasonable jury could have found that in the context of this sort of nail, a rounded bend of six degrees was not a "sharp angle." The jury's conclusion is bolstered by the testimony of Stryker's own technical expert, who noted in reference to the Stryker nail that "there's no sharp angle there." There may be some area of imprecision within the district court's "without sharp angles" construction, but this accused product is in no danger of falling within that area. The construction is correct, and the jury's finding that the Stryker nail possesses a "curved shank" is supported by substantial evidence.
amount of curvature. The only difference between the parties' proposed constructions is that Oreck refers to a small curvature "that is designed to be easily grasped by the hand." Joint Claim Constr. Statement at A-4. Oreck argues that this additional detail is justified by reference to the specification, which states that the "rounded compound curvature of arm surface 16 . . . is also helpful in that it tends to nest in the cupped inner portion 27 of the operator's closed hand 28 when arm 15 is grasped." '315 Patent at 4:4-8. But the language Oreck quotes does not purport to describe the slight curve contemplated by claim 7. Rather, as is clear from figures 3 and 7 of the '315 patent, the "rounded compound curvature of arm surface 16" to which the specification refers is the "curved outer rear surface" disclosed by claim two. This statement from the specification therefore has no relation to curvature along the length of the graspable arm, as described by claim 7. Accordingly, Oreck's additional language is unnecessary. The Court therefore construes claim 7 as simply permitting the graspable arm to have a small curvature along its length in the direction of the base unit.

1054

IV. Buttons curving from the front of the top surface to the top of the front surface (Claims 1, 6-10, 18-21)

The plaintiff's proposed definition is "curved buttons that run from the forward area of the top of the mouse to the upper area of the front of the mouse." The defendant's proposed definition is "the mouse buttons extend upwardly to a ridge from which the mouse's top surface slopes downwardly to the rear."

The Court finds the claim language to be sufficiently clear and self-explanatory, especially considering the detailed drawings contained in the specification, so that no further definition is necessary.

GO BACK

1055

II

On appeal, Hill-Rom asserts that KCI's original and modified triadynne beds infringe claims 1 and 10 of the '346 patent. Hill-Rom's principal argument on appeal is that the district court erred in construing the term "cushion," which is used in both claims 1 and 10. The court's claim construction error, Hill-Rom argues, resulted in an erroneous ruling of noninfringement.

The district court interpreted the term "cushion" to mean "an inflatable enclosure or bag, which, when inflated, should provide basic support and comfort, but which does not necessarily have to be inflated at all times." Hill-Rom argues that the term "cushion" should have been interpreted more broadly, to mean "an enclosure or bag capable of being inflated." In Hill-Rom's view, nothing in the claims, specification, or prosecution history requires that cushions provide basic comfort and support.

We reject Hill-Rom's arguments and hold that the trial court correctly construed the term "cushion" to mean a structure that provides basic support and comfort. The trial court's interpretation of the term "cushion" is consistent with the ordinary meaning of the word, which denotes an object providing some sort of support or comfort. See Webster's Third New International Dictionary 559 (1976 Ed.) (defining "cushion" as "a bag or case made typically of cloth, upholstery or matting that is stuffed with a soft, resilient material and used for sitting, reclining, or kneeling: pillow, pad"). Because the court's construction is consistent with the ordinary meaning of the term, we agree with KCI that the trial court did not import extraneous functional limitations into the claim. See York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2d (BNA) 1619, 1622 (Fed. Cir. 1996).

The trial court's interpretation of the term "cushion" is also consistent with intrinsic evidence from the '346 patent itself. The abstract of the disclosure emphasizes the support and comfort provided by the upper and lower inflatable layers, which are identified in claims 1 and 10 as consisting of sets of cushions. The abstract states that "the inflatable structure preferably has two components: a) lower inflatable layer which is selectively operable to provide basic support for the patient," and "a second inflatable layer including a plurality of zones for establishing optimal patient interface pressures and patient comfort levels." * In addition, the written description portion of the patent recites that the "lower support layer" and the "upper overlay assembly" operate in conjunction to provide support and comfort to the patient, See '346 patent, col. 13, ll. 31-55.
Moreover, the written description notes that the head section cushions of the lower layer "will lie under, and . . . will support, the patient's head," Id. at col. 9, ll. 41-48, and that "the lower inflatable layer has utility for supporting a patient directly, without the intervening upper support layer," Id. at col. 18, ll. 4-7.

* Citing 37 C.F.R. § 1.72(b), which provides that the abstract of the patent "shall not be used for interpreting the scope of the claims," Hill-Rom argues that it would be improper for us to consider the abstract in determining whether the district court correctly construed the claims of the '346 patent. Section 1.72(b), however, is a rule of the Patent and Trademark Office that governs the conduct of patent examiners in examining patent applications; it does not address the process by which courts construe claims in infringement actions. we have frequently looked to the abstract to determine the scope of the invention, See, E.g., United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1560, 41 U.S.P.Q.2d (BNA) 1225, 1230 (Fed. Cir. 1997); Stryker Corp. v. Intermedics Orthopedics, Inc., 96 F.3d 1409, 1412, 40 U.S.P.Q.2d (BNA) 1065, 1066 (Fed. Cir. 1996); Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1269, 229 U.S.P.Q. (BNA) 805, 810 (Fed. Cir. 1986), and we are aware of no legal principle that would require us to disregard that potentially helpful source of intrinsic evidence as to the meaning of claims.

the specification thus clearly teaches that one of the major objectives of the cushions recited in the claims is to provide support for the patient, even though that function may be performed in part by the upper support assembly. Because the patent contemplates that the lower layer may be used to support the patient directly, without the upper support layer, the lower layer must have the capacity to provide that function by itself.

Hill-Rom argues that the written description portion of the patent associates the function of providing comfort solely with the upper inflatable support layer, which claim 1 describes as "disposed generally above" the two longitudinal cushion sets. The written description, however, describes the upper layer as providing "optimal patient comfort," See id. at col. 2, l. 59, from which it can fairly be inferred that the upper layer can be adjusted to optimize the patient's comfort, but that the upper layer does not perform the entire task of providing comfort for the patient.

That inference is supported by an examination of independent claim 10. Claim 10, unlike claim 1, does not require an upper layer consisting of "an inflatable support layer disposed generally above said first and second cushion sets." instead, claim 10 requires only a "patient contacting assembly" between the patient and the first and second sets of longitudinal cushions. Nothing in the patent suggests that the "patient contacting assembly" of claim 10 necessarily provides all the required comfort and support. For purposes of claim 10, then, the lower layer, i.e., the layer consisting of sets of cushions, must be capable of providing whatever support and comfort is provided to the patient.

In arguing that the specification supports its broad construction of the term "cushion," Hill-Rom relies heavily on a sentence in the written description stating that the pressure in the working cushions of the invention will typically be equal within each cushion group "and will typically range between 0 and 20 inches of water." '346 patent, col 13, ll. 41-44. If the pressure inside the cushions can drop to zero, Hill-Rom argues, the cushions must not be required to provide comfort and support.

We do not attribute the same significance to that statement that Hill-Rom does. While the statement indicates that each cushion within the several sets of cushions in the lower layer of the patented support assembly has the capacity to operate at a pressure range from zero to 20, and thus particular cushions may not provide support and comfort at some point, such as during the patient rotation process, that does not cast doubt on the correctness of the district court's definition of the term "cushion" as a structure capable of providing comfort and support. The fact that at some point during the operation of the device a cushion may cease to have a "cushioning" effect does not make it any less a cushion, just as an automobile tire is no less a tire when it is deflated, even though it functions in its normal manner only when it is filled with air.
The sole issue presented with the parties' request for a partial Markman determination is the meaning of the term "cushioning" as it appears in the plaintiff's patent claims. The '401 patent includes 22 claims which describe an article of footwear which includes an "angled strip of resilient elastic material" that acts as an "external cushioning spring" fixed on the midsole such that a vertical force on said footwear created by a wearer of said footwear striking said outsole on a solid surface causes said angled strip to bend between said ends and absorb a portion of said force. The term "external cushioning spring" appears in claims 1, 2, 15 and 16 of the '401 patent and claims 1-4 and 45-48 of the '051 patent.

The ordinary and accustomed meaning of the term "cushioning" as defined by the dictionary, and as pertinent here, is "to protect against or absorb shock." Websters II, New Riverside University Dictionary (1984), p. 340.

The '041 patent abstract explains that the invention is useful because it acts to "absorb a portion of the force" created by the wearer when he walks, runs or engages in other sporting activities. In the summary of the invention, the patentee explains that the proposed angled elastic strip placed on the mid sole of the shoe is "fixed in a manner" such that the angled strip bends and absorbs a portion of the force. The specification also explains two particular advantages of the design and placement of the angled strip: the first being a "stabilizing effect" to minimize pronation; the second is expressed as follows:

The spring is particularly advantageous when used on athletic footwear for persons running at high speeds, e.g. during races, and for persons who constantly jump up and down, e.g. in basketball. Because of the shock-absorbing effect of the springs the vertical impact forces associated with such sports are reduced, and thus chronic and acute injuries to the lower limbs [are] prevented or reduced.

The defendant argues that the term "cushioning" as used in the plaintiff's patents necessarily includes a reduction in vertical impact forces to prevent or eliminate injuries to the lower limbs of the wearer. Defendant relies upon the above quoted language in the patent specification and the use of the term "cushioning" in prior art. Plaintiff contends that "cushioning" simply means the absorption of a portion of the vertical force of the shoes' wearer.

At the Markman hearing, defendant offered expert testimony from Dr. Joseph Hamill, a professor of biomechanics from the University of Massachusetts. Dr. Hamill is an expert in footwear biomechanics and, according to his testimony, the term "cushioning" as used in the footwear design industry generally means the absorption, reduction or "attenuation" of shock from vertical forces. Thus, in this case, there is no meaningful distinction between a layman's understanding of the term "cushioning" and that term as it is used in the footwear design industry. Therefore, the ordinary and accustomed meaning of the term "cushioning" is the absorption of vertical force. This is the definition urged by the plaintiff; because the defendant urges a different interpretation given other language in the file specification, defendant bears the burden of proving that its alteration is required. See K-2 Corp., 191 F.3d at 1362.

--- Footnotes ---

3 Dr. Hamill's industry definition appears on page 19 of his power point presentation. While Dr. Hamill ultimately agrees with Nike's definition of the term "cushioning," he did so only in reference to plaintiff's patent.

--- End Footnotes ---

The plaintiff's proffered construction is consistent with the actual claim language and the ordinary and accustomed meaning of the term "cushioning." The claims themselves repeatedly reference the absorption of force. The language of the specification relied upon by the defendant, when viewed in its full context, states a claimed advantage. As the court in Dow Chemical Co. v. Astro-Valcour, Inc. held, a stated advantage in a claim specification may not be relied upon to "limit the scope of the invention itself by adding a requirement not found there." 47 F. Supp. 2d at 298. Specifications may be used to assist in interpreting a claim, but may not be used to alter a claim. E.I. DuPont, 849 F.2d at 1433. Defendant's counter definition would violate this principal of claim construction. Further, defendant's own expert was unable to quantify the amount of force absorption necessary to prevent injuries given the large number of variables involved in activity related injuries. Thus, the plaintiff's failure to specify a claimed absorption rate does not create an ambiguity in the claim terms.

--- Footnotes ---

4 During oral argument, defendant argued that the amount of force absorption performed by several of the accused devices...
found on Nike shoes is so infinitesimal as to have no significance. The court notes that whether the accused devices have any viable function, so as to be patentable at all, goes to a separate question regarding patent viability and/or infringement defenses-- issues not presently before the court.

Finally, the defendant claims that the court must accept its claim construction because to do otherwise would render the term "spring" superfluous. Defendant argues that because plaintiff has defined the term "spring" as a device that absorbs a portion of force, the term "cushioning" must mean something else.

Defendant's argument construes the plaintiff's deposition testimony and his claim construction far too narrowly. Plaintiff's definitions of the terms "cushioning" and "spring" are not identical: plaintiff defines a "spring" as a device that absorbs some degree of force and then returns that force; plaintiff defines "cushioning" as absorbing and reducing vertical impact force. As defined by the plaintiff, "cushioning" does not repel force and a "spring" would not necessarily reduce vertical impacts.

CONCLUSION

Based upon the foregoing, I recommend that the plaintiff's definition of the term "cushioning" be sustained and the alternative definition urged by the defense be rejected. As such, the term "cushioning" should be construed to mean: "to reduce vertical impact forces."

In his Findings and Recommendation, Judge Ashmanskas found that "cushioning" had an ordinary and customary meaning, as defined by the dictionary. He concluded that plaintiff's proffered claim construction was consistent with that dictionary meaning.

Defendant contends that there is no ordinary and customary meaning of "cushioning" to one of ordinary skill in the art, and that Judge Ashmanskas should have resorted to the specification and to prior art in construing the claims. Nike urges that "cushioning" be construed to mean "to reduce vertical impact forces by a meaningful amount, i.e., absorb shock in an amount sufficient to prevent or reduce chronic or acute injuries to the lower limbs of the wearer."

I agree with Judge Ashmanskas that there is "no meaningful distinction" between a layman's understanding of the term and that term as it is used in the footwear industry. I further agree that the claim language is consistent with that understanding. I am not persuaded by defendant's contentions that 1) Judge Ashmanskas should have looked for guidance to the specification or the prior art and 2) that the specification and the prior art support defendant's proffered construction.

Accordingly, I ADOPT Magistrate Judge Ashmanskas's Findings and Recommendation filed April 9, 2002 (doc. # 292). The term "cushioning" is construed to mean "to reduce vertical impact forces."

Infringement

Claim 1 of the '739 patent, from which the three remaining asserted claims depend, claims:

A bumper edge member for chairs and the like which have structural portions defining perimeter edges, the edge member comprising:

a continuous resilient member having an elongate body portion and a pair of spaced flanges extending outwardly from said body member, said flanges being located on said body member to receive therebetween a structural portion of a chair;
a first cushioning means defined in said body member, said first cushioning means including a hollow chamber defined in said body member to be located between said flanges in front of an edge of said structural portion;

a second cushioning means defined in said body member to be located between said flanges; and said second cushioning means being positioned in said body member to be located between a chair structural portion edge and said first cushioning means.

'739 patent, cols. 3-4, ll. 27-12 (emphasis added). Because the final element of this claim is expressed in means-plus-function language, the district court looked to the specification for descriptions of corresponding structures. See 35 U.S.C. § 112(6) (1994). The specification describes corresponding structures to the second cushioning means in the following context: "the second [air space] is the space between the edge of the plywood 22 or other structural member and the convex outer surface 14 of the section of the bumper edge member which extends between the flanges 11 and 12." '739 patent, col. 2, ll. 61-65. The specification also includes the following figure:

[SEE FIGURE IN ORIGINAL]

Based on the specification, the district court held the second cushioning means to include "that portion of the bumper edge with a convex surface and any equivalent shape having an air space between the bumper edge and the edge of the chair." The court then determined that a concave surface would be a section 112(6) structural equivalent to the claimed convex surface of this second cushioning means and found Infanti's chairs to infringe Gasser's patent literally.

Infanti argues that its concave structure does not fulfill the same function as the convex structure disclosed in the '739 patent, which function it defines as "supporting the bumper edge in maintaining its position on the chair edge . . . by providing support against lateral forces at the limited point of contact between the convex surface and perimeter edge of the chair, and thus diverting those forces away from the flanges to prevent the staples from being pulled out." Thus, Infanti argues, its concave bumper edges cannot be a section 112(6) structural equivalent to the claimed convex structure. See, e.g., Pennwalt Corp. v. Durand-Wayland, Inc., 833 F.2d 931, 934, 4 U.S.P.Q.2D (BNA) 1737, 1739 (Fed. Cir. 1987) (literal infringement of a section 112(6) structure is not possible where the identical function is not performed). To support its definition of the function of the second cushioning means, Infanti cites to statements made by Gasser while prosecuting the '739 patent. Infanti argues that Gasser disclaimed structures that do not form a limited contact area between the bumper edge and the chair edge, or that consist primarily of air space between these two edges.

Infanti's definition of the function performed by the second cushioning means improperly reads in a function not recited by the disputed claims. Claims 1-4 call for merely a structure that performs a cushioning function. The statements identified by Infanti come from portions of the prosecution history related to claim 5, which depends from claim 1 and states: "said second cushioning means includes a portion of said body member which is convex in shape relative to said body portion to provide a limited area of contact with respect to a structural portion engaged thereagainst." '739 patent, col. 4, ll. 24-28 (emphasis added). Claim 5 is not at issue in this case, and to the extent that these statements could have identified an additional function of the second cushioning means in claims 1-4, there was sufficient expert testimony for the court to find that Infanti's concave bumper provided a limited contact area and therefore would perform the function identified by Infanti. While greater than the contact area of a convex bumper edge or a bumper edge shaped like the letters "T" or "V," a concave bumper edge's contact area is also limited.

Infanti's argument that Gasser disclaimed any structure that consists primarily of air space is equally incorrect. The statement to which Infanti refers reads as follows: "And Claim 1 does not require that the second cushioning means include, a hollow chamber space. All that is required is that the second cushioning means be disposed between the first cushioning means and the structural portion of the chair which defines the perimeter edge." This statement was not made to overcome prior art and merely explains that the second cushioning means in claim 1 does not require an air space. It cannot preclude from consideration as a structural equivalent a concave bumper edge that consists primarily of air space.

We agree that a concave structure presents an equivalent means for performing the cushioning function identified in the patent, and hold that the district court did not err in considering Infanti's structure as an equivalent. Because we affirm the finding of literal infringement, it is unnecessary to address Gasser's argument that Infanti infringes the '739 patent under the doctrine of equivalents.
4. "A customer service station"

For its proposed construction, Foodie offers the following: "any area(s) from which a customer can be served." Jamba Juice proposes: "a specific location where an employee stands to dispense the refrigerated source liquid and delivers the consumer consumption vessel to the consumer. All elements contained within the customer service station are within reach of a stationary employee." The main disputes between the parties regarding "customer service station" are whether the claims are limited to a single station, whether a customer service station and product finishing station can be one station or must be separate, and the boundaries or size of a customer service station.

Regarding whether the patent precludes more than one customer service station, the Federal Circuit has repeatedly held that an indefinite article "a" or "an" in patent parlance carries the meaning of "one or more" in open-ended claims containing the transitional phrase "comprising." KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000); Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999); Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1023 (Fed. Cir. 1997). When the claim language or context calls for further inquiry, courts consult the written description for a "clear intent to limit the invention to a singular embodiment." KCJ Corp., 223 F.3d at 1357. "When claim language or context suggests an ambiguity in application of the general meaning of an article, [the] court undertakes an examination of the written description and the prosecution history to ascertain whether to limit the meaning of "a" or "an." Id.

The Court notes that the claim uses "comprising" in conjunction with "a customer service station," which under Federal Circuit precedent does not preclude multiple customer service stations. The next step in the analysis requires courts to comb through the patent and determine if there was an overt attempt to limit the object or place associated with the article "a" or "an" to a single unit. In the present circumstances, there is no significant evidence in the specification indicating that the article "a" forecloses the possibility of more than one station. Jamba Juice argues that the definition of "station" is singular, and also that Figure 2 in the patent indicates two separate areas, thereby indicating (along with the claims) separate "customer service station" and "product finishing station" areas comprised of separate things. Jamba Juice claims that Foodie is trying to expand the construction such that the items the patent states are within the "customer service station" could be located in any part of the store without any relation to each other, thereby expanding the term "customer service station" to include most anything and everything. Jamba Juice's argument ultimately does not necessitate looking past the guidance provided by the Federal Circuit. While "station" is indeed singular, under Federal Circuit precedent the use of "comprising a" to reference a location or item means one or more unless otherwise limited in the patent. Finding no such limitation, the Court's construction of the term also does not preclude more than one "customer service station."

Regarding whether the "customer service station" must be a separate area from a "product finishing station," both parties note that the claims are silent on the question. Reading the claims, the "customer service station" includes certain items, and the "product finishing station" includes certain other items. However, it does not appear that the stations must be separate. So long as the items mandated in the claims are present in specific discernible location(s), the patent does not appear to preclude the possibility that the stations could overlap or even be one.

Finally, Jamba Juice argues that Foodie's construction is an overbroad definition. Jamba Juice claims Foodie is proposing that, while the claims mandate that certain items are in the customer service station, the items do not necessarily need to be located together. The Court agrees with Jamba Juice that the patent's claims and the specification seem to indicate that the "customer service station" is meant to be a specific area encompassing the items stated in the claims. However, Jamba Juice's arguments that "station" means an area within reach of an employee are not supported by the specification or claims. At the Markman hearing, Jamba Juice stated they offered this portion of the construction largely out of concerns for limiting the boundaries of the area(s). The best support for defining the boundaries of the customer service station's area comes from the claim itself. In the claim, "customer service station" is said to be comprised of certain items, including things such as a drip pan and breath guard. '448 patent col. 8 l. 11-12. The drawings accompanying the patent include the items stated in the claim, and seemingly limit the "customer service station" to a specific area(s) extending a short distance beyond the enumerated items stated in the claims.

With all of the above in mind, the Court's construction of "customer service station" attempts to take all of the parties'
concerns into account: "A station from which a customer can be served, and includes a cold pan, a drip pan, a breath guard, at least one refrigerated source liquid conduit line, and the refrigerated source liquid conduct line connecting said refrigerated source liquid and said consumer service station beverage tapping mechanism." 4 The Court's construction does not preclude more than one customer service station, and remains consistent with the claims by limiting the bounds of a customer service station to the inclusion of, at a minimum, the items stated in the claim. The construction also takes into account Jamba Juice's concerns that Foodie was expanding the boundaries beyond what the patent claims by using "station" instead of "area" or "location." A "station" inherently is easier to conceptualize as a limited area than more expansive terms such as "area" or "location." Station is in turn defined by what the claims mandate the "customer service station" encompasses, and is further limited to a station(s) where customers can be served.

4 In the parties' original proposed constructions, both parties included some language referencing service to the customer as part of their construction of "customer service station," which the Court construes as agreement between the parties on the "from which a customer can be served" portion of the Court's definition.

B. Effect of Prior Litigation

As stated above, SunTiger prevailed in a prior patent infringement suit against Scientific Research Funding Group (SRFG) on the same patents now in question. Both SunTiger and Sunglass Products have stipulated that the claim construction in the prior suit will control here:

The patents-in-suit have already been construed by the U.S. District Court for the Eastern District of Virginia [and that] construction . . . is binding on the parties in this case. To the extent that the terms in the asserted claims were not construed in the said prior litigation, the parties are asking the Court to make a claim construction based on the arguments submitted in the summary judgment motions.

Stipulation at 1-2. "In a patent litigation action, where the parties do not dispute any relevant facts regarding the accused product but disagree over possible claim interpretations, the question of literal infringement collapses into claim construction and is amenable to summary judgment." Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1324 (Fed. Cir. 2002).

The relevant terms and their stipulated construction are as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Stipulated Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;substantially block&quot;</td>
<td>&quot;... in reference to wavelengths, it is defined as blocking over 99% of the incident radiation at each and every wavelength&quot; and &quot;[in] reference to polarization, it is defined as blocking 80% or more of the horizontally polarized incident radiation at each and every wavelength&quot;</td>
</tr>
<tr>
<td>&quot;substantially transmit&quot;</td>
<td>&quot;... in reference to wavelengths, [it] is defined as transmitting more than 1% of the incident radiation at each and every wavelength&quot; and &quot;[in] reference to polarization, it is defined as transmitting more than 20% of the horizontally polarized incident radiation at each and every wavelength&quot;</td>
</tr>
<tr>
<td>&quot;sharp cut-on&quot;</td>
<td>&quot;... sharp cut-on is defined in the context of a dye or filter, having a cut-on slope that at some concentration or dye density rises more than one half percent (0.5%) change in transmission for every one nanometer of...&quot;</td>
</tr>
</tbody>
</table>
increasing wavelength change. The cut-on slope is
that portion of the transmission spectra of a cut-on
dye that represents the transition between [the]
substantially blocking and the substantially
transmitting region."

"cut-on filter"  "... an optical filter that substantially blocks all
wavelengths shorter than the cut-on wavelength and
substantially transmits all wavelengths that are longer
than the cut-on wavelength. The cut-on wavelength is
that wavelength in the transition zone at which the
transmission is 1%."

"portion"  "... part or share of something"

Plaintiff SunTiger contends that this Court cannot apply the stipulated construction in a way that would contradict the
finding of the Eastern District of Virginia that YE-82 infringed SunTiger's patents. Pl.'s Mot. at 1 ("[T]he YE-82 lens
material must literally infringe whatever claim construction the Court adopts in this case."). In essence, SunTiger argues the
following: (1) the parties have stipulated to the prior construction, (2) the decision in the prior suit does not bind this Court,
but (3) any ruling that this Court issues must not be inconsistent with the fact that YE-82 was found to infringe its patents.

I disagree with this assessment. My decision is not foreordained by the result in SunTiger, Inc. v. Scientific Research
Funding Group. SunTiger attempts to elevate the prior claim construction to the level of a decision. Despite the parties'
agreement that the prior claim construction would be binding, that prior court's decision applying its own construction is
only persuasive. Although the parties have agreed to be bound to the use of the prior construction, they have not agreed that
this Court's application of that construction must be consistent with prior decisions involving a different defendant and
different lenses. Indeed, were consistency with prior results necessary, that would be tantamount to an improper form of
collateral estoppel against a current party, i.e., Sunglass Products, which was not a party (nor a party in privity) to SunTiger
1994) ("[D]ue process requires that the party to be estopped must have had an identity or community of interest with, and
adequate representation by, the losing party in the first action as well as that the circumstances must have been such that the
party to be estopped should reasonably have expected to be bound by the prior adjudication.").

E. Means-Plus-Function Revisited: "Cutter"

Ken identifies the "cutter" of claim 12 as a means-plus-function claim. That claim is directed to a "system for folding
metallic ribbon stock comprising," inter alia,  "a cutter for cutting said ribbon stock at a predetermined location." Here Ken
seeks to limit the claimed cutter to that disclosed in the '919 patent and its structural equivalents. 35 U.S.C. § 112, P 6.
Again Ken points to the specification: "The above [referring to Figure 1] cutting molding unit 100 is applied from [Korean]
A detailed explanation for the cutting molding unit is therefore omitted below."

--- Footnotes ---

12 The original specification, erroneously referring to "Japan Patent No. 80607" (instead of "Korean Patent No. 80607"),
was later amended by a Certificate of Correction. Gilman Decl. Exh. 4 at 127. This discrepancy, already the subject of a
summary judgment motion and extensive oral argument, will not be further discussed. See March 28, 2000 Order denying
Ken's motion for summary judgment concerning inequitable conduct.

--- End Footnotes ---
SDS again objects that the absence of "means" language precludes application of the means-plus-function statute. SDS Br. at 32. And, it argues, the word "cutter" is "about as structural as one can get." SDS Br. at 32.

Once again, the court must determine whether the "cutter" is "expressed as a means . . . for performing a specified function without the recital of structure, material, or acts in support thereof." 35 U.S.C. § 112, ¶ 6. The court first notes the Federal Circuit's comment that the mere coincidence that a device takes its name from its function should not convert a claim into the means-plus-function format. Greenberg, 91 F.3d at 1583 (listing "filter," "screwdriver," "suture applicators" and "cutters") (emphasis added). The court next turns to the dictionary relied upon by defendant, the International Association of Diecutting and Diemaking "Glossary of Terms," which stipulates: "CUTTER -- A term used to describe a bench tool used to cut steel rule stock in the manufacture of steel rule dies." SDS Exh. 46. This definition, evidently familiar to those skilled in the diemaking and diecutting art, supports the legal presumption that the cutter, with no reference to "means," should not be analyzed under Paragraph 6. Like the elongate member, it is structure. See Envirco, 209 F.3d at 1365 ("The term 'baffle' itself is a structural term.").

The court adopts the I.A.D.D.'s definition of the disputed "cutter" in claim 12. That device is not expressed in means-plus-function terms; Ken's contention to that effect is rejected.

A. The '949 Patent

Landers asserts that the district court erred in construing the "cutter head" limitation of claim 33 as a means-plus-function limitation. Landers notes that the limitation does not contain the term "means," which presumptively indicates that it is not a means-plus-function limitation. Moreover, Landers argues that Sideways did not provide any evidence demonstrating that the term "cutter head" lacks sufficiently definite structure to justify its construction as a means-plus-function limitation. Instead, Landers contends that the court should have given the limitation its ordinary and customary meaning.

We agree with Landers that the district court improperly construed the term "cutter head" as a means-plus-function limitation. "A claim limitation that does not use 'means' will trigger the rebuttable presumption that § 112, P6 does not apply." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002) (citations omitted). The presumption may be rebutted by demonstrating that the claim term fails to recite sufficiently definite structure. Id. Despite Sideways' argument to the contrary, however, the presumption has not been rebutted here. Indeed, claim 33 contains several limitations providing structure to the cutter head, e. g., the cutter head must rotate, it is connected at one end to a "flexible shaft," and it must be moveable through the "inlet" and "outlet" of an L-shaped "passageway." Moreover, the court found that a person of ordinary skill in the art would have understood the term to "encompass[] a number of different cutting mechanisms." See Watts v. XL Sys., Inc., 232 F.3d 877, 880-81 (Fed. Cir. 2000) ("To help determine whether a claim term recites sufficient structure, we examine whether it has an understood meaning in the art.").

That the district court's construction, which limited "cutter head" to a ball cutter and its equivalents, is erroneous is further supported by dependent claim 34. Under the doctrine of claim differentiation, it is presumed that different claims will have different scopes. See Phillips v. AWH Corp., 415 F.3d 1303, 2005 U.S. App. LEXIS 13954, Nos. 03-1269, -1286, slip op. at 13 (Fed. Cir. July 12, 2005) ("the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim"). Claim 34 limits the "cutter head" recited in independent claim 33 to "a ball cutter." Thus, while the doctrine of claim differentiation is not absolute, it works against the court's interpretation, which gives claims 33 and 34 the same scope.

To support the district court's interpretation of the term "cutter head" as a means-plus-function limitation, Sideways argues that the term should not be given its ordinary meaning. According to Sideways, the patentee experimented unsuccessfully with many different types of cutter heads and succeeded only with a ball cutter. This argument, however, misses the point. The relevant inquiry is how a person of ordinary skill in the art would have understood the simple term "cutter head," not whether other cutter heads succeeded or failed in cutting well casings. Moreover, we note that the patent specification does not indicate that only a ball cutter is capable of making a hole in a well casing.
We also reject Sideways' contention that the term "cutter head" was properly construed as a means-plus-function limitation because it lacks sufficiently definite structure. Specifically, Sideways argues that the patent specification and claims do not provide any structural detail concerning the cutter head. The law does not require, however, that the specification and claims contain exacting details of every structure recited in the claims. As we explained above, the relevant inquiry focuses on whether a person of ordinary skill in the art would have understood the limitation "cutter head" to have a sufficiently definite structure.

Unless the intrinsic evidence compels a contrary result, a claim limitation should be given its ordinary and customary meaning. Phillips, 2005 U.S. App. LEXIS 13954, slip op. at 9. We note that Landers, in its appellate briefing, has provided a good starting point for this task on remand by providing examples of "cutter heads" in the prior art. 2 Appellants' Opening Br., at 23-25. Accordingly, we vacate the district court's finding of noninfringement of the '949 patent, to the extent that that finding was based on an erroneous claim construction of the term "cutter head." Furthermore, we remand for the court to give the term "cutter head" its ordinary and customary meaning, and redetermine whether Sideways' device meets that limitation.

--- Footnotes ---

2 Sideways argues that the district court did attempt to construe, to no avail, the term "cutter head" by applying its ordinary and customary meaning. Appellee's Opposition Br., at 17 n. 7. But Sideways provides no citation showing, nor can we discern any from the record ourselves, the court engaging in any relevant analysis.

3 On remand, we caution the district court regarding its reliance on testimony from any patent attorney on technical issues, as opposed to issues concerning legal procedure. In particular, a patent expert should not be permitted to construe claim terms unless he is first qualified as an expert in the pertinent art.

--- End Footnotes ---

1. "Cutting Disks"

The Court will begin with the term "cutting disks" as it appears in independent claims 1 and 12, elements 1(g) and 12(d), of the '780 Patent. Fellowes proposes that "cutting disks" are "generally round or ring-shaped elements that are designed for cutting paper." Michlin proposes the same definition with the limitation that such "cutting disks" "include end surfaces which lie in parallel planes." Intek argues that "cutting disks" are "unitary, flat, disk-shaped elements that include side surfaces which lie in parallel planes."

The Court will start with the claim itself. Claim 1 specifies that the "cutting disks" are "spaced apart," have "at least two circumferentially spaced teeth and a spacer," and are "displaced in the longitudinal direction of the cutting cylinder." '780 Patent, cols. 3-4, lines 46-48, 1-4. As stated above, Claim 12 provides:

A cross-cutting cylinder comprising:

a. a plurality of cutting disks with each disk having at least two circumferentially spaced teeth, with the disks arranged in a longitudinal direction of the cutting cylinder to provide a helix; and

b. a spacer located between each adjacent disk, wherein the surface of the spacer has a linear measure greater than the distance between each adjacent disk.

Id. at col. 4, lines 39-47. Claim 12 expressly limits the "cutting disk" to having "at least two circumferentially spaced teeth" and being "arranged in a longitudinal direction of the cutting cylinder to provide a helix." Id. at col. 4, lines 39-43. None of the limiting adjectives proposed by the defendants--"parallel," "unitary" or "flat"--appear, either expressly or inferentially, in Claims 1 or 12.
Moreover, the '780 Patent specifications do not support the view that the "cutting disks" are necessarily "flat" or "parallel." The specifications provide that the "cutting the [sic] disks" may have the construction and shape shown in U.S. Pat. Nos. 5,676,321 ["the '321 Patent"] and 5,295,633 ["the '633 Patent"], each of which is incorporated by reference. Id. at col. 2, lines 43-45. The Court has reviewed the '321 Patent and the '633 Patent, both of which involve "cutting disks" used in shredders, and nowhere in either patent did it find that the "cutting disks" must be "parallel" or "flat." Id. at FE 000366-71; id. at FE 000383-93. Intek correctly points out that the embodiment of the "cutting disk" shown as 14 in Figures 1, 2, and 3 of the '780 Patent appears to be "flat" and has "side surfaces" or "end surfaces" which, at least arguably, "lie in parallel planes" insofar as they were drawn using straight lines. Id. at figs. 1, 2, 3. The Court refuses to rely upon the specifications, however, in order to limit the definition of "cutting disks." See Electro Med. Sys., 34 F.3d at 1054 ("[C]laims are not to be interpreted by adding limitations appearing only in the specification.").

Michelin and Intek argue that the phrase "the distance between each adjacent disk" (emphasis added) in Claims 1 and 12 means that there must be only a single distance between the "cutting disks," and therefore the disks must be "flat" and "parallel." Markman H'g Tr. 141-145; Intek Br. 17. Although the word "the" in the phrase "the distance between two adjacent disks" could reasonably be read as meaning that the distances between two adjacent disks are identical at all points of the disks, this one word does not compel such a construction, and is, not in the Court's view, enough to justify limiting the "cutting disks" to being "flat" or "parallel." Although the Court may rely on dictionary definitions to construe claim terms, Phillips, 415 F.3d at 1317, any reliance on dictionaries must accord with the intrinsic evidence in the patent. Id. In any event, dictionaries consulted by the Court do not resolve whether a "disk" or "disc" is flat. See WEBSTER'S THIRD NEW INT'L DICTIONARY 651 (3d ed. 1981) ("a thin circular object"); THE RANDOM HOUSE COLL. DICTIONARY 381 (4th ed. 1973) ("any thin, flat, circular plate or object and "any surface that is flat and round, or seemingly so"); Michelin Ex. 3009 (Google.com definition of "disk" as, inter alia, "something with a round shape like a flat circular plate" and "a general term that is used to describe flattened circular objects").

An additional issue is whether, as Intek contends, the "cutting disk" is a "unitary" structure, or whether, as Fellowes argues, it can be either a single piece or comprised of multiple pieces. During prosecution of the '780 Patent, the USPTO rejected Claim 1, among others, as anticipated by Patent No. 5,988,542 ("Henreckson" or "'542 Patent"). '780 Patent, FE 000424. The invention disclosed in Henreckson relates to "document shredding devices mountable on various waste receptacles for shredding paper." Id. at FE 000431 ('542 Patent). The USPTO rejected Claim 1 pursuant to 35 U.S.C. 102(e), stating, "Henreckson et al disclose the apparatus as can be best understood in view of the 35 USC 112, second paragraph rejection set forth above. Note Fig. 8, V-shaped spacers between cutting disks '38' on shredding rollers '30' and '36'." 6 Id. at FE 000427. In an effort to overcome the USPTO's rejection, the patentees filed a July 21, 2000, response in which they argued:

Henreckson et al. disclose a conventional straight cut shredder. The shredder of Henreckson et al. cuts the paper into strips. Henreckson et al. do not disclose the crosscut shredder of the present invention. In a cross-cut shredder and according to the present invention, the cutting disks of the present invention are somewhat displaced in the longitudinal direction of the cutting cylinder so that a large pitch helix is formed.

It is respectfully submitted that Henreckson et al. do not disclose a separate spacer between cutting disks where the linear measure of the spacer along its surface is greater than the distance between two adjacent disks. It is respectfully submitted that Henreckson et al. teach the abutment of two cutting disks against each other to form a single cutting unit separated from other cutting units by spacers 30 and 36. The linear measure of the spacer of Henreckson et al. is equal to the distance between adjacent disks.

Id. at FE 000507 (emphasis added). According to Intek, the patentees' effort in the quoted text to distinguish between "cutting disk" and "cutting unit" (the latter being a combination of abutting "cutting disks") limits the term "cutting disk" in the '780 Patent to mean "one unitary cutting disk, not a combination of pieces." Intek Br. 12. The Court disagrees with Intek. The term "cutting units" appears nowhere in the '780 Patent itself. Moreover, neither the '321 Patent nor the '633 Patent, which are "incorporated by reference" into the '780 Patent on the question of the "construction and shape" of the "cutting disks," specify that the "cutting disk" is comprised of a single part or multiple parts. Consequently, the Court refuses to construe the "cutting disk" as being "unitary" and refuses to construe it as being comprised of multiple pieces. The Court FINDS that "cutting disks" are "generally round or ring-shaped elements that are designed for cutting paper."
6 35 U.S.C. § 112 P 2 provides: "The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention."

The 949 Patent contains the following claims:

1. A method for penetrating a well casing and surrounding earth strata comprising the steps of:
   - inserting an upset tubing having an elbow on an end thereof a preselected distance into a well casing;
   - inserting a flexible shaft having cutting means on an end thereof into said upset tubing, said cutting means extending through said elbow;
   - rotating said flexible shaft and said cutting means cutting a hole in said well casing;
   - removing said flexible shaft and said cutting means from said upset tubing;
   - inserting a flexible tube having a nozzle on an end thereof into the upset tubing and said channel;
   - pumping a fluid into the flexible tube and nozzle; and, cutting an extension of said channel in said earth's strata.

2. The method of claim 1, said nozzle being a nozzle blaster, with a fluid chamber therein in fluid communication with said flexible tube, said nozzle blaster having a front conical portion and a rear base portion, said nozzle blaster having a plurality of first openings therein in said conical portion extending into said chamber, said first openings being directed forwardly of said nozzle blaster and a plurality of second openings in said base portion directed rearwardly of said nozzle blaster.

3. The method of claim 1, said cutting means including a cutter and means to prevent said cutter from extending into said strata after making a cut in a well casing.

4. The method of claim 3, said means to prevent said cutter from extending into said strata including an elbow at the terminating end of said upset tubing, said elbow being octagonally shaped with an inlet on a top surface thereof and an outlet opening on a side at a 90 [degrees] angle from said inlet, said opening being larger at said inlet than said outlet, said flexible shaft having a plurality of balls at its cutting end with said cutter at a terminating end of said cutting end, said cutter having a maximum diameter less than a maximum diameter of at least an adjacent ball.

5. The method of claim 4, said cutter being a ball cutter.

6. An apparatus for cutting a hole in a well casing comprising:
   - a cutter;
   - a flexible shaft having said cutter on one end thereof; means to position said cutter at a preselected position within a well casing, said means to position said cutter includes an elbow at a terminating end of an upset tubing in a well casing through which said cutter is received there through, said elbow including a bowed channel between an inlet and an outlet, said bowed channel having a bottom portion, said bottom portion having an upslope towards said outlet.

7. The apparatus of claim 6 wherein said means to rotate includes a fluid motor coupled to said flexible shaft.
8. The apparatus of claim 7 wherein said means to rotate includes a speed reducer coupled to said fluid motor wherein said speed reducer is coupled to said flexible shaft.

9. The apparatus of claim 8 wherein said output of said speed reducer is from about 20 to 30 rpm.

10. The apparatus of claim 6, said elbow being octagonally shaped wherein said inlet is on one side thereof and said outlet is on another side at 90 [degrees] angle from said inlet, said opening being larger at said inlet than said outlet.

11. The apparatus of claim 10, said cutter being a ball cutter, said flexible shaft having a plurality of balls at a cutting end with said ball cutter at a terminating end of said cutting end, said ball cutter having a maximum diameter less than a maximum diameter of at least an adjacent ball.

12. The apparatus of claim 6, said upslope being approximately 5 [degrees].

13. The apparatus of claim 6, said means to rotate said flexible shaft being a motor.

14. The apparatus of claim 13, including means to prevent rotation of said motor.

15. The apparatus of claim 14, said means to prevent rotation of said motor including a vertically extending motor detent insert, said motor detent insert having diametrically opposed slots which receive detent wings of said motor.

16. The apparatus of claim 6, said cutter being a ball cutter.

17. The apparatus of claim 6, said flexible shaft having a plurality of balls at a cutting end with said cutter at a terminating end of said cutting end, said cutter having a maximum diameter less than a maximum diameter of at least an adjacent ball.

18. An apparatus for cutting a hole in a well casing and then a lateral channel outwardly from the casing, the apparatus comprising:

   a cutter head, a flexible shaft and a motor, said flexible shaft being connected between the motor and the cutter head;

   a cutting nozzle and flexible hose;

   an elbow providing an inlet and outlet with a passageway therebetween for the cutter head and the flexible shaft;

   guide tracks aligned with the inlet to the passageway;

   said guide tracks guiding the motor for movement of the cutter head and the flexible shaft down the well casing to move the cutter head out the outlet into cutting engagement with the well casing when the motor drives the flexible shaft;

   said elbow passageway being configured to guide said cutting nozzle and said flexible hose as the flexible hose is fed through the inlet and outlet so that the nozzle can cut the lateral passageway; and

   said motor, flexible shaft and cutter head being removable from the elbow to be replaced by said nozzle and said flexible hose.

19. The apparatus of claim 18, said cutter head being a ball cutter.

20. The apparatus of claim 18, said elbow inlet being larger than said elbow outlet.

21. The apparatus of claim 18, said guide tracks having diametrically opposed slots and said motor having detent wings, said detent wings being received within said diametrically opposed slots.
22. The apparatus of claim 18, said elbow passageway including a bowed channel.

23. The apparatus of claim 18, said bowed channel having a bottom portion, said bottom portion having an upslope towards said outlet.

24. The apparatus of claim 23, said upslope being approximately 5 [degrees].

25. The apparatus of claim 18, said flexible shaft having a plurality of balls at its cutting end with said cutter head at a terminating end of said cutting end, said cutter head having a maximum diameter less than a maximum diameter of at least an adjacent ball.

26. The apparatus of claim 25, said cutter head being a ball cutter.

27. An apparatus for cutting a hole in a well casing and then a lateral channel leading outwardly from the well casing, the apparatus comprising:
   upset tubing to be lowered down the well casing and having a lower end;
   an elbow fixed to the lower end of the upset tubing, said elbow providing an inlet and an outlet with a passageway therebetween and the outlet facing the well casing;
   a motor, flexible shaft and a cutter head, the flexible shaft drivingly connecting the motor to the cutter head, said flexible shaft having a plurality of balls at its cutting end with said cutter head at a terminating end of said cutting end, said cutter head having a maximum diameter less than a maximum diameter of at least an adjacent ball.

28. The apparatus of claim 27, said cutter head being a ball cutter.

29. The apparatus of claim 27, said inlet into said passageway being larger than said outlet.

30. The apparatus of claim 27, said elbow passageway including a bowed channel.

31. The apparatus of claim 30, said bowed channel having a bottom portion, said bottom portion having an upslope towards said outlet.

32. The apparatus of claim 31, said upslope being approximately 5 [degrees].

33. An apparatus for use with upset tubing having a lower end in a well casing to cut a hole in the wall of the casing and a lateral channel extending outwardly from the casing, the apparatus comprising:
   an elbow to be mounted on the upset tubing at its lower end to be lowered into the well casing, said elbow providing an inlet and outlet with a passageway therebetween, said inlet opening upwardly in the upset tubing and said outlet opening outwardly toward the wall of the casing;
   a motor, a flexible shaft and a cutter head, said flexible shaft extending between the motor and the cutter head to provide a rotary drive connection, said flexible shaft and cutter head being movable through the passageway to have the cutter head engage the well casing adjacent the outlet to cut a hole in the casing; and,
   a cutting nozzle and hose configured to be lowered into the elbow passageway to exit the outlet and cut the lateral channel outwardly from the hole by fluid pressure from the nozzle.

34. The apparatus of claim 33, said cutter head being a ball cutter.

35. The apparatus of claim 33 said passageway inlet being larger than said passageway outlet.

36. The apparatus of claim 33 said passageway including a bowed channel.
37. The apparatus of claim 36, said bowed channel having a bottom portion, said bottom portion having an upslope towards said outlet.

38. The apparatus of claim 37, said upslope being approximately 5 [degrees].

39. The apparatus of claim 33, said flexible shaft having a plurality of balls at its cutting end with said cutter head at a terminating end of said cutting end, said cutter head having a maximum diameter less than a maximum diameter of at least an adjacent ball.

The first independent claim of the 949 Patent is Claim 1. Claim 1 is a means-plus-function limitation because it utilizes the word "cutting means" and does not adequately define what it meant by that term. The only cutting means within the specification to which this limitation can refer is that of a ball cutter, a cutter head, or simply a cutter. The terms "cutter head" and "cutter" are not expressly defined within the patent. Nonetheless, the Court concludes that a person skilled in the art of oil drilling would conclude that the terms "cutter" or "cutter head," as used in the 949 Patent specification, refer to a ball cutter since those terms have no precise meaning and the specification expressly references a ball cutter. Although those skilled in the art of oil drilling would certainly understand the terms "cutter" or "cutter head" as encompassing a number of different cutting mechanisms, the Court does not believe that they would have known which particular mechanism would be capable of performing the claimed function -- i.e., penetrating through well casing. In fact, even Landers himself had to experiment with several cutters before finding one which met the application that he sought. Therefore, the terms "cutter" and "cutter head" must be construed as referring to a ball cutter.

C. Do the MPS 350 and the TRACC Have a "Cutting Section"?

The parties dispute the definition of "cutting section" and whether the MPS 350 and the TRACC have the claim 6 "cutting section" limitation. KKI defines "cutting section" as "the area where the claimed 'cutting means' cuts the claimed 'cutable member.'" (Def.'s Prel. Inj. Hrg. Ex. 68, Pl.'s Answers to Def.'s Interrogatories at 4). KKI asserts that "cutting section" does not refer to a structure, but rather is "[used] as a locative term to simply identify the area where the claimed cutting takes place." (Docket Entry No. 58, p. 12). KKI relies on the specification of the '003 Patent and Dr. Sicking's testimony to support its proposed definition.

Trinity defines a "cutting section" as "a structure that includes the 'cutting means,' that is aligned with the 'cutable member' and the 'impact head' along a common axis, and that is moved with respect to the 'cutable member' by the 'impact head' during an impact." (Pl.'s Prel. Inj. Hrg. Ex. 70, p. 6). Trinity relies primarily on the specification of the '003 Patent to support its proposed definition. Trinity contends that "the 'cutting section,' among other things, must be a structure." (Docket Entry No. 59, p. 20).

Claim 6 states that: (1) the "terminal" includes an "cutting section"; (2) the "cutting section" is "positioned in the energy-absorption terminal"; (3) the "cutting section" is "aligned" with the "cutable member" and the "impact head"; (4) "cutting section" and the "cutable member" are "forced together when the impact head . . . is impacted by a vehicle"; and (5) the "cutting section" and the "cutable member" are "moved with respect to each other by the impact head." (Docket Entry No. 33, Ex. A, col. 9, ln. 50 - col. 10, ln. 2). Trinity asserts that a structure can be "forced together" with another structure and "moved with respect to" another structure, but that an area or location in space cannot. (Docket Entry No. 59, p. 21).

Trinity points to the specification to support its position that the term "cutting section" describes a structure, not simply a location. The "Summary" section of the '003 Patent states that "the cutting section includes a tube having one or more cutting members within it and a deflection plate." (Docket Entry No. 33, Ex. A, col. 2, ln. 43-44). The "Detailed Description" section uses the words "cutting section" in the following ways:

. . . [the terminal's] narrower end connected to one end of the cutting section . . . (col. 4, ln. 26-27);

. . . [a vehicle] pushes the impact head 30 and the cutting section 36 forwardly along the guardrail . . . (col. 4, ln. 31-32);
the guardrail 16 may be severed into partly separated portions or only scored to provide partial grooves, depending on the nature of the cutting section . . . (col. 4, ln. 33-35);

. . . allow the guardrail to be fed through the cutting section . . . (col. 4, ln. 48);

the cutting section 36 is open, having supports such as support 44 forming a guide the receives the W-beam as the cutting section 36 and impact head 30 are moved with respect to the W-beam 16 so that the W-beam moves into the hollow portion of the cutting section 36 and hits the cutters . . . (col. 5, ln. 13-17);

the cutting section 36 includes a cutter holding section 52 and a hollow receiving section 42, each aligned with the other and fastened together so that there is a continuous passageway . . . (col. 5, ln. 40-43);

the cutting section 36 includes a square tubular steel frame 56 having the cutters 40A-40C welded within it to be horizontal . . . (col. 5, ln.55-57).

The language in the specification shows that the applicants used "cutting section" to refer to a structure, not simply a location in space where a certain activity occurs. The clearest illustrations are the language stating that the narrow end of the terminal is "connected to one end of the cutting section" and that the vehicle "pushes . . . the cutting section forwardly along the guardrail." (Docket Entry No. 33, Ex. A, col. 4, ln. 26-27 & ln. 31-32). The "cutting section" is described as having "supports," including a tube with cutters mounted or welded within it, and as moving with respect to a beam. These statements in the specification are inconsistent with KKI's proposed interpretation of "cutting section" as a location or area where an action takes place.

The drawings and summary of drawings in the '003 Patent support this court's finding. Figure 8 is described as "a fragmentary end view of a cutting section." (Id., col. 3, ln. 42). It shows three cutter blades spaced within a rectangular and hollow structure; the entire structure, including the blades, is labeled as the "cutting section." Figure 9 is described as "another cutting section [] having a single steel wedge [] having a forward pointed edge [] welded to the sides of the steel open frame [] of the cutting section." (Id., col. 7, ln. 16-19).

KKI relies on extrinsic evidence, including Dr. Sicking's testimony and Albritton's deposition testimony, to support its position that the term "cutting section" refers to a location or area, not a structure. If the intrinsic evidence, including the claim language and the specification, unambiguously define a claim term, resort to extrinsic evidence is inappropriate. See Vitronics, 90 F.3d at 1584; Markman, 52 F.3d at 983. The intrinsic evidence clearly defines a "cutting section" as a structure, making reliance on inconsistent extrinsic evidence, such as expert testimony, inappropriate.

Trinity's definition incorporates multiple elements of claim 6 that describe the function and position of the "cutting section." Trinity defines "cutting section" as "a structure that includes the 'cutting means,' that is aligned with the cuttable member and the impact head along a common axis, and that is moved with respect to the cuttable member by the impact head during an impact." (Docket Entry No. 59, p. 20). This court addresses the position and function of the cutting section separately, because they relate to the "alignment" and "cutting means" limitations of claim 6, rather than to the definition of "cutting section." Claim 6 clearly defines the "cutting section" as including the "cutting means." The specification of the '003 Patent consistently describes the "cutting section" as a structure that includes the "cutting means" and in which cutting occurs. The intrinsic evidence leads this court to conclude that "cutting section" in claim 6 means "the structure(s) or part(s) of a structure in which cutting occurs, including the cutting means." 9

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

9 This definition is similar to a definition that Trinity proposed earlier in the proceedings. In its Disclosure of Claims Terms Interpretation before the preliminary injunction hearing, Trinity defined "cutting section" as "a portion or part of an object where something is wholly or partly penetrated." (Pl.'s Prel. Inj. Hrg. Ex. 14, p. 2).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

The TRACC and the MPS 350 have a "cutting section" under this definition. KKI identified the "cutting means" in the
accused devices as the cutter plate and the backup plates. In the TRACC and MPS 350, cutting occurs as the outside angled edges of the cutter plate contact the rip plates, which are held in place by the backup plates. The "cutting section" includes the cutter plate and the sections of the backup plates that hold in place the sections of the rip plates that are cut.

KKI has met its burden of showing a reasonable likelihood of success in proving that each of the accused devices includes a "cutting section."

GO BACK

1066

a. Element b.

Cannondale argues its suspension system does not contain an "inner, hollow cylinder" or its equivalent, as found in element b. Cannondale argues its head suspension system "comprises an inner tube having flat sides and a basically square, not cylindrical, shape which flat sides mate with a corresponding flat sides inner bore in an outer tube." Motion at 7:14-16 (emphasis omitted). Essentially, Cannondale contends a "cylinder" must be perfectly circular at each end, and because its suspension system has an inner tube with flat sides, it is not a "cylinder" and does not infringe element b.

This limiting definition of the term "cylinder" belies a dictionary definition, an understanding of the term "cylinder" by one of ordinary skill in the art, Cannondale's own bicycle suspension patent language, and the statements made by Cannondale's patent attorney. The term "cylinder" is defined as "a surface bounded by parallel planes and generated by a straight line moving parallel to the given planes and tracing a curve bounded by the planes and lying in a plane perpendicular or oblique to them." Webster's Dictionary, Second Ed. 1997. There is nothing in the definition or the common understanding of the term which mandates the "curve traced" must be perfectly circular. Cannondale's own suspension patent supports this understanding of "cylinder." Despite the flat edges of Cannondale's inner tube and Cannondale's contention the tube is "basically square," Cannondale's patent describes it as "essentially a hollow cylinder." Sam Stone, Cannondale's patent attorney who prosecuted the head tube suspension patent, testified in deposition Cannondale's design consists of "two telescoping cylinders" 4 as did Michael Harrison, one of Cannondale's inventors responsible for Cannondale's head tube suspension system. Plaintiff also provides evidence that, in the bicycle engineering industry, many closed geometric tubular shapes are referred to as "cylinders" or "cylindrical," whether they have round, square, rectangular or other shapes of cross sections.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 While Mr. Stone later "corrected" his deposition by replacing all references to "cylinders" with "tubes," his original language is evidence of a common understanding of the term.

As a matter of law, Cannondale's device incorporates element b. of Claim 1 of the '185 patent.

GO BACK

1067

1. cylindraceous housing

* * *

The dispute that existed between the parties concerning the construction of "cylindraceous housing" was whether the entire housing has to be of cylindrical shape.

In its briefs, the plaintiff had argued that the dictionary definition of the term is appropriate here, noting that the term "cylindraceous" is not defined in the specification or file history of the '516 patent. MHL cited to the Oxford English Dictionary which defines cylindraceous as "of the form of or resembling a cylinder; cylindrical." See Oxford English
Dictionary (2d. ed. 1989). Based on this definition, MHL argued that the ordinary meaning of cylindraceous is not the same as cylindrical. 3 As such, MHL argued, the term "cylindraceous housing" only requires that a portion - not the entirety - of the housing be cylindrical.

--- Footnotes ---

3 MHL points out that The Webster's Third New International Dictionary of the English Language Unabridged (1993) has a similar definition: "somewhat like a cylinder." MHL notes that the suffix -aceous means "resembling."

--- End Footnotes ---

Defendants' position is that plaintiff's proposed construction would in effect rewrite the claims to say that only a portion of the housing - no matter how small - has be cylindraceous, thereby completely reading the term "cylindraceous" out of the claim. Further, defendants contend that use of the word "resembles" in plaintiff's proposed constructions imports a degree of subjectivity into the claims that is inappropriate. 4

--- Footnotes ---

4 With regard to this term, defendant Volkswagen separately argues that the housing resembles a "right circular cylinder" as shown in Figures 4-7 of the '516 patent. Volkswagen takes the position that the term should be limited to the embodiments disclosed in those figures.

--- End Footnotes ---

At the hearing, the defendants devoted a portion of their argument to convince the Court that it would be appropriate to construe the term "cylindraceous" as being "generally cylindrical." The plaintiff, in rebuttal, indicated that it was in agreement with the defendants on this construction. Therefore, the Court rejects plaintiff's proposed construction that only a portion - any portion - of the housing needs to be cylindrical. It adopts the parties agreed construction that the term "cylindraceous" means "generally cylindrical." "Cylindraceous housing," therefore, means "a housing that is generally cylindrical in shape."

Although it agrees with the defendants that the antecedent basis of term "the housing" is "cylindraceous housing," MHL insists that "the housing" does not warrant any further construction by the Court. The Court clarifies that the term "the housing" refers to "the cylindraceous housing."

Element 3 of Claim 29 requires "an inner contour of said scroll plate means having a cylindrical configuration in a vicinity of an axial median plane of the fan and extending towards an inlet side of the fan." This term refers to the inner surface of the fan housing surrounding the fan blades. The parties dispute the proper meaning of the term "cylindrical."

Papst argues that the Court should broadly construe the term "cylindrical" to mean "substantially cylindrical." In support of this construction, Papst relies on the following language in the specification: "The channel wall 67 which only for manufacturer tolerances is not exactly cylindrical, extends toward the inlet side from the center plane A . . . ." '015 patent, col. 4, l. 67 - col. 5, l. 1. Papst contends that the specification teaches that the inner surface of the housing is not exactly cylindrical in view of imperfections inherent in the manufacturing process.

Sunon argues that the term "cylindrical" is unambiguous, and that the ordinary dictionary definition of "cylindrical" controls. The Court agrees. There is a heavy presumption that the ordinary meaning of a word in a claim applies. 4 CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). The Court may consult dictionaries, encyclopedias and treatises to determine the ordinary meaning of a word. Texas Digital, 308 F.3d at 1202-1203. "As a general rule, the

4 The "heavy presumption" can be overcome by any of four ways, none of which is relevant here. "First, the claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history. . . . Second, a claim term will not carry its ordinary meaning if the intrinsic evidence shows that the patentee distinguished that term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention. . . . Third, . . . a claim term also will not have its ordinary meaning if the term 'chosen by the patentee so deprive[s] the claim of clarity' as to require resort to the other intrinsic evidence for a definite meaning. . . . Last, as a matter of statutory authority, a claim term will cover nothing more than the corresponding structure or step disclosed in the specification, as well as equivalents thereto, if the patentee phrased the claim in step- or means-plus- function format." CCS Fitness, 288 F.3d at 1366-67.

5 Because Sunon does not disclose the year in which its cited dictionary was published, the Court consults the 1981 edition of Webster's. The Court notes, however, that the definitions from the 1981 edition do not differ materially from the definitions proposed by Sunon.

The dictionary definition of "cylindrical" is "relating to or having the form or properties of a cylinder." Webster's Third New Int'l Dict. at 565 (Merriam-Webster Inc. 1981). The definition of "cylinder" is "the surface traced by any straight line moving parallel to a fixed straight line and intersecting a fixed curve." Id. Accordingly, the Court construes the term "cylindrical configuration" to mean that the inner contour of the fan housing must form a surface that is parallel to the axis of rotation of the fan at the mid-point between the inlet and outlet sides of the fan.

Papst complains that Sunon improperly reads the additional word "exactly" into the claim, and that in any event, Sunon's definition is overly technical and "mathematical." Papst contends that "nothing in the claim language . . . limits the term 'cylindrical configuration' to an exactly cylindrical shape." (R. 99-1, Pl.'s Claim Constr. Br. at 8.) Papst's argument is misguided. Papst--not Sunon--is improperly adding words to the claim. Sunon's proposed construction comports with the ordinary meaning of the word "cylindrical." In contrast, Papst's proposed construction incorporates the word "substantially," a broadening modifier that alters the ordinary meaning of the word "cylindrical." If Papst did not intend for the word "cylindrical" to take on its ordinary meaning, then Papst should have modified it with an adjective such as "generally," "substantially," "essentially," or "practically" when it drafted the claim. Papst hinges its argument on language from the specification, but fails to explain why the Court should look to the specification to alter the ordinary meaning when the term has a readily ascertainable ordinary meaning. See CCS Fitness, 288 F.3d at 1366-67. Papst cannot rewrite the claim to add the broadening modifier "substantially."

Accordingly, the ordinary meaning of "cylindrical" applies, and the Court construes Element 3 to mean that the inner contour of the fan housing must form a surface that is parallel to the axis of rotation of the fan at the mid-point between the inlet and outlet sides of the fan. Additionally, the cylindrical configuration must extend from the mid-point towards the inlet side of the fan.
3. "Length less than diameter" limitation

The court construed "cylindrical element" to mean "a radially expandable segment of a stent having a longitudinal length less than its diameter ["L<D"] with a circumferential undulating pattern." 20 (D.I. 639 at 1883:16-20) Medtronic asserts that all of its accused stents, except for the Driver and the MicroDriver stents, have longitudinal lengths greater than their diameter in the stents' non-expanded, or "crimped" state and, thus, can not have a cylindrical element with L<<D as required by the claims. (D.I. 654 at 19-22) ACS objects to Medtronic's interpretation that L<<D can only be met in the "crimped" state on several grounds: (1) Medtronic did not suggest that L<<D must be met in a particular state during Markman proceedings, and can not argue a narrower claim construction for the first time in connection with its JMOL motion; and (2) at trial, Medtronic asserted that all of the asserted Lau claims are invalid over various prior art references which it asserts disclose L<<D in the expanded state. (D.I. 673 at 23-25)

20 The court also gave this same definition to the terms "cylindrically shaped element" and "cylindrical ring." (D.I. 639 at 1883:16-20)

C. "Cylindrical Outer Surface Constantly in Surface-to-Surface Contact with a Cylindrical Inner Surface of the Drum"

Ramsey contends that the phrase "cylindrical outer surface constantly in surface-to-surface contact with a cylindrical inner
surface of the drum" should be defined as "a cylindrical outer surface in tight contact at all times and at substantially all points with a cylindrical inner surface of the drum."

Warn argues that the phrase "cylindrical outer surface constantly in surface-to-surface contact with a cylindrical inner surface of the drum" should be construed as "at least a portion of the outer cylindrical surface of the cylinder stays in close proximity with the inner cylindrical surface of the drum sufficient to establish a heat conducting connection." According to Warn, a portion of the outer surface of the stator must be in close proximity to, if not touching, the inner cylindrical surface of the drum at all times to enable the heat conduction. Warn argues, however, that the claim does not require direct physical contact with the drum at all points, as Ramsey contends, and that "constantly" is a temporal limitation. Warn notes the explanation in the specification that the tightness of the fit varies with the amount of heat. Further, the "surface-to-surface contact" occurs in a completely unheated state, when contact might be limited to a single line where the stator rests on the inner surface of the drum.

The phrase "surface-to-surface" is used a second time in Claim 1:

said one end surface providing the brake surface whereby axial movement of the braking member produces surface-to-surface braking engagement in the manner of a disk brake

Ramsey argues that the second use must mean physical contact between the two surfaces in order for the brake to function. Thus, it argues that the second use supports its position that "surface-to-surface" means the parts must be in actual contact. Claim terms are presumed to be used consistently throughout a patent. Research Plastics, Inc. v. Fed. Packaging Corp., 421 F.3d 1290, 1295 (Fed. Cir. 2005). Warn agrees with the legal proposition but argues that the second usage of the phrase does not support Ramsey's contention that the contact of the stator and the drum must be "substantially at all points." In particular, Warn argues that the braking contact is tight when the brake pad is cammed fully into the brake surface and less tight when the brake pad is not fully cammed into the brake surface.

I agree that the second use supports the contention that there must be actual contact, or in the case of the second use, the braking engagement would not take place. I do not agree, however, that it supports the contention that the contact must be "substantially at all points."

Ramsey argues that the specification describes the fluid conduction of heat between the stator and the drum as though they were one unified metal object.

The modification [of the prior art] basically includes a cylindrical stator which is fixed within the drum. The stator is produced from heat conductive metal and is in tight surface-to-surface fixed contact with the inner surface of the drum.

The stator is in effect an extension of the drum in that heat generated by the pad acting against the end surface is conducted through the stator material to the drums outer surface.

However, heat will cause expansion of the stator 72 and produce a tight fit of the stator to the inner wall of the drum.

The stator 72 is a highly heat conductive metal material that conducts heat from the faces 80,82 to the drum 10, through the drum wall and thus to the atmosphere.

Certainly the dissipation of heat is an important objective of the '255 patent. The claims specify structure to accomplish the
objective. There is no guarantee, however, that the claims specify the most efficient way to attain the objective.

Ramsey argues that the prosecution history supports its interpretation requiring contact "at all times" and "at substantially all points" because Warn had to distinguish U.S. Patent 5,261,646 ("the '646 patent").

Warn contends that the May 3, 1995 Amendment Ramsey cites was to contrast the '646 patent from the '255 application concerning the constancy of the contact and the conductivity of the stator material. Warn notes that the Amendment resulted in changes to the claims requiring the stator to be "constantly" in surface-to-surface contact and made from "heat conductive" material but did not require the contact to be tight or at substantially all points.

In reviewing the Amendment, it appears that the applicant was distinguishing the '646 patent in two main respects: (1) the '646 patent had brake pad segments composed of brake lining material which generally has a lower heat conducting capacity; and (2) the '646 patent's brake pads were allowed to move inwardly away from the interior surface of the drum, allowing them to retain a substantial quantity of heat within the interior of the drum. Heuser Decl. Ex. B at 2, 4:17-24, 4:11-21, 5:4-10, 6:7-10, 7:6-7. The Amendment does not illuminate the definition of "surface-to-surface."

Inventor Thomas Telford testified that the inventors "very deliberately in this patent design made sure that the stator in this case was in continuous contact around the circumference of the stator to the drum." Heuser Decl. Supp. Ramsey Mot. for Summ. J. as to Claim Construction Ex. C at 134.

I agree with Warn that "constantly" modifies time and not space. Moreover, the intrinsic evidence does not support Telford's explanation that the inventors wanted the stator to be in continuous contact with the drum around its entire circumference. On the other hand, there is no support for Warn's argument that close proximity is sufficient, even if it would allow heat conduction from the stator to the drum, albeit it less efficiently. Further, with the specification's acknowledgment that heat expansion will change the fit, I do not agree that the contact must be defined to be "tight" because that would have to be the case even when the device was cold.

Thus, I again construe the disputed term differently than either party. I conclude that "cylindrical outer surface constantly in surface-to-surface contact with a cylindrical inner surface of the drum" is defined as "a cylindrical outer surface in physical contact at all times but in a varying number of points with a cylindrical inner surface of the drum."

1. **Cylindrical Portion**

The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiffs</th>
<th>Defendant</th>
</tr>
</thead>
<tbody>
<tr>
<td>A portion that has the general shape of a cylinder, including variations in diameter along the length of the cylinder.</td>
<td>An opening shaped like a cylinder having walls that are parallel to each other in cross-section and to a central axis of the opening.</td>
</tr>
</tbody>
</table>

Unlike the term "cylindrical" in the '160 patent, the parties actually dispute the meaning of the term "cylindrical portion" in the '291 patent. The parties' dispute revolves around whether this portion of the implant must have parallel walls.

Plaintiffs have presented evidence showing that the standard dictionary definition of "cylindrical" is "relating to or having the form or properties of a cylinder." (Plf's Ex. 12 (Webster's) at 565.) Defendant has presented evidence that the standard dictionary definition of "cylinder" refers to an object with parallel walls. (Def.'s Opening Brief 10; Dugger Decl. P 5.)

Plaintiffs contend that the term "cylinder" and "cylindrical" have a special meaning in the dental implant industry. Specifically, Plaintiffs contend that the terms "cylindrical" and "cylinder" refer to cylindrically shaped implants with tapered, as well as parallel, walls. (Plf's Opening Brief 20.)
The language of the claim does not define the term "cylindrical portion." The claim simply states that the interlock chamber has a "cylindrical portion." (Swaroop Decl. Ex. 2, col. 9, l. 56.) The claim does not specifically describe the precise shape of that cylindrical portion.

The specification likewise lacks a precise definition of the contours of the "cylindrical portion" of the interlock chamber. The specification does, however, state that the interlock chamber includes a "substantially cylindrical portion." (Swaroop Decl. Ex. 2.) The Federal Circuit has previously explained that "substantially" generally means "considerable in . . . extent . . . or largely but not wholly that which is specified" and is "a descriptive term commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Ecolab, Inc. v. Envirotech, Inc., 264 F.3d 1358, 1366-7 (Fed. Cir. 2001) (internal citations omitted). The Court finds the inventor's use of the word "substantially" helpful in determining the meaning of the term "cylindrical portion" because such use indicates that the inventor may have wanted to avoid a strict interpretation of the term "cylindrical." Logically, it would make sense that the inventor would allow for some deviation from strictly parallel walls because the specification explains that the implant's body may be tapered, conical, or cylindrical. (Swaroop Decl. Ex. 2, col. 4, ll. 61-63.) Thus, to the extent the implant body is tapered or conical, the internal interlock chamber may need to be modified to accommodate the externally tapered walls.

Plaintiffs rely on various types of extrinsic evidence to support their contention that "cylindrical portion" includes a cylinder with tapered, as well as parallel, walls. Plaintiffs' expert has explained that "tapered cylinders are frequently referred to as 'cylinders' in dental implantology." (Brunski Decl. P 42.) Plaintiffs also point out that they market several types of implants and accessories that are referred to as "cylinders," but have tapered walls. (Swaroop Decl. Exs. 4, 7, 8, 9.) Plaintiffs have also presented evidence showing patents for other dental implants and accessories refer to objects as "cylinders" or "cylindrical" even though they have tapered walls. (Swaroop Decl. Exs. 20-21.) Plaintiffs also point out that, according to the Glossary of Oral and Maxillofacial Implants, a "cylindrical implant" is an "[i]mplant of variable design and configuration, depending on the implant system. One such design, determined either in cross-section or three-dimension, follows the shape of a cylinder for an endosteal implant." (Swaroop Decl. Ex. 3 at 41.)

Defendant contends that Plaintiffs' extrinsic evidence does not actually support their contention. At the Markman hearing, Defendant's counsel stated "that in, save one, every example cited by the plaintiff of a tapered cylinder uses the phrase tapered cylinder . . . so when the phrase tapered cylinder is used in the dental implants, we would concede, yes, when you talk about a tapered cylinder, that is a shorthand term that might be used in the field of dental implants to refer to something which is more precisely determined or denoted . . . as a frustocone. Tapered cylinder is a shorthand way of referring to a frustocone, but the patent doesn't say tapered cylinder. The patent says cylinder or cylindrical." (7/24/09 Transcript 76-77.) Defendant, however, appears to have overstated its position because Plaintiffs have actually presented evidence of several instances of the use of "cylindrical" or "cylinder," without the modifier "tapered," to refer to an object with tapered walls. (Swaroop Decl. Exs. 7-9.)

As a result, to the extent Defendant contends that "cylindrical portion" refers to a cylinder with strictly parallel sides, the Court declines to adopt Defendant's construction because it is not supported by the language of the patent nor use of the term in the dental implant field. However, to the extent Plaintiffs' proposed construction includes a cylinder that tapers sharply from one end to the other, the Court likewise rejects that construction as not supported by the language of the patent and too broad because, as Defendant's counsel pointed out at the hearing, it would include an object that is more accurately described as a frustocone.

In light of the foregoing, the Court adopts the following construction: a portion that has the substantial shape of a cylinder including slight variations in diameter along the length of the cylinder.

H. Cylindrical Sleeve

Defendant defines this term to mean "a non-tapered cylinder into which an object or device fits." This proposed construction has multiple problems. First, it is not useful because it fails to define the term "cylindrical sleeve" in the context of the '194 patent. Also, defendant attempts to read in a "non-tapered" limitation that is not included in the claims. Defendant argues that the ordinary meaning of "cylindrical" excludes objects that are tapered, but defendant's own definition of "cylindrical"
demonstrates the fallacy of this argument. Citing the American Heritage Dictionary, defendant defines "cylindrical" to mean "of, relating to, or having the shape of a cylinder, especially of a circular cylinder." Nothing in this definition, which is substantially the same as the one provided by Merriam-Webster, requires "cylindrical" objects to be perfect circular cylinders. A tapered object can still be "cylindrical." Even if the ordinary meaning of "cylindrical" required a perfect cylinder, it is clear that the patentee did not intend this definition to apply in the context of the '194 patent. The patent also discloses a "cylindrical body member," but it is clear from the various figures in the specification that the cylindrical body member is not a perfect cylinder; each of them has various irregularities. Thus, so long as the object is cylinder-like, it is still "cylindrical" within the meaning of the term as it is used in the '194 patent.

Defendant also points to the prosecution history of the '194 patent to support its construction. Defendant notes that, at one point, the application for the '194 patent included a claim describing a cylindrical sleeve with a "tapered section," but this limitation was absent from the patented claims. See Aff. of Jeffrey Morgan, dkt. # 94, exh. # 2, at 89-90 (July 21, 2000 Preliminary Amendment, at claim 11). Although accurate, this observation does little to further defendant's position. It does not follow from the absence of a requirement for a tapered cylindrical sleeve that the '194 patent prohibits a tapered sleeve. Without any language in the claims limiting the cylindrical sleeve to one that is non-tapered, I cannot infer such a limitation, particularly when one of the preferred embodiments includes a tapered cylindrical sleeve. See Pat. '194, col. 9, lines 30-32 ("As shown in Fig. 9, the connector body or cylindrical body member wall tapers as at 145 to facilitate the generally radial movement of the connector body.")

Plaintiff defines "cylindrical sleeve" as "the portion of the connector body that is not in contact with the tubular post," but this definition has potential problems as well. Plaintiff points to the specification's description of the second preferred embodiment (Fig. 7), which provides: "The inner surface of connector body 124 includes a cylindrical sleeve which is radially spaced from post member 126 to define a first outer cavity 138 at a first end accessible via opening 140." Pat. '194, col. 9, lines 10-15. However, this definition does not match the one provided by plaintiff. The specification states that the inner surface of the connector body includes a cylindrical sleeve; plaintiff's definition of cylindrical sleeve includes both the inner and outer wall of the connector body.

To complicate matters further, there is another description of "cylindrical sleeve" suggested in the description of the first embodiment (Fig. 1): "the inner surface or inner wall of the connector body 24 or the cylindrical sleeve." Pat. '194, col. 7, line 5-6. Again, this description suggests that the cylindrical sleeve includes only the inner wall of the cylindrical body member. (The patent uses the terms "cylindrical body member" and "connector body" interchangeably. See Pat. '194, col. 6, lines 48-50.) In addition, this definition suggests that the cylindrical sleeve encompasses the entire inner wall of the cylindrical body member and not just the portion of it that is "radially spaced" from the tubular post.

Despite these two descriptions in the specification, it is understandable that plaintiff would not limit its definition of "cylindrical sleeve" to include only the inner wall of the connector body. To do so would contradict the claims themselves, which disclose a cylindrical sleeve with both an "inner wall" and an "outer wall." However, the claims do not further define "cylindrical sleeve," with the exception that claims 1(c) and 2(c) state that the "first end" of the cylindrical body member "include[s]" the cylindrical sleeve.

Neither party addresses any of these apparent inconsistencies between the claims and the specification. Of course, to the extent that the specification contradicts the claims, it is the language in the claims that controls. See RF Delaware, Inc. v. Pacific Keystone Technologies, Inc., 326 F.3d 1255, 1265 (Fed. Cir. 2003) ("courts may not use the teaching of the specification to contradict the clear language of the claims"). If the definitions in the specification are rejected in favor of the claim language, this leaves unresolved the precise location of the cylindrical sleeve. However, this lack of certainty does not appear to be a problem for the purposes of this case. The central dispute between the parties regarding this term is whether the cylindrical sleeve may be tapered. I have concluded that the patent permits either a tapered or non-tapered cylindrical sleeve. The parties agree that the "cylindrical sleeve" includes at least the portion of the cylindrical body member that overlaps with the compression ring. Accordingly, I construe the term "cylindrical sleeve" as including "the portion of the cylindrical body member that is inside the compression ring when the compression ring is fully installed." To the extent that the parties believe this definition is incomplete, they may seek to supplement it at trial.
The second term in dispute is "said handle comprising a D-shaped portion." The shape of the handle claimed by the inventor is at the heart of the parties' dispute. One World would construe this claim as "the handle includes a portion generally in the shape of a 'D,'" while Rexon would construe the claim as "a portion of the handle is formed in the shape of a capital letter 'D' which, by definition, is uniplanar." The parties agree that "D-shaped handle" has an ordinary meaning to persons skilled in the relevant art. In fact, "D-type" handles or "D-handles" are a conventional structure for miter saw handles, well known to persons of ordinary skill in the art. In its review of prior art, the '976 Patent discusses three "common" handle shapes, including "a horizontal D-handle." (Id. at Col. 1, ll. 31-34.) The specification also discusses how the rotatable handle feature found in a preferred embodiment can be used in a "D-handle type miter saw handle." (Id. at Col. 4, ll. 31-35.)

Though the parties did not discuss this standard in their briefs or at oral argument, those of ordinary skill in the art would appear to be individuals with experience designing and using handtools, including miter saws.

One World does not cite to any part of the specification in support of its effort to broaden the ordinary meaning of D-shaped handles to handles "generally" in the shape of the letter "d." The inventor's use of the term "D-shaped" within the claim is consistent with references to the D-shaped handles common in the art that appear throughout the specification. The prosecution history also references conventional D-type handles commonly known in the art, and distinguishes these handles--on grounds other than shape--from the handle of the proposed invention. Nothing in the history suggests that the handles of the prior art or of the invention need be only generally in the shape of the letter "D." In sum, the intrinsic evidence does not support One World's effort to expand the ordinary meaning of "D-shaped."

Rexon's proposed limitation of the term is more challenging: it asks me to find that the shape disclosed by the invention is uni-planar. Rexon argues that its proposed construction does not improperly narrow scope of the claim, but only elucidates the inherent meaning of the term "D-shaped." Pointing primarily to the drawings and descriptions found in the '976 specification and prior art, Rexon argues that these indicate only uniplanar handles. Rexon argues that "something shaped like a 'D' must be generally uni-planar so that it resembles and can be recognized as having the shape of the letter." Although both the drawings and the descriptions in the '976 Patent specification depict the D-shape of the handle from the perspective of a single plane, I find no evidence that this aspect of the specification was intended as a strict limitation on the claim, or that it is otherwise inherent in the definition of "D-shaped." Therefore, I decline to adopt the limitations proposed by either party. Both the specification and the prosecution history support the ordinary meaning of the claim terms: that a portion of the handle is formed in the shape of the letter "D."

During oral argument, counsel for Rexon drew an analogy to a rectangular block of wood. Viewed from a single plane, the block would be recognized as rectangular by any elementary school student. Nevertheless, if held at a particular angle, the rectangle might appear more like a square: an optical illusion of a sort. While it is an interesting analogy, there is no evidence in the specification or prosecution history that one of ordinary skill in the art would find such a limitation inherent within the meaning of D-shaped.

1. "damaged tissue" (claims 1, 4, 7, 8, 9, 10, 11, 12, 13, and 15)
Plaintiff argues that this term means "injured tissue" while Defendant argues that it means "abnormal tissue." The specification reflects that the invention may be used to heal tissue injured as a result of trauma. See e.g., 1:23-32; 5:61-6:5; 17:4-15; Fig. 5a; 17:17-32; Fig. 5b. For example, the specification addresses wrapping the device around fractures to heal the tissue surrounded by the fracture. See 6:26-36; 6:44-49. The '760 patent, however, also encompasses tissue that is "damaged" by some means other than trauma. For example, at col. 6, ll. 5-10, the patent specification shows that the invention can be used to treat tissue affected by infection, disease, or other soft tissue metastases. See 6:5-10. Accordingly, the court construes the term "damaged tissue" to mean "tissue that has been injured by trauma as well as tissue that is abnormal because of disease, infection, or other soft tissue metastases."
The Data Surface comprises a writing surface such as paper or other material upon which the stylus can be used to form marks or to write a message and from which an instant original hard copy can be obtained without first requiring data processing and printing.

Each of the independent claims 1, 10 and 16 recite the term "data surface." Anoto initially argued that the term "data surface" is properly interpreted to mean: "A writing surface containing a detectable, human eye visible indicia." (Anoto's Claim Construction at 2.) However, in its last filing before this court Anoto apparently abandons this definition and it argues for the definition the court adopts above. (Anoto's Reply at 22.) Sekendur argues that no revision should be made to the term "data surface" because it is unambiguous. However, Sekendur also provided this court with a chart reflecting each side's position on the disputed language where Sekendur defines "data surface" as: "a data surface . . . whereby said data surface comprises a writing surface." (Sekendur's Resp. at 6.)

The definition this court adopts is the definition provided by Sekendur to overcome an obviousness objection asserted by the United States Patent and Trademark Office ("PTO"). (B0057.) This definition was also provided in the prosecution history of the '012 patent to overcome a similar objection from the PTO. (A0131.) 6 Anoto argues that Guttman, Inc. v. Kopykake Enter., 302 F.3d 1352, 1360-61 (Fed. Cir. 2002) stands for the proposition that a "district court err[s] in construing a claim term contrary to the explicit definition provided by the applicant in the prosecution history where nothing in the intrinsic evidence casts doubt on that definition." (Anoto's Reply at 22.) This court agrees with Anoto's conclusion that Sekendur has defined the claim term "data surface," but this case is not as directly on point as Anoto would have this court believe.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - -

6 On its face, the definition in the '434 prosecution history relied upon by this court purports to define the term "data space," not "data surface." However, this discrepancy in terms must be due to typographical errors. The '434 patent does not utilize the term "data space," but the '012 patent did. While the claim terminology in the '434 patent utilized "data surface" and not "data space," Sekendur used the term "data space" interchangeably with "data surface" in the section of the prosecution history of the '434 patent where he provided a definition of the term to distinguish his application from prior art. (B00057.) This use of term "data space" during the prosecution of the '434 patent, instead of "data surface", is likely explained by the fact that Sekendur seems to have, during the prosecution of the '434 patent, resubmitted the exact same materials he used in the prosecution of the '012 patent. Therefore, Sekendur defined the term "data surface," during the prosecution of the '434 patent despite the fact that he failed to update his materials. This error does not negate Sekendur's action of defining the term "data surface" in an attempt to distinguish prior art.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - -

In Jack Guttman, the Federal Circuit reversed the district court for not giving effect to the definition provided by the patentee in the specification. Id. at 1360 ("In this case, the definition of photocopy machine provided in the specification does indeed dispose of the claim construction dispute, and it was error for the district court to overlook it."). A definition in the specification, as opposed to Sekendur's alleged definition that is in the prosecution history, may be more "explicit," and therefore provide a stronger basis for holding the patentee to the definition. Nevertheless, case law relied on by the court in Jack Guttman explains that "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996); see also Markman, 52 F.3d at 979 ("For claim construction purposes, the description [in the specification] may act as a sort of dictionary, which explains the invention and may define terms used in the claims.") (citation omitted). And at least one other Federal Circuit opinion has not found it necessary to distinguish between the prosecution history and the specification when considering whether a patentee has provided an explicit definition of a claim term. Mycogen Plant Science v. Monsanto Co., 243 F.3d 1316, 1327 (Fed. Cir. 2001) ("[A] patentee is free to be his own lexicographer, so long as the special definition of a term is made explicit in the patent specification or file history."). Therefore, this court rules that a patentee is bound by the definition the patentee provided in the prosecution history.

Jack Guttman is also distinguishable because in that case the patentee's attempt to define a word was much more explicit than what Anoto alleges is Sekendur's attempt to define the term "data surface." In Jack Guttman, the patentee explicitly
signaled the use of a definition by attaching to that definition the words "as that term is used herein." Jack Guttman, 302 F.3d at 1360. Sekendur utilizes no similar language in the portion of the prosecution history Anoto alleges provides a definition of the term "data surface." Nevertheless, the prosecution history makes clear that Sekendur was defining the term in order to distinguish prior art, despite the absence of words clearly signaling a definition such as "as that term is used herein." Scimed Life Systems v. Advanced Cardiovascular, 242 F.3d 1337, 1343 (Fed. Cir. 2001) (explaining that it is not necessary to use a "definitional format" to define a claim term). Accordingly, this court rules that Sekendur has defined the claim term "data surface."

2. "Dead Band Distance"

Formula argues that this term should be construed based on the definition of "dead band" found in the section of the patent that discusses the background art. That definition provides that dead band is the travel between the start position of the piston and the timing port. SRAM, by contrast, points to the other end of the patent document, where claims 19 and 20 specify that "the distance between a leading edge of the seal and the port defines a dead band." Thus, the parties do not disagree that the dead band ends at the timing port; they part company with regard to where the dead band begins and how its length is shortened.

According to Formula, the start of the dead band is dependent on the starting position of the piston. As the piston moves up the chamber, the dead band corresponds. As the piston moves back toward the other end of the chamber, the dead band expands, reaching its maximum distance when the lever returns to its rest position. Formula contends that axial movement of the piston and the seal connected to it is required, so other types of movement, specifically rotational movement of the seal to adjust the starting point of the dead band, should not fall within this term as construed. In support of its assertion that the invention does not contemplate rotational movement of the seal, Formula points to discussion within the specification regarding the need to minimize rotation of the piston to prevent the integrity of the seal from being impaired or compromised. Col. 6, ll. 65-67; Col. 9, ll. 61-63.

SRAM insists that the mention of piston movement within the discussion of the background art is a generalized description of the term "dead band" and that the patent provides other descriptions that culminate in the definitions found within the claims themselves. A review of the specification reveals no fewer than five explanations of the term dead band or dead band distance, some of which refer to it in terms of the piston and some of which refer to it in terms of the seal. According to SRAM, the claims are the most appropriate place to look to decide which of these explanations defines the scope of the invention.

After considering the context of the instances in which the term appears, we conclude that SRAM's construction is the more accurate. Formula's assertion that SRAM disclaimed rotational movement of the piston is unpersuasive. The language to which they point appears in the description of the preferred embodiment, not within the summary of the invention or some other portion of the patent document referring to the invention as a whole. A description of a preferred embodiment does not necessarily exclude other embodiments that satisfy the requirements set forth in the patent claims. See, e.g., Phillips, 415 F.3d at 1323.

The cases Formula cites in its supplemental memorandum in support of its argument do not mandate a different outcome. In one, the inventor expressly disclaimed the aspect that was later asserted to be within the invention's scope. Safetcare Mfg., Inc. v. Tele-Made, Inc., 497 F.3d 1262, 1270-71 (Fed. Cir. 2007). In another, the Federal Circuit noted that inclusion of a feature of an invention in the general description of the invention as a whole accompanied by emphasis on the inferiority of products without that feature was tantamount to an express disavowal of the feature. Astrazeneca AB v. Mutual Pharmaceutical Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004). Neither of these scenarios is present in this case. The language upon which Formula relies in the '534 patent does not evidence an intention to disclaim or a criticism of a system including rotation of the seal. The phrasing to which Formula points is most consistent with a description of an embodiment that does not include rotation of the piston or seal, making it preferable over other embodiments that include the rotational feature that could present problems for the integrity of the seal. Moreover, unlike the language disputed in Astrazeneca, it appears in the description of the preferred embodiment, not the general summary of the invention as a whole.
Formula also cites a third case: Motionless Keyboard Co. v. Microsoft Corp., 486 F.3d 1376, 1380 (Fed. Cir. 2007). However, the portion of the case to which they direct our attention stands for the unremarkable proposition that a court will not construe a claim term broadly if the language of the claim, when read in the context of the specification, will not support the asserted breadth. In the case at bar, the specification does not counsel against an interpretation of dead band that is broad enough to include rotation of the seal. Rather, as discussed above, the language upon which Formula relies addresses the preferred embodiment, which does not prevent the patent as a whole from having a broader application.

Correspondingly, we construe the term "dead band" as the space within the cylinder before the leading edge of the seal engages and then passes the timing port, thus pressurizing the hydraulic fluid and engaging the brake.

1079

"Deck":

The top of a kayak.

1080

"deck support structure"

Claims 3, 4, 13, and 21 refer to the "deck support structure" portion of Life Fitness' treadmill. Precor asks the Court to construe this claim element as limited to only those deck support structures that necessarily permit limited longitudinal movement of the deck. Life Fitness argues that the phrase "deck support structure" should be given its ordinary meaning.

The Court finds that the patent language does not limit "deck support structure" to those structures which permit certain types of movement. The deck support structure is specifically described by the claim language itself. Precor's proposed construction is an attempt to read the preferred embodiment into the claim. The specification to the patent does not indicate that all embodiments of the claimed invention require a deck support structure which limits longitudinal movement of the deck. The disputed claim element will be given its ordinary meaning. The Court declines to read any additional or limiting meaning into this language.

1081

H. Claim 40

A device as in claim 39 wherein the thickness of the differential expansion portion decreases in a direction away from the limited expansion portion.

The court finds that this limitation means "a device as in claim 39 wherein the differential expansion portion has a lesser thickness at a point further from the limited expansion portion than it does at a point closer to the limited expansion portion."

1082

"Define" means to make or create.
2. "an air channel of a cross-sectional size defined by a member associated with the blades"

Plaintiff's Proposed Construction: "an air channel of a cross-sectional size defined by a member associated with the blades"

Defendant's Proposed Construction: "the cross-sectional size of the air channel is determined by the cross-sectional size of the member"

The Court’s Construction: "an air channel of a cross-sectional size defined by a member associated with the blades"

Plaintiff again asks the Court to apply the ordinary meaning of this phrase. Defendant asks the Court to substitute the word "determined" for "defined."

The Court agrees with plaintiff that this phrase should be construed to have its ordinary and customary meaning. Nothing in the specification or prosecution history is to the contrary. Defendant's arguments do nothing to persuade the Court that the word "defined" should be replaced by the word "determined." The Court finds the dictionary definitions supplied by defendant are not helpful.

GO BACK

5. The term "drain opening defined by the erosion control housing" (claim 9)

The Court construes this term as follows:

A drain opening is "defined by the erosion control housing" if it is an opening whose boundaries are formed by, and found within, the erosion-control housing.

As noted above, "drain opening" does not need to be construed. This larger phrase containing the term "drain opening" also may not need to be construed, but the Court construes it because a jury of laypersons may not be familiar with how the word "define" is used. The most common meaning of the word "define" is "to state the precise meaning" of something or "[t]o describe the nature or basic qualities" of something. American Heritage Dictionary of the English Language at 476 (4th ed. 2000). To "define" an opening, however, is to establish its boundaries. See id. (providing additional definitions of "define": “2a. To delineate the outline or form of: gentle hills that were defined against the sky. b. To specify distinctly: define the weapons to be used in limited warfare. 3. To give form or meaning to . . . .”).

The boundaries of an opening in an object are "defined" by that object because they are formed by, and found within, that object. This construction of the word "defined" in claim 9 is consistent with how the word is used in claim 6 and claim 12, the only other places in the '207 patent where the word is used. 11

11 Claim 6 describes a "storm sewer inlet having an opening on a lateral side of the grate frame above the grate opening and defined in the street curb . . . ." '207 Patent col. 4:35-37 (emphasis added). The "opening" of the storm sewer inlet is "defined" in the street curb because its boundaries are formed by, and found within, the street curb. Claim 12 describes "an opening for overflow defined by portions of the erosion control housing . . . ." '207 Patent col.6:4-5 (emphasis added). The boundaries of this "opening for overflow" are formed by, and found within, portions of the erosion-control housing.

GO BACK
3. "wherein, when in use, said second connecting edge defines at least a portion of a leg opening"

For this disputed claim term, First Quality proposes that no construction is necessary and the phrase be given its ordinary and customary meaning. (doc. 168 at 20.) KC proposes a construction that includes additional language, "such that the elastomeric ear contacts the skin of the wearer directly," because "First Quality has taken a position in its invalidity contention that this limitation is disclosed by prior art." (doc. 150 at 42.) In support, KC cites to portions of the specification that explain "in use, the elastomeric ears 24 may contact the skin of a wearer directly, and first connecting edge 38 may form part of the waste opening, and second connecting edge 40 may form part of a leg opening of the diaper 10 when in used on a wearer." U.S. Patent No. 5,496,298, col. 3, ll. 35-40; see also (doc. 150 at 43.) In response to KC's argument, First Quality contends that KC is attempting to limit the scope of the Claim 1 because it is concerned with the validity of the claim.

An examination of the claim and specification language reveal no evidence unequivocally supporting KC's proposed construction. As First Quality argues, the specification language offered in support by KC is permissive language that merely indicates that, when in use, the elastomeric ears "may contact the skin of a wearer." This language does not require that the elastomeric ears must contact the skin of the wearer directly. KC's construction would place just such a limitation into the claim without proper intrinsic support. Therefore, we reject KC's proposed construction, and construe "wherein, when in use, said second connecting edge defines at least a portion of a leg opening" to mean "wherein, when in use, the second connecting edge defines at least a portion of a leg opening."

iv. Defining a frontal plane

Plaintiffs interpret the phrase "defining a frontal plane" to mean "delineating, by rims or other means, the plane of glasses parallel to the lenses." Defendant disagrees with Plaintiffs' construction, in part because it rejects the notion that pins or screws can define a "plane," because three points all in a common line cannot define a plane, as there are infinitely many planes that contain a straight line in three-dimensional space. Rather, Defendant insists that a plane is a surface with the property that any line joining two points on the surface is contained entirely within the plane.

The phrase "defining a frontal plane" also clearly describes a function of the "retaining mechanisms." As such, the court finds that "defining a frontal plane" means "delineating, by rims, the plane of glasses parallel to the lenses."

1. The '010 Patent

Claim 1 of the '010 Patent reads as follows:

1. A concrete block for use in construction of retaining walls and the like, said block including:
   a. bottom, top, rear, side and frontal surfaces,
   b. said bottom, rear and side surfaces being generally planar and arranged generally normal to one another;
   c. said top including a first support area defined over a predetermined area of said top for the support of additional blocks, a vertically extending shoulder adjacent said frontal surface of said block and extending entirely therealong to provide a continuous block positioning member in close association to said frontal surface and a second top surface at the uppermost end of said extending shoulder;
d. said frontal surface defining a lower vertical portion normal to said bottom and an upper, rearwardly inclined portion extending from said vertical portion terminating at said second top surface;

e. said support area and said vertical shoulder providing a locating surface to receive an additional vertically positioned block thereon wherein the additional block is positioned rearwardly from the front surface of the receiving and supporting block whereby a wall of tiers of such blocks extend rearwardly and upwardly from a support surface.

The phrase "said frontal surface defining a lower vertical portion normal to said bottom" appears in claim 1(d) of the '010 Patent. Allan Block asserts that "normal to" is commonly understood and needs no further construction. To the extent that construction is warranted, Allan Block urges the Court to adopt the following meaning:

The lower portion of the front surface must be normal to the bottom surface of the block, meaning that the plane of the lower portion must make an angle with the plane of the bottom surface that is approximately 90 [degree]. The lower portion need not abut the bottom surface in order for the lower portion to be normal to the bottom surface.

County Materials asserts that this phrase should be construed as "the frontal surface has a lower vertical portion which is normal to (i.e., intersects to form a right angle with) the bottom surface."

The Court determines that the ordinary meaning of the disputed language is readily apparent. Claim 1 recites bottom, top, rear, side and frontal surfaces; said bottom, rear and side surfaces being generally planar and arranged generally normal to one another. Further, the claim language requires that the block have a lower vertical portion of the frontal surface that is "normal to" the bottom surface. The parties agree, at least in part, that "normal" means "forming a right angle" or "right-angled." The parties dispute whether the language "normal to" also requires the surfaces to abut. The Court notes that by definition an "angle" is formed by two lines extending from the same point. See Merriam-Webster's Collegiate Dictionary 44 (10th ed. 2001). Because the claim language expressly requires that the lower vertical portion of the frontal surface form a right angle with (be normal to) the bottom surface, the two surfaces necessarily meet. Or in other words, the surfaces must abut. See id. at 5 ("abut . . . 1: to touch along a border or with a projecting part . . . 2a: to terminate at a point of contact").

The specification supports a construction of "normal to" that requires the surfaces to abut. First, throughout the specification, the lower vertical portion of the frontal surface and the bottom surface are consistently depicted as meeting to form a right angle. For example, FIGS. 1, 4, 6, and 7, illustrate views of the block wherein the frontal and bottom surfaces abut to form a right angle. The specification also contrasts two different embodiments of the concrete block, one where the end (side) surfaces and the front surface are "in normal arrangement" to each other (forming a right angle), and a second embodiment where the end (side) surfaces "converge inwardly" (forming an acute angle). The specification provides:

The block 10 is generally rectangular in shape and of a predetermined height and, as best illustrated in the side elevation of FIG. 4 includes a bottom surface 15, a rear side 16, a frontal surface consisting of a rearwardly and upwardly directed portion 17a and a vertical portion 17b and end surfaces 18-19 in normal arrangement to the frontal surface 17b or which may be angularly arranged thereto as will be further described with consideration of form 12.

'010 Patent, col. 3, ll. 48-56.

In order to form a curved front surface the sides 18-19 may be directed to converge inwardly as illustrated by the dotted line configuration, designated 12 in FIG. 3. Obviously this same modification could be provided to include sides 18-19 which would converge in a forward direction such that curvilinear effects of both convex and concave design would be attainable. This requires a slight modification from the normal side elements in the straight line arrangement.

Id. at col. 5, ll. 14-22. Allan Block argues that the above-cited portions of the specification demonstrate that "normal" is used only to refer to the angle formed by the two surface's planes and does not bear on whether the surfaces abut. The Court disagrees. First, the specification does not mention the surface's planes; instead, the specification discusses the relationship between the surfaces themselves. Second, both embodiments are depicted as having end (side) surfaces that meet with or abut the front surface. In one embodiment, the surfaces meet to form a right angle; in the other, the surfaces meet to form an acute angle. That both embodiments require the abutment of the end (side) and front surfaces is consistent with the definition of angle, which, as discussed above, requires that the surfaces meet.
Consistent with the claim language, the specification, and the prosecution history, the Court concludes that the ordinary and customary meaning of "normal to" as used in claim 1 of the '010 Patent requires that two surfaces meet to form a right angle. Accordingly, the Court construes "said frontal surface defining a lower vertical portion normal to said bottom" as follows: "the frontal surface has a lower vertical portion which is normal to (i.e., abuts to form a right angle with) the bottom surface."

**1088**

a. "said first end cap defining an air inlet aperture"

The phrase "said first end cap defining an air inlet aperture" appears in claim 1 of the '366 Patent. The parties' arguments regarding the construction of "said first end cap being an open airflow inlet" in claim 7 of the '712 Patent apply to the construction of this phrase. For the reasons discussed above, the Court declines to construe this phrase.

**1089**

C. Whether Certain Versions of the TFN Have a "Larger Wall Thickness Defining the Head"

The '663 patent claims an intramedullary rod with "a second, larger wall thickness defining the head." (Column 8:12-14.) Similarly, claim 9 of the '406 patent recites a treatment method using an intramedullary rod wherein "the side wall of the rod is thicker at the head than the side wall of the rod at the distal stem." (Column 8:36.) The court has interpreted the limitation in claim 1 of the '663 patent to mean "the wall thickness of the head is thicker than the wall thickness of the stem; the thicker wall defines the head as distinct from the stem." (Markman Op. at 11.) The head of the intramedullary rod is defined as the "upper portion of the intramedullary rod extending from the end closest to the hip to the stem and includes any transitional wall thickness leading up to the stem." (Markman Op. at 11.) Smith & Nephew sought to show at trial that every version of the TFN infringed this element of the patents in suit.

The transitional portion in the head of every version of the TFN rod is thicker than the corresponding stem wall. In its prior summary judgment order, the court rejected Smith & Nephew's argument that the 'greater thickness in this transitional portion alone made the TFN rods infringe the patents in suit, instead holding that there was an issue of material fact about which portion or portions of the head wall were required by the patents in suit to be thicker than the stem wall.

In describing the disadvantages of the prior art, the specification states that "there is not sufficient mechanical support to allow usage of the locking screw in the direction towards the femoral head because the second pair of coaxial holes weaken the nail when loaded in that direction." U.S. Patent No. 5,167,663, Column 2:41-45. The application that became the patents in suit was initially rejected in light of prior art, particularly the Marino patent. After an interview that occurred on February
21, 1992, the Examiner noted that "Applicant has agreed to amend the scope of the claims to more fully describe the proximal portion to emphasize the coaxial bores and thickened wall portion for better sliding." (Pretrial Stip. 6.46.) (emphasis added). The proposed claims in the '663 patent were again rejected and, after another interview, the Examiner concluded that "it appears the suggested language overcomes the prior art." (Pretrial Stip. 6.48.)

Brumfield, the applicant, thereafter filed a "Response to Final Office Action," in which claim 1 of the '663 patent was amended to require a "hollowed" intramedullary rod and to claim only an intramedullary rod with a "second, larger wall thickness defining the head." Brumfield argued that "the apparatus allows a heavier load to be carried at the top of the rod due to the thickened portion provided in the proximal head region. These advantages were discussed with the Examiner during the recent interview and have now been incorporated into the claims by these amendments. The Marino device does not provide the thickened wall portion as claimed." (Pretrial Stip. 6.49.)

Brumfield's ultimately successful argument to the Examiner invoked his earlier statements that a thickened head wall portion would provide "better sliding." Only a thicker portion where the coaxial holes are located would provide for better sliding because the proximal screws would have more surface area on which to slide. This statement indicates that the head wall is meant to be thicker at a portion through which the coaxial holes are bored, not at the more distal transition portion between the head and stem. Thus, it appears that the "thicker portion defining the head" does not denote the transitional portion.

As noted in the order on motions for summary judgment, the claim language in the patents in suit, read within the context of the specification, is somewhat ambiguous as to which portion(s) of the head wall must be thicker than the stem wall. In such situations, the particular embodiments described in the specification are particularly instructive. See Astrazeneca AB v. Mutual Pharmaceutical Co., Inc., 384 F.3d 1333, 1340 (Fed. Cir. 2004) ("the patentee's choice of preferred embodiments can shed light on the intended scope of the claims"). In the specification of each of the asserted patents, the transition portion is shown to be no thicker than the upper part of the head. (TX 20 at Fig. 3, 12; Tr. 461; 23-463:6.) There is nothing in the specification or prosecution history of the '663 patent that suggests that the transition portion has or is meant to have a larger wall thickness as opposed to the upper part of the head where the screw holes are located. (Tr. 756:5-758:4.) Thus, it appears that the "greater wall thickness defining the head" describes the proximal portion through which the holes are bored.

The evidence offered at trial further supports this conclusion. Brumfield testified that downward weight-bearing forces on the proximal screw engaging the femoral head would exert a "cantilever" force on the intramedullary rod. Thus, the portions of rod that must withstand primary forces are immediately below the proximal hole nearest the femoral head and immediately above the opposite proximal hole, not in the transitional portion of the head. (Tr. 763:15-764:8; TX 54.)

Thus, the court concludes that those versions of the TFN in which only the transitional portion of the intramedullary rod has a thicker wall than the stem do not have a "greater wall thickness defining the head" and, therefore, do not practice claim 1 of the '663 patent. Excluding the transitional portion, the head wall thickness of all versions of the TFN rod is 3.175 mm. (Tr. 763:15-764:22; TX 55.) For all 11 mm and 12 mm versions of the TFN, this wall thickness is less than the wall thickness in the stem of the rod. For the foregoing reasons, the court concludes that the 11 mm and 12 mm versions of the TFN rod do not infringe the '663 patent, and the use of those versions of the TFN to treat intertrochanteric fractures does not infringe claim 9 of the '406 patent, which describes a device in which "the side wall of the rod is thicker at the head than the side wall of the rod at the distal stem."

1090

i. Type of Deformation

Throughout their briefs and oral arguments, the parties refer to two types of deformation: (1) horizontal, or "in-plane," changes to the substrate; and (2) vertical, or "out-of-plane," changes to the substrate. L&P contends that "deform" only encompasses the latter type of change. Vutek maintains that the term "deform" is used broadly to include both in-plane and out-of-plane changes to the substrate. After reviewing the '518 Patent and its specification, I agree with Vutek that the term "deform" does not contain any directional limitations.

The express limitations and qualifications which accompany the term "deform" in the claims demonstrate that the drafters of
the '518 Patent did not believe a person of ordinary skill in the art would understand "deform" to contain inherent limitations on the direction a substrate may move. For example, in both claims 1 and 10, the particular substrate on which this invention is designed to print is identified as a "rigid substrate formed of a material that has a tendency to at least temporarily deform in the direction of the printhead if exposed to radiant curing energy while at a printing station." (Emphasis added). Both of these claims qualify "deform" as referring only to out-of-plane movements of the substrate, that is, movement upward from the plane for printing and towards the printhead. If persons of ordinary skill in the art understood "deform" to only apply to out-of-plane movements, the explicit qualifications of claims 1 and 10 would be superfluous. See Phillips, 415 F.3d at 1324-25 ("Independent claim 17 further supports [the proposition that the term 'baffle' should be defined broadly]. It states that baffles are placed 'projecting inwardly from the outer shell at angles tending to deflect projectiles that penetrate the outer shell.' That limitation would be unnecessary if persons of skill in the art understood that baffles inherently service such a function.").

Similarly, a comparison of the three independent claims, 1, 10, and 20, demonstrates that "deform" should not be defined with inherent directional limitations. Claim 1 describes the amount of thermal energy provided by the '518 Patent's UV curing assembly as an amount sufficient "to substantially cure the ink without impinging radiation that would heat the substrate so as to deform it, even temporarily, while at the printing station." Likewise, claim 20 teaches the application of "sufficiently low thermal energy to the substrate in the vicinity of the printhead to avoid even temporary deformation of the substrate where ink is being jetted thereon." Claim 10, however, describes the required level of energy as enough "to substantially cure the ink jetted onto the substrate without heating and thermally deforming, even temporarily while at the printing station … so that the surface of the material being printed upon does not move from the plane for printing." (Emphasis added).

In review, claims 1 and 20 contain no limitation on the type of deformation that the invention was designed to prevent, while claim 10 explicitly limits the deformation to movement "from the plane for printing." In TurboCare Div. of Demag Turbomachinery Corp. v. General Elec. Co., the Federal Circuit faced a similar situation and held that claim terms should not be read to contain a limitation "where another claim restricts the invention in exactly the [same] manner." 264 F.3d 1111, 1123 (Fed. Cir. 2001). Likewise, "deform" should not be read in claims 1 and 20 as including the vertical limitation that is explicitly contained in claim 10.

Finally, as a matter of physics, even if "deform" were intended to apply only to situations where the substrate bubbled, rose, or warped toward the printhead, such movement is the product of both in-plane and out-of-plane changes in the substrate. L&P acknowledged this in the prosecution history when it stated that "[w]ith a heat sensitive rigid substrate … heat from the lamps expands the surface of the substrate relative to the core and opposite surface of the substrate and causes the substrate to bubble or bow away from the support and toward the printhead." For the foregoing reasons, I reject L&P's attempt to read any directional limitation into the term "deform," as it is used in the '518 Patent.

1091

ii. Degree of Deformation

The second issue raised with respect to the term "deform" is whether there is a threshold level of movement that the substrate must undergo before it can be said to have deformed. L&P proposes construing "deform" to refer only to a change in a substrate "which unacceptably degrades print quality." Vutek argues that "deform" should encompass any change in substrate shape "measurable by those of ordinary skill in the art." After reviewing the intrinsic and extrinsic evidence, I conclude that a person of ordinary skill in the art would interpret "deform" to mean a change in a substrate which degrades print quality such that the print is commercially unacceptable for its intended purpose.

First, as both parties' proposed constructions suggest, the term "deform" is inherently limited by degree. Not all changes in a substrate necessarily rise to the level of "deformation." Codos explained that it is a physical fact that exposure to any level of light, regardless of the level of IR, will result in some movement of the particles that make up a substrate. Thus, a person of ordinary skill in the art would not read the claim language "without heating and thermally deforming, even temporarily" to exclude any movement of the substrate particles.

The issue thus becomes where to draw the line. Vutek proposes to draw this line at those changes in substrate shape
"measurable by those of ordinary skill in the art." L&P proposes to draw this line at changes in a substrate "which unacceptably degrade print quality."

Although the claims themselves do not qualify the term "deform" by any threshold of degree, the specification and prosecution history demonstrate that the '518 Patent was solely concerned with changes in the substrate that affect print quality. There are numerous excerpts throughout the specification which establish the cause-and-effect relationship between deformations in the substrate and degradations in print quality. The drafters of the '518 Patent reinforced their concept of deformations as those changes in a substrate which degrade print quality in following remarks during the prosecution of the Patent:

The claims have been amended to more clearly focus the claims on the problem solved by the invention. The present invention deals with problems of temporary substrate deformation, and deformation at the printing site. This deformation changes the distance between the printhead and the substrate, which affects print quality.

(Emphasis added). I find that the specification and prosecution history would indicate to a person of ordinary skill in the art that deformations which do not affect print quality are outside the scope of the '518 Patent.

--- Footnotes ---

3 "[E]ven temporary deformation can adversely affect the print quality if it exists when ink is being jetted onto the substrate." Col. 1, ln. 50-52.

"Deformation of the substrate surface that occurs due to heat in spot curing can extend to the portion of the substrate that is still to be printed, thereby changing the printhead-to-substrate spacing and adversely affecting the quality of the ink jet printing operation." Col. 3, ln. 18-23.

"Deformation at the printing site, even if temporary such that the material returns to its undeformed state when it cools, adversely affects the print quality because spot curing deforms the substrate as the ink jets are making single or multiple passes over the print area." Col. 3, ln. 41-44.

"Where carriage mounted UV curing heads are used and the freezing of the dots at the point of jetting is desired, deforming the substrate at the location where the ink drops are being deposited would degrade the printed image." Col. 7, ln. 66 - Col. 8, ln. 3.

--- End Footnotes ---

Print quality depends on many variables including the type of printer, the substrate, the ink, and the intended use of the print. Once these parameters are determined, however, I find that a person of ordinary skill in the art would know what can be sold and what can't be sold. As Whittle explained in his deposition, by speaking with customers and considering the viewing conditions for a particular print, one can determine what print quality standard will be commercially acceptable. A particular print quality standard, of course, will not necessarily be acceptable to every customer or for every use. It is reasonable to expect, however, that those customers demanding a higher standard would be willing to pay more to satisfy their higher quality demands. In sum, I conclude that the ordinary meaning of "deform" to one of ordinary skill in the art only includes those changes in a substrate which degrade print quality such that the print is unacceptable for its intended purpose.

iii. Use of Mechanical Restraints

Vutek contends that an additional limitation should be included in the construction of "deform" which would provide that "deformation must be determined without use of a vacuum or other mechanical restraint to control deformation." According to Vutek, the '518 Patent does not teach the use of a vacuum or any other mechanical restraint to minimize the impact of
deformation of the substrate. L&P maintains that the ‘518 Patent does not prohibit the use of a vacuum or other mechanical
restraint to hold substrates flat on the printing plane. For several reasons, I agree with L&P.

First, while the claims may be silent as to the use of mechanical restraints, the are open-ended claims, and thus do not
preclude the addition of other elements. Specifically, claims, 1, 10, and 20 are prefaced with the word "comprising," a word
that "indicates that the claim is open-ended and allows for additional steps." Invitrogen Corp. v. Biocrest Mfg., L.P., 327
F.3d 1364, 1368 (Fed. Cir. 2003).

Second, the preferred embodiment of the ‘518 Patent explicitly teaches the use of a vacuum. In the written description of
the conveyor belt system, the specification provides that the conveyor "belt has a high friction rubber-like surface to help
prevent a horizontal sliding of a panel resting on it, through which an array of holes or open mesh is provided to facilitate
communication of the vacuum from the table to the substrate." Col. 5:6-10 (emphasis added).

Finally, Whittle confirmed during his testimony at the Markman hearing that vacuum tables are common throughout the
printing industry. In fact, all of the printers that Whittle himself had developed used some sort of fan or vacuum device
to ensure that the substrate remains flat during printing. For the foregoing reasons, I conclude that a person of ordinary skill
the art would not interpret the ‘518 Patent to preclude the use of a vacuum when determining whether a deformation has
occurred.

2. Deformable Base

The parties apparently substantially agree upon the meaning of the phrase "deformable base;" their major point of
disagreement centers around whether the entire needle head is housed, matingly engaged or locked by the deformable base.
Compare Pls.’ Reply, at 19-20 with Defs.’ Mem. in Opp’n, at 17. SDP argues that the claims and the specification only
require that the deformable base house, matingly engage or lock "at least a portion of the needle head." Pls.’ Reply, at 20
(emphasis added by Plaintiffs). In addition, SDP argues that the deformable base does not necessarily need to be made from
an elastomer. Id. at 19-20.

In contrast, rather summarily, NMT avers that the deformable base "houses, matingly engages, and locks the entire head of
the needle." Defs.’ Br. in Opp’n, at 17. In support of its construction NMT cites the ‘952 patent at column 2, lines 5-10,
column 5, lines 23-30, column 6, lines 7-32, column 7, lines 40 and 44, column 10, lines 30-37 and 76, column 11, line 51,
and column 12, line 32. Id. Further, NMT asserts that the deformable base must be made of an elastomer. Id.

The Court primarily agrees with SDP’s Construction and finds that the phrase "deformable base" means a portion of a
syringe that is made of a material that can move down around a needle head when pressure is applied against it, that
substantially houses, matingly engages or locks a portion of a syringe needle head, and that forms a liquid-tight seal
between the needle and the syringe barrel.

As it must, the Court starts with the claim language:

26. A syringe comprising:

    * * *

    a deformable base within said barrel intermediate said [sic] first and second end;

    * * *

    wherein a fluid can move from within said barrel through said needle as said plunger moves through said barrel to said
deformable base, and when said rupturable web contacts said deformable base, continued movement of said plunger moves
said deformable base toward said first end, said rear end of said needle thereby tearing said web wherein said rear end loses
contact with said deformable base . . . .

- 1530 -
30. A process for retracting a needle . . . comprising the steps of:

forcing a plunger of a syringe downwardly within said syringe to force a deformable base engaging a head of said needle downwardly around said head . . . .

38. A syringe apparatus comprising:

a deformable base positioned within said barrel adjacent needle [sic] assembly and defining a passage therethrough;
energy storing means within said passageway;
a hollow needle passing through said passageway;
an enlarged head on said needle engaged within said passage of said deformable base; . . .

. . . continued movement of said plunger moves said deformable base downwardly until such time as sufficient force is imparted to said rupturable web by said enlarged needle head of said needle to tear said rupturable web, said deformable base then releasing said needle . . . .

40. The apparatus according to claim 38 wherein said deformable base is cylindrical.

Other claims of the '952 patent that are not disputed by the parties also refer to a deformable base. Those references are recited here as additional context for construction of this claim term. The relevant claims state in part:

1. A syringe apparatus comprising:

a deformable base positioned within said barrel adjacent said [sic] needle assembly and defining a passage therethrough;
an enlarged head on said needle engaged within said passage of said deformable base; . . .

. . . continued movement of said plunger flexes said supports and moves said deformable base downwardly until such time as sufficient force is imparted to said rupturable web by said enlarged head of said needle to tear said rupturable web, said deformable base then releasing said needle with said enlarged head due to force applied thereto . . . .

2. The apparatus according to claim 1 wherein said enlarged head is generally matingly engaged by said deformable base.
A review of these claims, and other claims in the patent that reference a deformable base, reveals that the deformable base must house, matingly engage or support one end of a syringe needle. See id. col. 12, ll. 65-67; col. 13, ll. 3-5; col. 13, ll. 22-24; col. 14, ll. 55-60; col. 15, ll. 8-10; col. 15, ll. 16-21; col. 15, ll. 25-27; col. 15, ll. 32-40; col. 16, ll. 22-25; col. 16, ll. 27-29. The claims themselves provide no limitation that the entire head of the needle must be contained within the deformable base. Moreover, the claims reveal that the deformable base must move down around the needle and/or needle head as pressure is applied to the deformable base until the needle or needle head is free of the deformable base. See col. 13, ll. 12-18 ("continued movement of said plunger flexes said supports [on the deformable base]; and moves said deformable base downwardly until such time a sufficient force is imparted to said rupturable web by said enlarged head of said needle to tear said rupturable web, said deformable base then releasing said needle with said enlarged head"); col. 15, ll. 2-6 ("continued movement of said plunger moves said deformable base toward said first end [of the syringe barrel], said rear end of said needle thereby tearing said web wherein said rear end loses contact with said deformable base"); col. 15, ll. 25-27 ("forcing a plunger of a syringe downwardly within said syringe to force a deformable base engaging a head of said needle downwardly around said head"); col. 16, ll. 27-42 ("continued movement of said plunger moves said deformable base downwardly . . . said deformable base then releasing said needle").

Apparently, both parties agree that it is implied by the description of the apparatus and the process in the '952 patent that the deformable base must also provide a liquid-tight seal between the needle and the syringe barrel. See Defs.' Mem. in Opp'n, at 17; Pls.' Reply, at 20. This is a logical conclusion based on the function of the deformable base to house, matingly engage or support the needle head through which medication will be injected. The apparatus claims of the '952 patent that reference a deformable base state that the fluid from the barrel flows through the hollow needle. Id. col. 13, ll. 11-12; id. col 14, ll. 66-67; id. col 16, ll. 36-37. For that to happen in the apparatus described in those claims, the deformable base must create a seal between the barrel and the needle. Otherwise, medication would get trapped between the barrel and the needle assembly rather than get injected into the patient.

The specification supports such a purpose for the deformable base. The specification reads in pertinent part:

"Positioned between the passageway within the needle assembly and a shelf on an internal wall of the syringe barrel is a deformable base, with internal flexible supports. The deformable base forms a liquid tight seal with the barrel, at the needle end of the barrel. The deformable base houses an enlarged head of the needle which enlarged head is in contact with energy storage means within the passageway in the needle assembly."

Id. col. 2, ll. 5-12. Further:

"Upon completion of an injection, the boot-covered plunger contacts the deformable base, and upon application of force at the plunger, moves such base downward. Continued application of force causes the flexible supports to flex and move over the needle assembly, permitting the deformable base to move the enlarged head of the needle downward until further movement of the enlarged head is blocked by the needle assembly, continued force at the plunger causes the deformable base to move around the enlarged needle head."

Id. col. 2, ll. 16-27. In addition, "as the plunger moves the deformable base still further, the enlarged needle head looses [sic] contact with the deformable base . . . ." Id. col. 2, ll. 34-36. Clearly these passages teach that the deformable base houses an enlarged head of a needle and, upon application of force, is moved downwardly around the enlarged head until the needle is completely free of the deformable base. Moreover, the specification also teaches that the deformable base forms a liquid-tight seal at the needle end of the barrel. Id. col. 2, ll. 8-9.

Similarly, the description of the '952 patent's alternative embodiment reveals the purpose of the deformable base. The specification reads:

"In an alternative embodiment . . . the deformable base is positioned between sacrificial supports in the needle assembly and an internal wedged end of the barrel. Upon completion of injection, the boot contacts the deformable base, and upon application of force at the plunger, moves the base downward, initially breaking the liquid tight seal between the base and"
the barrel. Continued application of force causes the sacrificial supports within the needle assembly to sever, permitting the deformable base to move the enlarged head of the needle downward until further movement of the enlarged head is blocked by the passageway in the needle assembly. With the enlarged needle head blocked by the passageway, continued force at the plunger causes the deformable base to move around the enlarged needle head. As the deformable base moves forward, the enlarged needle head begins to protrude from the deformable base and come into contact with a thin, rupturable web on the boot of the plunger. Continued force causes the enlarged needle head to penetrate the web of the boot, positioning the enlarged needle head just inside a hollow portion of the plunger. As the plunger moves the deformable base still further, the enlarged needle head loses contact with the deformable base . . . .

Id. col. 2, ll. 51-67 to col. 3, ll. 1-7.

Therefore, the deformable base must house or matingly engage the head of a needle, must be capable of moving down around the needle head when pressure is applied against it until the needle is completely free, and, at least initially, it must provide a liquid-tight seal at the needle end of the syringe barrel.

The specification also reveals more about the inventors' intended position for the needle head within the deformable base. The description reads:

. . . By appropriately positioning the enlarged needle head 13 within deformable base 11 for a substantially mating engagement, the geometries of top 14 and area 15 of enlarged head 13 can be substantially mated and locked within deformable base 11 so that a liquid tight seal between needle head 13 and deformable base 11 is created at top 14 of enlarged head 13. As seen if FIG.1, all of enlarged head 13 but a portion of the bottom portion is contained within the deformable base.

* * *

. . . Deformable base 11 is designed to substantially matingly engage enlarged head 13. As seen in FIG. 4 base wedge 6 is provided, below where top 14 of enlarged head 13 can fit, for proper positioning of the needle in the deformable base. Further, cylindrical barrel seals 8 are provided to create proper sealing action between base 11 and barrel 5. The diameter and width of the barrel seals 8 can be made to create an optimum seal, while minimizing static and dynamic friction between base 11 and barrel 5. Also illustrated in FIG. 4 are supports 31, preferably formed as opposing, semicircular cantilevered beams projecting from the upper body 12 of base 11. Each support 31 has an inward engaging flange 32 for engaging a tower portion of enlarged head 13 and an end of the needle assembly, as shown in FIG. 1. needle head seal 10 is further illustrated in FIG. 4 and is where top 14 of enlarged head 13 can fit. The diameter and width of needle head seal 10 is designed to provide optimum sealing with top 14, while minimizing static and dynamic friction between enlarged head 13 and base 11.

Id. col. 5, ll. 23-31; id. col. 6, ll. 7-25. In this description, only a portion of the needle head is enclosed within the deformable base. The bottom portion remains free of the base until pressure is applied to force the deformable base downwardly. Moreover, the description uses the word "substantially" to describe the mating engagement of the deformable base and the needle head, which implies a majority, but not all of the needle head is contained within the deformable base.

Similarly, the alternative embodiment description reads:

Needle 103 has an enlarged head 113 mounted within deformable base 111. Enlarged head 113 has a wedge portion 115 and a circular flange portion 117. By appropriately positioning the enlarged head 113 within deformable base 111, the geometries of the flange portion and wedge portion of enlarged head 113 substantially lock such enlarged head portion within the deformable base, while also creating a liquid tight seal between needle head 113 and deformable base 111.

Id. col. 10, ll. 30-38. Again, this description uses the word "substantially" to describe the position of the needle head relative to the deformable base. This implies a portion of the needle is not "locked" by the base.

In a description of yet another embodiment, the position of the needle head within the deformable base is also discussed:

. . . This embodiment . . . includes a cylindrical deformable base 163 having a central passage therethrough which
matingly engages a cylindrical enlarged needle head 165 . . . . Enlarged needle head 165 includes two cylindrical sections of different diameters with the larger section being held entirely within base 163 prior to initiation of needle retraction and the lower cylindrical section extending partially into the needle assembly and having a contacting portion 175 on an end thereof for contacting spring 173. Base 163 is biased in position by spring 173 against shelf 177 and by friction from barrel 171 prior to initiation of needle retraction.

Id. col. 12, ll. 20-38. This description clearly contemplates that the lower portion of the needle head is not engaged within the deformable base, but "extends partially into the needle assembly." Id. col. 12, ll. 33-34.

In summary, although these descriptions reveal that the deformable base houses of matingly engages a substantial portion of the needle head, it is clear the inventors contemplated that a portion of the needle head would not be housed, matingly engaged or locked into the deformable base. The specification supports the broader construction revealed in the claims themselves that the deformable base must house, matingly engage or lock a portion of the needle head, but not all of the needle head. Moreover, the description also supports the inference that the deformable base is intended to create a liquid-tight seal between the needle and the barrel.

Finally, NMT argues that the deformable base must be made of an elastomer. The Court finds that although at least one description of the preferred embodiments states that a preferred material for the deformable base is an elastomer, see id. col. 6, ll. 28-29 ("A preferred material for base 11 is an elastomer."), there is no requirement that the deformable base must be an elastomer as NMT suggests. The '952 patent claims describe how the deformable base must function when other parts of the syringe put force or pressure upon it. As long as a part that houses, matingly engages, or locks the needle head can move down the needle head when pressure from the plunger is applied against it, any material that allows for such movement could be used for that part. The inventors merely suggest that an elastomer would be preferred over other materials; it is not part of the claims.

In the context of the '952 patent, the Court finds that the phrase "deformable base" means a portion of a syringe that is made of a material that can move down around a needle head when pressure is applied against it, that substantially houses, matingly engages or locks a portion of a syringe needle head, and that forms a liquid-tight seal between the needle and the syringe barrel.

1094

a. "deformable grommet"

Claim Language

Callicrate proposes that the phrase "deformable grommet" be defined as "a grommet that is capable of being deformed." On the other hand, NAIC argues that the phrase means "a single deformable grommet, preferably made from rolled flat wire," but provides no analysis or argument to support its proposed interpretation. The ordinary meaning of "deform" is "to alter the shape of by stress." 58 The ordinary meaning of "grommet" is "a flexible loop that serves as a fastening, support, or reinforcement." 59 A limitation or preference that the grommet be made of rolled flat wire is thus not suggested by giving the phrase "deformable grommet" its ordinary meaning.

59 Id. at 514.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Specification

The specification does refer to a grommet consisting of rolled flat wire. The specification states: "more preferably, the
grommet is comprised of rolled flat wire with a length and width sufficient to prevent the ligature material from slipping through the grommet 32 after the grommet 32 is deformed upon the endless loop 100." 60 This reference to rolled flat wire clearly evidences a preferred embodiment and does not limit the claim. The Court notes that the specification also states that the grommet "can be formed from aluminum or other deformable material" and "can be of any desired shape and dimension." Thus, the Court declines to limit the grommet to one "preferably consisting of rolled flat wire," and instead adopts Callicrate's proposed construction.

--- Footnotes ---

60 Emphasis added.

--- End Footnotes ---

Claim one of patent '340 states that ". . . said barbs prevent said hanger hook from exiting the slot absent deformation or destruction of at least one of said barbs. . ." (emphasis added). In particular, this Court focuses here on whether the term "deformation" included in Claim one of the patent encompasses both temporary and permanent deformation as Johannson maintains, or merely permanent deformation as Rose contends. 1 This is a decision exclusively for the Court. Markman, supra.

--- Footnotes ---

1 In simpler terms, Rose argues that its device is intentionally designed to snap on and off and still do the job, whereas the '340 patent claims a device that cannot be removed without permanently deforming at least one of the barbs.

--- End Footnotes ---

In determining the scope of a claim, the terms used in the patent are given their ordinary meaning unless another meaning is specified or evident from the patent history. Transmatic Inc. v. Gulton Industries, 53 F.3d 1270, 1277 (Fed. Cir. 1995); Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1577 (Fed. Cir. 1993). If there is a question raised about the appropriateness of the plain language approach, the court must look to the ordinary skill of the art in question. The court may use extrinsic evidence to determine the skill of the art to clarify any ambiguity. Markman v. Westview Instruments, Inc., 52 F.3d 967, 986 (Fed. Cir. 1995), aff'd, Markman v. Westview Instruments, Inc., 116 S. Ct. 1384, 1996 WL 190818, *8-10 (U.S., April 23, 1996). In this case, however, the plain language approach is applicable since there is no indication that the term deformation has any special meaning under the ordinary skill of the art. See Transmatic, 53 F.3d at 1277.

Johansson points to the affidavit of Dr. Mary Boyce, a mechanical engineering professor at MIT and an expert in polymers. Dr. Boyce states that Rose's marker undergoes both permanent and temporary deformation. However, Dr. Boyce does not maintain that the definition of deformation should include temporary deformation, nor would she be qualified to make such an assertion since she makes no claim that she is basing her opinion on the patent history. In short, Johannson attempts through the Boyce Affidavit to equate the ordinary wear and tear that the Rose device would undergo in use, to permanent deformation. Johannson's characterization of permanent deformation is the equivalent of stating that a knit hat undergoes both temporary and permanent deformation when worn, since some stretching of the wool occurs when worn and such stretching of the weave would eventually result in a slightly larger hat. This Court rejects the Johannson characterization of deformation.

For a court to find infringement of a patent, each and every element of the patent must be present in the allegedly infringing item. Carroll Touch, Inc., 15 F.3d at 1576 (Fed. Cir. 1993); London, 946 F.2d at 1538-39; Lemelson v. United States, 752 F.2d 1538, 1551 (Fed. Cir. 1985). The court does not have the freedom to determine what aspects of a claim are material and important, and what aspects are insignificant. See Becton Dickinson and Co. v. C.R. Bard, Inc., 922 F.2d 792, 798 (Fed. Cir. 1990). Therefore, this Court must assume that "all limitations in a claim are material and must be met exactly or equivalently in an accused device to find that the accused device works in the same way." Id. If this Court finds that even one structural limitation is not present in the accused device, summary judgment for the accused is proper. See id. Claim one
of the '340 patent requires that the marker contain barbs that "prevent said hanger hook from exiting the slot absent deformation or destruction of at least one of said barbs." As noted previously, Rose's marker does not contain barbs that undergo destruction or deformation when removed from a hanger hook. Therefore, an element of the '340 patent is not present in the Rose marker and thus the Rose marker cannot be said to infringe upon the '340 patent.

Claim 1 is the only independent claim of the '340 patent. The portion of the claim in dispute relates to the way in which the barbs restrain the marker on the hanger hook, and recites (emphasis added):

such that the clothes hanger hook in pushing through said slot and said passage, deflects the barbs away from each other to permit entry of the hook into the center of the cylindrical ring but said barbs prevent said hanger hook from exiting the slot absent deformation or destruction of at least one of said barbs, and wherein said marker further comprises a plurality of hook locating lugs extending from the inner periphery of the ring wall towards the center of the cylindrical ring wall, at circumferentially spaced positions. . . .

The parties dispute whether the barbs on Rose's accused MINI WISERSIZER clothing marker undergo the "deformation or destruction" required by the claims when removing the marker from the hanger hook.

Before the district court, the parties made cross-motions for summary judgment on the issue of infringement. In his motion, Johansson contended that Rose's barbs undergo the necessary deformation or destruction recited in the claims. He supported his motion, inter alia, with an affidavit of Dr. Mary C. Boyce. Dr. Boyce calculated the stress on the barbs of the MINI WISERSIZER during "pop-off" (i.e., the point during the removal of the marker from the hanger hook when maximum force is exerted on the barbs and the marker is removed from the hook) and conducted a series of experiments in which she analyzed the stresses during pop-off. Dr. Boyce concluded that after five to ten cycles of putting the marker on the hanger hook and popping it off, the barbs on the MINI WISERSIZER had undergone visible deformation. In a cross-motion for summary judgment of noninfringement, Rose asserted that the MINI WISERSIZER did not have "hook locating lugs extending towards the center of the cylindrical ring wall," as required by the claims.

The district court denied Johansson's motion and granted Rose's cross-motion. The court, however, did not base its ruling on Rose's argument that the MINI WISERSIZER did not contain hook locating lugs extending toward the center of the ring wall, and Rose does not renew that argument on appeal. Rather, the court ruled that "Rose's marker does not contain barbs that undergo destruction or deformation when removed from a hanger hook." Johansson appeals. We have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1) (1994).

II

Determining whether a patent claim has been infringed involves a two-step examination: First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device. Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1576, 27 U.S.P.Q.2D (BNA) 1836, 1839 (Fed. Cir. 1993). The first step, claim construction, must be conducted without regard for the accused device or process. Young Dental Mfg. Co. v. Q3 Special Prods., Inc., 112 F.3d 1137, 1141, 42 U.S.P.Q.2D (BNA) 1589, 1592 (Fed. Cir. 1997).

A

Claim construction begins with the words of the claim. See Bell Communications Res., Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995). As to the meaning of "deformation," claim
I merely requires that the barbs prevent the hanger hook "from exiting the slot absent deformation or destruction of at least one of said barbs." Because claim 1 refers to "deflection" ("deflects" the barbs) to describe temporary (elastic) deformation, the parties agree that where the claim uses the term "deformation," it requires some level of permanent (plastic) deformation. Beyond that, however, there is no agreement.

The district court did not explicitly define "deformation." The court stated that the question was whether "deformation" encompasses both permanent and temporary deformation or merely permanent deformation. However, the only analysis announced by the court simply rejected the notion that ordinary wear and tear could constitute deformation, and then concluded that Rose's barbs do not undergo the requisite deformation. A court must construe a claim before determining whether there is infringement; as a result, a court may not look to the accused device in construing the claims. See SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1118, 227 U.S.P.Q. (BNA) 577, 583 (Fed. Cir. 1985) (in banc). The district court's analysis does not indicate that the court formulated a claim construction before looking to the accused markers. We therefore conclude that the district court erred.

Deformation is a "change in either shape or size of a material body or of a geometrical figure," while destruction is "demolition or complete ruin [or] killing or annihilation." Webster's Third New Int'l Dictionary 593, 615 (1966). The claim describes the barbs functionally by stating that they are to hold the claimed marker on the hanger hook until they are deformed or destroyed.

The written description also speaks of deformation in several locations. The Summary of the Invention states:

The marker has a locking device which makes it impossible to remove the marker from the hook, except by use of excessive force, thus securely affixing the marker to the hook with connection thereto readily effected.

'340 Patent, col. 2, lines 15-19. The Description of the Preferred Embodiment notes:

It will be virtually impossible to remove the marker from the hook, unless excessive force is used sufficient to deform the barbs 5 backwards and also to deform the marker ring wall 2.

'340 Patent, col. 2, line 67 to col. 3, line 2. Like the claim language, these passages suggest the function to be performed by the barbs, i.e., to retain the hook until the barbs are deformed or destroyed. As a corollary, once the barbs are deformed or destroyed, they are no longer capable of retaining the hook. We thus conclude that "deformation," as used in the patent claims, is permanent deformation that impedes the proper use of the clothing marker. If an accused device experiences such deformation within a reasonable number of uses (i.e., mountings and demountings on hanger hooks), it literally meets the deformation limitation of the claims.

Rose contends that deformation, as used in the '340 patent, is synonymous with destruction, as demonstrated by the fact that the two terms are always spoken of together in the patent. We disagree. First, the ordinary meanings of deformation and destruction are different; deformation is a change in shape or size, while destruction is demolition or complete ruin. See supra. Second, we strive to give meaning to every term in a claim. Cf. Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1579, 40 U.S.P.Q.2D (BNA) 1019, 1024 (Fed. Cir. 1996) (explaining that if the terms "pusher bar" and "pusher assembly" described the same item, one would expect the claim to refer consistently to this element as either, but not both). The mere fact that the two terms are used together in the specification cannot, in light of the above considerations, prevent the two different words from having different meanings.

B

Under this construction of the claim and viewing the evidence in the light most favorable to Johansson, there is a genuine issue of material fact precluding summary judgment on the ground that the accused devices do not undergo destruction or deformation when removed from a hanger hook. In her affidavit, Dr. Boyce stated that through calculations and actual observation of the forces on the MINI WISERSIZER barbs and the strains resulting from those forces, she concluded that the barbs underwent both temporary and permanent deformation. She concluded: "After a relatively small number of cycles (5-10) the amount of damage accumulation becomes quite noticeable. By visually inspecting a marker, I can identify whether or not the marker is unused, even if it was used only once." In contrast, the declaration of Per I. Wernius, relied upon by Rose to establish noninfringement, is conclusory, based upon an improper claim construction, and, at best, merely
creates a triable issue of fact.

C

Rose nonetheless argues that there can be no infringement because the prosecution history limits the claim to "unidirectional" markers, i.e., markers that readily permit entry of a clothes hanger hook but prevent its removal. Rose asserts that its markers are bi-directional because they do not contain barbs that undergo deformation or destruction when removed from a hanger hook. Rose's argument here is dependent in part on its contention that deformation is synonymous with destruction. The argument thus loses much of its force when that contention falls.

Furthermore, contrary to Rose's assertion, the prosecution history does not make clear that the claims should be read to exclude markers such as Rose's MINI WISERSIZER. In the portion of the prosecution history at issue, Johansson distinguished his invention from the prior art Gantz reference, stating:

It is obvious [in Gantz] that the hook of the hanger may be pressed through the slot 20 inwards and outwards with the same amount of pressure. Thus, slot 20 acts as a two way slot, allowing the marker to be put on the hanger and removed therefrom with the same effort.

In contrast, the present invention is unidirectional, meaning that the flexible barbs move away from each other to permit the marker to be placed on the hook and centered therewith but it cannot be removed off the hook without deforming or destroying the marker or at least the bars.

Johansson later distinguished a prior art PCT Publication by noting that it had locking beads which were "symmetrical when it comes to mounting and demounting of the marker." The first comment, regarding the Gantz reference, simply repeats what is apparent from the claims and specification, i.e., that a unidirectional device undergoes deformation or destruction upon demounting but not upon mounting. As such, there are material disputed facts indicating that Rose's MINI WISERSIZER may or may not undergo such deformation or destruction.

The second comment distinguishes bi-directional devices as those that are symmetrical with respect to mounting and demounting. The barbs of the device in the PCT publication are directly opposed to each other and are perpendicular to the path of the hanger hook both during mounting and demounting. In contrast, the barbs of the MINI WISERSIZER marker point inward toward the center of the marker and converge as they near the center. The barbs are not perpendicular to the path of the hanger hook and thus are not symmetrical with respect to mounting and demounting. A simple analysis of the marker using a free-body diagram indicates that the forces for mounting the marker should differ from the forces for demounting the marker.

In conclusion, we hold that the "deformation" claim limitation calls for a device that is permanently deformed in such a way that its use is substantially impeded. Dr. Boyce's affidavit raised a disputed issue of material fact on this issue. We therefore vacate the summary judgment and remand for further proceedings consistent with this opinion.

The next phrase in dispute in the '648 patent is also contained in Claim 16 (and thus Claims 17, 18 and 22 as dependent claims), and reads as follows: "...said retaining means including a deformation of said housing first end against said exterior peripheral surface of said sealing means, said first end deformation applying axially directed forces to said sealing means." Specifically, the parties disagree as to the meaning of "a deformation." The court concludes that "a deformation" should be construed as a structure which is the result of a change or alteration in shape.

It is undisputed that the element "deformation" is a part of a means-plus-function claim, but it is not the means and therefore does not have to be construed as one. The "retaining means" is the means in this phrase, and "a deformation" is to be included as a part of that means. Therefore, deformation is construed independently of the means-plus-function element.

However, this does not mean the court ignores the function of the deformation, which is to apply axially directed forces to said sealing means. The function sheds light on the meaning of the term, as does the specification, including the drawings.
While the specification never uses the word "deformation," it does repeatedly discuss the use of swaged end members or a retaining member to apply the axial forces. For example, column 2, lines 36-42 read: "A retaining member carried by the first end of the housing can be used to retain the sealing member within the housing. The retaining member can be generally U-shaped. Alternately, the retaining member can be formed as a coiled spring. The retaining member applies axially directed forces to the sealing member."

The specification also indicates how the retaining member becomes U-shaped or a coil spring. Column 8, lines 40-41 state: "The first end has been swaged to form an annular U-shaped retaining member," while column 9, lines 41-43 state: "The first end can be swaged so as to form an annularly shaped, spiral, spring like member." Taking these parts of the specification as a whole, it becomes apparent that what is meant by "a deformation" in Claim 16 is the result of an alteration of the shape of the first end, namely by swaging.

Further illustrative of this conclusion are the figures contained in the specification. Figures 19, 20, 21, 24 and 26 show the first end of the housing before it has been changed in shape. Figures 22, 23 and 25 show the resultant structure, or deformation. It is quite clear from these figures, taken together with the specification, that plaintiff was describing the result of a changing of the shape by swaging.

Further support for the court’s conclusion can be found in the ordinary, literal meaning of the word "deformation", which is defined as the action of deforming or the state of being deformed. Thus, the definition of "deform" becomes relevant. Deform means to alter the shape of or to change the shape of a body by the action of forces. Therefore, "a deformation," as used in Claim 16, is the state after the change in shape.

Plaintiff has tried to argue that "a deformation" is broader than the court's interpretation, and that it should not take into account the process of making this structure. However, it is impossible to define this word, specifically chosen by the plaintiff in drafting the claims, without reference to its root word "deform." As Sheehan stated in his testimony, the process is inherent in the word itself. "A deformation" is simply the result of this process.

3. "deformation absorbing member"

Agere argues that the term "deformation absorbing member" should be construed as "at least one part of a paddle support arm that can localize deformation and maintain the desired physical characteristics of the paddle support arm." Atmel argues that the term "deformation absorbing member" should be construed as "a structure located on the paddle support arm(s) that performs the following functions at the following times: a) localizes deformation that may occur; b) during paddle downsetting; and c) thereby maintains the desired physical characteristics." The only significant difference between these two constructions is the absence in Agere's proposed construction of a reference to the fact that the deformation that is sought to be "localized" is the deformation that occurs "during paddle downsetting." The only reason offered by Agere for the omission of this language is that the claim language already includes such a reference, and therefore including such a reference in the definition of "deformation absorbing member" would be redundant. If this reasoning were accepted, both proposed constructions would be wholly redundant and unacceptable, as all of the language in both constructions already appears in (and is in fact taken directly from) the claim language itself.

The Court generally agrees with the premise, implied in both parties' constructions, that the meaning of the term "deformation absorbing member" is clear from the face of the claim language itself, and the Court perceives no reason why including the language "during paddle downsetting" is any more redundant than a reference to "localizing deformation" or "maintaining desired physical characteristics." Therefore, the Court will adopt Atmel's proposed construction, with a slight modification for purposes of simplicity. The Court construes "deformation absorbing member" as "a structure located on a paddle support arm that localizes deformation during paddle downsetting and maintains desired physical characteristics."
To reach the gist of the present dispute, this Court is able to make some initial, and what it considers obvious, determinations. Potassium polyacrylate as used in the Red-Z Zafety Pac meets an element of independent Claims 1,6,11 & 15 of the '266 Patent (and of all claims dependent therefrom, with the exception of Claims 2,8,13,14 & 17, which call specifically for sodium polyacrylate) in that it is a "first material" as described therein. Further, this Court concludes that potassium polyacrylate is the equivalent (as defined infra) of sodium polyacrylate, which is an element of Claims 2,8,13,14 & 17. Further, the biocide sodium disocyanurate as used in the Red-Z Zafety Pac meets an element of independent Claims 1,6,11 & 15 (and all claims dependent therefrom) of the '266 Patent in that it is a "second material" as described therein. To the extent that the Red-Z Zafety Pac was shown to be used and is usable in the environment claimed in Claims 6 & 15 (and claims dependent therefrom) of the '266 Patent, it meets such element. Additionally, the envelope used for the Red-Z Zafety Pac and that described in the '266 Patent each has its "physical properties impaired" in that a closed envelope which opens can be said to have its physical property impaired. Whether this means that the Red-Z Zafety Pac degrades or is degradable is another question -- the central question that remains regarding infringement.

This question is one of claim construction, a question of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 976-979 (Fed. Cir.) (noting and resolving inconsistencies in this standard and rejecting prior case law that stated that claim construction was a mixed question of law and fact), cert. granted, U.S. , 116 S. Ct. 40 (1995); Read Corp. v. Portec, Inc., 970 F.2d 816, 822 (Fed. Cir. 1992). The claims identify what the patentee regards and what has been allowed as his invention. 35 U.S.C. § 112. To ascertain the meaning of a claim, a court may consider the claim, the specification and the prosecution history. Read Corp., 970 F.2d at 823. Expert testimony, or other extrinsic evidence, may be used to assist the court in determining the meaning of a claim by describing how those skilled in the art would interpret the claims, to define the terms therein or to demonstrate the state of the prior art. Markman, 52 F.3d at 979-981. Max Daetwyler Corp. v. Input Graphics, Inc., 583 F. Supp. 446 (E.D. Pa. 1984). A patentee may act as his own lexicographer, assigning a chosen meaning to a term he uses, regardless of the term's technical or common meaning. But when an inventor does so, his intended meaning must be found within the patent's disclosure. "The Alice-in-Wonderland view that something means whatever one chooses it to mean makes for enjoyable reading, but bad law." Autogiro Company of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 397 (Ct. Claims 1967). "So long as the meaning of an expression is made reasonably clear and its use is consistent within a patent disclosure, an inventor is permitted to define the terms of his claims." Intellicall, Inc. v. Phonometrics Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992).

It is clear and undisputed that the '266 Patent teaches a combination of already-existing elements used in a new invention -- consisting of a first material that absorbs and immobilizes and a second material that treats the absorbed and immobilized liquid to nullify an undesirable quality thereof, both of which materials are contained in a degradable envelope that degrades upon contact with liquid, permitting the first and second materials to come into contact with the liquid and absorb, immobilize and treat said liquid. The essence of the dispute lies in the meaning of the terms "degrade" and "degradability" in Claims 1 & 6 and the absence of these terms in Claims 11 & 15.

When adding Claims 11-18, Multiform remarked as follows to the PTO:

"The word 'degrade' includes the definitions of 'to deprive of standing or true function' and 'to impair in respect to some physical property.' Thus when the envelope is dry and not degraded, its true function is to contain its contents. However, once it is exposed to liquid, it is deprived of its standing or true function and it has its physical property of containing its contents impaired."

Such statement was made, however and admittedly, after Multiform had become aware of the Red-Z Zafety Pac. 13 It is also noted that such statement of intended meaning is not disclosed by the patent itself. In light of the timing of such statement, this Court is inclined to accept that the Red-Z Zafety Pac prompted such. Indeed, Multiform continued: "the term 'degradable' may be subject to argument as to its meaning because others, in the event of an infringement, may tend to interpret this term as synonymous with 'disintegrate,' which is not necessary for the packet to function properly." Nonetheless and as was pointed out at trial, one does not degrade a door to enter a room. While "degrade" and "degradable" might not be synonymous with "disintegrate" or "dissolve" and their variant forms, the meanings with which Multiform attempts to imbue these former terms goes too far.
patents and prior art sufficiently support this Court’s rejection of Multiform’s overly-expansive meanings of degrade and the art would consider degrade to mean. Common usage, dictionaries, the file wrapper of the ‘266 Patent and certain other treating the absorbed liquid. Finally, this Court discounts Multiform’s expert testimony offered to show what those skilled in the art does not support Multiform’s proffered and broad meaning of that term. The McCabe Patent notes that Multiform’s BIODEGRADABLE.” Ibid. Likewise and to the extent that it might bear upon giving life to the term degradable, the prior

dictionary at 298 (1976) (Deft’s Exh. 105). Additionally, Medzam points out that the same dictionary used by INTERNATIONATL THESAURUS, at 903 (4th ed. 1977) (Deft’s Exh. 106); WEBSTER’S NEW COLLEGIATE DICTIONARY at 298 (1976) (Deft’s Exh. 105). Additionally, Medzam points out that the same dictionary used by Multiform to define "degrade" for the PTO -- viz., "to deprive of standing or true function" and "to impair in respect to some physical property" -- also defines "degradable" as "capable of being chemically degraded * * * << detergents> - compare BIODEGRADABLE." Ibid. Likewise and to the extent that it might bear upon giving life to the term degradable, the prior art does not support Multiform's proffered and broad meaning of that term. The Lastovich Patent notes that Multiform's starch paper envelope is slow to dissolve completely and that its invention improves upon this characteristic. The McCabe Patent discloses a packet partially comprised of dissolvable paper. Multiform distinguished this invention to the PTO, not by asserting a distinction between degrade and dissolve, but by noting that the ‘266 Patent included a second material for permitting the remainder of the soluble paper to dissolve even if the discontinuous coating is insoluble in the liquid in which the soluble paper is immersed." This discontinuous pattern is retained in the '266 Patent. The purpose of such, as the above screams out, is to increase the extent to which the starch paper envelope will dissolve (or disintegrate). In no other manner is the impairment of the envelope's physical properties -- e.g., its tearing, opening, bursting, rupturing, unsealing or peeling -- discussed. The language of the '069 Patent and of the '266 Patent specifications suggests that the term 'degrade' clearly encompasses "dissolve" and "disintegration" (which are themselves treated more or less as synonyms). To this effect it is noted that the '266 Patent lists "DISSOLVO" as a trade-name for the "degradable" starch paper envelope. Further, the term "degradable," while proffered by Multiform as the mere adjective form of its expansively-construed "degrade," is actually more closely associated with the terms "decomposable," "disintegratable" and "biodegradable." ROGET’S INTERNATIONAL THESAURUS, at 903 (4th ed. 1977) (Deft's Exh. 106); WEBSTER’S NEW COLLEGIATE DICTIONARY at 298 (1976) (Deft's Exh. 105). Additionally, Medzam points out that the same dictionary used by Multiform to define "degrade" for the PTO -- viz., "to deprive of standing or true function" and "to impair in respect to some physical property" -- also defines "degradable" as "capable of being chemically degraded * * * << detergents> - compare BIODEGRADABLE." Ibid. Likewise and to the extent that it might bear upon giving life to the term degradable, the prior art does not support Multiform's proffered and broad meaning of that term. The Lastovich Patent notes that Multiform's starch paper envelope is slow to dissolve completely and that its invention improves upon this characteristic. The McCabe Patent discloses a packet partially comprised of dissolvable paper. Multiform distinguished this invention to the PTO, not by asserting a distinction between degrade and dissolve, but by noting that the ‘266 Patent included a second material for treating the absorbed liquid. Finally, this Court discounts Multiform's expert testimony offered to show what those skilled in the art would consider degrade to mean. Common usage, dictionaries, the file wrapper of the '266 Patent and certain other patents and prior art sufficiently support this Court's rejection of Multiform's overly-expansive meanings of degrade and dissolve.
degradable. Degrade need not, however and as Medzam asserts, be considered synonymous with, e.g., the total disintegration, dissolution or disappearance of the envelope. The '266 Patent's specification states that an envelope can be "degraded" although "complete disintegration might not be obtained" because the portions of the starch paper coated with polyvinyl acetate may not have "dissolved." This Court concludes that "degrade" and "degradability" are most synonymous with "partially disintegrate" or "partially dissolve," and their adjective forms, but also encompass, e.g., dissolve and disintegrate. They cannot be taken to mean what was demonstrated to this Court to be the bursting of a closed envelope via the eruption of inner forces.

Claims 1 and 6

In the '266 patent the packet is claimed as a combination of the degradable envelope, the absorbing material, and the treating material. A second group of claims describes the envelope in terms of its function, in the form authorized by 35 U.S.C. § 112 P6; these claims are discussed post. Claims 1 and 6 are representative of the first group of claims:

1. A packet for absorbing and immobilizing a liquid comprising an envelope which is degradable in said liquid, a first material in said envelope for absorbing and immobilizing said liquid, and a second material confined in said envelope for additionally treating said liquid which is absorbed and immobilized to nullify a specific undesirable quality thereof.

6. In an outer container having an inner container with liquid from which said liquid can leak, an absorbent packet located between said inner and outer containers for absorbing and immobilizing said liquid, and a second material confined in said envelope for additionally treating said liquid which is absorbed and immobilized to nullify a specific undesirable quality thereof.

(Emphases added.) Medzam conceded that its packet contains all of the elements of claims 1 and 6 except the "degradable" envelope. Medzam argued that its envelope is not degradable, when that term is correctly construed, and thus that the claims are not infringed.

The disputed issue is the meaning of the term "degradable" in characterizing the claimed envelope. The district court defined this term with an eye to the accused envelope. The court held that the terms "degrade" and "degradable," as used in the '266 patent, mean that the envelope at least partially dissolves and thereby disintegrates in the liquid. The court held that this meaning of "degradable" does not include the mode of operation of the Medzam packet, wherein the envelope bursts open by expansion of the contents but the envelope itself does not dissolve and disintegrate by direct action of the liquid.

Multiform states that this claim construction is incorrect, and that upon correct construction a finding of infringement is inevitable. Multiform argues that "degradable" must first be construed based on the '266 patent documents, without reference to the accused device, see Jurgens v. McKasy, 927 F.2d 1552, 1560, 18 U.S.P.Q.2D (BNA) 1031, 1037 (Fed. Cir. 1991) ("claim is construed without regard to the accused product"); Scripps Clinic & Research Found. v. Genentech, Inc., 927 F.2d 1565, 1580, 18 U.S.P.Q.2D (BNA) 1001, 1013 (Fed. Cir. 1991) (the words of the claims are independently construed, focussing on the disputed elements), and that as used in the '266 patent "degradable" is not limited to dissolution and disintegration, but means any loss in the containment function of the envelope. Multiform cites dictionaries showing this broader meaning, and states that a person of ordinary skill would construe "degradable," as applied to these envelopes, as meaning a loss in their containment function.

It is the person of ordinary skill in the field of the invention through whose eyes the claims are construed. Such person is deemed to read the words used in the patent documents with an understanding of their meaning in the field, and to have knowledge of any special meaning and usage in the field. The inventor's words that are used to describe the invention -- the inventor's lexicography -- must be understood and interpreted by the court as they would be understood and interpreted by a person in that field of technology. Thus the court starts the decisionmaking process by reviewing the same resources as would that person, viz., the patent specification and the prosecution history. These documents have legal as well as technological content, for they show not only the framework of the invention as viewed by the inventor, but also the issues of patentability as viewed by the patent examiner.
During patent prosecution Multiform submitted dictionary definitions of "degradable" from Webster's New Collegiate Dictionary (1976), explaining the submission as follows:

The word "degrade" includes the definitions of "to deprive of standing or true function" and "to impair in respect of some physical property." Thus when the envelope is dry and not degraded, its true function is to contain its contents. However, once it is exposed to liquid, it is deprived of its standing or true function and it has its physical property of containing its contents impaired.

Multiform states that this definition is comprehensive of the degradation of the Medzam envelope that bursts apart and thus loses its true function, and is not limited to an envelope that degrades by dissolving. Multiform states that it is not necessary for the packet to disintegrate in order to degrade. Medzam responds that Multiform offered these definitions only after Multiform became aware of the Medzam packet, and that the definitions are at odds with the plain reading of the specification.

Multiform argues that, in keeping with the rule that an inventor may be his own lexicographer, its definition of "degradable" must prevail. When the meaning of a term is sufficiently clear in the patent specification, that meaning shall apply. See Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388, 21 U.S.P.Q.2d (BNA) 1383, 1387 (Fed. Cir. 1992); Lear Siegler, Inc. v. Aeroquip Corp., 733 F.2d 881, 889, 221 U.S.P.Q. (BNA) 1025, 1031 (Fed. Cir. 1988). This rule of construction recognizes that the inventor may have imparted a special meaning to a term in order to convey a character or property or nuance relevant to the particular invention. Such special meaning, however, must be sufficiently clear in the specification that any departure from common usage would be so understood by a person of experience in the field of the invention.

Thus we review, de novo, the meaning of "degradable" in claims 1 and 6. We start with the specification. See Slimfold Mfg. Co. v. Kinkead Industries, Inc., 810 F.2d 1113, 1116, 1 U.S.P.Q.2d (BNA) 1563, 1566 (Fed. Cir. 1987) ("Claims are not interpreted in a vacuum, but are part of and are read in light of the specification.") The '266 specification describes the Multiform envelope as made of soluble starch, such that "when the aqueous solution comes into contact with the envelope, it degrades it . . ." '266 patent, col. 1, lines 21-23. The specification explains that degradation of the envelope results from dissolution of the soluble envelope material. The specification illustrates an envelope whose inner layer contains a dot matrix pattern of insoluble material that permits heat-sealing, and in discussing this pattern the specification explains that it is the soluble portion that results in degradation of the envelope: "The dot matrix pattern, or any other suitable discontinuous pattern, permits liquid, which may not otherwise be able to dissolve the material of coating 17, to completely degrade envelope 11 because there are uncoated spaces 18 between the dots of the coating 17 through which liquid can pass." '266 patent, col. 3, lines 5-10. The district court discussed the specification in reaching its conclusion, and also reviewed the prosecution history. The court referred to United States Patent No. 4,124,116 to McCabe, which describes a water-soluble envelope that releases its contents upon contact with spilled aqueous liquid. The McCabe envelope is made of two sheets, one of which is made of soluble starch. The district court observed that "Multiform distinguished this invention to the PTO, not by asserting a distinction between degrade and dissolve, but by noting that the '266 Patent included a second material for treating the absorbed liquid." 1995 WL 737929 at *11. We agree that this analysis is correct.

The district court concluded that the specification and the prosecution history do not support a meaning of "degradable" that would include an envelope that bursts open from inner pressure without any dissolution. The district court defined "degradable" in light of the mode of action of the accused device, a pragmatic expedient relevant to the issue in litigation. Thus the court held that Multiform's dictionary definitions added during patent prosecution, although stating a broad definition of "degradable," could not serve to enlarge the scope of the claims in order to cover the Medzam device. The district court did not accept Multiform's position that the dictionary definitions provided during the prosecution simply clarified the inventor's original usage of "degradable." We agree with this analysis.

Courts must exercise caution lest dictionary definitions, usually the least controversial source of extrinsic evidence, be converted into technical terms of art having legal, not linguistic, significance. The best source for understanding a technical term is the specification from which it arose, informed, as needed, by the prosecution history. The evolution of restrictions in the claims, in the course of examination in the PTO, reveals how those closest to the patenting process -- the inventor and the patent examiner -- viewed the subject matter. See Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2d (BNA) 1126, 1129 (Fed. Cir. 1996) ("A technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and
the prosecution history that the inventor used the term with a different meaning.") When the specification explains and defines a term used in the claims, without ambiguity or incompleteness, there is no need to search further for the meaning of the term.

We conclude that the meaning of "degradable" in claims 1 and 6 (and the claims dependent thereon) is limited to the dissolution/degradation of the envelope as described in the specification. The court correctly excluded the meaning whereby the envelope "degrades" by bursting instead of dissolving, and correctly held that "degradable" means that there must be at least partial dissolution of the envelope. Upon this claim interpretation, the district court concluded that there could not be literal infringement of claims 1 and 6. We agree, for this claim interpretation eliminated the Medzam envelope, which bursts but does not dissolve, from the literal meaning and scope of the claims.

1101

11. "Controlled degree of freedom." An independent motion or direction of motion that the robot manipulator is capable of making.

1102

12. "At least one controlled degree of freedom." The robotic manipulator has at least one, but may have more than one, controlled degree of freedom. Usually the number of degrees of freedom the robot manipulator has corresponds to the number of independent motorized joints the robot manipulator has.

Xoft argues that the patent does not reveal how one goes about prescribing a dose using the device, and that the phrase "delivering a prescribed absorbed dose" is therefore fatally indefinite. The '204 patent, however, describes a tool for treating proliferative tissue disease. A patent could adequately describe and claim a new apparatus or method for making the corrective curves in contact lenses, but a description of the particular curves a patient might require would not be necessary. If those skilled in the art would know how to use the disclosed invention, describing how to use it is unnecessary--the patentee merely needs to adequately describe the invention. Since Xoft bears the burden of proving that those skilled in the art would not know how to use the tool or method described in the patent and has presented no evidence on the subject, the court rejects Xoft's contention that the phrase is indefinite. No construction is necessary.

B. Claims Construction in the '415 Patent

On September 19, 2003, the Court held a hearing in accordance with Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996), to construe the disputed terms and phrases of the asserted claims. The Court's October 7, 2003 Order Following Claims Construction Hearing construed the following disputed terms in the '415
jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

...patent which are relevant to the present findings on validity and invalidity:

"implant delivery assembly"  
"an apparatus for delivery of occlusive devices, such as embolic coils that comprises three distinct components: a pusher, a coupling, and an implant"

"pusher"  
"any device or structure intended to push another device or structure"

"selectively operable coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"said coupling operable by fluid pressure so that when a sufficient amount of fluid pressure is applied to the coupling, the fluid pressure a user causes the occlusive implant to separate from the pusher"

"the coupling is a connecting device that can be operated by selectively applying fluid pressure to the coupling to separate the implant from the pusher, and the application of the fluid pressure by the user to the coupling causes the detachment of the implant at the coupling"

"delivering fluid pressure through the pusher such that the implant detaches from the pusher by the fluid pressure"  
Plain and ordinary meaning applies, no specific construction by the Court

(The Markman Order at 22-29, Docket Item No. 177.)

1105

3. Density
A. Density means density

The Chappell patent claims an invention in which "the density of said absorbent in said inner portion is greater than the density of said absorbent in said outer portion." (6:38-40.) Tyco seeks to append to the standard definition of density the qualification that it is density "as measured by industry standard measuring techniques and taking measurement errors into account." Tyco argues that measuring density on something like a sanitary napkin is difficult and suggests that it has no way of knowing whether its napkins would infringe absent a more concrete method of measurement. Measurements obtained in the course of this litigation, it asserts, suggest that density in one portion might vary significantly. As both parties agree, density is not a term of any particular complexity and was not a sui generis term essentially invented in the patent. The fact that the patent does not describe how density is to be measured does not mean that the definition of density itself is somehow unclear or in need of further elaboration. This is made clear by the case Tyco relies on, Duplan Corp. v. Deering Milliken, Inc., 444 F. Supp. 648 (D.S.C. 1977). There, the court found that "[t]he ’397 patent provides no definition of what mechanical spatial shrinkage is, how to determine it, how to measure it, or how to set up a machine to obtain it. At trial, no witness was able to determine whether a given processing specification would infringe the ’397 patent without resorting to a series of complex tests developed by defendants’ expert, Mr. Platt, which purported to delineate shrinkage resulting from relaxing the yarn by overfeeding from shrinkage resulting from heat." Id. at 737. Because the term was so unclear, the court found, it would essentially require alleged infringers to play Russian roulette. Id. at 738. Here, in contrast, there is no debate about the meaning of the word "density" or how density should be measured. If errors or variations do arise in standard...
industry testing, as Tyco asserts, then that seems a matter of fact best left for the infringement stage rather than a concept capable of being imported into the very claim terms themselves. See also Superior Graphite Co. v. Timcal SA, 2006 U.S. Dist. LEXIS 29935, 2006 WL 1234926, *9 (N.D. Ill. 2006) (construing term "bulk density" and rejecting defendant's argument that term was indefinite because the patent failed to specify the method of density measurement.)

4. "Density" means "mass per unit volume."

GO BACK

1106

4. Density

The term density is used in the embodiments of the '529 Patent that include an electronic controller to control the meter of the device. The phrase "stored particulate matter density value" appears in Claim 40 of the '529 Patent. Plaintiffs assert that "stored particulate matter density value" should be construed as "a stored value that calibrates the desired weight to a unit of measure so that the weight of the particulate matter dispensed approximates the desired weight." Defendants, on the other hand, contend that the term "density" should be construed consistently through the '529 Patent as "a value that represents the mass of a particulate material per unit of volume that is kept within the controller." Defendants assert that the term "density," as used in Claim 49 of the '529 Patent ("density of the particulate matter"), should be construed as "a value that represents the mass of the particulate material per unit of volume." Plaintiffs assert that a separate construction of the phrase "density of the particulate matter" is not required.

The '529 Patent does not explicitly define the term "density" as it is used in the Patent. Nor does the Patent specifically define the terms "stored particulate matter density value" or "density of the particulate matter." The Court agrees with Defendants that the ordinary meaning of the term "density" is a value that represents the quantity of something per unit of measure (see American Heritage Dictionary of the English Language 499 (3d ed. 1996)) or the mass of a substance per unit volume (see Merriam-Webster's Collegiate Dictionary 309 (10th ed. 1998)). However, the Court must determine whether the terms "stored particulate matter density value" and "density of the particulate matter" are phrases that reflect a definition that has been created by the inventors.

The specification of the '529 Patent states that "in some instances, the controller is adapted to receive an operator input representing a desired weight of matter to be released and to calculate, based upon at least this input and a stored particulate matter density value, a corresponding volume of matter to be released." ('529, c. 2, ll: 19-23.) The specification further states:

Where the device includes an electronic controller for controlling the meter of the device, the method may further include, prior to the step of motivating, entering a value into the controller representing a desired amount of particulate matter to be released. The method may also include, prior to the step of motivating, entering a value into the controller representing the density of the particulate matter to be released.

('529, c. 3, ll: 14-21.) Further, the specification states that the calibration factor entered into the device at the time of calibration "represents the density of the bulk material, in pounds per pocket." ('529, c. 7, ll: 26-27.) Plaintiffs appear to argue that in the context of the '529 Patent, the terms "stored particulate matter density value" and "density of the particulate matter" refer to the relating value, or calibration factor, that is entered into the controller of the device. (See Plaintiffs' Opposition to Defendants' Motion for Summary Judgment on Noninfringement and Invalidity at 25.)

In the claims that use an electronic controller, the controller must initially be calibrated for use with a certain particulate matter. (See '529, c. 7, ll: 40-45.) As described to the Court, in order to calibrate the commercial embodiment of the '529 Patent, an individual enters a calibration factor and a desired weight of material and starts the machine. Plaintiffs note that this calibration factor "implicitly accounts for the density of the material" that is being dispensed through the machine. (See Plaintiffs' Opposition to Defendants Motion for Summary Judgment of Noninfringement and Invalidity at 25.) During the initial calibration steps, rather than allowing the material existing the bin to enter the liquid stream as it would during ordinary operation of the device, the individual performing the calibration catches the particulate material in a bucket. Once the device has finished running, the user weighs the particulate material that was dispensed on a separate scale that is not a part of the device and compares it to the weight that was entered into the controller. If the desired weight and the dispensed
weight do not match, the user adjusts the calibration factor and continues to repeat the exercise until, by trial and error, the desired weight equals the dispensed weight.

As the calibration process has been described to the Court throughout Plaintiffs' oral arguments at the Markman hearing and in the patent tutorial provided to the Court, the person who calibrates the commercial embodiment of the ‘529 Patent never enters the actual value of the bulk density of the particulate matter. The process of calibrating the machine, as described by Plaintiffs, is not nearly that precise. Although density is certainly one of many factors that are implicitly considered when arriving at this calibration factor, the density figure itself is not entered into the electronic controller. Rather, the calibration factor implicitly takes into account the bulk density of the particulate matter along with other factors that determine how the particulate material flows through the machine, including the wear on the surface of the auger, the angle of repose, and general flow factors. Certainly, these considerations include the bulk density of the material, but the bulk density value is not the only factor to be considered when an individual is determining the stored particulate matter density value or the calibration factor, however it is referred to.

Plaintiffs' description of the calibration factor as a number that is not directly correlated with density appears to be an accurate reflection of the commercial embodiment of the ’529 Patent. The Court agrees with Plaintiffs that a person calibrating the commercial embodiment need not precisely know the bulk density of the particulate matter. However, the ’529 Patent language and its prosecution history do not reflect this commercial embodiment. The ‘529 Patent does not specifically define the terms "stored particulate matter density value," "density of the particulate matter," or "calibration factor." The language of the ’529 Patent does not point to the broad construction of the term "density" that Plaintiffs assert encompasses the ordinary meaning of density along with all of the other flow factor variables. If the Court were to adopt Plaintiffs' construction, the Court would be required to construe the terms "stored particulate matter density value," "density of the particulate matter," and "calibration factor" as having one consistent meaning that is not specifically stated in the ’529 Patent claims, the specification, or the prosecution history. Plaintiffs' asserted construction reflects the commercial embodiment of the ’529 Patent, not the '529 Patent itself. The Court is not willing to adopt such a construction.

Thus, the Court is left to construe the term "density" by its ordinary meaning. The Court construes the term "density" to mean a value that represents the quantity of something per unit of measure, especially per unit of length, area, or volume. Likewise, the term "stored particulate matter density value" is construed as a value that represents the quantity of something per unit of measure, especially per unit of length, area, or volume, that is stored within the controller.

1107

a. Claim Construction: "barrier means depending vertically downward from the top of said tank"

The parties dispute the meaning of the following phrase of Claim 1-16: "barrier means depending vertically downward from the top of said tank."

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Defendant's Proposed Construction</th>
<th>Plaintiff's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;barrier means depending vertically downward from the top of said tank&quot;</td>
<td>&quot;a barrier that hangs vertically downward from, and is attached to, the top of the tank&quot;</td>
<td>&quot;This element describes a wall or plate that forces the oil-water mixture to flow toward the baffle and then the bottom of the tank before flowing to the outlet end of the tank.&quot;</td>
</tr>
</tbody>
</table>

Defendant PSI resorts to an extrinsic source, a generalist dictionary, to argue that the plain meaning of the term "depends" is "to hang down; be held up by being attached to something above." Defendant's Memorandum, at 23 (citing "Webster's Third International Dictionary," at p. 604). In light of this proffered definition, the Court notes the Federal Circuit's cautionary language, in both Phillips and other cases, regarding the weight to be assigned to extrinsic evidence, such as dictionaries. See, e.g., Phillips v. AWH Corp., 415 F.3d 1303, 1324 (Fed. Cir. 2005); Ferguson Beauregard/Logic Controls v. Mega Systems, LLC, 350 F.3d 1327, 1338 (Fed. Cir. 2003). Defendant PSI also offers another piece of extrinsic evidence, the
expert opinion of George Wharton, who defined "depend" to mean "to hang down, for example, a vine depending from a tree." Defendant's Memorandum, Appx. Ex. N., at 3. Defendant also argues that a "plain reading" of the specification shows that the "barrier means" is attached at the top of the tank. Defendant's Memorandum, at 23.

Plaintiff's briefing does not appear to directly challenge Defendant's argued construction. Upon assessment of this claim in the context of the specification, the prosecution history, and the expert reports, the Court finds that Defendant's interpretation is accurate. In particular, the specification assists in arriving at this construction, explaining as follows:

"Assembly 62 comprises a barrier member 64 which depends vertically downwardly from the top of the tank and across the entire upper hemisphere of tank 60 to segregate an inlet zone 66 which comprises a relatively small region of tank 60 to the left of the barrier 64." '800 Patent, 7:36-42.

Therefore, the phrase "barrier means depending vertically downwardly from the top of said tank" is hereby construed as meaning, as interpreted by one having ordinary skill in the art at the time of the patent filing, that the barrier means hangs vertically downward from, and is attached to, the top of the tank.

The phrases "deploying the filter" and "filter . . . deployment capabilities" appear in independent claim 1 and the preamble to independent claim 9, respectively. Boston Scientific proposes that the phrases be construed as "expansion of the filter from a smaller collapsed size to a larger open size" and "the ability to have the filter expand from a smaller collapsed size to a larger open size," respectively. ev3 argues that the phrases mean "manually releasing or manually expanding the filter by some additional action after and in addition to uncovering a filter."

There is no indication in the context of the claim language or elsewhere in the intrinsic evidence that the phrases "deploying the filter" or "filter . . . deployment capabilities" require manual action. The Court therefore construes "deploying the filter" and "filter . . . deployment capabilities," respectively, as "expanding the filter from a smaller collapsed size to a larger open size" and "the ability to have the filter expand from a smaller collapsed size to a larger open size."

Here the parties argue as to whether the "depression" or "indentation" contemplated by the patent claims require a structure that has two differing degrees of thickness. 4 Defendant maintains that it does, while plaintiff contends that claims 25 and 41 do not require the depression to be formed with absorbent layers of differing thickness. 5

4 The various claims use these terms interchangeably. Plaintiff does not argue that the court should consider them to have different meanings.

5 Plaintiff apparently concedes that claims 1 and 33 do require the depression to be made of differing thickness. See claim 1 ("a depression means in said relatively thick layer of disposable absorbent material, said depression means including a substantially thinner layer of disposable absorbent material . . . "); claim 33 ("said relatively thick inner layer of disposable absorbent material includes said disposing means for forming an elongated indentation portion of relatively thin absorbent material").
The present invention teaches a disposable woman's protective menstrual panty for holding a feminine napkin. A relatively thick layer of disposable absorbent material is provided with a depression including a substantially thinner layer of disposable absorbent material operably disposed longitudinally in the crotch area of the panty and extending at least partially upward in both the front and rear portions. The depression means is dimensioned for retainably receiving a feminine napkin therein for positioning same during use.

(Def. App. II Ex. E at KC 015.) Defendant accurately notes, the specification explicitly teaches that the depression means is made up of a "substantially thinner layer of disposable absorbent material." Nevertheless, plaintiff posits several arguments as to why this is not so.

First, plaintiff contends that reading the depression means as requiring differing thicknesses in the absorency layer "is inconsistent with the accepted definition of the term 'depression.'" 6 (Resp. at 14.) This argument is unpersuasive. The definition plaintiff provides states that a "depression" is "a depressed or sunken place or part; an area lower than the surrounding surface." (Id.) (quoting the Webster's Encyclopedic Unabridged Dictionary) Based on this definition there is nothing inconsistent with a depression being formed by absorbent layers of two different thicknesses. Such a formation would most certainly create both "a depressed or sunken place or part" and "an area lower than the surrounding surface." That a depression can be created by something other than material with differing layers of thickness does not mean that a formation with differing layers of thickness cannot also form a depression.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 Again, for the reasons stated previously, the Patent Examiner's "rejection" of defendant's argument is not dispositive. See Section A, supra.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Plaintiff also argues that because only claims 1 and 33 require the depression to be made by a relatively thinner layer of absorbent material, it would be error to read such a limitation into claims 25 and 41 as well.

The court finds this to be a difficult issue. A review of the claims at issue shows plaintiff's contention to be correct--claims 25 and 41 do not make mention of differing thicknesses with reference to the formation of the depression. 7 Moreover, the Federal Circuit has repeatedly cautioned that

"There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). "Where some claims are broad and others narrow, the narrow claim limitations cannot be read into the broad whether to avoid invalidity or to escape infringement." Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044 at 1054-55 [(Fed. Cir. 1988)] (quoting D.M.I., Inc. v. Deere & Co., 755 F.2d 1570 at 1574).

United States v. Telectronics, Inc., 857 F.2d 778, 783-84 (Fed. Cir. 1988). The Federal Circuit has also told courts to look first at "the words of the claims themselves, both asserted and nonasserted, to define the scope of the patented invention." Vitrionics, 90 F.3d at 1582. Based on these principles, then, it would appear that because a depression (as that term is generally defined) does not have to be created by material of non-uniform thickness, 8 the presence of such "differing thickness" descriptions in claims 1 and 33, coupled with the absence of such descriptions in claims 25 and 41, means that the depression in these latter claims need not be formed by material of differing thickness. 9 However, there is more here than meets the eye.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

7 Claim 25 states, in relevant part:

said disposing means including an elongated depression in said thick inner layer of disposable absorbent material, said
elongated depression being dimensioned for receiving said feminine napkin therein positioning said napkin during use.

(Def. App. II Ex. E at KC 023.)

Claim 41 states, in relevant part:

means for forming an elongated, feminine napkin-shaped depression in said relatively thick inner layer of absorbent material along the center of the crotch area . . . said depression being formed by said layer of relatively thick, absorbent, material surrounding said feminine napkin shaped depression.

(Id. at KC 024.)

8 A canoe is an excellent example of just such a depression.

9 Despite the foregoing discussion, defendant argues that claims 25 and 41, because they require that the depression be formed "in said relatively thick inner layer of disposable absorbent materials," mandate that the depression be formed by differing levels of thickness within the relatively thick inner layer. This argument has a persuasive allure.

Conversely, plaintiff's interpretation of this language would allow the depression to be formed by having a bow in the middle of uniformly thick inner layer absorbent material, similar to that of a canoe. While that is a possible interpretation, its plausibility would be greatly enhanced if the claims revealed a depression of, rather than in, the relatively thick inner layer. However, the court need not resolve this issue, for assuming that plaintiff's interpretation is correct, as will be seen there is no literal infringement in any event.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Specifically, there is the problem of the specification language itself. As noted above, the specification defines the depression as "including a substantially thinner layer of disposable absorbent material." Although the court must begin its analysis by looking at the claims themselves, because "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning," reference to the specification "is always necessary." Vitronics, 90 F.3d at 1582.

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. As we have repeatedly stated, "claims must be read in view of the specification, of which they are a part." The specification contains a written description of the invention which must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Thus, the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.

Id. (citations omitted) (alteration in original).

Clearly, the meaning of the "depression" required by the '381 patent is disputed. While plaintiff contends that "depression" is used throughout the patent in its ordinary and customary meaning, i.e., that the bottom layer need only be recessed like a cradle--without reference to how that cradle is created--the specification quoted above indicates otherwise. Plaintiff, by stating in her specification that the depression includes a substantially thinner layer of absorbent materials, has defined the make up of the depression required by her panty. See id. She simply cannot avoid it.

Moreover, a review of the diagrams accompanying plaintiff's patent only confirms this conclusion. As figures 3-5, 8-10 and 12 make abundantly clear, the elongated depression required by the panty is formed by creating a trough within the relatively thick absorbent material. That is to say, the depression is formed by differing levels of thickness within the absorbent material. It is clearly depicted as a hollowed out structure. This is damning to plaintiff's position.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - -

10 While plaintiff contends that, "in numerous places, the Specification of the Southwell Patent makes clear that the 'depression' need not be 'a portion of reduced thickness,'" a review of the specification citations provided failed to support plaintiff's statement.
In sum, although claims 25, 41 and 45 omit reference as to how the depression is formed, a review of both the specification and the figures depicting the panty make clear that the depression is formed by creating a trough within the absorbent layer itself. This trough or hollowed out structure is, in essence, a second, "substantially thinner layer of absorbent materials." Indeed, it is plaintiff's arguments to the contrary that ring hollow. 11

11 Defendant calls attention to the prosecution history of the '381 patent as evidence that the depression requires a hollowed out or multi-thickness type structure. Specifically, it argues that in trying to distinguish her patent from the prior Rickard patent, plaintiff is now bound by prosecution history estoppel. In light of the court's decision, it need not address this argument here. This argument does receive extensive treatment, however, in the court's analysis of the doctrine of equivalents. See Section II.D., infra.

A. The "Depression" Limitation

Solomon argues that the district court misconstrued the claim term "depression" by requiring the depression to be formed by material having two different thicknesses. Specifically, Solomon asserts that the district court improperly read limitations that appear in the specification and in claims 1 and 33 into claims 25, 41, and 45. Solomon asserts that the term is not limited to a depression formed by a relatively thin layer surrounded by a relatively thick layer, which is simply the best mode for practicing the invention, but not the only mode. Solomon contends that while claims 1 and 33 are expressly limited to this mode, other claims that do not specify how the depression is formed are not so limited. To support her arguments, Solomon cites a passage in the specification that states that the depression may be formed by either "removing" a portion of the relatively thick material or by "altering" it. We are not persuaded of the correctness of her arguments.

The district court extensively analyzed the patent specification in order to construe the term "depression." In the summary of the invention portion, the specification states,

A relatively thick layer of disposable absorbent material is provided with a depression including a substantially thinner layer of disposable absorbent material operably disposed longitudinally in the crotch area of the panty and extending at least partially upward in both the front and rear portions. The depression means is dimensioned for retainably receiving a feminine napkin therein for positioning same during use.

Solomon is bound by this definition. The district court correctly noted that the "depression" in the disputed claims is formed "in said relatively thick" material and that every disclosed embodiment contains a depression using a "hollowed out" structure. We agree with the district court that the claims contemplate a depression only being formed as described in the specification, i.e., by a substantially thinner layer surrounded by a thicker layer. The specification's use of the word "indentation" interchangeably with "depression" further supports this interpretation. There is no hint in the specification that the two-thickness structure was simply the best of a number of possible modes of practicing the invention. Accordingly, we agree with the district court that the term "depression" as used in the specification is formed by surrounding a region of substantially thinner material with a region of thicker material.

There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of
claim differentiation states the presumption that the difference between claims is significant.

This doctrine is inapplicable here. It addresses the situation in which an interpretation of one claim renders another claim superfluous, where an otherwise broad claim is interpreted narrowly such that it is coextensive with a narrower claim appearing in the patent. This is not such a case. Here, no claims are rendered superfluous under the district court's construction of the term "depression." Each claim in dispute has a different scope. For example, claim 15, cited by Solomon as being superfluous under the district court's construction of claim 25, requires a top portion having a mesh that is lightweight, relatively thin, and paper-like. Claim 25, however, only requires a lightweight mesh.

Because it is undisputed that the accused product's "cradle" is not formed by a combination of thick and thin layers as required by the claims, the district did not err in granting Kimberly-Clark's motion for summary judgment that the accused product does not literally infringe the '381 patent.

GO BACK

1111

I. Depressions

3M proposes that "depressions" be defined as "a depressed or sunken place or part of the carrier web." (Pls.' Claim Constr. Br. at 5), and contends that Avery's process of softening the carrier web and then pressing the inkdots into the EZ Liner carrier web creates depressions. Avery contends that its EZ Film does not have depressions because the inkdots are inserted into the carrier web leaving a flat surface without hollows or sunken places. 3 Avery proposes that "depressions" be defined as "a hollow or open area below the surface which is capable of being filled." (Def's Claim Constr. Br. at 12.)

3 The Court notes that the inkdots are removed from the carrier web when the carrier web is stripped from the film, indicating that the ink dot material does not combine with the carrier web material.

The express language of claim 1 dictates that the depressions referred to must be in the surface of the carrier web. (Col. 9, 11. 32-37)("A carrier web, comprising: at least one surface that has . . . an array of depressions"). Additionally, there can be little dispute that a "depression" is commonly understood to be a lower or sunken area of a surface. See Random House Webster's New Unabridged Dictionary (2d ed. 2001)(defining depression as "a depressed or sunken place or part; an area lower than the surrounding surface"); Webster's Third New Int'l Dictionary (1993)(defining depression as "a place or part that is depressed," and depressed as "to cause to sink, fall, or assume a lower level, position, point, situation, or attitude"); Webster's II New Riverside Dictionary (1st ed. 1984)(defining depression as "a sunken or depressed area: hollow").

Avery argues, however, that the definition of depression, as used in claim 1 of the '930 patent, must be limited to include only lower or sunken areas that, at the time of embossing or immediately thereafter, are empty of any other material. According to Avery, the patent distinguishes "depressions" from "filled depressions," requiring that the term be limited, for purposes of claim 1, to empty, or not yet filled, depressions. In support of this argument, Avery points to method claim 12, which recites "a method of using a web of claim 1 as a release liner for a pressure sensitive adhesive, comprising the step of filling the multiple embossed pattern with a pressure sensitive adhesive." (Col. 10 11. 40-43.) According to Avery, if the depressions in claim 1 are not empty, then they cannot be filled using the method of claim 12.

In considering 3M's appeal of this case, the Federal Circuit addressed the argument that because method claim 6 clearly indicated a sequential embossing process, "multiple embossed patterns," as used in claim 1, must be defined as involving a sequential embossing process. The Federal Circuit rejected this argument, stating that "the limitation of serial embossing clearly present in method claim 6 cannot be read into claim 1." 3M v. Avery Dennison, 350 F.3d at 1372.

The Court finds the instant argument very similar to that presented to the Federal Circuit. Essentially, Avery asserts that method claim 12 indicates a sequential process of depressions being created in one step and then filled in a second, later step. For the same reasons that the Federal Circuit rejected such a process based argument, this Court must also reject
Avery's process based argument. Claim 1 describes a structure, which contains depressions. The Federal Circuit has clearly indicated that claim 1 does not describe a product-by-process claim. 3M v. Avery Dennison, 350 F.3d at 1371-2 (noting that the specification language "neither transforms claim 1 into a product-by-process claim nor even limits the scope of the claim to a serial method of manufacture"), 1374 ("The patent does not limit how the embossed pattern, as defined in the specification, is created."). Claim 1 makes no mention of whether the depressions are empty or filled, or when or how the depressions might be filled or emptied. It is clear that the depressions described in claim 1 will often be filled with some material. However, nothing in the intrinsic evidence of the patent requires that a limitation of sequential creation of the depressions followed later by filling the depressions should be included in claim 1. Just as the Federal Circuit found with respect to method claim 6, the sequential limitation of claim 12 cannot be read into claim 1. 4 The Court therefore concludes that the term "depressions," as used in claim 1, may be either empty or filled according to any number of processes and uses and is most appropriately defined broadly as "lower, sunken, or depressed areas of the carrier web."

4 Furthermore, the Court concludes that the examples in the specification of depressions being filled in a second step are non-exclusive examples of uses of claim 1 that cannot be imported into claim 1. This conclusion is supported by the variety of uses described in the patent involving depressions that remain empty throughout (see e.g. col. 7 11. 46-63), that are filled and then emptied as part of the manufacturing process (see e.g., col. 2 11. 18-22), or remain filled (see eg., col. 211.27-33).

7. Depth: Echometer's position is that depth, as used generally in the claims of the '399 Patent, means the measure of distance below a reference level; as used within the context of the asserted claims, Echometer states that the reference level is the top of the borehole. Lufkin's position is that depth is the distance in the borehole below the well surface. Having no basis to find to the contrary, this Court concludes that the parties' agreed definition of this term holds. Depth, as used within the context of the asserted claims, means the distance in the borehole below the well surface.

IV.

Unlike claim 1, however, claim 32 does not explicitly limit the height of the ridge members forming the load locks in the sidewalls. Instead, claim 32 describes the load lock in terms of depth:

32. A protective liner for a cargo bed of a vehicle, said protective liner allowing a structure positioned in the trunk cargo bed to be supported and affixed in position in the vehicle cargo bed, including:

a liner floor portion having elevated portions formed thereupon to conform to wheel wells protruding from the cargo bed floor;

upwardly extending liner sidewall portions extending upwardly from opposite sides of the liner floor portion an upwardly extending liner frontwall portion extending upwardly from a front end of the liner floor portion; and

means formed on the upwardly extending liner sidewall portions including a plurality of spaced apart, vertically extending ridge members protruding from the liner sidewall portions and forming load locks in gaps separating adjacent ones of the ridge members, said load locks having a depth sufficient to anchor a structure positioned and supported in the cargo bed.

(Emphasis added). Despite the differences between claim 1 and claim 32, the district court interpreted claim 32 to require "the ridge member . . . [to] extend from near the bottom of the sidewall to near the top of the sidewall."

While the last paragraph of claim 32 begins with the word "means," what follows is a detailed recitation of structure. The clause begins with a description of "members formed on the . . . sidewall portions including . . . ridge members." This language describes generally, indeed expressly includes, ridge members that serve as anchors for load locks. The clause then refers to "load locks having a depth sufficient to anchor a structure positioned and supported in the cargo bed.).

The claim language, however, does not link the term "means" to a function. In language again suggestive of structure, the claim notes that the "means" "protrude from the liner sidewall portions and form[] load locks." This language vaguely hints at the function of anchoring a load in the cargo bed. Nowhere does the claim language following "means" state that function. Instead, the claim recites structure. Without an identified function, the term "means" in this claim cannot invoke 35 U.S.C. § 112, P 6. Without a "means" sufficiently connected to a recited function, the presumption in use of the word "means" does not operate. In any case, the express structural limits of the claim language limit its scope. Thus, this court construes this claim without reference to section 112, P 6.

Neither the language of claim 32, nor the specification, requires that the ridges extend over the entire height of the sidewalks. The claim language does not include a height limitation. Instead of referring to height, the claim discloses "load locks having sufficient depth." The specification supports this construction. For example, the specification calls for "gaps separating adjacent ones of the ridge members [to] form load locks of a depth sufficient to anchor an end of the structure." In other words, for this claim, the necessary height of the ridge members depends on the height of the structure to be anchored.

Figure 2 illustrates the height of ridge members necessary to form a load lock. Figure 2 designates a plurality of ridge members above the level of the wheel well as 28A. Similarly, Figure 2 designates the ridge members below the level of the wheel well as 28B. A support member which need not rise above the level of the wheel well might be fully anchored by and between only the 28B ridge members. In other words, a load lock may be formed using only ridge members 28B, which do not extend the entire height of the sidewalk. In sum, claim 32 contains no limitation analogous to the "substantially" language in claim 1. No limitation in the claim or the specification requires that the ridge members extend any distance beyond that sufficient to form a load lock.

In this case, the inventor's conduct during the administrative process for acquiring a patent did not evince a clear disavowal of claim scope. The art prior to the '876 patent, specifically Rye, U.S. Patent No. 4,767,149, shows a support surface in a truck bed liner that reaches about two-thirds the height of the sidewalk. Although the examiner at first rejected one claim based on Rye, the inventors eventually swore behind that reference to remove it as prior art. Moreover, the file history does
not contain a single statement that the inventors conceded any coverage based on Rye. In sum, the administrative record discloses no disavowal of coverage, unmistakable or otherwise, due to Rye. Therefore, the prosecution history does not supply any reason to construe claim 32 to contain a height limitation.

In sum, the language of claim 32, unlike claim 1, contains no height limitation referenced to the height of the sidewall. Instead, claim 32 keys the load lock to the depth "sufficient to anchor the structure." Therefore, the district court erred by reading the height limitation from claim 1 into claim 32.

The Court has construed the limitations of Claim 1, in relevant part, as follows:

"Active" means producing an intended action or effect: active ingredients.
"Pharmacologically effective" means an amount that is medically effective.
"Complex carbohydrates" means a polymer comprising more than two sugar moieties, such as heparin, hyaluronic acid, chondroitin sulfate 1, dermatan sulfate, keratan sulfate and acemannan, for example.
"Amount effective" means a quantity that produces a result.
"Allow penetration of the dermis of mammals by the complex carbohydrate" means the combination of the complex carbohydrate and the essential oil produces a treatment effect by the complex carbohydrate. That treatment effect is pain relief.
"Dermis" means the sensitive connective tissue layer of the skin located below the epidermis, containing nerve endings, sweat and sebaceous glands, and blood and lymph vessels.

These terms are a Markush group, as stated above. After consideration of each party's proposed definition, the undersigned finds that this phrase should be defined as "having the size and outer surface texture of pea gravel (a smooth surface with a few rough edges, as in figure 2), wood chips (a surface with only a few ridges), or tree bark (a rough surface with numerous ridges and valleys of differing heights and depths, as in figure 1), but not a combination of any of the three. (514 Patent, col. 3, lns. 50-62)

Claim 12 of the patent is directed to "[t]he apparatus as in claim 1 wherein the material containing a radionuclide comprises a plurality of radioactive solid particles placed at predetermined locations within the inner spatial volume to provide a desired composite radiation profile." Xoft argues claim 12 is indefinite on two grounds: first, that "desired composite radiation profile" is not defined, and second, that "inner spatial volume" is indefinite because no physical structure bounds
it. The court rejects Xoft's second argument for the reasons given when construing "inner spatial volume" above. The court rejects Xoft's first argument because it presents no evidence that one skilled in the art would not understand "desired composite radiation profile." 8 Cytyc's proposed construction does not clarify the meaning of claim 12. However, since the language is understandable as is, no construction of "a plurality of radioactive solid particles placed at predetermined locations within the inner spatial volume to provide a desired composite radiation profile" is necessary or appropriate.

1117

Construction of "determining a desired prescriptive correction."

57. To a person having ordinary skill in the art in 1995, the claim element "determining a desired prescriptive correction for a patient's eye" would have meant nothing more than the ordinary meaning of that phrase -- the correction that is desired relates to a doctor's prescription for improving the patient's visual acuity. The phrase "desired prescriptive correction" contains no technical terms of art. The Court agrees with Defendants that Plaintiff has offered no evidence to support its contention that the claim phrase "desired prescriptive correction" should be construed to mean a "mathematically precise, optically correct, measurement in terms of power (in diopters) of myopia (nearsightedness) and hyperopia (far-sightedness) and astigmatism (power and axis) for correction of a patient's eye." In fact, the 303 Patent's Detailed Description clarifies that the claim language is simply referring to a doctor's prescription:

The change in the corneal surface using the surgical device of the present invention will be determined by an optical correction formed into a custom made member or insert based upon a doctor's prescription. The prescription is similar to the prescription a doctor might give to an optical laboratory for the purpose of grinding lenses for eye glasses or for contact lenses.

Ex. 1 Col. 5, 11. 5-11. Plaintiff has not shown how or why the vague and subjective limitations of "mathematical precision" and "full correction" should be read into the claim term. The Court therefore finds that the word "prescriptive" in Claim 1 should be interpreted according to its ordinary meaning to describe that the "correction" that is "desired" relates to a doctor's prescription for improving a patient's visual acuity.

"Desired shape of the expandable surface element"

<table>
<thead>
<tr>
<th>Cytyc's proposed construction</th>
<th>Xoft's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no construction required)</td>
<td>(indefinite)</td>
</tr>
</tbody>
</table>

Xoft has again presented no evidence to back up an argument that the phrase is indefinite and therefore again fails to carry its burden of proof. No construction of "desired shape of the expandable surface element" is necessary.
Claim 1 reads:

A disposable diaper comprising:

- a body portion having two enlarged end portions and a narrowed intermediate portion therebetween, the body portion being shaped so that said diaper may extend about a waist and crotch of a wearer and have an inside and an outside with respect to the wearer;

- each end portion having a respective waistband portion at an edge thereof so that when the diaper is worn, the waistband portions gird the waist of the wearer;

- at least two body-portion layers including a layer of liquid-absorbent material and a plastic layer having an edge at the edge of the diaper;

- a soft padding member located along at least one of said waistband portions, being adjacent to said plastic layer edge, the soft padding member being distinct from all of said body-portion layer, the soft padding member including a material formed from a soft substance presenting a soft surface along at least a portion of said inside of the diaper waistband portion despite said plastic layer edge.

Claim 2 reads:

The diaper according to claim 1 wherein said padding member comprises a first strip of soft padding parallel to the waistband, the first strip providing an additional absorbent barrier against leakage.

U.S. Pat. No. 5,797,824 cl. 1, 2 (emphasis added to elements at issue in this motion). Tracy alleges infringement of two types of Arquest products: (1) the Arquest Diapers and (2) the Arquest Pants. As these two types of products contain different structural components, separate infringement analyses are required.

C. Despite Said Plastic Layer Edge

Tracy argues that the elastic member "present[s] a soft surface along at least a portion of said inside of the diaper waistband portion despite said plastic layer edge." Arquest argues that the elastic member does not satisfy the claim language because:

1. it does not wrap around the plastic layer edge as depicted in the only disclosed embodiment of the invention and
2. it does not otherwise provide protection from the plastic layer edge in its Arquest Diapers.

Claim 2 does not explicitly reference a soft padding member that wraps around a plastic layer edge, thereby protecting the baby's skin from the plastic layer edge. Arquest, however, maintains that claim 2, read in light of the specification and prosecution history, requires the padding member to wrap around the plastic edge. Tracy, on the other hand, urges us to avoid reading any limitations from the specification and prosecution history into the claims. The Federal Circuit has held that "foremost among the tools of claim construction is of course the claim language itself, but other portions of the intrinsic evidence are clearly relevant, including the patent specification and prosecution history." All Dental Prodx, LLC v. Advantage Dental Prods., 309 F.3d 774, 780 (Fed. Cir. 2002). Since the meaning of the claim language "despite said plastic layer edge" is not clearly discernible from reviewing the claim itself, we will examine the specification and prosecution history.

The specification discloses only one embodiment of the diaper invention. That embodiment employs a soft padding member wrapped around the plastic layer edge of the waistband. Tracy argues that it is merely a preferred embodiment of the invention while Arquest argues that it is the only embodiment of the invention. A specification does not need to specifically
illustrate all the subject matter of a particular claim in order to support that claim. Wang Labs. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). In order to be covered by that claim, however, the subject matter must be sufficiently described so as to enable a person of ordinary skill in the art to practice the claimed invention. Id. Furthermore, although invalidity is not at issue in this motion, we will not construe the claims "to have a meaning or scope that would lead to their invalidity for failure to satisfy the requirements of patentability." Id. Thus, claim 2 is limited to embodiments that the specification enables.

The specification of the '824 patent discloses a soft padding member (50) which wraps around plastic border sections (40 and 42) at the waistline. Together, the border sections (40 and 42) form the plastic layer edge referred to in the claims. Thus, in the absence of soft padding member, the plastic layer edge has three exposed surfaces. The plastic layer edge includes the plastic border section (40) exposed on the interior, baby-facing side of the waistline, the plastic border section (42) exposed on the exterior, mommy-facing side of the waistline, and both border sections (40 and 42) exposed at the termination of the waistline (in the upward direction when the diaper is worn by a baby standing upright). The soft padding member (50) is divided into three sub-parts (50a, 50b, and 50c) that cover all three exposed areas of the border sections (40 and 42). Claim 2 requires a soft padding member to present a soft surface along the inside of the diaper waistline. It does not require padding at the top or outside of the diaper waistline. With respect to the specification, claim 2 claims protection when the interior baby-facing side of the border section 40 is protected by sub-part 50c of the soft padding member 50 (for example, when sub-parts 50b and 50c are not necessarily present). Since claim 2 is enabled as written, there is no cause to read in the wrap-around feature.

The prosecution history simply readdresses the preferred embodiment in the specification and, for the same reasons, does not limit Tracy to embodiments having soft padding members that wrap around.

Although we have construed claim 2 to not require a wrap around feature, we must still construe the claim language "despite said plastic layer edge." The claim language appears to imply that, but for the soft padding member, a plastic layer edge would present a non-soft surface along the inside of the diaper. Indeed, the specification and prosecution history command this interpretation. In the specification, Tracy discloses a sub-part of the padding member (50c) that covers an otherwise exposed plastic layer edge (40). Moreover, in amending the claims to include "despite said plastic layer edge", she made the following representation to the PTO:

None of the prior art addresses the problem solved by the claims as amended . . . [A] problem addressed by the invention is that a plastic edge is involved. In the manufacture of diapers, the plastic edges may be heat sealed edges and/or may be sharp edges. The present invention adds soft padding located along a waistband portion. The effect of this is to provide some protection against the edge of the plastic.

Arquest 56.1 Statement, Exhibit C at 7. (emphasis added). Additionally, when distinguishing her invention over the prior art, she represented to the PTO Board of Patent Appeals and Interferences that she was claiming a "soft padding member located in the waist region and intended to avoid direct contact with the skin of the wearer of an edge portion of a plastic layer of the diaper." Arquest 56.1 Statement, Exhibit D at 5. (Emphasis added). In light of the specification and prosecution history, we interpret "despite said plastic layer edge" to mean that the plastic layer edge would be otherwise more exposed to the wearer's skin but for the padding member there between.

None of the prior art addresses the problem solved by the claims as amended . . . [A] problem addressed by the invention is that a plastic edge is involved. In the manufacture of diapers, the plastic edges may be heat sealed edges and/or may be sharp edges. The present invention adds soft padding located along a waistband portion. The effect of this is to provide some protection against the edge of the plastic.

Arquest 56.1 Statement, Exhibit C at 7. (emphasis added). Additionally, when distinguishing her invention over the prior art, she represented to the PTO Board of Patent Appeals and Interferences that she was claiming a "soft padding member located in the waist region and intended to avoid direct contact with the skin of the wearer of an edge portion of a plastic layer of the diaper." Arquest 56.1 Statement, Exhibit D at 5. (Emphasis added). In light of the specification and prosecution history, we interpret "despite said plastic layer edge" to mean that the plastic layer edge would be otherwise more exposed to the wearer's skin but for the padding member there between.

1120

L. No Destructive Lesion is Formed on a Disc

Smith & Nephew proposes that "no destructive lesion is formed on a disc" should be construed to mean "no ruinous change in the structure of tissue on a disc." ArthroCare would interpret the term to mean "a pathological change in tissue resulting in structural degradation, death and/or removal of tissue." The American Heritage Dictionary defines "destructive" as: "causing or wreaking havoc; ruinous." THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (4th ed. 2000). The American Heritage Dictionary defines "lesion" as: "a localized pathological change in a bodily organ or tissue." THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (4th ed. 2000).

The claims, specification and prosecution history do not counsel against giving the term its plain meaning. Thus the court
sees no reason not to combine the dictionary definitions of "destructive" and "lesion" to define "no destructive lesion" as "no ruinous change in the structure of tissue on a disc."

ArthroCare argues that this definition does not clarify the original term, but proposes no better construction. The patent states "discs with fissures can be treated non-destructively with or without the removal of nucleus tissue..." U.S. Patent No. 6,261,311, Column. 22:13-14. This patent language contemplates nondestructive procedures on the disc that involve the removal of tissue. This language contradicts ArthroCare's definition, which implies that removal of tissue necessarily has a negative impact on the intervertebral disc. Additionally, the phrase "structural degradation" and the word "pathological" are ambiguous and do not clarify the term "destructive lesion."

For these reasons "no destructive lesion" is defined as "no ruinous change to the structure of tissue on a disc."

1. **Claim 14 of the '977 patent**

Claim 14 of the '977 patent describes a method for augmenting the power of a gas turbine by "adding increasing amounts of liquid water comprising liquid droplets to the working fluid acquired by the compressor, with the mass flow rate of the liquid droplets being increased over time to avoid destructive thermal stresses within the gas turbine which are related to the providing of increased amounts of liquid water to the working fluid. . . ." The parties presently dispute the term "destructive" thermal stresses. As indicated above, the parties stipulated to the definition of "thermal stresses" to mean "forces, induced by heat, which tend to deform a body." (Doc. 185 at 6). 22 Destructive is not a technical term. Its ordinary meaning is causing destruction or tending to destroy; destroy, in turn, means "to ruin the structure, organic existence, or condition of." Merriam Webster's Collegiate Dictionary (10th ed. 1996). 23

2. **Footnotes**

22 While the Markman Order specifies that "thermal stresses" appeared in Claim 16 of the '990 patent, the parties have not argued that thermal stresses in the claims of the '977 patent should be defined differently.

23 The Federal Circuit has indicated that courts may use technical treatises and dictionaries at any time to understand the technology at issue, and may rely on dictionaries to construe claim limitations, as long as the dictionary definition does not contradict any definition found in or ascertained from reading the patent documents. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 n.6 (Fed. Cir. 1996).

The patent specifications do not provide a definition of "destructive" that is inconsistent with its ordinary meaning. The patent specifications refer to "destructive stresses" (P2, col. 22, l. 25) and "destructive thermal and mechanical stresses" (Id. at col. 24, l. 59). "Destructive stresses" is used to refer to a problem that can arise from cooling a portion of the housing unequally, which can then lead to "a stall or a rotating stall leading to destructive stresses in the components of the axial compressor section 103, or such distortion can induce mechanical rubbing between components of the axial compressor section 103, resulting in either damage to these components or, possibly in the most extreme case, a compressor wreck." (Id. at col. 22, ll. 24-30). "Damage" is defined, in pertinent part, as "harmful alteration of any of the components of the gas turbine beyond that which would be anticipated in the course of reasonable use and operation." (Id. at col. 11, ll. 11-13). "Destructive thermal and mechanical stresses" is used in the specifications to describe that increments should be added or subtracted so as to minimize such stresses.

The patent history of the '977 patent reveals that Claim 14 24 originally contained the following limitation: "adding liquid water comprising liquid droplets to the working fluid acquired by the compressor, the mass flow rate of the liquid droplets being modified with respect to time to moderate thermal stresses within the gas turbine which are related to the providing of liquid water to the working fluid." (P3, tab 1 at 152) (emphasis added). This claim was rejected by the patent examiner because the claim indicated both that the first paragraph (the one quoted here) calls for the mass flow to be varied, but the second paragraph indicates that the mass flow is "substantially constant" over time. (Id., tab 7 at 71). When the applicants
amended the claim language after the examiner's rejection of the claim, the applicants altered the language from "to moderate thermal stresses" to "avoid destructive thermal stresses."

24 In the patent application, Claim 14 was originally listed as Claim 32.

Finding that the patent specifications and patent history do not demonstrate that the inventors intended "destructive" to mean something different than its ordinary meaning, the Court defines "destructive thermal stresses" as "forces, induced by heat, which have a tendency to destroy, or ruin the structure of, a body."

3. Construction of "Said Retainer Being Detachably Cooperative with the Tabs to Rotate the Disc and a Tie Rod Engaged Therewith"

The parties also dispute the meaning of the phrase "said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith." Whereas the previous phrase suffered from mere grammatical imprecision, this phrase has been hit by a grammatical tornado. The juxtaposition of "detachably" with "cooperative" creates an apparent oxymoron for which neither party offers an adequate explanation. Additionally, it is unclear which part or parts of this phrase are "engaged therewith." It could be that the disc is "engaged therewith" the tie rod; or it could be that the disc and the tie rod together are "engaged therewith" the tabs; a third option would be that the disc and the tie rod are "engaged therewith" "said retainer"; a fourth option would be that the disc and tie rod are "engaged therewith" the tabs and "said retainer." Each of these constructions of this language would be plausible using only grammatical rules. For this reason, examination of the plain language of this phrase is unlikely to result in a conclusive claim construction.

The parties do offer proposed constructions of this disputed phrase. Defendant A.J. believes it should be defined to mean: "the retainer separates or disengages the tabs of the C-shaped wrench disc from their locked position, but acts at the same time as the tabs to rotate the disc and a tie rod locked into position therewith." (Def. Br. at 19). Plaintiff Lisle suggests the disputed phrase should be construed to mean: "the retainer separates or disengages from, but works together with, the tabs to rotate the disc and a tie rod that is interlocked with the disc."

Rather than get into the meaning of this disputed phrase, A.J. asserts that the parties' dispute over this claim duplicates the dispute over "cooperatively engaging". Simply because this phrase contains the word "cooperative" and the word "engage" does not render the dispute over the meaning of this phrase coextensive with the dispute over the previous phrase. While it is true that A.J.'s proposed construction is rooted in its proposed construction of "cooperatively engaging," that does not mean that the conclusive construction of "cooperatively engaging" in the prior portion of the claim will be conclusive as to this portion. When the two words combine to form one phrase as an adverb (cooperatively) and verb (engaging), the meaning of the single phrase is likely to be different from the meaning of the words when cast into a different context.

Lisle again proposes to construe this claim according to "its ordinary meaning." (Pl. Br. at 13-14). The proffered ordinary meanings of cooperative and engage are the same as in the previous phrase, that is, "to work together" and "to interlock" respectively. (Pl. Br. at 13). The proffered ordinary meaning of detachable is "separates or disengages from." (Pl. Br. at 12-13).

Lisle's proposed construction tackles the "engaged therewith" portion of the claim, positing that it should be the tie rod that is "engaged therewith" the C-shaped wrench disc. The invention does require that the tie rod and the C-shaped wrench disc engage. Additionally, both the disc and the tie rod would rotate when the invention was operating properly. In light of the nature of the invention, the Court agrees with Lisle that the latter portion of the disputed phrase should be construed to relate only to the disc and the tie rod. This construction also comports with the dictionary definition of "therewith" ("with that") 2, which implies that this somewhat archaic term modifies "that" which immediately preceded it.
Lisle did no better than A.J. at addressing the apparent oxymoron of "detachably cooperative." Both parties urge the same plain meaning of detachable, i.e. "to separate or disengage from." As an adverb, "detachably" must modify the adjective "cooperative", so, if the language and grammar is to be believed, the separation or disengagement must be part and parcel of the cooperation between the retainer and the tabs. While the Court can imagine items that would separate or disengage while they work together (the acorn and the oak, for example), the inner tie rod tool that is the subject of the '776 patent is not among them. In the context of this patent, where the tabs, slots, and retainer must "work together to interlock," it is unimaginable for the tabs and retainer to be "detachably cooperative."

In light of this enigmatic language, the Court consults the prosecution history for an answer to the riddle. In the prosecution of the patent, Lisle emphasized to the patent examiner in its request to reconsider that the patent "specifies the retainer is detachably cooperative with the tabs." (Pl. Ex. F at LIS 000871) (emphasis in original). This feature was clearly significant to the patentee. It is also clearly separate from the cooperative engagement between the tabs and the retainer, which was described immediately before the "detachably cooperative" feature in the request to reconsider. (Pl. Ex. F at LIS 000870). Although the patent history reveals that this is a salient feature of the invention, it does not provide a definite answer to the construction.

Under Lisle's proposed construction, the conjunction "but" separates the definition of detachable from the definition of cooperative. The effect of this construction would be to sever "detachably" from "cooperative" and interpret both terms separately, i.e. the retainer and the tabs are detachable from each other, and they are also cooperative with each other. A.J.'s proposed construction accomplishes the same results, though its language is slightly different.

While it is true that the retainer and tabs are both detachable and cooperative, the term "detachably cooperative" attempts to capture both concepts at once. Rotation is necessary both for engagement with the tabs and for detachment from the tabs. To engage the tabs, the tabs must be inserted into the slots on the tube, and then rotated into the retainer. To detach the tabs from the retainer, the retainer must be rotated so the tabs are aligned with the slots to permit full detachment. In order to capture the full meaning of the phrase "detachably cooperative" while remaining true to the claim of the '776 patent, the Court finds that this phrase refers to the rotation of the retainer and the tabs.

Consequently, the disputed phrase “Said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith” is constructed to mean: Rotation of the retainer and the tabs can result in separation or disengagement or it can result in rotation of the disc and a tie rod that is interlocked with the disc.

---

i. Claim 1 of the '776 patent

Claim 1 is the only independent claim of the '776 patent. It is directed to an inner tie rod removal tool. Here is the text of the claim, with the disputed claim language depicted in bold and underlined:

1. A tool for removal of inner tie rods comprising in combination:

---
(a) a nut engaging, C-shaped wrench disc having spaced arms for engaging a nut, and outwardly projecting tabs for cooperation with a retainer; and

(b) a hollow tube for placement over a tie rod, said tube having a retainer at one end and at least two slots for cooperatively engaging the tabs of the wrench disc and means for cooperation with tube rotation means at the opposite end, said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith.

In its claim construction, this Court construed the disputed claim language in claim 1 as follows. The term "retainer" means "any of various devices used for holding something." The term "cooperatively engaging" means work together to interlock." The phrase "said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith" means "rotation of the retainer can result in separation or disengagement or it can result in rotation of the disc and a tie rod that is interlocked with the disc."

At the most basic level, the accused tools match up with the subject matter of the invention disclosed by the '776 patent. It is beyond dispute that the accused tools are "tool[s] for removal of inner tie rods." Claim 1 goes on to recite that the tool would have two major components. The first component, described in part (a) of Claim 1 of the '776 patent, is a "nut engaging C-shaped wrench disc having spaced arms for engaging a nut, and outwardly projecting tabs for cooperation with a retainer." The accused tools utilize a C-shaped wrench disc, which A.J. refers to in its literature as a "crows foot." The C-shaped wrench disc of the accused tools has spaced arms for engaging a nut and outwardly projecting tabs. In order to meet all the limitations of part (a) of Claim 1, these outwardly projecting tabs must also be "for cooperation with a retainer." Reading this limitation in light of the Court's claim construction, the tabs must be "for cooperation with a device used for holding something."

The tabs of the C-shaped wrench discs in the accused tools are meant to cooperate with the retaining end of the accused tools. The retaining end of the accused tools is structured to hold the discs in place. A.J. disputes whether the retaining end of the accused tools should properly be considered the tube or the retainer. The Court will address that contention below in the analysis related to the limitations of part (b) of Claim 1. For now, it suffices to assert that the outwardly projecting tabs on the C-shaped wrench disc of the accused tools are present to hold the discs in place as the discs cooperate with the retaining end of the accused tools. This matches with the final limitation of part (a) of Claim 1.

Part (b) of Claim 1 discloses the other major component of the invention: "a hollow tube for placement over a tie rod, said tube having a retainer at one end and at least two slots for cooperatively engaging the tabs of the wrench disc and means for cooperation with tube rotation means at the opposite end, said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith." Part (b) of Claim 1 is more conceptually dense than part (a), so it must be parsed a little more closely.

Beginning with the basics, the accused tools meet the first limitation of part (b). They contain "hollow tube[s] for placement over a tie rod." The next limitation is that the tube must have a retainer at one end. A.J. concedes that the accused tools have a retainer at one end. A.J.'s contention is that the T-shaped slots at the retaining end of the accused tools constitute the retainer. In order to match all the limitations of part (b) of Claim 1, the retaining end of the tube must also have "at least two slots." In A.J.'s view, its device defeats literal infringement because the slots in the retaining end of the accused tools would be slots in the retainer not slots in the tube. A.J. misperceives the nature of the invention. The invention contains two primary components: the C-shaped wrench discs and the hollow tube. The hollow tube has a retaining end and a rotating end. At the retaining end, the tube has two claimed features: some structural component that will permit it to hold the C-shaped wrench discs in place, i.e. the retainer, and at least two slots that permit the outwardly projecting tabs on the wrench discs to engage with the retainer. The accused tools combine the slots and the retainer into one structural component: the T-shaped slots. The vertical aspect of the T-shaped slots are the "at least two slots" that the claim limitation requires. The horizontal aspect of the T-shaped slots in the accused tools functions as the retainer, or the device to hold the C-shaped wrench disc in place.

The slots at the end of the tube, the retainer, and the tabs of the wrench disc must "cooperatively engage" or, as construed by the Court, "work together to interlock." These three features of the accused tools meet this limitation. Although it is not in dispute, the Court notes that the accused tools do have "means for cooperation with tube rotation" at the end opposite the retaining end.
The final limitation of part (b) of Claim 1 is "said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith." The Court construed this portion of the claim to mean "rotation of the retainer can result in separation or disengagement or it can result in rotation of the disc and a tie rod engaged therewith." In the accused tools, the retainer has been integrated into the structure of the tube rather than added as a separable component. Consequently, rotation of the tube in the accused tools will ipso facto result in rotation of the retainer. With the accused tools, rotation of the tube can result in separation or disengagement from the discs or it can result in rotation of the disc and the tie rod engaged therewith. The accused tools meet this limitation as well.

The accused tools contain each limitation of the '776 patent exactly. Consequently, the Court holds that the accused tools infringe Claim 1 of the '776 patent. The remaining claims are dependent, but the infringement analysis must be conducted on them as well.

ii. Claim 2 of the '776 patent

Claim 2 of the '776 patent incorporates all of the limitations in claim 1 and adds that the "means for cooperation with tube rotation means comprise a socket." In other words, the rotating end of the hollow tube (as opposed to the retaining end) would have a socket as the means to begin rotation. There is no dispute but that A.J.'s accused tools contain a "socket" on the rotating end. Therefore, the Court finds that the accused tools literally infringe claim 2 of the '776 patent.

iii. Claim 3 of the '776 patent

Claim 3 of the '776 patent incorporates all of the limitations in claim 1 and adds that the C-shaped wrench disc "include first and second tabs radially projecting outwardly in opposite directions from the center of the disc." The C-shaped wrench disc in the accused tools contains outwardly projecting tabs that extend in opposite directions from the center of the disc. Therefore, the Court finds that the accused tools literally infringe claim 3 of the '776 patent.

iv. Claim 4 of the '776 patent

Claim 4 of the '776 patent incorporates all of the limitations in claim 1 and further requires that the "retainer include slots therein for the receipt of the tabs." The Court construed this term to mean "the retainer contains slots for receipt of the tabs on the C-shaped wrench disc." The retainer on A.J.'s accused tool does contain slots for receipt of the tabs on the C-shaped wrench disc. In fact, in the structure of the accused tools, the entire structure of the retainer consists solely of the horizontal slots of the T-shaped slot. A.J. contends that this raises a claim differentiation problem, as the slots of the retainer must be different from the retainer itself. This Court disagrees. The doctrine of claim differentiation, at its core, dictates that the limitations of a broad claim must not be so defined that they are the equivalent of the limitations of a dependent narrow claim. See U.S. v. Telelectronics, Inc., 857 F.2d 778, 784 (Fed. Cir. 1988) (holding that district court cannot construct limitations of a broader claim so that they are the same as the limitations of a narrower claim). Claim 1 of the '776 patent sets forth the invention in its broadest terms. Under the limitations of Claim 1, the retainer can be "any of various devices used for holding something." The limitations of Claim 4 dictate that the retainer must be structured in such a way so that it contains slots for receipt of the tabs of the C-shaped wrench discs. The accused tools have a retainer, as described in the analysis relating to Claim 1. As it happens, the retainer of the accused tools meet the limitations of Claim 4 as well. Therefore, the Court finds that the accused tools literally infringe claim 4 of the '776 patent.

v. Claim 5 of the '776 patent

Claim 5 of the '776 patent incorporates all the limitations in Claim 1 and adds that the tools include a plurality of different-sized C-shaped wrench discs to cooperate with different-sized inner tie rods. The parties do not dispute that the accused tools include a variety of different-sized discs to cooperate with different-sized inner tie rods. Therefore, the accused tools meet the limitations of Claim 5. Therefore, the Court finds that the accused tools literally infringe claim 5 of the '776 patent.

CONCLUSION

For the reasons given in this opinion, the Court denies A.J.'s Motion for Reconsideration of the claim construction opinion based on the asserted ground of indefiniteness. The Court, sua sponte, reconsidered its claim construction and enters the
following amended construction of the term "said retainer being detachably cooperative with the tabs to rotate the disc and a tie rod engaged therewith" to mean:

Rotation of the retainer can result in separation or disengagement or it can result in rotation of the disc and a tie rod that is interlocked with the disc.

The Court denies A.J.'s Motion for Summary Judgment of invalidity and non-infringement in its entirety. The Court grants Lisle's Motion for Summary Judgment on infringement in its entirety. Thus, the only issues remaining for trial relate to whether the '776 patent is invalid for the reasons discussed in parts II.B, II.C, and II.D of this opinion.

With respect to the claim limitation "said retainer being detachably cooperative with the tabs to rotate the disk and a tie rod engaged therewith," we will clarify the district court's claim construction. In its proposed claim construction, A.J. asserts a hyper-technical reading of the limitation that requires the wrench disc and the hollow tube to simultaneously detach from one another and rotate the tie rod. Obviously, that cannot be, since the tool disclosed by the patent is incapable of simultaneously detaching the wrench disc from the hollow tube and rotating a tie rod. We therefore reject A.J.'s proposed claim construction and instead rely on the patent specification to attain a common-sense meaning of that claim limitation.

As explained above, an object of the patented invention is to provide a single tool that can be used on many different tie rod configurations. Id. at col. 1, II. 56-68. That objective, however, is only realized because the retainer allows the body of the tool to engage or disengage the wrench discs. Id. at col. 1, II. 44-50. Moreover, figure 7 of the '776 patent illustrates that although the wrench disc is detachable, only when it is secured onto the body of the tool can it perform its stated function of rotating the tie rod. Given this disclosure, the meaning of the disputed claim limitation becomes apparent: the wrench disc is detachable from the body of the tool, but when not detached, the tabs of the wrench disc and the retainer work together to rotate the wrench disc and the tie rod that is interlocked with the wrench disc.

As to this phrase, the Court construes the following meaning: each magnet is secured to the tool body in a fashion that prevents it from being able to rotate except with the tool as the tool rotates, but that allows the individual magnet to be removed and replaced, if damaged. None of the five Abstracts mentions detachable securing of the magnets. 78 The 787 patent specification, 79 the 781 patent specification, 80 the 386 patent specification, 81 the 539 patent specification, 82 and...
the 117 patent specification reference this particular language. Further, the 117 patent specifies that "Each magnet member is individually secured and can be replaced, when necessary, without affecting other magnet members..." Even though the specifications do not go into detail explaining these concepts beyond the language in the 117 patent, the meanings of detachable and non-rotatable are readily apparent.

C. Claim Construction of "Detector"

Claim 1 of the '454 Patent claims an "apparatus for chemical polishing (CMP) of a wafer comprising: . . . (c) an endpoint detector." Defendants seek to have the term "detector" construed as the detection component of a laser interferometer because the specification only uses the term "endpoint detector" to refer to the detection component of a laser interferometer. Plaintiff's argue that the term "detector" should be given its plain and ordinary meaning as a device used in determining when the polishing or planarization process should be terminated.

To construe the term "detector," Plaintiff points to the Background section of the '454 Patent that discusses the early devices and methods used in prior art to perform in situ detection of endpoints during the CMP process. None of the discussed devices or methods involve the use of lasers. ('454 Patent, Col. 2, lines 23-43). On the other hand, Defendants argue that the summary section of the specification expressly describes the "endpoint detector" as a component of CMP that includes a laser interferometer.

The intrinsic evidence does not provide much guidance as to the proper construction of the term "detector." A "detector" is only mentioned in Claims 1 and 22 without much description. As Defendants point out, the specification describes the endpoint detector as a component of the laser interferometer. However, as with the construction of the term "light," the term "detector" cannot be narrowly construed based on the preferred embodiment of the patent. Phillips, 415 F.3d at 1323. Accordingly, the Court deems it proper to consult extrinsic evidence to define the term "detector." Defendants' expert, Dr. Gutmann, agreed that "a person of ordinary skill in the art would understand from reading the '454 specification that there were other end-point detector devices other than a laser interferometer device." (Gutmann Transcript at 210.) Additionally, Merriam-Webster defines "detector" as a device for detecting the presence of electromagnetic waves. Both of these sources provides broader definitions than that proffered by Defendants. Accordingly, the Court FINDS that the term "detector" refers to a device for detecting the presence of electromagnetic waves and is not confined to the detection component of a laser interferometer.
E. “detector operable to detect a fluorescence optical signal”

In its claim construction brief, Stratagene urged the court to construe "operable" as meaning "capable of being used." However, the claim is perfectly clear on its face, and there is no significant disagreement between the parties as to its meaning. Stratagene has done little to argue that this term needs to be construed, and it does not press this point in its post-hearing brief. Therefore, it is unnecessary to construe this term.

4) the word "detent" means "a mechanical stop or catch;"

83. As defined in the '656 specification, a "detent" is a ball comprising a spherical or curved surface which can project, extend or protrude outwardly of the solenoid housing. Col. 6, lines 12-22; Col. 7, lines 31-34; Col. 7, lines 43-46; Col. 7, lines 51-56; Figures 1, 3, 4-7. In the specification, "detent" is not described or illustrated in any way other than as a spherical ball capable of being projected above the surface of the solenoid housing. Thus, this definition is of controlling significance. McGill, Inc. v. John Zink Co., 736 F.2d 666, 674 (Fed. Cir. 1984).

84. In the usual engineering sense, a "detent" is a spring-loaded element that is driven into either a recessed area in another component or a slot or slide. A detent is almost without exception spring-loaded, or a spring-loaded component that goes into a mating hold slot, ridge, or the like. A detent may also be described as a mechanism that slides two pieces of metal together with a spring and ball to lock the pieces of metal together. A tooth on a gear is not considered a "detent".

85. The claims of the '656 patent also define a "detent" in terms of a member movable from one position to another (Claim 1) and where the "detent" protrudes from another member (Claims 8, 9, 14, 21). The claims of the '656 patent also define a "detent" in the conventional sense, as "spring-biased". See claims 10, 11, 12, 13, 15, 16, 17, 18. Both asserted and non-asserted claims may be used to define claim terms. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

86. Thus, as used in the '656 patent claims, "detent" means a separate spring-biased element such as a ball, which is movable from one position to another and that goes into a mating hole, slot or ridge in the blocking element and is capable of being driven by the solenoid into a position where it can contact the detent engaging member on the cam.

87. As used in the claims of the '656 patent, the detent engaging member is a member located on the cam wherein rotation of the dial drives the member against a detent which has been moved to the detented position.
8) in claim 23 of the '583 Patent, the limitation "detent means disposed on the corner surface thereof for engaging said first ridge to lock said tab to said tab holder" is subject to 35 U.S.C. § 112 P 6. The required function is to secure the tab to the tab holder to prevent the tab from being pulled off. The structure is "a mechanical stop or a catch;"

The primary dispute between the parties concerns the proper legal interpretation of certain language in claim 1 of Dr. Greenberg's patent. Claim 1, which describes his surgical instrument, reads as follows:

A surgical instrument comprising a pair of axially matable and relatively slidable shafts each having at their distal ends cooperating working tools, a sleeve mounted adjacent the proximal end of said shafts, one of said shafts being fixedly attached to said sleeve for conjoint movement therewith, the other of said shafts extending freely through said sleeve and being exposed at its proximal end, a pair of handle members pivotally attached to each other and arranged scissor-like for manipulation by one hand, one of said handles being attached to said sleeve for conjoint axial movement and relative free rotary movement therewith, said sleeve and said one handle being arranged so that said sleeve is manipulatable by a finger of the same hand simultaneous with the manipulation of said handle, a radially enlarged wheel on said sleeve and said wheel and said one handle having a cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals, said other handle being universally attached to the exposed proximal end of said freely extending shaft, said shafts being caused to reciprocate relative to each other on manipulation of said handle members and to rotate about their common axis by manipulation of said sleeve, whereby said tools may be operated and moved into selected rotary positions relative to the axis of said shafts.

Ethicon and Dr. Greenberg dispute the proper interpretation of the underlined phrase: "cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals." Specifically, they dispute whether this language is structural or functional. The characterization of the claim language is critical because functional and structural elements are subject to different tests for literal patent infringement. In essence, if the language is structural, as Dr. Greenberg contends, then the patent encompasses comparable instruments containing any detent mechanism. If the language is functional, as Ethicon asserts, then the claim language is governed by 35 U.S.C. § 112, P6, and Dr. Greenberg's patent covers only the specific detent mechanism recited in his specification and structural equivalents thereof.

Although Dr. Greenberg is asserting claims 2 and 3 against Ethicon as well as claim 1, he has conceded that claims 2 and 3 flow from claim 1. Therefore, if claim 1 is not infringed, neither are claims 2 and 3.

DISCUSSION
I. Summary Judgment Standard

Summary judgment is appropriate in a patent case, as in any other case, when the moving party demonstrates that no genuine issue of material fact remains for decision and that the moving party is entitled to judgment as a matter of law. DMI Inc. v. Deere Co., 755 F.2d 1570 (Fed. Cir. 1985). The moving party has the burden of demonstrating the absence of any disputed material facts and the court must resolve all ambiguities and draw all inferences in favor of the non-movant. Thompson v. Gjivoje, 896 F.2d 716, 720 (2d Cir. 1990).

The patentee in a patent infringement suit bears the burden of proving infringement by a preponderance of the evidence. To prove infringement, the patentee must prove that every limitation of the asserted claim is found in the structure of the accused device. An accused infringer is entitled to summary judgment if he can demonstrate that the patentee has failed to put forth evidence sufficient to support a finding that any one limitation of the asserted claim is found in the accused device. Scripps Clinic & Research Fdn. v. Genentech, Inc., 927 F.2d 1565. 1570-71 (Fed. Cir. 1991); Johnston v. IVAC Corp., 885 F.2d 1574, 1578 (Fed.Cir. 1989).

Determining whether a patent is infringed involves two steps: 1) interpreting the claims; and 2) comparing the properly interpreted claims to the accused device. The Federal Circuit has recently clarified that claim interpretation is exclusively a question of law for the court. Markman v. Westview Instruments, Inc., 52 F.3d 967 (Fed. Cir. 1995). The comparison of the

In order to determine whether there is a genuine issue of fact regarding infringement, the Court must first determine the scope of Dr. Greenberg's patent as a matter of law. The primary dispute over the scope of the patent concerns the interpretation of the following language in claim 1 of Dr. Greenberg's patent: "cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals."

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

Under this provision, the use of means-plus-function language has a "string attached." Valmont Indus., Inc. v. Reinke Mfg. Co., 983 F.2d 1039, 1042 (Fed. Cir. 1991). To satisfy a means-plus-function limitation literally, the accused device must perform the identical function required by the limitation. Moreover, the accused device must employ as the means for performing that function either the precise structure disclosed in the specification or a structural equivalent thereof. Id.; Johnston v. IVAC Corp., 885 F.2d 1574, 1580 (Fed. Cir. 1989); Pennwalt Corp. v. Durand-Wayland, Inc., 833 F.2d 931, 934 (Fed. Cir. 1987).

Ethicon argues that the phrase "cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals" recites means-plus-function language, because "detent mechanism" is a means and "defining the conjoint rotation of said shafts in predetermined intervals" is a function. According to Ethicon, Dr. Greenberg's patent therefore covers only the exact structure disclosed in his specification and structural equivalents thereof.

Dr. Greenberg insists that Ethicon has "parsed" his claim incorrectly and that the correct identification of the element at issue is as follows: "a radially enlarged wheel on said sleeve and said wheel and said one handle having a cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals." He claims that, when parsed in this way, the disputed element contains four well-defined structures: 1) a radially enlarged wheel; 2) a sleeve; 3) a handle; and 4) a detent mechanism. Therefore, he contends, the element is structural and 35 U.S.C. § 112, P6 does not apply. Dr. Greenberg further claims that, even if the element at issue is, as Ethicon claims, "cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals," that phrase recites structural language because the term "detent mechanism" has a specific structural connotation in the scientific community.

Dr. Greenberg's "parsing" argument has no merit. The Court of Appeals for the Federal Circuit has applied 35 U.S.C. § 112, P6 to means plus function "limitations" (In re Donaldson Co., 16 F.3d 1189, 1195 (Fed. Cir. 1994); Valmont Indus., Inc. v. Reinke Mfg. Co., 983 F.2d 1039, 1042 (Fed. Cir. 1993); Laitram Corp. v. Rexnord, 939 F.2d 1533, 1538 (Fed. Cir. 1991)); means plus function "language" (Donaldson, 16 F.3d 1189 at 1193; Valmont, 983 F.2d at 1042; Laitram, 939 F.2d at 1535); means plus function "clauses" (Laitram, 939 F.2d at 1536); means plus function "terms" (Valmont, 983 F.2d at 1044; Biodex Corp. v. Loredan Biomedical, Inc., 946 F.2d 850, 862 (Fed. Cir. 1991)); and means plus function "elements" (Johnston v. IVAC Corp., 885 F.2d 1574, 1580 (Fed. Cir. 1989)).

In this Court's view, Dr. Greenberg's position that the language "cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals" is structural does not withstand scrutiny. He and his expert, Dr. Joseph Dyro, repeatedly assert that the term "detent mechanism" is not functional because it refers to a "well known mechanical structure." Plaintiff's Memorandum in Opposition, at 8; A408. Yet every definition of "detent mechanism" that Dr. Greenberg provides describes what a detent mechanism does, but not what it is structurally. In response to an interrogatory, for example, Dr. Greenberg gave the following definition:

Any device for positioning and holding one mechanical part in relation to another so that the device can be released by
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

force applied to one of the parts is a detent mechanism within the meaning of the claims of the '501 patent. A136. A123.

In his deposition, Dr. Greenberg described a detent mechanism in "lay terms": "Anything that periodically stops the rotation is part of a detent mechanism." A365. And Dr. Dyro provides a similar definition of "detent mechanism":

a device for locking and unlocking one mechanical part in relation to another so that the device can be released by a force applied to one of the parts." A443.

Finally, the dictionary definition of "detent" which Dr. Greenberg relies upon reads:

a device (as a catch, dog, or spring-operated ball) for positioning and holding one mechanical part in relation to another so that the device can be released by force applied to one of the parts. Webster's Ninth Collegiate Dictionary.

All of these definitions describe a detent mechanism in terms of what it does ("position[s] and hold[s] one mechanical part in relation to another," "periodically stops the rotation," "allows the locking and unlocking of another part . . ."). While stating on the one hand that "detent mechanism" has a specific structural connotation, Dr. Greenberg insists on the other hand that every structure which operates as a detent, and there are concededly many, 1 satisfies the definition of "detent mechanism." A408. The inconsistency of this position is evident.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

1 Dr. Greenberg's dictionary definition alone suggests that there are several structures that can operate as a detent -- catch, dog, spring-operated ball, etc. See also Interspiro USA v. Figgie Int'l, 815 F. Supp. 1488, 1498 (D. Del. 1993).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - 

Interspiro USA, Inc. v. Figgie Intern. Inc., 815 F. Supp. 1488 (D. Del. 1993), is directly on point. At issue in that case was claim language which read: "detent means . . . for moving and maintaining said moveable member. . ." The district court held that the language "detent means" must be construed in accordance with 35 U.S.C. § 112, P6 and that therefore the patent at issue encompassed only the specific type of detent which was described in the specification and structural equivalents thereof. The Court of Appeals for the Federal Circuit implicitly ratified the district court's finding that "detent means" is means-plus-function language:

Specifically at issue are two limitations contained in claim 1 that are written in means-plus-function format: one reciting . . . and the other directed to a "detent means." Interspiro USA v. Figgie Int'l, 18 F.3d 927, 930 (Fed. Cir. 1994).

Although Dr. Greenberg's claim uses the term "mechanism" rather than "means", it is clear that a claim need not contain the precise term "means" in order to constitute means-plus-function language. Expressions such as "mechanism", "device" and the like have long been construed as means-plus-function language. See Lipscomb's Walker on Patents § 11.16; Ex parte Stanley, 121 USPQ 621, 627-28 (Pat.Off.Bd.App. 1958); Davis Sewing Mach. Co. v. New Departure Mfg. Co., 217 F 775 (1914); Ex parte Demming, 1884 C.D. 18. In fact, Dr. Greenberg himself has implied that the terms "mechanism" and "means" are synonymous. In his own summary of his invention, he referred to the detent mechanism several times as a "detent means." A4, column 2, lines 28 and 55. Likewise, the court in Interspiro used the two terms interchangeably. Interspiro, 815 F. Supp. at 1498.

The prosecution history of Dr. Greenberg's patent is consistent with the limitation of the patent to the patent specification and structural equivalents thereof. Dr. Greenberg initially made very broad claims to one-handed rotation and the use of a detent mechanism to fix the rotation of the shafts of the surgical instrument. His broad claims were rejected, however, as obvious in light of the prior art. The claim which was ultimately allowed was limited to the very specific detail which reads as follows:

a radially enlarged wheel on said sleeve and said wheel and said one handle having a cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals.

The Court finds that the language of the disputed phrase is functional and therefore governed by 35 U.S.C. § 112, P6.
Accordingly, Dr. Greenberg's patent encompasses only the detent mechanism recited in the specification and structural equivalents thereof.

Following discovery, Ethicon moved for summary judgment. Ethicon's motion focused on the "detent mechanism" element of claim 1 of the '501 patent, the claim on which Dr. Greenberg's lawsuit was principally based. After briefing and argument, the district court granted the motion.

Claim 1 of the '501 patent reads as follows, with the "detent mechanism" element highlighted:

   A surgical instrument comprising a pair of axially matable and relatively slidable shafts each having at their distal ends cooperating working tools, a sleeve mounted adjacent the proximal end of said shafts, one of said shafts being fixedly attached to said sleeve for conjoint movement therewith, the other of said shafts extending freely through said sleeve and being exposed at its proximal end, a pair of handle members pivotally attached to each other and arranged scissor-like for manipulation by one hand, one of said handles being attached to said sleeve for conjoint axial movement and relative free rotary movement therewith, said sleeve and said one handle being arranged so that said sleeve is manipulatable by a finger of the same hand simultaneous with the manipulation of said handle, a radially enlarged wheel on said sleeve and said wheel and said one handle having a cooperating detent mechanism defining the conjoint rotation of said shafts in predetermined intervals, said other handle being universally attached to the exposed proximal end of said freely extending shaft, said shafts being caused to reciprocate relative to each other on manipulation of said handle members and to rotate about their common axis by manipulation of said sleeve, whereby said tools may be operated and moved into selected rotary positions relative to the axis of said shafts. S=I

After analyzing the term "detent mechanism" as used in the '501 patent, the district court concluded that the element containing that term set forth a means for performing a specified function and thus was subject to the provisions of 35 U.S.C. § 112, paragraph six (hereafter, section 112(6)). That statute permits a patent applicant to express an element in a combination "as a means or step for performing a specified function without the recital of structure . . . in support thereof," but provides that when an applicant drafts a claim element in that fashion, the element will be construed to cover only "the corresponding structure . . . described in the specification and equivalents thereof."

The district court determined that the detent-type mechanisms in each of the Ethicon devices performed the function set forth in the "detent mechanism" element: "defining the conjoint rotation of [the] shafts in predetermined intervals." The court concluded, however, that the evidence Dr. Greenberg proffered in response to Ethicon's summary judgment motion was inadequate to show that the detents found on Ethicon's devices were structurally equivalent to the detent mechanism disclosed in the specification of the '501 patent. According to the district court, the only evidence of structural equivalence appeared in an affidavit and accompanying materials submitted by Dr. Greenberg's expert, Dr. Joseph Dyro. The court ruled that Dr. Dyro's assertions of structural equivalence were "extremely conclusory" and that they were therefore insufficient to raise an issue of fact as to infringement under section 112(6).

The district court also rejected Dr. Greenberg's argument that Ethicon's devices infringed under the doctrine of equivalents. With respect to that issue, the court again found that Dr. Greenberg had failed to raise a genuine issue of fact, principally because in the court's view Dr. Dyro's evidence was insufficient to raise a triable factual question of equivalency.

Dr. Greenberg's principal contention on appeal is that the district court erred in construing the "detent mechanism" element of claim 1 of the '501 patent as a "means-plus-function" element within the meaning of 35 U.S.C. § 112(6). Dr. Greenberg argues that the "detent mechanism" element recites structure and is not in "means-plus-function" form. Accordingly, he contends that the "detent mechanism" element should not have been limited to the particular detent mechanism disclosed in the specification and its structural equivalents.

As this court has observed, "the record is clear on why paragraph six was enacted." In re Donaldson Co., 16 F.3d 1189, 1194, 29 U.S.P.Q.2D (BNA) 1845, 1849 (Fed. Cir. 1994) (in banc). In Halliburton Oil Well Cementing Co.
v. Walker, 329 U.S. 1, 71 U.S.P.Q. (BNA) 175, 91 L. Ed. 3, 67 S. Ct. 6 (1946), the Supreme Court held invalid a claim that was drafted in means-plus-function fashion. Congress enacted paragraph six, originally paragraph three, to overrule that holding. In place of the Halliburton rule, Congress adopted a compromise solution, one that had support in the pre-Halliburton case law: Congress permitted the use of purely functional language in claims, but it limited the breadth of such claim language by restricting its scope to the structure disclosed in the specification and equivalents thereof. See Valmont Indus., Inc. v. Reinke Mfg. Co., 983 F.2d 1039, 1041-42, 25 U.S.P.Q.2d (BNA) 1451, 1453-54 (Fed. Cir. 1993); In re Fuetterer, 50 C.C.P.A. 1453, 319 F.2d 259, 264 n.11, 138 U.S.P.Q. (BNA) 217, 222 n.11 (CCPA 1963).

The question whether a claim element triggers section 112(6) is ordinarily not a difficult one. Claim drafters conventionally use the preface "means for" (or "step for") when they intend to invoke section 112(6), and there is therefore seldom any confusion about whether section 112(6) applies to a particular element. In this case, the pertinent claim language ("detent mechanism defining the conjoint rotation of said shafts . . .") is not in "means plus function" form, but the district court found that the claim language is equivalent to the more conventional "means plus function" formulation and should be accorded the same legal effect. The district court gave two principal reasons to support its ruling. First, the court concluded that "detent mechanism" in itself invoked section 112(6), because the term did not describe a particular structure but described any structure that performed a detent function. The court noted that both the dictionary definition of the word "detent" (i.e., "a device for positioning and holding one mechanical part in relation to another") and the definition of "detent mechanism" provided by Dr. Greenberg's expert (i.e., "any device for positioning and holding one mechanical part in relation to another so that the device can be released by force applied to one of the parts") were expressed in functional terms.

In addition, the district court reasoned that although claim 1 of the '501 patent employed the term "detent mechanism," the summary of the invention twice used "detent means" when referring to the detent that defined the rotation of the shafts at predetermined intervals, and that the two terms should therefore be viewed as synonymous, at least as used in the '501 patent. Thus, the court concluded that the term "detent mechanism" was equivalent to "means for," and the phrase "defining the conjoint rotation of said shafts in predetermined intervals" stated the function performed by the means.

We disagree with the district court's conclusions. In our view, the factors on which the district court relied do not justify treating the claim language at issue in this case as falling within the purview of section 112(6).

First, the fact that a particular mechanism -- here "detent mechanism" -- is defined in functional terms is not sufficient to convert a claim element containing that term into a "means for performing a specified function" within the meaning of section 112(6). Many devices take their names from the functions they perform. The examples are innumerable, such as "filter," "brake," "clamp," "screwdriver," or "lock." Indeed, several of the devices at issue in this case have names that describe their functions, such as "graspers," "cutters," and "suture applicators."
