I conclude that the term "snowplow blade fixed to the A-frame" as used in claims 1, 38 and 45 of the '700 patent does not need construction because its plain and ordinary meaning is easily discernible from the claim language. The term is clear and nothing in the claim language or the specification requires a special definition. Therefore, the plain and ordinary meaning controls. Northern Telecom Ltd., 215 F.3d at 1295. I note that defendant's proposed construction seeks to impose limitations from the specification, such as a requirement that the blade be attached directly to the A-frame without any intermediate structures. Such limitations do not appear in the claims themselves and nothing suggests that the patentee was attempting to give a narrower construction to "fixed to" than the plain and ordinary meaning of the term. Such a construction would be improper. Golight, 355 F.3d at 1331 ("[L]imitations from the specification are not to be read into the claims.").

1615

B. "Fixed upon a Solid Support According to an Array Comprising Discrete Regions"

Claim 1 also describes the capture molecule in the '829 Patent as being "fixed upon a solid support according to an array comprising discrete regions." '829 Patent, col. 1, II. 50-52. Each of the parties' proposed constructions is lengthy and composed of multiple parts, which must be addressed in turn.

First, insofar as the parties seek to explain the words "fixed upon," their constructions do not differ greatly. They agree that these words refer to the capture molecule's attachment to a solid support "surface," but Nanosphere also seeks to describe such attachment as being either "direct[] or indirect[]," whereas Eppendorf describes the capture molecule as being "attached or linked" to a solid support surface. However, the parties have neither provided intrinsic or extrinsic support for their word choices, nor expressly disagreed with one another's proposed language, and the patent itself does not use the words "direct," "indirect," "link," or "attach" to describe the relationship between the capture molecule and the solid support surface. After considering both parties' proposed language concerning "fixed upon," the Court has determined that "attached or linked" actively describes the relationship between the capture molecule and the solid support surface, whereas "direct[] or indirect[]" attachment is ambiguous, given that it is unclear what either of those types of attachment entails.

As for "solid support," the parties, after submitting their Markman briefs, agreed that the words should be construed to mean "any kind of solid support that allow [sic] the formation of arrays of capture molecules (specific pattern) upon one or more of its surfaces. Said solid support can be made of glasses, filters, electronic device, polymeric or metallic materials, etc." (Supp. Markman Letter, App'x at 1.) In light of this agreed-upon definition, "fixed upon a solid support according to an array comprising discrete regions" need not reiterate the lengthy "solid support" definition included in Nanosphere's proposed construction.

Turning next to "array," although the parties agree that the word is composed of "discrete regions," Eppendorf contends that it also has a "linear or two-dimensional spatial layout . . . according to a specific pattern," whereas Nanosphere avers that the array "may or may not be in specific locations or presented according to a specific pattern." The only part of the '829 Patent that uses the words "specific pattern" is the following excerpt from the "Summary of the Invention" section of the
specification:

The "hybridisation chips" according to the invention are any kind of solid support that allow the formation of arrays of capture molecules (specific pattern) upon one or more of its surfaces. ... Preferably said arrays contain specific locations (advantageously presented according to a specific pattern), each of them containing normally only one species of capture molecule.

'829 Patent, col. 2, II. 62-65, 67-col. 3, 1. 3 (emphases added). This quoted language at no point explains what a "specific pattern" entails, and only provides that the arrays are "[p]referably" "presented according to a specific pattern." Id. col. 3, 1. 1. Because the Federal Circuit in Phillips made clear that the construction of a claim term should not be restricted to the patent's preferred embodiments, thereby reading in unnecessary and unintended limitations, 415 F.3d at 1323, this Court is not persuaded that the capture molecule arrays described in the '829 Patent must be presented "according to a specific pattern." In any event, the Court does not find any language concerning "specific pattern" to be helpful in explaining how the arrays should be organized, and in particular, Nanosphere's proposed language of "may or may not be in specific locations or presented according to a specific pattern," adds unnecessary confusion.

As for whether the array encompasses three-dimensional layouts, as Nanosphere contends (Def.'s Resp. 15-21), or solely "linear or two-dimensional layouts," as Eppendorf avers (Pls.' Resp. 6-7), the Court is not persuaded that the arrays described in the '829 Patent are limited to "linear or two-dimensional layouts." Although Nanosphere has provided numerous references to three-dimensional "solid support[s]," for example disclosing the arrays of capture molecules can form "upon one or more of [a solid support's] surfaces," '829 Patent, col. 2, II. 64-65 (see also Def.'s Resp. 15 21), such language does not indicate that the arrays themselves, rather than solid supports, can be three-dimensional. Neither, however, does the '829 Patent indicate that an array must be limited to "a linear or two-dimensional array." The Court declines to include any language regarding the possible dimensions encompassed by the '829 Patent's arrays, because "a court, under the rubric of claim construction, may [not] give a claim whatever additional precision or specificity is necessary to facilitate a comparison between the claim and the accused product," PPG Indus. v. Guardian Indus. Corp., 156 F.3d 1351, 1355 (Fed. Cir. 1998).

Given the reasons detailed above, the Court has construed "fixed upon a solid support according to an array comprising discrete regions" to mean "attached or linked to a surface of a solid support." The parties did not oppose this construction either at the Markman hearing or in their subsequent letter to the Court.

Axon argues that the district court's interpretation of the "suspension means" limitation in claims 1 and 25 ignored the plain meaning of the phrase "fixed vertical position" and that the district court's instructions to the jury were therefore erroneous and prejudicial. In its instructions to the jury, the district court stated in relevant part: "The language "in a fixed vertical position above the containers" means that the suspension means holds the side portion of the band in a stationary location above the container." We disagree with Axon's assertion that the district court's claim construction was in error. Having reviewed the instructions to the jury regarding claim interpretation, we find no error in the district court's claim construction as presented to the jury. The interpretation given to the claim as embodied in the court's jury instructions clearly explains that the suspension means must hold the cut band in a vertically stationary position above the containers. While the claim does not restrict movement of the suspension means in the horizontal plane, it does require that the band not move in the vertical plane. Considering the plain meaning of the claim, the specification, and the prosecution history, we believe this to be the correct interpretation of the limitation "in a fixed vertical position." Consequently, we affirm the claim construction of the district court.

The second phrase requiring construction is "band fixedly attached to the strand." Pandora asserts that "fixedly" does not require permanence; its proffered construction is a "band creating a raised surface on the strand by either a permanent or reversible method of attachment so that when the band is attached to the strand, it does not move relative to the strand, it is
fixed." Chamilia construes this term in two parts, contending that a "band" means "an element separate and distinct from the strand and the keeper, that is 'fixedly attached' to the strand, and fully circumscribes the strand, thereby increasing the entire circumference of the strand," and that "fixedly attached" means that "bands are connected to the strand by the manufacturer, at predetermined points selected by the manufacturer, with an intended degree of permanence that precludes a necklace wearer from (a) adding bands to a strand, (b) removing bands from a strand, or (c) in any way adjusting the bands' location along the strand, which in turn restricts the location of keepers." In essence, the parties dispute whether the word "fixedly" implies permanence, at least in regard to the wearer, or reversibility: may the bands be detached and moved to different positions along the strand, like the keepers, or are their positions on the strand determined and fixed by the manufacturer. For the reasons that follow, I will construe the term "fixedly attached" to mean the degree of permanence suggested by Chamilia. 8

8 I cannot, however, find any reason why the requirement that the band "fully circumscribe the strand" must be part of the claim construction.

Beginning with Claim 1, it is worth noting that the connector assembly "reversibly" couples the ends of the strand, consistent with the wearer's need to securely fasten but also remove the bracelet or necklace (strand) from her person. While this is not part of the specific term under construction, the use and meaning of the term "reversibly" in this context supports the same understanding in the context of the disputed term "band." In claim 1, the band is "fixedly" attached, the ornament passes over the band, and the keeper is "configured for reversible attachment" over the band (emphasis added); thus the keeper is the element that must be added to the band by the wearer to restrict the movement of the ornament and that may be removed to permit a different arrangement of the ornaments on the strand. In Claim 13, the independent method claim, the process of "reversibly" restricting the movement of ornaments on a strand which has a band "fixed" on it comprises only two steps: (a) stringing an ornament on the strand, and (b) attaching a keeper to the band. Again, it is the keeper, not the band, that permits "reversible" restriction of the ornaments by the wearer. Claim 16, the independent apparatus claim, describes a strand "selectively configurable by the wearer for positional ornament retention," further claiming a keeper "configured and arranged by selective placement around the band," while the band "fixedly" circumscribes the strand (emphasis added). In summary, nothing in the claim language suggests that the wearer will be expected or be able to reverse, select, or otherwise move the bands from their predetermined positions along the strand. Bands, strands, ornaments and keepers are separate elements with separate, though related and complementary, functions.

The language of the remaining sections of the patent, including the "abstract" and "brief summary" as well as the "detailed description," is consistent with a construction of the disputed terms that includes permanently attached bands and reversibly attached keepers. 10 As the Federal Circuit has stated, it is "entirely appropriate for a court, when conducting claim construction, to rely heavily on the written description for guidance as to the meaning of the claims." Phillips, 415 F.3d at 1317; see also Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) ("Thus, the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.") The detailed description explains, e.g., that the movement of beads are restrained by threaded and hinged
keepers, "removably fixed on bands . . . which are fixedly attached to the strand." (Col. 3, ll. 41-43) (emphasis added). Further, it explains the role of the wearer as follows:

In use, the wearer strings beads and one or more threaded keepers on a strand having one or more threaded bands. The order of the beads and keepers is chosen in order to provide the desired distribution of beads on the necklace. The use of a hinged keeper provides additional flexibility for the wearer, as the hinged connector can be attached after the beads and the threaded keeper have been strung. The arrangement of beads and keepers may be altered by simply restringing the components on the strand.

(Col. 6, ll. 33-41). Again, nothing suggests that the wearer may alter the position of the bands.

Continuing with the analysis of the claims and specifications, both sides point to Claim 27, a means-plus function claim within the meaning of 35 U.S.C. § 112 P 6. Construction of Claim 27 would require (1) determining the claimed function and (2) identifying the corresponding structure in the written description of the patent that performs that function. Applied Medical Resources v. U.S. Surgical Corp., 448 F.3d 1324, 1332 (Fed. Cir. 2006). Claim 27 refers to a "means for adapting a circumference of the strand to permanently increase the circumference at a locus that permits passage of an ornament over the locus." As Chamilia contends, the only structure in the written description that could perform the function of permanently increasing the circumference of the strand is the "fixedly attached" band. This point is not dispositive; indeed Pandora argues that the use of the word "permanently" here and not in the other claims suggests a distinction between fixedly and permanently. Yet Pandora's argument applies equally well to the much more frequent contrast between "fixedly" and "reversibly" in the claims at issue. Again, nothing in the language of claims 1, 13, and 16 suggests that the wearer would be altering the position of the band on the strand.

Chamilia also argues that its construction of "fixedly attached" as requiring some degree of permanence is supported by the methods specified for fixing the band to the strand, which include "compression on the strand, interaction with the links of a chain, . . . adhesive or any other suitable means of fixation of a band on a strand." (Chamilia's Brief at 10.) Chamilia contends that "compressing a metal band onto a strand, interlocking a band with the links in a strand's chain, or attaching a band by adhesion - all methods that require the use of tools and skill - are properly performed by a manufacturer prior to sale." (Id.) In isolation, this language might not strongly support Chamilia's position, as the words "compression," "interaction" and "adhesive" could suggest methods performed by a wearer that could be undone, though perhaps with some difficulty. 11 In the context of the entire patent, however, as explained above, there is nothing to suggest that the wearer would be performing that attachment or in any way moving the band from its predetermined position on the strand. Indeed, there would be no need to define an ornament as having "a through opening of greater circumference than the outer circumference of the band," so that it could pass over the band, if the wearer were expected to freely move both the band and the keeper to different positions along the strand.

11 The parties' experts disagree about whether those processes could readily be performed by the user as compared to the manufacturer. (See Altobelli Dep. at 31-32; Brown Dep. at 138-41.) Were I to rely on the expert testimony, I would find Brown more persuasive in light of his experience and more thoughtful explanation of his reasoning.
examiner, amending its claims to overcome the rejections based on prior art, Pandora emphasized the distinction between the band, "fixedly attached," and the keeper "configured for reversible attachment over the band," with the ornament having an opening such that it is "free to pass over the band but is restrained by a selectively attached keeper." Pandora's amendment to claim 1 further included the deletion of a phrase recognizing a "reversible attachment of the band and keeper." These amendments were necessary to distinguish the teachings of patents issued to Kanno (4,907,322) and Kuhn (3,983,716), neither of which taught of a permanent band that would allow the free passage of an ornament. (See Hansen Dec., attachment). Thus, in differentiating the '507 patent from the prior art, Pandora highlighted the interaction of a permanent band with a reversible keeper mechanism.

In summary, a "band" is an element separate and distinct from the strand and the keeper, that is connected to the strand by the manufacturer at predetermined points with an intended degree of permanence that precludes a wearer from adding, removing, or adjusting the location of bands along the strand. A "keeper" is a device which can attach over a band to prevent further movement of ornaments, the device being configured for reversible attachment over the band. An "ornament" is a bead, bauble, bangle, pendant, or trinket that may be removably strung on the strand, with an opening in its center large enough to permit complete passage over a band but not so large as to permit passage over a keeper when the keeper is attached to a band. An "ornament" does not include a "keeper." 12

--- Footnotes ---

12 Although a keeper may have a decorative effect, the patent requires that an ornament have an inner opening (bore) of a circumference large enough to pass over a band, while a keeper does not.

--- End Footnotes ---

A separate Order follows.

1618

The phrase "fixedly connected to the drive assembly" means "fastened securely to the drive assembly."

1619

B. "Fixedly Mounted"

Ramsey contends that the term "fixedly mounted" should be defined as "firmly attached in a manner that prevents relative movement between components."

Warn contends that a stator "fixedly mounted" to the drum interior means that the stator is secured so as to prevent relative rotation between the stator and the drum. Warn argues that the lock screw prevents relative rotation between the stator and the drum but axial movement along slot 76 is permitted. Warn also points to the fact that the specification documents the expectation of radial expansion due to heat.

The specification states:

The modification [from the prior art] basically includes a cylindrical stator which is fixed within the drum. The stator is produced from heat conductive metal and is in tight surface-to-surface fixed contact with the inner surface of the drum.

A cylindrical stator 72 is fixedly secured to the inner wall of the drum 10. A lock screw 74 is projected into slot 76 in the stator 72. However, heat will cause expansion of the stator 72 and produce a tight fit of the stator to the inner wall of the drum.
The plain meaning of "fixed" would be no movement in any direction. The specification neither states that axial movement along slot 76 is expected nor gives the purpose of the slot. A lock screw inserted far enough into the slot would stop axial movement. The radial expansion from heat is clearly contemplated and will not be prevented by the lock screw.

I conclude that the term "fixedly mounted" is defined as "firmly attached in a manner that prevents relative rotation or axial movement between the stator and the drum."

6. "Flange"

The parties dispute the meaning of the term "flange" and the related phrases: "defines stepped-down flanges on opposite sides of a front face of said post that receive vertical sides of respective said adjacent liner panels" (claim 19 of '018 Patent); "stepped-down flanges" (claim 14 of '493 Patent); and "said flanges" (claim 14 of '493 Patent). Plaintiff argues that the term requires no construction because the phrase "stepped-down flange" is a visually descriptive phrase that requires no clarification. Defendants counter that the term "flange" is likely unfamiliar to jurors and that clarification of the term using a dictionary is therefore appropriate. The Court agrees. The term "flange" is not used in common parlance. The parties agreed at the Markman hearing that a "flange" is a projecting rib or rim for attachment to another object. Cf. Oxford American Dictionary 329 (1980) (defining "flange" as "a projecting rim or edge"); Merriam-Webster's Online Dictionary, http://www.merriam-webster.com/dictionary/flange (defining "flange" as "a rib or rim for . . . attachment to another object"). The Court therefore construes the term "flange" to mean "a projecting rib or rim for attachment to another object." The Court finds that it is unnecessary to construe the terms "stepped-down flanges" or "said flanges" in light of this construction.

The district court interpreted "flange" to mean "the portion of a structure to either stiffen or attach it to another structure, not requiring the five-degree angle as described in the preferred embodiment, and not necessarily requiring any angles." Waner v. Ford, No. 98-5061-KES, slip op. at 10 (D.S.D Aug. 30, 2000) (Claim Construction Order). The court further found "that nothing in [claim 1], the specification, or the prosecution history requires that the flange exist prior to installation of the liner." We disagree with the district court's claim construction.

Claim construction begins with determining the ordinary and customary meaning, if any, that would be attributed to the term by those skilled in the art. Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342, 60 USPQ2d 1851, 1854 (Fed. Cir. 2001). Dictionary definitions are useful in this process. See Boehringer Ingelheim Vetmedica, Inc. v. Schering Plough Corp., 320 F.3d 1339, 1346, 65 USPQ2d 1961, 1965 (Fed. Cir. 2003) (citing Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202-03, 64 USPQ2d 1812, 1818-19 (Fed. Cir. 2002)). As this court has explained,

by examining relevant dictionaries, encyclopedias and treatises to ascertain possible meanings that would have been attributed to the words of the claims by those skilled in the art, and by further utilizing the intrinsic record to select from those possible meanings the one or ones most consistent with the use of the words by the inventor, the full breadth of the limitations intended by the inventor will be more accurately determined and the improper importation of unintended limitations from the written description into the claims will be more easily avoided.

Tex. Digital, 308 F.3d at 1205, 64 USPQ2d 1820.

In this case, the term "flange" is not given a specific meaning in the intrinsic record. However, a dictionary definition is readily available: "flange, n. . . . 1. a raised or projecting edge, rib, or rim for strength, as in a T-rail; for guidance, as on a rail to keep wheels in place; for connection with some other object, as in some pipes; 2. a tool for making flanges." Webster's New Twentieth Century Dictionary, Unabridged 696 (2d ed. 1962). The specification and drawings of the '710
2. Flange

The patentee also uses the term "flange" throughout the claims of the reexamined 097 patent and specifically in asserted claims 11, 19-22, 24, 26-28, 31-40, 42. Again, the court begins with the ordinary meaning of "flange" as set forth in the dictionary. Webster's Universal defines "flange" in relevant part as, "a projecting rim, collar, or ring on a shaft, pipe, machine housing, etc., cast or formed to give additional strength, stiffness, or supporting area or to provide a place for attachment of other objects" or "a broad ridge or pair of ridges projecting from the edge of a rolled metal shape generally at right angles, in order to strengthen or stiffen it." Webster's Universal, Stant Ex. 103, p. 729. Similarly, the dictionary definition advanced by Gerdes states that a "flange" is "a rim or edge projecting at right angles, to provide strength or means of attachment to another part." Webster's Third New International Dictionary, Unabridged (1993) ("Webster's Third"), Gerdes Exhibits for Opening Markman Brief ("Gerdes Ex. ") 226.

To arrive at the definition of "flange" in this context, the court must refine these possible dictionary definitions in light of the patent's claims and specification. See Texas Digital Sys., Inc., 308 F.3d at 1205 (holding that by examining the dictionary definition of a term in combination with the "intrinsic record to select from those possible meanings the one or ones most consistent with the use of the words by the inventor, the full breadth of the limitations intended by the inventor will be more accurately determined and the improper importation of unintended limitations for the written description into the claims will be more easily avoided."). This is also precisely what the court in Warner v. Ford Motor Co., 331 F.3d 851 (Fed. Cir. 2003), did in arriving at the definition of "flange" as used in the context of the patent at issue in that case. In that case, the court determined that the proper definition of flange was a simple one -- "a raised or projecting edge." Because the patent at issue before this court is not the same as that in Warner, this court may not simply accept that court's definition, but must engage in a similar analysis to determine the meaning of "flange" as used in the context of the 097 patent and the reexamined 097 patent.

One of the refinements of the definition that Gerdes urges the court to adopt is to limit "flange" to only disc-shaped structures. Gerdes Br., p. 10. Nothing in the actual claim language clearly expresses an intention to so limit the definition. In support of its argument, Gerdes points to the specification and drawings of the 097 patent where the patentee uses only examples of disc-shaped flanges and describes the flange in the drawings using "disc portion" interchangeably with "flange." See 097 patent, Stant Ex. 1, figures 1, 3, 5; col. 2, 11. 41-43; col. 3, 11. 64-66. The drawings and references to the flange in the specification, however, are simply illustrations of the preferred embodiment of this invention. The fact that the patentee describes only disc-shaped flanges in the preferred embodiment does not prohibit the patent from covering other types of flanges. See e.g., Teleflex Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1328 (Fed. Cir. 2002) ("To the extent that the district court construed the term clip' to be limited to the embodiment described in the specification, rather than relying on the language of the claims, we conclude that the district court construed the claim term clip (28)' too narrowly."). The court sees nothing in the actual claim language that indicates the clear intention of the patentee to have these limitations read into the definition of the flange claimed in the actual claims. Thus, the court may not import this limitation. See Liebel-Flarsheim Co., 358 F.3d at 906-07 (listing cases in which the court found specific reason in the patent's specification to restrict the claim to only what was described in the preferred embodiment); Texas Digital Sys., Inc., 308 F.3d at 1204-05.

Under its ordinary meaning, the word "flange" may consist simply of an edge that functions as a flange. Webster's Third, Gerdes Ex. 226. Throughout the specification and claims, the patentee refers to the first and second "flanges" generally without any indication that he or she intended the term include any particular design for the flange. The preferred embodiment, as described in the specification and depicted in the figures, includes only one type of flange -- the disc-shaped structure with an upper, lower, and outer edge -- as stated above, although the court cannot not simply import these
On the structure of the flange into the claims without finding that the patentee intended this outcome. See Liebel-Flarsheim Co., 358 F.3d at 906-07. Thus, although the court finds that it is important to include an edge as a possible flange structure along with rim, collar, or ring, the court finds that logically even an edge must still include boundaries -- that is, an upper, lower and outer surface. This finding does not, however, limit the structure of the flange in any way -- it is a projecting rim, ring, collar, or edge -- other than by requiring it to include its outer boundaries made up of an outer, lower, and upper edge.

One of the dictionary definitions for the word "flange" includes the requirement that the rim or edge projecting from the other structure be attached at a right angle. It is clear to the court that if the definition of "flange" included attachment at a right angle, that Claim 19's requirement that the two flanges be "substantially parallel" would be meaningless because two flanges attached to the same structure at right angles will always be parallel. Reexamined 097 patent, col. 2, 11. 20-22. Under the doctrine of claim differentiation, this outcome should be avoided. Comark Communications, 156 F.3d at 1187. Further, nothing in the specification dictates that any particular attachment angle be included in the definition of the word "flange." Thus, the court finds that the dictionary definition of "flange" which includes the requirement of attachment at a right angle is not consistent with the definition of the word that the patentee intended in the 097 patent and therefore the court will not use this definition either. See Waner, 331 F.3d at 854 (finding that because one dictionary definition "most adequately represents what the inventor intended to claim in his invention," the court began with that definition rather than another).

From this discussion, the court concludes that in the context of the 097 patent and the reexamined 097 patent, the term "flange" means: a projecting rim, ring, collar, or edge attached to a structure to provide additional strength, stiffness, or supporting area or to provide a place for attachment of other objects.

1623

a. "rim connecting flanges"

The parties agree that Claim 7 is an independent claim that requires outward facing connecting flanges as the means for connecting. The parties again dispute, however, whether Plaintiff's modifier "short" is appropriate. For the reasons stated above in section (III)(A)(1)(c), the court finds that Plaintiff fails to support its argument that the connecting means must constitute only short flanges.

1624

3. "the flanges are located behind the studs to further secure the auxiliary frame to the primary frame"

Defendant objects to the magistrate judge's proposed construction of this element. As set forth above, the magistrate judge recommended that "the flanges are located behind the studs to further secure the auxiliary frame to the primary frame" should be construed as "the flanges are located behind the studs to further secure the auxiliary frame to the primary frame, either through contact or magnetic attraction between the magnetic materials within the flanges and studs." Report and Recommendation at 20. The magistrate judge rejected Defendant's proposed claim construction, namely, that "the flanges are located behind the studs to secure the auxiliary frame to the primary frame in addition to the support provided by the stud and the securing provided by the magnetic force." Under Defendant's proposed construction, the flanges themselves would provide a mechanism for securing the auxiliary frame to the primary frame, which would operate independently of the studs and magnetic materials.

Defendant argues that the magistrate judge's proposed construction is incorrect because: (1) it eliminates the requirement of Claim 12 that flanges "further secure" the auxiliary frame to the primary frame; (2) the patent requires that the flanges contact the studs to "independently" secure the frames together; and (3) the flanges operate independently of the magnetic materials. See Def. Obj. at 11-14.

The court overrules Defendant's objection. According to Defendant, because Claim 12 already requires that the magnetic
materials of the flanges and studs engage to secure the auxiliary frame to the primary frame, "it makes no sense to 'further secure' the frames by 'magnetic attraction between the magnetic materials within the flanges and studs.'" Def. Obj. at 12. The court rejects Defendant's contention that the magistrate judge's recommended construction has the flanges "performing the same function twice." See id. The patent discloses that by locating the downwardly extending flanges behind the studs, the flanges provide a "hook means" to further secure the auxiliary frame to the primary frame. "747 Patent, col. 2 lines 61-65. As Plaintiffs correctly argue, "the element the magistrate construed requires the flanges be 'located behind the studs to further secure the auxiliary frame to the primary frame.'" Pl. Resp. at 12 (original emphasis). The requirement that the magnetic materials of the flanges and studs secure the frames together does not speak to the location of the flanges with respect to the studs; the magistrate judge's recommended construction concerns the claim element that does speak to where the flanges are located relative to the studs to facilitate the back-mounting connection. Id. Accordingly, the court rejects Defendant's argument that the magistrate judge's recommended claim construction somehow results in the flanges performing the same function twice.

The court further rejects Defendant's argument as another attempt to read out of the patent the inclusion of magnetic material. The magistrate judge's construction properly reflected her rejection of "Defendant's contention that the mechanism by which the flanges secure the auxiliary frame to the stud of the primary frame is necessarily by contact between the flanges and studs." Report and Recommendation at 19. In support, the magistrate judge noted that Claim 12 indicates that the flanges and studs include magnetic materials, and that it is these magnetic materials, rather than the flanges and studs themselves, that engage to secure the frames. Also, as set forth previously (see supra), the magnets in the flanges and studs may engage through magnetic attraction without actual contact. Once again, Defendant does not point to any language in the claim or specification requiring contact.

Cone, Nose, Flank, and Shoulder Region

Claims in the '249, '715, and '631 Patents contain the terms "cone" or "cone region," "nose" or "nose region," "flank" or "flank region," and "shoulder region." The parties dispute whether these regions extend around the circumference of the drill bit face or are limited to the blades of the drill bit face. The parties further dispute the construction of these regions with respect to each other. Whether the Regions Extend Around the Circumference of the Drill Bit Face

Baker Hughes contends "cone," or "cone region," means "the area or region extending around the entire circumference on the drill bit face and which is located radially closest to the centerline or longitudinal axis of the drill bit body (and which is shaped more or less like an inverted cone)." Baker Hughes proposes similar constructions for the other claim terms and contends these regions extend around the entire circumference of the bit face.

ReedHycalog contends "cone," or "cone region," means the "region, defined by the blades of the bit, radially between the nose and the center longitudinal axis of the bit." ReedHycalog proposes similar constructions for the other claim terms and claims these regions are defined by the drill bit blades and do not extend around the entire circumference of the bit face.

The specifications of the '249, '715, and '631 Patents support a construction that limits the "cone," "nose," "flank," and "shoulder" regions to the blades. The '249 and '715 Patents refer to the "cone," "nose," "flank," and "shoulder" regions as being regions within the bit profile. '249 Patent col. 5:66-col. 6:1; '715 Patent col. 9:34-39. As the blades define the bit profile, and each of these regions are located in the bit profile, the blades likewise define the "cone," "nose," "flank," and "shoulder" regions.

Second, figures in the '249, '715, and '631 Patents confirm that these regions are limited to the area defined by the drill bit blades. Fig. 10 of the '249 and '715 Patents, displayed in Appendix C and annotated, shows the "cone," "nose," "flank," and "shoulder" regions along the bit profile. Fig. 13 of the '715 Patent, a quarter-sectional side view of the three-region embodiment of the claimed drill bit, similarly shows the disputed regions along the bit profile. '715 Patent Fig. 13. Figs. 14A and 14B of the '631 Patent, reproduced in Appendix C and annotated, show the "cone," "nose," "flank," and "shoulder" regions on the blades of the drill bit. While Fig. 14C of the '631 Patent, annotated and shown in Appendix C, tends to support Baker Hughes's contention that the "cone region" extends circumferentially around the drill bit, the above intrinsic
evidence more clearly shows that this region, in addition to the "nose," "flank," and "shoulder" regions, is limited to the drill bit blades. Thus, the Court construes these terms to only extend on the blades of the drill bit.

Radial Location of Each Region With Regard to Other Regions

Baker Hughes and ReedHycalog additionally dispute the definition of each region on the drill bit in relation to the other regions. In short, Baker Hughes defines "cone" as "... located radially closest to the centerline or longitudinal axis of the drill bit body ..." and subsequently defines "nose" as the area or region radially between the cone and the "flank," which includes the leading most point on the drill bit body. Similarly, Baker Hughes defines "flank" as the area or region radially between the "nose" and the "shoulder" or "gage," and "shoulder region" as the area or region radially between the "flank" and the "gage," although in a given drill bit, the "flank" and "shoulder" regions may be the same part of the bit.

ReedHycalog's constructions are similar, except that ReedHycalog starts with the "nose," which it construes as "extending radially and proximately about the leading-most point." ReedHycalog defines "cone" as the region radially between the "nose" and the longitudinal axis of the drill bit body, "flank" as the area or region radially between the "nose" and the "shoulder region," and the "shoulder region," and the "shoulder region" as radially proximate the "gage."

* * *

Flank

The parties propose nearly identical constructions of "flank" and "flank region." Baker Hughes contends the "flank" is radially less distant than the shoulder or gage regions. ReedHycalog contends the "flank" is located radially between the "nose" and "shoulder region."

The '631 Patent specification states that, as understood in the art, the "shoulder region" will often incorporate the "flank region." '631 Patent col. 19:60-66. The '715 and '631 Patents, in their Summary of the Invention sections, also describe the present invention in terms of cutters located in the "nose," "shoulder," and "cone" regions without mention of the "flank" region. '715 Patent col. 5:65--col. 6:1-6; '631 Patent col. 5:37-43. However, the '249, '715, and '631 Patents only disclose embodiments of the invention that include a "shoulder" or "shoulder region" radially between a separate, disjoint "flank" region and the "gage." '249 Patent Fig. 10, col. 5:59--col. 6:2; '715 Patent, Figs. 10, 13, col. 9:35-39, col. 12:55-63; '631 Patent, Figs. 14A, 15A, 15C, 16, 17, col. 19:60-65.

Despite the more limited embodiments, the language in the '631 Patent shows that whether the "flank" is its own region or incorporated within the "shoulder region," the "flank" region is always radially between the "nose" and the "gage" of the drill bit. The '249, '715, and '631 Patent disclosures are consistent with this result, even if the embodiments only show the "flank" and "shoulder" regions as separate and adjacent.

Accordingly, "flank" and "flank region" mean "region defined by the blades of the bit, located radially between the nose and the gage regions, labeled 234 in Fig. 10 of the '249 and '715 Patents." 8

8 Ref. No. 7 of Appendix B contains the disputed terms and their construction.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
a central recessed portion, and a base portion,

said shoulder portion being located above said central recessed portion and including a top wall having an opening therein,

said base portion being located below said central recessed portion and including a bottom wall,

said shoulder portion including a sidewall portion of circular periphery having a first predetermined outside diameter measured perpendicularly from said central longitudinal axis,

said central recessed portion including a smooth continuous oval sidewall having a major outside diameter and a minor outside diameter, said major outside diameter being less than approximately 2 inches (50.8 mm) and the same dimension as said first predetermined outside diameter measured perpendicularly from said central longitudinal axis, said minor outside diameter being approximately 1 inch (25.4 mm) measured perpendicularly from said central longitudinal axis,

said opening having an ink applicator mounted thereon for receipt of ink from the interior of said bottle,

said central recessed portion of said body merging with said sidewall portion of said shoulder portion at an upper flared surface, said upper flared surface being shaped to comfortably receive the thumb and index finger of one hand of a person to enable the person to hold said bottle so that said minor axis of said recessed portion of said bottle is located within the crook formed between the person's thumb and index finger to enable said bottle to be readily inverted to orient said applicator downward.

--- Footnotes ---

1. Claim 1 has been separated into segments for purposes of clarity.

--- End Footnotes ---

4. The parties agree that all of the elements contained in Claim 1 of the ‘681 patent are found in the Stuart bottle, with the exception that Stuart contends that its bottle does not contain an "upper flared surface" that is shaped "to comfortably receive the thumb and index finger of one hand of a person," as Stuart construes those terms. ‘681 patent, Col. 5-6.

5. The parties have agreed that the only aspect of Claim 1 of the ‘681 patent that requires interpretation is the reference to the term "flared". No other part of Claim 1, and no other claims, require interpretation.

6. The term "flared" as used in Claim 1 of the ‘681 patent is interpreted to mean "a surface that spreads outward" without any further limitation on that meaning.
by the intrinsic evidence found in the embodiment figures in the patent itself. In figure 10 seen below, it shows a concave surface where the end cap (114) meets the valve component (144). Therefore, according to Plaintiffs, any construction that requires the end cap to be perfectly smooth or without planar alteration is contrary to the patent and would exclude embodiments disclosed in the specifications.

Defendants contend the term "flat" should mean without projections or indentations and cite dictionary definitions in support. In figure 8 as seen below, Defendants contend the embodiment shown clearly supports Defendants' construction as the outer surface of the outer end cap at 114, is a smooth surface free of protrusions. Also, in other claims contained in the 537 patent, Plaintiffs included language indicating when a projection extended from a flat surface. No such descriptor is found in claim 12. Therefore, the Court should not permit Plaintiffs' broad interpretation of the plain term "flat".

The Wix Court held that the term "flat" was easily understood per common usage and construed the term as "flat means flat". Relying on dictionary definitions and common parlance including the Oxford English Dictionary which defined flat as "Of a surface: Without curvature, indentation, or protuberance; plane, level," and Merriam-Websters definition of "flat" as:

"having a continuous horizontal surface b : being or characterized by a horizontal line or tracing without peaks or depressions; having a relatively smooth or even surface; arranged or laid out so as to be level or even; having the major surfaces essentially parallel and distinctly greater than the minor surfaces."

The Court's Construction

The Court sees no reason to depart from the Wix Court's interpretation. Flat as a descriptor carries no loaded meanings. The Court holds "flat" means "flat" as construed by the Wix Court.

1. Flat

Claim 5 describes the patented device as "a flat and rectangular shaped member." The parties dispute the construction of the term "flat." Plaintiff argues it should be construed to mean "providing an essentially horizontal surface when laid out for use." Pl. Brief on Claim Construction at 9. Plaintiff points to Webster's Third New International Dictionary for support, citing its definition as "horizontal or nearly so and without significant curvature or inclination [and capable of being] arranged or laid out so as to be level, smooth or even." Id. at 10. Defendants argue the construction of "flat" should be "characterized by a horizontal line or tracing without peaks or depressions," Def. Claim Construction Chart at 1, or "completely flat," Def. Mem. in Support of Proposed Claim Construction at 17. There was little debate about the term "flat" during the Markman hearing. Tr. at 9-10. This Court will construe the term "flat" as having a surface which is "horizontal or nearly so without significant curvature or inclination and without noteworthy elevations or depression," level, smooth, or even. Webster's Third New International Dictionary, Unabridged 865 (1969).

Plaintiff contends that there is a disputed issue of material fact over whether removal of the post left behind a flat surface for polish securing. Through the affidavit of his patent attorney (presumably testifying as an expert as to the ultimate issue in the case), plaintiff contends that the Birthstone Heart is not flat, but concave, and is secured to the fingernail only at either end of the bow connector--not all the way across--which renders it far less able to withstand a slight pull while breaking free if the adornment snagged in someone's clothing.

Plaintiff is incorrect. Exhibit 18 offered in support of the motion for summary judgment, and marked as Exhibit 4 to the Deposition of Marlene Sortino, the publisher of the Snails catalogue, is a Birthstone Heart, complete with gold-plated bow connector, with the post removed. It is attached to an artificial fingernail in the "Polish Secure" mode. The connector does not simply adhere to the nail at either end, but is glued firmly to the tip of the artificial nail from one side to the other, with absolutely no gaps. Furthermore, the connector is glued across the very tip, the end, of the nail -- not down the middle of the
nail from tip to cuticle, as plaintiff's expert suggests it would have to be worn. Thus, contrary to the suggestion (made without any evidentiary support) in plaintiff's opposition papers, the adornment does indeed "dangle" from the nail, ready to catch on anything passing by and snap it.

Moreover, having seen the evidence first-hand, I can only conclude that proposed statement of material fact 16 is correct, and that the removal of the post from the underside of the gold-plated bow connector does indeed leave behind "a flat surface for polish securing . . . ." The determination of what a word in a patent claim means presents a question of law. That question, as with any question of claim construction, can be determined only by resort to "intrinsic" evidence -- i.e., the language of the patent claim; the specification of the patent and the prosecution history of the patent. Expert testimony (as from plaintiff's patent attorney Mr. Amer) about the meaning of a particular word in a patent is not admissible. See, e.g., Endress + Hauser, Inc. v. Hawk Measurement Sys. Pty. Ltd., 122 F.3d 1040, 1042 (Fed. Cir. 1997).

The word "flat" is used in the patent claim as part of the description of the connector ("... said connector having a flat base adhesively connected to said fingernail . . . "). but the word "flat" does not appear in the patent specification (the text and drawings of the patent). (See Ex. A attached to Complaint). Therefore, the term is to be given its ordinary meaning. See York Products, Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996). As defendant correctly notes, the word "flat" has two common meanings -- either "a continuous surface that is horizontal or nearly so, without significant curvature" or "having a smooth or even surface, whether horizontal or not." (See Defendant's Reply Brief, pp. 8-9.) The patent's file wrapper is apparently silent about which of those two definitions plaintiff had in mind (if either), but since fingernails have some curvature to them, and an item of sufficient size could not be made to adhere at all points unless it displayed some modest curvature as well, it would appear to this court that the "smooth or even" definition is the more logical of the two. Of course, plaintiff's connector (which can be seen in Exhibit 19 in support of the motion) is considerably smaller than the gold-plated bow connector, so even though it has a flat (in the horizontal sense) bottom, it can be made to adhere to a naturally curved fingernail: However, there is nothing in the claimed invention that limits the size of the connector attachment element. A larger connector (like the bow connector) falls just as surely within the scope of the claimed invention as does a tiny connector (like plaintiff's). Therefore, the word "flat" as used in the '989 patent claim necessarily encompasses the "smooth or even surface" definition.

I therefore conclude that there is no competent evidence in the record to support any conclusion that there remains a genuine issue of fact; that removal of the post from the Birthstone Hearts connector does indeed produce a flat surface in the sense of "a smooth or even surface, whether horizontal or not"), that adheres to a fingernail at all points, not just at the ends. If the surface were not flat (in the dictionary definition sense of "a smooth or even surface, whether horizontal or not" (see Webster's Third New International Dictionary (1969 ed.)), then it would not be possible for every square centimeter of it to adhere to a fingernail when attached thereto with an adhesive. But Exhibit 18 in support of the motion leaves no doubt that the underside of the gold-plated bow is quite capable of doing just that. Thus, proposed undisputed material fact No. 16 is accepted by this Court as an undisputed fact.

1630

III.

The district court found "the idea of flat, coplanar supporting surfaces was not only essential, but pivotal to the patent claim." Iscar, slip op. at 24. Further, the trial court concluded that Iscar's products did not meet the "flat and coplanar" claim limitation because the insert-supporting surfaces on those products were not ground. The district court relied particularly on Sandvik's efforts to differentiate its invention from the prior art during prosecution by labeling its insert-supporting surface portions as flat and coplanar. In the same submission to the Patent and Trademark Office (PTO), Sandvik also noted that, to ensure the invention supports the insert in a precise position relative to a workpiece, "the edge surface portion of the insert is typically ground to provide as flat a profile as possible." Echoing these statements, the district court concluded: "The full meaning and scope of the '679 claims . . . was to patent an insert which was flat and coplanar, made so typically by grinding." This recitation captures accurately the importance of the "flat and coplanar" element, and also describes a process by which flatness might "typically" be achieved, but does not offer a meaning for "flat and coplanar." Notwithstanding this ambiguity in its understanding of the "pivotal" element of the claim, the district court concluded that Sandvik did not show that Iscar's inserts are flat and coplanar. To determine whether Iscar's inserts satisfy the limitation, however, this court must address the central question: how flat is "flat"?
The meaning of "flat and coplanar" in the context of the insert-supporting surface portions of the '679 patent depends primarily on intrinsic evidence, i.e., the patent itself and its procedural history. See Markman v. Westview Instruments, 52 F.3d 967, 979, 34 U.S.P.Q.2d (BNA) 1321, 1329 (Fed. Cir. 1995) (en banc), aff'd 517 U.S. 370, 38 U.S.P.Q.2d (BNA) 1461, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The '679 patent claims do not expand on "flat and coplanar" in the required context of the claim's "insert-supporting surface portions." A preferred embodiment of the invention has a surface portion "formed by grinding of the cutting insert" '679 patent, col. 3, ll. 38-39, but a preferred embodiment does not necessarily constrain the meaning of claims. See Application of Phelps, 422 F.2d 1360, 1363, 57 C.C.P.A. 971, 974 (1970) ("Appellants may not read into claims limitations not expressed therein although emphasized in the specification.").

The summary of the invention in the specification states:

In a process aspect of the invention, a powder is pressed to form an insert body having . . . at least one edge surface . . . . The press-formed body is then sintered. Finally, the edge surface is ground . . . .

'679 patent, col. 2, ll. 12-19. The import of this statement depends on a full understanding of the patent's procedural history. This statement is a remnant of the original patent application, which was, at the behest of the examiner, divided into separate process and apparatus patents. The process patent - issued as U.S. Patent No. 5,356,805 - included the process step of grinding the edge surface in its claims. The patent at issue here is an apparatus patent that includes no such claim limitation. Thus, this statement from the summary of the invention does not necessarily limit the meaning of the apparatus claims.

In addition, the prosecution history of the '679 patent notes that grinding is typically used in the fabrication of these inserts. "Typically" is an additional indication that the patent did not necessarily limit the apparatus claims to surfaces produced by grinding. The district court's definition of "flat and coplanar" as "flat and coplanar and produced by grinding" impermissibly reads, therefore, a limitation from the specification into the claim.

Further, the meaning of "flat" in the context of the '679 patent requires recourse to the prosecution history. The inventor introduced the "flat and coplanar" limitation into his claim in the amendment to his application which finally resulted in the issued '679 patent, in order to differentiate his invention from that of Erkfritz in U.S. Patent No. 4,294,565. In his remarks to the PTO, the inventor contrasted his invention with that of Erkfritz, asserting that "the surfaces 32, 32 disposed on respective sides of the flat 30 in Erkfritz are neither flat nor coplanar, nor do they support the insert in the tool holder." Indeed, the surfaces 32, 32 in the Erkfritz patent are curved, with a radius in the illustrated embodiment of about one-eighth of the side of the cutting insert. The inventor of the '679 patent also mentioned that the edge surface portion of the insert must abut a surface of the tool in such a way as to support the insert "in a precise position relative to the workpiece. For that reason, the edge surface portion of the interface is typically ground to provide as flat a profile as possible." This history provides an excellent context to understand the meaning of "flat." As used in these statements, "flat" in the amended phrase "flat and coplanar" meant, at the time of its addition to the patent, "not curved," and also "sufficiently flat to support the insert in a position relative to the workpiece that is sufficiently precise for the designer's purpose." Because in that context, "flat" must have the meaning it carried at the time of its addition to the patent, the district court erred by narrowing the meaning of this limitation to an overly restrictive meaning of "flat," and by adding the requirement of grinding to achieve flatness.

GO BACK

1631

10. "flat apex"

The phrase "flat apex" is found in claims 59-60, 62-63, 65-66, 68-69, 71-72, and 74-75 of the '037 Patent, and claims 17, and 19-25 of the '255 Patent. Plaintiffs contend that the phrase should be construed to mean "highest or uppermost surface that is horizontal or nearly so without significant curvature or inclination and without noteworthy elevations or depression," while defendants and the intervenor contend that the phrase should be construed to mean "an apex that is not curved or rounded."

Preliminarily, neither party disputes that the ordinary meaning of "flat apex" should control, even though they submit
differing dictionary definitions of "flat." Plaintiffs' definition construes "flat" as "horizontal or nearly so without significant curvature or inclination and without noteworthy elevations or depressions," while defendants' definitions construe "flat" as a "horizontal face without a slope, tilt, or curvature," or "without peaks or depressions." See Pls. Op. Br. at 30:9-16; Defs. Opp. Br. at 33:7-16. The parties' critical dispute, based on these definitions, is whether "flat" should be construed as allowing for any curvature. Plaintiffs contend that a "flat apex" should be construed to allow for insignificant curvatures, while defendants and the intervenor reject this contention. Given the differing definitions, the court will look to the intrinsic evidence for guidance as to which ordinary meaning should control.

Beginning first with the claim language, it clearly contrasts apexes that are "flat," from those that are "rounded." Claim 68 of the '037 Patent, for example, covers a stent design wherein "one of the first wall and the second wall has a flat apex and the other of the first wall and second wall has a rounded apex." See Joint Statement, '037 Patent at 18:34-36. It is obvious, therefore, that "flat" and "rounded," described in opposition to each other within the same claim, must have differing meanings. "Flat" cannot mean "rounded," and vice versa. And since neither party appears to dispute that "rounded" would be defined to include curves, this implies that "flat" should be construed as neither curved nor rounded.

The specification language also describes "flat" in opposition to either "curved" or "rounded," further implying that a "flat apex" should be construed as one that is neither curved nor rounded. See id. at 4:7-9 (noting that, in the "present invention," the flexure means comprises at least one lateral section, the "apex" of which "may be pointed, rounded, or substantially flat"). Moreover, the specification goes on to describe, with reference to the illustrated figures of the '037 Patent, what a "flat apex" looks like. In discussing Figure 1A, for example, the specification notes that "segment 54 is a flat apex and results in the provision of a pair of substantially square shoulders." Id. at 8:46-48. Turning to segment 54 on Figure 1A, it is depicted as a flat horizontal apex, with no curvature, significant or otherwise. Similarly, in discussing the illustration of an apex depicted in Figure 2, the specification states that "the flat apex in concave-shaped wall 150 has been modified such that it comprises a pair of substantially rounded shoulders." See id. at 9:35-38. Viewing Figure 2, segment 150 is still depicted as a flat horizontal apex, without curvature. The difference, however, is that the shoulders on either ends of the apex are now depicted as curved, or rounded. As illustrated, therefore, the presence of curved or rounded shoulders in no way changes the depiction of a "flat apex" as having no curvature, or rounding itself.

In sum, then, both the claim language and the specification support defendants' and the intervenor's proposed construction that a flat apex is an apex that is neither curved nor rounded, whether significantly or not. The court therefore adopts defendants' and the intervenor's proposed construction and construes "flat apex" as: "an apex that is not curved or rounded." The court declines to rely on the Declaration of Jeffrey Allen because the proper construction can be determined here with reference to the intrinsic evidence -- i.e., the claim language and the specification.

6 The '575 Patent uses the term "flat car" in a way that is consistent with the term's ordinary meaning. Claims 1 and 2, for example, claim a "flat car supported on end truck assemblies." The truck assemblies in the '575 Patent contain the parts of the rail car that support the flat car such as the center sill, side sill, and draft sills that are main structural pieces of the rail car's underframe. The wheels of the rail car are also in the truck assemblies, and the wheels also help support the rail car. The '575 Patent also does not include in the claims or in the specification any structures that could be construed as sides, ends, or a roof.

In describing the prior art in standard center beam flat cars, the '575 Patent discusses how standard center beam flat cars
carry lumber and other construction material and that the invention in the '575 Patent is designed to carry these same materials. Lumber and other construction materials are commodities not needing protection from the weather. See Findings of Fact, PP 111-112, 119, 122, 125-136, 139-142.

B Flat contact

Ameritex argues that flat contact, which is used in independent claims 31 and 35, requires unbroken contact between a flat surface of the mounting member and the flat boat deck. 6 Dependent claim 19 in patent 449 and dependent claim 2 in patent 410 describe the contact between the lower portion and the boat deck as continuous flat contact. Independent claims 31 and 35 describe this contact as substantially continuous flat contact. Independent claims 26 and 41 describe this contact as substantially continuous contact.

--- Footnotes ---

6 Ameritex's mounting member shifts on round pivots. The mounting member is not secured through the flat sections on the lower portion.

--- End Footnotes ---

Independent claims 26 and 41 leave out the term flat from the description of the type of contact made between the lower portion and the deck, but the context of the claims do not indicate a difference between flat contact and continuous contact.

The specification states that the lower portions of the prior art did not allow the mounting member to maintain "flush continuous contact" with the boat deck (449 patent, col. 1, ll. 33-35) and that the present invention allows the mounting member to maintain "continuous flush contact without gaps between the mounting member and boat deck throughout the length of the member." (449 patent, col. 2, ll. 15-17). In the next sentence, the specification rephrases flush contact as an "edge or line contact." 449 patent, col. 2, ll. 20-23.

In the description of figures 2 and 3, the specification refers to the contact made by the circular lower portion and boat deck as "line contact" and states that the arcuately spaced openings allow the mounting member to remain flush with the deck without any gaps. 449 patent, col. 4, ll. 39-40 and col. 5, ll. 39-47.

The extrusion illustrated in figure 4 has a lower portion consisting of a flat section and an arcuate outer section. When describing the contact between the flat section of the lower portion and the boat deck, the specification, uses the term "flush contact." 449 patent, col. 6, ll. 13-14. When describing the contact between the arcuate outer section and the boat deck, the specification uses the term "continuous line contact." 449 patent, col. 6., ll. 16-18. Finally, when summarizing the description and drawings, the specification states that the "present invention provides methods for mounting a curved windshield to a flat boat deck wherein flush contact between the mounting member and the deck is provided." 449 patent, col. 6., ll. 23-25.

In the prosecution history, the examiner rejected independent claim 48 as reading on Loxcreen 5923. Examiner action dated January 21, 1988, P 4. The revised claim 48 included the limitation, among others, that the lower portion maintained "continuous flat contact" throughout the length of the member. Amendment dated January 26, 1988, p. 2. However, this amendment does not indicate that flat contact provides a limitation in addition to the flush, edged, line, or continuous contact described in the other claims and in the specification.

"The claim construction that stays true to the claim language and most naturally aligns with the patents description of the invention will be, in the end, the correct construction." Nystrom, 424 F.3d at 1142. Flat contact is not distinguished by the claims, is not mentioned by the specification, and is not referenced in the prosecution history. Consequently, the best construction to give the phrase is the meaning given to the only contact described in the patent document, which is contact without gaps and no requirement that the contact is between two flat surfaces as is suggested by Ameritex.
We agree with the Special Master's conclusion that the term "flat leading edge" as used in the patent claims and the specification requires only a flat top surface of the leading edge of the skimming device.

First, the language of the claim itself suggests that cross-sectional flatness is not claimed because the term is "flat leading edge," the adjective "leading" indicating a structure that is particularly positioned in regard to its purpose. Thus, there is support in the claim language that a forward motion is relevant in determining which surface of the leading edge must be "flat." Claims 2 and 5 provide that the leading edge is placed "in substantial parallel relationship with the surface level of the water." This limitation must refer to placing the slurry flowing over the front of the edge so that a uniform amount of water and eggs can be skimmed. It therefore also supports the view that the top surface of the leading edge must be "flat" or "level" because the relevant point of view is where the edge is placed in relation to the incoming slurry. Similarly, claims 1, 5, and 8 require that the flat leading edge be positioned under water "to collect" the slurry, and claim 20 requires that the leading edge "divide off suspended brine shrimp eggs at the surface of the water for delivery into the channeling structure," again indicating that the forward motion of the water is the relevant perspective to evaluate "flatness."

Additionally, the specification refers to the "flat leading edge" as the "forward receiving end" of a "concentrating funnel" or a "skimming device." It states that a slurry mixture is received at the leading edge, which "divides and separates the layer of eggs from the rest of the salt water body," so that the slurry mixture is "collected at the leading edge and falls into the funnel cavity." Thus, at most the specification places a limitation on the meaning of "flat that is functional -- that the edge must be flat to skim the brine eggs off the surface of the water. Any straight edge in the plane parallel to the eggs -- a horizontal plane - - would produce a flat edge in this sense, meeting that limitation regardless of whether it was or was not also "flat" in its cross-section. Placing a limitation that the edge is flat in cross-section appears to go beyond what the claims required with the term "flat leading edge."

Additionally, we find nothing in the prosecution history that would require or even suggest that cross-sectional "flatness" is required. The CIP patent explicitly treats the phrase "flat leading edge" as comparable in scope to the "flat receiving lip" discussed in the parent application. Also, Figure 2 in the parent and CIP applications is an identical drawing of a rectangular, pan-like skimmer, as an example of a specific embodiment of the claims.

Finally, SLB argues that "flat" means having a smooth, flat surface and that its devices which stretch material over a cylindrical pipe to form the edge cannot therefore infringe. However, SLB does not adequately address the emphasis the claims and specification place on the orientation of the edge. Thus, as long as the edge is "flat" in terms of the flow of the shrimp eggs and water, the patent does not appear to describe what the cross-section of the "lip" or edge must look like.

**Sub-element 1.** A base plate with a flat, leading edge at forward end of the channeling structure

BAI argues that a "flat" leading edge must be horizontal, i.e., parallel to the water surface. 25 This court rejects this asserted limitation, and interprets a "flat" surface to mean "relatively smooth or even." Merriam Webster's Collegiate Dictionary, (Tenth Edition), 1993, at 443. BAI's interpretation, coming from an extrinsic source (the dictionary) cannot be used for the purpose of varying or contradicting the terms of the claims. Markman, 52 F.3d at 980-81, 34 U.S.P.Q.2D (BNA) at 1330. Interpreting flat to mean a relatively smooth or even surface, as opposed to requiring the surface to be horizontal, finds more support in the specification. The flat, leading edge, feature 45 of figure 2, discloses a relatively smooth or even surface. "The flat receiving edge 45 is attached a [sic] the forward receiving end of the funnel and is adapted for positioning and use immediately below the surface of the water and the entrained eggs which are to be withdrawn." Col. 6, lines 29-31 ('062
The disclosure emphasizes the importance of skimming the entrained eggs and an appropriate amount of water to create the slurry mixture. The flat, or relatively smooth or even leading edge serves this purpose. Therefore, this court interprets "flat" to only require a relatively smooth or even leading edge which enables the harvesting device to skim or extract brine shrimp eggs from the surface of the water.

25 BAI cites the Random House Unabridged Dictionary, defining "flat" as "horizontally level." Furthermore, BAI relies heavily on a position taken by Sanders in the Salt Lake Brine Shrimp litigation which appears to support their definition of flat. However, claim interpretation is a matter of law, and since judicial estoppel is not followed in the Tenth Circuit, this court declines to force Sanders to adhere to this definition. See, section II.A. of this opinion.

Furthermore, even if this court were to adopt interpretations of the word "flat" made by this District Court and the Federal Circuit, the Federal Circuit did not limit its definition of flat to requiring the leading edge to be horizontal: "the term 'flat leading edge' as used in the patent claims and the specification requires only a flat top surface of the leading edge of the skimming device." Salt Lake Brine Shrimp, 1995 U.S. App. LEXIS 14255, *3. Finally, the specific language cited by BAI which requires the "flat" leading edge to be horizontal to the water surface is in reference to support for the definition of "flat" in claims 2 and 5, which require that the leading edge be placed "in substantial parallel relationship with the surface level of the water." Id. Therefore, the judicial conclusions in the Salt Lake Brine Shrimp litigation would support Sanders' definition of "flat" in this litigation to only require a flat top surface of the leading edge of the skimming device.

Furthermore, BAI's working platform was designed to be horizontal, but is slightly slanted because it was bent during operation and remains unfixed. This court doubts whether a device which would infringe as designed could escape infringement based upon its damaged condition.

5. Flat-Panel Display Device/ LCD Device

a. The Parties' Constructions

LPL argues that the "flat panel display device" is simply an apparatus with at least a flat display panel and supporting frames. Defendants assert that in the context of the invention, a "flat panel display device" includes a sandwich of layers or stack of components, including the flat display panel, held together or assembled by the first and second frames. ViewSonic further asserts that the stack of components are assembled along the edges. Defendants argue that the intrinsic record mandates such a construction and specifically point to the description in the common specification of an LCD device for support. n19 ViewSonic also submits that under LPL's construction, a portable computer would be a flat-panel display device, thereby rendering superfluous the non-asserted claims' term "portable computer."

For example, Defendants cite to the '641 patent, 1:42-45: "The LCD device 130 has an LCD panel 132, a backlight device 134 fixed to the back of the LCD panel 132, and a supporting frame 136 for assembling the LCD panel 132 and the backlight device 134 along the edge."

b. The Special Master's Constructions

Based on the express language of the claims, the Special Master does not adopt that portion of Defendants' constructions requiring multiple layers assembled or held together, along the edge or otherwise. The Special Master does agree with the Defendants, however, that the flat-panel display device includes the first and second frames.
The language of claims 55 and 56 provides a definition of flat-panel display device. '641 patent, 12:1-18. Tellingly, both claims recite that the flat-panel display device includes only three main elements, namely a first frame, a second frame, and a flat display panel disposed there between. Thus, to limit the flat-panel display device to one that includes multiple layers would be contrary to the claim language and would, in the Special Master's view, improperly read in the preferred embodiment of an LCD device. Mindful that other claims recite multiple layers, such as the backlight unit of claim 35 of the '641 patent, the Special Master adopts a construction that includes at least a flat display panel.

Additionally, the claim language further specifies that the flat display panel of the device is located between, or sandwiched by, the first and second frames. Claim 35 of the '641 patent recites, for example, that the "flat display panel is between the first and second frames." The claim term "between" does not require, however, that the panel and frames be assembled as Defendants argue. Instead the claim merely defines the location of the flat-display panel relative to the frames. The Special Master therefore concludes that requiring the frames and panel to be assembled, whether along the edges or not, improperly reads in the preferred embodiment from the common specification.

The term "LCD device," on the other hand, is specifically called out in claim 40 of the '718 patent. Because the language of claim 40 itself does not expressly define an LCD device, the common specification provides the best definition for that term. Phillips v. AWH Corp., 415 F.3d at 1315 (“The specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'”) (internal citation omitted). Referring to Figures 4A-4C, the common specification defines the LCD device as an LCD panel, a backlight unit, and a supporting frame. '718 patent, 4:17-21. Also, Figure 4C shows that the backlight unit 14 and the panel 12 are disposed between the frames 14g and 16.

Accordingly, the Special Master's constructions are as follows:

<table>
<thead>
<tr>
<th>CLAIM TERM</th>
<th>SPECIAL MASTER CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>flat panel display device</td>
<td>A display device having at least a flat display panel sandwiched by the first and second frames</td>
</tr>
<tr>
<td>liquid crystal display (LCD)</td>
<td>A display device including a LCD panel and a device backlight unit both of which are sandwiched by the first and second frames</td>
</tr>
</tbody>
</table>

THE PATENTED INVENTION

The invention of the '580 patent is described by Modine as a highly efficient and environmentally advanced condenser for use in automotive air conditioning. It is more compact, lighter, uses less refrigerant, outperforms prior condensers, and has the additional advantage of being usable with refrigerants other than chlorofluorocarbons. Modine states that it converted the entire industry to a new standard.

Claims 9 and 10 of the '580 patent, the only claims in suit, are shown with emphasis added to point out the two terms that are the focus of the infringement issues:

Claim 9. A condenser for a refrigerant in a cooling system comprising:

[1] a pair of spaced, generally parallel, elongated cylindrical tubes defining headers;

[2] a vapor inlet in one of said tubes;

[3] a condensate outlet from one of said tubes;

[4] said header tubes each having a series of elongated generally parallel slots with the slots in the series on one header tube aligned with and facing the slots in the series on the other header tube;
[5] a tube row defined by a plurality of straight, tubes of flat cross-section and with flat side walls and having opposed ends extending in parallel between said header tubes, the ends of said flat cross-section tubes being disposed in corresponding aligned ones of said slots and in fluid communication with the interior of said header tubes, at least some of said tubes being in hydraulic parallel with each other;

[6] web means within said flat cross-section tubes and extending between and joined to the flat side walls at spaced intervals to (a) define a plurality of discrete, hydraulically parallel flow paths within each flat cross-section tube that extend between said header tubes; to (b) absorb forces resulting from internal pressure within said condenser and tending to expand the flat cross-section tubes; and to (c) conduct heat between both said flat sides and fluid in said flow paths,

[7] said flow paths being of relatively small hydraulic diameter which is defined as the cross-sectional area of the corresponding flow path multiplied by four (4) and divided by the wetted perimeter of the corresponding flow path;

[8] serpentine fins incapable of supporting said flat cross-section tubes against substantial internal pressure extending between facing flat side walls of adjacent flat cross-section tubes;

[9] each of said flow paths including at least one elongated crevice extending generally along the length of the associated flow path.

Claim 10. The condenser of claim 9 wherein each flow path has a plurality of said crevices.

It is not disputed that all of the elements of the claimed invention have counterparts in the accused condensers, and that infringement turns on the meaning and scope of the terms "flat side walls" and "relatively small hydraulic diameter." Modine challenges the correctness of the Commission's claim interpretation and the ensuing finding of non-infringement.

II

INFRINGEMENT

As we have recently held, "because claim construction is a matter of law, the construction given the claims is reviewed de novo on appeal." Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321, 1329 (Fed. Cir.) (en banc), cert. granted, 116 S. Ct. 40 (1995). Disputes as to the meaning and scope of terms as used in the claims are determined as a matter of law, based on the patent specification and the prosecution history if it is in evidence. Id. at 979-80, 34 U.S.P.Q.2D (BNA) at 1329-30. As stated in Markman, "when legal 'experts' offer their conflicting views of how the patent should be construed, or where the legal expert's view of how the patent should be construed conflicts with the patent document itself, such conflict does not create a question of fact nor can the expert opinion bind the court or relieve the court of its obligation to construe the claims according to the tenor of the patent. This opinion testimony also does not change or affect the de novo appellate review standard for ascertaining the meaning of the claim language." Id. at 983, 34 U.S.P.Q.2D at 1333.

A. THE FLAT SIDE WALLS

The Commission, adopting the ALJ's Initial Determination, held that the term "flat side walls" means the interior walls of the condenser tubes, and that although the Showa side walls are flat in that they are not rounded, they are not "flat" because most (but not all) of the Showa models have fin-like projections on their interior surfaces. On this term construction the Commission concluded that the Showa tubes do not have "flat side walls" and therefore that the claims are not infringed by any of the Showa models.

Modine states that "flat side walls" describes the shape of the tubes, and refers to the '580 specification which describes the condenser tubes as "noncircular in cross section" and as a "flattened tube." Modine states that the side walls are flat whether or not they have fins on their inner surfaces, pointing out that the specification as well as the claims show fins on the outer surfaces as well as webs on the inner surfaces. Claim 9 mentions "flat side walls" in several clauses:
[5] a plurality of straight tubes of flat cross-section and with flat side walls . . .

[6] web means within said flat cross-section tubes and extending between and joined to the flat side walls . . .

* * *

[8] serpentine fins incapable of supporting said flat cross-section tubes against substantial internal pressure extending between facing flat side walls of adjacent flat cross-section tubes;

Clause [5] uses the word "flat" to describe both the cross-section and the side walls, but neither usage of "flat" requires that the interior or exterior wall surfaces be clear, without web or fin. Clause [6] requires a web "joined to" the interior flat side walls, negating the ALJ's reading that the wall surfaces must be clear. Clause [8] describes serpentine fins on flat side walls that are necessarily the exterior surfaces of the walls, contravening the ALJ's ruling that "flat side walls" means the interior walls.

The entirety of the claim's usage of flat side walls is consistent with the specification's description of the condenser tubes as "flattened" and "not circular." This plain reading is not affected by webs or fins on either the interior or the exterior surfaces of the walls, or by the crevices of claim 10. Indeed, a claim interpretation that would exclude the inventor's device is rarely the correct interpretation; such an interpretation requires highly persuasive evidentiary support, whereas in this case it received none, whether from the specification, the prosecution history, or the prior art.

We conclude that the term "flat side walls" means that the tube structure is flat, as the specification states, and does not prohibit the presence of fins, webs, or other attachments to either the interior or exterior surfaces. Those Showa tubes that bear inner fins (the 3mm models), and those that do not (the 2mm models), all have flat side walls as the term is correctly construed. This claim limitation is not a ground for a finding of noninfringement.

GO BACK

1638

1. Claim Construction

This Court now turns to Defendant Sashco's '014 patent, which describes a transparent squeeze tube that has a region of reduced thickness which allows the substrate to be viewed prior to application of the compound. The specific portion of Claim 1, the only independent claim, implicated in this case is the statement that "the compound in the region of reduced thickness has a substantially uniform, flattened configuration." Plaintiff argues that this requirement does not encompass its product, which is best described as a toothpaste-type squeeze tube. Defendant argues that its patent does extend to toothpaste-type tubes, similar to the product marketed by the Plaintiff.

As before, this Court will use the dictionary as a starting point for its analysis, focusing on the requirement that the caulking compound in the specified region have a "substantially uniform, flattened configuration." The term "flat" is defined as "having or marked by a continuous surface that is horizontal or nearly so without significant curvature or inclination." Webster's Third New International Dictionary 865 (unabridged 1976). The term "flattened" means "reduced to an even or more nearly even surface." Id. at 867. Therefore, a straightforward interpretation of this claim requires the slope or inclination of the tube to be noticeably reduced in this particular region, so that the surface of the tube (and the compound within it) becomes more horizontal and even. Accordingly, a toothpaste tube which does not have an appreciably "flattened" region, but which merely has an unchanging, tapered slope from one end of the tube to the other, will not fall within this patent's definition.

This interpretation of "flattened" is supported by specific language in the patent's specification, which describes this region as "a packet of caulking compound [having] a uniform dimensional thickness to facilitate preview of the caulking compound… [which] may be generally a rectangular pillow of caulking material… [which] allows the transparent facing sidewall portions to be oriented substantially parallel to one another to reduce distortion when the substrate surface is viewed." See also Figure 2 (demonstrating that letters of words may be viewed through this region of the product without significant distortion). These descriptions, taken either separately or together, indicate that the region of reduced thickness described in the patent is indeed intended to be "flattened" by having less of a slope (and, ideally, no slope) than the
remainder of the tube. Simply put, these descriptions do not describe a toothpaste tube.

Bearing this construction in mind, this Court now turns to an examination of the Plaintiff’s tube to determine if there exists a genuine issue of material fact as to whether this product infringes the Defendant’s patent.

Finally, claim 24 concludes:

(g) Flattening and applying the tissue flap to a recipient area larger than the area of the separated layer.

The parties agree that the tissue is to be applied to a recipient area larger than the original area. Nowhere in the patent does it appear that claim 24 must apply only to planar recipient areas. In the written description, it is noted several times that this method would be appropriate for breast mound reconstruction, a non-planar recipient area. Col. 1, lines 48-50; col. 7, lines 39-40. Therefore, “flattening” must, by implication, require the tissue to be placed onto the surface of the recipient area and the folds and wrinkles smoothed or flattened out.

Accordingly, the court finds this limitation to mean “smoothing and applying the differentially expanded tissue flap to a recipient area larger than the area of separated tissue.”

C. Flexible

Plaintiff’s proposed construction of the word “flexible,” as used in the claim element “a flexible shoulder guard,” is “capable of being bent or flexed.” (Pl.’s Br., at 11.) Plaintiff contends that “flexible” is a commonly understood word that can simply be construed in light of its dictionary definition: “capable of being bent, usually without breaking; easily bent.” WEBSTER’S ENCYCLOPEDIC UNABRIDGED DICTIONARY 733. According to Plaintiff, nothing in the specification or prosecution history of the ’226 Patent is inconsistent with this definition. (Pl.’s Br., at 12.)

TAG’s proposed construction of “flexible” is “made of plastic or other material that is able to bend without breaking.” (Def.’s Br., at 18.) TAG relies on the description of the shoulder guards in the preferred embodiment, which, as noted, states that the “flexible” shoulder guards are “preferably made of plastic or any other material that [are] sufficiently rigid to maintain a ‘U’ or ‘J’ shape but that [are] flexible enough for comfort.” (’226 Patent, col. 2, ll. 31-38.) TAG also points to the fact that during prosecution, the patentees differentiated their invention from the rigid Siemens protector for hockey goalies. (Def.’s Br., at 17.)

The court agrees with Plaintiff that “flexible” is a “commonly understood word[]” with a ”widely accepted meaning” that is “readily apparent.” See Phillips, 415 F.3d at 1314. Indeed, the ordinary meaning of “flexible” is so apparent, “even to lay judges,” that this appears to be a case in which the court may simply apply the commonly understood meaning, perhaps with the aid only of a dictionary definition. Id; see also Ormco Corp., 463 F.3d at 1306-07 & nn.5 & 6. Notably, the latter part of TAG’s own proposed construction is entirely consistent with that definition, for “able to bend without breaking” is materially indistinguishable from “capable of being bent, usually without breaking.” But the remainder of TAG’s proposed construction--“made of plastic or other material” that can bend without breaking--indeed imposes a significant limitation that is far removed from the commonly understood meaning of the term. To be viable, this proposed limitation must find clear support in the specification. MBO Laboratories, 474 F.3d at 1334; Teleflex, 299 F.3d at 1327.

The only support for TAG’s proposed construction in the specification, however, appears in the patentees’ description of the preferred embodiment. As explained above, TAG has failed to persuade the court to depart from the general rule that claims are not to be limited in accordance with a preferred embodiment. Nor does the prosecution history provide any reason to impose the limitation TAG seeks. As noted, the patentees differentiated their invention from the Siemens invention because the hockey goalie body protector disclosed by that patent was “comprised of a rigid frame,” whereas the ’226 chest protector was “flexible enough for comfort” and could more easily be taken on and off during a game. (Amendment, Ex. 11 to Def.’s
Br.) The patentees never used the word "plastic" in this prosecution history; indeed, the patentees merely stated that the shoulder guards "may be made of a different material" from the main pad. (Id.) By adding the term "flexible" to their claim, the patentees surrendered coverage only of chest protectors that, like the Siemens, were made of a "rigid frame" and were not "flexible." The patentees thus provided no differentiation with the Siemens protector that could be construed as imposing any further limitation on the scope of the term "flexible."

The court thus construes "flexible" as "capable of being bent or flexed."

2. Flexible

The district court construed the term "flexible" to mean "flexible enough for use in the vascular system as a conduit for an introducing catheter and other devices." Summary Judgment Decision, 345 F. Supp. 2d 466. Grayzel argues that such a construction "reverses the relationship between the SDH sheath and the introducing catheter in the SDH apparatus." The sheath, he contends, does not act as a conduit for the introducing catheter. Rather, Grayzel asserts that the introducing catheter enters the puncture site carrying the sheath and that the sheath would "bend, fray, or buckle" if unsupported by an introducing catheter. Grayzel relies on the language of claim 13, which recites that the sheath "coacts with" and is "supported by" the introducing catheter, to support his contention. Hence, he advocates that the correct construction for the term "flexible" is "sufficiently flexible such that the sheath must be carried into the vessel wall puncture by the introducing catheter" and "would bend, fray, or buckle if it were introduced into the puncture site without the benefit of being carried in by the introducing catheter."

Grayzel's proposed construction is not consistent with the intrinsic record. The specification makes clear that the sheath may be supported by the catheter, but that it is not required to be. The specification states in the "Summary and Objects of the Invention" section: "After insertion of the catheter, the sheath can be inserted by sliding it over the catheter if the sheath is not already on the body of the catheter." '960 patent, col. 5, ll. 34-36 (emphasis added). Contrary to Grayzel's argument, this disclosure suggests that the introducing catheter may be inserted first followed by the sheath. Once inside the vessel, the sheath will be slid onto the introducing catheter so that the two are positioned in the vessel as a single unit. The specification does not caution that the sheath may "bend, fray, or buckle" if introduced without the support of the introducing catheter. Nor does it disclose that special care is necessary when handling an independent sheath. Alternatively, this disclosure suggests the way that St. Jude apparently contemplates for inserting the introducing catheter and sheath under the '960 patent, specifically, that the sheath may be placed over the introducing catheter at the outset and the two are inserted and positioned into the vessel as a single unit.

Significantly, either approach is consistent with the language of claim 13, which merely states that the bore of the sheath will "coact with" and "be supported by the said flexible catheter." This language does not preclude that such coaction and support exist before the sheath is inserted into the vessel. Grayzel plainly misapprehends this language in arguing otherwise. Hence, because the specification teaches two approaches for inserting the sheath into a vessel, one where the sheath is independent of an introducing catheter, we conclude that the district court correctly construed the "flexible" limitation simply as "flexible enough for use in the vascular system as a conduit for an introducing catheter and other devices."

C. "Flexible"

Finally, the parties ask this Court to construe the term "flexible," although oral argument revealed no real dispute between the parties. (Tr. at 64-65.) However, the parties proposed slightly different constructions, and to the extent there are differences, this Court will construe the term.

The '079 Patent teaches that "wherein said at least two end portions are each made of flexible material so as to be flexible at least under the effect of a lateral action due to the displacement of a fluid." (Col. 4, lines 1-4.) Defendants argue that
"flexible" in this instance should be construed as "capable of being bent or flexed at least under the effect of a lateral action due to the displacement of a fluid." (Def. Mem. at 23.) Plaintiffs argue for an almost identical construction, "capable of being flexed or bent due to the action of bodily fluid flow." (Pl. Mem. at 18.)

There is no material difference between the proposed constructions. Defendants, however, properly limit their proposal to the functional limitation stated in the claim itself, that it be "capable of being bent or flexed at least under the effect of a lateral action due to the displacement of a fluid." (Col. 4, lines 2-4.) In contrast, plaintiffs attempt to engraft a functional requirement that the fluid flow in question be "bodily fluid flow," a limitation found nowhere in the claim and presumably gleaned from the specification. Therefore, this Court construes "flexible" in the '079 Patent as "capable of being bent or flexed at least under the effect of a lateral action due to the displacement of a fluid."

1643

Claims 1 and 5 describe a fan employing external flexible fan blades. The specification states that "the fan blades are formed of a flexible foam material such that they are very light weight, and unobtrusive and non-harmful to a human even when in striking contact with the human body." The '495 patent, col. 5, lines 43-46. The lower-weight blades also extends battery life because a lower-power motor may be employed to drive the fan. Defendant argues that the term "flexible" is a relative term, since all materials have some degree of flexibility. As a result, this part of the claim is anticipated by the '106 patent. The court finds this distinction unavailing.

There is no indication in the '495 patent that the inventors intended to give the term "flexible" any special definition. Webster's Dictionary defines "flexible" as "pliant." "Pliant" is synonymous with "pliable," meaning "supple enough to bend freely or repeatedly without breaking." 8 This definition is consistent with the term's usage in the patent, especially in light of the description of the blades being unobtrusive and non-harmful to a human. This element and its benefits are not taught by the '106 patent, which has its rigid fan blades completely encased within the device's head. The external flexible fan blades as used in the '495 patent are therefore not disclosed in the '106 patent.

1644

16. Flexible, Resilient, and Resiliently Urging

The next group of terms for construction are flexible, resilient, and resiliently urging. These terms are used in various combinations in '410 patent claims 1, 4, 5, 8, 9, 12, 13, 17, 18, 21, 22, 25, 26, 30, 31, 34, 35, and 38 (flexible and resilient locking strip); in '410 patent claims 39, 48, 50, 53, 54, 57, 58, and 61 (locking strip . . . is flexible and resilient); in '410 patent dependent claim 42 (flexible strip); in '410 patent claims 1, 13, and 26 (resiliently urging the flexible locking strip); in '410 patent claims 40 and 50 (resiliently urging the flexible strip at one of said short edges); in RE '439 patent claim 42 (flexible resilient material); and, in '907 patent claim 9 (resilient locking strip). These terms are used in claims providing for the snap joining of panels.
The Plaintiffs assert that "resilient" means "springing back or rebounding" and "flexible" means "capable of being bent, usually without breaking" relying on the common meaning of the words. (Pls.' Open. Br. 36.) Pergo proposes that "a flexible and resilient strip is one made out of a material that at the time of the invention was known to be capable of repeatedly bending and then returning to its original shape and position, such as aluminum or other metals, or plastics." (Unilin's Open. Br. 42-46.) Pergo maintains that the definition should not include "particle board" or other wood based material.

In arguing for its interpretation of the terms, Pergo relies upon the patent specification and the ordinary meaning of the terms flexible and resilient. In addition, Pergo proffers the declaration of Joseph R. Loferski, Ph.D. ("Loferski"), a professor of the Department of Wood Science and Forest Products at Virginia Polytechnic Institute, in Blacksburg, Virginia. (Unilin's Open Br. Ex. 17.) Loferski indicates that, based on what was known about high density fiberboard ("HDF") and medium density fiberboard ("MDF") at the time the first Pervan patent was filed in 1994, one skilled in the art would believe that making floor panels with snap-locking elements formed of HDF and MDF was not possible. (Ex. 17 P 22.)

Claim 39 of the '410 patent, previously quoted in full, includes the terms "flexible," "resilient," and "resiliently urging" as follows:

"the first and the second mechanical connections are so constructed as to allow mutual displacement of the panels in the direction of the long edges, the second mechanical connection along the long edges is so constructed as to allow the locking element to leave the locking groove if the panel associated with the locking groove is turned about its long edge angularly away from the strip, and each locking strip at the short edges is flexible and resilient such that two of the floor panels, having already been mechanically joined to a common long edge of a third of the floor panels, can be mechanically joined together at their adjacent short edges by displacing said two panels horizontally towards each other, while resiliently urging the flexible strip at one of said short edges downwards, until said adjacent short edges of the two panels have been brought into complete engagement with each other horizontally and the locking element at said one short edge thereby snaps into the locking groove at the adjacent short edge." ('410 patent, 14:39-46.) (Emphasis added). "Flexible" means "capable of being bent or flexed." Webster's II New Riverside University Dictionary 487. "Resilient" is a synonym for "flexible." See id. "Resilience" means "the property of a material that enables it to regain its original shape or position after being bent, stretched, or compressed." See id. at 1000. The definition of "urging" includes "to exert an impelling force." Id. at 1271.

The invention is described as being well suited for use in joining floor panels, especially thin laminated floors. (410 patent, 1:28-29.) The specification states that the invention provides a system for making a joint along the adjacent floor panels in which the "locking device further comprises a strip integrated with the other of said panels, termed strip panel, said strip extending throughout substantially the entire length of the joint edge of the strip panel and being provided with a locking element projecting from the strip, such that when the panels are joined together, the strip projects on the rear side of the groove panel with its locking element received in the locking groove of the groove panel." (410 patent, 4:10-20.)

In discussing the strip, the specification states: "Preferably, the strip may consist of a material which is flexible, resilient and strong, and can be sawn. A preferred strip material is sheet aluminium." (410 patent, 5:18-20.) Such discussion of the strip materials is not limited to a particular method of joining the panels -- e.g., angling the panels or by snapping the panels.

In discussing the preferred embodiments, the specification refers to Figures 1a and 1b and to Figures 4a and 4b showing the basic design of the panels and states:

"The strip 6, which is made of flexible, resilient sheet aluminium, can be fixed mechanically, by means of glue or in any other suitable way. In FIGS. 1a and 1b, the strip 6 is glued, while in FIGS. 4a and 4b it is mounted by means of a mechanical connection, which will be described in more detail herein below. Other strip materials can be used, such as sheets of other metals, as well as aluminium or plastics sections. Alternatively, the strip 6 may be integrally formed with the strip panel 1." (410 patent, 7:4-13.) (Emphasis added). An integrally formed strip could be formed of laminate, which the specification described as the material used in the panel itself. (See '410 patent, 6:53-55.)
Reading the claim terms in the context of the specification, the Court is not persuaded that the terms "flexible," "resilient," and "resiliently urging" should be construed as excluding "particle board" or other wood-based material. The terms should be given their ordinary meaning as one skilled in the art at the time of the invention would understand them. The noun "laminate" is defined as "a laminated product, as plywood." Webster's II New Riverside University Dictionary 674. "Plywood" is a wood based material. See id. at 906.

The qualities embodied by the terms "flexible," "resilient," and "resiliently urging," inherently limit the material types without the need further for specific limitations that are not provided for by the patent specification or claims. Loferski's declaration is extrinsic evidence, which may not be used to contradict the intrinsic evidence. See Phillips, 415 F.3d at 1318. Furthermore, Loferski's opinion relies, in part, upon Unilin's European patent for the MDF invention -- adding an additional layer of extrinsic evidence. Pergo's inclusion of the adjective "repeatedly" to modify bending is not supported by the ordinary meaning of "flexible." Thus, the Court construes "flexible and resilient strip" as "one made out of a material that at the time of the invention was known to be capable of bending and then returning to its original shape and position."

"Flexible" means "capable of being bent or flexed." "Resilient" means "able to regain its original shape or position after being bent, stretched, or compressed." "Resiliently urging" means to "exert an impelling force which allows it to regain its original shape or position."

4. "Rigid"

I construed the term "flexible cell" (relevant to the asserted claims of the '381 Patent) to mean "an arrangement of structural elements that defines an enclosed space. The cells must be substantially flexible prior to expansion of the stent and substantially rigid after expansion of the stent." 116 The term "rigid" can refer to two different attributes of a stent, and the parties disagree about which attribute is necessary under my claim construction. 117 Medinol contends that "rigid" refers to radial support -- that is, the capacity of the stent to support the vessel wall after deployment. Guidant contends, however, that both "rigid" and "flexible" refer to longitudinal flexibility, and so "rigid" in this context means the opposite of "flexible." As the accused products, unlike the patents-in-suit, are designed to maintain longitudinal flexibility even after expansion and deployment (so as to avoid straightening blood vessels), Guidant asserts that its interpretation of "rigid" compels the conclusion that the accused products do not have "flexible cells," and thus do not infringe the '381 Patent.

117 Among the dictionary definitions of "rigid" are: (1) deficient in or devoid of flexibility; and (2) appearing stiff and unyielding. See Merriam-Webster Dictionary.

The term "rigidity" is used twice in the text of the patents-in-suit. Most notably, the specification discloses that:

It will be appreciated that the two orthogonal meander patterns 11 and 12 and the compensation they provide to each other provides flexibility to the unexpanded stent of FIG. 1. However, when the stent is expanded, the changes in each of loops 14 and 16 provide rigidity to the resultant stent and thus, enable the stent to maintain a blood vessel at a desired inner diameter. 118

118 '381 Patent, col. 4, ll. 26-30 (emphasis added). The other two patents-in-suit contain the identical passage -- thus, all citations to the '381 Patent in this section apply equally to the '120 and '982 Patents.

Both parties point to this passage as support for their interpretation of my construction of rigid. 119 But the only sensible reading of this passage, given the usage of "thus," is that "rigidity" is intended to relate to the ability of the stent to hold open the vessel. In other words, the specification clearly connects the concept of "rigidity" to the stent's purpose of maintaining proper scaffolding of the artery once deployed.

119 See Pl. Mem. at 20 ("thus, the Patents-in-Suit teach that, on expansion, the first meanders [of which the loops 14 and 16 referenced in the patent are a part] become more resistant to radial compression (i.e., more radially rigid) as they open, enabling the stent to provide good support"); Def. Mem. at 19-20 ("the critical point Medinol misses -- as the transition [word however] used in the specification [makes] clear -- is that when the stent expands, there is a definite transformation
from a flexible state to an inflexible state).

To be sure, the patents-in-suit use "rigid" in a different sense when describing the prior art Palmaz and Schatz stent designs, which the patents-in-suit describe as follows: "since [their] tubular grafts are relatively rigid, the flexible connectors are needed so that the stents can bend when being fed through a curved blood vessel." 120 However, the limited point made by this quotation, which does not contradict the specification's description of the invention, is that some prior art designs tended to be inflexible prior to expansion. The Palmaz designs, in particular, were well-known in the stent art to be relatively inflexible before expansion, which was one of the concerns the patents-in-suit sought to address in the first place.

120 '381 Patent, col. 1, ll. 43-46 (emphasis added).

121 See Medinol III, 2005 U.S. Dist. LEXIS 35866, 2005 WL 3535062, at **3-4 (citation omitted).

The prosecution history relied upon by Guidant does not support its position. Guidant asserts that "Medinol overcame a rejection to the prior art Pinchasik '373 Patent arguing that the 'present invention' -- unlike the 'rigid' prior art articulated stent design -- was 'uniformly flexible' prior to expansion. . . . By contrasting flexible and rigid as essentially opposing qualities, Medinol made it quite clear its use of the term rigid meant the opposite of flexible." 122 However, the prosecution history cited by Guidant merely shows that Medinol distinguished the patents-in-suit from the '373 Patent's pre-deployment rigidity. 123 The '373 Patent, unlike the patents-in-suit, is an "articulated" stent design that can be bent pre-deployment only at certain intervals where connectors hold together "rigid" lengths of stent. 124 In fact, the statements from the prosecution history cited by Guidant all relate to pre-deployment flexibility. 125

122 Def. Mem. at 19.

123 During prosecution, Medinol asserted that:

The '373 patent is directed to an articulated stent which includes at least two substantially rigid segments and a flexible connector disposed between the substantially rigid segments for connecting adjacent rigid segments of the articulated stent. Thus, the '373 patent discloses an articulated stent that is comprised of at least three distinct portions and does not disclose the meander patterns of the claimed invention, their cooperative relationship, or the flexible structure disclosed and claimed by Applicants. Furthermore, the articulated stent disclosed in the '373 patent is flexible only at the articulation points where the connectors connect the substantially rigid segments. In contrast, the Applicant's invention and the pending claims are directed to a flexible expandable stent whose unique meander patterns and structure define a plurality of flexible expandable cells that are substantially flexible prior to expansion of the stent and substantially rigid after expansion of the stent that permit the stent to be substantially uniformly flexible along its entire length prior to expansion of the stent.

Excerpts from the Prosecution History of the '120 Patent at 8, Ex. 8 to Shaffer Decl. (emphasis added).

124 See, '373 Patent, Title Page (patent entitled "ARTICULATED STENT"); id. col. 2, ll. 16-22 ("The objective of the present invention is achieved by an articulated stent, comprising: (a) at least two substantially rigid segments; and (b) a flexible connector for connecting adjacent segments, wherein the connector assumes a substantially cylindrical configuration when relaxed and a differentially stretched and compressed curved configuration when flexed.").

125 See, e.g., Medinol PTO Statement at 5 ("The stent of the present invention is flexible in two directions, throughout its body, rather than having rigid areas and flexible areas as in the stents of the prior art. This flexibility enables it to bend anywhere along its length and to expand without significantly changing its length. In addition, because the structure of the stent is generally uniform, the flexibility is present generally throughout the structure, a fact which enables it to bend at all locations throughout the structure.").

Finally, Medinol's position is consistent with the stated goal of the patents-in-suit. As I have already noted, the chronic problem with early stent designs, which the patents-in-suit sought to address, is that there was an unfortunate trade-off between pre-deployment flexibility and post-deployment radial strength. 126 A stent could be flexible yet do a poor job of holding open a vessel once deployed, or it could be strong once deployed yet hard to maneuver through a blood vessel. The whole purpose of the patents-in-suit was to be flexible pre-deployment yet radially strong post-deployment. Thus, whether a
stent based on the patents-in-suit is flexible or inflexible after deployment is largely beside the point. 127 Accordingly, Guidant's interpretation of "substantially flexible prior to expansion of the stent and substantially rigid after expansion of the stent" would, in effect, construe the patents-in-suit as teaching an attribute (post-deployment inflexibility) unrelated to their stated purpose. 128

127 Although a court should not compare the accused products and a commercial embodiment of an asserted patent, see, e.g., Glaxo, Inc. v. Torpharm, Inc., 153 F.3d 1366, 1373 (Fed. Cir. 1998), I note that the chapter on the NIR and NIRFLEX Stents, co-authored by Richter and cited by Guidant, states that once the stent is deployed, "the stent loses its flexibility, but this lost feature is no longer important since the stent is not required to move anywhere." Jacob Richter et al., The NIR and NIRFLEX Coronary Stents, in Handbook of Coronary Stents 217 (4th ed., Patrick Serruys and Benno Rensing eds.) 2002, Ex. 10 to Shaffer Decl. See also BSC Trial Testimony at 73-76 ("Flexibility . . . is needed when you are trying to track it through the curviness of the artery. But once you get to the position, you don't need it. The strength or the rigid support of this stent is needed after you deployed it, but not when it is crimped on the balloon.").

128 Guidant asserts that Medinol missed the boat with its lack of concern with post-deployment flexibility. See Def. Mem. at 20 (citation omitted) ("In 1999 . . . Medinol finally realized what Guidant had known all along -- that a flexible, and not a rigid or inflexible stent after expansion led to better overall stent performance and thus, improved patient outcomes."); Def. Noninfringement 56.1 P71 (Richter discussing physician complaints regarding the post-deployment inflexibility of Medinol stents: "some could refer to it as straightening of vessel, some could refer to it as making it more rigid longitudinally") see also supra note 37. While Guidant may be correct, this point is not relevant to the literal infringement inquiry.

Because the intrinsic evidence establishes the proper definition of "rigid" in this context, there is no need to turn to extrinsic evidence to construe "rigid." 129 In any case, the extrinsic evidence presented by the parties is largely irrelevant. Both parties collect various statements made by Medinol and Guidant employees, retained experts and third-party patents purporting to establish that their opponent has conceded the proper construction of "rigid." 130 These collected statements prove nothing. As already demonstrated, "rigid" in the context of stent technology can be used in two senses -- pre-deployment, it means the opposite of "flexible," and post-deployment (at least as used by the patents-in-suit), rigid refers to the ability of the stent to hold open a blood vessel. 131 The various uses of "rigid," "rigidity," or "radial rigidity" cited by the parties cannot be divorced from the contexts in which those statements were made, and thus they shed no particular light on the proper meaning of "rigid" as used in the patents-in-suit. 132

129 See Vitronics Corp., 90 F.3d at 1583 ("Resort to extrinsic evidence is appropriate only when an ambiguity remains after consulting the intrinsic evidence of record.").

130 For example, Guidant collects various statements made by Richter, as well as Medinol's experts during depositions, purporting to be "highlights" of the many instances "where Medinol has used the term 'rigid' to mean inflexible or stiff." Def. Mem. at 21 (citation omitted). By contrast, Medinol catalogs an assortment of stent patents, belonging to Guidant as well as third parties, purporting to use "rigid" to mean radial support. See Pl. Infringement 56.1 PP73-76 (citation omitted).

131 This is well illustrated by Richter's testimony at the Markman hearing. When describing the Palmaz stent, he used "rigidity" in both senses within the span of three sentences, but at the same time he clearly distinguished the different usages: "the support, the rigidity of the vessel wall was very good. The problem with that . . . it is totally inflexible, totally rigid . . . if you have a very tortuous vessel you will not be able to push it through to the target. So [the Palmaz stent] had good support, good rigidity for support." Markman Tr. at 11 (Richter) (emphasis added).

132 For example, Guidant correctly notes that much of Medinol's evidence actually employs a different term, "radial rigidity," to refer to radial strength. See Def. Reply at 8-9 ("Guidant does not dispute that 'rigidity,' when modified by 'radial,' relates to 'radial strength.' But . . . when used alone, rigid simply means inflexible."). However, it does not follow that Medinol is precluded from using "rigidity" in its own patents, without the adjective, to convey the same concept. Moreover, many, if not all, of the statements made by Medinol officials or experts, purportedly establishing that rigidity refers to post-deployment inflexibility, show no such thing when read in context. See, e.g., BSC Trial Testimony at 73 (Richter testifying that, inter alia, "the strength or the rigid support of this stent is needed after you deployed it"); Sherman
Dep. Tr. at 127-29 (describing the Palmaz stent as longitudinally rigid before deployment); see also supra note 127 (quotation from Richter's chapter in the Coronary Stent Handbook, clearly indicating that "rigidity" in relation to the NIR stent was meant in terms of vessel wall support post-deployment).

In sum, based on the intrinsic evidence Medinol's interpretation of "flexible cell" is correct. Accordingly, "rigid" as used in my construction of "flexible cell" means "able to hold open the blood vessel at the desired inner diameter." Because it is based on a false premise as to the relevant meaning of "rigid," I do not reach Guidant's argument that infringement of the flexible cell claims is determined by comparing a stent's pre-expansion longitudinal flexibility with its post-expansion longitudinal flexibility. See Def. Mem. at 22-24.

1646

(8) "Flexible compensating member or flexible link." A structural element that is flexible with respect to the stent's longitudinal axis and must be aligned along the longitudinal axis of the stent. A "flexible compensating member or flexible link" must connect adjacent cells, but the physical connection need not be made at points directly opposite each other.

GO BACK

1647

J. "a single flexible connecting device secured to the free end of said elongate member;"

Defendants assert that the term "flexible connecting device" connotes a means-plus-function element, thereby falling within the purview of 35 U.S.C. § 112, P 6, and limiting the element to structures delineated in the specification.

Under 35 U.S.C. § 112, P 6, [a]n element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof." The statute states that these types of claims are not construed to cover all possible means for performing the stated function, but are "construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112, P 6; see O.I. Corp v. Tekmar Co., 115 F.3d 1576 (Fed. Cir. 1997).

In identifying which claims shall be read as means-plus-function, courts have construed those claims using the term "means" as creating a rebuttable presumption that § 112 P 6 applies, while not including the term "means" creates a rebuttable presumption that § 112 P 6 does not apply. Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). Thus, "[t]he use of the term 'means' is central to the analysis, because the term 'means,' particularly as used in the phrase 'means for,' is part of the classic template for functional claim elements, and has come to be closely associated with means- plus-function claiming." Id. (citations omitted). This presumption stems largely from the idea that § 112 P 6 "provides that an element in a claim for a combination 'may be expressed' as a means for performing a function, which indicates that the patentee is afforded the option of using the means-plus-function format. The question then is whether, in the selection of claim language, the patentee must be taken to have exercised that option." Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996) (quoting § 112 P 6).

The presumption against construing an element of a claim as invoking § 112 P 6, absent the term "means," may be rebutted "if it is demonstrated that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Lighting World, 382 F.3d at 1358 (citations omitted). However, it must be understood that the presumption against § 112 P 6 treatment is "a strong one, that is not readily overcome." Id.

In Lighting World, the Federal Circuit explained the test for determining whether a claim element lacked sufficient structure, thereby overcoming the presumption. In that case, however, the court found that the term "connector assembly" did provide sufficient structure, and thus did not fall within § 112 P 6. Id. at 1360-63. The court stated:

In considering whether a claim term recites sufficient structure to avoid application of section 112 P 6, we have not required the claim term to denote a specific structure. Instead, we have held that it is sufficient if the claim term is used in
common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function.

Id. at 1359-60. The court continued: [T]he fact that a particular mechanism . . . is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of section 112(6)." Id. at 1360 (quoting Greenberg, 91 F.3d at 1583). In concluding that "connector assembly" did not fall within the purview of § 112 P 6, the court noted:

[W]hile it is true that the term "connector assembly" does not bring to mind a particular structure, that point is not dispositive. What is important is whether the term is one that is understood to describe structure, as opposed to a term that is simply a nonce word or a verbal construct that is not recognized as the name of structure and is simply a substitute for the term "means for."

382 F.3d at 1360.

The Lighting World court also distinguished "connector assembly" from the "lever moving element" which was found to be means-plus-function element in Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206 (Fed. Cir. 1998). In Mas-Hamilton, the court found that "lever moving element" did not define structure, in that it did not have a well understood structural meaning in the art. 156 F.3d at 1213-14. Lighting World distinguished Mas-Hamilton on the ground that "connector assembly" did in fact have an understood structural definition in the art, as defined by the patent specification, dictionaries, and expert testimony. 382 F.3d at 1363.

Conversely, in Mass. Inst. of Tech. ("MIT") v. Abacus Software, the Federal Circuit determined that the term "colorant selection mechanism" did not connote sufficient structure to a person of ordinary skill in the art to avoid § 112 P 6 treatment. 462 F.3d 1344, 1354 (Fed. Cir. 2006). In doing so, the court noted that generic structural terms such as "means," "element," or "device" do not recite sufficient structure to avoid § 112 P 6, but that "[c]laim language that further defines a generic term like 'mechanism' can sometimes add sufficient structure to avoid 57 Ore. 541, 112 P 6." Id. However, in that instance the Court found that the phrase "colorant selection" did not add sufficient structure to define the term "mechanism" so as to avoid § 112 P 6. Id.

In making its determination, the MIT court first looked to the prosecution history of the patent and noted that the patentee used "mechanism" and "means" as synonyms. Id. The court also looked disfavorably upon the fact that the term "colorant selection," which modified "mechanism," was not defined in the patent specification or in dictionaries, nor did it have a generally understood meaning in the art. Id. The court thus found that the phrase did not recite sufficient structure to one of ordinary skill in the art, and was therefore limited by § 112 P 6. Id.

In this instance, the phrase "flexible connecting device" does not fit neatly into the standard means-plus-function analysis. Obviously the phrase does not contain the term "means," thus the strong presumption against § 112 P 6 is applicable in this case. However, that presumption may be rebutted upon a showing of a lack of structural specificity or a recital of function without reciting sufficient structure for performing that function. Lighting World, 382 F.3d at 1358. Facially, it does not appear that the phrase "flexible connecting device" connotes any particular structure, and could be interpreted as describing a device according to the function that it performs. However, it is clear that neither the delineation of a specific structure, nor the identification of structure distinct from its function, is required to escape § 112 P 6. Id. at 1359-60. What is required to escape § 112 P 6 is that the phrase be used in common parlance or by persons of skill in the pertinent art to designate structure, even if the structure described is of a broad or amorphous class.

This Court believes that Lighting World controls and that "flexible connecting device" does in fact connote such a structure. This Court cannot distinguish between the "connector assembly" of Lighting World and the "flexible connecting device" of the present case. Just as that court found that "connector" had a reasonably understood meaning as a name for structure (noticeably, not a structure), despite the fact that this structure was defined in terms of the function that it performs, so does this Court find "connecting device" to connote structure. Admittedly, there is a distinction in the terms, in that the term "connector" is a noun whereas "connecting" is an adjective describing the function of the generic phrase "device," however the Court finds this to be a distinction without difference. Absent any evidence on the issue, this Court cannot see any substantial difference between a person of ordinary skill in the art of lighting fixtures describing something as a "connector assembly" and a person of ordinary skill in the art of small motorized devices describing something as a "connecting
device."

Additionally, the factors present in MIT, which the Federal Circuit relied upon to construe "colorant selection mechanism" as a means-plus-function element, are not present in this instance. The prosecution history of the '448 patent lacks any synonymous usage of the terms "device" and "means," and the term "connecting" (which modifies "device") is clearly defined in common knowledge and dictionaries. Thus, the term "connecting device," in the context of this patent, connotes a sufficient degree of structure to one of ordinary skill in the art so as to avoid § 112 P 6.

Furthermore, this Court gives consideration to the fact that the presumption against construing an element as means-plus-function stems from the premise that § 112 P 6 affords the patentee the option of using the means-plus-function format. Greenberg, 91 F.3d at 1584. In light of this fact, an important distinction within the patent becomes apparent. Claim 10 is dependent upon Claim 1, and further limits the "flexible connecting device" of Claim 1:

[W]herein said connecting device comprises an elongate flexible member, first flexible connecting means at one end of said flexible member for flexibly connecting it to the free end of said elongate member, and second connecting means at the opposite end of said flexible member for connecting it to the object to suspend it below the free end of said elongate member.

(′448 patent, column 4, line 50-57.) It is clear from Claim 10 that the patentee was indeed familiar with the means-plus-function terminology, and the method of exercising his option to invoke § 112 P 6, as he added the limitations of a "first flexible connecting means" and a "second connecting means." It seems to this Court that if the patentee wished to exercise this option in claim 1, he would have done so in the same manner. In light of this inconsistency, the Court does not believe that the patentee exercised his option to invoke § 112 P 6 in this element of Claim 1.

As the Court has determined that § 112 P 6 does not apply, and the words of the phrase are commonly understood, the Court does not believe that "flexible connecting device" requires any additional construction. 6

--------------------- Footnotes ---------------------
6 Defendants have requested that "single" be construed as "only one." However, the Court finds that the word "single" is readily understood and requires no further definition.

--------------------- End Footnotes ---------------------

1648

The next element in dispute in claim 17 is the phrase "by at least one flexible connector member disposed between adjacent grafts." "Flexible" means capable of being bent or flexed. Webster's at 427. A "connector member" is a structure disposed or particularly arranged between adjacent grafts in order to join them together. The word "flexible" clearly modifies the phrase "connector member." Although it is a purpose of the invention to describe an intraluminal graft "able to flexibly bend, or articulate, with respect to the longitudinal axis of [the] graft" (PX 1/API 1: '417 patent, col. 12, lns. 44-5), there is no requirement in the claim language that each individual graft be flexible, only that the connector member be flexible. This interpretation is consistent with the disputed language of claim 25, which more specifically requires that the connector member be particularly arranged "to flexibly connect" adjacent structures; again, it is the connector member and not the adjacent structures which must provide flexibility, as is the case with the Palmaz-Schatz stent.

GO BACK

1649

The next element in dispute in claim 17 is the phrase "by at least one flexible connector member disposed between adjacent grafts." A "member" is defined as a constituent part of a whole, a component serving to form, compose or make up a unit or whole. Webster's at 1408, 486. A "connector member," therefore, is a discrete structure disposed or particularly arranged between adjacent grafts in order to join them together. "Flexible" means capable of being flexed, turned, bowed, or twisted
without breaking. Id. at 869. The word "flexible" clearly modifies the phrase "connector member." Although it is a purpose of the invention to describe an intraluminal graft "able to flexibly bend, or articulate, with respect to the longitudinal axis of [the] graft" (’417 patent, col. 12, lns. 44-45), there is no requirement in the claim language that each individual graft be flexible, only that the connector member be flexible. This interpretation is consistent with the disputed language of claim 25, which more specifically requires that the connector member be particularly arranged "to flexibly connect" adjacent structures; again, it is the connector member and not the adjacent structures which must provide flexibility.

6 Connecting "by means of something intervening . . . ." Webster's at 480 (emphasis added).

The dictionary definition sets forth the common meaning of a word, and normally we ascribe to a claim term its common meaning unless the patentee has otherwise limited or defined the term. Cf. Vitronics Corp. v. Conceptronic Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996) ("The specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term."); Slimfold Mfg. Co. v. Kinkead Indus. Inc., 810 F.2d 1113, 1116, 1 U.S.P.Q.2D (BNA) 1563, 1566 (Fed. Cir. 1987) ("Claims are not interpreted in a vacuum, but are part of and are read in light of the specification."). In addition, "the record before the Patent and Trademark Office is often of critical significance in determining the meaning of the claims." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577. In this case, the patentee, throughout the specification and prosecution history, used the term "flexible" to describe a physical quality of the diaphragm that allows the craft to traverse rugged terrain.

The specification has a number of references to the ability of the "flexible diaphragm" to pass over obstacles. It states that the craft's "curtain can extend upwardly from the lower edge of the columnar construction for a relatively great distance to permit such curtain to flex and pass over relatively large obstructions, such as large stones, etc., without harm to the relatively rigid upper supporting member." The "curtain" is also distinguished from the "rigid wall" of the craft, which "would not yield when encountering a stone or the like, so the vehicle would have to stop suddenly or the wall . . . would be broken." Summing up with respect to the "flexible diaphragm," the patentee posits, in the specification, that "the curtain is so constructed that it yieldingly glides over relatively high objects." It is clear from the specification that the inventor defined the term "flexible" to connote the ability of the curtain to be deflected by obstacles.

This interpretation of the term "flexible" is further cemented by the prosecution history. During prosecution, the patentee distinguished his invention over the prior art by noting the ability of the claimed craft to "ride over obstacles." In addition, the patentee further stated that the "flexible . . . curtain . . . allows the platform to . . . pass over obstructions in a surprising manner."
Therefore, reading the claim in light of the specification and prosecution history, we conclude that the patentee limited the term "flexible" to encompass a physical property of the diaphragm to flex or give when the hovercraft encounters obstacles.

1651

B. Flexible Element

ICU argues that the term "flexible element" should be defined as "portion that is capable of being bent or flexed" while Braun argues that it should mean an element that is "capable of being bent without breaking, easily bent" but "not using mechanical or moving parts such as springs or diaphragms." Revised Joint Claim Construction and Prehearing Statement for '673 Patent ("RJCCPS") at 3. Thus, Braun's definition is narrower than ICU's in two respects: 1) "flexible" means flexible without breaking; and 2) "flexible" means not using mechanical or moving parts.

1. Bent Without Breaking

The parties agree that the construction of the term "flexible" begins with its dictionary definition. ICU Opening Brief at 11; Braun Brief at 10. The parties further agree that the 1987 edition of the Random House Unabridged Dictionary is the proper general-usage dictionary for this claim construction. ICU Opening Brief at 11; Braun Brief at 10. Random House defines "flexible" as:

1. capable of being bent, usually without breaking; easily bent . . . 2. susceptible to modification or adaptation.; adaptable . . .; 3. willing or disposed to yield; pliable . . . 4. a flexible substance or material, as rubber or leather.

Random House Unabridged Dictionary 733 (2d ed. 1987). This Court thus may easily dispose of Braun's limitation that a "flexible" object must be able to be bent without breaking. The dictionary definition makes no such categorical statement. Both parties would have been more consistent with their dependence on the dictionary had they argued that "flexible" means "usually without breaking." Accordingly, this Court will construe the term as including structures that are capable of being bent, but usually without breaking.

This construction is consistent with the use of the term in the patent. The claim states that the flexible element must be "movable between an uncompressed position . . . and a compressed position," while also being able to "flex[] to accommodate axial compression." Col. 16:4-12. The specification refers to the "seal" 3 as being "reusable," and "resilient." Col. 2:43-44, 3:35. A construction of the term "flexible" as being easily broken upon compression would conflict with these statements and thus is excluded. However, a construction of the term as being so resilient as to stand up to very strong compression such that it could never be broken would define term in a way not supported by the patent.

3 The parties agreed at oral argument that the term "seal" in the specification is equivalent to the term "flexible element" in the claim. Thus in construing the term "flexible element," this Court will take into consideration the use of the term "seal" in the specification.

2. Mechanical Parts, Springs and Diaphragms
Braun is incorrect in asserting that the specification "disavows or distinguishes" the "flexible element" from "prior art valves and connectors that use springs or diaphragms" such that an interpretation of the "flexible element" including mechanical parts is foreclosed. Braun Brief at 14. The specification's description of the advantages of the invention over prior art devices cannot limit the definition of the claim unless it constitutes a clear disavowal. See Brookhill-Wilk 1, 334 F.3d at 1301 ("Advantages described in the body of the specification, if not included in the claims, are not per se limitations to the claimed invention.") (citations omitted); Astrazeneca AB, Aktiebolaget Hassle, KBI-E, Inc. v. Mutual Pharmaceutical Co., Inc., 384 F.3d 1333, 1340 (Fed. Cir. 2004) (criticism of prior art may be a disavowal if implication is clear from discussion of particular feature of the invention). Contrary to Braun's reading of the patent, it can not be said that the specification "repeatedly, consistently and exclusively" discusses seals as not having mechanical parts. Irdeto Access, 383 F.3d at 1303.

The specification describes the prior art mechanical connectors as inferior because they were more prone to malfunction upon repeated use. Col. 1:35-46. The specification does not say that the invention in the '673 Patent will never have mechanical parts. Nor does it say that all inferior designs have mechanical parts. Col. 1:35 (stating that prior art connectors "often have mechanical or moving parts" (emphasis added)). Instead, the specification describes the claimed invention as superior to prior art devices because "the fewer the mechanical parts the more these connectors can be relied on. . . ." Col. 1 44-45. Thus the specification merely states that it is preferable for medical valves of the type disclosed in the '673 Patent to have few, although not necessarily zero, mechanical parts. If Braun's interpretation of this portion of the specification as a clear disavowal of all flexible elements using mechanical parts were accepted, then the claimed invention could also never have "moving parts." See Col. 1:41-43 ("the more mechanical or moving parts such as springs and diaphragms, the more likely that they will function improperly." (emphasis added)). However, the claimed invention undisputedly does have at least one moving part -- the flexible element itself. Col. 9:37 (describing the seal in one preferred embodiment as a "movable part").

Accordingly, this Court construes the term "flexible element" to mean a portion of the valve that is capable of being bent, usually without breaking.

1652

2. Plate . . . Which is Flexible Enough to be Wound Around the Inner Tube (Claims 9 and 15)

Three words of this phrase, "plate," "flexible," and "wound," drew special attention from the parties. The court addresses each word separately and then places them in the context of this entire phrase.

Plaintiffs find it unnecessary to give the term "plate" any specific definition. 19 But, in response to Defendant's proffered definition, Plaintiffs argue that the patent itself provides the following definition: a three-dimensional structure that fits within the sealed annular space lying between the inner and outer tube, which forms a casing around the inner tube. 20 Defendant originally offered the following definition: "a smooth, flat thin piece of material." 21 At the hearing, Defendant dropped the adjective "smooth" from its definition. 22 Plaintiffs insist that a plate need not be flat either. 23

22 Defendant's Markman hearing arguments.

23 Plaintiffs' Markman hearing arguments.

--- End Footnotes ---
The word "plate" is used at least seventeen times throughout the sixteen patent claims with no apparent variation in meaning. Cf. Nazomi Communs., Inc., 403 F.3d 1364, 2005 WL 820491, at *5 (generally referring to the rule that a claim term is construed consistently throughout the patent); Rexnord Corp., 274 F.3d at 1342 (same). As defined in the design engineering field, a "plate" is "[a] rolled, flat piece of metal of some arbitrary minimum thickness and width depending on the type of metal." McGraw-Hill Dictionary of Scientific and Technical Terms 1524 (5th ed. 1994). In more common parlance, a "plate" has several definitions, including "[a] flat, smooth, relatively thin, rigid body of uniform thickness." Webster's II New Riverside University Dictionary 900 (1984). Although some aspects of both of these definitions obviously are not accurate descriptions of a plate in the context of this patent, the court notes that both describe a plate as flat. "Flat can be defined as "[a] smooth, even surface" or as "an object with a broad, shallow or thin form." McGraw-Hill Dictionary of Scientific and Technical Terms 769 (5th ed. 1994). As the adjective "flat" is the most significant point of contention, the court looks to the intrinsic evidence for verification that the plates of this invention have either a smooth, even surface or a broad, shallow or thin form.

From the claims themselves, the court can determine little about the precise shape of the plates of insulation. The claims generally indicate that the plates are made of microporous insulating material, are flexible, and are self-sustaining. 24 Some of the claims that are not in issue in this suit specify the thickness of the plates of insulation, indicating that the plates are quite thin. 25 Nothing in the claims specifically requires that the plates be smooth or even. The specification does not offer much additional guidance, except to emphasize that the layer of microporous insulation is thin. 26

26 See, e.g., id. at 4:8-14 (suggesting a thickness of ten millimeters for use with oil pipelines and a thickness of up to thirty millimeters for other applications).

The portions relied on by Plaintiffs indicate that the structure is three dimensional and forms a casing around the inner pipe. 27 Plaintiffs convincingly argue that not all commonly recognized plates have smooth, even surfaces, e.g., a plate of armor, a gold plate on a piece of jewelry and that nothing in the patent requires smooth, even surfaces of the plates. 28

27 See id. at 2:2-6, 40-44; 3:63-64.
28 See Plaintiffs' Markman hearing arguments.

Even Defendant dropped the word "smooth" from its proposed definition as not being descriptive of the invention. However, Defendant cites the court to a reference in the specification to "planar plates." The specification reads, "The plates of microporous material which are commercially available as planar plates have enough flexibility to be intimately wound around the inner tube or plated thereon with no trouble." 29 The court agrees that "planar" can mean "flat" or "two dimensional," 30 but disagrees that "planar" should be read into the claims from this reference. Cf. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) (reaffirming that limitations from the specification cannot be read into the claims). Instead, this quoted portion seems to address the flexibility of certain commercially available planar plates of microporous material and their compatibility with the invention, rather than to require planar plates. In fact, the use of planar in that context, but not in the claim language leads the court to the conclusion that the plates of insulation need not be flat in the two-dimensional sense. Based on the above discussion, the court finds that a "plate," in the context of this patent, is a broad, thin, flexible piece of material.
This brings the court to the second of the three terms in this phrase to be interpreted: flexible. Plaintiffs state that flexible means capable of bending without cracking. As it appears that Defendant does not dispute Plaintiffs' definition, the court adopts it.

The third and final term in this phrase, wound, remains a sticking point for the parties. Plaintiffs argue that wound is part of the phrase that describes a characteristic of the plate. They also contend that the word "wound" could be replaced by words such as "placed," "located," or "fitted," referring to where the insulation is applied, rather than how it must be attached to the inner tube during the assembly process. Defendant contends that the term means that "the plate of insulation is bent from its initial flat shape into a different, final shape wrapped around the inner tube."

Every appearance of the term "wound" in the patent claims is within the same nonessential phrase: "which is flexible enough to be wound around the inner tube." Without a doubt, wound denotatively and connotatively carries a meaning that involves wrapping, encircling, spiraling, curving, twisting, coiling, or some similar motion around another object. Therefore, the court is unconvinced that the word could be replaced with a term indicating the location of the insulation plate, as argued by Plaintiffs. On the other hand, the phrase in which it is used describes the plate of open-pore microporous material, not the manner in which that plate is attached to the inner tube. The claims do not require that the insulation necessarily be fitted onto the inner tube by being wound around it, only that the plate of insulation be flexible enough for such action. The specification supports this understanding. The specification discusses an assembly method whereby the insulation is applied in parallel plane strips longitudinally along the inner pipe.

29 547 patent at 5:3-6.

31 Plaintiffs' Markman hearing arguments; see also Plaintiffs' Brief in Opposition to Defendant's Opening Claim Construction Brief, Docket Entry No. 27, pp. 5-6. Plaintiffs' definition is supported by Federal Circuit case law interpreting "capable of flexing" as "capable of bending." See Arlington Indus. v. Bridgeport Fittings, Inc., 345 F.3d 1318, 1326 (Fed. Cir. 2003).

32 Plaintiffs' Markman hearing arguments.

33 Id.

34 Defendant's Markman hearing arguments; see also Defendant's Brief on Claim Construction, Docket Entry No. 23, pp. 2, 9.

36 See id. at 4:60-63.
Under these circumstances, the court finds it inappropriate to infer from the use of the word "wound," as is suggested by Defendant, that the plate is initially flat. Rather, the court agrees with Plaintiffs that the phrase "which is flexible enough to be wound around the inner tube" refers to the degree of flexibility necessary within the plate of insulation.

Putting all of these terms together, the court recommends that "plate . . ., which is flexible enough to be wound around the inner tube" means a broad, thin piece of material that is sufficiently capable of bending that it can be wound around the inner tube without cracking or breaking.

Zeppelin challenges the district court's construction of the term "flexible joints between the units." The court construed the term to mean "a point or position in the interval or position separating the floatation units of the dock, which point or position is capable of bending or flexing." Zeppelin argues that the district court erred in its construction because the term "joint" in the claims must refer to a tangible object, not merely a "conceptual" "point." According to Zeppelin, a "point" cannot be characterized as "capable of bending or flexing." Zeppelin argues that the district court "mechanically combined" definitions of the claim terms, and should have excluded a point from the possible definitions of "joint." Zeppelin proposes that the term "flexible joints between the units" should be construed to mean "a configuration or component connecting the floatation units of the dock, which configuration or component is capable of bending or flexing."

Jet Dock defends the district court's claim construction, analogizing to the human body: "an elbow is a flexible joint between [the] forearm and upper arm, yet there is no component that can be considered apart from the bones [that] the joint connects." (Br. of Appellee, at 31.) Jet Dock further argues that the district court's construction is consistent with the specification, because the tabs that connect the floatation units help form the "flexible joint" but are not disclosed as components separate and apart from the floatation units themselves. See '833 patent, col. 1, l. 67-col. 2, l. 1.

We see no error in the district court's construction of "flexible joints between the units." We think that Zeppelin's proposed construction is incorrect because the "flexibility" referred to in the '833 patent is not that the material forming the joints itself is flexible, but rather that the joints permit the floatation units to flex and bend relative to each other. This is clearly recited in the claim language: to "permit adjacent units to flex downwardly with respect to each other upon the imposition of a downward load." Id. col. 7, ll. 43-45 (claim 1). Consistent with this notion, the specification teaches that "when joined together the floatation units 12 and 14 show some flexibility relative to one another." Id. col. 4, ll. 23-24.

Phoeni contend that flexible lip means "resilient portion." Silgan contends that it means "the end portion of the neck of a
container which is configured to resiliently flex under load about one or more hinged areas."

Both parties agree that a flexible lip must be resilient, meaning it can flex under pressure and then spring back into its original position once the pressure is released. The disagreement is whether the flexible lip must contain a hinged, or V-shaped, area. Silgan points out that the specification, at column 2, lines 19-21, says, "it is preferable if the neck initially doubles back creating a flexible lip . . .," and at column 2 lines 55-60 says, "it is preferable that materials and the geometry of the top, the first protrusion, and the neck render them sufficiently flexible to allow for some temporary deformation of shape. This is facilitated by the curvature of the top and the bends in the neck." Thus, as Silgan argues, the patent describes flexibility as something created by a bend or curve in the material.

Phoenix argues that the word "preferable" in the quoted language from the specification indicates that the curved or hinged lip is not a necessary part of the patent, but only a preferred embodiment, which the Federal Circuit has warned should not be imparted into the claims as a limitation. See Toro Co. v. Deere & Co., 355 F.3d 1313, 1319-1320 (Fed. Cir. 2004). The Court recognizes this principle of construction, but does not believe that defining flexible as curved or bent in this instance would run afoul of the general rule.

Rather, what is preferable according to the specification is a flexible lip. If the Court was construing the word "lip," it would arguably be wrong to require a flexible lip on the ground that the specification said a flexible lip was preferable. Here, however, we are construing "flexible lip," not just "lip," and the specification says -- in two different places -- that flexibility is created by a bend or curved shape. The Court, therefore, adopts the following construction: a resilient, curved or bent, portion of the neck near the mouth of a container. This construction is consistent with the specification and does not require a V-shaped or hinged-shaped bend or curve, as these appear to be preferred embodiments of the term "flexible lip."

1656

G. "Flexible Link"

The following claims incorporate the phrase "flexible link": 28 of the '303 Patent; 51 of the '018 Patent, 56-58, 61, 63, 65-66, 68-70 of the '381 Patent. 108 For Medinol, "flexible link" means "a structural element that is flexible with respect to the stent's longitudinal axis and must be aligned along the longitudinal axis of the stent." 109 Guidant views a "flexible link" as "[a] structural element connecting the apices of adjacent cells, that is flexible and aligned with respect to the stent's longitudinal axis." 110

109 Pl. Mem. at 19. Accord Cordis Order at 3 (defining "flexible compensating member or flexible link").

110 Def. Mem. at 24.

The parties' disagreement over this term arises from Guidant's proposed inclusion of a requirement that the flexible links connect the "apices of adjacent cells." 111 During prosecution, the patentee distinguished the Palmaz '417 Patent by explaining that:

Applicants have also amended Claim 1 to include the limitations of Claim 3 to adjacent cells of adjacent rigid segments. This is in contrast to Palmaz '417 and Cardon whose links are spiral-shaped and therefore, do not connect the apices of adjacent segments. Instead, they connect the apex of a first cell on one segment with the apex of a second cell (of the second segment) which is shifted from the one which is adjacent to the first cell. 112

This statement reveals that (1) the Palmaz '417 and the "Cardon" Patents connect the apices of non-adjacent cells and (2) the
key distinction between claim 1 of the Pinchasik '373, as amended, and the prior art, was the requirement that the flexible links connect the apices of adjacent cells. 113 The amendment related not to the "apices" of the cells, but to the relative location of the connected cells (adjacent versus non-adjacent). The use of flexible links to connect adjacent segments was intended to improve upon designs based on the prior art by avoiding twisting on expansion. It is therefore logical to impart the following definition to the term "flexible link": a structural element connecting adjacent cells that is flexible and aligned with respect to the stent's longitudinal axis.

1657

C. "Flexible Member."

The term "flexible member" appears in claims 1, 4, 5, and 7. Claim 4 recited (col. 17:35-39):

4. An improvement in a bundle breaker as defined in claim 1 wherein:

   a. said first and second flexible members have a width extending substantially the width of said logs and in close proximity to said weakened plane in said log.

Plaintiffs propose that this term should mean "a structure that is capable of deformation in response to a force exerted upon it." Defendant disagreed and originally proposed the definition "a pliable sheet of material."

Once more, defendant has changed its proposed construction midstream. It now contends that the term should mean "a material that deforms in response to changes in force exerted upon it and is capable of recovering its size and shape after distortion." As to the first part of the construction, plaintiffs and defendant disagree on whether the proper term is "material" or "structure."

This order holds, however, that the plain language of the term itself is sufficient. Defining this phrase further is not necessary. At the hearing on this motion, both plaintiffs and defendant agreed. Accordingly, the phrase "flexible member" needs no further construction or clarification -- it will have its commonly understood meaning.

1658

(1) flexible pad

Plaintiffs propose the construction "The object or base to which a plurality of actuators are attached or in which a plurality of actuators are embedded, where such object or base is capable of being flexed. As the term 'flexible pad' is used in the context of the '941 patent, it includes, among other things, handheld game pad controllers." (Joint CC Chart at 7; Doc. No. 31.) Defendants' construction is "A foam or cushion-like structure. The "flexible pad" is not the hand-held game pad described in the '941 patent." (Joint CC Chart at 7; Doc. No. 31.) The parties' constructions differ primarily with regard to two elements. First, the constructions differ because Plaintiffs propose that "flexible" means "capable of being flexed."
Second, the constructions differ on whether "flexible pad" includes the hand-held game pad described in the '941 patent; Plaintiffs argue the term includes the hand-held game pad, but Defendants argue that a "flexible pad" must be a foam or cushion-like structure and not a hand-held game pad.

Turning to the first issue, Plaintiffs' interpretation of "flexible" as "capable of being flexed" is inappropriate because that construction is far broader than the ordinary meaning of the term. Many objects that are capable of being flexed are not flexible. A steel I-beam is capable of being flexed, but no one would call it "flexible." An I-beam flexes somewhat when a person walks across it and transmits vibrations when someone hits it with a hammer, but it is not flexible because it cannot be noticeably flexed without substantial force. Thus, this example suggests that the ordinary meaning of the term "flexible" is closer to "capable of being noticeably flexed with ease." See In re Buszard, 504 F.3d 1364, 1367 (Fed. Cir. 2007) ("We agree with Buszard that it is not a reasonable claim interpretation to equate 'flexible' with 'rigid[.]'"). As such, Plaintiffs' construction violates the basic canon that claim terms must be construed based upon the ordinary meaning of the terms. NTP, Inc. v. Research In Motion, Ltd., 392 F.3d at 1346; Interactive Gift Express, 256 F.3d at 1331.

Further, there is no definition in the specification that suggests this Court depart from the ordinary meaning of the term. (See '941 patent.) Indeed, the patent never even uses the term "flexible pad" except in the claims. (See id.) Additionally, many embodiments of the invention are made out of structures that would be easily flexed. For example, several embodiments attach actuators to a "semi-rigid foam structure," a "semi-rigid flexible foam structure," or a "semi-rigid foam cushion," which can all be easily flexed. ('941 Patent, 2:29-36, 32:47-52, 37:6-12, 37:23-25, 37:48-50.) Thus, given the consistency of many of the patent's embodiments with the Court's construction of the term, there is no reason to ignore the ordinary meaning of the term "flexible" to include structures that generally would be considered rigid. In re Buszard, 504 F.3d at 1367.

The second issue concerns whether a hand-held game pad is included in the term "flexible pad." Because the ordinary meaning of "flexible pad" suggests a hand-held game pad would be included in the term if it was flexible and because the specification suggests that the hand-held pad could be flexible, this Court finds that the term includes a hand-held game pad.

First, a hand-held game pad and a flexible pad are both "pads." Second, the specification discloses attaching actuators to a hand-held game pad:

"One very common control input device used for 1st person perspective combat games, and for most console games, is a hand-held game pad. FIG. 38A depicts a front view of an illustrative hand-held control input device. . . . Vibratory motors and/or solenoids can be attached to the hand-held game pad as depicted in FIGS. 83 and 84. In FIG. 38C, a vibratory tactile sensation generator 590 is attached to the back of the hand-held control input device. The single tactile sensation generator is effective for both hands, due to the small size of the hand-held game controller. In FIG. 38D, tactile sensation generators for the left hand 590 and right hand 591 are contained within a single housing. A first vibratory motor 590 predominately services the left hand, and a second vibratory motor 590 services the right hand. Additionally, a solenoid 594 rattles the hand-held controller (see FIG. 29E). These tactile sensation generators may be embedded within the hand-held controller at its point of manufacture.

('941 patent, 43:15-35 (some emphasis added.) Thus, nothing in the term "flexible pad" would exclude a hand-held game pad if it were flexible. The remaining question, then, is whether the hand-held game pad disclosed could be sufficiently flexible to be included within the scope of the term "flexible pad."

The specification suggests that it would be. As used in the specification, the term "pad" implies some flexibility because it is repeatedly used as a more general stand-in for flexible materials. The best example of the word "pad" being used as a stand-in for flexible matter appears in the specification's discussion of Figures 27-30:

"In Figs. 27-30, the tactile feedback seating unit 510 is a semi-rigid flexible foam structure, sealed with a cloth or vinyl layer, with a leg portion and a back portion, substantially shaped to easily rest upon any given seat, with a plurality of actuators embedded within the foam structure, such that the actuators in the pad produce localized vibration.

('941 patent, 37:6-12 (emphasis added.) On this, and several other occasions, the specification uses "pad" to refer to structures that are flexible. ('941 patent, 32:47-52; see also '941 patent, 37:48-50, Figs. 27A, 27C.) As such, the hand-held game pad could be flexible, and is specifically disclosed in the patent.
Defendants' argument that "flexible pad" refers only to "a foam or cushion-like structure," (Defs.' Br. at 8-10; Doc. No. 148), is unavailing because it improperly reads a limitation of an embodiment into the claim term. See Phillips, 415 F.3d at 1323; SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337 (Fed. Cir. 2001) ("[O]ne of the cardinal sins of patent law [is] reading a limitation from the written description into the claims."). There is no doubt that specification discloses foam or cushion-like structures; however, the word "pad" does not require the use of these materials. Certainly, a rubber pad would be one example of a pad that would not be made of foam or be cushion-like. Therefore, the Court also rejects Defendants' construction for this term.

Thus, because portions of both Plaintiffs' and Defendants' constructions are improper, 1 the Court adopts its own construction that is in line with the ordinary meaning of the term "flexible pad" and does not import any limitations from the specification into the claim. The Court construes the term "flexible pad" to mean "an object or base, where such object or base is capable of being noticeably flexed with ease, including, among other things, hand-held game pad controllers that are capable of being noticeably flexed with ease."

--- Footnotes ---

1. Plaintiffs' construction also improperly attempts to import their construction for "attached" into this term. That construction is discussed below under the appropriate heading.

--- End Footnotes ---

2. "Flexible plate"

According to Akeva, the "flexible plate" in the '300 patent should be defined according to its plain and ordinary meaning of "a smooth, thin piece of material that is bendable but which does not deform permanently when bent." adidas argues that the plain and ordinary meaning is rebutted because the term is "coined" by the patentee. The specification uses the terms "flexible" and "plate" in a manner inconsistent with their ordinary meanings. The plain and ordinary meaning of "flexible," adidas argues, is "capable of being bowed [i.e., bent down] without breaking" and the plain and ordinary meaning of "plate" is a piece of material that is flat, relatively thin, smooth and of uniform thickness, (adidas' Markman Br. at 12-13.) However, in the specification, a "plate" is not flat, smooth, or of uniform thickness, and "flexible" requires a convex or arched shape. To stay true to the patent, adidas argues, the flexible plate should be defined as "a separate and removable piece of material that is capable of being repeatedly bent from a normal, unflexed state (in which its central portion is elevated relative to its periphery) into a flexed state (in which the central portion is bent downward), without deforming permanently." (Id. at 12-13.)

adidas cites the following statement in support of its argument that the flexible plate must be elevated in the interior: "In each of the embodiments the central portion of the flexible member is raised relative to its outer perimeter so that when placed in the shoe, the interior portion in its normal state does not touch the rear sole support and/or rear sole." '300 Patent, col. 12, 11. 34-41. This statement does not support any limitation on the term "flexible plate." The structure with an elevated center is carefully set out as one possible embodiment of the flexible plate. The first phrase of the sentence, "in each of the embodiments," appears to refer to the embodiments described in the preceding sentence. That sentence begins "in each of the above described embodiments, . . . " The "embodiments" in these sentences are not meant to encompass all possible embodiments of the invention, but only the ones the patentee has chosen to describe in the specification. In any case, to find any limitation in the structure of the flexible plate, the court would require a more direct and clear reference, along the lines of the "all embodiments" language used in SciMed, or a more explicit definition of the "flexible plate."

adidas argues, also, that the plate need not have a uniform thickness because the specification discloses an embodiment that is thicker at the center than at the periphery. See '300 Patent, col. 11, 11. 27-32. The description of one embodiment that does not fit within the technical definition of "plate" is not enough of an inconsistency to limit the claim. The word "plate" is not being used here in a highly technical or scientific way, but instead is a description of the shape of the component. Additionally, there is no indication that the plate must be thicker at the center than at the periphery, only that it may be so
constructed.

Finally, adidas argues that a "flexible plate" cannot be integral with the shoe and must be construed as a separate and removable component. adidas contends that the written description refers mostly to a flexible region, which can take several forms, but the flexible plate is an embodiment of the flexible region that cannot be integral with other parts of the shoe. For example, the written description provides that "flexible region 200 can be incorporated into other elements of the shoe or can be a separate flexible member or plate." '300 Patent, col. 7, 11. 63-64. In the court's view, however, the patent appears to use the terms interchangeably. For instance, in referring to components depicted in the figures, the written description refers to both "flexible region 200" and "flexible member 200," and also to "flexible member 500" and "flexible plate 500." Additionally, the specification states that "any of the above-described flexible members may be used as flexible region 700." Id., col. 12, 11. 58-59. The written description also contemplates that the flexible members may be integral with other components. For example: "flexible member 200 could be . . . incorporated as an integral part [] of either the rear sole support or the rear sole," and "similar configurations of an integral flexible region are within the spirit of the invention." Id., col. 9, 11. 41-45; see also id., col. 10, 11. 28-30 ("the following disclosed embodiments of flexible members can be integrally incorporated into a portion of the shoe"). Even if the flexible plate is an embodiment of the flexible member or flexible region, both the "member" and "region" are envisioned as being integral with other parts of the shoe in at least some embodiments. See, e.g., id., col. 12, 11. 46-47 ("each of the above-described flexible members may be made integral with the rear sole support"). Thus, the court cannot find that the flexible plate must be a separate and removable component.

Therefore, the term flexible plate should be defined according to its plain and ordinary meaning. The dictionary definition of "plate" as a noun defining a shape is "a smooth usu. nearly flat and relatively thin piece of metal or other material" or "a perfectly flat sheet of material of uniform thickness throughout." Webster's Third New Int'l Dictionary 1734 (1986). Because there is some difference between the two definitions, the court must look to the specification to discern the appropriate choice. Here, the specification discloses several embodiments that are neither perfectly flat nor of uniform thickness. This indicates that the first, more general, definition is the better choice. The dictionary definition of "flexible" is "capable of being flexed," or more specifically, "capable of being turned, bowed, or twisted without breaking." Webster's Third New Int'l Dictionary 869 (1986). Again, the specification indicates that the properties of flexibility, cushioning, and springiness are important to the flexible plate. However, there is no indication that the plate need be capable of being turned or twisted. Akeva's proposed definition uses "bendable," and is otherwise consistent with the dictionary definition.

Thus, the term "flexible plate" should be construed to mean "a smooth, usually nearly flat, and relatively thin piece of metal or other material that is bendable."

**1660**

Claim 31 continues:

flexible wall means defining a fluid impervious chamber.

The parties agree that even though this limitation uses the word "means," it recites sufficient structure to take it outside of the means--plus--functions limitation recognized by 35 U.S.C. § 112, P6. Both parties also agree that the wall means is pliable, demarcates an enclosed space and does not allow fluids to pass through. Therefore, the court finds this limitation to mean "a pliable barrier that demarcates an enclosed space and does not allow fluids to pass through."

**1661**

4. "Flexible web" (Claims 1, 17)

a. The Parties' Proposed Constructions

<table>
<thead>
<tr>
<th>Motorola's Proposal</th>
<th>VTech's Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plain and ordinary meaning.</td>
<td>Requires construction.</td>
</tr>
</tbody>
</table>
Should the Court require a construction, the "flexible web" is "an elastic sheet of material." In the alternative, Motorola would be amenable to a construction of "a flat layer of elastic material."

"A flat layer of material placed on the backside of the key caps which allows the key caps to move independently and preventing the key caps from being pulled up."

b. Discussion

Again, the Court is of the opinion the term "flexible web" should be construed. Column 2, lines 51-53 does provide that the "flexible web" is applied to a backside of the key cap layer as VTech proposes. ('349, 2:51-53). In one embodiment, a "flexible web" interconnects at least some of the plurality of user interface key caps. ('349, 3:48-51). As noted above, the specification indicates that the flexible web may also be located in spaces between key caps. ('349, 3:49-52). Figure 9 also provides another exemplary key pad assembly where a "flexible web" portion 906 is disposed between adjacent key caps. . . . A backing material 908 is disposed on a backside of key caps. . . . ('349, 7:7-11). In these examples, the "flexible web" is not only on the backside of the key caps as VTech proposes. Thus, in the context of the specification a flexible web has a broader meaning than VTech proposes. It is also noted that the claim itself elsewhere states that the flexible web in question "is disposed on a backside of at least some for the plurality of user interface key caps." ('349 8:18-20). The construction of "flexible web" therefore does not require the placement language sought by VTech.

Both parties agrees to a "flat layer." The remaining issue is the type of material. In one exemplary embodiment, the "flexible web" is a resilient material, for example, silicone. More generally, in other embodiments, the "flexible web" may be some other elastomer material. ('349, 3:59-63). The "flexible web" may also be a flexible web film. ('349, 4:18-19). The "flexible web" and the key caps may comprise a common material ('349, 4:20-22, claim 3).

The purposes of the web include the following: it "allows the key caps to move independently." This is not the only stated purpose however. For example, the web also "generally prevents debris from entering" the device. ('349, 3:53-56). Therefore, VTech's proposed phrase "allows caps to move independently" is too limiting. Motorola's construction is consistent with the specification.

c. The Court's Construction

Accordingly, the Court construes the term "flexible web" to mean: "a flat layer of elastic material."

1662

3. "Flexibly coupled to the carrier portion" (Claim 6)

a. The Parties' Proposed Constructions

Motorola's Proposal
Plain and ordinary meaning.
Should the Court require construction, "flexibly coupled to the carrier portion" means "attached in such a manner as to allow individual key caps to be pressed; not rigid."

VTech's Proposal
Requires construction.
"The key caps are coupled to the carrier portion so that the key caps flexes in relation to carrier portion when pressed."

b. Discussion
Contrary to Motorola's contention, the Court is of the opinion that the phrase "flexibly coupled to the carrier portion" requires construction. The Court is not convinced a person of ordinary skill in the art would have a clear understanding of what this phrase means. The Court also declines to adopt Motorola's alternative proposal for this term for the following reasons. Motorola contends that "key caps flexibly coupled to the carrier portion" does not mean that the key caps must flex in relation to the carrier portion, but instead means only that key caps be attached in a manner allowing them to be pressed. However, Motorola's proposed construction is overly broad in view of the specification. Motorola's construction tends to describe any and every phone, allowing the keys to be pressed individually, and Motorola's proposal does not adequately capture the flexing as described in the specification. What is more, the prior art cited by Motorola in the background section also allows individual keys to be pressed in order for the phone devices to work.

Rather, with some modifications, the Court utilizes VTech's proposed construction. As urged by VTech, the Court finds that the flexible coupling should allow the key caps to flex in relation to carrier portion when pressed. Motorola's citation from the specification tends to support VTech's contention rather than its own. Column 2, lines 7-11, of the '349 Patent provides as follows:

each key cap is flexibly coupled to the carrier along at least one side of the key cap, and other remaining sides of the key cap are separated from other key caps and/or carrier portions by a space, thereby allowing the key caps to flex in response to a tactile depressing action by a user.

('349, 2:7-11) (emphasis added). This description states that the key cap is allowed to flex for two reasons: (i) its flexible coupling to the carrier on one side, and (ii) its separation from other key caps along its other sides. VTech's construction is more consistent with the language of the claim itself and the specification.

c. The Court's Construction

Accordingly, the Court construes the term "flexibly coupled to the carrier portion" to mean: "the key caps are coupled to the carrier portion so that the key caps flex in relation to the carrier portion when pressed."

II. ANALYSIS

A. "Capable of Flexing"

In its instructions to the jury, the district court construed the claim limitation "capable of flexing" in Claims 1 and 15 to mean "a generalized combination of cantilever bending and bowing about the general area of the base or base end." Trial Tr., Vol. 5 at 120. Bridgeport takes issue with the district court's construction. It argues that the court erred in construing the "capable of flexing" limitation of Claims 1 and 15 to encompass anything more than "cantilever flexing." It is unclear precisely what "cantilever flexing" means as used by Bridgeport, but we infer from Bridgeport's arguments that it uses the phrase to mean a specific type of flexing: bending of a rigid wing or side solely about its base end connection, without other bending or bowing.

Claim terms are presumed to be given their ordinary and customary meaning. Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999). The context of the surrounding words in a claim also must be considered in determining the ordinary and customary meaning of a disputed claim limitation. Brookhill-Wilk 1, LLC, v. Intuitive Surgical, Inc., 334 F.3d 1294, 1300 (Fed. Cir. 2003). The intrinsic record, comprising the claims, the written description, and the prosecution history if in evidence, "must be examined in every case to determine whether the presumption of ordinary and customary meaning is rebutted." Tex. Digital Sys., 308 F.3d at 1204. A patentee may rebut this presumption by "defining claim terminology in a manner inconsistent with its ordinary meaning," Biovail Corp. Int'l v. Andrx Pharms., Inc., 239 F.3d 1297, 1301 (Fed. Cir. 2001), or by disclaiming a particular interpretation of a claim term during prosecution, Biodex, 946 F.2d at 863.

We begin with the ordinary and customary meaning of the terms used in the claim limitation at issue. Johnson Worldwide, 175 F.3d at 989. The verb "flex" is defined as "to bend." Random House Unabridged Dictionary 733 (2d ed. 1993). The
ordinary and customary meaning of "capable of flexing" is thus simply "capable of bending." Neither party disputes that the ordinary and customary meaning of the term "flexing" encompasses not only cantilever flexing but also bowing or bending. Bridgeport concedes that "the term 'flexing,' standing alone, would connote a wide range of movements." Accordingly, we begin with the broad meaning of the term, and look to the intrinsic record to determine whether anything in that record overcomes the presumption that "flexing" has this broad ordinary meaning. See Tex. Digital Sys., 308 F.3d at 1204.

1. Claim Language

Bridgeport first turns to the language of the claims themselves. The "capable of flexing" limitation describes the wings (in Claim 1) or sides (in Claim 15), which are said to be "capable of flexing about said base toward said axis through said face." '674 patent, col. 6, ll. 47-49; col. 8, ll. 26-27. In Claim 15, this limitation is followed by the following claim language:

"corners connecting said side edges of said sides . . . with said sides furthermore capable of having their corners removed to increase the degree of flexing about said base toward said axis through said face member." Id. at col. 8, ll. 31-35.

The district court based its construction of "flexing" in part on the fact that in Claim 15, the corners of the box extender "need not be removed," and that, if the corners are not removed, "it is fair to say that . . . cantilever flexing cannot exist." Arlington Indus., Inc. v. Bridgeport Fittings, Inc., No. 3:CV-99-1857, slip op. at 8-9 (M.D. Pa. Oct. 25, 2001) ("Memorandum"). The court noted that Claim 15 provides that the corners are capable of being "removed to increase the degree of flexing." '674 patent, col. 8, ll. 33-34. This indicated to the district court that "the corners can be removed . . . [to] provide cantilever flexing where there was none before." Memorandum, slip op. at 9.

Bridgeport argues that corners "removed to increase the degree of flexing" mandate a different construction of "flexing." According to Bridgeport, the reference to an "increase" in the degree of flexing means only a change in the amount of flexing, not in the type of flexing as the district court held. Bridgeport notes that "nothing in the claim language or the specification suggests bowing." It also speculates that the corners depicted in the embodiment to which Claim 15 pertains are "specially designed to fold in on themselves to permit cantilever flexing about said base." It is unclear what basis Bridgeport has for this speculation. There is no reference in the specification to corners that are specially designed to permit folding. The specification states that the corner walls "may be trimmed away to create an extender with wings," and Figure 7 depicts "cut lines" that may be employed for this purpose, but there is no indication that the corner walls are designed to facilitate folding in an uncut state, as Bridgeport suggests. We see no reason to read the words "increase [in] the degree of flexing" in the manner argued by Bridgeport, and decline to find error in the district court's construction of "flexing" on this basis.

2. Written Description

Bridgeport next contends that the meaning of "flexing" must be limited to cantilever flexing because the written description "teaches only cantilever flexing." Bridgeport draws our attention to the "Description of the Invention" section, where the "flexing of the wings" is described as a "cantilever bending." '674 patent, col. 4, ll. 1-2. Bridgeport equates this "cantilever bending" with "cantilever flexing," and essentially invites us to import a limitation from the preferred embodiments to restrict the meaning of a claim term. We have consistently warned against this approach to claim construction, which is seldom justified. See Amgen, Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed. Cir. 2003) ("Because the claims are best understood in light of the specification of which they are a part . . . courts must take extreme care when ascertaining the proper scope of the claims, lest they simultaneously import into the claims limitations that were unintended by the patentee."); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) (holding that the presumption of ordinary meaning cannot be rebutted "simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history"). There is no indication in the written description of the '674 patent, for example, that Gretz "acted as his own lexicographer and clearly set forth a definition of the disputed claim term." CCS Fitness, 288 F.3d at 1366. Nor do we discern therein any express disclaimer of a particular meaning of "flexing." See id. at 1367; Biodex, 946 F.2d at 863. We accordingly decline Bridgeport's invitation to restrict the meaning of the claim term based on the description of the preferred embodiments.

3. Prosecution History
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

a. Kleinatland

Turning to the prosecution history of the '674 patent, Bridgeport argues that Gretz disclaimed non-cantilever flexing in arguments he made to distinguish prior art references. Bridgeport principally relies on the argument distinguishing Kleinatland that Gretz submitted in the course of prosecuting the '674 patent. As depicted in the figure below, Kleinatland disclosed an electrical outlet box 12, together with an extension plate 14 having "a center tubular flange portion sized for telescopic engagement with [the] outlet box." Kleinatland, col. 2, ll. 49-50. In the tubular flange portion, the side walls were connected to one another through their entire length.

[SEE ILLUSTRATION IN ORIGINAL]

The Examiner rejected Gretz's application as obvious over a combination of references, including Kleinatland. In his response, Gretz distinguished the Kleinatland box extender in the following terms:

There is no teaching in Kleinatland et al providing an electrical box extender for extending electrical boxes so that the extender is flush with a newly installed surface. There are no plurality of inwardly extending flat wings which flex about a face to allow the extender to be received within an existing electrical box. In Kleinatland et al the box is a relatively rigid telescoping member.

Bridgeport sees in this a redefinition of "flexing" to exclude bowing or bending.

In the course of prosecuting a patent application, a patentee may redefine a claim term. Biovail, 239 F.3d at 1301 ("We review both the specification and applicable prosecution history to determine whether the patentee defined claim terminology in a manner inconsistent with its ordinary meaning."); Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 955 (Fed. Cir. 2000) ("The court . . . must examine a patent's specification and prosecution history to determine whether the patentee has given the term an unconventional meaning."). An amendment or argument made in the course of prosecution may also serve as a disclaimer of a particular interpretation of a claim term. Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1304 (Fed. Cir. 1997) ("Since, by distinguishing the claimed invention over the prior art, an applicant is indicating what the claims do not cover, he is by implication surrendering such protection."); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution. . . . Claims may not be construed one way in order to obtain their allowance and in a different way against accused infringers."). We are not persuaded that Arlington's arguments distinguishing Kleinatland operate either as a redefinition of the claim term "flexing" or as a disclaimer of any particular interpretation of that term.

As shown above, Kleinatland discloses an electrical outlet box and extension plate. The extension plate "is a rigid molded plastic insulator member having a center flange portion sized for telescopic engagement with [the] outlet box." Kleinatland, col. 4, ll. 59-61. The extension plates described in the Kleinatland specification are shaped to be accommodated within the outlet boxes. There is no indication in Kleinatland that the "rigid" extension plates are intended to flex, bow, bend, or give in any manner to accommodate differently sized outlet boxes. Gretz's description of the Kleinatland device as "a relatively rigid telescoping member" was thus factually accurate and does not amount to a redefinition of "flexing" or a disclaimer of any part of the ordinary meaning of that term. Nor did Gretz's reference to the lack in Kleinatland of "inwardly extending flat wings which flex about a face to allow the extender to be received within an existing electrical box" operate as a redefinition or disclaimer. As noted above, there is no indication in Kleinatland that the extension plates flexed or yielded at all, and that is the gravamen of the argument. The reference to the "wings" set forth in one of the Arlington embodiments simply emphasizes the lack of any reference to flexing in Kleinatland, and cannot be taken as a disclaimer of everything other than cantilever flexing of separate wings, as Bridgeport would have it.

b. Reexamination Request

The arguments made by Arlington in its reexamination request relating to the McShane patents and the DADJ device described in the McShane brochure also fall short of a redefinition or disclaimer. As in the Kleinatland device, the box extenders described in the McShane documents include a tubular body "sized . . . to be received within an electrical box." '673 patent, col. 7, ll. 32-33; '996 patent, col. 6, l. 68 - col. 7, l. 1. There is no indication in any of the McShane references that the tubular body was designed to flex or yield in order to be accommodated within differently sized electrical boxes.
Indeed, McShane provided for different box extension sizes and shapes to fit different boxes: "the electrical box extension of the present invention can be manufactured for use with an electrical box of any shape or dimensions." '673 patent, col. 6, ll. 35-37. The specification shows examples of such specially manufactured box extensions for use with cylindrical or multi-outlet boxes. Id. at col. 6, ll. 37-48. The tubular body of the McShane patents is also designed specifically to avoid contact with the box. It has a taper to allow it to be "easily . . . inserted" into the electrical box in a manner that makes the body "less likely to be obstructed by rough edges, indentations, out-of-line-knockouts, broken-off or short screws, or the like." Id. at col. 4, ll. 29-34; '996 patent, col. 4, ll. 21-24. In the request for reexamination, Arlington asserted that "there is no flexing of the sides or walls involved in the McShane box extenders and they are not capable of flexing about the base." It also stated that "the four sides or walls are substantially rigid." Both McShane patents state that the tubular body can be made of plastic. '673 patent, col. 9, l. 2; '996 patent, col. 7, l. 37. However, Arlington's characterizations of the McShane references are accurate in light of any discussion of flexing of the tubular body in those references, and we see therein no disclaimer or redefinition affecting the scope of the claim term "flexing."

Gretz's testimony that the DADJ box extender "bellied out" or "flexed inwardly" to some degree when it was subjected to pressure may have prompted Arlington to request reexamination of the '674 patent in light of the written references relating to the DADJ device, namely the McShane patents and brochure. Although Gretz's testimony was before the district court during the Markman hearing, it is of little consequence in the claim construction analysis. That analysis must be based primarily on the record established at the time the patent was granted. See Tex. Digital Sys., 308 F.3d at 1202 ("When a patent is granted, prosecution is concluded, the intrinsic record is fixed, and the public is placed on notice of its allowed claims."); Vitrionics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996) ("The claims, specification, and file history, rather than extrinsic evidence, constitute the public record of the patentee's claim, a record on which the public is entitled to rely."). Moreover, Gretz's testimony does not appear to be inconsistent with Arlington's characterization of the box extender disclosed in the McShane references. Arlington characterized the sides or walls of the McShane devices as "substantially rigid." The fact that the sides of the device are caused to bow when sufficient pressure is applied does not mean that they are not "substantially rigid." Indeed, the fact that the DADJ device introduced into evidence at the trial broke when a witness tried to cause it to flex proves the very point that the sides of the DADJ device were "substantially rigid." Trial Tr., Vol. 4 at 95.

4. Invalidity

Finally, Bridgeport argues that the broad construction of the "capable of flexing" limitation must be erroneous, because it renders the claims invalid in light of prior art box extenders. Specifically, Bridgeport argues that the district court's construction renders the '674 claims obvious over a combination of the McShane patents and Kleinatland. Arlington counters that because Bridgeport has not challenged the jury's finding that the '674 patent is not invalid in view of those prior art references, Bridgeport has waived any argument that the content of the references limit the terms of the claims.

Arlington's waiver argument is unavailing. The McShane and Kleinatland prior art references are of record in the prosecution history and may be consulted in the process of claim construction for what they indicate about the state of the prior art. See Tate Access Floors, Inc. v. Interface Agric. Res., Inc., 279 F.3d 1357, 1371 n.4 (Fed. Cir. 2002) ("Prior art cited in the prosecution history falls within the category of intrinsic evidence."). However, Bridgeport does not establish that the district court's construction of "capable of flexing" renders any claim of the '674 patent invalid. Its invalidity argument is chiefly based on a repetition of the assertion we have not found persuasive, namely that the DADJ device "did in fact flex or 'bow' when pressure was applied to the sides." Bridgeport also asserts that the McShane '673 patent discloses an embodiment, allegedly depicted in Figure 7 of that patent, that "is used to function in the same way as the '674 patent--i.e., to flex to fit a variety of different shaped and sized electrical boxes without using multiple screws and brackets." However, that embodiment simply indicates that "such boxes can be provided alone, or together with or assembled with electrical box extensions of the present invention for use in new construction or the like." '673 patent, col. 7, ll. 10-13. There is no indication that this embodiment contemplates the use of a single box extender with electrical boxes of different shapes and sizes, as Bridgeport contends.

5. Conclusion

The district court's construction of "flexing" as "a generalized combination of cantilever bending and bowing about the general area of the base or base end" is consistent with the ordinary and customary meaning of "flexing," which is "bending." Because Bridgeport has not established that the district court's construction is in error based on the claim...
language, the written description, the prosecution history, or the prior art, we decline to disturb that construction on appeal.

I agree that the judgment should be affirmed. However, I respectfully dissent from the majority's construction of "capable of flexing" limitation in claim 1 of the '674 patent. The majority's claim construction allows the patentee to claim the very device disclaimed in the course of patent prosecution, a result plainly at odds with our precedent. However, I would affirm on the ground that the appellant did not preserve this error in its objection to the jury instruction.

The contested limitation of claim 1 of the '674 patent requires that the device have a plurality of wings "capable of flexing about said base." In its request for reexamination, Arlington distinguished claim 1 of the '674 patent from the McShane patents and the DADJ device described in the McShane brochure (which was also before the examiner) as follows:

There is no flexing of the wings involved in the McShane box extenders. The wings or sides are not capable of flexing about the base. The four wings of the electric box extender are substantially rigid. There is no adjustability by flexing of the wings designed into the McShane box extenders to allow the tubular body portions to be received in an existing electrical box. The McShane box extenders telescope into the electrical box without engaging the sides or walls.

(emphasis added). The examiner relied on this statement to deny the request for reexamination, finding that the newly cited McShane references did not "raise a substantial new question of patentability" as to the claims of the '674 patent.

The doctrine of prosecution disclaimer "limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003) (quoting Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985)). Arguments made in a reexamination proceeding will constitute a disclaimer of claim scope if they are "clear and unmistakable statements of disavowal." See Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1358 (Fed. Cir. 2003).

Here, Arlington has unmistakably disclaimed box extenders like those disclosed in the McShane patents and the McShane brochure featuring the DADJ device because they are not capable of flexing about the base as claim 1 requires. The question then is--what is the extent of this disclaimer? In other words, "we must determine what one of ordinary skill in the art would believe to have been disclosed" by the disclaimed references. Pall Corp. v. PTI Techs. Inc., 259 F.3d 1383, 1393 (Fed. Cir. 2001), vacated on other grounds, 535 U.S. 1109 (2002).

At trial there was undisputed testimony from both the inventor and Arlington's expert that the DADJ product, a device embodying the McShane patents and disclosed in the McShane brochure, was capable of bowing. Gretz, the inventor of the '674 patent, testified that when the DADJ product was inserted, "the body portion bowed in." Likewise, despite the statements in Arlington's request for reexamination regarding the inflexibility of the McShane device, Arlington's expert testified that the DADJ product was capable of bowing:

Bridgeport's Counsel:

If you apply pressure to the end walls of the DADJ product it does flex, does it not?

Witness:

You can see . . . it flex to a modest degree, yes.

Bridgeport's Counsel:

When you pressed on the walls of the DADJ there was some cantilever bending, correct-isn't that correct?

Witness:

No, sir, there is not. There is a slight bowing that takes place.
Moreover, defendants' contrary arguments in support of its proposed construction are unconvincing. They correctly note issue, as disclosed by the relevant intrinsic and extrinsic evidence.

For example, the term "flexure member" as "part of a longitudinal portion that provides flexibility" is consistent with the ordinary meaning of the phrase at issue, as disclosed by the relevant intrinsic and extrinsic evidence. Accordingly, plaintiffs' proposed construction of "flexure member" as "part of a longitudinal portion that provides flexibility," as informed by its dictionary definition, is expressed by the claim language as part of a longitudinal portion.

The majority notes that there is no indication in the McShane references themselves that the disclosed extender boxes or the DADJ product were designed to flex. Ante at 17. But even if this is true, the uncontradicted testimony of Arlington's experts establishes that one of skill in the art would recognize that the DADJ device embodying the references that were before the examiner was capable of bowing. Under these circumstances, Arlington disclaimed a device that merely bowed, but did not flex about the base. See Pall, 259 F.3d at 1383 (holding that the relevant inquiry is what one of ordinary skill in the art would believe to have been disclosed by the prior art). Therefore, the claim term, "capable of flexing about said base" must be construed to require something more than bowing. Rather, it must be construed to require flexing about the base.

The district court instructed the jury that the "capable of flexing" limitation in claims 1 and 15 means "a generalized combination of cantilever bending and bowing about the general area of the base or base end." Trial Tr., Vol. 5 at 120. While confusing, the instruction appears to permit the jury to find that the "capable of flexing" limitation is satisfied by mere bowing. To that extent the instruction was erroneous.

Neither party disputes that the phrase "flexure member" is absent from the patents' specification. Plaintiffs contend, however, that the phrase should be construed with reference to its ordinary dictionary definition, while defendants contend that the phrase should be construed in the context of the specification's language describing "flexure means," since a flexure member should be viewed as part of the general flexure means described in the specification. Defendants' arguments are at first blush appealing; however, a close review of the claim language and the specification suggests that plaintiffs have proposed the better construction.

Beginning with the claim language, the '037 patent covers a stent design that is comprised in part of "longitudinal portion[s] having a flexure member...". See, e.g., Joint Statement, '037 Patent at 14:50. These flexure members, when viewed in two dimensions, can be "non-sinusoidal and arcuate," or "U-shaped." Id. at 14:5-52, 15:40-42. The '255 patent, for its part, covers a stent design that is similarly comprised in part of a "plurality of longitudinal portions having a single flexure member...". See, e.g., Joint Statement, '255 Patent at 15:29-34. The flexure members are described as "U-shape[d]." Id. From the claim language set forth in both patents, therefore, the court can discern that a "flexure member" is part of a "longitudinal portion" and can be "non-sinusoidal and arcuate," or "U-shaped." In other words, the term "member," in reference to the phrase "flexure member," is expressed by the claim language as part of a longitudinal portion.

Although it provides some guidance as to how the "member" portion of the phrase "flexure member" should be construed, however -- i.e., by noting that a flexure member forms a part of a "longitudinal portion[s]" -- the claim language provides no further insight as to how the "flexure" portion of the phrase should be construed. Nor does the specification. Indeed, the specification never even mentions the phrase "flexure member." Given this, and the fact that neither party urges the court to refer to or rely on the prosecution history for further elucidation, plaintiffs correctly urge the court to rely on the ordinary meaning of the phrase "flexure," as informed by its dictionary definition. See Vitronics, 90 F.3d at 1583 (reliance on extrinsic evidence, such as dictionaries, and learned treatises appropriate, where intrinsic evidence fails to resolve ambiguity in claim language). Turning to the dictionary definition, "flexure" is defined as the ability to flex, or to turn, bend, or fold. See Merriam-Webster's Collegiate Dictionary 479 (11th ed. 2003). Accordingly, plaintiffs' proposed construction of "flexure member" as "part of a longitudinal portion that provides flexibility" is consistent with the ordinary meaning of the phrase at issue, as disclosed by the relevant intrinsic and extrinsic evidence.

Moreover, defendants' contrary arguments in support of its proposed construction are unconvincing. They correctly note
that, while the specification does not expressly refer to a "flexure member," it does refer to "flexure means." Based on this, they contend that a "flexure member" is part of a "flexure means," not part of a "longitudinal portion." However, there are two fundamental errors in defendants' approach.

First, as plaintiffs point out, the term "flexure means" is not a part of the actual claim language, whereas "longitudinal portion" is. Therefore, to define "flexure member" with reference to "flexure means" instead of "longitudinal portion" would improperly import a limitation from the specification into the claim language. See, e.g., Teleflex, Inc. v. Ficosa North Am. Corp., 299 F.3d 1313, 1324-26 (Fed. Cir. 2002)("The claims must be read in view of the specification, but limitations from the specification are not to be read into the claims.").

Second, and more importantly, the specification's description of "flexure means" actually seems to support plaintiffs' proposed construction, rather than defendants'. The specification, for example, states that the claimed design is a tubular wall comprised in part of a "series of longitudinal struts disposed substantially parallel to the longitudinal axis of the stent, each of the longitudinal struts comprising flexure means for substantially complementary extension and compression of a diametrically opposed pair of the longitudinal struts...". See Joint Statement, '037 Patent at 3:21-29 (emphasis added). In other words, the specification describes "flexure means" as the longitudinal struts themselves, which struts achieve complementary extension and compression with respect to diametrically opposed struts. Id. The specification then goes on to state: the "specific shape of the flexure means disposed in the longitudinal strut is not particularly restricted provided that it confers lateral flexibility" by allowing "substantially complementary extension and compression." Id. at 3:57-62. In the court's view, the specification therefore indicates that it is the shape of the overall flexure means disposed in the longitudinal struts that must confer lateral flexibility by allowing for opposing struts in the same horizontal plane or in different horizontal planes, to extend and compress. See id. at 3:57-66. In other words, it is the longitudinal struts -- which in turn constitute flexure means -- that must confer flexibility through substantially complementary extension and compression. And since the actual claim language at issue indicates that a "flexure member" is part of a "longitudinal portion," it follows from this that "flexure members," as lesser parts of the longitudinal portions, are not themselves required to provide for such extension and compression.

In sum, the court finds that defendants' (and the intervenor's) proposed construction is at odds with the intrinsic evidence, while plaintiffs' proposed construction is consistent with it. Accordingly, the court adopts plaintiffs' proposed construction of "flexure member," and construes it as: "part of a longitudinal portion that provides flexibility."

1666

Because we vacate the judgment of invalidity, we turn to Jones' cross-appeal that the district court erred in its claim construction of the term "flight bars." In a pre-trial Markman ruling, the district court construed the term "flight bars" to mean:

A term of art describing a type of structure that is used to select and transport articles along a cartoner, and may be driven by one conveyor or may include multiple conveyors moving in synchronization. This structure includes at least one part having a wedge-shaped or pointed tip and at least one part having a wall. The term may include a plurality of pieces driven by one conveyor or by multiple conveyors moving in synchronization.

Jones argues that the district court improperly relied upon extrinsic evidence in reaching its claim construction. Jones submits that "flight bars" are "unitary structural members having wedge shaped tips at one end."

"In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to use to 'particularly point[] out and distinctly claim[] the subject matter which the patentee regards as his invention.'" Interactive Gift Express, Inc. v. Compuseve, Inc., 256 F.3d 1323, 1331, 59 USPQ2d 1401, 1406 (Fed. Cir. 2001) (quoting 35 U.S.C. § 112, P 2); see generally Tex. Digital Sys., Inc. v. Telegenix Inc., 308 F.3d 1193, 1201-02, 64 USPQ2d 1812, 1817 (Fed. Cir. 2002). The terms used in the claims bear a "heavy presumption" that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 USPQ2d 1658, 1662 (Fed. Cir. 2002). Moreover, unless compelled otherwise, a court will give a claim term the full range of its ordinary meaning as understood by persons skilled in the relevant art. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342, 60 USPQ2d 1851, 1854 (Fed. Cir. 2002).
2001).

Here, both parties agree that "flight bars" must be interpreted the same way for each patent-in-suit. The parties further agree that the term "flight bars" should be given its ordinary and accustomed meaning. However, none of the patents-in-suit explicitly defines the term, and the court has not found the term in any dictionary or treatise. See In re Paulsen, 30 F.3d 1475, 1480, 31 USPQ2d 1671, 1674 (Fed. Cir. 1994) ("an inventor is indeed free to define the specific terms used to describe his or her invention"); Tex. Digital Sys., 308 F.3d at 1202-03, 64 USPQ2d at 1818 ("Dictionaries, encyclopedias and treatises, publicly available at the time the patent is issued, are objective resources that serve as reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art.").

The district court held, inter alia, that the "term [flight bars] may include a plurality of pieces driven by one conveyor or by multiple conveyors moving in synchronization." In other words, a flight bar is not limited to a unitary structure. Jones argues that the district court erred by not limiting the term "flight bars" to a unitary structure. After a de novo review of the entire record, we are in accord with the district court and find no reason to limit the term flight bars to a unitary structure. The term "flight bars" is used generally throughout the patents and consistently refers to structure that intersects articles on a conveyor, forms groups, and moves the articles. Nothing in the claim language, specification, or prosecution history suggests that flight bars must be of a unitary structure.

The district court, consistent with our guidance that a claim term is to be given "the full range of its ordinary meaning as understood by an artisan of ordinary skill," Rexnord, 274 F.3d at 1342, 60 USPQ2d at 1854, instructed the jury not to limit the term to the unitary structure found in the specification. We agree with that conclusion.

As noted above, the district court also construed flight bars to include, inter alia, a "structure that is used to select and transport articles along a cartoner, and may be driven by one conveyor or may include multiple conveyors moving in synchronization." In addition, the district court held that flight bars "include[] at least one part having a wedge-shaped or pointed tip and at least one part having a wall." While Jones does not challenge these holdings of the district court, we hold that the district court erred by holding that flight bars "may be driven by one conveyor or may include multiple conveyors moving in synchronization" and by holding that flight bars include "at least one part having a wall." Nothing in the intrinsic evidence requires us to construe the term "flight bars" to include these limitations. These errors, however, are of no consequence to the disposition of the case because Jones does not argue that its device does not meet these limitations.

Jones also complains that the district court improperly relied on extrinsic evidence, including the expert testimony from an engineer at a corporation defending infringement allegations in another case involving the same patents. While the district court did consider that extrinsic evidence, district judges are free to do so "to help the court come to the proper understanding of the claims." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584, 39 USPQ2d 1573, 1578 (Fed. Cir. 1996). Of course, extrinsic evidence "may not be used to vary or contradict the claim language" or "the import of other parts of the specification." Id., 39 USPQ2d at 1578. Here, the district judge did not impermissibly use extrinsic evidence.

4. "flight shape"

Defendants argue that "flight shape" in the '133 patent means "the shape the projectile must maintain for at least 20 yards and until impact." Def. Br. at 19. The plaintiff responds that nothing in the patent requires that the flight path be a minimum of twenty yards. Plaintiff notes that the claim should not be limited to a numerical limit disclosed in the specification, as discussed in Part 8, supra. "Flight shape" is properly construed as "the shape of the projectile after it is propelled out of the weapon shell and during the course of its flight."
Claim Term | Davis-Lynch's Proposal | Weatherford's Proposal
--- | --- | ---
"float equipment" Components or parts fitted together to comprise equipment at or near the bottom of a casing string that is operable for preventing the flow of wellbore fluid through the casing toward the surface or starting position of the wellbore. | Well tool having a one-way check valve(s).

"float equipment tubular" Components or parts fitted together to comprise equipment, shaped like a tube, at or near the bottom of a casing string that is operable for preventing the flow of wellbore fluid through the for a casing toward the surface or starting position of the wellbore. | Weatherford contends that the term "float equipment tubular" does not need to be defined in view of the construction of "float equipment." A tubular well tool having a one-way check valve(s).

Because the term "float equipment" does not appear separately in the claims at issue, the Court will not construe it. Weatherford's proposed construction of "float equipment tubular" is derived from two extrinsic sources. See A DICTIONARY OF PETROLEUM TERMS 33 (2nd ed., The University of Texas at Austin, Division of Continuing Education, Petroleum Extension Service 1979) (Drill-Pipe Float: "A valve installed in the drill stem that allows mud to be pumped down the drill stem but prevents flow back up the drill stem; a check valve"); D. LANGENKAMP, HANDBOOK OF OIL INDUSTRY TERMS & PHRASES 478 (5th ed., Penn Well Books 1994) (Valve, Check: "A valve with a free-swinging tongue or clapper that permits fluid in a pipeline to flow in one direction only; back-pressure valve"). Davis-Lynch's proposed construction is derived from the patent specification's definition of "float equipment":

As used herein, float equipment refers to equipment typically positioned near or adjacent the bottom of the tubular string such as casing or liner which contains valves that may be used to control back pressure that might permit cement to flow back into the casing/liner after cementing.

'336 patent at 1:64-2:2. Because the patentee has explicitly defined the term "float equipment," the Court will presume that this definition is an appropriate construction. See Phillips, 415 F.3d at 1316.

At the hearing, Davis-Lynch argued that Weatherford's proposal was overly broad because it did not explain that fluid is only blocked from flowing toward the surface. However, the patentee's definition of "float equipment" merely states that the valves "may be used to control back pressure that might permit cement to flow back into the casing/liner after cementing." '336 patent at 1:64-2:2 (emphasis added). Thus, Davis-Lynch's argument imposes a limitation not present in the patentee's explicit definition of the term float equipment. Weatherford argued, at the hearing, that Davis-Lynch's proposal impermissibly imports its proposed construction of tubular string and adds the limitation that the equipment must be located at the bottom of the tubular string. Weatherford's arguments are well taken. Having rejected Davis-Lynch's construction of the term "tubular string," the Court sees no reason to replace the phrase "tubular string" with the phrase "casing string." Similarly, the Court sees no reason to import the limitation that float equipment must be located at the bottom of a tubular string, when the patentee's definition states only that float equipment is "typically" located there. The use of the word "typically" implies that float equipment need not always be located at the bottom of a tubular string. See '336 patent at 1:65-66.

The Court finds the patentee's own definition of the term at issue to be understandable for a jury. However, the terms casing and liner could be confusing since the claims at issue only refer to tubular strings. In addition, the phrase "may be used to control back pressure . . ." must be removed because it merely describes a possible use for the flapper valves. Therefore, the Court will construe the term "float equipment tubular" as "tube-shaped equipment typically positioned near or adjacent to
Zeppelin also challenges the district court's construction of the term "floatation units." The court construed the term to mean "an individual structural constituent of a whole (i.e., the dry dock claimed in the '833 patent) which is buoyed on water." The court also determined that the "floatation units" must be "airtight" but not necessarily "hollow." Zeppelin argues that the claimed "floatation units" must be hollow as well as airtight.

Jet Dock agrees that the claimed "floatation units" are properly construed to be "airtight." It argues, however, that construing the claims as requiring the units to also be "hollow" imports a limitation into the claims. According to Jet Dock, "floatation units" should be construed broadly because the claims are not limited to the single embodiment that is disclosed in the '833 patent's specification.

In Phillips v. AWH Corp., 415 F.3d 1303, 2005 U.S. App. LEXIS 13954, Nos. 03-1269, -1286, F.3d (Fed. Cir. 2005) (en banc), we noted that "the line between construing terms and importing limitations can be discerned with reasonable certainty and predictability if the court's focus remains on understanding how a person of ordinary skill in the art would understand the claim terms." 2005 U.S. App. LEXIS 13954 at *55. We further noted that, "[i]n the end, there will still remain some cases in which it will be hard to determine whether a person of skill in the art would understand the embodiments to define the outer limits of the claim term or merely be exemplary in nature." 2005 U.S. App. LEXIS 13954 at *57. However, we stated that "we nonetheless believe that attempting to resolve [the] problem in the context of the particular patent is likely to capture the scope of the actual invention more accurately than either strictly limiting the scope of the claims to the embodiments disclosed in the specification or divorcing the claim language from the specification." 2005 U.S. App. LEXIS 13954 at *57 (emphasis added).

With those principles in mind, we turn to the term "floatation units" in the '833 patent. Doing so, we conclude that one skilled in the art would understand the term to be referring to units that are hollow as well as airtight. The very first sentence of the patent characterizes the overall invention of the '833 patent as a "floating, drive-on dry dock assembly for small craft [that] is assembled from two kinds of hollow floatation units." '833 patent, abstract (emphasis added). This communicates to one skilled in the art that a characteristic of a "floatation unit" in the invention of the '833 patent is that it is hollow.

Continuing, the '833 patent's specification describes the claimed floatation units with reference to prior art devices that also contain hollow units. The "Background of the Invention" section of the patent describes the prior art with reference to U.S. Pat. Nos. 3,824,644 and 4,603,962. According to the '833 patent's specification, "these patents describe hollow cubical units[.]" '833 patent, col. 1, ll. 21-24 (emphasis added). In particular, the prior art units were "provided with bungholes so that the units could be partially flooded to lower the water line of some or all of the units." Id. col. 1, ll. 28-32.

Most importantly, the "Summary of the Invention" section of the patent states: The dock is "assembled from a combination of tall and short, hollow, air-tight floatation units." Id. col 1, ll. 66-67 (emphasis added). Finally, in the preferred embodiment "all of the floatation units 12a-l and 14a-g are hollow and air tight." Id. col. 3, ll. 27-28 (emphasis added). In the preferred embodiment, the tall floatation units (12a-l) are described as being "substantially similar to that shown in U.S. Pat. Nos. 3,824,644 and 4,604,962[.]" '833 patent, col. 3, ll. 31-34. These are the same two patents previously described in the Background of the Invention section as containing "hollow" units that can be flooded with water. See id. col. 1, ll. 22-24.

We think that one skilled in the art reading the '833 patent claims, in light of the '833 patents' disclosure, would understand that the "floatation units" in the claimed invention are hollow. See C.R. Bard, Inc. v. United States Surgical Corp., 388 F.3d 858, 863-864 (Fed. Cir. 2004) (where a patentee had "globally" defined a "plug" for an implantable prosthesis as having a pleated surface, the term "plug" was so construed); Scimed Life Sys. v. Adv. Cardiovascular Sys., Inc., 242 F.3d 1337, 1343 (Fed. Cir. 2001) ("The characterization of the coaxial configuration as 'part of the present invention' is strong evidence that the claims should not be read to encompass the opposite structure."). Jet Dock's argument to the contrary presumes the conclusion that it seeks. To assert that "hollow" is improperly importing a limitation into "floatation units" is to presume that the "floatation units," as claimed in the '833 patent, are not characteristically hollow. That argument, however, presumes to know the meaning of "floatation units" to one skilled in the art—which is the very issue at hand. We do not think that to construe the "floatation units" as hollow is importing a limitation into the claims when the specification makes clear that
hollowness is an inherent characteristic of the "floatation units" in the claimed invention.

In sum, we construe claim 1 of the '833 patent as directed to floatation units that are airtight and hollow.

II. PROCEDURAL HISTORY

On July 31, 2000, this court held a Markman hearing on the proper construction of the terms "floatation unit" and "flexible joint between the units" in Claim 1. In an Order dated September 16, 2003, this court performed a claim construction analysis of the two terms. (See Markman Order, ECF No. 121.) This court found that a "floatation unit" is an airtight, individual structural constituent of a whole which is buoyed on water and that a "flexible joint between the units" is a point or position in the interval or position separating the floatation units of the dock, which point or position is capable of bending or flexing. This court also rejected Zeppelin's argument that Claim 1 of the '833 patent is drafted in step-plus-function format and subject to the strictures of 35 U.S.C. § 112, paragraph 6. (See id.)

As with other terms, three of US Foam's proposals use "allowing," suggesting that certain steps of the methods need only be permitted and not necessarily be performed. The Court rejects any construction that transforms a required method step into an optional one. The Court will not include "allowing" in its construction for these terms.

Defendants' proposal for the "flooding" term incorporates the remainder of the claim limitation into the disputed phrase. Claim 2 of the '965 patent reads, "The method of claim 1 further including the step of flooding said area of said mine shaft involved in the fire with water prior to directing said stream containing said expanded foam fire suppressant." '965 Patent, claim 2. The additional phrase, "prior to injecting or placing the foam mixture on the combustible material" in Defendants' proposal merely restates the remainder of the claim. The parties also appear to dispute whether flooding requires that the mine shaft be "fully" covered. US Foam relies on a dictionary definition, but chooses the one definition that requires the least amount of water. For example, other definitions recite "to become filled to excess with some fluid", "to cover or overwhelm", or "to fill more or less completely with water or other fluid." Based on both parties proposed terms, however, the parties apparently agree that the mine shaft must be covered with water and need not be filled with water. The Court construes "flooding said area of said mine shaft involved in the fire with water" to mean "covering the surfaces of the mine shaft that are on fire with water."

d. Floor

The ordinary meaning of the term "floor" is "the layer of material which is placed on top of the underframe of a car and provides the direct support for the car contents." See id. at 54. This is the way the term is used in the '575 Patent.

Claim 20 of the '575 Patent focuses on the floor of the rail car. Both the upper floor section and the intermediate floor section which is below the upper floor sections are carried on the body of the rail car. The body is comprised of the structures in the underframe of the car. This underframe is supporting the floor.

Additionally, the preferred embodiment of the '575 embodiment discusses how the contents of the rail car disclosed in the '575 Patent are to be placed directly on the floor. The floor provides direct support for the rail car's contents as the rail car in the '575 Patent is designed to carry approximately 200,000 pounds of lumber, and the preferred embodiment calls for the contents to be placed on the floor. See Findings of Fact, PP 111-120, 123-136, 139-142.
B. Claim 1 of the ’739 patent, which is the only claim at issue, reads as follows:

1. A personal mobility vehicle comprising:
   (a) a main frame unit including:
      (1) a floor pan having a back end;
      (2) a front wheel spindle pivotally connected to said pan;
      (3) a front ground engaging wheel rotatably mounted on said spindle; and
      (4) a steering tiller connected to said spindle;
   (b) a rear drive unit including:
      (1) a drive unit frame;
      (2) a rear axle means rotatably mounted on said drive unit frame;
      (3) a pair of spaced apart ground engaging rear wheels mounted on said rear axle means in spaced apart relation;
      (4) a motor mounted on said frame;
      (5) transmission means drivingly connecting said motor to said rear axle means; and
      (6) frame connection means removably connecting said drive unit frame to said floor pan of said main frame unit with
          said floor pan back end adjacent said rear wheels;
   (c) a seat unit including a seat member, said seat unit being connected to said floor pan of said main frame unit in
       proximity to said floor pan back end with said seat member in spaced relation to said pan;
   (d) a battery unit including a battery member; said battery unit being removably positioned on said floor pan of said main
       frame unit in proximity to said back end thereof; and
   (e) control means removably interconnecting said battery member with said motor to selectively operate said motor to
       propel said vehicle.

In its initial summary judgment decision in this case, the district court held that Bruno's vehicle did not infringe because
"Bruno's floor pan and battery pan structure function as separate components and there is a valid distinction between
Bruno's battery pan structure and the [’739 patent's] floor pan." The distinction the district court saw related primarily to the
location of the rider's feet. Relying on the California district court's claim interpretation on remand in In re Burke, Inc.,
MDL Docket No. 809-JSL, 11-12, the Wisconsin court noted that "the part of [Bruno's] vehicle where one places one's feet'
only reaches to the portion of the vehicle which Bruno refers to as 'the battery pan structure.'"

In its decision on the renewed summary judgment motion, the Wisconsin district court recognized, after this court's reversal
in Burke II of the California district court's judgment and claim interpretation, that "unobstructed access for feet is no longer
a valid basis upon which to define the contours of the 'floor pan.'" It quoted our language in Burke II that the floor pan of
the ’739 patent "is not limited to an unobstructed place where the rider's feet rest." The court then interpreted "floor pan" as
that term is used in claim 1 of the ’739 patent as composed of sheet metal which is contiguous and in a single plane.

The court compared this claim interpretation with Bruno's vehicle and found that none of these requirements of the floor pan
was satisfied. It determined that the horizontal frame of Bruno's vehicle comprises three pieces of sheet metal. Two of the pieces adjacent to the rear wheels are pans for the batteries. Because these are welded to the underside of the frame and not to the topside like the larger pan, the court held that they were not contiguous with the larger pan and were not in the same plane. Accordingly, the court found no infringement under its claim interpretation.

Burke challenges the district court's claim interpretation and urges that the court erred by reading unstated limitations into the claim to find noninfringement. It cites to this court's precedents and states that we have consistently and repeatedly cautioned against reading limitations into the claims of a patent. Moreover, according to Burke, nothing in the specification or prosecution history supports the district court's added requirements for the structure of the floor pan. Finally, Burke argues that the district court's added requirements and resulting interpretation of claim 1 of the '739 patent are inconsistent with our decision in Burke II.

In its appeal brief, Bruno has not directly responded to Burke's arguments and has not tried to support the added requirements of the floor pan imposed by the district court's claim interpretation. Instead, it urges that the district court's earlier interpretation of the floor pan limitation in its vacated Decision and Order should be sustained. That interpretation required that the entire floor pan be accessible to the rider's feet. Bruno argues that the two battery pans in its vehicle were not accessible to the rider's feet. In part, this argument is premised on Bruno's view that this court's claim construction in Burke II cannot be used for any purpose because it was in a nonprecedential opinion. As discussed above, we have concluded that the district court and Burke properly relied on our decision in Burke II and we are not persuaded that our claim construction in that case was incorrect.

The district court interpreted the term "floor pan" in the '739 patent to mean a contiguous assemblage of sheet metal when it stated:

The Court believes that a floor pan necessarily involves sheet metal and hence construes Claim 1's "floor pan" (qua entire horizontal frame, per [Burke II]) to mean a contiguous assemblage of sheet metal . . .

Burke, Inc. v. Bruno Independent Living Aids, Inc., Case No. 94-C-290, 9 (E.D. Wis. March 5, 1997). The court further explained this interpretation by saying that "by 'contiguous' the Court means either a single piece of sheet metal or several pieces of sheet metal welded directly to each other." Id. at 6 n.3. Using this interpretation, the court determined that Bruno's vehicle could not infringe because frame members were welded between portions of sheet metal. Moreover, the court interpreted "floor pan" as requiring that the sheet metal be in one plane. Bruno did not satisfy this requirement, according to the court, because the battery pans in the Bruno vehicle were lower than the larger sheet metal pan where the rider's feet are placed. Thus, the court based its finding of noninfringement of the floor pan limitation on the failure of Bruno's vehicle to have added characteristics not specifically set out in the claim - viz., a contiguous sheet metal floor pan entirely in the same plane.

The Supreme Court in Markman, 517 U.S. 370, 116 S. Ct. 1384 at 1387, 134 L. Ed. 2d 577, emphasized that the public is entitled to be apprised of what is and is not protected by a particular patent and that that is the purpose of claims. See also Corning Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257, 9 U.S.P.Q.2D (BNA) 1962, 1966-67 (Fed. Cir. 1989) ("A claim in a patent provides the metes and bounds of the right which the patent confers on the patentee to exclude others from making, using or selling the protected invention."). This court has held that the language of the claims, the specification and the prosecution history are principally involved in construing patent claims because these constitute the public record. See Markman, 52 F.3d at 976, 34 U.S.P.Q.2D (BNA) at 1326; Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996).

Consistent with the principle that the patented invention is defined by the claims, we have often held that limitations cannot be read into the claims from the specification or the prosecution history. See, e.g., Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053, 12 U.S.P.Q.2D (BNA) 1474, 1476 (Fed. Cir. 1989) ("This court has consistently adhered to the proposition that courts cannot alter what the patentee has chosen to claim as his invention, that limitations appearing in the specification will not be read into claims, and that interpreting what is meant by a word in a claim 'is not to be confused with adding an extraneous limitation appearing in the specification, which is improper.'") (quoting E.I. duPont de Nemours & Co. v. Phillips Petroleum Co. 849 F.2d 1430, 1433, 7 U.S.P.Q.2D (BNA) 1129, 1131 (Fed. Cir. 1988)). We are satisfied that the district court in this case has improperly read additional limitations into claim 1 of the '739 patent.
Looking first at the language of claim 1 of the '739 patent, there is no mention of "sheet metal" or "one piece of sheet metal or several pieces of sheet metal welded directly to each other" in the claim and there is no language that would exclude parts of the floor pan from being in a "different plane." All that the claim requires is "a floor pan having a back end" which can be connected to the rear drive unit in a manner that will place the floor pan back end adjacent to the rear wheels. The claims further state that the steering spindle and the seat unit are connected to the floor pan and the battery unit is positioned on the floor pan near the back end. The literal language of the claim, therefore, does not warrant the added requirements imposed by the district court.

Beyond the language of the claim, we must also look to the specification and prosecution history to see whether the patentee defined any of the pertinent terms of the claim or whether such terms would have the meaning to one skilled in the art ascribed to them by the district court. We do not glean from the specification the district court's definitions. "Floor pan" is not specifically given any special meaning by the inventor. While the pan disclosed in the preferred embodiment is sheet aluminum, an attribute of the preferred embodiment cannot be read into the claim as a limitation. See Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563, 231 U.S.P.Q. (BNA) 833, 835 (1986) ("This court has cautioned against limiting the claimed invention to the preferred embodiments as specific examples in the specification."); Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 U.S.P.Q.2d (BNA) 1289, 1299 (Fed. Cir. 1989) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations.").

There is also nothing in the specification which sets out design details such as whether one piece of sheet metal or several pieces welded together form the pan or whether frame members must be present or absent from certain locations in relationship to the surface of the pan. The written description, however, states that "the preferred embodiment has a floor pan frame composed of a center beam, a front lateral member and a rear lateral member" and that these frame parts are a steel beam and angle stock welded together. Thus, frame members were contemplated by the patentee to be part of the "floor pan." Finally, the single plane requirement found by the district court is inconsistent with the specification and would operate to exclude the preferred embodiment. The written description shows that the preferred embodiment does not use an entirely flat piece of aluminum; rather, it has a "raised center ridge" that goes over the central frame member and "outer edges . . . . upturned to strengthen the side portions." The district court's claim interpretation requiring a single plane would exclude the preferred embodiment described in the specification and, thus, cannot be sustained. See Howes v. Medical Components, Inc., 814 F.2d 638, 643-44, 2 U.S.P.Q.2d (BNA) 1271, 1274 (Fed. Cir. 1987).

Finally, the prosecution history contains no limiting definitonal arguments or concessions that would require the term "floor pan" to be interpreted with the added requirements imposed by the district court.

As noted by Burke in its appeal, this court previously construed the term "floor pan" in Burke II. There we said that "when all of the limitations of claim 1 are considered . . . the floor pan of the '739 patent essentially constitutes the horizontal frame of the claimed scooter," Burke II, 82 F.3d at 435 (table), 1996 WL 137527, **3. We reached this claim construction by examining the specification which describes the term "floor pan" as used in the patent as including not only the surface on which the feet and battery are placed but also framing, such as the center beam, front lateral member and rear lateral member shown for the preferred embodiment. We concluded that claim 1 and the specification make clear that the floor pan of the '739 patent is not limited to an unobstructed place where the rider's feet rest. Rather, it is essentially the entire horizontal frame, including the place where the battery is placed. See id.

For the reasons stated, we must conclude that the added requirements of the floor pan that the district court relied on for its finding of non-infringement cannot be upheld. The summary judgment based on the court's interpretation of the claim term "floor pan" is therefore vacated.

1. The "Floral Holding Material" Limitation

The district court construed the claim language "floral holding material" to mean "a three-dimensional solid, semi-solid, or granular material capable of giving support to individual flowers when their stems are inserted into the material," and required that the flower stems be "inserted into and through" the floral holding material. For the reasons given below, we
conclude this construction was erroneous. Neither the phrase "inserted into" nor "inserted through" appears in any of the asserted claims. Instead, all of the claims at issue require that the "floral holding material" be constructed of "material capable of receiving a portion of the floral grouping and supporting the floral grouping without any pot means." '856 patent, col. 8, ll. 19-22. The claim language does not require that the stem end of the flower be inserted into and through the floral holding material. Moreover, we find the teaching of the written description is at most ambiguous whether "capability of receiving a portion of the floral grouping" requires insertion into and through the floral holding material because floral holding material, as we discuss below, is not limited, as the district court held, to floral foam or soil. Similarly, the claim language requiring flower stem ends to be "disposed in" the floral holding material does not require that floral stem ends be "inserted into and through" the material. We cannot conclude from the foregoing that the patentees unambiguously limited the scope of the claimed invention to require flowers to be "inserted into and through" the floral holding material. For us to do so here would be to impermissibly read a limitation into the claims from the written description. Comark, 156 F.3d at 1186, 48 USPQ2d at 1005 ("While . . . claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims." (quoting Sjolund v. Musland, 847 F.2d 1573, 1581, 6 USPQ2d 2020, 2027 (Fed. Cir. 1988))). Here, the claims only require that the "floral holding material" have an upper end, a lower end, and an outer peripheral surface, and be constructed of a substance capable of receiving and supporting a floral grouping without any pot means.

While Polypap recognizes that none of the claims at issue explicitly require that the flower stem ends be "inserted into and through" the floral holding material, it nonetheless suggests that a proper interpretation of the terms "floral holding material" and "material capable of receiving a portion of the floral grouping and supporting the floral grouping without any pot means" compels such a limited claim scope. In doing so, Polypap points out that Figure 2 of the '856 patent, and at least some of the language of the written description and prosecution history, suggests that the preferred embodiment of the invention narrows the scope of "floral holding material" to floral foam or soil. Figure 2 of the '856 patent, which refers to one preferred embodiment, is shown below:

[SEE FIG. 2 IN ORIGINAL]

Polypap bases its argument on the following language in the written description:

As shown in FIG. 2, the floral holding material 18 has an upper end 20, a lower end 22 and an outer peripheral surface 24. The floral holding material 18 shown in FIG. 2 is spherically shaped, although the floral holding material 18 may be any shape desired in any particular application. The floral holding material 18 is constructed of a material capable of receiving a portion of a floral grouping 26 and holding or supporting the floral grouping without any pot means such as a separate flower pot for example. The floral holding means [sic] 18 may be the type of material commonly referred to in the art as floral foam or Oasis TM or may be soil or artificial soil or other earth composition so long as the material is capable of holding its predetermined shape and capable of receiving and supporting the floral grouping 26 without any additional pot means. The floral holding material 18 may be capable of receiving and holding water for supplying water to the floral grouping 26.

'856 patent, col. 3, ll. 40-58.

We find this argument unpersuasive. First, the written description does not describe "with reasonable clarity, deliberateness, and precision" the definition of "floral holding material" proposed by Polypap. See In re Paulsen, 30 F.3d 1475, 1480, 31 USPQ2d 1671, 1674 (Fed. Cir. 1994). The written description only states that the floral holding material "may be" (not must be) the type of material commonly referred to in the art as floral foam or soil. Indeed, the many uses of the term throughout the '856 patent are consistent with a broader definition, one encompassing material of any shape or type. '856 patent, col. 3, ll. 44-45 ("The floral holding material 18 may be any shape desired in any particular application."); id. at col. 3, ll. 50-52 ("The floral holding means [sic] 18 may be the type of material commonly referred to in the art as floral foam or Oasis TM or may be soil . . . ."). The written description makes quite clear that the open-ended examples of "floral holding material" are merely illustrative; that is, they do not exhaustively delineate the "floral holding material" that is clearly defined in the claims. The general rule, of course, is that claims of a patent are not limited to the preferred embodiment, unless by their own language. See, e.g., Va. Panel Corp. v. Mac Panel Co., 133 F.3d 860, 866, 45 USPQ2d 1225, 1229 (Fed. Cir. 1997) ("It is well settled that device claims are not limited to devices which operate precisely as the embodiments described in detail in the patent."). Varied use of a disputed term in the written description demonstrates the breadth of the term rather than
providing a limited definition. See, e.g., Enercon GMbH v. Int'l Trade Comm'n, 151 F.3d 1376, 1385, 47 USPQ2d 1725, 1731-32 (Fed. Cir. 1998) (refusing to limit a term used "interchangeably" in the written description to only one of the uses of the term). There is nothing in this case that warrants departing from the general rule. That the term "floral holding material" is used at various points in the written description to refer to a material of any shape or type is simply not "a special and particular definition created by the patent applicant," Renishaw plc v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249, 48 USPQ2d 1117, 1121 (Fed. Cir. 1998), and is thus an insufficient reason to limit the scope of the claim.

Polypap also argues that the patentee ascribed a special meaning to the term "floral holding material" in the prosecution history. See, e.g., Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378, 49 USPQ2d 1065, 1068-69 (Fed. Cir. 1998) (stating that explicit meanings given to claim terms in order to overcome prior art will limit those terms accordingly). In particular, Polypap asserts that the examiner's statement in an October 1, 1993 office action citing U.S. Patent No. 3,316,675 to Cartwright as having "roots in the holding material" and citing U.S. Patent No. 2,774,187 to Smithers as having "a system in which flower stems are stuck into a block of holding material" is a clear definition of "floral holding material." It is undisputed that the examiner's statements were focused on the requirement that the Cartwright and Smithers patents used "holding material" in the form of soil or an earth composition as a means of holding the roots of a growing plant in place. However, the examiner never stated that "holding material" is equivalent to the "floral holding material" claimed in the patents. We note that drawing inferences of the meaning of claim terms from an examiner's silence is not a proper basis on which to construe a patent claim. See DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1326, 57 USPQ2d 1889, 1896 (Fed. Cir. 2001).

We conclude that the prosecution history does not attribute a special meaning to the phrase "floral holding material," and there were no express representations made in obtaining the patent regarding the scope and meaning of the claim terms. Moreover, the scope of the asserted claims may be ascertained from the plain language of the claims. See Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.3d 855, 865, 9 USPQ2d 1289, 1299 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."). We refer to portions of the specification which specifically define the terms of the claim, i.e., the terms of the phrase "floral holding material having an upper end, a lower end and an outer peripheral surface, the floral holding material being constructed of a material capable of receiving a portion of the floral grouping and supporting the floral grouping without any pot means" must be given their ordinary meaning.

1. "flowpath," "flowpath . . . between"

Four of the patents at issue claim, in various forms, a "flowpath" situated "between" the basin and tank. Generally speaking, there are two classes of these claims. In the first class the claims use language which presuppose a unidirectional flow -- i.e., they explicitly contemplate that fluid will flow "from the basin. . . to the tank." For example, claim 1 of the '110 patent recites:

1. A system for cleaning hydrocarbons from a part, comprising a biodegradable, non-toxic, non-caustic, nonflammable oil dispersant cleaner and degreaser fluid, a parts washer including a tank for containing the fluid and a basin for receiving the part, a pump and conduit assembly for pumping the fluid from the tank into contact with the part within the basin, a flowpath defined between the basin and the tank through which the fluid flows from the basin back to the tank, and microorganisms within the parts washer for biodegrading the hydrocarbons:

    the microorganisms substantially sustained within and flowing with the fluid; the parts washer further includes a heater for heating the fluid; and

    means for controlling said heater to maintain the fluid approximately at a desired temperature and for disabling said
heater as the fluid drops to below a desired level in the tank.

'110 patent, col. 8, ll. 24-40; see also '125 patent, col. 9, ll. 3-4 ("a flowpath defined between the basin and the tank through which the fluid flows from the basin into the tank"). The other claims, however, use "flowpath" language that does not presuppose a unidirectional flow. For example, claim 5 of the '835 patent recites:

5. A system for cleaning hydrocarbons from a part, the system comprising a biodegradable, non-toxic, non-caustic, nonflammable, oil dispersant cleaning and degreasings [sic] fluid, a parts washer including a tank for containing said fluid and a basin for receiving the part, a conduit assembly, a pump for pumping said fluid from said tank through said conduit assembly and into contact with the part within said basin, a flowpath defined between said basin and said tank through which said fluid flows between said basin and said tank, and microorganisms within said parts washer, said microorganisms at least partially flowing with and substantially sustained within said fluid, said fluid being non-toxic to said microorganisms, whereby the microorganisms biodegrade the hydrocarbons while retained within said tank.

'835 patent, col. 8, l. 66 - col. 9, l. 12; see also '491 patent, col. 8, ll. 36-37 ("providing a flowpath for the fluid between the basin and a tank"); '125 patent, col. 10, ll. 1-2 ("providing a flowpath for the fluid between the basin and a tank"); id., col. 10, ll. 40-41 ("providing a flowpath for the fluid between the basin and a tank");

1 Unless otherwise noted, all formatting in the claims is added by the Court to emphasize the disputed claim language.

In all of these claims, the parties dispute whether the term "flowpath," standing alone, requires structure. Plaintiff ChemFree argues that it does not and that the term should be construed simply as "the path taken by the fluid." In contrast, Defendant argues the term does require structure, and thus that "flowpath" should mean "structure establishing a course followed by the fluid from the basin, through the drain in the basin, and then directly into the tank." In the second set of claims -- those that do not explicitly recite a "from-to" directional limitation -- the parties dispute whether a "flowpath . . . between" the basin and tank encompasses bidirectional flow or only the flow of fluid from the basin to the tank. Plaintiff argues that the absence of directional language contemplates a bidirectional flow -- i.e., the flow of cleaning fluid either from the basin to the tank or from the tank to the basin. Defendant argues that "between" when associated with "flowpath" should encompass only the flow of fluid from the basin to the tank.

The Court addresses whether "flowpath" is bidirectional, the more difficult issue, first. 2 The claims, regardless of whether they explicitly contain language indicating a direction of flow, make clear that the Applicant regarded the flow of fluid from the tank to the basin to be distinct from the flow of fluid from the basin to the tank. In order to deliver cleaning fluid from the tank to the basin to wash a part, the Applicant contemplated and claimed a pump and conduit arrangement. In order to return the cleaning fluid and hydrocarbons removed from the part to the tank, the Applicant contemplated and claimed only a "flowpath," which allows the fluid to flow via gravity through one or more drain holes in the bottom of the basin. For example, claim 1 of the '110 patent recites "a pump and conduit assembly for pumping the fluid from the tank" and "a flowpath defined between the basin and the tank through which the fluid flows from the basin back to the tank." The Applicant's choice of language confirms that it intended the path for delivery of the fluid to be separate from the path for draining the fluid. In other words, it reveals the Applicant regarded "flowpath" as "the path taken by the fluid from the basin to the tank," not as a general purpose word to describe the path of the cleaning fluid wherever it may flow.

2 The parties first raised this issue at the Markman hearing. Thus, the Court construes it without the benefit of detailed briefing.

Notably, the same dichotomy is present in claims where there is no explicit recitation of a direction of flow. For example, claim 5 of the '835 patent recites "a pump for pumping said fluid from said tank through said conduit assembly" and "a
flowpath defined between said basin and said tank through which said fluid flows between said basin and said tank.
Although the "flowpath" language does not contain an explicit unidirectional limitation, it is clear from the recitation of both a "conduit assembly" and a "flowpath" that the Applicant intends the "flowpath" portion of the claim to accomplish only the returning of the fluid to the tank. Otherwise, reference to the conduit assembly would be redundant.

The same result obtains in claims that expressly recite a non-directional flowpath standing alone. Claims 12 and 22 of the '125 patent and claim 1 of the '491 patent recite "a flowpath for the fluid between the basin and [the] tank." These claims do not, however, impose a direction of flow limitation or contain a complementary "conduit assembly" limitation. Generally speaking, a "claim term should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). As discussed above, the "flowpath" recited in claim 1 of the '125 patent -- which contains both a unidirectional limitation and a complementary "conduit assembly" limitation -- clearly and unambiguously refers to the path taken by the cleaning fluid from the basin to the tank. Plaintiff has presented no persuasive reason why the "flowpath" limitation in claims 12 and 22 of the same patent (which are materially identical to claim 1 of the '491 patent) should be construed any differently.

3 Notably, each of these claims does contain an "exposing the part to a [cleaning] fluid" limitation that appears to take the place of the "conduit assembly" limitation.

It is evident that the Applicant consistently, among all patents, used the word "flowpath" to refer to the draining of the fluid from the basin. It is worth noting that Plaintiff initially argued as much in its claim construction briefing: "[A]fter a part is washed, the cleaning fluid flows back down to the tank. The path taken by the cleaning fluid as it returns to the tank is referred to consistently throughout the claims as the 'flowpath.'" (Pl.'s Opening Claim Construction Brief [hereinafter "Opening Brief"] at 21 (emphasis added).) In that briefing Plaintiff also attempted to dispel any notion that "flowpath" may carry a different meaning depending upon the claim in which it appeared: "All of the patents that contain flowpath and flowpath positioning terms share a common specification. Use of the term Towpath' is consistent between all four patents." 4 (Id. at 22 (emphasis added)).

4 Based upon comments made at the Markman hearing, Plaintiff's change of position is an obvious attempt to expand the scope of the claims to read upon a device it discovered after claim construction briefing was complete.

The specification common to these four patents also supports this construction of the "flowpath" terms. Although the specification does not explicitly use the term "flowpath," it does make several informative disclosures related to the general flow of cleaning fluid in the parts washers, both from the tank to the basin as well as from the basin to the tank. These teachings include:

The tank is partially filled with the cleaning fluid and a pump and conduit assembly direct a flow of the cleaning fluid to the basin. The cleaning fluid discharged into the basin flows through a drain hole in the false bottom, through the filter and support grid, and then through a drain hole defined through the bottom panel of the sink member and cleaning fluid is then returned to the tank for reuse.

'110 patent, col. 2, ll. 6-13. 5

When the pump 73 is operating, it draws the cleaning fluid 72 from the bottom region of the tank cavity 44 and discharges the cleaning fluid 72 into a conduit 74. The conduit 74 is connected to and discharges into a base (not shown) of the faucet 24, whereby the fluid discharges from the nozzle 26.

Id. col. 4, ll. 22-27.
In operation, the pump 73, conduit 74, and faucet 24 circulate cleaning fluid 72 from the depths of the tank cavity 44 to the basin cavity 18 where parts cleaning takes place. . . . In accordance with one method of the present invention, cleaning fluid 72 flows out of the nozzle 26 and the part being washed is oriented within the stream of cleaning fluid 72 exiting the nozzle 26. The cleaning fluid 72 removes organic waste from the part being washed, and then the cleaning fluid 72, along with the organic waste and any small particulate washed from the part, flows by gravity through the drain hole 64 and the strainer (not shown) associated therewith. The strainer will, of course, keep certain objects from passing through the drain hole 64. The cleaning fluid 72, organic waste, and remaining particulate matter then encounter the filter pad 60. Subsequently, the fluid 72 and organic contaminants pass through the support grid 58, and drain hole 52 to deposit into the tank cavity 44.

Id., col. 6, ll. 32-51.

--- Footnotes ---

5 Except when discussing terms found exclusively in the '226 patent, for ease of reference the Court will generally cite to the specification of the '110 patent.

--- End Footnotes ---

These disclosures reveal that the Applicant intended for distinct language to govern the two types of flow. As succinctly put by Plaintiff in its Opening Brief,

The specification uses different language to describe: (i) the movement of the cleaning fluid from the tank to the basin before the part is cleaned; and (ii) movement of the cleaning fluid from the basin back to the tank after the part is cleaned. . . . During the ascent, the fluid travels through a conduit. In contrast, during the descent, the fluid travels in accordance with a flowpath.

(Pl.'s Opening Brief at 24.)

The Court thus determines that "flowpath . . . between" the basin and tank does not encompass bidirectional flow, but only the flow of fluid from the basin to the tank.

The second, and easier, question relates to whether the "flowpath" terms must be construed by reference to structure. Defendant insists "[t]he ordinary meaning of the disputed phrases in these claims is 'structure establishing a course followed by the fluid from the basin, through the drain in the basin, and then directly into the tank.'" (E.g., Def.'s Opening Brief at 18.) Defendant's argument is not clear, but it appears to construe the claim by reference to the preferred embodiment discussed in the specification. As seen from the specification excerpts dealing with the flow of cleaning fluid, as well as from the Court's discussion of the nature of the "flowpath," it is clear that the "flowpath" is simply the path taken by the fluid as it returns to the tank after it is used to wash a part in the basin. Nowhere in the intrinsic or extrinsic evidence does is it indicate a structural limitation is required. Nor does the specification impose any artificial constraints requiring a construction where the "flowpath" begins at the drain in the basin and ends at some point immediately thereafter. Thus, the Court declines to impose these arbitrary limitations.

For the reasons discussed above, the Court construes the "flowpath" and "flowpath . . . between" terms to mean "the path taken by the cleaning fluid from the basin to the tank."

GO BACK

1676

F. Flow Channel

The term "flow channel" appears in steps (f) and (g) of claims 1 and 21. Claim 1 recites:

(f) adjusting the mold system to thereby eject the product, wherein the first mold cavity comprises a first-cavity-flow-
channel which is located adjacent the first-layer-defining-mold-cavity-section, with a flow channel being defined as a portion of a mold cavity which is significantly thicker and wider than the adjacent mold cavity thickness for the purpose of directing the flow of injected plastic, and wherein step (a) comprises the step of:

(g) directing the first plastic into the first-layer-defining-mold-cavity-section via the first-cavity-flow-channel, so that the first plastic flows in the first-cavity-flow-channel in a direction which is positively different from said first predetermined general direction.

'282 Patent, col. 8, lines 46-62 (emphases added). Claim 21 similarly recites:

(f) adjusting the mold system to thereby eject the product, wherein the second mold cavity comprises a second-cavity-flow-channel which is located adjacent said second-layer-defining-mold-cavity-section, with a flow channel being defined as a portion of a mold cavity which is significantly thicker and wider than the adjacent mold cavity thickness for the purpose of directing the flow of injected plastic, and wherein step (d) comprises the step of:

(g) directing second plastic into the second-layer-defining-mold-cavity-section via the second-cavity-flow-channel, so that the second plastic flows in the second-cavity-flow-channel in a direction which is positively different from said second predetermined general direction.

Id. at col. 11, lines 20-35 (emphases added).

As Turn-Key notes, the claims themselves explicitly define the term "flow channel" to be "a portion of a mold cavity which is significantly thicker and wider than the adjacent mold cavity thickness for the purpose of directing the flow of injected plastic." Such an explicit definition in the intrinsic evidence is, of course, controlling. See Jack Guttman, Inc. v. Kopykake Enterprises, 302 F.3d 1352, 1360 (Fed. Cir. 2002). This definition provides both a structural and a functional limitation to the term "flow channel." Structurally, it is a part of the mold cavity that is significantly thicker and wider than the adjacent cavity thickness. Functionally, the flow channel directs the flow of injected plastic, i.e., the flow channel is thicker and wider than the adjacent mold cavity "for the purpose of directing the flow of injected plastic." Furthermore, step (g) qualifies the functional "directing" limitation of step (f) by providing that the flow channel directs flow so that the plastic flows in the flow channel "in a direction which is positively different from said . . . predetermined general direction." Turn-Key concedes that a structural element, even if thicker and wider than the adjacent mold cavity, cannot be a "flow channel" as claimed in the '268 patent "if it does not direct plastic melt into a layer-defining-mold-cavity-section in an unquestionably different direction than it had in the 'flow channel' prior to being so directed."

Perhaps because the claim language itself so thoroughly defines a "flow channel," the written description shines little additional light on this term. However, Figure 1, supra, illustrates the relationship between a flow channel and the rest of the mold cavity. As described in the written description and illustrated in Figure 1, mold cavity 1 includes both flow channel 6 and layer-defining-mold-cavity-section 2. Thus, as provided in the claims, the flow channel is a portion of the mold cavity. In addition, as can be seen from the figure, flow channel 6 is much deeper and wider than the adjacent mold cavity section. This is consistent with the definition provided in the claim language, which requires the flow channel to be "significantly" thicker and wider than the adjacent cavity section.

The prosecution history provides further support for the definition of flow channel found in the claims. The patentee amended the claims to add steps (f) and (g) in response to an anticipation rejection over U.S. Patent No. 3,822,107 to Wogerer (the "Wogerer patent"). The examiner explained:

The sections of the cavity extending from the gate for nozzles 1 and 2, as shown in the figures of Wagerer [sic], are equivalent to first-cavity-flow-channel and second-cavity-flow-channel. The section of the cavity (where pin 5 extends) is equivalent to the first-layer-defining-mold-cavity (figure 1) and the second-layer-defining-mold-cavity (figure 2). Part 3 (fixed mold) is a shared gate means.

(Turn-Key Tech's Markman Exhibit 3 at 65). The limitations that became steps (f) and (g) were previously recited in a dependent claim, and were incorporated into independent claim 1 in response to the rejection. Relying on the both the structural and functional limitations recited in the amendment, the patentee distinguished Wogerer by noting that:
Wogerer does not describe an injection molding system in which injected plastic is directed by flow channels, as recited in amended claim 1 and new Claim 28 [which became independent claim 21 in the issued patent] . . . . The definition of "flow channel" added to these claims by this amendment precludes the Examiner's interpretation of Wogerer's cavity as including sections that are equivalent to flow channels. If the flow channels are not significantly thicker and wider than the adjacent mold cavity thickness, they do not significantly direct the flow of the injected plastic.

(Id. at 121). This explanation reinforces the structural and functional definition of "flow channel" provided in the claims. And, the patentee relied both upon the unique structural features of the claimed flow channel, as well as its ability to direct the flow of plastic into the mold, in order to distinguish the claimed invention from the prior art Wogerer patent. Furthermore, as Turn-Key notes, by specifically referring to "the definition of flow channel added to these claims by this amendment," the patentee's explanation also clearly refers the public to the claim language itself to find a definition of "flow channel."

In short, the patent claims themselves define "flow channel" to be "a portion of a mold cavity which is significantly thicker and wider than the adjacent mold cavity thickness for the purpose of directing the flow of injected plastic," and further require (in step (g)) that the flow channel directs flow so that the plastic flows in the flow channel "in a direction which is positively different from said . . . predetermined general direction."

Koito does not disagree with the general definition of "flow channel" provided above. However, it seeks either to add to or clarify that definition in several respects. First, Koito urges that the court construe "flow channel" to require a structure that directs the plastic to flow in a single direction through the flow channel. Koito argues that the use of the article "a" before "direction" in step (g) mandates this result. The Federal Circuit "has repeatedly emphasized that an indefinite article 'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims containing the transitional phrase 'comprising.'" KJ Corporation v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000). Only if the intrinsic evidence indicates that the inventor intended "a" to carry its normal, singular meaning, will the court so limit the claim. See Atofex, Inc. v. Exitron Corp., 122 F.3d. 1019, 1023 (Fed. Cir. 1997). Koito contends that in context, these claims require a singular definition because they require comparison with the "predetermined general direction" of flow in the layer-defining-mold-cavity-section. Koito argues, in essence, that it is impossible to have the predetermined general direction be "positively different" from the direction through the flow channel unless there is only one direction through the flow channel. Koito is mistaken. That there may be more than one direction of flow through the flow channel does not necessarily prevent one of those flow directions from being "positively different" from the predetermined general direction. In short, the intrinsic evidence in this case does not indicate that the inventor intended "a" to carry a singular meaning, and therefore the court construes "a direction" to carry its normal meaning in patent parlance, i.e., one or more. Thus, the claims do not require that the plastic flow through the flow channel in a single direction.

Koito also argues that the claimed flow channel must possess a discrete shape. Specifically, it argues that "the flow channel is defined by two discrete side walls, a beginning wall, and an end wall, and is shaped so that plastic flows in only one direction along the length of the flow channel" as illustrated in Figures 3 and 6 of the patent. Koito cannot provide any reason, other than by reference to the preferred embodiments, why a flow channel must be limited to a specific shape that includes four discrete walls. The claim language does not so limit the term, and the court declines Koito's invitation to import additional structural limitations based on the preferred embodiment.

Finally, Koito asks the court to construe "significantly thicker and wider," which appears in the claims as part of the definition of "flow channel," to mean much thicker and wider. Turn-Key argues that "significantly thicker and wider" simply means thick and wide enough to direct flow in accordance with step(g). The parties apparently agree that the ordinary meaning of "significantly" is "of a noticeably or measurably large amount." Merriam-Webster's Collegiate Dictionary; (Joint Claim Construction and Prehearing Statement at 20). Nowhere in the written description or drawings does the patentee define exactly what is meant by "significantly thicker and wider," and in the absence of such a definition the term generally carries its ordinary meaning, which in this case would lead the court to adopt Koito's proposed construction, much thicker and wider.

Turn-Key supports its construction by referring both to the functional language in the claim itself ("for the purpose of directing the flow of injected plastic") and to the patentee's response to the examiner's rejection over Wogerer. As discussed above, in the response to the Wogerer rejection the patentee explained the "significantly thicker and wider" language in a functional manner: "If the flow channels are not significantly thicker and wider than the adjacent mold cavity thickness,
they do not significantly direct the flow of the injected plastic." Turn-Key argues that this functional language provides a complete definition of "significantly thicker and wider," i.e., that it simply means thick and wide enough relative to the adjacent cavity to perform the function of directing flow.

The court is persuaded by Turn-Key's argument, which relies on the explicit language of the claim itself. Moreover, as discussed above, the prosecution history specifically directs one of skill in the art to look to the amended claim language itself for the definition of "flow channel." This language directly links the required thickness and wideness of the flow channel to its purpose: directing the flow of injected plastic.

For the reasons given above, the court construes the term "flow channel" to be a portion of a mold cavity that is significantly thicker and wider than the adjacent mold cavity thickness for the purpose of directing the flow of injected plastic, and the claim further requires that the flow channel direct flow so that the plastic flows in the flow channel in at least one direction that is positively different from the predetermined general direction. Finally, "significantly thicker and wider" means thick and wide enough relative to the adjacent cavity thickness to direct the flow of injected plastic as required by the claim.

1677
"A Soil/Water Flow Channel" in Claim 4 32

32 This text discussion also covers identical language from the '100 Patent's claim 8 (see W. Mem. 25, M. Mem. 29).

33 [Footnote by this Court] Although "soil/water flow channel" is used in the claims of the '100 Patent, while "guide chamber" was used in the '433 Patent, the '100 Patent's specification also uses the term "guide chamber."

34 As Optical Disc Corp. v. Del Mar Avionics, 208 F.3d 1324, 2000 WL 354753, at *9 (Fed. Cir.) has recently reconfirmed:
Without evidence in the patent specification of an express intent to impart a novel meaning to a claim term, the term takes on its ordinary meaning.

"Soil/water flow channel" is not defined or even used in the specification. In an effort to support Whirlpool's contention that the phrase has a plain and ordinary meaning, W. Mem. 24 quotes a dictionary definition of "channel" as "a conduit, pipe, duct, gutter, groove or furrow." But that broad set of alternatives would not enlighten a person skilled in the relevant art. Rather such amorphous terms are not "plain" because they can mean whatever a patentee wants them to mean.

Because the claim language itself thus fails to give notice as to just what is claimed, the specification becomes relevant in the construction process. In that respect the primary referent for the term "soil/water flow channel" is "annular guide chamber 100" (col. 4, l. 42). And even though the word "means" is absent from this claim element, it is nonetheless in means-plus-function form (see discussion in Micro Chem., 194 F.3d at 1257): In this instance "soil/water flow channel" is
obviously the means, and its stated function is just as obviously framed as "receiving water with entrained soil from adjacent said surrounding wall." That being so, the exact (and only) structure adverted to in the specification limits the claim. In short, the "channel" in the '100 Patent, like the "guide chamber" in the '433 Patent, is annular. 35

35 That is hardly surprising, given the earlier-mentioned fact that the basic structure of the '433 Patent is incorporated into the '100 Patent.

The specification describes a U-bend at the ends of the supply and return conduits. Through this configuration, the liquid in neighboring tubes, one a supply tube and one a return tube, moves in opposite directions. If a person were to look at a pair of these conduits from the side, the liquid in one tube would be moving to the left while the liquid in the other tube would be moving to the right. This specification suggests a construction of the claim which requires liquid to move through neighboring tubes in different directions axially.

During the prosecution of the '078 patent, Calmac argued that claim 16 is different from Czechoslovakian patent no. 123,424 because liquid in the tubes of the Czech patent flows in the same direction. Calmac argued:

Furthermore, inviting attention to FIG. 1 of Reference L [Czech '424], it is seen that all of the tubes in any given spiral wall have the fluid therein travelling in the same direction which is entirely contrary in concept and operation from the present invention.

Amendment to the Application for the '078 Patent at 16. 6 Also, Calmac distinguished Roma patent no. 4,054,980 on the same basis. Id. at 18.

5 A copy of the '078 patent appears in the record as Exhibit A to DB's memorandum of law.

The specification describes a U-bend at the ends of the supply and return conduits. Through this configuration, the liquid in neighboring tubes, one a supply tube and one a return tube, moves in opposite directions. If a person were to look at a pair of these conduits from the side, the liquid in one tube would be moving to the left while the liquid in the other tube would be moving to the right. This specification suggests a construction of the claim which requires liquid to move through neighboring tubes in different directions axially.

During the prosecution of the '078 patent, Calmac argued that claim 16 is different from Czechoslovakian patent no. 123,424 because liquid in the tubes of the Czech patent flows in the same direction. Calmac argued:

Furthermore, inviting attention to FIG. 1 of Reference L [Czech '424], it is seen that all of the tubes in any given spiral wall have the fluid therein travelling in the same direction which is entirely contrary in concept and operation from the present invention.

Amendment to the Application for the '078 Patent at 16. 6 Also, Calmac distinguished Roma patent no. 4,054,980 on the same basis. Id. at 18.

5 A copy of the '078 patent appears in the record as Exhibit A to DB's memorandum of law.

The specification describes a U-bend at the ends of the supply and return conduits. Through this configuration, the liquid in neighboring tubes, one a supply tube and one a return tube, moves in opposite directions. If a person were to look at a pair of these conduits from the side, the liquid in one tube would be moving to the left while the liquid in the other tube would be moving to the right. This specification suggests a construction of the claim which requires liquid to move through neighboring tubes in different directions axially.

During the prosecution of the '078 patent, Calmac argued that claim 16 is different from Czechoslovakian patent no. 123,424 because liquid in the tubes of the Czech patent flows in the same direction. Calmac argued:

Furthermore, inviting attention to FIG. 1 of Reference L [Czech '424], it is seen that all of the tubes in any given spiral wall have the fluid therein travelling in the same direction which is entirely contrary in concept and operation from the present invention.

Amendment to the Application for the '078 Patent at 16. 6 Also, Calmac distinguished Roma patent no. 4,054,980 on the same basis. Id. at 18.
From the language of the claim, the specification of the patent, and the prosecution history, it is clear that the proper construction of claim 16 is that it requires liquid in adjacent tubes to flow in opposite directions. Calmac argues that, properly construed, claim 16 covers devices wherein liquid flows in the same axial direction in neighboring tubes but flows in opposite directions radially. In other words, one tube flows inside to outside in a clockwise direction while the other tube flows outside to inside in a clockwise direction. This construction of claim 16 would implicate the ICE-CEL, which has the same axial flow but opposite radial flow in its coolant tubes.

The construction of claim 16 for which Calmac argues is contrary to the plain language of the claim and the specification of the patent. Axial flow, i.e., up and down, is the common understanding of the term "flow." If Calmac had intended its invention to cover both axial and radial counterflow, it could have stated as much in claim 16. The fact that it did not differentiate between axial and radial flow supports DB's contention that the concept of "radial counterflow" was invented by Calmac for purposes of this litigation. Furthermore, the specification of the '078 patent, describing pairs of conduits joined by a U-bend, clearly shows that Calmac had axial flow in mind when it stated that liquid in adjacent tubes must flow in opposite directions.

Having determined the proper construction of this portion of claim 16, the court must now consider whether the ICE-CEL infringes upon that claim. The parties are in agreement that liquid in neighboring tubes in the ICE-CEL flows in the same axial direction: if the liquid in one tube is flowing counterclockwise the liquid in its neighboring tube is also flowing counterclockwise. Therefore, no issues of material fact remain on this question, and the ICE-CEL does not literally infringe upon the "opposite direction" portion of claim 16.

Calmac contends, however, that the ICE-CEL infringes upon this portion of claim 16 under the doctrine of equivalents. It argues that the ICE-BANK and the ICE-CEL serve substantially the same function, in substantially the same way, to achieve substantially the same result. There may be genuine issues of fact on the question of whether the ICE-CEL is the equivalent to claim 16; however, Calmac is precluded by prosecution history estoppel from expanding its claim in this manner.

Patent '078 was initially rejected by the patent office due to the prior art contained in the Czech patent. Paragraph D of claim 16 was added to limit the invention to devices which employ counterflow in neighboring tubes. When reasserting its claim, Calmac informed the patent office that the Czech patent used a system wherein refrigerant flowed through grid tubes in the same direction. Calmac argued to the patent office that the Czech "same flow" system was "entirely contrary in concept and operation from" the ICE-BANK system of opposite flow. Amendment to the Application for the '078 Patent at 16. Calmac raised the same argument to differentiate the '078 patent from the prior art contained in the Roma patent. Id. at 18. Importantly, the Roma patent used straight tubes with liquid flow in the same direction. Thus, the Roma patent had no radial flow, only axial flow. Calmac argued that its invention was different from the Roma patent because the liquid in neighboring tubes in the ICE-BANK flows in opposite directions.

A review of this uncontested prosecution history clearly reveals that Calmac surrendered the technique of same flow during the patent application process. Calmac is now estopped from resurrecting this technique in order to implicate the ICE-CEL through the doctrine of equivalents. See, e.g., Hughes Aircraft Co., 717 F.2d at 1361. Because the ICE-CEL does not literally infringe upon claim 16 and Calmac is precluded from employing the doctrine of equivalents to expand its claim to include the ICE-CEL system of opposite radial flow, DB is entitled to summary judgment on the issue of infringement.

2. Flow Rate

This phrase is found in Claims 3 and 24 of the '802 Patent and Claims 9, 44, and 53 of the '193 Patent.

Phrase: Flow rate

Construction: The volume of breathing gas moving per unit of time.

Reasoning: The dispute between the parties centers on whether flow rate must account for a volume of gas, or merely the
movement of gas. Plaintiffs propose that the phrase flow rate means a signal indicative of the movement of gas (e.g., direction) over time. Defendant contends that flow rate means a quantified volume of gas moving per unit of time. Resolution of this dispute is easily reached by reviewing the specification. The '802 patent gives various examples of flow rates. These consistently are expressed in terms of "cc's per second" [i.e., volume per time]. '802 Patent, cl. 11-12, Ins. 68-1, 22-31. No other examples, measurement tools, or definitions of flow rate are given in the patent. It is clear, when viewed objectively, that plaintiffs used the term "flow rate" in a particular way in their patents.

While an individual with ordinary skill in the art may be able to modify the teachings of the patent to allow flow rate to account for weight of gas, or some other quantified value, plaintiffs' contention that the term flow rate simply means gas movement is contradicted by the patent itself, and plaintiffs' other claim construction arguments. Both parties agree that the term flow means a signal indicative of movement of breathing gas. Therefore, flow rate must mean something more than gas movement.

Furthermore, the volume per time definition used in the specification is in accordance with the common definition of flow rate which is a "weight or volume of flowable material flowing per unit of time." McGraw Hill Dictionary of Scientific and Technical Terms (4th ed.). A construction that accounts for volume also makes sense in the overall context of the patents because flow rates are relevant to these patents, which measure leakage. Leakage is an amount of gas that is being lost due to movement of the nasal mask during sleep. By measuring the various rates, accounting for leakage, and comparing them, the circuitry is able to distinguish between inhalation mode and exhalation mode, and apply the appropriate corresponding pressure.

The term "flow record" appears in steps (b) and (e) of claims 1 and 21:

(b) solidifying at least partly the flowed first plastic in the first-layer-defining-mold-cavity-section to thereby form said first plastic layer having a first-direction-flow-record, . . .

(e) solidifying the flowed second plastic in the second-layer-defining-mold-cavity-section to thereby form said second plastic layer, so that the second plastic layer has a second-direction-flow-record which is positively different from said first-direction-flow-record, to thereby form said plastic product with said cross-laminated section that includes both the first plastic layer and the second plastic layer . . .

'268 Patent, col. 8, lines 23-26, 37-45; col. 10, lines 65-68; col. 11, lines 11-19 (emphases added). Neither the claims themselves, the written description, nor the prosecution history provides an explicit definition of flow record. Turn-Key argues that a flow record is the flow direction of plastic when it is at least partially solidified. For its part, Koito notes that a "flow record" reflects the direction of flow of injected plastic, but is different from the "predetermined general direction" in that it is the preserved record of the flow.

The Oxford English Dictionary defines "record" as "the fact or condition of being preserved as knowledge, esp. by being put into writing; knowledge or information preserved or handed down in this way." See also Random House Dictionary of the English Language 1612-13 (2d Ed. 1987) (defining record as "the state of being recorded, as in writing"). Thus, the ordinary meaning of "flow record" refers to a preservation in the solidified plastic layer of the flow of liquid plastic used form the solidified layer. Furthermore, the court agrees with Koito that a "flow record" cannot be precisely the same as the predetermined general direction of flow. By the plain terms of the patent, the plastic must be at least partially solidified in order to form a flow record. By definition, solidified plastic no longer flows, and therefore it cannot have a flow direction (general or otherwise). Thus, contrary to Turn-Key's argument, the "flow record" is not synonymous with flow direction. Rather, the flow record in some way preserves a history of the flow direction in a permanent form.

Koito argues, and the court agrees, that the flow record is a preservation of the direction of the plastic's flow as it filled the mold. Because the claims require that the plastic flow in a first or second predetermined general direction to fill the first and
second layer-defining-mold-cavity-sections respectively, it follows that the flow record is a preserved record, or history, of
the predetermined general direction created when the plastic solidifies or partially solidifies in the mold.

This interpretation of flow record is consistent with the written description and drawings. Figure 3 of the patent, which
illustrates a partial view of a cross-laminated product, shows the first and second predetermined general directions as arrows
12 and 14 respectively. '268 Patent, col. 3 line 60 - col. 4, line 16. The patent uses the identical arrows 12 and 14 to refer to
the first and second flow records. Id. Thus, the patent teaches that the flow record in a layer runs in the same direction as the
predetermined general direction of flow of the plastic that formed the layer.

For the reasons discussed above, the court construes "flow record" as a preserved record, or history, of the predetermined
general direction of flow created when the plastic layer solidifies or partially solidifies in the mold.

1682

4. Fluid Characteristic Associated with the Flow of a Gas

This phrase is found in Claim 23 of the '532 Patent. It is also found in Claims 29 and 32 of the '517 Patent.

Phrase: Fluid characteristic associated with the flow of a gas

Construction: flow rate.

Reasoning: Both parties agree that this phrase refers to flow rate. The real dispute as to the meaning of the term "flow rate".
However, in construing the claims of the Early Patents, we have already arrived at the appropriate meaning of that term, i.e.,
the volume of breathing gas moving per unit of time.
continuous function of communicating intrauterine pressures from the first chamber means through the second chamber means to the pressure transducer. Thus, Utah Medical argues that this element of the claim reads upon the Koala. Claim 1 uses the term "fluid communication" twice. First, it requires that the first volume, which is in the first chamber, be in fluid communication with the amniotic liquid such that the amniotic liquid will enter the first chamber. Second, it requires that air-filled second volume be in fluid communication with the first chamber means. The Court finds that in order to be in fluid communication with the amniotic fluid, as in the first case or the air as in the second case, the amniotic fluid or air must be allowed to enter the first chamber and form, or come in contact with, the liquid column that has been created so that when the pressure changes the liquid column can move within the first chamber, as indicated by the possible surfaces of amniotic fluid depicted above in Figure 3. The term "fluid" is an adjective describing the ability for the liquid and air to move within the catheter, and, depending on the pressure exerted by the amniotic fluid, communicate that pressure to the transducer. Thus, all this element requires is that the amniotic pressure has the means to communicate with the air pressure so that pressures are able to be transmitted from one end of the catheter to the other end.

7. Fluid Flow Control Valve

The term "fluid flow control valve" only appears in one independent claim in the '130 application (claim 1) and the '674 patent (claim 13). The preamble of both those claims reads: "A fluid flow control valve comprising: [body of claim]." '130 application claim 1 at 35; '674 patent claim 13 at 27:30-35, 40-41. Because the phrase "fluid flow control valve" appears in the preamble, a preliminary question exists as to whether the preamble is, in fact, a separate limitation. See Symantec Corp. v. Computer Assocs. Int'l, Inc., 522 F.3d 1279, 1288 (Fed. Cir. 2008) (stating that when evaluating the significance of a preamble, the first step is to determine whether the disputed language is a claim limitation).

There is no bright-line rule that determines when preamble language should be deemed to constitute a limitation of the claim. This determination requires a review of the entire "patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim." Corning Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir. 1989); see Bell Commc'n's Research, Inc. v. Vitalink Commc'n's Corp., 55 F.3d 615, 620 (Fed. Cir. 1995) ("[W]hen the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects.").

Language within a preamble generally does not limit the scope of the claim. See, e.g., Symantec, 522 F.3d at 1289. In certain circumstances, however, the language of a preamble may act as a limitation if it is "necessary to give life, meaning, and vitality" to the claim. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999); see NTP, Inc. v. Research in Motion, Ltd., 418 F.3d 1282, 1305 (Fed. Cir. 2005) ("[I]f the preamble helps to determine the scope of the patent claim, then it is construed as part of the claimed invention."). Giving "life, meaning, and vitality" to the claim may occur where the preamble provides an antecedent basis for elements in the body of the claim. See Eaton Corp. v. Rockwell Int'l Corp., 323 F.3d 1332, 1339 (Fed. Cir. 2003) ("When limitations in the body of the claim rely upon and derive antecedent basis from the preamble, then the preamble may act as a necessary component of the claimed invention."); C.R. Bard, Inc. v. M3 Sys., Inc., 157 F.3d 1340, 1350 (Fed. Cir. 1998) (determining that if a preamble provides antecedents for ensuing claim terms then the preamble limits the scope of the claim).

In NTP, for example, the phrases "to at least one of the plurality of destination processors" and "electronic mail system" occurred in the preamble as well as the body of the claim. 418 F.3d at 1305. The Federal Circuit held that because the antecedent use was necessary to provide context for the rest of the claim limitations, the terms in the preamble were limiting. Id. at 1305-06.

Under this framework, Aqua-Lung contends that "fluid flow control valve" appears in the preamble to provide antecedent
basis to claim language that functions as a limitation. Two Forty counters that the term is nothing more than introductory
and the Court should not attempt to read it as a limitation, but instead adopt a broad meaning. Beginning the analysis with
the words of the claim, Aqua-Lung points to claim thirteen of the '674 patent as evidence of the use of the term as an
antecedent. That claim reads in pertinent part:

a fluid flow control valve, comprising:

a housing defining an internal passageway, where the passageway has a gas inlet opening near an upstream end of said
housing and a gas outlet opening near a downstream end of said housing and spaced from the gas inlet opening; . . .

wherein the housing of the fluid flow control valve includes a portion threaded into the bore[.]

Claim 13 at 27:30-35, 40-41 (emphasis added). Aqua-Lung is correct that the term does not only appear in the preamble of
the claim, but also within the body. Consequently, at first glance this subsequent use of the introductory term in the body of
the claim appears to be exactly what occurred in NTP.

"Fluid flow control valve," however, does not rely upon and derive any antecedent basis from the preamble. In NTP, if
"electronic mail system" is removed from the body of the claim, then the entire claim falls apart as the antecedent
connection is severed. By contrast here, "fluid flow control valve" appears to provide nothing more than context for the
body of the claim and can be excised without any resulting collapse in the understanding of it. See Symantec, 522 F.3d at
1289 (stating that it is assumed that the preamble language merely provides context for the claims, absent any indication to
the contrary in the claims, the specification or the prosecution history). That is, the body of the claim is not dependent on
the preamble term to act as an antecedent to any language in the claim. 4

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 To hold that the term is a preamble term that limits the claim additionally would lead to a superfluous definition. A review
of the entire patent provides understanding of what the inventor actually invented and intended to encompass by the claim.
The body of the claim sets out the complete invention, and thus, importing all the words to the right of the word
"comprising" would incorporate a definition into the preamble term followed by different limitations in the claim body
rendering the set meaningless.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Having determined that "fluid flow control valve" is a preamble term and not a claim limitation, the remaining step is to
construe it. As noted above, "fluid flow control valve" is mentioned in one independent claim of the '130 application and
'674 patent and in two dependent claims of the '674 patent. See '130 application claim 1 at 35; '674 patent claim 13 at 27:30-
35, 40-41; claim 15 at 28:9-12, claim 20 at 28:32-34.

Aqua-Lung proposes that "fluid flow control valve" be construed as: "A valve including a housing which defines a central
passageway having gas inlet and outlet openings, a gas pressure-responsive closure element disposed within the passageway
for selectively opening and closing of the inlet opening to gas flow in response to gas pressure exerted thereon at the inlet
opening, a spring that urges the gas pressure responsive closure element toward its closed position, a filter disposed within
the passageway and a c-clip that holds the closure element, spring and filter within the passageway against the spring force."
Two Forty seeks to have the term defined as "a mechanism which controls the flow of fluid." Aqua-Lung's definition
attempts to track the summary of the invention. Two Forty argues that since the phrase is used in the preamble, with specific
elements of the valve claimed individually, any resulting definition should be defined broadly.

Two Forty is correct that the term should be interpreted broadly because a "fluid flow control valve" is what the inventor is
claiming was his invention. See '609, '958, '674 patent abstract ("A fluid flow control valve is disclosed."). Two Forty's
proposed broad construction is therefore preferable because the inventor specifically set forth that the purpose of the "fluid
flow control valve" was to control the flow of fluid flowing into a scuba regulator to stop dust and other particulars from
entering it. See '609 patent summary at 3:66-4:2 ("To achieve the foregoing and other objects and in accordance with the
purpose of the present invention, as embodied and broadly described herein, a fluid flow control valve is disclosed."). Based
on the foregoing, the Court construes a "fluid flow control valve" to mean "a mechanism which controls the flow of fluid."

- 2121 -
The phrases "fluid inlet end" and "fluid outlet end" are used in the patent to describe the ends of the tip through which fluid enters and exits. (Doc. 29, Ex. A). Dentsply argues that these phrases refer to the most proximal and distal "point[s]" on the tip. (Docs. 34, 55). Hu-Friedy contends that the phrases refer to two regions of the tip: the fluid inlet end is the region from the discharge orifice to the proximal point of the tip; the fluid outlet end is the region from the discharge orifice to the distal point. 3 (Docs. 44, 47, 55).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 
3 The discharge orifice is the drilled opening, located near the bend in the tip, out of which fluid flows. (Doc. 29, Ex. A).
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - 

The latter interpretation, that inlet and outlet ends refer to regions of the tip, is required by the claim language. The claims instruct that the tip body, with a "fluid inlet end and a fluid outlet end," should be bent so that "a centerline through said fluid outlet end intersects a centerline through said fluid inlet end at an angle greater than 5 degrees." (Doc. 29, Ex. A). These claims contemplate that lines be drawn through the inlet and outlet ends. Each line requires, at the least, two points. AMERICAN HERITAGE COLLEGE DICTIONARY 804 (4th ed. 2002). Thus, contrary to Dentsply's proposed construction, each "end" must consist of more than one point. The claim language requires that "end" be interpreted as a region of the tip.

The specifications confirm this construction. They identify the "fluid outlet end" as a region of the tip. The figures illustrate the "fluid inlet end" as the portion of the tip from the discharge orifice to the proximal point and the "fluid outlet end" as the portion from the discharge orifice to the distal point. To interpret "end" as a point of the tip--as proposed by Dentsply--would contradict these embodiments of the invention. See Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1308 (Fed. Cir. 2003) ("[A] claim construction that excludes a preferred embodiment . . . is rarely, if ever correct and would require highly persuasive evidentiary support.") (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996)).

Reference materials also support interpreting "end" as a region, rather than as a point. They define "end" as the "last part lengthwise" of an object and the "extremity of something that has length." AMERICAN HERITAGE COLLEGE DICTIONARY 462 (4th ed. 2002); MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 380 (10th ed. 2002). These definitions are consistent with the use of the term in the claims and specifications of the patent. Accordingly, the court will construe "fluid inlet end" as the region extending from the discharge orifice to proximal point of the tip and "fluid outlet end" as the region extending from the discharge orifice to the distal point of the tip.

B. "Fluid Pressurized Structure."

The term "fluid pressurized structure" appears in claims 1, 3, 5, 6, and 12 though 15. Claim 3 recited (col. 17:28-34):

3. An improvement in a bundle breaker as defined in claim 2 wherein:

   a. said first and second compliance structures respectively having first and second fluid pressurized structures for engaging a plurality of logs in side by side relation with at least one log having a height greater than at least one other log.

For this term, plaintiffs contend that it should mean "a structure containing a liquid or a gas that applies force to the inside
of the structure," while defendant originally argued that the term should be construed as "a sealed structure inflated by liquid or gas, under pressure."

Again, defendant gave up on the construction it proposed in the prehearing statement. It now proposes the construction "a sealed structure containing liquid or gas under greater than normal atmospheric pressure." Given this new proposed construction, the parties have two points of disagreement -- whether the structure must be sealed and whether the pressure within the structure must be greater than atmospheric pressure. As an initial matter, both sides agree that the definition of a "fluid" encompasses both liquids and gases.

Defendant first argues that the proper construction of the claim requires that the structure necessarily be sealed. By defendant's reasoning, plaintiffs parse this phrase too finely -- any proper construction would demand that the structure is pressurized by the fluid, so the structure must necessarily be "sealed" in some way. Plaintiffs in their opening brief used the example of a car tire as a fluid pressurized structure. In that example, the air pumped into the tire creates the seal by sealing the tire to the rim. The increased pressure inside the tire creates any seal in that system; there is no independent attachment to the rim. In response, defendant argues that the mere fact that a tire includes a valve for adding air, or increasing the pressure, indicates that the pressurized structure is sealed. This does not necessarily follow. Moreover, the specification indicated that fluid be allowed to flow into and out of the pressurized structure to change the pressure. The specification taught that "fluid pressure is increased or decreased through fluid pressure lines 105 and 106 . . . connected to fluid port 87 . . . " (col. 12:60-63). This indicated that the fluid pressurized structure by itself need not be sealed because the pressure within it changes. It does, however, need to be capable of being sealed when pressure is applied, much like plaintiffs' tire example.

Plaintiffs and defendant also part company on the meaning of "pressurized." Plaintiffs contend that it means only that the fluid inside the structure applies pressure to the inside of the structure. Defendant argues that this proposed construction is far too broad. It could even include, it says, a glass of water -- the water being the fluid exerting pressure against the walls of the glass -- or even an empty glass where air puts pressure on the walls of the glass. The effect of adopting such a construction is not so dire as defendant argues. No one, skilled in the art or otherwise, would use a structure only at atmospheric pressure in a bundle breaker because it could not be used to apply pressure to another surface.

Defendant argues that the limitation should include the requirement that pressure in the pressurized structure should be greater than atmospheric pressure. The specification, as described above, indicated that fluid pressure can be increased or decreased. Given that the logs apply greater or lesser degrees of pressure to the pressurized structures to clamp the logs into place, this makes sense. In order to exert pressure on another surface, the pressure needs to be greater than atmospheric pressure.

This order holds that "fluid pressurized structure" means "a structure, capable of being sealed, containing a liquid or a gas that applies force greater than atmospheric pressure to the inside of the structure."

1. fluid reservoir

3M a container or receptacle for supporting the liner

ITW a receptacle with side walls and a base for supporting a liner

The parties agree a fluid reservoir involves a receptacle that supports a liner but disagree as to whether there is an additional requirement that the receptacle have a base and side walls. 3M asserts that no such requirement exists, pointing to the fact that the specification itself makes it immaterial "for the walls of the receptacle to be solid: the receptacle could, for example, have the form of a framework for containing the liner." ITW counters that the term fluid reservoir is always used in the specification to describe a receptacle with side walls and a base and that the common dictionary definition of reservoir is actually more restrictive than the definition it proposes because the dictionary definition requires a reservoir itself be capable of holding a liquid.
The definition proposed by 3M is broader than the ordinary and customary meaning of receptacle because its definition does not include the general requirements that a receptacle have side walls and a base. Courts can use broader definitions for disputed claim terms but not without "support in the intrinsic record indicating that such a broad meaning was intended." Nystrom v. Trex Co., 424 F.3d 1136, 1145-46 (Fed. Cir. 2005). 3M has cited no such support for its definition, and ITW is correct in that the specification consistently refers to the reservoir as having a base and side walls. As a result, the Court adopts ITW's proposed definition for this term.

c. Fluid Seal

The term "fluid seal" appears in independent Claims 1, 7, and 8 of the '644 Patent. '644 Patent at 6:67, 7:59, 8:50. Plaintiffs propose that "fluid seal" be construed as "a structure that operates to seal fluid." Pls.' Mem. in Opp'n to Summ. J. at 26. Defendants contend that claim construction of "fluid seal" is unnecessary. Defs.' Reply Mem. [Docket No. 60] at 6. Instead, Defendants advocate a limited construction of "fluid seal" as including a standard o-ring. Id. at 6.

The Court finds it is necessary to construe the term "fluid seal" in order to decide Defendants' Motion for Summary Judgment. Plaintiffs' proposed definition of "fluid seal" fails to define "seal." Plaintiffs have provided three dictionary definitions from 1996. Courts may "rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents." Phillips, 415 F.3d at 1322-23. The 1996 Merriam-Webster's Collegiate Dictionary defines "seal" as a "tight and perfect closure (as against the passage of gas or water)." Merriam-Webster's Collegiate Dictionary 1052 (10th ed. 1996). The 1996 Webster's New World College Dictionary defines "seal" as "a tight closure, as against the passage of air or water." Webster's New World College Dictionary 1210 (3d ed. 1996). The 1996 Random House Compact Unabridged Dictionary defines "seal" as "anything that tightly or completely closes or secures a thing . . . ." Random House Compact Unabridged Dictionary 1726 (Special 2d ed. 1996). The Court construes the term "fluid seal" as "a structure that operates as a tight or complete closure against the passage of a fluid." This definition is consistent with the use of the term "fluid seal" in the claims, specification, and prosecution history of the '644 Patent.

Defendants' request for a limited claim construction that the term "fluid seal" includes a standard o-ring is rejected. Defendants argue that the term "fluid seal" in the '644 Patent is a structural claim element, rather than a functional claim element. Defendants rely on Schwing GmbH v. Putzmeister Aktiengesellschaft, 305 F.3d 1318, 1324 (Fed. Cir. 2002), for the proposition that "[w]here a claim uses clear structural language, it is generally improper to interpret it as having functional requirements." However, the term "fluid seal," by itself, does not amount to clear structural language. The use of the word "seal" carries with it the ordinary meaning and function of a "seal." Under Defendants' proposal, an o-ring is automatically a "fluid seal" regardless of whether it actually performs this function in the filter cartridge. The intrinsic evidence regarding the '644 Patent does not support such a construction.

The term "fluid seal" also appears in independent Claim 14 and dependent Claim 11 (which depends from Claim 10) of the '884 Patent. The definition of "fluid seal" is the same in the '884 Patent as in the '644 Patent.

A. "Fluid Treatment Module"

The following chart contains both parties' interpretations of the disputed term "fluid treatment module." Patent at Col. 19:50, 55, 59-60; Col. 20:7, 44-45, 50-51, 56-57, 62-63.

<table>

<td>An assembly including a head that is fluidly coupled to a cartridge that alters the characteristics of a fluid passing through the cartridge in the same way</td>
</tr>
</tbody>
</table>
flow of fluid. regardless of the direction in which fluid flows through the cartridge.

The Court adopts Everpure's interpretation of the term "fluid treatment module." Everpure's interpretation rests soundly on intrinsic evidence, whereas Selecto relies on extrinsic evidence that impermissibly contradicts the specification.

The specification clearly states, "[A]ny device employed for treating or processing fluid of any type, or for moving or controlling the flow of fluid can be employed as a cartridge in each module." Patent at Col. 7:44-47. This contradicts Selecto's interpretation that the module must "alter[] the characteristics of a fluid passing through the cartridge," which is based upon extrinsic evidence, namely the testimony of Selecto's expert, John Tadlock, and a dictionary from the Water Quality Association. Tadlock Decl. P 11, Ex. 2. A Court may not rely on extrinsic evidence when it contradicts intrinsic evidence. See Vitronics, 90 F.3d at 1584 n.6; Phillips, 415 F.3d at 1318.

Furthermore, the specification, in combination with the testimony of Everpure's expert, Peter Cartwright, demonstrates the flaw in Selecto's construction that the cartridge must "alter the characteristics of a fluid passing through the cartridge in the same way regardless of the direction in which fluid flows through the cartridge." (emphasis added) The specification lists a number of various fluid treatment devices that can be used as cartridges in each module, including "filters." Patent at Col. 7:39. According to Mr.Cartwright, a filter does not always treat fluid in the same way regardless of the direction in which the fluid flows through it. Cartwright Reply Decl. PP 6-7. The efficiency of a filter is diminished when flow is reversed through it, so a module using a filter as its cartridge--as contemplated by the specification--would treat fluid to a lesser degree--not in the same way--when flow through the cartridge is reversed. Id. This is additional evidence that Selecto's interpretation of the term "fluid treatment module" is not grounded in the Patent.

In contrast, Everpure's interpretation is based upon language found in the specification. See Patent at Col. 7:44-47. Thus, the Court adopts Everpure's interpretation and finds that a "fluid treatment module" is "any in a series of standardized units for use together, for treating or processing fluid or for moving or controlling the flow of fluid."

CLAIM 1

Four issues remain with respect to claim 1, below, with the disputed language in italics:

1. A fuel delivery system for removing undesired components from fuel delivered from a fuel tank to an engine comprising, in combination: [issue # 1]

   an engine; 2

   initial fuel filter means for removing water from fuel received from the fuel tank; and [issue # 2]

   secondary fuel filter means including an outlet in fluidic communication with said engine and an inlet in fluidic communication with said initial fuel filter means and located downstream therefrom for receiving fuel containing an undesired gas from said initial fuel filter means and separating substantially all of said undesired gas from fuel received therein prior to passage of said fuel through the outlet, [issue # 3]

   said secondary fuel filter means including a vessel defining a hollow interior chamber in fluidic communication with a return line in fluidic communication with said fuel tank for returning fuel and undesired gas thereto, and a filter media positioned within said chamber for immersion in fuel received therein and a conduit located within said filter media for delivering fuel passing through said filter media to said outlet. [issue # 4]

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 The parties initially disputed the construction of "an engine," but agreed at the Markman hearing that their differences were not material and to construe it as "an internal combustion engine."
Claim 1; Issues 3 & 4 -- The Secondary Fuel Filter Means and The Vessel

With regard to the secondary fuel filter means, the Court must first determine whether it is in fact a means-plus-function claim. Defendants assert that it is a means-plus-function claim governed by § 112, P6, with two separate functions: first, a means "for receiving fuel containing an undesired gas from said initial fuel filter means," and second, a means "for separating substantially all of said undesired gas from fuel received therein prior to passage of said fuel through the outlet." While Plaintiffs essentially agree that the element provides for these two functions, Plaintiffs assert that there is sufficient structure in the claim elements themselves to take the claim elements out of the scope of § 112, P6.

"The use of the word 'means,' which is part of the classic template for functional claim elements, gives rise to 'a presumption that the inventor used the term advisedly to invoke the statutory mandates for means-plus-function clauses.' Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1422-23 (Fed. Cir. 1997) (quoting York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1574 (Fed. Cir. 1996)). The case law recognizes two specific rules, however, which "overcome this presumption." The first is where a claim element uses the word "means," but does not recite any function. Such an element does not invoke § 112, P6. Rodime PLC v. Seagate Technology, Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 120 S. Ct. 933, 145 L. Ed. 2d 812 (2000). "Second, even if the claim element specifies a function, if it also recites sufficient structure or material for performing that function, § 112, P6 does not apply." Id.; accord, Phillips, 415 F.3d at 1311 ("Means-plus function claiming applies only to purely functional limitations that do not provide the structure that performs the recited function."); Sage Prods., 126 F.3d at 1427-28.

To determine whether the element specifies a function, the court relies primarily on the claim language itself. York Prods., 99 F.3d at 1574. Here, the Plaintiffs do not dispute that the claim element specifies the two functions recited by Defendants, and the plain language of the claim supports this conclusion. Plaintiffs assert, however, that there is sufficient structure recited in the claim element itself to take it outside the bounds of § 112, P6. To avoid P6, it is not necessary to recite "every last detail of the structure disclosed in the specification for performing the claimed . . . function. . . . Instead, the claim need only recite 'sufficient' structure to perform entirely the claimed function." Rodime, 174 F.3d at 1304.

The Court agrees that the element contains sufficient structure with respect to the first function of "receiving fuel containing an undesired gas from said initial fuel filter means." The claim element itself specifies a structure, namely, "an outlet in fluidic communication with the engine and an inlet in fluidic communication with the initial fuel filter means," and the location of the inlet is further specified as being "downstream" from the initial fuel filter means. 4 See Phillips, 415 F.3d at 1311 (no means-plus-function claim where claim language identifies "internal steel baffles" as the structure for performing the function of increasing the shell's load-bearing capacity); Envrco Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1365 (Fed. Cir. 2000) (use of term "baffle," itself a structural term, together with the description in the claim, overcomes presumption of § 112, P6).

4 Assuming arguendo the Court were to construe the element as a means-plus-function claim, it would make little difference in interpretation. The corresponding structure appears at col 1., lines 65-67; col. 2, lines 45-49; col. 3, lines 45-47. It includes an inlet in fluidic communication with an inlet line and an outlet fluidically connected to an outlet line leading to the engine, and equivalents thereof.

Read in isolation, however, this element would not appear to specify any structure for the second function of "separating substantially all of said undesired gas from fuel received therein prior to passage of said fuel through the outlet." Plaintiffs assert that the necessary structure is found in the next element, which describes in detail the structure of the function of separating the gas from the fuel. The Court agrees. Read together, the two elements sufficiently describe the structure of this secondary fuel filter means, as understood by those skilled in the art, to rebut the presumption that it is a means-plus-
With regard to the second function, as set forth in the claim itself, the secondary fuel filter means includes (i) "a vessel defining a hollow interior chamber," (ii) which vessel is "in fluidic communication with a return line," (iii) which return line is "in fluidic communication with said fuel tank for returning fuel and undesired gas thereto," and there is also (iv) "a filter media positioned within said chamber," (v) which filter media is immersed in the fuel received in the chamber, and (vi) a "conduit" which is "located within said filter media for delivering fuel passing through said filter media to said outlet."

Again, these terms are sufficiently clear to one skilled in the art for the structure and location of the elements to be understood. As such, the Court construes the claims pursuant to "standard claim construction rules." Envirco, 209 F.3d at 1365. 5

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 Again, even if the Court were to assume that § 112, P6 controlled, it would make little difference to this Court's interpretation. See col. 1, lines 62 - col. 2, line 2; col. 2, lines 22-35; col. 3, line 56 - col. 4, line 48; col. 5, lines 21-49.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Looking to the disputed language related to the first function, Defendants assert that the term "communicate" means "to be connected," and that elements thus include "an inlet connected to the initial fuel filter means and "an outlet connected to the engine." The language proposed by Defendants implies a direct physical connection. There is no support for such a limitation, however, in either the claim language itself or the specification. The claim language states that the inlet and outlet will be in "fluidic communication." One with ordinary skill in the art would understand this to mean that fluid would flow from the initial fuel filter to the inlet and from the outlet to the engine, but no direct connection is necessarily required by this language. For example, in another embodiment of the invention, the fuel presumably could travel through yet another process before delivery to the engine. Consistent with such a possibility, the Court notes that claims 8 and 14, which describe the filter, speak of "direct fluidic communication," while other claims, including claims 1 and 15, which describe a more generalized fuel delivery system, do not.

In connection with the second function, Defendants assert that the elements of the secondary fuel filter include "a vessel with an uppermost housing portion and a lowermost canister portion defining a hollow chamber." While these limitations are part of the preferred embodiment, they are not suggested by the claim language itself, which describes only "a vessel defining a hollow interior." As such, there is no basis for importing this limitation into this term. See Arlington Indus., Inc. v. Bridgeport Fittings, Inc., 345 F.3d 1318, 1327 (Fed. Cir. 2003). Moreover, the limitations suggested by Defendants are found in dependent claim 3, and under the doctrine of claim differentiation, it is improper to incorporate these elements into claim 1. Liebel-Flarsheim, 358 F.3d at 910; Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998).

Next, again construing "fluidic communication," Defendants assert that the return line is "connected to the vessel and the fuel tank." The Court rejects this interpretation for the same reason stated above. The claim language requires only that the interior chamber be "in fluidic communication with" a return line "in fluidic communication with" the fuel tank. Use of the term "connected to" unnecessarily limits the element.

With regard to the filtering function itself, Defendants assert that the proper construction is "a filter media, which allows fuel to pass but not air, positioned with the chamber and immersed or submerged in the fuel." Plaintiffs propose for their construction, that "the second fuel filter separates substantially all of the undesired gas from the fuel prior to the passage of the fuel through the outlet. . . . Undesired gas is any undesired entrained air and other vapors and gasses entrained in the fuel."

While the Court rejects Defendants' contention that this should be construed as a means-plus-function claim, the Court finds that the words "undesired gas" and the function of "separating substantially all of said undesired gas," are ambiguous, thus requiring an examination of the intrinsic evidence. The Court cannot accept Defendants' construction, however, that the filter "allows fuel to pass but not air," as it is not supported by the specification. In referencing the secondary fuel filter, the specification repeatedly references the removal of "residual air bubbles, entrapped and entrained in the fuel." Col. 1, lines
52-54 (emphasis added). The specification and drawings state that the filter media separates these bubbles. See col. 2, lines 22-23, 29-31; col. 5, lines 26-39. Thus, the Court finds that "undesired gas" means any "undesired bubbles of entrained air or other vapors and gasses entrained or entrapped in the fuel."

Finally, Defendants assert that the word "immersion" should be construed to mean "submerge which in turn means immerse which means to cover completely with liquid; submerge," citing to the American Heritage Dictionary (1986). Asserting that the language is not ambiguous, Plaintiffs assert the following construction: "The second fuel filter also includes a filter media positioned within the interior chamber of the vessel so that the filter media can be immersed in the fuel received in the chamber." The Court believes that the term "immersion" as used herein would be understood by those skilled in the art, and that further definition is unnecessary. Multiform Desiccants, 133 F.3d at 1477. Moreover, the definition proposed by Defendants does not do anything to better clarify the language.

As such, the Court construes the secondary fuel filter means and vessel as follows:

"The secondary fuel filter, which is located downstream from the initial fuel filter, includes an outlet in fluidic communication with the engine and an inlet in fluidic communication with the initial fuel filter. The secondary fuel filter receives fuel containing an undesired gas from the initial fuel filter and separates substantially all of said undesired gas prior to passage of the fuel through the outlet. Fluidic communication means that fluid can transfer from one element to another. Undesired gas is any undesired bubbles of entrained air or other vapors and gasses entrained or entrapped in the fuel.

The secondary fuel filter also includes a vessel defining a hollow interior chamber, which chamber is in fluidic communication with a return line, which is in fluidic communication with the fuel tank, for returning fuel and undesired gas to the fuel tank. The secondary fuel filter also includes a filter media positioned within the chamber of the vessel so that the filter can be immersed in the fuel received in the chamber. The secondary fuel filter also has a conduit located within the filter media for delivering fuel passing through said filter media to the outlet."

This evidence is insufficient to raise a question of fact that the process for manufacturing the 23DS projectile infringes the 562 patent. First, to the extent any "folds 1" are ever formed by the female technician, they are created as part of the process of insertion and not prior to it. As construed in the April 19 Opinion, the "forming folds" element of the claim does not refer to folds "created through disorganized stuffing movements when the projectile is inserted into the empty shell."

As explained in the April 19 Opinion, the ordinary meaning of "fold" is "to bend over or double up so that one part lies on another part." Am. Heritage Dictionary 681 (4th ed. 2000). Given that the rear portion of the 23DS projectile is cut into four individual tails, it is not clear that the notion of "folding" or "folds" is even applicable to the accused process. Moreover, even when the female technician bends the tails over her finger during insertion, the tails do not lie on themselves. It is more accurate to describe the tails of the projectiles as bunched together, rather than folded, by the process of inserting them into the shotgun shell.

Claim 5 describes the patented device as having "horizontal creases allowing said member to be manually folded in half to reduce the vertical dimension of said shirt." Plaintiff suggests "folded in half should be interpreted to mean: 'bent at its approximate mid-point along a horizontal crease."

Pl. Brief on Claim Construction (DE # 40). Defendant argues that "half" should be defined as "one of two equal parts into which a thing is divisible . . . also: a part of a thing approximately equal to
the remainder." Def. Mem. in Support of Proposed Claim Construction (DE # 37) at 19, Def. Claim Construction Chart (DE # 38).

This Court holds that "folded in half" is a clear and unambiguous description, and therefore requires no construction.

1693

CLAIM CONSTRUCTION

The first step in the analysis is construction of the claims in suit, which is a question of law to be decided by the court. Markman v. Westview Instruments, Inc., 517 U.S. 370, 391, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Claim construction is pertinent to both validity and infringement, as the relation of the invention to prior art and the relation of the patents in suit to the Maestro product hinge upon the scope of the claims. The same claim construction made here will be used in both validity and infringement analysis. Kimberly-Clark Corp. v. Johnson & Johnson, 745 F.2d 1437, 1449 (Fed. Cir. 1984).

The primary issue of claim construction is whether the claims in suit are subject to a process limitation. Springs contends that the following italicized language, found in both claims, limits the scope of those claims to devices made by a strip method:

"[A] strip of shade material folded lengthwise to form an upper cell wall and a lower cell wall extending from a fold, each upper and lower cell wall having a free edge and a folded edge …"

Plaintiffs characterize the italicized language as a structural definition rather than a process limitation and contend that the claims extend to any cell described in the claims, regardless of the method of manufacture.

This question derives from an ambiguity in the word "folded." Springs' interpretation would read "folded" as a past participle, requiring that at some stage of manufacture a strip of shade material be folded to create one free edge and one folded edge. Plaintiffs would read "folded" as an adjective, requiring merely that the final product contain a strip of material with a fold in it.

Claim interpretation must first be considered in light of intrinsic evidence such as the claim language, the other claims, the prior art, the prosecution history, and the specification. Extrinsic evidence will only be considered should the intrinsic evidence fail to resolve the issue. All other terms in the patents will be given their "ordinary and accustomed" meanings. Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1578 (Fed. Cir. 1996).

The intrinsic evidence overwhelmingly supports Plaintiffs' reading of the claims. Independent claim 1 of each patent discloses a plurality of interconnected cells, at least one of which "comprises" the cell structure described. The grammatical structure of the claim suggests that the claim be read as a product; putting aside the language cited by Springs, all of the remaining constituent parts which the cell "comprises" are termed unmistakably in structural terms. It would be incongruous to interpret that last constituent part to be a process limitation.

Indeed, the '981 and '593 applications originally contained both method and product claims before the examiner required a restriction to one or the other. Plaintiffs elected to restrict the applications to product claims, and the amended claims apparently satisfied the examiner that they had done so.

Springs' reading is most plausible when taken out of the context of the patent as a whole. Placed in context, Springs' reading would find an anomalous process limitation among unambiguous product claims. This reading of the italicized language strains the language of the claim well beyond its most natural meaning.

This construction does not result in surplusage. The italicized language establishes that the strip of shade material has a fold in it; the second reference to a "fold" in the same clause merely specifies the relation of the upper and lower cell walls to the fold. Moreover, the italicized language specifies the type of material from which the cell is made and specifies the orientation ("lengthwise") of the fold in question, limitations which are not otherwise contained in the claim.

Athletic Alternatives, relied upon by Springs, is not to the contrary. The court in Athletic Alternatives held that "where there is an equal choice between a broader and a narrower meaning of a claim, and there is an enabling disclosure that indicates
that the applicant is at least entitled to a claim having the narrower meaning, … the notice function of the claim [is] best served by adopting the narrower meaning," Athletic Alternatives, 73 F.3d at 1581. The court resorted to this rule only after exhausting the other claim construction tools available -- neither the ordinary and accustomed meaning, the specification, the prosecution history, nor the doctrine of claim differentiation resolved the issue. This court has not been forced to such a rule of last resort. Moreover, there is no harm to the public notice function of § 112 that drove the Athletic Alternatives decision where the proper claim construction is so easily discerned from review of the claim in context.

The court notes that the APJ in the Judkins v. Ford interference also concluded that these claims did not contain process limitations. Springs distinguishes the APJ's opinion on the ground that patents are given their broadest possible reading in interference proceedings, citing DeGeorge v. Bernier, 768 F.2d 1318, 1321-22 (Fed. Cir. 1985). Nothing in the APJ's opinion indicates such a basis for his opinion; to the contrary, the APJ dismissed the process limitation argument altogether as a "red herring." This court has arrived at the same conclusion and concurs in the APJ's judgment.

The court therefore concludes that neither claim 1 of the '550 patent nor claim 1 of the '940 patent contain a process limitation. The court construes the claims-in-suit to extend to any cellular structure exhibiting the physical characteristics claimed therein.

1694

c. "A distance sufficient to insure that the adhesive does not interfere with rollers." A distance sufficient so that the adhesive does not interfere with the rollers of the printer during processing. This distance must be, at minimum, greater than the impression area caused by the rollers of the particular printer used. See Id. ("There is nothing wrong with defining the dimensions of a device in terms of the environment in which it is to be used.")

1695

The accepted meaning of the term "fold," when used as a verb, is: "to lay one part over another part," or "to reduce the length or bulk by doubling over." Webster's Ninth New Collegiate Dictionary at 478-79 (1990). When used as a noun, "fold" means: "a part doubled or laid over another part," or "a crease made by folding something." Id. at 479.

In this case, the district court erred by restricting the term "folding" to the "V" fold featured in the specification. Specifically, in construing the term "folding" in claim 1, the court turned to a portion of the specification that defines the "V-folded condition." 1 860 patent at col. 1 lines 28-33; 724 patent at col. 1 lines 26-31. The trial court then compared that portion of the specification to claim 1 and concluded that the term "folding" in claim 1 is synonymous with "V-folding" in the specification. 2 By this conclusion, the district court impermissibly imported the "V" limitation from the specification into the claim term "folding."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 According to the specification, the term V-folded condition refers to a length of material that has been folded over onto itself to form what may subsequently be identified as a front sheet and a rear sheet joined by the fold at the bottom, to approximate the letter "V" in cross section. 860 patent at col. 1 lines 28-33; 724 patent at col. 1 lines 26-31. 2 The court found that claim 1 speaks of only one fold, with the film on one side of the fold constituting a front sheet and the film on the
other side constituting a rear sheet - the same as the V-fold definition. 860 patent at col. 1, lines 28-33; 724 patent at col. 1 lines 26-31.

The district court also relied on the prosecution history to construe "folding." During prosecution of the 860 patent, Schreiber amended claim 1 by deleting the "V-" in "V-folding." The examiner entered the amendment. Later, during prosecution of the 724 patent, Schreiber attempted to make the same amendment to the specification. This time, however, the examiner rejected the amendment as new matter. Specifically, the examiner stated:

The original disclosure does not support the added material [deletions of "V" and insertion of a paragraph, etc.] because the added material sets forth folding a web in any manner known to one skilled in the art, with V-folding merely an example of such folding. The original disclosure supported only folding or V-folding. Further, the added material also sets forth other examples (cylindrical and oval) of folding a web. The original disclosure did not set forth any other examples of folding. . . . It is also not clear that a web which has been folded in a cylindrical or oval manner, had a fold (as claimed in the parent application 08/098,752, now U.S. Patent 5,440,860).

Examiner's Office Action in Application Serial No. 08/482,862, at 3 (Jan, 9, 1997) (emphasis added). The trial court found that Schreiber's acquiescence by canceling the amendment amounted to disclaiming a broader interpretation of "folding" advanced. Based on these conclusions, the trial court specified that the folding step of claim 1 requires that (1) the front and rear sheet be joined by a fold at the bottom, such that (2) the V-fold approximates the letter "V" in cross section.

The district court erred by applying this restrictive definition of "folding" in its JMOL decision. Although barring Schreiber from inserting into the specification examples of "cylindrical and oval" folding, the examiner also stated that the original disclosure supported "folding or V-folding." In other words, the examiner found that the original disclosure supported a broader concept of "folding" as well as the more specific example of "V-folding." Moreover, the specification does not exclude other types of "folding" from the broader generic concept of "folding."

This court's precedent forbids a construction of claim terms that restricts claims beyond the limits in the claim terms themselves, or beyond any unambiguous restriction in the specification or prosecution history. Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347, 49 U.S.P.Q.2D (BNA) 1199, 1203 (Fed. Cir. 1998) ("[A] court may not import limitations from the written description into the claims."); Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1997) ("While . . . claims are to be interpreted in light of the specification, it does not follow that limitations from the specification may be read into the claims."); In re Donaldson Co., 16 F.3d 1189, 1195, 29 U.S.P.Q.2D (BNA) 1845, 1850 (Fed. Cir. 1994) ("General claim construction principle that limitations found only in the specification of a patent or patent application should not be imported or read into a claim."); SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121, 227 U.S.P.Q. (BNA) 577, 585 (Fed. Cir. 1985) (en banc) ("It is the claims that measure the invention.") (emphasis in original). Accordingly, this court does not limit the meaning of the term "folding" to only a "V fold."

E. Foot and Leg Support at Each Side of the Front Wheel

Brike contends that the term "foot and leg support at each side of the front wheel" means a structure which supports both the foot and the leg, and which overlaps the front wheel, is near the front wheel, and which allows the feet and legs to extend forwardly at the sides of the front wheel. Invacare contends that the term "foot and leg support at each side of the front wheel" means a support that supports the leg by contacting the foot, ankle or leg, but does not necessarily require contact with the leg, with the supports on opposite sides of the plane defined by the front wheel.

Focusing on the first part of the term, "foot and leg support," Brike notes that the claims and specification refer to the foot and leg as distinct parts of the body and do not refer solely to the foot. Brike points to the secondary cross member which supports the leg and argues that if only the foot was supported, this structure would have no function. Thus, Brike contends that both the foot and leg must be directly supported by contact.
Invacare's basic position is that a foot support also supports the leg because the two are connected. Invacare argues that Claim 6 never requires direct contact with the leg, in contrast to the claim's express requirement of engagement, or contact, between the cross brace and the person's feet. In Figure 3, Invacare points to leg support strap 83, which is drawn at or below the smaller rider's ankle bone rather than his leg. Furthermore, Invacare notes that the claim does not expressly require a foot support and a leg support, stated separately.

The specification discusses the foot and leg supports in a few places. It states:

The invention provides a means for supporting and protecting the rider's legs and feet simultaneously while providing adjustment to accommodate different size riders.

'184 Patent, 1:40-43.

The present invention also recognizes the need for support of both the rider's legs and feet and not just the rider's legs in a cradle type device. The present invention provides a wrap around style of footrest and leg support that telescopes forward and rearward on the mainframe to accommodate different leg lengths. By wrapping around the rider's foot the footrest-leg [sic] support combination keeps the rider's foot from flopping to the side while at the same time supporting the leg. This type of support also provides protection to the rider's feet and legs from collision or side impact. Previous handcycles left the rider's feet to dangle in front of the front leg support.

Combined footrests and leg supports 82 telescope in a forward and rearward direction within tubing 48 and 49 respectively. Leg support straps 83 attach to footrests 82 and tubing 48 or 49 to form a sling for the purpose of supporting the rider's leg and foot. Straps are the preferred method of leg support in this case, however, any means of supporting the rider's legs at the rear of the "U" shape 82 would work as well or even closing the back of the "U" shape 82 to make a long rectangle that supports the rider's foot and calf.

'184 Patent, 4:41-49.

I am most persuaded by the fact that Claim 6 does not expressly require contact with the leg but does expressly require engagement, which I construe to mean contact, of the cross brace with the person's feet. The claim also does not require anything to be in contact with the secondary cross member. The specification states that by wrapping around the foot, the footrest support also supports the leg. This intrinsic evidence is highly persuasive that Invacare's position is the correct one.

I have reviewed Invacare's argument based on the prosecution history but I cannot glean much from it.

I construe the term the term "foot and leg support" to mean a support that supports the leg by contacting the foot, ankle or leg, but does not necessarily require contact with the leg.

Turning now to the term "at each side of the front wheel," it appears from the briefing that the parties agree that the term does not require the foot and leg supports to be bounded fore and aft by the front and rear edges of the front wheel. I also agree.

Brike contends that the use of the word "at" implies a close proximity. Brike contends that Invacare's use of a plane, which is an unbounded geometric figure, would allow the supports to be so far forward of the front wheel, or even behind the seat or back wheel, that they would not support the feet and legs.

I do not agree that the use of a plane in the definition of the term would allow the supports to be behind the back wheel because the claim requires them to be at the side of the front wheel. Thus, I construe "at each side of the front wheel" to mean overlapping at least a portion of the front wheel and on opposite sides of the plane defined by the front wheel.

Putting the two phrases together, I construe the term the term "foot and leg support at each side of the front wheel" to mean a support that supports the leg by contacting the foot, ankle or leg, but does not necessarily require contact with the leg and
overlapping at least a portion of the front wheel and on opposite sides of the plane defined by the front wheel.

1697

F. Foot Portion

'092 patent claim 102 states that the table comprises "an elongated portion and a foot portion of the first and second support pedestals" and that "the foot portion . . . [is] less than the width of the table top." (Id., Claim 102.) GSC claims that four of its tables (the Enduro four foot table, the Enduro Rochester table, the 2003 Enduro six foot table, and the Enduro eight foot table) do not have feet portions. The patent is silent about the proper meaning of this term, and neither party proposed a possible construction. We, therefore, construe this term consistent with its ordinary meaning. Portion means "an often limited part set off or abstracted from a whole." Foot, in this context, means "the lower end of the leg of a chair or table." We construe the term "foot portion" to mean "the lower part of a support pedestal."

1698

3. Footprint

* * *

The language of claim 1 requires "at least one ball projecting wheel . . . mounting a pneumatic tire having . . . a footprint ranging between about 4-13 cm." '325 patent, col. 4, lines 4-9 (emphasis added). Dependent claims 2 and 3 include the same "footprint" element as independent claim 1. See id. at col. 4, lines 4-15. The parties' dispute is whether "footprint" is the contact surface of the tire encountering a ball or the thickness of the tire from the edge of one sidewall to the edge of the opposite sidewall. Trend argues that "footprint" should be construed to be its plain and ordinary meaning which is a track left by a contacting surface. Furthermore, Trend argues that its proposed construction is proper because it covers tires with relatively flat surface treads as well as tires with rounded surfaces.

On the other hand, Jugs argues that Trend's speculated plain meaning of "footprint" is incorrect because the specification must be consulted to determine the meaning of a term with respect to the claims at issue. See Phillips, 415 F.3d at 1315-16. Jugs asserts that figure 2 of the '325 patent unequivocally represents "footprint" as the distance from the outermost edge of one sidewall of the tire to the outermost edge of the opposite sidewall. See '325 patent at fig.2. Furthermore, Jugs points out that Trend's proposed construction improperly requires that tires having different cross-sectional or tread shape, or having varying degrees of inflation, would have their footprints measured in different ways. See Liquid Dynamics Corp. v. Vaughan Co., Inc., 355 F.3d 1361, 1367 (Fed. Cir. 2004) (commanding courts to "assign a fixed, unambiguous, legally operative meaning to the claim.").

The court finds that the intrinsic evidence supports Jugs' proposed construction that "footprint" is the distance from the outermost edge of the one sidewall of the tire to the outermost edge of the opposite sidewall. The specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. Phillips, 415 F.3d at 1316. In such cases, the inventor's lexicography governs. See id. In the instant case, the claims and specification of the '325 patent reveal that "footprint" is the distance from the outermost edge of one sidewall of the tire to the outermost edge of the opposite sidewall, not a track left by a ball. Looking at the '325 patent, the claims do not describe the footprint in reference to a ball. See '325 patent at col. 4, lines 4-22 ("at least one ball projecting wheel . . . mounting a pneumatic tire having . . . a footprint ranging between about 4-13 cm). And, figure 2 of the '325 patent clearly defines "footprint" as the distance from the outermost edge of one sidewall of the tire to the outermost edge of the opposite sidewall. See id. at fig.2. There is nothing in the specification that suggests a different construction. 1 See Phillips, 415 F.3d at 1314-16. Thus, the court construes "footprint" to mean:

thickness as measured from the outermost edge of one sidewall of the pneumatic tire to the outermost edge of the opposite sidewall.

- 2133 -
At the Markman hearing, Trend asserted that the '325 patent was limited to throwing baseballs. Trend's assertion only fortifies the court's position that Trend's proposed construction of the term "footprint" is wrong because a baseball, having a diameter of only about 7.5 cm and a semicircular arc length of less than 12 cm, is incapable of producing the maximum footprint of 13 cm recited in claim 1.

Aspex argues that the limitation "said arms respectively containing second magnetic members for cooperation with said first magnetic members" means "the arms include second magnetic members which work together with the first magnetic members, such that the second magnetic members magnetically engage the first magnetic members either by contacting corresponding surfaces of the first magnetic members or by magnetically attracting corresponding surfaces of the first magnetic members without actual contact." Ps. Br. 12. E'Lite contends that it means "a second magnet horizontally contained in each of the arms for magnetic engagement with the first magnets." 14 D. Br. 14-15.

Aspex argues that its proposed construction is consistent with both the ordinary meaning of the words "contain" and "cooperate" and the disclosure of the specification. Aspex cites the description of FIG. 7 in the specification, which indicates that the corresponding magnetic members of the primary frame and the auxiliary frame can engage without touching, and that the description of the invention employing magnetic members that do not physically contact is only one embodiment of the invention. E'Lite responds that as similarly stated in its construction of the previous limitation, "contained" means "horizontally contained."

E'Lite maintains that the implied limitation of horizontal orientation discussed supra in § III(D)(4) applies to the matching second magnets as well. E'Lite also contends that the term "magnetic engagement" is a less confusing construction of "cooperation," as is the phrase "the first magnets" for "said first magnetic members." Aspex maintains that there is nothing in the intrinsic record to support limiting the disputed limitation to magnets or horizontally oriented magnetic members. Moreover, Aspex argues that E'Lite should not be permitted to rewrite the claims to suit its grammatical preferences, and that Aspex's construction should be adopted because it is supported by the intrinsic record and the ordinary meaning of the words.

Consistent with § III(D)(1), the court refrains from construing "magnetic members." Following the analysis of § III(D)(4), the court construes the "second magnetic members" as possessing horizontal orientation. The only disputed term that remains to be construed is "cooperation." Aspex argues for replacing "cooperation" with "work together," but nevertheless acknowledges that "cooperation" is not a confusing term in this context. Both parties advance a construction that elaborates on the meaning of "cooperation" to mean "magnetically engage" or "magnetic engagement." Thus the only real difference in the proposed constructions is that Aspex's proposal further clarifies that claim 18 is consistent with the first and second magnetic members' engaging in two distinct ways: by direct contact with each other and by attraction at a distance. Aspex
contends that the preferred embodiment of the '545 patent and the figures demonstrate that the magnetic members do not need to be in contact with each other to be engaged. The description of the preferred embodiment clearly indicates that having the magnetic members not actually touch is just "one" embodiment of the invention. The commonsense understanding of magnetic engagement also includes magnetic members actually touching one another. Nothing in claim 18 suggests otherwise. Therefore, the court construes "said arms respectively containing second magnetic members for cooperation with said first magnetic members" to mean "the arms include second magnetic members with horizontal orientation that cooperate together with the first magnetic members, such that the second magnetic members and first magnetic members magnetically engage either by direct contact of corresponding surfaces or by magnetically attracting corresponding surfaces without physical contact." 15

1701

4. "For connection to a floating vessel via an anchor line or chain"

APL contends that the limitation "directly" should be read into the claim phrase "for connection to a floating vessel via an anchor line or chain." Hence, according to APL, the phrase should read, a rigid mooring arm "connected directly to the vessel via an anchor line or chain with no intermediate floating buoy." SBM, on the other hand, construes the phrase as requiring the arm to "have the capability for connection, either directly or indirectly, to a floating vessel with an anchor line or chain." APL argues that permitting an indirect connection would prevent the vessel from weathervaning around the "completely submerged buoy," as set forth above. Moreover, APL contends that allowing the anchor lines or chains of the buoy to be connected indirectly, such as to an intermediate floating structure, defeats the purpose and function of the device as presented by SBM to the PTO, namely, so that "it can stay clear from the keel of the vessel" and to avoid the "drawbacks of the influence of wave motion." See Amendment, Document No. 55 ex. B, at SBM 00276-00277.

SBM argues, correctly, that Claim 1 imposes no "direct connection" requirement of the rigid mooring arm to the floating vessel via anchor lines or chains. Further, the extrinsic evidence submitted by APL suggests that the vessel weathervanes around the submerged buoy whether or not there is a surface buoy present. See Deposition of F. Tim Pease, Document No. 56 ex. E, at 152:25-153:5 ("Q. And thus, you'd still have rotational moment exerted on the turntable? A. Yes. Q. Regardless of whether there's a surface buoy there or not? A. That's correct."). Accordingly, the Court declines to impose the limitation of a "direct connection" on the claim phrase "for connection to a floating vessel via an anchor line or chain."

1702

4. "[F]or deflecting the striking force of said metal particles"

This phrase is contained in an independent claim in the 787 patent, 93 a dependent claim in the 781 patent, 94 an independent claim in the 386 patent, 95 and an independent claim in the 117 patent. 96

93 Col. 6, line 24-25.

94 Col. 6, line 32-35. The Court notes the language is slightly different: "each of said magnet protectors deflects a string [sic] force of said metal particles on said magnet members." The Court assumes "string" is a typographical error that should properly read "striking," as it does in the other patents.
As to this phrase, the Court construes the following meaning: the magnet protector prevents debris from hitting the surface of the magnet member when the tool is rotated. The Abstracts of the 787, 781, 386, and 539 patents all explain that a protector deflects particles from hitting a magnet during rotation of the tool. In patents 787, 781, 386, and 539, the Summary of the Invention explains that each protector has a triangular cross section and slanted surface angled in the direction of the rotation of the tool. 97 The specifications of the 787, 98 the 781, 99 the 386, 100 and the 539 101 patents all explain the process by which a protector prevents particles from hitting a magnet directly when the tool rotates, instead causing particles to hit the casing wall, get pushed upward, and then attach themselves to the magnets. The specification of the 117 patent contains slightly different language, explaining that the "protectors shield the magnets from a forceful impact with the metal objects attracted by the magnets when the tool is rotated in a well bore." 102 The drawings contained in all five patents support this interpretation as well. Construction of this phrase involves little more than the consistent application of the widely accepted meaning of commonly understood words used throughout the patents.

102 Col. 4, line 42-44.

--- End Footnotes ---

2. For Each Finger, a Finaer-Associable Cluster of Input Keys

Microsoft argues that this phrase should be construed to mean that "for each of the four (non-thumb) fingers of the hand, the device includes a separate group of multiple input keys for use by the associated finger." Microsoft's Memorandum in Support of Non-Infringement of '477 patent, p. 14. Microsoft further maintains that the term "cluster" requires at least two keys for each finger, and the term "each finger" means each finger of each hand, i.e., a two-handed device.

Plaintiff contests Microsoft's construction that the device must be designed for two hands and argues that the claim language does not include such a limitation. I agree. While Microsoft relies on the preferred embodiment depicting a two-handed keyboard, the court "must use the written description for enlightenment and not to read a limitation from the specification." Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 906 (Fed. Cir. 2005) I find that the claim language and the specification neither require nor exclude a one-handed embodiment.

Otherwise, plaintiff does not contest Microsoft's proposed construction, and I find it consistent with the plain language of the claim and the patent specification. See Col 1:4-18, Figures 1, 3. Thus, I construe the claim language to mean that for
each of the four fingers, the device must include a separate group of multiple input keys that correspond to the associated finger.

3. "[A] magnet protector for each of said magnet members"

This phrase, "providing a magnet protector for each of said magnet members," is contained in independent claims in the 787 patent, 85 the 781 patent, 86 and the 386 patent. 87 It is contained in the Abstracts of the other patents as detailed below.

As to this phrase, the Court construes the following meaning: each magnet has its own protector, that is, a one-to-one correspondence exists between magnets and their protectors. The Abstracts of all five patents explain that "magnet protectors are secured immediately adjacent to a corresponding magnet member." 88 The five patent specifications state explicitly that "[e]ach magnet… is provided with a 'heel,' or magnet protector…" 89 "Each protector member has a triangular cross-section with one side of the protector being longer than the side of the magnet positioned next to it." 90 "Each magnet member is provided with a protective member, or magnet protector." 91 The drawings accompanying each of the five patents illustrate that each magnet has its own protector. 92 The meaning of "a" for "each" is readily apparent.

5. "the orientation parameter for each of the two successive entities are the same" (claim 4)

Flow proposes this construction: "The orientation parameter is the same from one entity to the next. The value changes, not the type of parameter." Omax seemed to agree in the joint claim chart, but now argues that the claim should be construed simply as "the parameters are the same." Omax argues that the term "values" should not be inserted, as it adds limitations
not found in the claim. However, the parties already agreed that the claim term "orientation parameter" should be construed as "a value designating the alignment of the cutting head relative to the material being cut." '216 Patent Joint Claim Chart, Item 15. Because this term already is defined, the only remaining undefined claim terms are "for each of the two successive entities." The parties appear to largely agree that this phrase can be designated as "from one entity to the next." 5 Thus, the Court adopts Flow's construction, without the second sentence. The construction will read: "The orientation parameter is the same from one entity to the next."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 Omax originally signaled its agreement with this formulation in the joint claims chart.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

5. "For electrical connection"

Claim 9 includes "a contactor having a spring . . . and at least one contact for electrical connection with the first terminal of the battery. . . ." '900 Patent col.11 1.36-44. Invisible fence says that the term "for electrical connections" means "allows for electrical connection," and Perimeter argues that it means "the spring and the elongated contact arms make electrical connection to only one terminal of the battery (i.e., the first terminal)." 16 (Joint Statement 5.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

16 Both parties ostensibly agree that Claim 9 clearly reads that the electrical connection is made with the first terminal of the battery.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The parties disagree as to what components of the contactor are required to make the electrical connection. Invisible Fence argues that any combination of contact arm(s) and/or the spring can make the electrical connection, while Perimeter argues that the pair of contact arms and the spring are all required to make the electrical connection. 17

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

17 Perimeter's claim that there must be a pair of contact arms was rejected supra, Part III.B.3.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

As a threshold matter, the Court construes the term "for electrical connection" as modifying "a contactor" and not "at least one contact." If the term were read to modify "at least one contact," then claim 9 would curiously exclude the possibility that the spring might also make an electrical connection with the first terminal of the battery, a position neither party advocates and one clearly not supported by the Summary. See '900 Patent col.2 1.1-6 ("The flexion spring may be positioned within the battery holder so that . . . a resiliently bowed center portion is positioned for electrically contacting the first terminal of the battery . . . ").

While claim 9 provides that the contactor makes electrical connection with the first terminal of the battery, it does not specify which component makes the connection. The Summary, however, contemplates that any combination of contact arm(s) and/or the spring can make this connection:

The flexion spring may be positioned within the battery holder so that the respective ends of the spring are in contact with the base of the battery holder and a resiliently bowed center portion is positioned for electrically contacting the first terminal of the battery when the battery is inserted into the battery holder. The electrical contact may be connected with one end of the spring for electrical connection with the first terminal of the battery.
In addition, the doctrine of claim differentiation supports the proposition that the spring is not always required to make an electrical connection. Claim 20, which is ultimately dependent on claim 9, provides that the spring has a "resilient center portion for electrically contacting the first terminal of the battery." '900 Patent col.12 1.61-64. In sum, a presumption is created whereby claim 20 specifically recites that the spring must make the electrical connection, while broader claim 9 merely provides that the spring may make the electrical connection. See Seachange Int'l, Inc., 413 F.3d at 1368-69.

In light of the foregoing, the Court interprets the term "for electrical connection" to mean "any combination of contact arm(s) and/or the spring makes the electrical connection with the first terminal of the battery."

D. "having a lower surface for freely seating on a substantially flat surface"

Defendants suggest that this term should be construed to mean having a "flat lower surface that rests directly onto a flat ground surface, in contact with the surface." (Joint Claim Construction Chart ("Claims Chart"), p. 2, section 1.3.) In support of this definition, the Defendants propose that the remainder of the phrase implies that the lower surface must be flat in order that it may "freely [sit] on a substantially flat surface." However, the Court believes this definition overreaches, in that the lower surface need not necessarily be flat to enable it to rest on a flat surface. The surfaces of many objects are not flat - an upturned bowl for example - yet those objects are quite capable of resting on a substantially flat surface.

Plaintiff contends that the phrase should be construed to mean that the base member is not secured to the flat surface, and cites to the prosecution history as evidence. During prosecution, the Patentee was faced with a prior art rejection by the patent examiner, and was forced to argue around the Postings reference. To avoid Postings, the Patentee argued both the above-mentioned "amusement" angle, as well an argument that Postings disclosed a device whereby the animal was tethered to the device and the device was secured to a surface (generally, the ground) - thus ostensibly forcing the animal to run circles around a stationary object. In contrast, Patentee argued, his invention describes a device in which the animal is neither tethered to the device, nor is the device secured to the surface.

The Court finds Plaintiff's argument persuasive. The prosecution history provides for a definition of the phrase which is consistent with the language of the claims, specification, and the plain meaning. As such, the Court construes "having a lower surface for freely seating on a substantially flat surface" to mean: "having a lower surface that sits on, but is not secured to, a mostly flat surface."

Aspex argues that "downwardly extended end portions for hooking said auxiliary spectacle frame to said primary spectacle frame" should be construed to mean that "each arm includes an end portion that extends downwardly relative to the remainder of the arm, and which is bent in a manner to connect or catch with the primary spectacle frame as if with a hook." Ps. Br. 12. E'Lite maintains that the phrase "downwardly extended portions" should be construed to mean "end portions extending downwardly towards, but not behind, the primary spectacle frame," and that the phrase "for hooking said auxiliary spectacle frame to said primary spectacle frame," and that the phrase "for hooking said auxiliary spectacle frame to said primary spectacle frame," should be construed to mean "for interlocking the auxiliary spectacle frame to the primary spectacle frame." D. Br. 15, 18. E'Lite later accepted Aspex's construction with the exception.
of the limitation "but not behind." D. Resp. Br. 5. Because E'Lite concedes that Aspex's proposed construction is acceptable--except to the extent that it fails to include the limitation "but not behind"--the court need not recount the parties' construction arguments concerning the undisputed claim limitation.

Based on the prosecution history of the '545 patent, E'Lite argues that the limitation includes "but not behind." E'Lite points to the patentee's numerous failed attempts to add a FIG. 8 showing end portions that extend downwardly as well as rearwardly behind the primary frame's extensions. The patent examiner rejected the patentee's first rendition of FIG. 8 because it disclosed new matter not disclosed in the application. D. App. 157. The patent examiner rejected a later version of FIG. 8 because it introduced new matter. Id. at 124. In the second rejection, the examiner repeated that the basis for the rejection was that, in FIG. 8, the "end portion extends laterally past the rear edge of the projections." Id. Aspex later submitted a third version of FIG. 8, in which the end portions of the auxiliary frame's arms did not extend behind the rear edge of the projection. See id. at 168. Although the patent examiner ultimately approved this last version of FIG. 8, Aspex canceled its attempt to add a FIG. 8 to the '545 patent.

E'Lite interprets the cancellation of FIG. 8 as acquiescence to the patent examiner's determination that having the end portions extend laterally past the rear edge of the primary frame's projection was new matter. Aspex responds that E'Lite's attempt to limit the claims based on the patentee's cancellation of FIG. 8 should be rejected in view of the Federal Circuit's decision in Aspex Eyewear, Inc. v. Miracle Optics, Inc., 170 Fed. Appx. 710 (Fed. Cir. 2006) ("Miracle II"). Although Miracle II implicated the district court's construction of claims 12, 16, and 24 of the '545 patent, the claim language at issue is substantially the same as the limitation at issue in claim 18. Id. at 711. Moreover, the arguments in favor of limiting claims 12, 16, and 24 to require that the arms of the auxiliary frames do not extend past the rear edge of the primary frame's projections containing or securing the magnetic members are identical to E'Lite's contentions with respect to claim 18. Id. at 712-14. The Federal Circuit clearly rejected the interpretation of the prosecution history that E'Lite now advances. "In view of the applicant's statements, we cannot say that the canceling of Figure 8 was a clear and deliberate disclaimer of the claim coverage suggested by Figure 8." Id. at 714. Because Miracle II resolves this construction issue, the court refrain from discussing the reasons the Federal Circuit gave in dismissing E'Lite's interpretation of the prosecution history. Thus the disputed limitation does not contain the limitation of "but not behind." Because E'Lite does not challenge the balance of Aspex's proposed construction, the court adopts it. Therefore, "downwardly extended end portions for hooking said auxiliary spectacle frame to said primary spectacle frame" means "each arm includes an end portion that extends downwardly relative to the remainder of the arm, and which is bent in a manner to connect or catch with the primary spectacle frame as if with a hook."
'943 Patent, col. 5, 11. 3-4 (emphasis added). Formula I is a formula for an acrylic, which includes both acrylamides and acrylcarbamates. Bausch & Lomb contends that since Formula I is part of the definition of the "first portion," the claim term "a first portion for increasing wettability," as used in claims 1, 27, and 50, must be limited to acrylics. 2 As further support for its definition, Bausch & Lomb also points out that all of the specific monomers disclosed in the exemplary embodiments in the specification are acrylics. Thus, Bausch & Lomb contends, the invention of the '943 patent is limited to materials that include an acrylic, and the claims should be so construed. Since TRIS-VC, the component in Bausch & Lomb's Balafilcon A material and PureVision contact lenses which gives rise to the infringement allegations in this case, is a vinyl carbamate monomer - a "vinyl" rather than an "acrylic," Bausch & Lomb argues that the accused products are not covered by the claims of the '943 patent.

2 It should be noted that the acrylic structures of Formula I are expressly claimed in claim 19, which includes Formula I in the generalized monomer structure that is claimed.

In the alternative, Bausch & Lomb contends that the phrase "a first portion for increasing wettability" is a means-plus-function limitation, whose structure is limited to include acrylics, in that the structure of Formula I is the only corresponding structure.

b. Wesley Jessen

In response, Wesley Jessen contends that "a first portion for increasing wettability" is not limited to acrylics in independent claims 1, 27, and 50 of the '943 patent. Instead, that term is expressly defined by the words that follow it in the claims themselves, which require only that the "said first portion" be "hydrophilic" and include a "side-chain functionality" selected from one of two shown structural formulae, which are an amide and a carbamate. Thus, while Wesley Jessen concedes that each of the examples in the specification uses an acrylic as the first portion, it contends that Harvey claimed his invention more broadly in independent claims 1, 27, and 50 than the specific embodiments of the specification. Wesley Jessen argues that the language and structure of those claims provide a readily understandable definition of the meaning of this claim term.

In response to Bausch & Lomb's alternative argument that the claim term is a means-plus-function limitation, Wesley Jessen contends that it is not drafted in means-plus-function format and that there is no reason to construe it as such.

3. The Court's Construction

To determine the meaning of the claim term "a first portion for increasing wettability," the court begins by looking to the language of the claims themselves. Bell-Atlantic Network Servs., Inc., 262 F.3d at 1267. The claims recite a monomer having:

a first portion for increasing wettability, said first portion being hydrophilic and including a side-chain functionality selected from the group including the following structural formulae:

[SEE FORMULAE IN ORIGINAL]

Thus, the phrase "a first portion for increasing wettability" is given a specific definition by the words that follow in the claims themselves. The claims precisely define what "a first portion for increasing wettability" means, and this meaning does not include the acrylic formula referenced in the specification. Rather the claims state, more broadly, that the "first portion" must be "hydrophilic" and include a "side-chain functionality" selected from one of two shown structures, which are an amide and a carbamate. In other words, the "first portion" must be hydrophilic and include an amide functional group or a carbamate functional group as a side chain extending from the backbone of the polymer.

Bausch & Lomb argues that "a first portion" does not have a common meaning that is recognized and understood by those in the art, and that therefore the court must examine the specification to define the term. But where, as here, the claims specifically define the term at issue, it is unnecessary to import a more restrictive definition from the specification.
Consideration of the specification is instead restricted to determining if "a deviation from the clear language of the claims is specified." Interactive Gift Express, Inc., 256 F.3d at 1331. No such deviation is found in the specification.

Bausch & Lomb nonetheless argues that the claims of the '943 patent should be limited to the specific embodiments (acrylics) disclosed in the specification, on the theory that where the invention is described in limited terms in the specification, the claims are equally limited. See Toro Co., 199 F.3d at 1302; SciMed, 242 F.3d at 1339-40. In Toro Co., the court construed the claims for a hand-held convertible vacuum/blower for yard work to require that a "restriction ring" must be permanently attached to the device's cover, as described in the specification. The court noted that the specification "describes the advantages of the unitary structure as important to the invention" and that the specification "stressed" that the ring and cover are one part. 199 F.3d at 1301. Stating that this was not a case of limiting the claims to a preferred embodiment, id., the court found "the invention is described throughout the specification as it is claimed," id. at 1302, and therefore construed the claims as described in the specification. In SciMed, the Federal Circuit affirmed the district court's narrow claim construction, because the abstract explicitly limited the patents to particular lumen catheters, the patents distinguished the prior art on the basis of such catheters, and the 'Summary of Invention' portion of the specification characterized the invention as having that type of catheter. SciMed, 242 F.3d at 1347.

Here, unlike the Toro and SciMed cases, no explicit or express disclaimer of monomers other than acrylics exists in the '943 patent or its prosecution history. Given the absence of any disclaimer of broader coverage, Bausch & Lomb's proposed construction would impermissibly import a narrowing limitation from the specification to the claims. Renishaw, 158 F.3d at 1248.

This is a case where the patentee has claimed his invention more broadly in independent claims 1, 27, and 50 than in the specific exemplary embodiments of the specification. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1344 (Fed. Cir. 2001) (citing SRI Intl v. Matsushita Elec. Corp. of America, 775 F.2d 1107, 1121 (Fed. Cir. 1985) (en banc) ("If structural claims were to be limited to devices operated precisely as a specification-described embodiment is operated, there would be no need for claims. Nor could an applicant, regardless of prior art, claim more broadly than the embodiment"). As the meaning of "a first portion for increasing wettability" can be determined by a person of ordinary skill in the art from the language of the claims themselves, there is no reason to limit that meaning to a narrower embodiment in the specification. Moreover, the '943 patent claims the specific acrylic embodiments of the specification in dependent claims; the independent claims are more broadly claimed. If the patentee intended to limit his invention to acrylics, he would not have claimed his invention in this manner.

Neither does the specification necessarily require that the "first portion" of the invention be limited to the acrylics of Formula I. While certain language, such as that in the Summary of Invention indicates that the claimed material has the "generalized structure" of Formula I, other language indicates a broader scope of invention. For example, the Abstract, like the claim language, defines the invention in broad terms, noting only that the first portion includes a side-chain functionality of an amide or carbamate and that it be hydrophilic; it does not limit the first portion to the Formula I structure. See Hill-Rom Co. v. Kinetic Concepts Inc., 209 F.3d 1337, 1341 (Fed. Cir. 2000) (noting that courts frequently looks to the abstract to determine the scope of the invention).

As for the references Bausch & Lomb cites from the "Detailed Description of the Preferred Embodiments," they are just that - preferred embodiments. They do not purport to define the entire invention. For example, the reference to the Formula I structure that Bausch & Lomb relies upon, states at the outset that it is describing "A monomer embodying the principles of the present invention . . ." '943 patent, col. 5, l. 42 (emphasis added). The fact that the specification provides a wealth of teaching about the preferred embodiments does not mean that the claims are limited to those preferred embodiments.

Again, the court comes back to claims such as claim 1, which do not mention a limitation involving Formula I. This clearly indicates that the scope of invention was intended to be broader than one that is limited to acrylics.

The prosecution history also confirms that both the Examiner and the applicant considered the claims to be broader than Formula I. During the prosecution of the patent application that led to the '943 patent, the Examiner imposed a rejection of claims 25-53 as being obvious over Fort in view of Friends alone or together with Gaylord. Fort teaches vinyl and allyl carbamates, neither of which are acrylics. Specifically, Fort relates to carbamate-containing polysiloxane copolymers useful as emulsifiers, dispersing agents, lubricants, surface active agents, and coagulants. See U.S. Patent No. 3,652,629, col. 1, ll. 16-18. Fort describes making these copolymers by reacting ethylenically unsaturated carbamates, such as vinyl and allyl
carbamates, with the polysiloxanes. See, e.g., id. at col. 3, ll. 4-30. Thus, Fort teaches vinyl and allyl carbamates, and does not teach or describe any "acrylic" amides or carbamates.

The Examiner reasoned that the primary references (including Fort) disclose monomers having "nitrogen and silicone groups," and the secondary references show the use of co-monomers. Thus, the Examiner concluded, the choice of the applicant's claimed co-monomers would have been obvious. This rejection makes clear that the Examiner considered the applicant's claims to cover vinyl and allyl carbamates, and thus that the claims were not limited to acrylics. The applicant argued against this rejection in his July 16, 1986 response. Therein the applicant distinguished Fort, not by disclaiming vinyl carbamates, but by arguing that Fort's compounds were emulsifiers and were unusable as contact lens materials. In distinguishing Friends and Gaylord, the applicant argued that his claims required the amide or carbamate structure, and that the secondary references failed to teach siloxane monomers having an amide or carbamate. He did not specify that the first portion was limited to acrylics or that acrylics were an important or necessary aspect of his claimed monomer structure.

In sum, at no time in the prosecution history did the applicant disclaim vinyl monomers or assert that his invention is limited to acrylics. If the applicant intended to disclaim vinyls or limit his claim to acrylics, such a disclaimer would have been an appropriate basis upon which to distinguish Fort. That no such disclaimer was made, supports the court's interpretation that the claims are not limited to acrylics.

Last, construing the phrase "a first portion for increasing wettability" as not being limited to acrylics is also supported by the doctrine of claim differentiation. The doctrine of claim differentiation provides that because each claim is presumed to have a different scope, it is presumptively unreasonable to construe one claim so as to render another claim superfluous. Beachcombers, Int'l v. Wildewood Creative Prod., Inc., 31 F.3d 1154, 1162 (Fed. Cir. 1994); Intel Corp. v. Broadcom Corp., 172 F. Supp. 2d 478, 496 (D. Del. 2000) ("In interpreting claims, it is improper for courts to read into an independent claim a limitation that is explicitly set forth in another [dependent] claim"); see also Intermatic Inc. v. Lamson & Sessions Co., 273 F.3d 1355, 1364 (Fed. Cir. 2001) (noting that this presumption is "strengthened" when there is a dispute over whether "a limitation found in a dependent claim should be read into an independent claim, and that limitation is the only meaningful difference between the two claims"); cf. Wenger Mfg. v. Coating Machinery Sys., 239 F.3d 1225, 1233 (Fed. Cir. 2001) (noting that the doctrine of claim differentiation is a guideline and not a hard and fast rule and that claim differentiation cannot be relied upon to broader claims beyond their correct scope). While the court realizes that claim differentiation is a guide and not a strict rule, the guidance provided by this doctrine strongly supports the court's construction.

Bausch & Lomb asserts that the term "a first portion for increasing wettability" is limited to those structures that have the chemical structure of an acrylic (as shown in Formula I of the specification). The structural limitations that Bausch & Lomb would have the court read into the "first portion" of independent claims 1, 27, and 50 are found in the dependent claims of the patent. For example, claim 5, which depends from claim 1, recites the specific structure found in Formula I for the first portion of the monomer. Similarly, claim 2, which also depends from claim 1, claims "the contact lens material of claim 1 wherein said first portion comprises an acrylamide or a methacrylamide." Under the doctrine of claim differentiation, however, reading the limitation of the specific acrylic structure into claim 1 would render dependent claim 5 superfluous, which is presumptively unreasonable. Beachcombers, 31 F.3d at 1162. This presumption is heightened here, since the acrylic structure limitation is the only meaningful difference between claim 1 and claim 5.

--- Footnotes ---

3 A similar analysis can be applied to independent claims 27 and 50, in light of dependent claims 41 and 54, respectively.

--- End Footnotes ---

Neither does the court agree with Bausch & Lomb's alternative contention that the claim term must be construed as a means-plus-function claim. First, no "means" language is present in the phrase. The failure to include the word "means" creates a presumption that § 112, P6 does not apply. Personalized Media Communications L.L.C. v. Int'l Trade Comm'n, 161 F.3d 696, 703-04 (Fed. Cir. 1998). This presumption may only be rebutted where the properly construed claim does not "recite[] sufficiently definite structure to avoid the ambit of § 112, P6." Id. at 704. In this case, the claims do recite a structure that corresponds to the specified function of increasing wettability, the amide or carbamate side-chain functionality. As Dr. Goodman testified, amides and carbamates are both hydrophilic and perform the function of increasing wettability. Because there is sufficient structure shown to perform the function of increasing wettability, the claim cannot be
In conclusion, for the reasons stated above, the phrase "first portion for increasing wettability" is not limited to the acrylic structure set out in Formula I or the '943 patent specification. It covers structures that are hydrophilic and include carbamate or amide sidechain functionality. This includes both vinyls and acrylics.

1710

A. CLAIM CONSTRUCTION

The Court finds the testimony of Dr. Corbett and Mr. Witherspoon to be persuasive on the issue of claim construction. The dispute is over the following limitations which Combustion contends are not present in its RT Kiln, the terms at issue being underlined: (1) "for the continuous electric heating and/or fusion..."; (2) "a ...conical extension fixed to one end thereof"; and (3) "a crane support mounted upon each said housing and removable conical extension for lifting and tilting the housing to remove the contents thereof." [PTX 533 and 534].

CONTINUOUS

Dr. Corbett testified that the term "continuous" modifies "heating", not "fusion" such that electric heating without interruption, as well as fusion, takes place in the patented furnace [Tr. II(2)(Corbett), 30-31, 33-34 and 38-40]. Based upon this testimony, the court finds that term "continuous" modifies "heating and not "fusion" for purposes of claim construction in regard to this limitation.

CONICAL EXTENSION FIXED TO ONE END THEREOF

The dispute with respect to this limitation revolves around the meaning of the word "fixed" in Claims 3 and 4. Dr. Corbett testified that "fastened" is a synonym for "fixed", and that "fixed" means "securely fastened" such that, when the main portion of the housing is lifted, the end follows [Tr. II(2), 40-41]. The court finds that terms "fixed", "fastened", and "securely fastened" are synonyms for purposes of claim construction in regard to this limitation. This interpretation is supported by the reading of the claim, the testimony of witnesses, as well as the prosecution history. DTX 180, PTX 460, p. 277.

CRANE SUPPORT FOR LIFTING AND TILTING THE HOUSING

The language of subparagraph D, properly interpreted, simply requires that there be a crane support mounted on the removable, detachably secured, conical extension ("dumping" end) and a crane support mounted on the remainder of the housing, with both such crane supports being involved in facilitating the lifting and tilting of the housing "so that" the contents of the furnace (e.g., a fused silica ingot) can be removed out the detachably secured end. In this regard, the reading of the claim language supports this interpretation [PTX 2, Col. 1, lines 40-43, 63-66], as does the prosecution history.

GO BACK

1711

With regard to the central issue of nearly every patent appeal, claim construction, the district court reached an interpretation fully supported by the record. See Markman v. Westview Instruments, Inc., 134 L. Ed. 2d 577, 116 S. Ct. 1384, 1395-96, 38 U.S.P.Q.2D (BNA) 1461, 1470-71 (1996). Claims 3 and 4 of the '462 patent call for two crane supports -- one on the main housing and another on the removable conical extension "for lifting and tilting the housing and removing the contents thereof." Construing this limitation, the trial court held that "both such crane supports [must be] involved in facilitating the lifting and tilting of the housing 'so that' the contents of the furnace . . . can be removed out the detachably secured end." The trial court did not construe this language to require that the crane supports actually lift and tilt the furnace housing.

The claim language and the patent specification support this interpretation. The claim language does not require each crane support to actually lift and tilt the furnace housing. The claims specify only use of the crane supports during lifting and
tilting. Indeed, as is evident to one of ordinary skill in rotary furnace operations, crane supports alone do not lift a furnace. Rather a crane lifts the weight of the furnace. The supports, by their nature, only facilitate this lifting process by connecting the furnace to the crane.

The specification further supports the trial court's construction. In relevant part, the specification provides: "Upon completion of the fusion process, the entire kiln is crane lifted from the driving cradle support 156 and the cone 120' removed, whereupon the kiln is tilted and the formed ingot dumped." This language in the specification discloses that removal of the detachable extension precedes the tilting process. Thus, the district court correctly determined that the patent does not require that the crane support on the detachable end receive force that directly tilts the housing. Rather, the specification suggests that this crane support plays a part in the lifting and tilting process.

In light of its correct claim construction, the district court found that the claims read on the accused RT kiln. This court detects no clear error in this finding of fact. Accordingly, this court affirms the trial court's finding of literal infringement. [GO BACK]

1712

II. Effect of Preamble Language Regarding "Reducing Vibrations and Slippage"

The magistrate judge rejected Mitsubishi's argument that the phrase "for reducing vibrations and slippage," as used in the preambles of the asserted claims of the '048 and '981 patents, was a claim limitation. Rather, the magistrate judge held that this phrase was merely a "statement of purpose and therefore [did] not act as a limitation of the claimed invention."

Mitsubishi claims that the magistrate judge erred by holding that this phrase was not a claim limitation. Mitsubishi emphasizes that, during the prosecution of the '048 patent, the applicants originally added this phrase as part of a means-plus-function limitation to overcome the examiner's obviousness rejections based on U.S. Patent No. 4,953,461 ("the Gaffney patent") in view of U.S. Patent No. 4,913,048 ("the Tittgemeyer patent"). Despite the applicants' addition of this limitation, the examiner continued his obviousness rejections, but relied upon a different combination of references. The applicants then replaced the term "means" with "mechanism." When the examiner persisted with his obviousness rejections, the applicants cancelled the claims and inserted entirely new claims with the language regarding "reducing vibrations and slippage" in the preamble.

Given the significance of the "reducing vibrations and slippage" language in the prosecution history, Mitsubishi contends that the magistrate judge should have construed this phrase as a claim limitation. Because Mitsubishi contends that its presses are intentionally designed to promote slippage, it asserts that it cannot infringe either the '048 or '981 patent claims.

The determination of the effect of preamble language is but a part of the broader task of claim construction, see Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 621, 34 U.S.P.Q.2D (BNA) 1816, 1820 (Fed. Cir. 1995), which we undertake without deference to the district court, see Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). While the phrase "for reducing vibrations and slippage" was originally added to the body of the '048 claims in the context of means-plus-function language, which indisputably would have acted to limit the claimed inventions, its movement to the preamble of the newly-added claims did not create a similar effect. The only relevance of the phrase "reducing vibrations and slippage" is to illustrate the intended purpose of the invention. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 U.S.P.Q.2D (BNA) 1161, 1165-66 (Fed. Cir. 1999). The phrase is plainly not "necessary to give life, meaning, and vitality to the claim." Kropa v. Robie, 38 C.C.P.A. 858, 187 F.2d 150, 152, 88 U.S.P.Q. (BNA) 478, 480-81 (C.C.P.A. 1951). It does not, for example, provide an antecedent basis for terms later used in the body of the claim. See Gerber Garment Tech., Inc. v. Lectra Sys., Inc., 916 F.2d 683, 688-89, 16 U.S.P.Q.2D (BNA) 1436, 1441 (Fed. Cir. 1990). Nor could such an expression of the intended use and function of the offset press have distinguished over the prior art. See In re Lechene, 47 C.C.P.A. 923, 277 F.2d 173, 176, 125 U.S.P.Q. (BNA) 396, 399 (C.C.P.A. 1960). Consequently, we hold that the phrase "reducing vibrations and slippage" is not a claim limitation.

Because Mitsubishi does not challenge the jury's finding that its accused presses satisfy every structural limitation recited by the asserted claims of the '981 patent, we affirm the jury's finding of literal infringement of the '981 patent. Mitsubishi challenges the magistrate judge's construction of another limitation of the '048 patent, however, and thus our construction of
the "reducing vibrations and slippage" language in the preambles of the asserted claims does not conclude our review of the jury's finding of literal infringement with respect to that patent.

GO BACK

1713

B. Element B of Claim 1

1. Construction

Element of claim 1 describes "spokes attached to the rings for supporting the rings." The parties agree about the meaning of the terms "rings" and "spokes," and Wilshire concedes that the Versailles frames have both. The parties dispute, however, the meaning of the clause "for supporting the rings." Wilshire argues that spokes support rings, within the meaning of this element, only if the spokes actually bear the weight of the rings. Wilshire concludes that its Versailles chandeliers do not infringe the 805 patent because only one inner ring is borne by the spokes, while the other inner ring (itself borne by the center plate hanging from the ceiling) bears the weight of the spokes. 2 Schonbek counters that when the rings and spokes of the accused chandelier frames are attached to each other, they "support" each other, like the stones in an arch, regardless of which is attached to the ceiling and bears the weight of the other.

2 The language of element B suggests that the spokes must support a plurality of rings.

Schonbek's definition of "support" in the context of element B has a somewhat more attenuated connection to dictionary definitions than does its definition of the same term in the context of element A. Those definitions do not expressly speak to the question of direct or indirect attachment, but they do fairly convey a sense of "keep from falling."

Again, analysis of the meaning of "support" in the context of this element must take into account the patent specification, and in particular, the embodiment depicted at Figures 17 and 18. That embodiment, after all, does not even feature a single ring whose weight is as clearly borne by the spokes as the lower ring in Wilshire's Versailles frames, insofar as both rings of the embodiment depicted at Figures 17 and 18 are attached to the center column hanging from the ceiling. Again, adopting Wilshire's more restrictive definition of "support" would necessitate ignoring the 805 patent specification in this regard.

It might be argued that doing just that is appropriate in order to avoid expanding element B's reference to "support" beyond a narrow meaning. In particular, a leading treatise states that "the specification may be referred to in order to explain any ambiguity in the claim and to limit the claim, . . . [but] the specification is never available to expand the claim." Ernest Lipscomb, Walker on Patents 3d, § 21:22, at 337. However, recent Federal Circuit decisions appear to refine this pronouncement, instead suggesting that what must be considered, in light of the specification, is whether the drafter of claim language "intended to use the claim language in a manner different than its ordinary meaning." Pall Corporation v. PTI Technologies, 259 F.3d 1383, 1391 (Fed.Cir.2001); see also DeMarini Sports, 239 F.3d at 1323 ("the specification is reviewed to determine whether the patentee used terms in a manner inconsistent with their ordinary meaning"). 3

3 By contrast, the Federal Circuit has clearly maintained that extrinsic evidence -- like expert testimony, articles, and inventor testimony -- "may not be used to vary, contradict, expand, or limit the claim language from how it is defined, even by implication, in the specification or [prosecution] history." Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1269 (Fed.Cir.2001).

No doubt, it would be helpful if the 805 patent's specification more precisely defined element B's use of "support." It does not do so. However, evidence of the claim drafter's intent to use "support" in a somewhat broader fashion than ordinary is not here limited to a random and unexplained figure. Rather, at two separate points, the patent specification clearly details
what Figures 17 and 18 depict, and describes that structure as one embodiment of the invention. '851 patent, column 5:33-38, column 11:12-37. See MSM Investments Company, LLC v. Carolwood Corporation, 259 F.3d 1335, 1339 (Fed. Cir. 2001) (specification suggests that inventor intended to use term more broadly than its ordinary meaning, even thought it "does not specifically define the term"). Furthermore, as noted above, I am not persuaded that the embodiment is meant to be -- or even can logically be read as -- independent from claim 1. Accordingly, I decline to construe element B's use of the term "support" to convey only the function of "bear the weight," such as would exclude the embodiment depicted at Figures 17 and 18.

It remains for me to specify what element B's language of "for supporting the rings" affirmatively means. I note in this regard that mere attachment does not seem to be an interpretive option: to read element B's use of "support" as broadly as that would render the claim language ("spokes attached to the rings for supporting the rings") entirely redundant. Rather, "for supporting the rings" must reference some degree of functionality, consistent both with spokes bearing the weight of rings and with rings bearing the weight of spokes, over and above attachment alone.

I conclude that a variation of the dictionary definitional language of "hold in position" can serve the necessary purpose. I read claim 1 of the 805 patent as contemplating different configurations of rings and spokes sharing the following common feature: in each configuration, whether the rings are bearing the weight of the spokes or the spokes are bearing the weight of the rings, the two sets of parts "support" each other insofar as they hold each other in a fixed position necessary for the structural integrity of the overall chandelier frame.

A. CLAIM CONSTRUCTION

The Court finds the testimony of Dr. Corbett and Mr. Witherspoon to be persuasive on the issue of claim construction. The dispute is over the following limitations which Combustion contends are not present in its RT Kiln, the terms at issue being underlined: (1) "for the continuous electric heating and/or fusion..."; (2) "a ...conical extension fixed to one end thereof"; and (3) "a crane support mounted upon each said housing and removable conical extension for lifting and tilting the housing to remove the contents thereof." [PTX 533 and 534].

Dr. Corbett testified that the term "continuous" modifies "heating", not "fusion" such that electric heating without interruption, as well as fusion, takes place in the patented furnace [Tr. II(2)(Corbett), 30-31, 33-34 and 38-40]. Based upon this testimony, the court finds that term "continuous" modifies "heating and not "fusion" for purposes of claim construction in regard to this limitation.
In introducing embodiments of the invention, the written description states:

Electrothrombosis is facilitate by placing the ground electrode on the distal end of the microcatheter and flowing current between the microcatheter electrode and the tip.

('962 Patent, Col. 6:64-67.) Thus, as previously discussed, the Court declines to impose as a limitation on the claim that thrombosis be achieved to any particular degree.

The Court construes "a catheter wire for use in electrothrombosis" as it is used in Claim 1 of the '962 Patent to mean:

a catheter wire used with an electrical current to form a thrombus in a vascular cavity.

The statement "for use in sports and casual activities" does not limit the invention. This is because "where a patentee defines a structurally complete invention in the claim body and uses the preamble only to state a purpose or intended use for the invention, the preamble is not a claim limitation." STX, LLC v. Brine, Inc., 211 F.3d 588, 591 (Fed. Cir. 2000). This is further buttressed by the fact that "preambles describing the use of an invention generally do not limit the claims because the patentability of apparatus or composition claims depends on the claimed structure, not on the use or purpose of the invention." Catalina, 289 F.3d at 809. Furthermore, the intended use of the sunglasses does nothing to distinguish the invention over the prior art.

"Foraminous Hydrophobic Water-Vapor-Permeable Pellicle"

Claim 16 of the '693 patent includes reference to a "foraminous hydrophobic water-vapor-permeable pellicle" (sometimes, "FHWVP"). As noted above, the inventors of the '693 patent stated that the identified problems in the prior art could be avoided through the use of a FHWVP in the 3-ply sandwich wrap: "The sandwich wrap of the present invention provides greatly improved moisture control while decreasing adhesive tendencies between sandwich components and the absorbent inner layer by interposing a foraminous hydrophobic water-vapor-permeable pellicle on fibers positioned between the sandwich and the moisture-vapor-impermeable polymeric layer." ('693 patent, col. 1, lines 60-66.)

The parties offer two different proposed interpretations of FHWVP, which overlap in many regards but also differ in important ways. Fort James proposes the following: "A thin film that may have gaps in it and that also contains small pores. The film repels water, but water vapor may pass through the gaps or the pores in the film." 39 Coating Excellence proposes the following construction: "a thin film on and between certain fibers in the fibrous absorbent layer that is porous and not necessarily continuous. The thin film repels liquid water, but permits water vapor to pass through. The film being the deposit or precipitate left behind after hydrophobic precursor is applied to the fibers and the carrier removed." 40

--- Footnotes ---

39 This proposed construction is set forth in Plaintiffs' Final Proposed Claim Constructions [Dkt. No. 175] at p. 3.

--- End Footnotes ---

As confirmed at the Hearing, the parties agree on a number of the aspects of the proper construction of FHWVP: The parties agree that foraminous means porous; and they agree that "hydrophobic water vapor permeable" means repelling water but
permitting water vapor to pass through. There are, however, three primary areas of disagreement between the parties: (1) whether the pellicle should be described as being "on" the fiber or "on or between" the fiber; (2) whether or not the pellicle must form a distinct sublayer; and (3) whether the construction should include language describing how the pellicle is formed.

a. Review of the intrinsic evidence

As was the case with the term "water vapor impermeable polymer layer," the undersigned finds that, read by itself, the meaning of the term "foraminous hydrophobic water-vapor-permeable pellicle" is not "immediately apparent" and consideration of additional "sources" is appropriate. Phillips, 415 F.3d at 1314.

With respect to the word pellicle, the inventors clearly and unambiguously intended to be their own lexicographers. Id., at 1316. They state as follows: "We use the word 'pellicle' to describe the 'deposit' or 'precipitate' left behind after hydrophobe precursor has been applied to fibers and the carrier removed. We chose the word 'pellicle' because it has the connotation of being very thin and not necessarily continuous." ('693 patent, col. 2, lines 7-11.) There are no statements in other portions of the specification or the file history that would suggest that a different meaning should be given to the word pellicle.

The pellicle need not necessarily be a film. The specification, for instance, provides that the "pellicle may be present on fibers in a distinct sublayer as indicated in FIG. 4 or it may be present as a film, coating or crust on at least some, and surprisingly even possibly all, of the fibers in layer 20." ('693 patent, col. 5, lines 9-13.) A number of claims not in dispute use the word "residue" to describe the form of the pellicle. (E.g., Claim 19.) See Dorel Juvenile Group, Inc. v. Graco Children's Prods., 429 F.3d 1043, 1045-46 (Fed. Cir. 2005) (citing Phillips, 415 F.3d at 1315-17) (noting that the claims are part of the specification).

The specification indicates that the pellicle bearing fibers may be in a distinct sublayer in certain embodiments. But, as can be observed in the quoted material in the previous paragraph, not all embodiments require a sublayer. ('693 patent, col. 5, lines 9-13.) For instance, the specification explains that all of the absorbent layer may be treated with the pellicle in certain circumstances. ('693 patent, col. 2, lines 1-4.) There would be no distinct sublayer under such scenario.

The pellicle properly is described as being "on" the fiber. The specification consistently describes the pellicle in this fashion. (E.g., '693 patent, col. 1, lines 64-65 ("pellicle on fibers"); col. 4, lines 64 ("pellicles on the fibers"); col. 5, line 52 ("pellicles present on the surface of individual fibers").) The specification no where refers to the pellicle being "on and between certain fibers."

Finally, the parties debate whether the construction of this term should include reference to the means by which the pellicle is formed. Coating Excellence, as noted above, suggests that the construction should conclude with a statement providing, "The film being the deposit or precipitate left behind after hydrophobe precursor is applied to the fibers and the carrier removed." Fort James suggests that such additional language is not needed because the last portion of claim 16 itself provides, "said pellicle having been formed by application of an aqueous mixture of a hydrophobe precursor to the surface of a sheet of absorbent material." The undersigned agrees with Coating Excellence that the inventors have defined pellicle to be the "deposit" or "precipitate" "left behind after hydrophobe precursor has been applied to fibers and the carrier removed." ('693 patent, col. 2, lines 7-9). But the undersigned also agrees with Fort James that this concept is provided as an express limitation of claim 16. Therefore, it should not also be incorporated as part of the construction of the term at issue. Such redundancy potentially could lead to juror confusion.

b. Review of extrinsic evidence

The undersigned finds that the proper construction of the disputed term can be ascertained without reference to extrinsic evidence. 41

--- Footnotes ---

41 In their final claim construction statements [Dkt. Nos. 175 and 176], Fort James offered two dictionary definitions relating to the undisputed meanings of hydrophobe and foramen. Coating Excellence offered no extrinsic evidence in support of their positions.
c. Recommended claim construction

For the above reasons, the undersigned recommends that the term "foraminous hydrophobic water-vapor-permeable pellicle" be construed to mean: "A very thin and not necessarily continuous residue on fibers. This residue may be in, but is not limited to, the following forms: a distinct sublayer, a film, a coating, a crust, a deposit and a precipitate. This residue has holes or pores, repels water and permits water vapor to pass through it."

D. Specific Disputes

Snap Edge makes three specific arguments regarding certain elements of Claims 115 and 144. First, Snap Edge argues that the force conversion referenced throughout the patent should be interpreted to require conversion of most, if not all, horizontal forces into vertical forces. Second, Snap Edge asserts that the term "substantial" as used in Claim 144 is indefinite. Finally, Snap Edge contends that term strip as used in Claim 115 and Claim 144 must be interpreted to mean continuous.

Force conversion is a ubiquitous concept in the '550 Reissue patent from the Abstract through the specifications through numerous claims. Essentially, Claim 115 purports to detail a means for converting the horizontal forces, which act upon the paving stones and can cause shifting, into vertical forces in order to use the ground to keep the pavers in place. This purported force conversion is accomplished using a connecting strip and a restraining means. Snap Edge argues that this term must be interpreted to require that most if not all horizontal forces received by the vertical restraint strip be converted into vertical forces. The Court does not agree. Nowhere in the specification is a set amount of horizontal force required to be converted into vertical force. The Court finds that there is no mandate that all horizontal force, or even most of it, be transferred via the force converting means into vertical forces. Whether any conversion actually occurs in these elements, and more importantly, whether any conversion occurs in the Snap Edge product, is a question of fact not properly before the Court at this time.

"force for centering"

Building upon its proposed construction of "centering," Xinyi asserts that the phrase "force for centering" also requires construction. This phrase appears in claims 14, 15, and 16 of the '395 patent, and in claims 9 and 16 of the '669 patent, all of which have been asserted against Xinyi.

Consistent with its construction of "centering," Xinyi argues that the "force for centering" must be "pressure sufficient to overcome friction and move the weight of the window to provide a constant gap of even width all around the glazing." However, once the Court's conclusion regarding the term "centering" in the '395 patent is taken into account, Xinyi's proposed construction of "force for centering" -- which presupposes adoption of its construction of "centering" -- necessarily fails. If, as the Court finds to be the case, centering occurs only where a spacer is present, there is no support for finding that the force for centering must have an effect even in areas where no spacer is present. To the contrary, the force for centering is (as the plain language of the claim indicates) provided by the spacer, and "sufficient to maintain centering of the glazing on the bracket and to provide a gap between" the edge of the glazing and the bracket, along the portion of the periphery where there is a spacer. This accords with the plain language of the claims. As a result, no construction is required.

- 2150 -
"force producing assembly"
Means plus function

Fitness Quest contends that this term is a means-plus-function element, arguing that, as such, it does not identify a particular structure, but instead looks to the specification for its structure. Monti acknowledges that the term requires construction, but contends that this term is a structural element, rather than a means-plus-function element. He offers a proposed construction of the term as a structure and an alternative construction if the term is found to be a means-plus-function element. The term is not a means-plus-function element, and Monti's proposed structural construction is adopted.

In general, in the absence of the word "means," the disputed term is presumed not to be a means-plus-function element.

It is well settled that "[a] claim limitation that actually uses the word 'means' invokes a rebuttable presumption that § 112, P 6 applies. By contrast, a claim term that does not use 'means' will trigger the rebuttable presumption that § 112, P 6 does not apply." "The term 'means' is central to the analysis."

If the party who must bring forth evidence fails to proffer sufficient evidence to meet its burden, the presumption, either for or against the application of § 112, P 6, prevails.

Fitness Quest does not even acknowledge the presumption against "force producing assembly" being read as a means-plus-function term. Fitness Quest instead argues that "force producing assembly" contains an insufficient delineation of structure to permit this Court to find that it is a structural term rather than a means plus function term. Presumably, Fitness Quest intends to argue that its proposed construction overcomes the presumption against means-plus-function treatment because "force producing assembly" "fails to 'recite sufficiently definite structure' or else recites a 'function without reciting sufficient structure for performing that function.' See CCS Fitness, Inc., v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002), quoting Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000).

"Our cases make clear, however, that the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, Inc., v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). Fitness Quest makes no meaningful effort to overcome this presumption.

In the context of a non-means-language term, the patentee is entitled to substantial latitude in the generality of the structure described therein before the presumption against means- plus-function analysis is overcome. In a case construing closely analogous claim language, the Federal Circuit considered the term "connector assembly," which the district court had held to constitute a means-plus-function term, and reversed, finding the district court's approach "unduly restrictive." See Lighting World, 382 F.3d at 1359.

In considering whether a claim term recites sufficient structure to avoid application of section 112 P 6, we have not required the claim term to denote a specific structure. Instead, we have held that it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function.

Id. at 1359-60 (citations omitted). In construing the term "connector assembly," the court explained that the fact that the term did not call to mind a particular structure was not dispositive. "What is important is whether the term is one that is understood to describe structure, as opposed to a term that is simply a nonce word or a verbal construct that is not recognized as the name of structure and is simply a substitute for the term 'means for.'" Id. at 1360.

Here, Fitness Quest has not carried its burden of establishing that "force producing assembly" is not a structure. The term "assembly" sufficiently defines a structure - albeit a general structure -- so that the patent appropriately may cover more
Monti proposed the only construction for this element in the event it was found not to be a means-plus-function element, offering the construction, "The components that are used together to store and release energy to produce a force." Fitness Quest has objected that the construction is too general, but has proposed no substitute, preferring only to argue in favor of a means-plus-function construction.

This Court finds Monti's proposed structural construction proper. It provides additional information to help understand the language of the disputed term, without improperly limiting the patent language beyond that intended by the patentee and approved by the Patent and Trademark Office. Monti's proposed construction will be adopted.

C. "Force Sensor"

The second term to construe, "force sensor," is found in claims 1 and 3 of the '486 patent and claims 1, 7 and 8 of the '677 patent. Hysitron asserts that "force sensor" means "a device that indicates force by assessing force, weight, or position." Joint Claim Construction Statement at 16. MTS asserts that "force sensor" means a "stacked configuration of five substrates sandwiched together calibrated to measure force; the third substrate of the five includes a planar or flat control plate suspended between spring-like members which are imbedded in and integral to this substrate and which measures the force between the probe tip and the sample." Id. at 20.

Hysitron's construction is remarkably broad. It also ignores express limitations contained in the claim. Independent claim 1 states:

the improvement comprising: . . . a force sensor . . . wherein said force sensor includes,

i. a pair of capacitive transducers, each transducer including a separate drive plate, the first said drive plates having a hole centrally disposed therethrough, and a shared pick-up plate, said pick-up plate positioned between said drive plates and separated from each drive plate by an insulating spacer, said drive plates having spaced opposing conductive surfaces when said pick-up plate is mounted therebetween, said pick-up plate further including a conductive central plate suspended by spring means between said drive plates, wherein said central plate is capable of deflection between the conductive surfaces of said drive plates. . . .

'486 patent, col. 15:36-47. "Force sensor," as defined in these patents, is more complex than Hysitron's construction implies. Tellingly, Hysitron admits in its Markman Brief that the claims are more specific than its proposed construction requiring "a force sensor that includes a pair of capacitive transducers and that each have a separate drive plate and shared moveable pick-up plate." Hysitron's Markman Br. at 35. However, the limitations in the claim are not entirely clear, requiring the Court to consider the specification and prosecution history to determine the proper construction of this term.

Most of the specification describes the preferred embodiment of the force sensor. See, e.g., '486 patent, col. 4:6-31. However, the specification does describe the present invention more broadly in a number of places. For example, the patent teaches that the "sensor element of the present invention comprises first and second, serially connected variable capacitors . . . . More specifically, the sensor comprises a stacked configuration of five substrates." Id., 5:16-20 (emphasis added). A portion of the inner side of the first and fifth substrates "each comprise the first (drive plates) of a different variable capacitor." Id., col. 5:22-25. The second and fourth substrates abut the first and fifth substrates respectively and "comprise insulating substrates or frame members having an open central portion at least as large as a central plate of the third substrate." Id., col. 5:37-40. Finally, the third substrate is "sandwiched" between the second and fourth substrates and "includes a planar central plate which is suspended by spring-like members. In the preferred embodiments, the spring-like members include four relatively thin L-shaped springs." Id., col. 5:42-49. When the written description refers to "this invention" or "the present invention," a court may conclude that the following description covers the claim--not just the preferred embodiment. See Honeywell Int'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006). Additionally, the majority of this description of a force sensor does not describe a particular embodiment because the language "[i]n the
preferred embodiments," is directed specifically to the "four relatively thin L-shaped springs."

The prosecution history confirms that the construction of "force sensor" is more specific than Hysitron suggests. Under the '979 application, the PTO rejected claims 1-40 for various reasons. In explaining the rejection, the examiner stated that "[p]rior art was not relied upon to reject claims 1-40 because the prior art fails to teach and/or make obvious a force sensor having the claimed structure/details in combination with a probe and means for translating output signals from the force sensor into surface topography readings/images." Pearson Aff., Ex. 14 at 5. Thus, the PTO believed that the force sensor contained some level of "structure/detail" that is more specific than "a device that indicates force by assessing force, weight, or position." The language in claim 1 expresses that "structure/detail." Hysitron's proffered construction is rejected as overly broad.

MTS's construction, however, also is not appropriate as it is too narrow. Adhering more closely to the specification and prosecution history, the court construes "force sensor" to mean "a stacked configuration of five substrates consisting of a pair of drive plates found in the first and fifth substrate, a pair of insulating substrates found in the second and fourth substrate, and a third substrate sandwiched between the second and fourth substrate that includes a planar central plate which is suspended by spring-like members operatively located to measure the force between the sample and the probe tip."

2. "a spring operatively connected between the blade and the handle to force the blade to pivot toward an open position when the oversized tang portion of the blade is pushed into the handle until the blade reaches an equilibrium point"

Plaintiff proposes the construction of

the spring, handle, and blade are arranged such that the spring operates to assist in opening the blade. The spring operates to force the blade toward an open position when the oversized tang portion of the blade is pushed sufficiently far into the handle. Some of the oversized tang portion of the blade must enter the handle before the spring operates to provide an opening force. It is the blade, not the spring, which passes an equilibrium point to cause the spring to assist in opening the blade.

Defendant proposes the construction of

a spring connected between the blade and the handle which, in operation, imparts a rotational force onto the blade to rotate it to an open position when the oversized tang portion of the blade is pushed into the handle until the blade reaches a point at which the forces acting on the blade are balanced.

Defendant proposes the inclusion of "rotational force" into this claim construction, as it did in the construction of a similar term in claim one of the 476 patent. In this patent, there is no statement in the prosecution history containing the term "rotational force." Additionally, the term is not included anywhere in the patent. Accordingly, the court finds the inclusion of "rotational force" in this term to be improper.

Defendant proposes to construct "equilibrium point" as "a point at which the forces acting on the blade are balanced." The court finds "equilibrium point" to be clear on its face.

As discussed in the construction of the 476 patent, the term "operatively connected" means arranged such that it can perform its designated function. The court's construction of this term is: "The spring, handle, and blade are arranged such that the spring operates to force the blade to an open position. The spring is activated when the oversized tang portion of the blade is pushed until the blade reaches an equilibrium point."

6. What is the Proper Construction for the Phrase "forced point-bonds" in the '311 and the '722 Patents?
Claim 94 of the '311 patent and claim 77 of the '722 patent contain the phrase "forced point-bonds." KXI contends this phrase means that two or more primary particles are joined together by an adhesive. Culligan contends this term is indefinite, as the specification offers no meaningful description of the term. If the court determines the term is sufficiently definite, Culligan accepts KXI's definition. The court will not address Culligan's indefiniteness argument at this time, as this goes to the validity of the claim, and not to its meaning. Accordingly, the court finds "forced point-bonds" means two or more primary particles joined together by an adhesive.

E. "forces said metallic grounding clip into clamping engagement"

For the reasons stated below, the court construes the term "forces said metallic grounding clip into clamping engagement" in claim 37 to mean:

The bail in its closed position, contacts the grounding clip and retains or forces the clip into tight engagement with the exposed portion of the conductor.

The parties agree that this construction is identical to the construction of "forcing said grounding clip into clamping engagement" in subheading C. The court need not reiterate its reasoning for that construction here.

D. "forcing said electrical conductor of said transmission cable through said axial opening"

For the reasons stated below, the court construes the term "forcing said electrical conductor of said transmission cable through said axial opening" in claim 37 to mean: 6

The electrical conductor must be forced or pressed into the axial opening defined by the clip.

6 Andrew cites to claims 19-20, 22, 24, 25, 27, 47, 50, and 53-54, none of which contain the disputed phrase, and so the court assumes Andrew's citations to be a typographical error. (Pl. Mem. at 14.)

The dispute between the parties in essence is whether to give the term forcing its ordinary meaning, as Beverly seeks, or to construe forcing to mean passing or pressing, as Andrew contends. In support of Andrew's position, Andrew argues that the teaching and the prosecution history demonstrate that the term should be construed beyond its ordinary meaning. In support of its expanded construction, Andrew cites to a phrase in the specification referring to illustrated figure 5, which states that:

The clip 10, which has a C-shaped cross-sectional profile, is pressed over the outer conductor 44 as the rounded surfaces of the two folded portions 15a and 15b engaged the outer conductor 44. . . . With its C-shape the clip 10 acts like a spring by returning to its original position after the conductor 44 of the coaxial cable 40 has passed through the axial opening 17.

(Ex. 3, Col. 4, ln.57-59, 63-66.)

The court rejects Andrew's construction as too expansive based on Andrew's contention that the term forcing could mean pressing or passing. From the court's understanding of the context of the cited paragraph, the specification's use of the word "passed" was not meant as a teaching for the term "forced," but as a descriptive phrase, several sentences after the explanation of the action at issue. The court interprets the specification's use of the word "pressed" differently. The word "pressed" is a synonym in the context of the specification for the term forced, where "pressed" is used as a teaching for the
action at issue. Additionally, without relying on dictionary definitions, the court notes that the definition of the word "press means to use continuous force. 7 The court finds that the term "passed" within the context of the specification was not meant to expand the definition of "forced" beyond its ordinary meaning, while the word "pressed" in the specification is a synonym for "forced." Hence, the court construes "forcing" in this context to mean either forcing or pressing.

--- Footnotes ---

7 Press is defined as: "To act upon (a body) with a continuous force directed towards or against it (the body by or through which the force is exerted being in contact with that acted upon)." See Oxford English Dictionary (2d ed. 1989), available at http://dictionary.oed.com.

--- End Footnotes ---

The court additionally disagrees with Andrew's assertion that Beverly "implies that 'forcing' entails some degree of violent motion," (Pl. Reply at 14); the court did not find Beverly's memorandum to suggest the requirement of violent motion and Andrew does not provide a citation for its interpretation of Beverly's position. Regardless, the court does not construe the term forcing to entail some degree of violent motion.

1726

C. "forcing said grounding clip into clamping engagement"

For the reasons stated below, the court construes the term "forcing said grounding clip into clamping engagement" in claims 19, 22, 47, 50, and 54 to mean:

The bail, once in its closed position, forces or retains the clip in tight engagement with the exposed portion of the conductor.

At issue is whether the bail alone is responsible for providing the force necessary to achieve and maintain clamping engagement when in the closed position, as Beverly contends that the specification teaches. Both parties look to the specification to support their positions. Beverly interprets the phrase in the specification that "in the closed position, the bail contacts the clip so as to force the clip into tight engagement . . ." (Ex. 3, Col. 2, ln. 15-16), to mean that the bail alone must provide this force.

The court agrees with Andrew, however, that the specification, and the '056 patent, do not so limit the bail only to forcing the clip into tight engagement with the conductor. In the context of the specification and prosecution history, "a patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant community, and thus expand or limit the scope of the term in the context of the patent claims." CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1231 (Fed. Cir. 2005). The court finds that the claim term's construction was used more expansively in the specification and thus broadened the claim construction. In the same paragraph of the specification from which Beverly cites to "the bail 30 forces the inner surface 14 of the clip 10 into tight, clamping engagement around the outer conductor 44" to support its own construction, there is language demonstrating that the applicant intended a broader meaning of the term, contrary to Beverly's construction. (Def. Mem. at 14 citing Ex. 3, Col. 5, ln. 12-13.) The last sentence of that same paragraph of the specification states that the "bail acts to further secure the clip on the outer conductor and maintain tight engagement over an extended period of time." (Ex. 3, Col. 5, ln. 18-20 (emphasis added.)) The use of the term "maintain" in same context and paragraph as "force" leads this court to conclude that the "as to" language cited by Beverly was intended to be descriptive rather than limiting. Because the '56 patent's interchanges "forces" and "maintains," the construction "forces or retains" best describes the context in which the phrase is used.

1727

Claim 24 continues with limitation (c):
(c) Forcing the cover against the separated tissue to expand the tissue layer substantially uniformly away from the underlying tissue;

The parties agree that this limitation requires moving or pushing the cover against the separated tissue away from the underlying tissue. They also agree that "substantially uniformly" requires all but minor variations. The court finds this limitation to mean "pushing the cover against the separated tissue to expand the tissue layer consistently, but with acceptable minor variations, from the underlying tissue."

Claim 1 requires that the pressure-sensing means is comprised of a "first chamber means for defining a first volume which is in fluid communication with said liquid such that said liquid will enter said first chamber means and form a liquid column therein having a liquid-air interface, and further comprising second chamber means for defining a second volume which is air-filled and is in fluid communication with said first chamber means." The first chamber must have a volume of amniotic fluid that comes in contact with the air coming from the second chamber. The second chamber must contain air that is pumped into the catheter from an external source to provide a means of measuring the amount of pressure asserted against it from the first chamber when the air therein is compressed. Clinical contends that Claim 1 requires a first and second chamber means that are distinctive from the Koala. Clinical argues that the first chamber means must be interpreted to require a cavity inside of rigid, physical walls or other such surrounding structure so as to surround the first volume. However, Utah Medical argues that all that is required is an area that holds amniotic fluid, such that when the amniotic fluid enters the Koala and surrounds the air-filled balloon, it comprises the first chamber and the air-filled balloon comprises the second chamber. While the Court finds Utah Medical's interpretation very broad, the specification appears to allow such a broad reading. However, the first chamber in Claim 1 must have the capacity to enclose within its surrounding structure a first volume of amniotic fluid, forming a liquid column that comes in contact with the air-filled second volume. In order to form a liquid column, the first chamber must be completely enclosed without any holes that would prevent a liquid column from functioning properly.

Claim 1 requires that the amniotic liquid will enter the first chamber and "form a liquid column therein." As established above, the first chamber must be enclosed by the walls of the catheter. This is because according to Claim 1 the liquid column forms below the section of the catheter where the holes allow the amniotic fluid to enter the catheter and is enclosed where it comes into contact with the air from the second chamber. The column must be formed on the inside of the plastic housing, as the claim requires it to be "therein." The column is an uninterrupted volume of liquid between the air from the second chamber and the free flowing amniotic fluid that enters the tip of the catheter through the holes in the tip. A column is defined as "a rigid, relatively slender, upright support, composed of relatively few pieces or a decorative pillar, most often composed of stone and typically having a cylindrical or polygonal shaft . . .; any column like object, mass, or formation: a column of smoke." THE RANDOM HOUSE DICTIONARY OF THE ENGLISH LANGUAGE 407 (2d ed. 1987). Taken from the plain meaning of the word column, the liquid column--cylindrical in shape--must fill the interior of the first chamber and be bound by the cylindrical side walls of the first chamber. While Clinical argues that the accused device does not have a liquid column as required by Claim 1, Utah Medical argues that the Koala does in fact have a liquid column. Applying the Court's interpretation of the required liquid column to the accused device, the Court finds that a liquid column does not exist in the Koala, either literally or under the doctrine of equivalents. The Koala could only be substantially equivalent by eliminating necessary structural and functional requirements from Claim 1, which would be improper. The "doctrine of equivalents cannot be used to erase 'meaningful structural and functional limitations of the claim on which the public is entitled to rely in avoiding infringement.'" Conopco, Inc. v. May Dep't Stores Co., 46 F.3d 1556, 1562 (Fed. Cir. 1994). Utah Medical argues that the Koala has a column that is in fact a hollow cylinder that surrounds the air balloon within what Utah Medical argues is a first chamber. However, the area that Utah Medical argues is the liquid column is in reality the same as the area in the tip of the 161 device where the holes allow the amniotic fluid to enter the
catheter. The housing around the Koala is for the purpose of inserting the catheter into the uterus. If the plastic housing were removed from the Koala once in the uterus, the device would still provide an accurate reading based on the amniotic pressure exerted on the balloon. Conversely, the 161 device is dependent upon the plastic housing wherein a liquid column is formed between the amniotic fluid and the air. Without such a housing, the 161 device would not operate.

A. Claims 1 & 18

Claims 1 and 18 are two of the three independent claims in the '161 patent. Both include the limitation of a first chamber into which bodily fluid enters and forms a "liquid column." The district court held that the liquid column limitation must be construed in the context of the structural limitation of the first chamber because the claims specify that the liquid column is formed therein. Utah Medical, 79 F. Supp. 2d at 1300. The court also held that the liquid column is "an uninterrupted volume of liquid between the air from the second chamber and the free flowing amniotic fluid that enters the tip of the catheter." Id. The court referred to a dictionary definition of "column," and held that the liquid column must be enclosed by the first chamber and cylindrical in shape, as disclosed in the '161 patent. Id. The court, therefore, construed the liquid column limitation as requiring an uninterrupted cylindrical mass of liquid that is constrained by the walls of the first chamber.

Utah Medical argues that "liquid column" is interpreted by those in the art to mean simply a height or continuum of liquid capable of transmitting pressure that does not have to be cylindrical in shape. Even accepting Utah Medical's definition of "liquid column," there can be no infringement because the Koala TM does not contain a liquid column, or an equivalent. A liquid column does not have to be of any particular shape, but it must have a varying pressure throughout its height. This pressure variation is the result of gravity, i.e., the weight of liquid at a lesser depth within the column upon that portion of the liquid at a greater depth within the column. The columns of liquid in a U-tube manometer are examples of liquid columns.

Utah Medical argues that "liquid column" is interpreted by those in the art to mean simply a height or continuum of liquid capable of transmitting pressure that does not have to be cylindrical in shape. Even accepting Utah Medical's definition of "liquid column," there can be no infringement because the Koala TM does not contain a liquid column, or an equivalent. A liquid column does not have to be of any particular shape, but it must have a varying pressure throughout its height. This pressure variation is the result of gravity, i.e., the weight of liquid at a lesser depth within the column upon that portion of the liquid at a greater depth within the column. The columns of liquid in a U-tube manometer are examples of liquid columns.

Because the liquid column of the claimed device is constrained by chamber 1, the pressure at different locations along the liquid column will vary if chamber 1 is inclined so that its distal and proximal ends are at different heights. This would result in erroneous pressure measurements because the liquid at the liquid-air interface would not be at the same pressure as the fluid entering the tip of the catheter. The '161 patent teaches that the volume of bodily fluid entering chamber 1 should be minimized "so as to minimize hydrostatic pressure errors resulting from the liquid column." Col. 5, ll. 26-27. Thus, we agree with Judge Benson, who construed the "liquid column" limitation to require a continuum of liquid constrained by the first chamber.
4. Occlusive Volume

The final disputed term involves the interpretation of the nature of one of the invention's primary teachings, namely, the channels' forming of an occlusive volume. The term arises in both claims 1 and 4. Claim 1 teaches that the channels allow the napkin edges to fold upward "to form an occlusive volume between said napkin and the wearer's body." (6:14-16.) Claim 4 teaches the same, with the addition that the folding mechanism is activated by the thighs of the wearer's body. (6:39-42.) Tyco believes the phrase should mean, "sealing to the user so as to form a space, like a container, that prevents passage of fluid therefrom." K-C argues it should simply mean, "form a space for the accumulation of fluids."

Tyco's reading is based on several sources. First, it begins by noting that the dictionary definition of occlusive includes such synonymous concepts as obstructed, barred, or stopped up to prevent the passage of something. Thus, the occlusive volume should be viewed as a space that "prevents the passage of fluid therefrom." Its use of the word "container" comes from the specification and prosecution history. For example, the specification describes the invention as follows: "This sanitary napkin forms an occlusive container to help reduce the incidence of side leakage." (1:15-16.) And in the prosecution history, the inventors referred to a "fluid receptacle." Thus, the claim term "volume" should be read as meaning a container. Finally, Tyco believes the container must "seal to the user" because the purpose of the invention is to "eliminate leakage," and if the napkin does not seal to the user's body, the invention's occlusive properties are not achieved.

Once again, however, Tyco's proposed alterations seek to interpolate qualities into the claims without a reasonable basis in the evidence. First, Tyco's reliance on the dictionary is unhelpful in view of the relative clarity of the claim terms and the specification themselves. Although the goal of the invention is certainly to "prevent" (i.e., "occlude") the passage of fluids, this does not mean that the goal will universally be achieved. In fact, the specification reveals that the "primary object" of the invention is to "minimize[] the possibility of side staining or side leakage." (2:36-37.) Minimizing leakage is different than "preventing" leakage altogether, and Tyco's definition would fundamentally alter the meaning of the claim term as it is used in the patent. By the same token, there is no basis to read into the claim the limitation that the occlusive volume must "seal" to the user. Tyco's only support for the limitation is found in the general purpose of the invention, which is to occlude fluid; without a seal, Tyco asserts, occlusion will be impossible. But just as with its use of the word "prevent," Tyco's attempt to limit the claims to forming occlusive spaces that "seal" to the body takes the invention a step too far and would import a substantial functional narrowing into the claims without any basis in the evidence. In a perfect embodiment and use of the invention, a seal might conceivably be formed -- but nowhere in the patent or other evidence is there any indication that the edges are to fold up so as to produce a seal. As with "prevent," the word "seal" implies there would never be any leakage, yet the specification itself acknowledges that the invention's goal is merely to minimize leakage. Indeed, as a general principle, one expects that when a paper-based device like the present invention interacts with something so malleable and unpredictable as the human body, there will never be a claim to perfect operation: channels will not always "direct" edges to fold upward, the edges will not always completely "prevent" leakage, and the fluid-occluding volume will not always "seal" to the body. The patent itself teaches none of these properties, and I will accordingly reject Tyco's attempt to append such limitations onto the claims. "Where the function is not recited in the claim itself by the patentee, we do not import such a limitation." Ecolab, 264 F.3d at 1367.

Finally, Tyco believes "volume" should mean "container." For this proposition it has far more support: throughout the specification the inventors refer to a "container" instead of a "volume." For instance, it notes that the "sanitary napkin forms an occlusive container to help reduce the incidence of side leakage." (1:15-16.) The specification also notes that the "prior art has not attempted to develop an occlusive container out of the sanitary napkin to eliminate leakage." (2:29-30.) In describing the most advantageous implementation of the invention, the specification states that the channels allow the "formation of an occlusive container by the sanitary napkin." (2:67-68.) K-C does not appear to object specifically to the word "container" (although it prefers "space"). Whether the area in question is described as a container or a space (or simply a volume), the important point is that there is nothing in the patent that indicates the container or space must seal to the body or to completely prevent passage of fluid.

4. "Form an occlusive volume" means "form a space, or container, for the accumulation of fluids."
A. The first critical issue is the correct construction of the term "form set." According to the trial court's construction, "form set" includes "single-ply" form sets, Paymaster Techs., Inc. v. United States, 54 Fed. Cl. 579, 590 (2002) ("Paymaster I"). The government argues that "form set" must be interpreted to exclude "single-ply" form sets because, it says, the claim language itself recites and the specification discloses more than one "sheet" in every form set described. Paymaster responds that, while claims 1 and 5 recite a form set including three specific "sheets," the plain language of claim 10 allows a form set that includes only one such specific "sheet." Furthermore, it asserts, the written description discloses a form set having only one specific "sheet." We agree with the trial court.

We start with the claim language. Independent claim 10 recites in relevant part:

[a] form set . . . comprising . . . at least one negotiable instrument sheet.

'283 patent, col. 18, ll. 5-12. In contrast, claim 1 recites in relevant part:

[a] form set . . . comprising . . . an upper negotiable instrument sheet . . . , a lower customer receipt sheet, an intermediate voucher sheet . . . , a first transfer medium positioned between said upper negotiable instrument sheet and said intermediate voucher sheet, and a second transfer medium positioned between said lower customer receipt sheet and said intermediate voucher sheet. . .

Id. at col. 16, ll. 25-37. Claim 5 uses the exact same relevant language. Id. at col. 16, l. 60 - col. 17, l. 5.

According to its plain language, claim 10 reads on a form set that includes a negotiable instrument sheet. Under conventional construction of "comprising," a form set as recited in claim 10 may include only one negotiable instrument sheet, so long as it includes another form. See Vehicular Techs. Corp. v. Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383 (Fed. Cir. 2000).

Claims 1 and 5 add the limitation that their form sets must include two specific additional sheets, a lower, customer receipt sheet and an intermediate, voucher sheet. But this limitation cannot mean that the form set of claim 10 must have these same two specific additional sheets. It merely recites that the form set of these two claims will also include these two other specified sheets.

The issue, then, is whether a form set with "at least one negotiable instrument sheet" may be "single-ply." We hold that a form set as recited by all three claims and disclosed in the specification may be single-ply. A "form set" is simply a set of forms, i.e., more than one form. For example, a negotiable instrument sheet may constitute one form, a customer receipt sheet may constitute another form, and a voucher sheet may constitute another form. Together, these forms constitute a form set. Yet each form in a form set does not have to occupy a separate layer, or ply. Rather, multiple forms in a form set may be in a single ply, as perforated, detachable forms. But there must be at least two different forms to constitute a form set.

Every relevant part of the specification accords with this meaning of the term "form set." Indeed, the key to understanding the correct construction of the term "form set" is to apprehend that the summary of the invention describes two different types of form sets: (1) a set of forms with at least one negotiable instrument sheet, and (2) a set of forms with specifically an upper negotiable instrument sheet, a lower customer receipt sheet, an intermediate voucher sheet, and transfer medium sheets positioned between.

The first two paragraphs of the Summary of the Invention describe a form set as recited in claims 1 and 5, a form set with five specific sheets - including the "upper" negotiable sheet, the "lower" customer receipt sheet, the "intermediate" voucher sheet, and the two transfer medium sheets "positioned between" these sheets. '283 patent, col. 2, ll. 10-44. Because the five specific sheets are disclosed as "upper," "lower," and "intermediate," and because the transfer medium sheets are "positioned between" the forms or sheets, id. at col. 16, ll. 40, 43, col. 17, ll. 8, 11, this type of form set has to be multi-ply. This type of form set is the type later disclosed as the preferred embodiment. Id. at col. 4, ll. 15-17.
The third paragraph of the summary of the invention, however, describes a form set as recited in claim 10 - a form set only specifying a negotiable instrument sheet. Id. at col. 2, ll. 52-53. This "negotiable instrument sheet" is not described as an "upper" negotiable instrument sheet. No transfer medium sheets are "positioned between" the negotiable instrument sheet and any other sheet. The additional form in this second type of form set may be part of a single ply. This reading of all three paragraphs of the summary of the invention - and the two different types of form sets that they describe, multi-ply and single-ply - is the key to understanding the meaning of "form set."

It is true that also disclosed in the summary of the invention are form sets with the specific three sheets as described above and their interlayered transfer medium sheets. Id. at col. 2, ll. 12-17. A "multicopy form set" comprised of a "plurality of sheets" is further disclosed in detail in the written description, id. at col. 7, ll. 17-18, but only under the heading "Description of a Preferred Embodiment." It is axiomatic that claims are only rarely, if ever, construed as limited to the preferred embodiment. See, e.g., Johnson Worldwide Assocs., Inc. v. Zebo Corp., 175 F.3d 985, 992 (Fed. Cir. 1999).

Our cases recognize that the specification is the single best guide in construing patent terms, and that language in the specification describing the "present invention" should limit the claims to the invention described. For example, in SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc. 242 F.3d 1337 (Fed. Cir. 2001), the court held that "[t]he characterization of [a particular arrangement] as part of the 'present invention' is strong evidence that the claims should not be read to encompass the opposite structure." Id. at 1343; see Liebel Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 908 (Fed. Cir. 2004). Similarly, in Watts v. XL Systems, Inc., 232 F.3d 877 (Fed. Cir. 2000), the court construed a patent claim limitation stating that two pipes had to be "sealingly connected." Id. at 879. The court determined that the claimed connection was limited to connections with "misaligned taper angles" because the specification stated that "[t]he present invention utilizes [the varying taper angle] feature." Id. at 883 (brackets in original). The court therefore found that the specification "limit[ed] the invention to embodiments with misaligned taper angles." Id. Significantly, these cases are cited with approval in Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005) (en banc).

Here, the specification makes clear that a "form set" includes more than one sheet. The first paragraph of the Summary of the Invention states that "[t]he present invention provides a form set for use with an imprinting apparatus for imprinting indicia with dye-based ink on negotiable instruments. The form set includes an upper negotiable instrument sheet . . . a lower customer receipt sheet, and an intermediate voucher sheet . . . ." '283 Patent, col. 2, ll. 12-17 (emphasis added). Contrary to the majority, nothing in paragraph 3 of the Summary of the Invention supports a single sheet construction or undermines the significance of the first paragraph. I Paragraph 3 simply describes a ribbon-based mechanism for imprinting the form set described in the first paragraph. Thus in my view, the "present invention" language in the specification limits the term "form set" in claim 10 to a group of multi-ply sheets.

Paragraph 3 of the Summary of the Invention states:

1
Further, in accordance with the present invention, there is provided a form set for use with an apparatus having an imprinting mechanism including a ribbon bearing dye-based ink for imprinting negotiable instruments with characters indicative of the dollar and cents amount for which the negotiable instrument is drawn. . . . The form set comprises at least one negotiable instrument sheet comprised of an absorbing type paper sheet material for absorbing the dye-based ink, whereby when the form set is impacted by the imprinting mechanism of the apparatus, the dye-based ink permeates through the sheet from the printed front surface to the back surface to provide the indicia in mirror image form on the back.

Young also challenges the court's interpretation of claims in the '679 patent, focusing on the following limitation common to all asserted claims:

an elongated hollow body comprising a tubular handle and a tubular extension extending from the handle at one end thereof, the extension having a bore therethrough from the end thereof at the handle to its other end constituting its forward end, the extension having at its forward end a recessed forward end formation defining a forwardly opening recess.

(disputed language emphasized). The district court ruled that the patent equates "forward end formation" with "head" and that the phrase emphasized above "describes a requirement that there must be an aperture at the front of the head." The court thus construed the claims of the '679 patent in the same way as those of the '547 patent, and accordingly granted summary judgment of no literal infringement.

We agree with the district court. Although limitations may not be read into the claims from the specification, claims are to be read in view of the specification of which they are a part. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321, 1329 (Fed. Cir. 1995) (in banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The specification that is relevant to claim construction is the specification of the patent in which the claims reside. Here, the district court's construction of the disputed claim language is wholly consistent with the specification of the '679 patent. Furthermore, in Bailey's "Request for Declaration of an Interference" with Kraenzle's application, Bailey stated, in an effort to avoid a finding that he had added new matter to his disclosure by copying Kraenzle's claims, that the disputed claim terms were merely "alternative names" for the elements disclosed in his application (i.e., the application that is common to the '547 patent). See Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1580-81, 40 U.S.P.Q.2D (BNA) 1019, 1024-26 (Fed. Cir. 1996) (relying on patentee's prosecution history to interpret claim where specification provided minimal guidance because claim had been drafted to provoke an interference with a patent owned by accused infringer). The district court correctly decided that the "forward end formation" of the '679 patent is the same as the "head" and that the accused device does not have an aperture in its head as required by the "forward opening recess" limitation. We therefore affirm the district court's grant of summary judgment that the accused device does not literally infringe.

Callicrate's proposed interpretation for this phrase is forming the loop during the process of placing a linear length of bulk ligation material into the tool and where the two ends of the looped linear length of ligation material are free after passage through a crimpable grommet for securing to a tightening structure.

Wadsworth proposes interpreting the language as "forming a loop in a length of ligation material forwardly of a grommet."
Callicrate argues formation of ligation material in a loop means the loop is formed while placing a linear length of ligation material into the tool and that the two ends of the looped linear length of ligation material must be free after passing through the grommet for securing to a tightening structure. Much of Callicrate's argument is based on requirements set forth in the specification.

Wadsworth counters that the language of the claim itself is clear and does not require analyzing the specification. Wadsworth argues the phrase requires only that material be formed in a loop ahead of a grommet that will fasten the ends together. According to Wadsworth, the language does not set forth when the loop needs to be formed or how the ends need to come out.

Wadsworth's argument on this point is strained. First, the language is not as clear as Wadsworth asserts. Without clear language, it is necessary to review the specification, which confirms Callicrate's proposed interpretation. Even if the language is clear, however, that the ends of the ligation material end up behind the grommet is implied. If the ligation material is passed through the grommet and the loop is in front of the grommet, it follows that the ends of the ligation material forming the loop will be behind the grommet.

6. Conclusion

According to the analysis above, the language of Claim 6 is interpreted as follows:

(1) "The formation of ligation material in a loop forwardly of a crimpable grommet" means forming a loop of ligation material during the process of placing a linear length of bulk ligation material into the tool forward of a grommet;

I. The Term "Protrusions Formed"

Claims 1 and 5 of the '969 patent both require "protrusions formed on the closed end of the holder and extending therefrom . . . ." ( '969 Patent Col 5, Ln. 54-55); ( '969 Patent Col 6, Ln. 27-28). U.S. Can argues that the term "protrusions formed" should be construed to include those either "formed to be one piece or to be secured to the holder bottom." (P Mem. 12). In support of this contention, U.S. Can argues that the specification does not expressly limit the protrusions to those that are formed from the same piece as the holder and that "the term 'formed' has the customary and ordinary meaning of 'bring together parts or combine to create (something) . . . .'" (P Mem. 11)(quoting Oxford Dictionary of English). Limited argues that "[a] person of ordinary skill in the art would understand that the candle tin is a stamp-formed can with protrusions or recesses formed in the one piece of sheet metal." (D Resp. 12). The '969 Patent does not discuss in any way the attachment of external protruding feet to the bottom of the candle holder. Therefore, we agree with Limited that the term "protrusions formed" in Claims 1 and 5 means protrusions actually formed from the same piece of sheet metal as the holder, and does not mean protrusions that are attached to the holder. See Wang Lab., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999)(holding that because "the only embodiment described in the [patent at issue's] specification is the character-based protocol, and the claims were correctly interpreted as limited thereto").
requiring the first lumen to be a cavity within rigid, physical cylindrical walls of a tube that is physically attached to the interior catheter wall as depicted by the cross-section of the 161 device in Figure 4 (161 Patent Figure 7). See supra p.7. However, Utah Medical contends that all that Claim 33 requires is a cylindrical tube on the interior of the catheter capable of conveying air pressure from the chamber to the transducer. Utah Medical further argues that just because the tube is "formed along an interior wall" of the catheter does not require that the tube be attach to part of the catheter. The 161 specifications show that the actual design of the 161 device attached the first lumen to the wall of the catheter, stating: "As best illustrated in FIGS. 7 and 8, the first lumen [] is comprised of a cylindrical tube [] which is formed along the interior wall of the catheter . . . ." (161 Specification at Column 10). Figure 7 of the 161 specifications clearly shows that the first lumen is attached to the interior wall of the catheter. However, Utah Medical argues that according to the Federal Circuit, such additional limitations appearing in the specification should not be read into the claim. See Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347 (Fed. Cir. 1998) (noting the "well-established principle that a court may not import limitations from the written description into the claims"); Electro Med. Sys. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994) (stating that "claims are not to be interpreted by adding limitations appearing only in the specification"). Accordingly, the Court does not look to how the device was actually constructed according to the specification, but rather looks to the language of the claim. The relevant meaning of "form," when used as a verb, is defined as "to give a particular form or shape to; fashion in a particular manner." THE RANDOM HOUSE DICTIONARY OF THE ENGLISH LANGUAGE 752 (2d ed. 1987). "Along" is defined as "through, on, beside, over, or parallel to the length or direction of; from one end to the other of." Id. at 59. Based on the plain meaning of the claim language the Court finds that "formed along" only requires that a circular tube run within the catheter parallel to the interior walls of the catheter. The Koala has an interior tube that transmits air from the air pressure source into the balloon that is within the chamber of the catheter. Utah Medical argues that the Koala tube is in fact a first lumen and this portion of the claim reads literally on the Koala. There is no doubt that the Koala has a lumen that runs within the catheter walls. The Koala's air lumen is an independent tube. Although not attached to the interior wall of the catheter, it does run parallel to the interior walls of the catheter.

1738

B. DEFENDANT'S SECOND MOTION: THE TROUGH

1. Literal Infringement

a. Scope of the Vaida Patent

The Court looks first to the Vaida patent itself, including the claims, the specifications, and the prosecution history (if in evidence) to define the scope of the patented invention. Vitronics, 90 F.3d at 1582. Independent Claim One and dependent Claim Three of the Vaida patent describe the relevant element of the invention -- i.e., the trough. Claim One relates: "in said closed position, each of said actuated members form a trough which receives any fluid which penetrates said louver assembly." Vaida Patent, p. 6, lines 41-43, Plaintiff's Exhibit 1. Claim Three 16 describes:

A louver assembly in accordance with claim One wherein each of said actuated sections are constructed to form a trough when in said closed position which causes any fluid which penetrates said louver members to flow away from said louver assembly, said trough formed between the actuating section of one louver member and closing section of an adjacent louver member.

Vaida Patent, p. 6, lines 56-60, Plaintiff's Exhibit 1. As used in the Vaida patent, the word "trough" means "a large, long, and usually comparatively shallow open vessel that is often V-shaped in cross-section and used especially to hold water or feed for domestic animals," or "a conduit for water," or "a long and narrow or shallow channel or depression (as between waves or hills)." Webster's Third New International Dictionary (Unabridged) 2453 (1981). Neither party contests the meaning of the word trough, and as with the claims at issue in the first Motion for Summary Judgment, Claims One and Three are plainly understood. The Vaida patent clearly contemplates the formation of a trough, defined on one side by the closing section of one louver and on the other side by the actuating section of the adjacent lower louver member. See Figure # 1. 17 That conclusion is supported by the patent specifications. The Vaida patent's Detailed Discussion of Preferred Embodiment of the Invention contains:

actuating sections . . . constructed to form a trough when in their closed positions. That is, as shown in FIG. 3, each of the
actuating sections 32 cooperates with the closing section 30 of an adjacent louver member 14 to form a substantially V-shaped trough 50 when the louver members 14 are in their closed position.

Vaida Patent, p. 4, lines 31-34, Plaintiff's Exhibit 1. Nothing contained in the intrinsic evidence could support a different definition of the scope of Claim Three of the Vaida patent. 18

Footnotes
16 Henceforth, reference to Claim Three incorporates reference to the relevant section of independent Claim One.
17 In Figure # 1, the trough is labeled 50, the closing section 14, and the actuating section 32.
18 The Plaintiff contests what it considers the Defendant's assertion that the trough described by the Vaida patent is limited to the V-shape described in the preferred embodiment. Although the Court is not certain the Defendant actually makes that assertion, the shape of the trough is not relevant to the Court's holding, and it need not be addressed.

GO BACK

5. "[T]he lens body formed by a process including cast molding using a first polymeric mold section having a surface in a general shape of a negative of the posterior face and a concave outer peripheral surface." Used in '538 patent, claims 1 and 7; '706 patent, claim 13.

CooperVision argues that this term should be construed as "the lens body is formed by a process including cast molding using a polymeric mold section having a surface in a general shape of a negative of an insert tool that has a first surface portion and a convexly curved peripheral edge surface." CIBA proposes "the lens body is formed by a process including cast molding using a first polymeric mold section having a surface in a general shape of a negative of the posterior face of the lens and the entire outer peripheral surface of the first polymeric mold section is curved inward like the inside of a bowl so as to produce a contact lens with a rounded outer peripheral edge surface."

Claim 13 of the '706 patent and claims 1 and 7 of the '538 patent recite a lens that has a rounded edge formed by mold section. The mold section must have a first surface "in the general shape of a negative of the posterior face" of the lens and must have a second, outer peripheral surface that is "concave."

The specification defines a mold with a "concave outer peripheral surface" in terms of the "negative of the back surface tool with a convexly-curved peripheral surface that created the mold." '706 patent, col. 2, ll. 40-52; col. 6, ll. 48-57. For example, it states that "[t]he portion of the back surface tool that forms the lens periphery is convex in form . . . . Correspondingly, the first mold section formed by the tooling insert has a concave outer edge surface."'706 patent, col. 3, ll. 16-20.

As previously discussed, CIBA's definition improperly adds that the outer peripheral edge surface must be "rounded." A contact lens with a rounded edge surface is only a preferred embodiment. See '706 patent, col. 3, ll. 52-53. Additionally, CIBA inserts the word "entire" before "outer peripheral surface," which may seem as if the surface cannot be comprised of small flats closely simulating a continuous curve. There is no basis to import such a limitation from the specification to this claim term.

The court defines this term as follows:

"[T]he lens body formed by a process including cast molding using a first polymeric mold section having a surface in a general shape of a negative of the posterior face and a concave outer peripheral surface" means: the lens body formed by a process including cast molding using a polymeric mold section having a surface in a general shape of a negative of the posterior face of the lens and a concave curved peripheral surface. A concave curve is the negative image of a convex curve. GO BACK
F. "Formed by Cutting"

Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs claim that "formed by cutting" means "formed by the act of a person or thing that cuts," while Gore claims that "formed by cutting" means "created using a blade or through die cutting."

The parties agree that the terms "formed" and "created" are synonymous. The specifications of the '418 patent contemplate using a specific material that is "easily cut by a knife or by using die cutting technique." U.S. Patent No. 6,921,418, at 8:44-45. Plaintiffs contend that the phrase "formed by the act of a person or thing that cuts" is consistent with the ordinary meaning of "cutting" based upon the dictionary definition of the term. Although courts attempt to construct patent terms according to ordinary and customary definitions, when patent specifications expressly limit the meaning of general terms, the limitations contained within the patent control. See Wang Labs., Inc. v. Am. Online, Inc., 197 F.3d 1377, 1381-84 (Fed. Cir. 1999). Here, the patent expressly described "cutting" by use of a knife or a die cutter. Although there are other ways to cut material, such as through the use of lasers, the patent only disclosed cutting by a knife or a die cutter. Plaintiffs contend that the limitation on the term "cutting" exists only to differentiate cutting from tube extrusion. Nonetheless, in differentiating cutting from tube extrusion, the inventor specifically limited the term "cutting" to the use of a knife or die cutter. Because the patent specifically identifies two ways to cut the channels in the sheet, the intrinsic evidence shows that the term "cutting" as used in the '418 patent does not carry its ordinary meaning. Therefore, the Court determines that the term "formed by cutting" means "created using a blade or through die cutting."

F. "Formed by Cutting"

Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs claim that "formed by cutting" means "formed by the act of a person or thing that cuts," while Gore claims that "formed by cutting" means "created using a blade or through die cutting."

The parties agree that the terms "formed" and "created" are synonymous. The specifications of the '418 patent contemplate using a specific material that is "easily cut by a knife or by using die cutting technique." U.S. Patent No. 6,921,418, at 8:44-45. Plaintiffs contend that the phrase "formed by the act of a person or thing that cuts" is consistent with the ordinary meaning of "cutting" based upon the dictionary definition of the term. Although courts attempt to construct patent terms according to ordinary and customary definitions, when patent specifications expressly limit the meaning of general terms, the limitations contained within the patent control. See Wang Labs., Inc. v. Am. Online, Inc., 197 F.3d 1377, 1381-84 (Fed. Cir. 1999). Here, the patent expressly described "cutting" by use of a knife or a die cutter. Although there are other ways to cut material, such as through the use of lasers, the patent only disclosed cutting by a knife or a die cutter. Plaintiffs contend that the limitation on the term "cutting" exists only to differentiate cutting from tube extrusion. Nonetheless, in differentiating cutting from tube extrusion, the inventor specifically limited the term "cutting" to the use of a knife or die cutter. Because the patent specifically identifies two ways to cut the channels in the sheet, the intrinsic evidence shows that the term "cutting" as used in the '418 patent does not carry its ordinary meaning. Therefore, the Court determines that the term "formed by cutting" means "created using a blade or through die cutting."

F. "Formed by Cutting"

Claim 1 of the '418 patent describes "a plurality of continuous, parallel channels extending into the thickness dimension of the sheet, the channels being formed by cutting the second surface of the sheet . . . ." Plaintiffs claim that "formed by cutting" means "formed by the act of a person or thing that cuts," while Gore claims that "formed by cutting" means "created using a blade or through die cutting."

The parties agree that the terms "formed" and "created" are synonymous. The specifications of the '418 patent contemplate using a specific material that is "easily cut by a knife or by using die cutting technique." U.S. Patent No. 6,921,418, at 8:44-45. Plaintiffs contend that the phrase "formed by the act of a person or thing that cuts" is consistent with the ordinary meaning of "cutting" based upon the dictionary definition of the term.

Here, the patent expressly describes "cutting" by use of a knife or a die cutter. Although the patent specifically mentions using a knife or die cutting technique, nothing in the language of the claims, the specification, or the prosecution history suggests that these are the only methods that may be used to form the channels. While claims are to be read in light of the specification, limitations are not to be imported into the claims by confining the claims to disclosed embodiments in the specification. See Phillips, 415 F.3d at 1323. Indeed, it is well established that a specification that describes only a single embodiment is insufficient, without more, to limit otherwise broad claim language. Howmedica Osteonics Corp. v. Wright Medical Tech., Inc., 540 F.3d 1337, 1345 (Fed. Cir. 2008). Gore points to nothing more than a single statement describing a particular embodiment in the '418 patent to suggest that the invention is limited to cutting done using a blade or a die. Because there is no disavowal or specific limitation anywhere in the intrinsic evidence, the Court cannot limit read such a limitation into the term "formed by cutting." Therefore, the Court adopts Plaintiffs' proposed construction of "formed by cutting" to mean "formed by the act of a person or thing that cuts."
The critical language of the '561 patent claims "[a] high pressure injection nozzle member formed by liquid phase sintering without imparting external pressure ...." For reasons explained in depth in his report, the magistrate judge recommends that this language be construed as limiting the claimed invention to "nozzles produced by a process known as liquid phase sintering without applying additional pressure during the sintering process." Report and Recommendation, p. 3. This recommendation is clearly correct.

The prosecution history shows that the patentee originally claimed "[a] high pressure injection nozzle member formed of a super hard alloy ..." The critical language "by liquid phase sintering without imparting external pressure" was added by the patentee specifically in order to overcome the patent examiner's objections that the claims as originally submitted were anticipated by two other patents (Timm and Becker). Notwithstanding plaintiff's objections to the magistrate judge's report and recommendation, the added language clearly describes the process by which the nozzles are made. That is, the patentee added this language specifically in order to satisfy the patent examiner's objection, and in order to distinguish the new invention from the prior art. Under these circumstances, the magistrate judge is correct in concluding that the language "by liquid phase sintering without imparting external pressure" serves as a limitation on the claims of the '561 patent.

2) Single Piece of Material

Claim 1 of the '219 patent also requires that the "elongated neck encircling band" be "formed entirely of stiff, flexible, plastic sheet material." Tecnol contends that this language requires that the band be formed out of a single piece of material. Tecnol's argument proceeds in two stages. First, Tecnol contends that the term "band" taken alone describes a single piece of material. Second, Tecnol contends that even if the term "band" includes several pieces joined together, the additional limitation requiring that the band "be formed entirely of stiff, flexible, plastic sheet material" requires the band to be formed out of a single piece of material.

a) "Band"

Tecnol contends that the term "band" defines a single continuous strip of material. [TAB at 20]. The Court finds that the ordinary meaning of "band" is not limited to a single unblemished and uninterrupted piece of material, but also encompasses two or more pieces of material which are joined together to encircle an object. Wristwatch bands, for example, are sometimes made from a single piece of metal, leather, or plastic, but they are also made from pieces of metal, leather, or plastic which are fastened together during manufacture. All are referred to as "bands."

Tecnol does not rely solely upon its understanding of the ordinary meaning of "band", but also argues that the specification of the '219 patent, specifically the portion entitled "Background of the Invention," provides a special definition of "band" that excludes two pieces that are joined together:

Cervical collars are commonly formed of relatively thick material, usually in two pieces which are assembled about a wearer's neck. These collars are too bulky and cumbersome for field use by paramedics. Some attempts have been made to provide cervical collars from stiff flexible sheet material which is cut into an elongated band that is encircled about the wearer's neck. Although rolled edges of leather or plastic foam have been provided on some of these collars as in U.S. Pat. No. 3,075,521 [Grassl], none of these cervical collars adequately provide support and restraint for the wearer's chin.

[PX 520, 1/12-23].

The Court finds that this portion of the specification does not support restricting "band" to exclude two pieces of material joined together. The specification contrasts collars which consist of two separate pieces which must be secured into position by the user (and are not described as "bands") with collars that do not have pieces (and are described as "bands"). A band consisting of two pieces that have been permanently attached during manufacture is not inconsistent with the description of a band contained in the specification, notwithstanding the fact that the specific example of a band disclosed in the specification, U.S. Pat. No. 3,075,521 [Grassl, DX 25], was formed from a single piece of material.

As discussed previously, the Court's construction of the term "band" is not dispositive of the single piece dispute because
the Court must also construe the more crucial "formed entirely" limitation.

b) "Formed Entirely"

Tecnol contends that the claim 1 language requiring that the band be "formed entirely of stiff flexible plastic sheet material" excludes any band which is formed of two pieces of stiff flexible plastic sheet material which are permanently attached, at least where the attachment means does not also consist of stiff flexible plastic sheet material. [TAB at 21]. Tecnol relies upon the '219 patent prosecution history to support its interpretation of "entirely."

In his initial reissue application, Garth attempted to remove many of the band limitations from Claim 1 by claiming only "an elongated neck encircling band." [PX 522 at 13]. The patent examiner initially rejected claim 1, inter alia, as anticipated by Grassl:

Grassl discloses a cervical collar having a neck encircling band (16), a chin support brace (15) with fastening means (24) and collar retention means (18, 17) located on each end of the brace. The limitation of (c) of the claim does not structurally define over the same as disclosed by Grassl. [PX 522 at 27].

In response, Garth submitted a new amendment putting some of the previously deleted band limitations back into claim 1:

(a) a collar formed of an elongated neck encircling band formed entirely of stiff, flexible plastic sheet material;

[PX 522 at 31]. This amended language does more, however, than simply restore some of the previous limitations. Garth added strict language requiring that the band be formed entirely of the requisite material. In his remarks, Garth specifically distinguished claim 1 over Grassl:

The Grassl collar bears no apparent relationship to applicant's collar, and the rejection under 35 USC 102 is thus made on the basis that the rejected claims do not exclude the Grassl collar. Claim 1, however, includes the following recitations which are not present in the Grassl collar:

(1) "formed entirely of" (lines 1, 5 and 7);
(2) "conically convex chin rest" (line 16); and
(3) "having a generally C-shape" (lines 8 and 9).

Perhaps the most apparently distinguishing of the aforementioned recitations are those which limit the band and the chin support brace of the collar to being formed entirely of stiff, flexible plastic sheet material. This clearly is not present in Grassl, as the tubular elements of formed of soft material which is padded with foam rubber. The foam rubber in Grassl tubular elements 13 and 14 is necessary not simply for comfort of the patient, but is necessary for structural shape and support of the soft material. in contrast, applicant's claims cover a collar in which the structural elements are formed entirely of the recited stiff, plastic sheet material, but in which nonstructural padding such as foam strip 21 can be optionally included.

[PX 522 at 34-35 (text uncorrected)]. Through these remarks, Garth emphasized the importance of the "entirely" limitation. Following this explanation, the examiner rejected claim 1 as indefinite, but found that providing some wording changes were made, which are not important to the present issue, "the claims appear to be allowable over the art of record," and further stated "Applicant's arguments regarding the claimed limitations of Claim 1 are persuasive." [Id. at 41].

In the portion of the prosecution history quoted above, Garth argued that the "claims cover a collar in which the structural elements are formed entirely of the recited stiff, plastic sheet material." Tecnol contends that whatever means are used to connect the pieces of a multiple-piece band constitute "structural elements," and therefore the claims require that any such fastening must also be formed entirely of stiff, flexible plastic sheet material.

- 2167 -
In response, CalMed makes two arguments.

First, CalMed contends that a band that is made entirely out of one piece of material does not cease being made "entirely" out of that material if the band is cut into two pieces and the two pieces are then reattached. At trial, CalMed demonstrated its point using the clear piece of stiff flexible sheet material found in the collar of a man's shirt when it is first removed from its packaging. [PX 565]. All parties agreed that this material, when formed into a band, was made "entirely" from flexible sheet material. All parties agreed that this band was still made "entirely" from flexible sheet material if a sticker was placed upon the band, or if a metal staple was put through the band. The parties disagreed on how to describe the band, however, once counsel for CalMed cut the band in half and then reattached the two pieces with a metal staple. Tecnol's expert, Preston, opined that the band was then no longer formed entirely out of stiff flexible sheet material because "now you are lending structure" with the metal staple. [Preston Tr. at 1870].

The Court finds that Tecnol's construction of the "entirely" limitation is correct. Taken in its ordinary meaning, "entirely" implies that all pieces of the band are to be formed out of stiff, flexible plastic sheet material. Garth's comments during the prosecution of the reissue application clarify and do not alter this basic understanding of "entirely." Garth stated that the band's "structural elements" must be formed entirely out of the requisite material, as opposed to "nonstructural" elements such as foam padding provided for comfort, which do not. [PX 522 at 35]. The claims require, therefore, that any element of an accused band which is properly described as a "structural element" must be formed entirely out of stiff, flexible plastic sheet material.

2. "An opening formed in the abutment portion of the projection is in communication with an aperture framed in a side wall of the offset power box adjacent the duct."

HellermannTyton breaks the above clause into disputed phrases two ["... abutment portion"], three ["aperture formed in a side wall"] and four ["opening... is in communication with an aperture"]). However, for purposes of judicial efficiency, the Court finds that it makes more sense to discuss phrases two and three together.

Panduit asks the Court to define the "opening formed in the abutment portion" as an "open area made within the cross-section of the projection at its end portion." Linguistically, this is nearly identical to HellermannTyton's preferred reading, in which the phrase means "the abutment portion must have a void space within its limits." However, although similar in wording, the two parties place different conditions and limitations on the phrase. The Court discusses these disagreements in claim construction below.

Panduit and HellermannTyton clash as to whether the "opening" is located in the "abutment portion" or the "projection at its end portion." Panduit argues that the phrase "opening formed in the abutment portion of the projection" really means "open area made within the cross-section of the projection at its end portion." Panduit states that this construction is "made clear in the specification," but does little else to support its construction. In contrast, HellermannTyton notes that earlier the patent described the "abutment portion" as "depending from a farthest extent of the top portion." HellermannTyton defines (and Panduit offers no counter-definition) "depends" as "hang down, be suspended from." From this HellermannTyton concludes that the abutment portion must hang down from the farthest extent of the top portion. In doing so, HellermannTyton argues that the '732 Patent distinguishes between the effective end portion of the projection, and the abutment portion of this projection. This Court agrees with HellermannTyton. The patent clearly requires an opening in the "abutment portion," which is an area that hangs down or descends from the farthest point of the top surface of the projection. Accordingly, the opening must be in the descended portion, and cannot be in the top portion's end portion.

The parties also spar over the definitions of "in" and "formed in." Technically, HellermannTyton contests these definitions only with respect to the "aperture" and not as to the "opening." However, given the general rule that a claim means the same thing each time in a given patent, the Court infers that HellermannTyton believes its definitions should apply to the entirety of Claim 1.

To begin, HellermannTyton's claim construction places several limits on "in" that Panduit mostly does not contest. Specifically, HellermannTyton argues that "In' does not mean 'on,' 'in' does not mean 'near,' 'in' does not mean 'over,' 'in' does
not mean 'above,' 'in does not mean 'behind.'" HellermannTyton thus asks the Court to define "in" as "within the limits." With respect to the definition of "in," Panduit specifically disputes only HellermannTyton's contention that "'in' does not mean 'on'
- correctly noting that the Shorter Oxford English Dictionary lists "on" as one possible definition (Panduit also disputes that "in' does not mean 'above'") but provides no support for its assertion). This leads Panduit to argue for the broader definition of "in" as "with reference to." However, although Panduit correctly notes that "on" is indeed a possible definition of "in," it is certainly not a common or typical one. For example, if Dick told Jane to look for a pen on the desk, he would be asking her to look on the top of the desk. Conversely, if Dick asked Jane to look inside a desk drawer. Here too, the specifications and diagrams clearly show an opening/aperture in the abutment portion/side wall, and not on the abutment portion/side wall. The Court therefore accepts HellermannTyton's above listed limitations on the definition of "in."

Although not generally objecting to HellermannTyton's limitations on "in," Panduit does argue for a specific definition of the term "formed in." Panduit argues that the term "formed in" requires merely that the opening and aperture consist of "open space." In Panduit's view, these terms do not demand that this open space take any particular shape or form. Conversely, in connection to the aperture, HellermannTyton contends that the term "formed in" requires a hole bounded by something on all sides, as that is the only type of void space that "completely resides within the limits or boundaries of the side wall." However, none of HellermannTyton's provided dictionary definitions state that "in" means "completely resides within the limits." Indeed, the preferred specification of the "opening" shows that the "opening formed in the abutment portion" does not "completely reside within" the abutment portion. Rather, the opening is bounded by the abutment portion on the right, left, and top -- but not on the bottom. The Court infers from this that although the aperture and opening both require open space, the open space does not need to take any particular shape or form. It could indeed be completely encircled -- such as the void space contained within a square, like so -- "
[...] Alternatively, it could be bounded on multiple sides, with one empty side -- as in the English letters "U" or "C" or the Hebrew letters "[SEE ILLUSTRATION IN ORIGINAL]" or "[SEE ILLUSTRATION IN ORIGINAL]." The Court uses these analogies because its limited word processing capabilities do not enable it to copy the elaborate graphs found in the parties' briefs. Therefore, the Court mostly agrees with HellermannTyton that "formed in" means "formed within," but disagrees that it requires something that "completely resides within."

However, just because the opening and aperture is not limited to a specific configuration, e.g., a square, does not mean that the "732 Patent grants Panduit unlimited breadth in defining its scope. In particular, the Court takes issue with one portion of Panduit's proposed construction of an "aperture formed in a side wall." Panduit contends that the aperture can "extend the full height and width of the offset power box" (emphasis in original). In doing so, Panduit states that the "open side wall area would occupy the entire side wall area . . . there would be no solid side wall area." Panduit reaches its construction by noting that in the description of the preferred embodiment, "the longitudinal extent of the aperture 82 may be as large as the distance between the two alignment bosses 76 depending on the application." However, Panduit fails to acknowledge, as HellermannTyton points out, that the description also states that "the box side wall 40 also has an aperture 82 formed therein." This is consistent with the actual claim language, in which the aperture is "formed in a side wall." If, as Panduit claims, the aperture can consist of the entire side wall area, then there would be no "side wall" in which the aperture could be "formed in." Therefore, while the Court agrees with Panduit that the aperture and opening need not take any specific shape, they clearly cannot be so expansive so that they cease to be "formed in" something else -- namely, something solid. The '732 Patent, by stating that the opening is "formed in the abutment portion" and that the aperture is "formed in a side wall," by the necessity of plain English requires both a solid abutment portion and a solid side wall to exist. Still, Panduit's argument that the patent grants flexibility as to the longitudinal extent of the aperture has merit. Therefore, the Court finds that while the aperture and opening cannot be so wide that the corresponding abutment portion or side wall ceases to exist, the '732 Patent nevertheless permits substantial leniency in how wide or narrow the opening or aperture must be.

1745

The system is recited in claim 1, which is representative of the claims on appeal. At issue are the structural limitations of the offset power box, which are highlighted below.

1. A modular raceway outlet station for use with a trunking duct which has a divider wall and a top access opening comprising:
an offset power box having, a projection extending laterally from a top wall of the offset power box having a top portion and an abutment portion depending from a furthest extent of the top portion adapted to be disposed substantially aligned with an adjacent edge of the top access opening; and

an opening formed in the abutment portion of the projection is in communication with an aperture formed in a side wall of the offset powerbox adjacent the duct; and

a communication extension adapted to be disposed over the duct top access opening having,

an abutment surface depending from a top surface of the extension adapted to be disposed flush against the abutment portion of the projection;

a routing notch formed in the abutment surface and

a guide wall depending from the extension interiorly adjacent the routing notch, adapted to be substantially vertically aligned with a divider wall,

wherein power conductors may be routed out of and over the duct, through the routing notch, and opening, and into the offset power box before installation of the extension, such that the power conductors are isolated from communication conductors when the extension is installed.

'732 patent, col. 7, ll. 14-41 (emphasis added).

*   *   *

With respect to the "opening" limitation, the district court stated in its summary judgment opinion that "the opening must be in the descended portion [of the abutment portion], and cannot be in the top portion's end portion." The court also concluded that the limitation requires a solid abutment portion and solid side wall; and that "while the '732 Patent permits substantial leniency in how wide or narrow the opening must be, the term 'formed in' means that 'the aperture and opening cannot be so wide such that the corresponding abutment portion or side wall ceases to exist.'" Although in its claim construction order the district court held that the opening need not be bounded on all sides (including the top), in analyzing the accused product, the district court held that "the open space identified by Plaintiff clearly does not descend or hang down from any structure, and is not 'formed in' the projection's abutment portion as construed."

Panduit argues that the claims do not require that the opening descend or hang down from any structure and that the district court improperly imported this limitation from the preferred embodiment, in which the opening is bounded at the top. Specifically, Panduit argues that we must construe "formed in" consistently throughout the specification, that "formed in" means "made within a cross-section of" or "created within an exterior surface or dimension of," and that nothing requires the opening to be bounded at its top. Panduit asserts that the opening in the accused device is bounded by the two "[SEE CHARACTER]"-shaped surfaces and the horizontal section, or between the inner legs of the two "[SEE CHARACTER]"-shaped surfaces.

Citing the preferred embodiment, HellermannTyton counters that the opening must hang off of the top portion of the projection because it must be in the abutment portion of the projection, which itself must hang. HellermannTyton asserts that what Panduit refers to as an opening is not in a hanging portion of the structure because there is nothing from which the abutment portion hangs. Moreover, HellermannTyton argues that because the horizontal structure and two "[SEE CHARACTER]"-shaped surfaces are not co-planar, there is no "opening formed in" the abutment.

In determining the meaning of the disputed claim limitation, we look principally to the intrinsic evidence of record, examining the claim language itself, the written description, and the prosecution history, if in evidence. See Phillips, 415 F.3d at 1312-17. Here, the "opening" limitation is defined by two recitations in the claim language. First, the opening must be formed in an abutment portion of the projection. To be "formed in" an abutment portion of the projection requires us to determine the location of an abutment portion. According to the claim, an abutment portion is located to "depend[] from the furthest extent of the top portion" of the projection. See '732 patent, col. 7, ll. 19-21. Although Panduit challenges what constitutes an abutment portion, it does not dispute that to depend from the top portion, an abutment portion must hang.
down or descend from such top portion. We agree. Therefore, to be "formed in" an abutment portion, the opening must be formed in an area that hangs down -- i.e., extends downward -- from a top portion of the projection. Second, the claim language requires that the opening be "in communication" with an aperture formed in the side wall. We agree with the district court -- and the parties do not dispute -- that "in communication" simply requires a passage through which wires may be routed.

This construction is consistent with the written description, which describes "an opening formed in the abutment portion of the projection which is in communication with an aperture formed in a side wall" and an abutment portion "which depends from the furthest extent of the top portion." '732 patent, col. 2, ll. 30-36. Although in the preferred embodiment depicted in Figure 4, the aperture 82 formed in the side wall 40 is not bounded at the top, this does not suggest that the opening 80 formed in the abutment portion 74 does not require a top portion. See '732 patent, col. 4, ll. 46-52. An "abutment portion," unlike a "side wall," is described consistently by both the claim language and the written description as depending -- i.e., extending downward -- from a top portion of the projection. '732 patent, col. 2, ll. 30-31, col. 7, ll. 19-21. To be "formed in" an area that extends downward from a top portion of the projection necessarily requires that the opening be bounded at top. The prosecution history is consistent with this interpretation and provides no further guidance.

For the foregoing reasons, we conclude that the "opening" must be formed in an area that extends downward from a top portion of the projection and must provide a passage through which wires may pass.

c. "said duct formed inside the caliper body"

The claim language states that the duct is "formed inside the caliper body." Brembo construes this phrase to mean that the duct is built at least partially within the caliper body. Alcon argues that the proper construction is that the duct is surrounded entirely along its length by the caliper body.

For the reasons stated in the previous section, the Court rejects Alcon's definition to the extent it requires the duct to have openings only at either end. Alcon's contention, however, is also that the duct must be entirely within the caliper body. This is consistent with the ordinary meaning of the phrase "formed inside." The ordinary meaning of "inside" is "within the boundaries of." Webster's Third New Int'l Dictionary at 1169. Another relevant source defines inside as "situated within the confines of (something): he fitted a light inside the cupboard," The New Oxford American Dictionary at 878 (1st ed. 2001), with "within" meaning "inside (something)," id. at 1938, and "confines" denoting "the borders or boundaries of a place." Id. at 360.

Brembo argues that the ordinary meaning of the term "inside" does not require the duct to be entirely within the caliper body. By way of example, Brembo says that ",[a] person can be 'inside' a pool even though their head protrudes above the top surface of the pool." Pl. Reply Mem. at 13. The Court does not find Brembo's example helpful, as a swimming pool is not an enclosed structure. A more pertinent example is the reference to a cupboard used in The New Oxford American Dictionary. An object ordinarily would not be considered to be "inside" a cupboard if it were partly sticking out of the cupboard. Similarly, an object is not "inside" a room if it is partly outside the room.

Brembo argues that Alcon's proposed definition excludes the preferred embodiment of the invention disclosed in the specification. Brembo contends that the duct referenced in the claim includes several ducts described in the preferred embodiment, some of which are outside the caliper body. The first is duct 19, which is in fact within the caliper body (the quoted passages include numeric references which correspond to one or more of the diagrams in the patent):

The duct 19 has a first portion 25 in the form of a hole extending in an end portion 27 of the central bridge 12 disposed adjacent the hub-side elongate element 8, as well as a second portion 26 extending along and inside a central portion of the central bridge …

'766 patent, col. 3, lines 1-5. The specification also refers to other ducts that are located within the "diffuser bodies" that, according the specification, distribute the cooling air onto the radiator elements:
The outlet openings 21 and 22 preferably comprise respective diffuser bodies 37 and 38 which are substantially fan-shaped and are fixed to the elongate elements 8 and 9 by means of respective pairs of screws 37a and 38a. These diffuser bodies 37 and 38, which are made of aluminum alloy, have respective inlet openings 39 and 40 for the supply of cooling air.

In particular, respective ducts 41 and 42 formed in the diffuser bodies 37 and 38 extend respectively, from the inlet openings 39 and 40 and branch, respectively, into three ducts 13c, 14c and 15c opening from the outlet openings 13b, 14b and 15b directly on the radiator elements 13a, 14a and 15a, and into three ducts 16c, 17c and 18c opening from the outlet openings, 16b, 17b and 18b directly onto the radiator elements 16a, 17a and 18a.

It should be noted that each diffuser body 38, 38 is in the form of a half-shell in which the ducts are formed as channels. When each diffuser body 37, 38 is fixed by the screws 37a, 38a to the respective elongate element 8,9 in a position against the internal surfaces 8a, 9a, the half-shell and hence also its channels, are covered by the elongate body.

Id., col. 3, lines 18-24, 29-43. The diffuser bodies are not, it appears, within the central bridge or the caliper body; the passage quoted above says they are "fixed to" the caliper body's elongate elements by means of screws. Accordingly, Brembo argues, if "inside the caliper body" is construed as meaning these ducts must be entirely inside the caliper body, the preferred embodiment would be excluded. A construction excluding the preferred embodiment is presumed to be improper.

Vitronics, 90 F.3d at 1583.

1 The central bridge is also relevant to the construction of "inside" because claims three, four, nine, ten, and thirteen make reference to a "duct formed inside the central bridge."

2 Brembo also asserts that "inside" cannot mean "entirely inside" because duct 19 has a connector which extends it outside the caliper body. The specification states that "the inlet opening 20 preferably has a connector 23 for the connection of the duct 19 to a cooling-air feed pipe 24, for example, for air coming from a suitable air-intake of the motor-vehicle." '766 patent, col. 2, lines 64-67. This statement from the specification, however, describes a connector outside of the caliper body, not the duct.

Alcon claims that the ducts within the diffuser bodies cited by Brembo are not the duct referenced in the disputed claim language. Alcon cites the following portions of the specification:

The outlet openings 21 and 22 preferably comprise respective diffuser bodies 37 and 38 which are substantially fan-shaped and are fixed to the elongate elements 8 and 9 by means of respective pairs of screws 37a and 38a. These diffuser bodies 37 and 38, which are made of aluminum alloy, have respective inlet openings 39 and 40 for the supply of cooling air. The diffuser bodies 37 and 38 have, respectively, three outlet openings 13b, 14b and 15b, spread out like a fan and three outlet openings 16b, 17b and 18b also spread out like a fan, all directly facing and close to the respective radiator elements.

... In operation, the cooling air coming from an air intake of the motor vehicle passes through the pipe 24, reaches and passes through the duct 19 until it reaches the diffuser bodies 37, 38 and the outlet openings. The cooling air emerges from these and passes directly over the radiator elements.

'766 patent, col. 3, lines 18-28, 44-49 (emphasis added). Alcon argues that the outlet openings, of which the diffuser bodies (and thus the ducts within those bodies) are a part, are not part of the duct referenced in the disputed claim language.

The claim language and its context and the other intrinsic evidence indicates that Alcon's interpretation of "inside" is the correct one. First, the claim states that the disk brake contains a duct for the passage of cooling air, not multiple ducts. Second, the specification makes it clear that duct 19 is the duct referenced in the claim as being used for the passage of cooling air.
The disk brake 1 according to the present invention comprises a duct 19 provided for the passage of cooling air for cooling the radiator elements 13a-18a, the duct 19 being formed inside the caliper body.

Id., col. 2, lines 53-57 (emphasis added). Finally, the specification consistently refers to duct 19 as "the duct." For example, it states, as cited above, that "the cooling air coming from an air intake of the motor vehicle passes through the pipe 24, reaches and passes through the duct 19 until it reaches the diffuser bodies 37, 38 and the outlet openings." Id., col. 3, lines 44-47 (emphasis added).

Thus, the claim language, the specification, and the drawings support Alcon's position that the duct is entirely within the caliper body. The Court construes "inside" as meaning "entirely within."

The parties also disagree over the meaning of "formed" in the phrase "formed inside." Brembo urges that the definition of formed is "built." Alcon construes "to form" as "to give form or shape to" or "to give a particular shape to." Alcon's definition is consistent with the dictionary definition of the term, see Webster's Third New Int'l Dictionary at 893, and Brembo's is not. Specifically, there is no support in the dictionary or the intrinsic evidence for reading "formed" to mean "built." The only support Brembo provides for its proposed construction is expert testimony. Brembo's expert states that a person of ordinary skill in the art would understand form to mean "build through known manufacturing techniques." Pl. Ex. G, Declaration of Albert V. Karvelis P 31. The expert does not explain to the Court why this is so. We cannot rely on expert testimony for the proper construction of a claim term when its meaning is discernable from the intrinsic record, Vitronics, 90 F.3d at 1585, which is the case here. The Court therefore adopts Alcon's proposed definition; "formed" means "given form or shape by."

The parties also dispute the meaning of "formed inside" in the context of claims three, four, nine, ten, and seventeen, which state that the duct is "formed inside the central bridge." Neither side contends, however, that the phrase has a different meaning when referring to the central bridge than it does when referring to the caliper body. Thus, "formed inside" in claims one, three, four, nine, ten, and seventeen is construed to mean that the duct is entirely within, and given form or shape by, the central bridge.

1747
4. Claim 6

Both parties seek construction of the following highlighted term of Claim 6: "Apparatus as claimed in claim 1 wherein the nozzle is formed integrally with the housing." ('886 patent, col. 4, ll. 26-27.) Rose Art construes this term as describing "a nozzle that is molded such that 'the housing' and 'the nozzle' are one piece." (Def.'s Pre-Markman Br. at 32.) P&M agrees that this is the correct construction of the term, as long as the construction is not limited to a nozzle and housing which are "formed in a 'mold' or 'molded together.'" (Pls. Supp. Mem. at 17.) Accordingly, the Court construes the term "is formed integrally with" in claim 6 to describe "a nozzle that is constructed such that the housing and the nozzle are one piece." Since the entirety of the intrinsic evidence with regard to this term is not ambiguous, the Court did not consider the extrinsic evidence submitted by Rose Art with respect to this term.

1748

The Court held a Markman hearing and subsequently issued a Memorandum opinion (Docket No. 138) in which the Court construed the disputed claim terms of the '981 Patent and the '306 Patent. At issued were the following claim terms of the '981 Patent and the '306 Patent: 1) "Frame"; 2) "Formed Integrally Within"; 3) "Integrally Formed Within"; 4) "Integrally Formed With"; 5) "Including"; 6) "Attached"; and 7) "Manifold". The Court construed the terms as follows:

"Frame": "the underlying structure of the cone crusher to which other constituent parts may be fitted, attached or integrated."
Claim 1 of the '516 patent reads, in relevant part:

A forming roller for use with a heated thermoplastic film as brought to this forming roll and when in contact with an outer diameter surface portion of said roller is vacuum-shaped and cooled to bring this heated film to a condition whereat said film is weldable to another film, this roller including:

* * *

(b) a central axial bore formed in this metal roller and having a precise size and with a counterbore formed in each end of the roller and substantially concentric with the axial bore;

* * *

(d) a multiplicity of fluid-conducting passageways formed longitudinally and substantially parallel to the axis of said roll, each of these passageways open at each end to a counterbore; . . .

'516 patent at col. 5, l. 20 - col. 6, l. 15 (emphases added). Independent claim 10 was also at issue. Limitation (b) of claim 10 reads: "a central axial bore formed in this metal roller and having a precise size." '516 patent at col. 6, ll. 65-66 (emphasis added). Other than this limitation, the district court found claims 1 and 10 similar in all respects.

On May 3, 2001, the district court granted Caputo personal access to review the March 30, 2001 opinion, even though the opinion contained restricted confidential information. Based upon this review, Caputo filed a motion for reconsideration on March 6, 2002, approximately eleven months after the March 30, 2001 opinion. The court issued a second opinion on August 8, 2002 addressing various motions from both parties. The court dismissed Caputo's motion for reconsideration as untimely and denied both parties' motions for sanctions and attorney's fees. The court also reprimanded Caputo for retaining an unredacted copy of a page from Sealed Air's brief in support of its motion for summary judgment (in violation of the protective order), but nevertheless, declined to impose sanctions. Final judgment was entered on September 3, 2002. Caputo appealed to this court and we have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1).

DISCUSSION

Our review of a grant of summary judgment of patent infringement or noninfringement is plenary. Cole v. Kimberly-Clark Corp., 102 F.3d 524, 528, 41 USPQ2d 1001, 1004 (Fed. Cir. 1996). We first determine whether "the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to a judgment as a matter of law." Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311, 1316, 48 USPQ2d 1099, 1102 (Fed. Cir. 1998) (quoting Fed. R. Civ. P. 56(c)). "In
determining whether there is a genuine issue of material fact, the evidence must be viewed in the light most favorable to the party opposing the motion, with doubts resolved in favor of the opponent.” Chiuminatta Concrete Concepts, Inc. v. Cardinal Indus., Inc., 145 F.3d 1303, 1307, 46 USPQ2d 1752, 1755 (Fed. Cir. 1998). "Claim construction, as a purely legal issue, is subject to de novo review on appeal.” Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1451, 46 USPQ2d 1169, 1171 (Fed. Cir. 1998) (en banc).

On appeal, Caputo alleges a host of errors by the district court. They can be reduced to the following: (1) Sealed Air continues to infringe the '516 patent, as evidenced by the district court's April 4, 2001 opinion; (2) the district court improperly granted trade secret status to Sealed Air's roller; (3) Sealed Air offered misleading evidence, testimony, and argument; and (4) the burden to prove that the bubble wrap produced by Sealed Air does not use Caputo's patented process shifts to Sealed Air under 35 U.S.C. § 295.

The district court properly construed limitation (b) to mean that the forming roller requires "a counterbore formed in each end of the roller and substantially concentric with the axial bore." The court noted that these counterbores provided a reservoir for fluid that passes through limitation (d). The district court construed limitation (d) to mean that "within the roller is another set of longitudinally formed water-conducting passageways that run substantially parallel to [the] axis of the roller." The district court noted that at least one purpose of these passageways was to control temperature along the roller during operation. We find both these constructions to be correct.

1. Claim Construction

The Federal Circuit has set forth a two-step analysis for determining whether there is infringement under either theory:

First, the claims must be correctly construed to determine the scope of the claims. Second, the claims must be compared to the accused device.

Kahn, 135 F.3d at 1476. Claim interpretation is a question of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Courts are directed to consider three sources to ascertain the meaning of a claim: (1) the literal language of the claim; (2) the patent specification; and (3) the prosecution history. Claim construction always begins with the claim language, which defines the scope of the claim. See York Prods., Inc. v. Central Tractor Farm & Family Ctr, 99 F.3d 1568, 1572 (Fed. Cir. 1996). In analyzing claim language, the court must employ "normal rules of syntax," Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1553 (Fed. Cir. 1997), for "[a] claim must be read in accordance with the precepts of English grammar." In re Hyatt, 708 F.2d 712, 714 (Fed. Cir. 1983). When interpreting the words of the claim, the court should "ascribe [to the words] their ordinary meaning unless it appears the inventor used them otherwise." Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995). In addition, the words must be construed in the light of the specification, whose "description may act as a sort of dictionary, which explains the invention and may define terms used in the claims." Markman, 52 F.3d at 979; see also Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

The last source of intrinsic evidence relevant to claim interpretation is the prosecution history of the patent, as it constitutes an "undisputed public" expression of what the patentee understood in terms of claim construction. Markman, 52 F.3d at 980.
The court, in its discretion, may consider extrinsic evidence "to assist in its construction of the written document." Id. at 981. However, neither the prosecution history nor any extrinsic evidence can "enlarge, diminish, or vary" the limitation in the claims. Id. at 980.

Plaintiffs assert that defendant's modified device infringes claim 1 of the '297 patent. This independent claim is an apparatus claim and describes an obturator body consisting of

an elongated slender body having a proximal end and a distal end, the body having a handle portion at said proximal end, the body having a shaft portion from the handle portion to said distal end, such shaft portion being dimensioned so that the portion thereof adjacent said distal end may be received in an endodontically prepared root canal and such portion has a surface adapted to receive filler material thereon;

a plurality of integral spaced apart length indicators formed on the exterior surface of said body shaft portion between said handle portion and said portion adjacent said distal end to be received in an endodontically prepared root canal, the indicators serving to indicate the length of said shaft portion to said distal end; and canal filler material formed on said body shaft portion adjacent said distal end leaving at least a substantial portion of said length indicators visually exposed.

The emphasized language denotes the only disputed claim element, that of "a plurality of integral spaced apart length indicators formed on the exterior surface of said body shaft portion . . . ." According to the '297 patent, the length indicators allow the practitioner to

insert the obturator with the filler material thereon in the prepared canal to the proper depth as indicated by markers on the obturator body shaft portion, assuring complete filling of the root canal.

(D.I. 20, Ex. B col. 2, lns. 35-39; see also D.I. 20, Ex. B col. 4, lns. 9-14, 17-20) 8 Complete filling and, thus, entombment of any remaining pupal material and contaminants, is essential to the success of endodontic therapy. (D.I. 20, Ex. B col. 1, lns. 23-26)

7 The parties apparently agree that defendant's obturator is "an elongated slender body," despite the fact that it is comprised of two separate pieces.

8 Prior to obturation, the length of the root canal is determined by insertion of a "verifier." If an x-ray of the tooth reveals that the verifier has been inserted all the way to the apex, the verifier is removed and the length of the canal determined from the length of the inserted portion of the verifier. (D.I. 20, Ex. B col. 2, lns. 20-30)

Claim 1 of the '297 patent requires "a plurality of integral spaced apart length indicators formed on the exterior surface of said body shaft portion." (D.I. 20, Ex. B col. 5, lns. 26-28) (emphasis added). The specification further provides that the length indicators be "integral formed on [the] shaft portion." (D.I. 20, Ex. B col. 3, ln. 33) (emphasis added). Likewise, the prosecution history speaks of "a plurality of length indicators formed on the exterior surface of the shaft between the handle portion and the portion adjacent the distal end to be received in a root canal." 9 (D.I. 24 Ex. A5 at 4) (emphasis added). "Formed" is defined as "to give form or shape to" or "to give a particular shape to: shape, mold, or fashion into a certain shape or condition or after a particular model." Webster's Third New Int'l Dictionary 893 (1971). Thus, the exterior surface of the body shaft must be "given a particular shape" for a particular purpose, i.e., to indicate length. By this construction, therefore, the mere presence of a physical feature on the exterior surface of the body shaft does not necessarily mean that the feature was "formed" or "given a particular shape" in order to indicate length.

9 Initially, claim 1 of the '297 patent was rejected in light of United States Patent No. 3,919,774 ("the '774 patent") because
the prior art patent "shows an obturator body 18 having a plurality of indicators." (D.I. 24, Ex. A4 at 3) The '774 patent stated in pertinent part:

Additionally, the indentations or projections could be located to form a graduation of the post for its utilization as a depth gauge. Also, numerical values could be applied for calibration in accordance with depth for facilitating proper placement of the sealer element.

(D.I. 23, Ex. A col. 4, lns. 11-16)

In the present case, the limitation of claim 1, and the dependent claim 3, require that "the opposite face of the [toothbrush's] head have at least one groove formed therein." (U.S. Patent # 5,651,158 Abstract at col. 1 ln. 63-64). In simpler terms, the limitation is that the side of the toothbrush head opposite the bristle-bearing face must have a groove. Smithkline contends that because the Colgate NAVIGATOR TM "retains two semicircular cut-outs at the edges of [its bristle-side] groove that allows that groove to be filled [with an] elastomer," the NAVIGATOR TM groove is "'formed' at least in part in the non-bristle side of the brush" and, therefore, literally infringes the '158 patent. (Smithkline Opp'n Br. to Colgate Mot. for Summ. J. of Non-Infringement, at 38.)

There are two reasons why Smithkline's argument fails. First, the '158 patent specifically and unambiguously gives Smithkline the patent right over toothbrushes whose "opposite face" has "at least one groove formed therein." (U.S. Patent # 5,651,158 Abstract at col. 1 ln. 63-64). The plain meaning of the term "groove" is a "long narrow channel or depression." Webster's Ninth New Collegiate Dictionary 538 (1988). Moreover, the deposition testimony of the Smithkline patent attorney, Dr. Walker, who drafted the '158 patent confirms that the nomenclature "groove" refers to a "space or a gap" with a bottom that does not penetrate both faces of the brush's head. (Walker Dep. at 176-77.) Such a channel or depression is not present on the "opposite face" of the NA VIGATOR TM product. The Colgate toothbrush has two furrows which could qualify as "grooves." However, these channels are conspicuously on the same side of the head as the bristles.

Second, a plain reading of the '158 patent limitation of an "opposite face" groove "formed therein," necessarily requires that such a groove must be "in" the specified face. So, a "groove" that is, as Smithkline argues, "formed" during the manufacturing process but that is distinctly absent in the final product is not a "groove formed therein" under the unambiguous language of the '158 patent. The proposed Smithkline construction is completely inconsistent with the plainly expressed limitation of the patent. Such a reading would emphasize the "formed" language of the patent and wrongly imply that Smithkline had patented a toothbrush groove production process. Instead, the limitation of the '158 properly focuses on the finished product's groove location -- "opposite face" -- and groove characteristics -- "formed therein." Because the "opposite face" claim limitation is not present in the NAVIGATOR TM product, there is no literal infringement of the '158 patent. Accordingly, summary judgment is granted in favor of Colgate on Smithkline's literal infringement claim.
"notably long in comparison to its width." Id. at 737. 7 Claim 25 of the '417 patent requires that each tubular member have a wall surface with a "plurality of slots formed therein . . . " The word "wall" is defined as "the external layer of structural material surrounding an object." Id. at 2572. The word "surface" is defined as "the exterior or outside of an object or body . . . ." Id. at 2300. A "slot" is "a long and narrow opening or groove." Id. at 2146; accord '762 patent, col. 7, lns. 17-20. 8 To "form" is "to give a particular shape to." Webster's at 893. "Therein" means "in or into that thing." Id. at 2372.

8 "Use of the term 'slot' encompasses an opening whose length is substantially greater than its width, such as an elongated oval opening."

Cordis maintains that a "tubular member" is a "basic 'building block' of the slotted tube invention," that is, "a tubular member the length of a half-slot with alternating opened and closed slots at each end of the tubular member." (C.A. No. 97-550, D.I. 327, P 20) Cordis relies for its argument on the following language:

Accordingly, slots 82 are preferably uniformly and circumferentially spaced from adjacent slots, and slots 82 adjacent to one another along the longitudinal axis of tubular member 71 are in a staggered relationship with one another. Alternating slots disposed about the circumference of tubular member 71 at both the first and second ends 72, 73 of tubular member 71 will only have a length equal to approximately one-half of the length of a complete slot 82, such half-slot 82 being bounded by members 78, 79 at 70 both at the first and second ends 72, 73 of tubular member 71.

( '762 patent, col. 7, lns. 3-13; see also '417 patent, col. 7, lns. 49-68 and col. 8, lns. 1-3; '984 patent, col. 6, lns. 26-36) As further explained in the specification, the use of alternating "half-slots" at either end of the tubular member permits the graft or prosthesis "to be expanded uniformly, and outwardly, in a controlled manner . . . ." (417 patent, col. 7, lns. 65-67; '984 patent, col. 6, lns. 42-44)

Cordis' interpretation finds some support in the language of the specification and claim 25 of the '417 patent. Although the specification describes both "complete slot 82" and "half-slot 82," it refers to both generally as "slots." Given that the presence of "half-slots" apparently is essential to the functioning of the graft as contemplated in the patent, the failure of the claim to differentiate between complete and half-slots is a further indication that the term "slots" refers to both complete and half-slots. Therefore, the court concludes that the term "slots" referred to in claim 25 is not limited to "complete" slots. 9

9 The court found nothing in the patent or the dictionary definition to limit "slots" to those which are bound on all sides, i.e., "complete" slots. The court notes, however, that in Figures 1A, 1B, 7, and 10, only the "complete slots" are labeled "slots 82"; the half-slots are not similarly labeled.

This conclusion is consistent with the description given in the specification of the length of each "graft, or prosthesis, 70." The specification indicates that each "graft, or prosthesis, 70" has a length of at least "one slot 82." 10 If each "graft, or prosthesis, 70" is comprised of at least two tubular members and each tubular member may be the length of only a "half-slot 82," one could argue that the length of such a graft is "one slot." 11 Consistent with the court's holding that a graft or prosthesis must be functional, however, a graft or prosthesis comprised of only two "tubular members" must be capable of "retaining its expanded and deformed configuration with the enlarged diameter . . . and resist radial collapse." ('417 patent, col. 7, lns. 6-14; '984 patent, col. 5, lns. 51-54)

10 Compare '417 patent, col. 7, lns. 59-63 with col. 11, lns. 51-55.
It is always difficult for a court to differentiate between what the claim language arguably describes and the preferred embodiment actually describes in the specification. This difficulty is particularly acute in a case such as this, where a preferred embodiment has been described in a series of patents. For instance, building on the invention of the '762 patent (i.e., "utilizing a thin-walled, tubular member as the prosthesis," col. 4, lns. 7-8), the specification of the '417 patent contemplates that the graft or prosthesis disclosed "generally includes a plurality of prostheses, or grafts 70 as defined previously in connection with FIGS 1A, 1B and 2," which figures are taken from the '762 patent. ('417 patent, col. 11, lns. 48-51) In Figures 1A, 1B and 7 of the '417 and '984 patents, the graft or prosthesis "70" and tubular member "71" are identified as the same structure. Likewise, the various written descriptions given of "thin-walled tubular members" are substantially the same as those given of "prostheses." (Compare, e.g., '417 patent, col. 3, lns. 57-63 with col. 5, lns. 4-10) The "connector members" are described as flexibly connecting both "adjacent tubular members" and "adjacent prostheses." (Compare, e.g., '417 patent, col. 3, lns. 63-65; col. 4, lns. 23-25, 59-61; col. 5, lns. 10-13; col. 12, lns. 7-21, 41-51, 59-63) Given the apparent "interchangeability" of the phrases "tubular members," "grafts," and "prostheses," it is with some reluctance that the court distinguishes between these structures for purposes of claim construction.

In sum, although a "thin-walled tubular member" may be comprised of only "half slots," each tubular member must be elongated (i.e., its length is greater than its width) and, in combination with only an additional tubular member, must be capable of functioning as an expandable intraluminal graft.

Also in dispute is whether the language "wall surface having a substantially uniform thickness and a plurality of slots formed therein" implicates a manufacturing requirement. Initially, the court agrees that the claim language does not specifically incorporate the manufacturing description given in the specification. ( '762 patent, col. 6, lns. 41-44) The court further acknowledges the general principle that "[a] product patent gives the patentee the right to restrict the use and sale of the product regardless of how . . . it was manufactured." United States v. Studiengesellschaft Kohle, 216 U.S. App. D.C. 303, 670 F.2d 1122, 1127 (D.C. Cir. 1981). Because the claim language is somewhat confusing, 12 the court finds it helpful to review the history of the language.

The '665 patent includes in the specification two embodiments of a graft generally described as a "wire mesh tube." Both embodiments are comprised of intersecting elongate members, the elongate members being either "small diameter stainless steel wires having a cylindrical cross-section" 13 or "small bars" formed by etching openings in a thin-walled stainless steel tube. ('665 patent, col. 6, lns. 12-44 and col. 7, lns. 3-20) Despite the differences between the two embodiments, presumably they both fall within the scope of the following claim language:

[A] tubular shaped member having first and second ends and a wall surface disposed between the first and second ends, the wall surface being formed by a plurality of intersecting elongate members . . . .

( '665 patent, claim 13 at col. 10, lns. 48-54; see also claim 18 at col. 11, lns. 21-27; claim 23 at col. 12, lns. 6-10; claim 26 at col. 12, lns. 33-37) (emphasis added). Only the second embodiment found its way into the '762 patent, the specification describing it as such:

Preferably, tubular member 71 is initially a thin-walled stainless steel tube having a uniform wall thickness, and a plurality of slots 82 are formed in the wall surface 74 of tubular member 71.

('417 patent, col. 7, lns. 19-22)
13 The court notes that the intersecting elongate members of this embodiment preferably were "fixedly secured to one another" at the point of intersection by any conventional manner, "such as by welding, soldering, or gluing . . . ." ('665 patent, col. 6, lns. 36-52)

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

For whatever reason, the emphasis from the '665 to the '767, '417, and '984 patents changed from describing what formed the wall surface (intersecting elongate members which implicitly form "openings," '665 patent, col. 7, lns. 15-16) to what was formed in the wall surface (a plurality of slots forming "intersecting elongate members"). 14 Nevertheless, the structure (and the method of manufacturing the structure) remained the same. Therefore, although the phrase "a plurality of slots formed therein" modifies the phrase "wall surface" (arguably implying a manufacturing limitation), 15 the court concludes that, whether the presence of material (elongate members) or the absence of material (slots) is emphasized, the structure of the product claimed is adequately described and does not implicate a manufacturing requirement.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

14 "Thus, the formation of slots 82 results in at least one elongate member being formed between adjacent slots 82 . . . ." ('417 patent, col. 7, lns. 33-35)

15 Cordis' argument that the phrase modifies "thin-walled tubular members" neglects the normal rules of syntax.

GO BACK

1753

II. "A Plurality of Slots Formed Therein"

With regard to the grant of summary judgment of no literal infringement, the district court ruled that the phrase "slots formed therein" requires that the slots be manufactured by removing material from a pre-existing wall surface. We disagree. Slots can be "formed" in a wall surface by means other than removing material, such as by constructing the wall with openings built into it.

Nothing about the phrase "slots formed therein" suggests that the slots must be formed by a particular process; the phrase certainly does not indicate that the wall must be formed first and the slots formed later. A piece of wire mesh can fairly be described as a metal surface with holes formed in it, but that description does not mean that the screen was made by starting with a solid piece of metal and drilling holes in it. The phrase "slots formed therein" describes the physical characteristics of the product, not the method of its manufacture.

We also reject AVE's contention that the '762 patent's definition of a slot as an "opening" indicates that the stent must be made by forming an opening in previously solid material. An opening can arise by leaving a gap during the construction of a wall surface as well as by removing material from the surface. Because the language "formed therein" does not require the removal of material as the method of formation, we decline to superimpose a process limitation on the product claims at issue. See Vanguard Prods. Corp. v. Parker Hannifin Corp., 234 F.3d 1370, 1372 (Fed. Cir. 2000) (holding that the limitation of a thin layer "integral therewith" described the product and did not designate a specific manufacturing process, and that a "method of manufacture, even when cited as advantageous, does not of itself convert product claims into claims limited to a particular process").

The specifications of the '762 and '984 patents do not define the "slots formed therein" as openings created by the removal of material from a pre-existing wall surface. AVE relies on the statement "preferably, tubular member 71 is initially a thin-walled stainless steel tube having a uniform thickness and a plurality of slots are formed in the wall surface 74 or tubular member 71." '762 patent, col. 6, ll. 41-44; '984 patent, col. 5, ll. 64-67. But the use of the term "preferably" makes clear that the language describes a preferred embodiment, not the invention as a whole.

The district court based its holding that the "slots must be formed in the wall surface of a tubular member, as by the removal
of material" in part on the progression of the written description of the '762 patent from its parent, U.S. Patent No. 4,733,665 ("the '665 patent"). Specifically, the district court relied on the fact that one of the embodiments disclosed in the '665 patent was not carried over into the specification of the '762 patent application, which was filed as a continuation in part ("CIP"). The '665 patent discloses two differing embodiments, which are shown in Figures 1A and 2A:

[SEE FIGURES 1A AND 2A IN ORIGINAL]

The written description of the '665 patent states, "Preferably, tubular shaped member 71 [of Figure 1A] is made of continuous, stainless steel wire woven in a criss-crossed tubular pattern to form what can be generally described as a wire mesh tube." '665 patent, col. 6, ll. 49-52. Because the wire is criss-crossed, the tube is twice as thick at the cross points as at other points on the structure. That embodiment is not present in the specification of the '762 patent or the '984 patent.

Like the district court, AVE relies on the absence of the Figure 1A embodiment from the '762 and '984 patents as indicating that Cordis disclaimed bent-wire stents lacking a pre-existing wall surface from which material is removed to create the slots. We reject this basis for narrowing the claims. In neither patent is there any language surrendering bent-wire stents, and the fact that the patentee chose not to include Figure 1A from the '665 patent as an embodiment in the '762 specification does not indicate that the patentee was no longer claiming any stent composed of bent wire. Rather, it is likely that the patentee chose not to include that embodiment because its overlapping members caused it not to be of substantially uniform thickness, smooth, or thin-walled (all features claimed in the '762 patent, but not in the '665 patent).

A patentee may choose not to carry forward a particular embodiment from a parent patent to a CIP because that embodiment does not satisfy a limitation that was added in the CIP. That choice, however, does not mean that the scope of the CIP is limited to the preferred embodiment that was carried forward. Thus, we reject AVE's contention that the failure to include a wire mesh embodiment in which wires have been bent and overlapped to form the stent should limit the construction of the claims to exclude all embodiments created by bending wire in any form.

The district court compared the methods of making the preferred embodiments of the '665 patent and concluded that the difference between the Figure 1A and Figure 2A embodiments is that "the elongate bars of the 'thin bar' [Figure 2A] embodiment 'may be formed integral with one another,'” a method of manufacture that the district court found to be "singularly descriptive of the slotted tube preferred embodiment." However, expert testimony established that one of skill in the art would understand "formed integral with one another," in the context of the patents at issue, to refer to formation from a single piece of material, which does not require construction by removal of material from a pre-existing piece of metal.

We also disagree with the district court's conclusion that it is significant that the '665 patent claims a "plurality of intersecting elongate members" while the '762 patent claims a "wall surface having . . . a plurality of slots." Claiming a wall having slots is essentially the same as defining a hole in terms of the structure that forms the hole.

We next consider statements made in the prosecution history of the '984 patent regarding the prior art Wiktor patent to determine whether the patentee effected a disclaimer of claim scope. Such a disclaimer requires clear and unmistakable statements of disavowal. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 2003 U.S. App. LEXIS 13570, Nos. 01-1546, 02-1478, slip. op. at 17 (Fed. Cir. July 7, 2003).

Dr. Schatz, the inventor of the '984 patent, characterized Wiktor as disclosing "a coiled wire stent which is a 'tubular shape of coiled wire wound in a special manner comprising a number of groups of turns 2.'" The coiled wire stent in Wiktor has openings spiraling around its circumference as shown herein:

[SEE ILLUSTRATION IN ORIGINAL]

In response to the examiner's rejection of the application for the '984 patent in view of the Wiktor patent, Dr. Schatz stated:

\"Wiktor does not disclose a plurality of "thin-walled tubular members, each having first and second ends and a wall surface disposed between the first and second ends, the wall surface having a substantially uniform thickness and a plurality of slots formed therein, the slots being disposed substantially parallel to the longitudinal axis of each tubular member". Wiktor discloses a single stent, or graft made up of coiled wire. There is no wall surface having a plurality of slots, nor slots disposed parallel to the longitudinal axis of each tubular member. Applicant's claimed invention is not "coiled wire wound
in a special manner comprised of a number of groups of turns” as illustrated in Wiktor.

The first sentence of Dr. Schatz's statement about Wiktor is a general allegation that Wiktor does not disclose the precise combination of elements claimed in the '984 patent. That statement cannot be read to disclaim any device not containing a pre-existing wall from which material is removed. Dr. Schatz more specifically distinguishes the Wiktor patent in his statement that "there is no wall surface having a plurality of slots, nor slots disposed parallel to the longitudinal axis of each tubular member." Clearly, he is correct that Wiktor does not have slots disposed parallel to the longitudinal axis of the member; even if the openings in Wiktor do constitute slots, they are perpendicular to the longitudinal axis of the member. It is not clear, however, what Dr. Schatz meant by "no wall surface having a plurality of slots." He could have meant either that coiled wire is not a wall surface or that the openings in the coil do not constitute slots. The statement is amenable to multiple reasonable interpretations and it therefore does not constitute a clear and unmistakable surrender of all stents that lack a pre-existing wall surface from which material is removed to form the slots. In addition, the statement does not clearly disclaim any stents made of bent wire on the ground that a stent made of wire lacks any "wall surface," as A VE contends.

Rather than supporting a narrow construction of the "slots formed therein" limitation, the prosecution history of the '762 patent—and particularly the reexamination—indicates that the patentee did not intend for the phrase "slots formed therein" to require the removal of material. For example, the examiner, in discussing the Kornberg patent, stated that "Webster's Ninth New Collegiate Dictionary defines 'slot' as 'a narrow opening or groove.' The spaces between the Kornberg struts certainly meet this definition. The slots are formed in the tubular member since the struts are part of the wall of the tubular member." The examiner's remarks indicate that he understood that "slots formed therein" describes the location of the slots, not how they are made. The patentee did not dispute that statement by the examiner. The examiner also described the Ersek patent's device as having "a plurality of slots 23 formed therein" even though Ersek's slots are not made by removing material. The patentee distinguished the Ersek patent, but did not dispute that Ersek's device has a plurality of slots formed therein. Accordingly, the patentee did not rely on the method of manufacturing as a means of distinguishing the invention from the prior art. Because the prosecution histories of the '762 and '984 patents do not support the narrow reading of the "slots formed therein" limitation, we conclude that the district court erred in construing the "slots formed therein" limitation in the two patents to require that the slots be formed by removing material from a pre-existing wall surface.

Because we disagree with the district court's construction of the "plurality of slots formed therein" limitation, we reverse the district court's grant of summary judgment of no literal infringement based on that limitation. For the same reason, we also reverse the district court's ruling on the doctrine of equivalents, which was based on the court's construction of that limitation.

The '760 patent relates to a "slotted track" or "slotted header" wall assembly used to alleviate stress on a wall's infrastructure caused by environmental forces, such as earthquakes. Slip Track alleges that Metal Lite's product, a particular slotted track wall assembly, infringes the claims of the '760 patent. The patent contains two independent claims and eight dependent claims. Claim 1 of the '760 patent is representative of the claims at issue and reads:

A building construction assembly that includes a header and a stud wherein the header is capable of vertical movement relative to said assembly comprising:

a header having a web and flanges with said flanges connected to said web;

at least one of said flanges having at least one vertical slot therein;

a stud having a width less than the distance between said flanges of said header and having a top end;

said stud having at least one hole formed therein proximal to said top end;

said top end fitting between said flanges perpendicular to said header positioned so that said hole is aligned with said vertical slot; and
an attachment means passing through said slot and through said hole to slideably unite said header to said stud whereby said slot permits said header to move vertically with respect to said stud while restricting horizontal movement of said header.

The sole claim construction issue relates to the limitation "said stud having at least one hole formed therein proximal to said top end." Metal Lite argues that the prosecution history requires the stud to have a "pre-existing hole," meaning a stud with a hole in existence prior to inserting the stud between the flanges of the header. Slip Track argues that the limitation in no way requires a pre-existing hole and that the claim encompasses assemblies wherein the hole is formed before or after inserting the stud between the flanges. Requiring a pre-existing hole, Slip Track argues, would impermissibly limit the apparatus claim to a product-by-process claim and also would exclude the preferred embodiment.

We agree with Metal Lite that claim 1 is limited to a stud having a hole in existence prior to inserting the stud between the flanges of the header. Claim construction starts with the language of the claims as understood by one of ordinary skill in the art. See ResQNet.com, Inc. v. Lansa, Inc., 346 F.3d 1374, 1378 (Fed. Cir. 2003); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002); Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999). Intrinsic evidence - namely, the specification and, if in evidence, the prosecution history - are also highly relevant to claim construction. See Vitronics, Corp. v. Conectronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). One reason "this court … considers the prosecution history … [is] to determine whether the applicant clearly and unambiguously 'disclaimed or disavowed [any interpretation] during prosecution in order to obtain claim allowance." " Middleton, Inc. v. Minn. Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002) (quoting Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985)); see also Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003) (explaining that prosecution disclaimer does not apply "where the alleged disavowal of claim scope is ambiguous").

In this case, the prosecution history of the '760 patent reveals that the patentee limited its invention to studs having pre-existing holes. Claim 1, as originally drafted, read, in pertinent part, "said stud being aligned with said vertical slot." On March 29, 1991, the Examiner issued a first rejection finding the claim obvious and "indefinite for failing to particularly point out and distinctly claim the subject matter which applicant regards as the invention." The Examiner specifically asked: "Re: claim 1 …line 10, how is the stud 'aligned' with the vertical slot …?" The patentee responded by amending claim 1 to read: "said stud having at least one hole formed therein proximal to said top end; said top end fitting between said flanges perpendicular to said header positioned so that said hole is aligned with said vertical slot." The patentee also made the following remark accompanying the amendment:

First, the Examiner's question of how the stud is aligned with the vertical slot has been answered by adding hole 22 proximal to top end 40 of the stud as an element of the claims. The hole 22 serves as a reference point on the stud which is used to align the stud and the slot. This amendment should overcome the Examiner's §112 rejection based upon indefiniteness with respect to claim 1 and the claims dependent therefrom.

In short, we hold that the limitation "said stud having at least one hole formed therein proximal to said top end," means that a hole must be formed in the stud prior to insertion of the stud between the flanges so that the hole can be used to align the stud with the vertical slot before passing the attachment means through the vertical slot and into the stud. In the infringement proceedings that are to follow on remand, the district court is to apply this claim construction.
Floe asserts that this phrase should be construed as "brought together or connected in a functional relationship." Newmans, however, contends that it should be construed as "flowing directly from." Floe alleges that its proposed construction is consistent with how "formed with" is used in the claim. Floe also asserts that it is improper to add modifiers, such as "directly," when the modifiers are not recited in the claim. Newmans supports its proposed construction by arguing that, in the prosecution history, the patentee specifically disclaimed any structure that does not flow directly from the protected deck edge. In particular, Newmans cites the patentee's characterization of the relationship between the "ramp means" and the "edge protection means" in an attempt to overcome a rejection based on Remde:

[The claimed invention has] a structure that is substantially different from that of Remde. The different structure has an advantageous resulting functionality in that the rear edge of the supported deck is protected, and the ramp flows directly from the deck surface and protected deck edge, rather than the separated structure shown by Remde.

(Frederick Decl., P 3, Ex. Bat FL000183.)

Here, Claim 11 states that the "ramp means" is "formed with said edge protection means for assisting in loading the vehicles when the frame structure is positioned for loading[.]") (379 Patent, c. 8, ll: 26-28.) Thus, the Court finds that the meaning of "formed with" in the claim means "brought together or connected in a functional relationship." Furthermore, the Court rejects Newmans' contention that the patentee disclaimed embodiments wherein the ramp does not "flow[] directly from" the deck surface. After reviewing the relevant prosecution history, the Court finds that in distinguishing the structure of the claimed invention from that of Remde, the patentee was making the argument that the structures are not equivalents under a means-plus-function analysis. The Court does not find that the patentee was indicating what "formed with" means. Thus, the patentee did not disclaim any structure that does not flow directly from the protected deck edge.

The Court therefore construes this phrase as "brought together or connected in a functional relationship."

Defendants' proposal for "forming" impermissibly relies upon other, unrelated patents. The definition of "form" is "to give form or shape to : FRAME, CONSTRUCT, MAKE, FASHION." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY OF THE ENGLISH LANGUAGE UNABRIDGED 893 (1993). The Court construes "forming" to mean "making or constructing."

CooperVision argues that these phrases do not require construction. CIBA construes "forming a contact lens member in the lens shaped cavity of the assembled mold sections" to mean "forming a contact lens member with a rounded edge in the lens shaped cavity of the assembled mold sections" and "a tool useful in making a mold section for cast molding a contact lens" to mean "a tool useful in making a mold section for cast molding a contact lens with a rounded edge." (emphasis added). CIBA adds only the words, "with a rounded edge" to each of the terms.

CIBA contends that the term "contact lens member," as used in the Edge Design Patents, requires the presence of a "rounded edge" and that both the specification and prosecution history suggest that the term "contact lens member" requires such an
edge. For that reason, CIBA argues, claim 1 and claim 15 produce a contact lens with a rounded edge.

Claim terms generally are given the meaning those terms would have to a person of ordinary skill in the art. Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005). The ordinary meaning of the term "contact lens member" does not require the presence of a rounded edge. The asserted claims can be assigned a narrower scope only if there is some indication in the patent or prosecution history that the term contact lens member was meant to have a more restrictive meaning as used in the patent, or a broader meaning was disclaimed during prosecution. See Phillips, 415 F.3d at 1316; Honeywell Int'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1319-20 (Fed. Cir. 2006). CooperVision's counsel granted in oral argument that when the back surface mold insert tool is used correctly, the resulting mold will produce a rounded edge lens. Tr. at p. 18. Moreover, the preferred embodiment, i.e., the method that creates the most comfortable contact lenses, will have a substantially smooth, rounded edge. See '706 patent, col. 7, ll. 40-42. But that is not required by the claim language.

The strongest indication that the term "contact lens member," as used in claim 1 and claim 15, was not meant to include a "rounded edge" limitation can be found by comparing independent claim 1 and dependent claim 2. Claim 1 recites the formation of a "contact lens member" but does not expressly require a "rounded edge." Claim 2 recites: "The method of claim 1 wherein the contact lens member formed has a rounded edge." It does not add any additional limitation other than the limitation of a "rounded edge."

Given that claim 2 adds the "rounded edge" limitation to claim 1, the doctrine of claim differentiation supports the inference that claim 1 encompasses a contact lens without the rounded edge. Otherwise, claim 2 would add nothing to claim 1, and the two would cover identical subject matter. See Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374,1380 (Fed. Cir. 2006) (holding that the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim).

CIBA points to various features of the patent and the prosecution history in support of its argument that one of skill in the art would necessarily conclude that only contact lenses with a rounded edge are within the scope of claim 1 and claim 15 of the '706 patent. CIBA first contends that such a limitation is evident from the claim language requiring that the back surface tool be capable of forming "a contact lens having the desired rounded edge without the need for post formation processing steps." '706 patent, col. 2, ll. 50 - 55. Because the specification describes a contact lens with a rounded edge, and because the specification does not disclose any other way to avoid a pointed or chiseled edge profile, CIBA argues that a person of skill in the art would understand that a contact lens created by the back surface tool must have a rounded edge.

A patent that describes only a single embodiment is not necessarily limited to that embodiment. Liebel-Flarsheim v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). "Even where a patent describes only a single embodiment, claims will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope . . . ." Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1117 (Fed. Cir. 2004). While an assertion by the patentee that a contact lens with a rounded edge is the only invention that can be created by a back surface tool would evidence an intention to narrow the scope of the independent claims, the '706 patent contains no such assertion.

In fact, the specification of the '706 patent contains passages expressly differentiating a contact lens from a contact lens with a rounded edge. In "Summary of the Invention," the specification states: "The demolded contact lens member may be the final contact lens. However, the demolded contact lens member may be hydrated to form the final contact lens with a rounded edge surface." '706 patent, col. 3, ll. 4-7. When the first and second mold sections are assembled together, either a "rounded edge contact lens or contact lens member in accordance with the present invention" may be formed. '706 patent, col. 3, ll. 64-65 (emphasis added). See also '706 patent, col. 3, ll. 52-53 ("preferably, a contact lens with a rounded edge surface, is provided"); '706 patent, col. 1, l. 7. Finally, the specification states:

Although there has been hereinabove described specific methods of manufacturing a rounded edge contact lens having a rounded peripheral edge surface or form, in accordance with the present invention, . . . it should be appreciated that the invention is not limited thereto. '706 patent, col. 7, l. 64 - col. 8, l. 2.

CIBA relies on dependent claim 4 in support of its argument that the method steps of claim 1 create a contact lens with a rounded edge. CIBA argues that the rounded edge in claim 4 does not come from demolding or hydration, and so dependent claim 4 makes clear that the method steps of claim 1 are what produce a contact lens with a rounded edge.
Claim 4 specifically calls for a "contact lens having a rounded edge" after the lens is demolded and hydrated. It is true that in a preferred embodiment, "[p]ost-formation processing such as demolding, hydration . . . does not alter [the] rounded edge surface configuration." '706 patent, col. 3, ll. 12-15. However, hydration "may to some extent change the finished lens manufactured" to become much more rounded or less clearly defined. See '706 patent, col. 7, ll. 51-55. A "much more rounded or less clearly defined edge surface" may also be achieved by varying the angle of intersection of the two mold halves to 140 degrees. '706 patent, col. 8, ll. 40-42; see also Figure 8. Accordingly, neither the claim language nor the specification supports the narrowing construction that CIBA proposes.

The court, therefore, adopts CooperVision's position, and will not construe these phrases.

1758

The "placing step"

Claim 11 states, in relevant part:

11. A method of making a pizza comprising the steps of:

(a) forming a generally flat dough base;

(b) forming a plurality of closed pockets each pocket enclosing a portion of food;

(c) placing the closed pockets on portions of the dough base . . .

Defendant says this step must be construed to require that the closed pockets are formed separately from the dough base and then placed upon the base. Plaintiff argues that the word "on" in 11(c) can encompass "pushing" or "moving" the folded dough pocket around, where the dough is not made of material separate from the base.

The plain meaning of the terms do not permit plaintiff's interpretation. "Placing on" does not mean "pushing" or "moving around." See Senmed, Inc. v. Richard-Allan Medical Indus., Inc., 888 F.2d 815, 819-20 n.8 (Fed. Cir. 1989) ("there is nothing ambiguous or linguistically obscure about "on" as used in the present claim") (construing "on" in its ordinary sense of "upon" or "on the surface," "on it"). In addition, pushing pockets of dough already attached to the dough base around is not disclosed anywhere in the specification, whereas creating closed pockets separately from the based "and then placed thereon" is disclosed.

The court concludes that claim 11(c) requires that the dough pockets be formed separately from the dough base, and then placed upon that base.

1759

11. a second portion of said wall extending from said first point to a second point forming a lowermost end of said wall ('826 patent, claim 13)

a second location on said wall, whereby said first and second locations form end points of said second wall portion, said second wall location being the lowermost point of said wall ('875 patent, claim 32)

Crown's proposed construction is "[a] second point that marks the lowest end of the can end wall." 47 Rexam's proposed construction is "[t]he specific place on the wall nearest the central panel (toward the bottom of the can)." 48

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

47 Id. at 3, 6.
The court adopts Rexam's proposed construction.

The parties' proposed constructions are very similar. Crown criticizes the reference to the central panel in Rexam's proposed construction by arguing that nothing in the claim language refers to the central panel. As a result, Crown insists that Rexam's definition is flawed by reference thereto. When read in its entirety, however, claim 13 of the '826 patent references various parts of the claimed can end including: a peripheral cover hook, a central panel, and a wall extending inwardly and downwardly from the peripheral cover hook. Likewise, the common specification describes the invention of Crown's patents in suit as comprising various features, including a central panel. Therefore, Rexam's definition is not flawed by its reference to the central panel of the can end.

As noted, three major parts of the can end recited in claim 13 of the '826 patent are: (1) a peripheral cover hook, (2) a central panel, and (3) a wall extending inwardly and downwardly from the cover hook. The parties agreed that the proper construction of "a wall extending inwardly and downwardly for said cover hook" refers to "a can end wall extending inwardly [toward the center of the can relative to the outside of the can] and downwardly [toward the bottom of the can relative to the top of the can]." The can end illustrated in figure 4 shows the can end wall (designated "chuck wall 24") extending inwardly and downwardly from the "peripheral cover hook 23". That figure illustrates chuck wall 24 terminating, or having its lowermost end, or point, at the outer wall of anti-peaking bead 25, which head extends radially inward from the chuck wall. Because the end wall, or chuck wall, extends inwardly and downwardly from the peripheral cover hook toward the central panel, the lowermost point on the end wall will necessarily be the location "nearest the central panel (toward the bottom of the can)." This would be true whether the can end has an annular reinforcing bead, as in the embodiment illustrated in figure 4, or a can end that does not have an annular reinforcing bead as Crown contends is the case with the invention described in claim 13 of the '826 patent.

Consequently, the court adopts Rexam's proposed construction: "the specific place on the wall nearest the central panel (toward the bottom of the can)."

The Court of Federal Claims also considered the following limitation:

forming a rigid connection between the lever and the knob with at least one substantially rigid member while maintaining...
the lever in a position where the protrusion cannot contact the surface of the cam wheel, in response to a receipt of an unlock signal.

'711 patent, col. 8, ll. 29-33. The court construed this limitation to require "a rigid connection between all parts in the chain of parts between the lever and the knob during the unlocking procedure." Claim construction ruling Masco, 47 Fed. Cl. at 459. Masco argues that this limitation should be construed to require that after the lever and knob are operably connected, any knob rotation yields predetermined lever movement. Masco's proposed construction departs significantly from the words of the claim, on which we must focus in construing the claim limitations. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996) ("First, we look to the words of the claims themselves, both asserted and nonasserted, to define the scope of the patented invention."). The court's construction, in contrast, focuses correctly on the words of the claim. We discern no error in that construction.

23. said wall and said reinforcing bead forming a transition therebetween ('875 patent, claim 50)

Crown's proposed construction is "[f]orming a place between two things at which one changes to the other." 93 Rexam's proposed construction is "[a] radiused portion of the can end, when looking at a cross section of the end, between the vertical wall of the annular reinforcing bead (countersink) and the second portion of the wall (chuck wall)." 94

93 Id.

94 Id.

The court adopts Crown's proposed construction.

As with 19, above, the court determines that the plain meaning of "transition" set forth by Crown is appropriate. Rexam's proposed construction is not supported by the language of the claim. For instance, the limitation in Rexam's definition describing "the vertical wall of the annular reinforcing bead" is not found in that claim. "Vertical" implies that the wall of the annular reinforcing bead must be at a right angle, or perpendicular, to the central panel of the can end. 95 Claim 50 makes no reference to annular bead wall angles. The common specification also is at odds with Rexam's proposed construction. Although common specification states that "preferably the anti-peaking bead 25 is parallel sided," which would be consistent with Rexam's "vertical" limitation, it also states that "the outer wall may be inclined to a line perpendicular to the central panel at an angle between -15 [degree] to +15 [degree]." 96 which would be inconsistent with that limitation.

95 That "vertical," with reference to the wall of the annular reinforcing bead would mean that that wall would be understood to be at a right angle, or perpendicular, to the central panel is supported by the common specification's use of "vertical" and "perpendicular" with respect to orientation of the chuck wall to the central panel. In describing figure 4, the chuck wall 24 is described as "inclined to an axis perpendicular to the exterior of the central panel at an angle C, between 20 [degree] and 60 [degree]; preferably between 40 [degree] and 45 [degree]." '875 patent, 3:47-49 (emphasis added). In a table of "[t]ypical dimensions of the example of the invention," the "chuck wall angle to vertical" for angle C is listed as 43 [degree]. '875 patent, 3:60-4:10 (emphasis added).

96 875 patent, 3:51-53.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -
Also, Rexam's inclusion of "the second portion of the wall (chuck wall)" adds confusion. While claim 32 of the '875 patent specifies "a circumferentially extending wall comprising first and second portion[s]," 97 claim 50, of which the disputed phrase is part, does not specify different can end wall portions. Therefore, Rexam's proposed language introduces a "second portion of the wall" not required by claim 50. 98 Rexam also provides no support for its inclusion of "a radiused portion of the can end" and the claim has no such limitation. Nor does it explain why "radiused portion" is a necessary limitation to the "transition" between the can end wall and reinforcing bead here, when no such limitation was proposed for the "transition" between the double seam to the second wall portion of claim 32.

--- Footnotes ---

97 '875 patent, claim 32, 13:8-9 (emphasis added).

98 Claim 50 recites "a rotatable chuck comprising first and second circumferentially extending walls," '875 patent, claim 50, 15:23-24, but the "circumferentially extending wall" pertinent to the disputed claim term is the wall of the can end, not the walls of the rotatable chuck.

--- End Footnotes ---

The court, therefore, adopts Crown's proposed construction: “forming a place between two things at which one changes to the other.”

1762

7. Claim 1 - "forming an opening"

Bradford proposes that "forming an opening" means "to give form to an open space". Defendants propose that "forming an opening" means "constituting or composing a basic element or part of an upwardly facing aperture serving as a passage." This term is a further limitation on "upper edge" in that the upper edge must form an opening "for receiving product placed in the container for shipment." This term also concerns the orientation of the dunnage structure.

The Court notes that "forming an opening" seems self-defining. In any event, however, "form" as a verb means "to give form or shape to: frame, construct, make, fashion." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 893 (1971). "Opening", in the context of the container, is appropriately defined as an "aperture". WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 1580 (1971). In turn, an "aperture" is defined as "an opening or open space." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 99 (1971). If the upper edge of the dunnage structure is defined so that it must face upwardly, then logic dictates that the opening formed by the upper edges must face upwardly as well. Therefore, it seems redundant to repeat that this term includes "an upwardly facing aperture" as Defendants propose. In other words, the orientation of the upper edges controls the orientation of the opening. Neither party suggests that "forming an opening" has any specialized meaning. Therefore, it is appropriate to give this term its ordinary meaning.

Accordingly, the Court holds that "forming an opening" means "making an open space".

1763

B. "Forming Appendages Extending From Either Side of Said Auxiliary Eyeglasses"

Plaintiff argues that the phrase "forming appendages extending from either side of said auxiliary eyeglasses" refers to "an appendage to each side of the auxiliary eyeglasses." (Opening Brief at 8:5-6.) Defendants argue that the phrase means that "two or more appendages are found on at least one side of the auxiliary eyeglasses." (Responsive Brief at 11:5-6; Joint Statement at p.15.) The dispute centers on the interaction between the plural form of "appendages" and the term "either."

The ordinary meaning of the word either is "being the one and the other of two" or "being the one or the other of two."
Webster's Ninth New Collegiate Dictionary (1986); Oxford English Dictionary (2d Ed.) (defining "either" as "each of the two" or "one or the other of two"). Defendants provided only the second definition -- being the one or the other of two; however, the Court finds that the first definition -- being the one and the other of two -- is appropriate here. Under that first definition, the Oxford English Dictionary provides that when "either" is used with a plural noun, it has the same meaning as "both," e.g., appendages extending from both sides of the auxiliary eyeglasses.

Defendants argue that the claim language unambiguously sets forth limitations that exclude a preferred embodiment, i.e., one appendage on each side of the auxiliary eyeglasses, and the Court cannot alter the ordinary meaning of the words to cover that embodiment. Further, Defendants argue that if Plaintiff wished to claim the preferred embodiment of one appendage on each side in the '913 patent, then Plaintiff had the duty to draft specific and clear claims to that embodiment. In response, Plaintiff argues that Defendants are seeking to create a limitation in requiring two or more appendages on at least one side of the auxiliary eyeglasses; but, the limitation is not identified in the claims, specification, or prosecution history. Plaintiff argues that the language of the claim does not limit it to two or more appendages on one side of the auxiliary eyeglasses.

The Court finds that in order to properly construe this phrase, it must consider the claim specification and the illustrations contained therein, which support the claim and show the embodiment of the claim. The written description and drawings, which indicate what the patent holder is protecting, aid the Court in construing the meaning of disputed claim terms. See Prima Tek II, 318 F.3d at 1148. Although the illustrations depict a particular embodiment of the claims, the claims are not limited to that particular configuration. See Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 956 (Fed. Cir. 2000).

Here, the illustrations indicate one appendage on each side, which the Court finds is a reasonable construction of the claim language and is consistent with the ordinary meaning of the word "either," when used in conjunction with a plural noun. (Trojan Decl. at Ex.A, FIGS. 1-9.) The Court declines to limit the definition of the phrase "forming appendages extending from either side of said auxiliary eyeglasses" to mean at least two appendages extending from each side of the auxiliary eyeglasses.

Based on the specification and the illustrations, the Court construes the phrase "forming appendages extending from either side of said auxiliary eyeglasses" to mean forming at least one appendage extending from each side of the auxiliary eyeglasses.

II.

Claim 1 recites a "method of shaping a projectile so as to have a specified low lethality consequence upon impact against an individual," including the step of "filling through [the] rear opening of [a] tubular sock-like projectile body a selected amount of lead shot to assume a position therein against [its] closed end . . . ." '562 patent, col. 4, ll. 21-24. It further recites the steps of "forming folds in said tubular sock-like projectile body immediately forward of said rear opening thereof," and "inserting said formed folds of said tubular sock-like projectile body into [the front opening of the] projectile compartment" of "an empty 12 gauge shotgun shell . . . ." '562 patent, col. 4, ll. 13-14, 24-28 (emphasis added).

The district court relied in part on the American Heritage Dictionary definition of "fold," namely "to bend over or double up so that one part lies on another part," which, according to the court, "when combined with the gerund 'forming,' requires the deliberate and systematic creation of folds." Apr. 19 Op. This "ordinary meaning[,]" the court stated, "is reinforced by the claim's introductory phrase: 'method of shaping.'" Id. The court then looked to the specification "to determine whether the patentee has given the phrase 'forming folds' an unaccustomed meaning." Id. The court noted that the specification uses "variations of the term 'fold'" in connection with both the prior art and the "patented invention" and stated that such uses, as well as the figures in the patent, are "consistent with" the "deliberate and systematic" construction. Id.

CSI argues that the district court erred in construing the "forming folds" limitation to require the "deliberate and systematic creation of folds." It contends that the "forming folds" limitation should be construed to mean "the step of forming folds (crease) by closing the opening of the body compartment of the sock-like projectile body, and may, if desired, include
forming additional folds (creases) in the tail before, during or after insertion of the projectile into the projectile compartment." CSI further argues that the district court incorrectly construed claim 1 to require that the "referenced folds" be "formed prior to, not during, the insertion [of the projectile] in the empty shotgun shell."

Specifically, CSI contends that the district court's resort, at least in the first instance, to the dictionary definition of "fold" was improper. It also argues that the district court erred in relying on the dictionary definition for the verb form of "fold" when "folds" is used in the claim as a noun, that the written description's uses of the term "fold" are "unrelated" to the claim language and that the district court improperly relied on (1) "the figures in the preferred embodiment" (2) "in view of extrinsic evidence to support a previously flawed conclusion that any folds must be formed deliberately and systematically." 2 We conclude, based on our examination of the relevant evidence, that the claim construction and hence the grant of summary judgment was correct.

--- Footnotes ---

2 CSI contends that DTCA performs the "forming folds" step when it (1) ties off its projectile after filling the closed end with lead shot, dividing the projectile into a closed (filled) compartment and a tail end, and/or (2) inserts the shot-containing projectile, tail end first, into the shotgun shell. Under the first alternative, the "folds" are creases, gathers, or bends formed when the fabric of the projectile is cinched together by the tie. Under the second, the "folds" are formed in the tail section of the DTCA projectile when the projectile is urged, tail end first, against the inside of the closed end of the shotgun shell.

--- End Footnotes ---

Claim Language

The claim recites a "shaping method comprising . . . using an empty 12 gauge shotgun shell having a cylindrical wall bounding a projectile compartment[,]" placing "a selected amount of lead shot" into a "tubular sock-like projectile body" through its rear opening, "forming folds in said tubular sock-like projectile body immediately forward of said rear opening thereof," and "inserting said formed folds of said tubular sock-like projectile body into said projectile compartment front opening . . . ." The claim language thus indicates that the "folds" are formed in the "tail" end -- as opposed to the lead shot-filled end -- of the projectile. Also, the affirmative recitation of "forming folds . . ." as a step in the claimed process is consistent with the district court's construction -- at least its determination that the claim requires the "deliberate" forming of "folds."

Furthermore, plainly as a matter of grammar, the recitation of "inserting said formed folds . . . into said projectile compartment" forecloses -- at least in the absence of compelling evidence to the contrary in the written description or prosecution history -- a construction permitting the "folds" to be formed after or during insertion of the projectile into the projectile compartment in the shotgun shell. Cf. Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1343 (Fed. Cir. 2001) (holding that a method claim not reciting an order of steps is not construed to require one, unless the "method steps implicitly require that they be performed in the order written"). For example, a method claim reciting introducing acetic acid into groundwater and "introducing a turbulent flow of an aqueous solution of ferrous ion into said groundwater region, for mixing with said acidified groundwater" requires the acetic acid introduction step to occur before the "turbulent flow" introduction step. Mantech Envtl. Corp. v. Hudson Envtl. Servs., Inc., 152 F.3d 1368, 1376 (Fed. Cir. 1998) (emphasis added) ("In order for the aqueous solution to mix with the acidified groundwater, the acid must have already mixed with the groundwater to form acidified groundwater."). Similarly, for the "formed folds" to be inserted into projectile compartment, they must already have been formed.

Written Description and Drawings

The written description describes the placement of the lead shot in the "tubular sock-like body" and, referring to FIG. 2:

[SEE FIG. 2 IN ORIGINAL]

[SEE FIG. 3B IN ORIGINAL]

describes the "completion" of "the construction of the projectile 10" "by a tie or the like, as at 44, which delineates the lead
shot-filled body 46 from a length portion or tail 48 of the fabric construction material 32." '562 patent, col. 2, ll. 54-60. After describing the construction of the "projectile compartment" (in the shotgun shell) and the preferred dimensions of the projectile, the written description, referring to FIG. 3A and FIG. 3B:

[SEE FIG. 3A IN ORIGINAL]

describes the insertion of the "FIG. 2 constructed projectile 10" into the projectile compartment, as follows:

The bulk of the FIG. 2 constructed projectile 10 is then manually stuffed through the front opening 58 into the compartment 54 which, not only of course properly positions the projectile 10 for firing, but also reshapes the projectile 10 so it can qualify for low lethality end use . . . .

In the loading of the projectile 10 into the cartridge compartment 54, the tail 48 is folded into a resulting bulk, as at 84, and in this folded configuration is urged in movement 86 into the compartment 54, as illustrated in FIG. 3A. Continuing to apply the force 86, the lead-filled projectile front 34 is worked fully into the compartment 54, as illustrated in FIG. 3B, aided by rotational twists of the projectile front end 34 in addition to the longitudinally directed force 86.

'562 patent, col. 3, ll. 18-35 (emphasis added). The rest of the written description does not otherwise use the term "fold" or any variation thereof in connection with the claimed invention, nor does it include any other description corresponding to the "forming folds" limitation in the claim. It does, however, use variations of the word "fold" in discussing the prior art:

A known projectile which currently is a low lethality munition of choice consists of a flat bag which is folded in half to fit within a 12 gauge shotgun shell, and after exiting from the muzzle is supposed to unfold into a flat bag shape and impact in this flat bag shape upon a target. As such the kinetic energy is distributed over the area of the bag instead of at a point as in regular ammunition. As a consequence there is less of a possibility of an undesirable penetration while permitting the delivery of a desirable incapacitating impact.

The shape of the above described projectile at impact is not always predictable based solely on its construction as a bag, because the bag can be flat at impact only if it unfolds after exiting from the muzzle. However, on numerous occasions in practice it does not unfold and contacts a target with its folded together side edges and thus, with a shape that can, and often does, inflict serious injury.

'562 patent, col. 1, ll.16-31 (emphasis added). As noted above, the district court concluded, without much explication, that "all of these uses of fold are consistent with the ordinary meaning of the phrase 'forming folds' as the systematic bending over or doubling up of fabric." Apr. 19 Op. Whether so, and even if the written description's uses of "fold" are, as CSI contends, "unrelated" to the "forming folds" limitation in the claim, it does, however, use variations of the word "fold" in discussing the prior art:

As discussed above, the language of the claim itself compels the conclusion that the claim requires the "folds" to be formed before the projectile is inserted into the projectile compartment of the shotgun shell. 3 CSI does not contend that DTCA forms "folds" before inserting its projectile into its shell other than when DTCA ties off the projectile to close the lead shot-containing portion. Thus, the only remaining issue is whether the "forming folds" limitation was properly construed to exclude the "gathers in the material that incidentally occur when a string is pulled to close the compartment." See Apr. 19 Op. We conclude that it was.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

3 To the extent that CSI contends that this conclusion is undermined by the language in the written description that states: "In the loading of the projectile 10 into the cartridge compartment 54, the tail is folded into a resulting bulk, as at 84" ('562 patent, col. 3, ll. 27-28 (emphasis added)), it is incorrect. First, the language CSI relies upon is itself immediately followed by language ("and in this folded configuration is urged in movement into the compartment 54, as illustrated in FIG. 3A" (emphasis added)) inconsistent with CSI's position and consistent with the district court's construction. Second, the claim language clearly requires that "said formed folds" be "formed" before they are "inserted . . . into said projectile compartment . . . ." Thus, "even if . . . a disclosure" of forming folds during insertion into the compartment "existed, [this] embodiment[] would not be covered by the language selected by the claim drafter." Oak Tech., Inc. v. ITC, 248 F.3d 1316,
As noted above, the claim affirmatively recites "forming folds . . ." as a distinct step in the claimed method. Thus, the language of the claim is consistent with the district court's "deliberate and systematic" construction. Further, according to the claim, the "folds" are formed "immediately forward of [the] rear opening" of the "tubular sock-like projectile body . . . ." When these claim limitations are read in the context of the entire specification, it becomes apparent that the district court's construction -- at least to the extent it required the deliberate forming of folds in the tail of the projectile -- is correct. 4

4 Contrary to CSI's contention, the prosecution history of the '562 patent does not undercut the district court's construction. The U.S. Patent and Trademark Office ("PTO") allowed claim 1 on first action, and issued the following examiner's statement of reasons for allowance: "Although the prior art it [sic] pertinent, it does not disclose a method of preparing a low lethality projectile wherein an empty 12 gauge cartridge is loaded with a shot filled tubular sock-like projectile where the open end is closed by forming folds in the material" (emphasis added). According to CSI, the examiner's statement "unmistakably supports [its] contention that at least one embodiment of the claimed invention could include the 'folds' as the securing means for the lead shot[,]" and because the district court's construction does not cover this embodiment, it is incorrect. We disagree. Nothing in the specification can be fairly read as disclosing an embodiment that includes closing the open end of the projectile "by forming folds in the material." Accordingly, the examiner's statement is, as the district court recognized, ambiguous.

Specifically, the written description, in the only language that, at least on its face, corresponds with the claimed "forming folds . . ." step states: "the tail . . . is folded into a resulting bulk . . . and in this folded configuration is urged in movement . . . into the compartment . . . ." '562 patent, col. 3, ll. 28-30. Further, neither in its discussion of "completing" the "construction of the projectile . . . by a tie or the like[,]" nor in the associated figure (FIG. 2) of the patent, does the description make any reference to any folds, bends, creases or the like formed as a result of or in association with the closing of the compartment, 5 and CSI produced no expert testimony or other extrinsic evidence that fold-forming would inherently result therefrom. To summarize, all of the intrinsic evidence is consistent with a construction requiring the deliberate forming of folds in the tail section of the projectile. Because CSI does not contest the district court's conclusion, as a matter of law, that DTCA's process does not include this step, we affirm the grant of summary judgment.

5 To the extent the drawings show "folds," they are shown formed in the tail section of the projectile ('562 patent, FIGS. 3A, 3B, and 4), i.e., behind, and not resulting from, the tie.

III.

As noted above, CSI also assigns error to the methodology by which the district court used the dictionary in its claim construction analysis, including its "place[ment of] primary importance on the extrinsic evidence before consideration of the intrinsic evidence." Had the district court relied exclusively on the dictionary definition or allowed it to overcome clear language in the patent itself, its methodology (although not necessarily its conclusion) would have been clearly wrong. As we have previously noted:

[A] common meaning, such as one expressed in a relevant dictionary, that flies in the face of the patent disclosure is undeserving of fealty. As one of our predecessor courts stated . . .: Indiscriminate reliance on definitions found in dictionaries can often produce absurd results . . . . One need not arbitrarily pick and choose from the various accepted definitions of a word to decide which meaning was intended as the word is used in a given claim. The subject matter, the context, etc., will more often than not lead to the correct conclusion.
Renishaw PLC, 158 F.3d at 1250 (citation omitted) (emphasis added). The district court, however, did not rely solely on the dictionary definition; rather, it reviewed and considered the written description and the figures of the patent. In addition, it did not allow a dictionary meaning to overcome clear language in the patent. Its opinion on claim construction, though, suggests it may have read some isolated statements in certain recent opinions too rigidly and in isolation from the entire body of our claim construction jurisprudence.

Specifically, after discussing the dictionary definition of "fold," and before reviewing pertinent portions of the written description, the district court stated: "Even when the ordinary meaning of a term appears to be clear from the claim language, however, it is necessary to read the claim in the context of the specification to determine whether the patentee has given the phrase 'forming folds in said . . . body' an unaccustomed meaning." Apr. 19 Op. If, which we doubt, this language indicates that the district court believed that our cases permit consulting the specification solely for the limited purpose of determining whether it contradicts the dictionary meaning of a claim term, 6 such a view is not supported by our case law, read as a whole. As we have recently stated, "the written description must be examined in every case, because it is relevant not only to aid in the claim construction analysis, but also to determine if the presumption of ordinary and customary meaning is rebutted." Brookhill-Wilk, 334 F.3d at 1298. Thus use of the specification to "determine if the presumption of ordinary and customary meaning is rebutted" is no more important than examining it "to aid in the claim construction analysis . . . ."

6 We note also here that when we, the district courts, and parties refer to the "ordinary meaning" of a claim term, such references are "short-hand" for the appropriate connotation under the law: the meaning, to a person of ordinary skill in the art. E.g., Teleflex, 299 F.3d at 1325 ("The ordinary meaning must be determined from the standpoint of a person of ordinary skill in the relevant art.").

CONCLUSION

Regardless of how it described its approach, we conclude that the district court conducted the proper analysis using correct methodology and sources and reached the correct construction. Accordingly, we

AFFIRM.

C. "Having four periphery surfaces"

As discussed above, plaintiff argues that the enclosure's faces can be slightly curved, and the enclosure's sides can be substantially quadrilaterally shaped. The periphery surfaces define the substantially quadrilaterally shaped sides of the enclosure, and, plaintiff argues, it follows that the periphery surfaces can have some curvature. Plaintiff argues that the periphery surfaces need not meet at straight-edged corners or corners with any particular angle. Defendant argues that the phrase "four periphery surfaces" requires four distinct surfaces intersecting at angled corners. Defendant explains that there must be four distinct periphery surfaces, because the periphery surfaces define the substantially quadrilaterally shaped sides of the pad.

As explained above, the construction of claim terms relating to the pad's enclosure is with reference to the enclosure in a substantially filled state. The claim language, specification, and prosecution history do not reveal the ordinary and customary meaning of "periphery" and "surface," and the Court will consult a dictionary. Periphery is defined as: "the external boundary of any surface or area." Random House College Dictionary (1973). Surface is defined as "1. the outer face, outside, or exterior boundary of a thing. . . . 5. Geom.: any figure having only two dimensions; part or all of the boundary of a solid." Id.

- 2194 -
The claim reads, "having four periphery surfaces." Absent from the phrase are any words of approximation or generality. The claim's language does not refer to any corners. A solid having four periphery surfaces necessarily must have four areas where the surfaces meet and their planes intersect, but the claim does not require these areas to be angled corners. The drawings of the pad structure in the specification depict the four periphery surfaces intersecting at sharp, angled corners. However, "the mere fact that the patent drawings depict a particular embodiment of the patent does not operate to limit the claims to that specific configuration." Anchor Wall, 340 F.3d at 1306-7. The Court finds that the claim term "having four periphery surfaces" means that the pad structure has four periphery surfaces which meet, but not necessarily at corners; if the surfaces do meet at corners, the corners need not have any particular angle.

Defendant alleges that the plaintiff disclaimed a pad structure having less than four periphery surfaces. During prosecution, plaintiff amended the claim by changing the language "at least three" periphery surfaces to "four periphery surfaces." As defendant notes, "where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Liquid Dynamics Corp. v. Vaughan Co., Inc., 355 F.3d 1361, 1368 (Fed. Cir. 2004) (citation omitted). The Court finds that the plaintiff disclaimed a pad structure with at least three periphery surfaces.

1766

a. Construction of the terms "four-side-seal type bag body" and "side seal portion" as used in the '121 patent

The parties do not dispute that the sides of the bags described in the Kirin patents are formed by folds instead of seals. 7 Instead, Shield Pack argues that the '121 patent claims must be construed to encompass a bag that can have sides formed by either seals or folds. If so, the Kirin patents disclose the "four-side-seal type bag body" and "side seal portion" limitations of the '121 patent. CDF, conversely, insists that a proper construction of the '121 patent claims requires the sides of the bags to be formed by seals, not folds. Shield Pack argues that the terms "four-side-seal type bag body" and "side seal portion" in the '121 patent claim are not limited to bags formed by side seals because they include the broadening words "type" and "portion" following "seal."

Shield Pack argues that inclusion of the term "portion" after "side seal" leaves the term "side seal portion" open to definition by reference to the specification. [Doc. No. 42, p. 12]. CDF argues that the terms "four-side-seal type bag body" and "side seal portion" in the '121 patent claims are limited to bags made with side seals only. CDF asserts that "seal portion" is properly construed as "an area of the bag in which a fluid tight bond is used to join two different parts of the bag together," not an area of the bag joining two parts by seals, bends, or folds. CDF argues that the language in the specification discussing ways that parts of "side seal portions" can be omitted describes methods of forming a bag that would not be covered by the '121 patent because the '121 patent requires that the bag have "side seal portions."

The language in the specification is awkward, but the Court agrees with CDF's claim construction. Claim 1 of the '121 patent requires that the bags it describes have "side seal portions." However, according to the specification, the "seal
portions," including "side seal portions," are "omitted" when the bag body is formed by bending or folding. This implies that when bending or folding is used to form the bag body, the connecting portions of the bag body must be something other than "seal portions." 8 If the drafter of this language intended it to allow the '121 patent to encompass different methods of forming the bag's connecting portions, he thwarted himself when he included the term "seal portions" in the claim.

8 Perhaps they would be "bend portions" or "fold portions." The use of the full term "seal portions" instead of simply "seals" in this sentence of the specification supports CDF's argument that it means an area of the bag with a seal, not an area of the bag with a seal, a bend, or a fold.

Shield Pack also argues that the term "four-side-seal type bag body" refers to a bag "similar to" one that has four side seals connecting its front, back, and side portions, which includes bags that have bends or folds connecting those portions. [Doc. No. 42, p. 16]. Shield Pack supports this argument by pointing out that the claim could have omitted the word "type" and simply stated "four-side-seal bag body," which would have been narrower. However, the claim could also have stated "four-side type bag body," which would have been broader. In this light, the claim's limitation to a "four-side-seal type bag body" supports CDF's argument that the claim requires the bag to have four side seals.

The Court construes "type" as used here to limit the claim to a category of bag bodies having the characteristic of four side seals.

Under the Court's construction of the '121 patent, no reasonable fact finder could find that the Kirin patents, which do not disclose side seals, disclose every limitation of the '121 patent claims. 10 Therefore, the Court DENIES Shield Pack's Motion for Summary Judgment of Non-Infringement and Invalidity and GRANTS CDF's Cross Motion for Summary Judgment of No Invalidity.

9 Specifically, under this construction, the claim limitations requiring "a four-side-seal type bag body"; "oblique seal portion[s]. . . formed such that . . . opposing inner surfaces of the bag body are bonded . . . between a first arbitrary point on top seal portion or bottom seal portion to a second arbitrary point on a side seal portion"; and "triangular fin portion[s] being defined by the side seal portion" [Doc. No. 1-3, p. 27] could not be disclosed in the Kirin patents.

10 Because the Court finds no reasonable fact finder could find that the Kirin patents anticipate claim 1 of the '121 patent because it does not disclose "side seal portions" or a "four-side-seal type bag body," it is unnecessary for the Court to reach CDF's second argument that the '121 patent is not anticipated by the Kirin patents because it does not disclose flat and side portions of the bag composed of "at least two sheets of synthetic resin films that are superposed to each other in a non-bonded state." Also, because no reasonable fact finder could find that the Kirin patents anticipate claim 1 of the '121 patent, no reasonable fact finder could find that they anticipate claims 2 through 10 of the '121 patent, which are dependent on claim 1.
reference to "clad" or "cladding" apply to both clad and unclad products.

d. "Minimum" and "maximum." A level referring to guaranteeable property values established by repeated testing of many pieces of metal to establish consistent, uniform values.

e. "Long transverse yield strength." As understood by one of ordinary skill in the art, the stress, applied across the width of a product, that a product can sustain before yielding or breaking.

f. "Fracture toughness." Consistent with the understanding of one of ordinary skill in the art, resistance to extension of a crack, often measured in terms of the stress-intensity factor (K) at which applying progressively greater stress to a structure that contains a pre-existing crack causes the onset of rapid catastrophic propagation of that crack.

"FRAGILE GEL DRILLING FLUID" and "FRAGILE GEL"

The asserted claims of the '832 Patent are directed to methods and products involving fragile gel drilling fluids or drilling fluids exhibiting fragile gel behavior. Claims 1 through 3 cover methods for drilling in a subterranean formation using a fragile gel drilling fluid and Claim 5 is a composition of matter claim that covers a fragile gel drilling fluid. According to these independent claims, the claimed fragile gel drilling fluid comprises four elements: an invert emulsion base, one or more thinners, one or more emulsifiers, and one or more weighting agents. '832 Patent, cols. 14:20-25, 29-33, 37-41, 15:30-34. With respect to the "fragile gel drilling fluid limitation," Claim 1 is representative of each of the asserted independent claims:

1. A method for conducting a drilling operation in a subterranean formation using a fragile gel drilling fluid comprising:

   (a) an invert emulsion base;

   (b) one or more thinners;

   (c) one or more emulsifiers; and

   (d) one or more weighting agents, wherein said operation includes running casing in a borehole.

During prosecution, the PTO initially ruled that certain prior art references "would inherently possess the properties of the present invention, since the same composition is being claimed." June 4, 2004, Non-Final Office Action Application No. 10/175,272 at 3, 4. To distinguish the invention from the prior art and rebut the PTO's findings that the prior art disclosed the claimed composition, the patentees stated that the claims are directed to and limited by "a fragile gel drilling fluid or a method of using a fragile gel drilling fluid. The patentees further asserted that the invention's "fragile gel characteristics . . . are not inherent [in prior art] fluids." Id. at 32. Therefore, the patentees relied on the fragile gel characteristics to distinguish the prior art. Accordingly, the parties do not dispute that the term "fragile gel drilling fluid," which is found in the preambles of each of the asserted independent claims (Claims 1-3 and 5), is a limitation on all asserted claims of the '832 Patent.

Halliburton argues "fragile gel drilling fluid" and "fragile gel" should be construed as:

a gel that easily transitions to a liquid state upon the introduction of force (e.g., when drilling starts) and returns to a gel when the force is removed (e.g., when drilling stops); the fragile gel drilling fluid, at rest, is capable of suspending drill cuttings and weighting materials. A fragile gel drilling fluid contains no organophilic clay or lignite or can contain low amounts of organophilic clay or lignite individually or in combination so that the fragile gel drilling fluid can still easily transition between a gel and liquid state and suspend drill cuttings and weighting materials.

For the reasons set forth below, the Court finds that the term "fragile gel drilling fluid" cannot be construed and therefore the
asserted claims are indefinite.

1 "Fragile gel" appears to be used in the claims as an adjective to modify "drilling fluid." However, both Halliburton and M-I refer to "fragile gel" and "fragile gel drilling fluid" interchangeably. See Halliburton Opening Brief at 8-14; M-I's Responsive Brief at 7-21. Indeed, Halliburton proffers one definition for both "fragile gel" and "fragile gel drilling fluid." Halliburton Opening Brief at 8-9. The '832 Patent also uses "fragile gel" as a noun. See, e.g., '832 Patent, col. 2:5-57. Thus, there is no reason for the Court to treat those terms as different in its analysis. The meaning of "fragile gel" is integral to both terms.

2 M-I did not offer a definition of "fragile gel" and "fragile gel drilling fluid" because M-I contends those terms are indefinite.

3 Halliburton's Opening Claim Construction Brief, pp. 8-9 (Docket No. 98).

Any Possible Construction Of "Fragile Gel" Would Include Subjective Terms That Render the Claims Indefinite

The Court starts with the claim language in defining "fragile gel drilling fluid." The independent claims do not define a fragile gel drilling fluid other than in terms of the four basic components described above. The dependent claims add additional limitations to what the fragile gel drilling fluid is. For example, the claims dependent upon Claim 1 specify that the fragile gel drilling fluid (i) is a structure capable of suspending drill cuttings at rest and that may be immediately disrupted by movement of said fluid (Claim 9), (ii) reverts to a flowable or liquid state immediately upon resumption of drilling after a period of rest (Claim 10), and (iii) forms a structure that is capable of suspending drill cuttings at rest and that is instantaneously disruptible by movement (Claim 42). Under the doctrine of claim differentiation, there is a presumption that those limitations are not part of the independent claim. Nazomi Commc'ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005); Comark Commc'ns, 156 F.3d at 1187.

Turning to the specification, Halliburton points to the specification's description of a "fragile gel" as a "starting point" in the construction of that term:

a "gel" that is easily disrupted or thinned, and that liquefies or becomes less gel-like and more liquid-like under stress, such as caused by moving the fluid, but which quickly returns to a gel when the movement or other stress is alleviated or removed, such as when circulation of the fluid is stopped, as for example when drilling is stopped... [Fragile gels] seem to break instantaneously when disturbed, reversing from a gel back into a liquid form with minimum pressure, force and time and with less pressure, force and time than known to be required to convert prior art fluids from a gel-like state into a flowable state.

'832 Patent, col. 2:26-41. Halliburton's proposed construction of fragile gel states that "it is a gel that easily transitions to a liquid state upon the introduction of force (e.g., when drilling starts) and returns to a gel when the force is removed (e.g., when drilling stops); the fragile gel drilling fluid, at rest, is capable of suspending drill cuttings and weighting materials." However, both the specification's and Halliburton's descriptions fail to define "fragile gel" and distinguish the claimed "fragile gel" from the prior art.

There must be some objective standard for the terms "easily transitions," "easily disrupted or thinned," "less gel-like," "more liquid-like," "quickly returns to a gel," "break instantaneously," and "minimum pressure, force and time" in order for the above descriptions to be a definition for the claimed term. See Datamize, 417 F.3d at 1350-51. Neither the specification nor any other evidence provides an objective standard for determining the scope of these amorphous terms. For instance, there is no evidence of whether skilled artisans would agree on whether "ease of disruption or thinning" is a function of force, time, or some other factor, or combination of factors. And even if skilled artisans could agree on the determining factors, there is still no evidence they would agree on a particular amount or range of force, time, etc., that would make disruption or thinning "easy" or what it means to be "easy." Similarly, although "quickly" is clearly a reference to a temporal factor, skilled artisans may differ greatly in their opinions of what constitutes the fluid's "quick" return to gel form or
"instantaneous" breaking. There is no evidence of what type or amount of force is needed to create the fluid stress that makes the fragile gel "less gel-like" or "more liquid-like." These terms' meanings—and thus the meaning of fragile gel—depend on an individual's subjective view of the drilling fluid's performance. 4 See Expert Report of Martin Chenevert, Exh. 4 to M-I's Responsive Brief on Claim Construction (Docket No. 116). Accordingly, while the quoted passage is descriptive of fragile gels, the subjective nature of its description causes it to fail as a definition for the term. Defining "fragile gel" according to this description would be meaningless and not apprise the public of its bounds.

--- End Footnotes ---

"Brookfield tests" and the Brookfield figures"

Halliburton argues that the "Brookfield tests" mentioned in the specification and depicted in Figures 3 and 4—involving use of a device called a "Brookfield viscometer"—distinguish the claimed invention from the prior art. A Brookfield viscometer is a commercially-available instrument for measuring fluid properties, such as gel-strength and resistance to shear. The Brookfield viscometer's vanes are inserted into a sample of liquid and spun at various rates and for various durations. Torque readings at various times are plotted on a graph. Figure 3 compares gel-formation and breakage characteristics of the present invention's fluids and prior art fluids and Figure 4 compares those fluids' relative relaxation rates after exposure to stress. '832 Patent, col. 4:11-16; 5:53-6:28.

According to Halliburton's experts, "upon resumption of shear stress [at approximately the 70-minute mark in the Figure 3 Brookfield test], the graph [corresponding to a fragile gel] extends vertically to the point at which the gel breaks and transitions to a fluid." Docket No. 94-5 at 3 (citing Clark Rep. at 79; Report of Roger Bonnecaze ("Bonnecaze Rep.") at 12). "The graph then falls directly back upon itself to a point where it levels off to its liquid state . . . indicat[ing] that the transition from a gel to a liquid occurs quickly, immediately, and instantaneously." Id. The specification states that the preferred-embodiment samples build up more gel than the prior-art samples when at rest, yet break quicker when exposed to...
stress, indicating less resistance to shear. '832 Patent, col. 6:5-15. Halliburton contends that skilled artisans would recognize the supposedly distinctive L-shaped curves of the preferred-embodiment samples as depictions of fragile gels. Docket No. 94-5 at 20 (citing Clark Rep. at 30, 38-42, 78-80; Bonnecaze Rep. at 21); see also Apr. 13, 2006 Dep. of Ronald Clark ("Clark Dep.") at 324:8-14. Such curves would presumably appear in data graphs from Brookfield tests performed on all embodiments of the invention's drilling fluid.

Halliburton produces no evidence, and the Court is aware of none, to indicate precisely how high the vertical leg of a fluid's L-shaped curve must reach i.e., how "strong" a gel must be for that fluid to exhibit "fragile gel behavior." For instance, there is no specific numeric cutoff point for percentage torque applied, below which a fluid falls under the category of "non-fragile gel." See Burrows Dep. at 180:25-181:6; Siems Dep. 30:16-23, 31:14-18, 186:22-187:7. In the absence of such objective baselines, Halliburton's assertion that skilled artisans merely need to "look at the shape of the curve" to identify fragile gel characteristics is dubious. Although "a patentee need not define his invention with mathematical precision to satisfy the definiteness requirement," there must be some "objective anchor" by which skilled artisans can identify whether they are practicing the patented invention. See Datamize, 417 F.3d at 1350; see also Oakley, Inc. v. Sunglass Hut Int'l, 316 F.3d 1331, 1341 (Fed. Cir. 2003).

Halliburton's inventors indicate that skilled artisans can do this by visually comparing the graphed results of Brookfield tests on different fluid samples. See Burrows Dep. at 180:1-6. As a preliminary matter, however, it is unclear from the specification's description of Figure 3 precisely what distinguishes the curves of the two preferred-embodiment samples (Accolade) from the curves of the two prior-art samples (Petrofree SF). The vertices connecting the legs of the curves are not significantly sharper for the Accolade-sample curves than for the curve of at least one of the Petrofree SF-samples. The Petrofree SF sample's curve assumes the same distinctive L-shape as the Accolade-sample's curves. All three curves "fall back on themselves." Thus, despite the specification's and Halliburton's experts' assertions, Figure 3 reveals no difference in the amount of time necessary to change the Accolade and Petrofree SF from gel to liquid form.

The only apparent aspect that distinguishes Figure 3's Accolade curves is that those curves' vertical legs—which apparently indicate gel strength at the time force is reapplied--peak higher than do the Petrofree SF curves' vertical legs. Clark Dep. at 141:21-142:18. But there is no definitive evidence that this aspect of the preferred-embodiment fluid's curves is attributable to that fluid's inherent characteristics. Halliburton's scientists conducting the Brookfield tests on which the Figure 3 results are based used a proprietary modified viscometer not available to the general public. Siems Dep. 28:4-23; 160:7-161:1. The device has a proprietary test programming sequence that includes specific changes in temperatures, rotation periods, and rotation speeds, and uses a uniquely-shaped six-finned vane. Burrows Dep. at 32:20-33:20; Siems Dep. at 160:7-164:2; Carbajal Dep. at 40:4, 41:7. But the '832 Patent does not disclose that these results come from usage of the modified viscometer, nor is there any other intrinsic evidence indicating the type of machine used or whether speeds, temperatures, and periods were applied consistently to different fluids.

Halliburton contends that the differences between the preferred embodiment fluids and prior art fluids would be apparent regardless of vane geometry. However, Halliburton's expert admits that differences in vane geometry affect curve peak height in Brookfield tests. See Clark Dep. at 113:21-114:3. A recent Halliburton Brookfield test—in which both the modified six-finned vane and an unmodified vane were applied to the same Accolade sample at the same speeds—revealed curve peaks that varied as much as about 53%. Report of Jeff Miller ("Miller Rep."), Exhibit B. Meanwhile, the difference between the lowest Accolade peak and the highest Petrofree SF peak in Figure 3 is about 57%. Halliburton's own evidence shows that simple modifications to the vane's shape can make the Brookfield test curves of a preferred-embodiment fluid vary in peak height the same way (and to nearly the same extent) in which that fluid's curves and prior-art fluid's curves supposedly differ in peak height.

Additionally, Halliburton's expert, Dr. Roger Bonnecaze, confirms that by adjusting the vane rotation speed, one can manipulate the torque readings and thus the curve peak height. Bonnecaze Rep. at 14. One of the named inventors, Donald Siems, likewise admitted that adjustments in temperature could also alter the fluids' properties. Siems Dep. at 163:16-164:10.

By adjusting vane geometry, rotation speed, and temperature, one can substantially affect the peak heights of Brookfield test curves independently of the type of fluid being tested. Because the '832 Patent did not adequately disclose the geometry, speed, and temperature parameters surrounding the Figure 3 Brookfield tests, skilled artisans cannot duplicate those parameters. See Honeywell Int'l, Inc. v. Int'l Trade Comm'n, 341 F.3d 1332, 1339-41 (Fed. Cir. 2003) (finding a patent's
failure to disclose test parameters and method rendered claims indefinite because it was impossible to duplicate test results on which claims were based). There is no evidence to verify that the one apparent consistent difference between the preferred-embodiment samples and the prior art samples depicted in Figure 3 is attributable to inherent differences in the fluids' characteristics.

Halliburton also contends that M-I ignores the differences between the Accolade and Petrofree SF fluids depicted in Figure 4. Figure 4 is illustrated below:

GET DRAWING SHEET 5 OF 33

The specification describes the Figure 4 test results:

The time required for the fluids to relax or to return to their pre-stressed state is recorded. The curves for the fluids of the invention seem to level out over time whereas the prior art fluids continue to decline. The leveling out of the curves are believed to indicate that the fluids are returning to a true gel or gel-like structure.

'832 Patent, col. 6:23-29. Halliburton again insists that "the 'L' shaped curve is, in reality, all that is necessary to determine whether a drilling fluid is a 'fragile gel drilling fluid.'" 6 However, this cannot be so. Even cursory examination of Figure 4 shows that the L-shaped curve corresponding to one of the Accolade samples (10.6 Accolade) levels off in precisely the same shape as a curve corresponding to one of the Petrofree SF samples (12.1 SF) and at precisely the same torque level. Two other L-shaped Accolade sample curves (15.6 Accolade and 12.4 Accolade) level off at what appears to be the same rate as another L-shaped Petrofree SF (15.6 SF) sample curve. Finally, the curve of 12.65 Accolade does not even appear to level off.

6 Halliburton's Sur-Rreply at 17 (Docket No. 129).
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

There is no genuine issue of material fact that the "shape of the curves" depicted in Brookfield graphs provide a purely subjective means of identifying whether a fluid exhibits fragile gel behavior. Halliburton argues that, under Datamize, such pure subjectivity does not necessarily render the "shape of the curve" criteria inappropriate and result in indefiniteness. See Datamize, 417 F.3d at 1351 ("[W]hen faced with a purely subjective phrase like 'aesthetically pleasing,' a court must determine whether the patent's specification supplies some standard for measuring the scope of the phrase."). Datamize makes clear that adequate support in the specification can make a purely subjective claim term definite. However, when, as here, the specification provides only a subjective definition for a subjective claim term, there is no "objective anchor" by which skilled artisans can identify the bounds of the claims. Id. at 1350; see Vitronics, 90 F.3d at 1584 (finding inventor's subjective intent as to claim scope, unexpressed in the patent documents, is ineffective).

A skilled artisan cannot verify merely from the "shape of the curve" the bounds of the fragile gel claimed in the '832 Patent. Neither the specification, nor any other intrinsic or extrinsic source identify an alternative way to discern from the Brookfield tests whether a fluid exhibits fragile gel behavior. Therefore, the Brookfield tests do not provide the asserted claims sufficient definiteness.

Other figures in the specification

In addition to Figures 3 and 4, Figures 1A, 1B, 1C, 2, 5, and 10 and Tables 1 and 3 all compare properties of preferred-embodiment fluids and prior art fluids, but none of these figures or tables permit skilled artisans to discern inherent characteristics of the asserted fragile gel drilling fluid. The figures merely compare the effects that preferred-embodiment fluids and prior-art fluids have on certain drilling operations. Figures 1A, 1B, 1C, and 2 compare mud losses incurred during drilling and indicate that use of Accolade samples resulted in loss of less drilling mud than use of prior art samples. See '832 Patent, cols. 3:66-4:5, 4:63-5:51. The figures illustrate a benefit of using the invention over the prior art, but do not shed light on the characteristics that supposedly make Accolade a fragile gel drilling fluid.
Moreover, Halliburton's arguments fail to overcome the presumption of the doctrine of claim differentiation, under which a limitation found in a dependent claim is presumed to not belong to the independent claim because each claim is presumed to require by the specification, and the Court cannot rewrite a claim to make it more definite. See Nova Indus., L.P. v. Micro Molds Corp., 350 F.3d 1348, 1354-57 (Fed. Cir. 2003).

7 The Court notes that the patentees pointed to these figures and tables, in addition to figures 3 and 4, during the prosecution of the '832 Patent. Sept. 2004 Amendment at 31. However, there was no specific discussion of how those figures and tables distinguished the claimed invention from the prior art.

Figure 5 compares the differences in fluid density at certain points in comparable wells ("ECDs") when either Accolade or Petrofree SF is used. See id. at cols. 4:16-21, 6:48-67. Again, though the fluid-density differences are less for both samples of Accolade than for the Petrofree SF sample, there is no evidence that the differences are attributable to fragile gel behavior or other factors such as greater viscoelasticity. See id. at col. 4:30-36.

Figure 10 compares the viscosity of preferred-embodiment samples and prior art samples. See id. at cols. 4:45-48, 9:10-14. The specification asserts that "[t]he base fluid for the drilling fluid of the present invention is one of the thickest or most viscous." Id. at col. 9:13-14. However, this fact does not distinguish the prior-art fluids because Figure 10 shows that one Petrofree sample was even more viscous than the Accolade sample and does not correlate them to the alleged differences in ECDs.

Like Figure 5, Table 1 merely compares ECDs that occur among preferred-embodiment and prior-art fluids. Id. at cols. 7:1-25, 6:48-67. Finally, Table 3 illustrates how a preferred-embodiment fluid is capable of functioning without addition of organophilic clays or lignites. Id. at cols. 11:16-66, 10:62-11:15. But, as noted earlier, the invention's fragile gel properties supposedly exist independent of whether it contains such additives.

Neither the figures or tables shed any light on what makes the present invention a "fragile gel drilling fluid."

Organophilic clay or lignite

The Court next turns to the portion of Halliburton's proposed definition that adds the requirement that a fragile gel drilling fluid contain no or low amounts of organophilic clay or lignite. The Court finds no basis to import that limitation into the definition of a fragile gel drilling fluid. That limitation is imported from a preferred embodiment and is not properly part of the claim construction. The specification describes "the drilling fluid of the present invention[']s" ability to "suspend drill cuttings and weighting materials for delivery to the well surface . . . . through its gel or gel-like characteristics, without need for organophilic clays to add viscosity to the fluid." See '832 Patent, col. 2:43-51. The specification also describes a method for preparing an invert emulsion drilling fluid "that forms fragile gels or that has fragile gel behavior, preferably without the addition of organophilic clays or organophilic lignites." The specification states that "[t]he invert emulsion drilling fluid of the present invention preferably does not have added to it any organophilic clays . . . [and] does not need organophilic clay or organophilic lignites to provide it needed viscosity, suspension characteristics, or filtration control to carry drill cuttings to the well surface." Id. at 3:19-25; 13:66-14:4.

This asserted limitation of no organophilic clay belongs to a group of preferred-embodiment descriptions that the Court cannot read into the claims, absent clear disclaimer or disavowal of the broader scope encompassed by the claim language. See Phillips, 415 F.3d at 1316; Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004); Comark Comm'ns, 156 F.3d at 1187; see also '832 Patent, col. 14:11-15 (stating that descriptions of the invention are intended as descriptions of preferred embodiments). There is no evidence of a clear disclaimer or disavowal, nor is there evidence that skilled artisans would import the additional limitation of the specification's preferred embodiments into the asserted claims. The limitation of no added organophilic clays or lignites is not required by the specification. Instead, the specification states that the "drilling fluid is obtained or prepared . . . preferably without the addition of organophilic clays or organophilic lignites" and "the present invention preferably does not have added to it any organophilic clays." See '832 Patent, cols. 3:19-25, 13:66-67 (emphasis added). Thus, such a limitation may be characteristic of a preferred embodiment, but it is clearly not required by the specification, and the Court cannot rewrite a claim to make it more definite. See Nova Indus., L.P. v. Micro Molds Corp., 350 F.3d 1348, 1354-57 (Fed. Cir. 2003).

Moreover, Halliburton's arguments fail to overcome the presumption of the doctrine of claim differentiation, under which a limitation found in a dependent claim is presumed to not belong to the independent claim because each claim is presumed to
have a different scope. Nazomi Commc'ns, 403 F.3d at 1370; Comark Commc'ns, 156 F.3d at 1187. Numerous dependent claims in the '832 Patent add the limitation of a drilling fluid that forms a structure capable of suspending drill cuttings at rest and that is instantaneously disruptible by movement. '832 Patent, cols. 16:27-29 (Claim 9), 18:31-33 (Claim 42), 19:28-30 (Claim 47), 21:32-34 (Claim 80), 22:28-30 (Claim 85); 24:31-33 (Claim 117), 26:8-11 (Claim 121). Each of the asserted independent claims has dependent claims that add the limitation "wherein said drilling fluid is substantially free of organophilic clay," or "does not require organophilic clays to provide filtration control." Id. at cols. 16:57-58 (Claim 20, dependent on Claim 1), 16:61-62 (Claim 22, indirectly dependent on Claim 1), 19:58-59 (Claim 58, dependent on Claim 2), 19:62-64 (Claim 60, indirectly dependent on Claim 2), 22:57-58 (Claim 95, dependent on Claim 3), 22:61-62 (Claim 97, dependent on Claim 3), 26:20-24 (Claims 125 and 126, dependent on Claim 5). Halliburton's own expert witness, Dr. Ronald Clark, relied on dependent claim 20 for the "substantially free of organic clay" limitation in opining that those of ordinary skill in the art would adopt Halliburton's definition. See Expert Report of Ronald Clark ("Clark Rep.") at 40. 8 The dependent claims are meaningless if, as Halliburton suggests, a fragile gel drilling fluid must contain no or low amounts of organophilic clays. The doctrine of claim differentiation prohibits such an interpretation absent strong evidence that the patentees intended to narrow the independent claims' scope. See Liebel-Flarsheim, 358 F.3d at 910.

--- Footnotes ---

8 Halliburton argues that Dr. Clark merely stated his opinion that the dependent claims describe fragile-gel-drilling-fluid characteristics and did not take the position that Halliburton's definition requires importing the dependent claims' limitations. See Docket No. 125 at 13. However, Dr. Clark's report states that "[s]everal of the dependent claims expressly teach the fragile gel properties," that "Claim 9 teaches that the claimed fragile gel drilling fluid is 'capable of suspending drill cuttings at rest and . . . may be immediately disrupted by movement,'" that "[C]laim 20 teaches that the fragile gel drilling fluid is 'substantially free of organophilic clay,'" and that skilled artisans would "therefore understand that . . . 'fragile gel drilling fluid' would have [Halliburton's proposed construction]." Clark Rep. at 40 (emphasis added). Dr. Clark clearly relied on these dependent claims for adopting Halliburton's definition.

--- End Footnotes ---

Further, nothing in the prosecution history of the '832 Patent that was brought to the Court's attention indicates that the lack of organophilic clay should be a part of the definition. As discussed above, to distinguish the invention from the prior art and rebut the PTO's findings that the prior art disclosed the claimed composition, the patentees stated that the claims are directed to and limited by "a fragile gel drilling fluid or a method of using a fragile gel drilling fluid or a drilling fluid having fragile gel characteristics." Sept. 2004 Amendment at 31. The patentees pointed to several figures and tables in the specification to show those allegedly distinguishing characteristics. At no time did the patentees refer to the organophilic clay limitation as distinguishing the claimed invention from the prior art. The Court will not now add that limitation to the definition of fragile gel drilling fluid without some clear basis to do so.

CONCLUSION

For the foregoing reasons, the asserted claims, i.e. independent Claims 1, 2, 3 and 5 and related dependent claims, are invalid as a matter of law because they are indefinite. The Court is unable to construe "fragile gel drilling fluid" or "fragile gel" such that those terms would have a meaning that is not purely subjective. Accordingly, the Court GRANTS M-I's Motion for Summary Judgment of Invalidity based on indefiniteness. Because the Court has found that the asserted claims of the '832 Patent are indefinite, it is unnecessary to address M-I's allegations of invalidity based on non-enablement or inadequate written description. All other pending motions are DENIED as moot.

GO BACK

1769

1. Claim 1 - "frame"

Bradford proposes that "frame" means "a structure that gives shape or support." Defendants propose that "frame" means "a basic structure, but excluding a substantially continuous surface (i.e., walls), that gives shape or support to the rack container." The difference between the parties' definitions is Defendants' additional limitation that a "frame" cannot have substantially continuous surfaces. In other words, according to Defendants, a "frame" cannot include a "wall".

- 2203 -
The dispute over "frame" is essentially the flip side of the discussion concerning the term "side walls" in the '119 Patent. As will be recalled, as to the '119 Patent, the issue was whether "side walls" requires substantially, continuous surfaces. The Court held that it does because the specification of '119 Patent consistently uses "side walls" in reference to embodiments with substantially continuous surfaces and "sides" in reference to embodiments without substantially continuous surfaces (i.e., embodiments with a frame-like structure).

"There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." The Toro Co. v. White Consol. Ind., Inc., 199 F.3d 1295, 1302 (Fed. Cir. 1999). Moreover, the same claim term in related patents is presumed to carry the same construction. Omega Eng., Inc. v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003). The corollary to both of these propositions would be that different terms in related patents are presumed to have different meanings.

As indicated above, the '916 Patent is a divisional application of '119 Patent. Therefore, it is presumed that "side walls" in the '119 Patent carries a different meaning from "frame" in the '096 Patent. If "frame" were construed to include substantially continuous surfaces, then "side walls" would be rendered superfluous. Additionally, if "frame" encompassed containers with substantially continuous surfaces, there would presumably be a problem with double-patenting vis-a-vis the '119 Patent. Finally, the Court again points out that in prosecuting the '119 Patent office, Bradford argued that containers with frame-like structures, such as that claimed by Janus, do not teach "side walls". Therefore, for all of those reasons, the Court agrees with Defendants that "frame" must exclude substantially continuous surfaces.

Accordingly, the Court holds that "frame" means "a basic structure, but excluding a substantially continuous surface (i.e., walls), that gives shape or support to the rack container."

**ii. Frame**

The Plaintiffs contend that the term "frame" should be construed as: the entirety of the frame with the exception of the lenses and including the lens rims (if provided), the frame magnetic members, the nose bridge, and the arms. Crucially, Plaintiffs insist that the term "frame" should be read to encompass both rimmed and rimless eyeglasses, such that a frame made up only of pins or screws is as much a "frame" as one taking the form of a rim around the lenses. The Defendant, on the other hand, argues that a "frame" is an eyeglass device that includes, at least, a bridge and rims. Defendants insist that the rims have to at least partially surround the lenses and, if the rims do not completely encircle the lenses, the frame must include some sort of rim wire to hold the lenses in place.

Defendant's argument, which focuses on the language of the claim itself, is more faithful to the principles of claim construction outlined in Phillips, and is more persuasive to this court. As Defendant points out, the relevant claim describes the frame as supporting lenses "therein" and "including" a middle bridge portion. Because the claim discloses a frame that supports lenses "therein," the frame must be capable of supporting the lenses in the frame, and only a frame with rims is capable of supporting lenses in the frame. In addition, the claim language requires that the frame "include" a middle bridge portion, which indicates that the frame must also have other components, i.e. rims. Therefore, considering the term "frame" in the context in which the term is used in the asserted claims, which the Federal Circuit instructed district courts to do at the outset of their claim construction analysis, see Phillips, supra, strongly compels the finding that the term "frame" includes some kind of rim surrounding the lenses.

This conclusion is supported by an analysis of the specification. Specifically, the Patents-in-Suit are devoid of any language disclosing any kind of "frames" other than those containing rims. On the contrary, the specification of the '054 Patent discloses "an eyeglass device in accordance with the present invention comprises a primary spectacle frame 10 for supporting primary lenses therein," col. 1, l. 66 -- col. 2, l. 2, and explains that "an auxiliary spectacle frame 20 is provided for supporting the auxiliary lenses therein," col. 2, ll. 7-9; crucially, the primary spectacle frame 10 in Figures 1 and 2 and the auxiliary spectacle frame 20 in Figures 1-3 of the '054 Patent all include rims. In fact, each of the over thirty diagrams and figures in the Patents-in-Suit disclose eyeglass devices that clearly include rims.
Plaintiffs respond by pointing to a series of generalized disclaimers explaining that the specifications provided in the Patents-in-Suit are not intended to foreclose other variations that are within the scope of the claims. See, e.g., '054 Patent, col. 2, ll. 56-62 ("Although this invention has been described with a certain degree of particularity, it is to be understood that the present disclosure has been made by way of example only and that numerous changes in the detailed construction and the combination and arrangement of parts may be resorted to without departing from the spirit and scope of the invention hereinafter claimed."). Although this court is mindful of the Federal Circuit's repeated admonition to avoid "reading limitations from the specification into the claim," Phillips, 415 F.3d at 1323, 2 Plaintiffs' generalized statements are nevertheless unpersuasive, for several reasons.

2 That said, this court agrees with the Federal Circuit that the distinction between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim can be a difficult one to apply in practice. See Phillips, 415 F.3d at 1323 (citing Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186-87 (Fed. Cir. 1998) ("there is sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification").

First, Plaintiffs have pointed to various places in the Patents-in-Suit in which the patentee described specific ways in which the disclosed inventions could be changed. See '811 Patent, col. 6, ll. 33-35 (acknowledging that an illustration shows a magnetic member with only one or two parts, but explaining "that a magnetic member can have more than two parts"); '896 Patent, col. 6, ll. 50-53 (same); '811 Patent, col. 8, 1. 65 -- col. 9, 1. 1 ("Different embodiments in the present invention can be combined in different ways. For example, the vertical flange can be combined with the lateral flanges. The hinge can be combined with the lateral flanges."); '896 Patent, col., 9, ll. 22-25 (same). 3 The absence of any specific statement about the possibility of frames with or without rims argues against construing the term "frames" to include rimless frames. Generalized disclaimers provide no guidance in defining which variations are within the scope of claim language and which are not. See Les Traitements Des Eaux Poseidon v. Kwi, Inc., 135 F. Supp. 2d 126, 135 (D. Mass 2001) (boilerplate language in the specification asserting that the general description is non-restrictive carries "little weight"). Therefore, the court finds that the specifications in the '054 Patent and the other Patents-in-Suit clearly suggest that "frames" include rims.

3 Admittedly, two of the Patents-in-Suit also contain language explaining that, "different types of auxiliary frames and different forms of primary frames, individually, is also a different embodiment of the present invention." '811 Patent, col. 9, ll. 7-9; '896 Patent, col. 9, ll. 31-33. But this language simply begs the question of whether "frames" can be rimless. It says nothing about the ways in which frames can differ from each other, and can easily be read as allowing for frames with rims made up of different materials.

In addition, Plaintiffs argue that this court should be persuaded by other district courts that have rejected many, if not all, of Defendant's arguments and adopted Plaintiffs' interpretation of the term "frame" in the '054 Patent and in related patents. See Aspex Eye-wear, Inc. and Contour Optik, Inc. v. E'Lite Optik, Inc. (Dist. Ct. Nev. CV-S-00-1116-PMP (PAL)) (finding that the term "frame" in both the '054 and '811 Patents refers to both rimmed and rimless spectacles because it is commonly understood to refer to some structures that surround an object and other structures that connect parts but do not surround anything); Aspex Eyewear, Inc. v. Miracle Optics, Inc., 2003 U.S. Dist. LEXIS 26355, (C. Dist. Cal. CV 01-10396 (Order Construing Claims, p. 37-38, February 14, 2003) (refusing to construe the term "primary frame" (in a different patent) as requiring a pair of lens rims of a continuous eye-loop type because the claim language is broader and the specification does not require a particular type of lens rim construction). Although this court has reviewed these decisions, the court is not persuaded by them.

First, these decisions were made before the Federal Circuit clarified the principles of claim construction in Phillips. Second, the unwillingness of the Federal Circuit to itself give any deference to the claim construction findings of District Courts further dissuades this court from giving significant precedential value to judgments of its colleagues. See Cybor Corp. v.
FAS Techs., 138 F.3d 1448, 1455 (Fed. Cir. 1998) (the Supreme Court endorsed this court's role in providing national uniformity to the construction of a patent claim, a role that would be impeded if we were bound to give deference to a trial judge's asserted factual determinations incident to claim construction). Evidently, the Federal Circuit believes that it is its responsibility--not the collective responsibility of federal courts--to ensure uniformity of claim construction, and the Federal Circuit will likely have the opportunity to bring uniformity to the construction of the claim language at issue in this case.

4 Plaintiffs and Defendant support their arguments with testimony from outside experts and other sources. For example, Plaintiffs point to the Defendant's marketing materials, which allegedly refer to frames as "frames" even when they are rimless, and to testimony by Richard Chao, one of the inventors. The Defendant supports its argument with expert testimony from Allen Leck, who claims that the ordinary meaning of the term "frame" to a person having skill in the eyeglasses industry is that it should include at least a bridge and rims. Plaintiffs have filed a motion to exclude Mr. Leck's testimony. The court finds none of this evidence to be particularly helpful, particularly in light of the intrinsic evidence, which provides the basis for this court's interpretations. As such, the court declines to reach Plaintiffs' motion to exclude Mr. Leck's testimony at this time.

Therefore, the court finds that a "frame" is an eyeglass device that includes, at least, a bridge and rims.
The specification defines frame broadly. First, it states that the frame may comprise side rails, may comprise end rails, and that "the end rails and the side rails need not interrelate at all, but could simply be attached to the respective interior opposing side walls of the mounting surface of the table top." 3 (Id. at 5:42, 6:22, 6:67.) The specification also states that "the frame may be configured in a variety of shapes and configurations, including, but not limited to, a circle, polygon, square, rectangle, triangle, or any other suitable geometric configuration." (Id. at 7:13.) In these ways, the specification indicates that the term "frame" should be broadly construed to include structures that consist only of side rails.

This construction is also supported by the ordinary meaning of the term "frame." See Texas Digital Sys., 308 F.3d at 1202. The dictionary lists two possible definitions: (1) "something composed of parts fitted together and united" and (2) "the constructional system that gives shape and strength." 4 The first definition would require that the frame components be "fitted together and united," so this definition would exclude frames consisting of side rails because side rails are neither fitted together nor united. The second definition is much broader and would include many different types of frames. The second definition is consistent with the patent's claims and specification, which indicate that a frame can consist solely of side rails. **We therefore construe the term "frame" broadly to include structures consisting only of side rails.**

--- Footnotes --

3 Throughout this claim construction, all bolded numbers in the specification, which refer to the specification's figures, have been omitted.

4 Throughout this claim construction, the ordinary meaning of all terms were obtained from the Merriam-Webster Online Dictionary. This dictionary is located at <<UNDERLINE>www.m-w.com> and was last accessed by this Court on May 18, 2004.

--- End Footnotes ---
U.S. Dist. LEXIS 26355, No. CV 01-10396 (C.D.Cal. February 14, 2003); See Contour's Mot., Ex. E. In Miracle, the court considered whether the accused device avoided infringement by including "rim locks," "a structure built in the lens rim … which allows the spectacle frame to be opened so that lenses can be easily inserted," in the frame. Id. at 11-13. Although the specification did not contain pictures of the design with rim locks, the court held the term "primary spectacle frame" included: "the lens rims (if provided), nose bridge, extensions, projections (if provided), the first magnetic member and conceivably rim locks." Id. at 13. The claims construed by the Miracle court were as follows: "a primary spectacle frame having two side portion extensions, each of said extensions having a front side, a rear side and a first magnetic member secured to said rear side" or "a primary frame adapted to support an auxiliary frame, which includes a first bridge and two sides …" Id. at 6-8.

The Court is persuaded by Contour's argument that nothing in the wording of patents '054 or '811 limits the term "frame" to the narrow interpretation proposed by E'Lite. Because "frame" is commonly understood to refer to some structures that surround an object and other structures that connect parts but do not surround anything, the Court construes the patent to refer to both kinds of structures. Consequently, the Court interprets the words "second or auxiliary frame" in Claims 1 and 31 of the '811 patent to include both rimmed and rimless spectacles and concludes that a lens may be supported "therein" if they are secured to the frame.

The C-Clip, which connects the secondary lenses with a foldable metal bridge, contains an element that corresponds to a "frame" as used in the '054 and '811 patent claims. Thus, this defense proffered by E'Lite against Contour's charge of infringement fails.

1774

A. Frame

PMG's proposed interpretation of the term "frame" is that a frame is "generally a multi-element structure and … that the frame actually claimed in Claim 15 is a frame with rocker arms and base supports." Mem. in Supp. of PMG's Renewed Mot. for Summ. J. at 15.

Federal's proposed interpretation of the term "frame" is that a frame is a "structure (which may consist of one or more elements) that supports two or more spikes and that includes holes into which the spikes are inserted." Defs.' Opp'n to Pl.'s Renewed Mot. for Summ. J. at 3.

PMG asserts that the plain meaning of the word "frame” excludes Federal's proposed interpretation and that an examination of the patent specification shows that the term "frame" refers to a rocker arm and base support arrangement as disclosed in the patent specification. PMG further asserts that the prosecution history precludes the interpretation advanced by Federal because the patent applicants expressly limited themselves to the frame as set forth in the patent specification.

This Court disagrees with plaintiff PMG and finds that, following a review of the patent's claim, specification, and prosecution history, the ordinary meaning of the word "frame” does not require the frame to have base supports and rocker arms. Further, this Court believes that the patent specification does not require this Court to adopt the narrow or limiting interpretation of the term "frame,” as being only a type of frame with rocker arms and base supports. Finally, this Court agrees with Federal that the prosecution history broadens rather than narrows the scope of Claim 15.

Consequently, this Court, following a review of the claim, specification, and prosecution history, interprets the '373 frame element as being a structure, which may consist of one or more elements, that supports two or more spikes and that includes holes into which the spikes are inserted.

1775

1. Claim 1, Element 1, "frame"
To define frame, BMS proposes: "A pre-assembled unit with a top jamb, and two side jambs that is ready for insertion into a
doors opening in a wall." Endura proposes that the definition be merely: "Spaced vertical side jambs connected at the top by
a horizontal top jamb, and excluding a sill."

Both sides agree that a frame has a top jamb and two side jambs, which is in the language of the claim itself. The points
of contention are whether one skilled in the art would understand from the definition that the frame is pre-assembled, whether
it is ready for insertion into a door opening, and whether it would exclude a sill.

The patentee did not demonstrate a clear intent to deviate from the ordinary and accustomed meaning of the term "frame" by
redefining the term in the specifications. See Johnson Worldwide, 175 F.3d at 990. Such a claim should be read in
accordance with precepts of English grammar, and with the presumption that the ordinary and accustomed meaning
attributed to the term, by those skilled in the art, is correct. Of course the claim should be read in view of the specification,
which cannot expand the scope of the claim, but can provide guidance as to its meaning.

Endura's proposed definition incorporates language from Col. 2, l. 25-27: "The door frame F is comprised of spaced vertical
side jambs 1 and 2 connected together at the top by a horizontal top jamb." BMS uses the same language at page 13 of its
initial brief on claim construction. While a description of a preferred embodiment is instructive, it is not, per se, a definition
of a claim term.

The first point of contention is whether, in the context of this claim, a "frame" is pre-assembled. Neither claim 1, the
independent claim, nor claim 2, the dependent claim, refer to a kit with parts for a frame, or to a group of separate parts
which may be put together into a frame. The claim starts with "A frame comprising . . . ." Endura's own proposed definition
states: "side jambs connected together at the top by a horizontal top jamb . . . ." Even Endura does not propose a set or group
of parts, or a kit containing parts, which may be assembled into a frame. It seems evident that until the parts are connected
or assembled, there is no frame, so a "frame" must be already assembled or pre-assembled.

The abstract, drawings, and specification comport with this interpretation. The abstract states that the members are
connected to provide "a single, low cost structure." Figure 1 shows a complete door frame. The "Background of the
Invention" describes providing builders with completed frames, built from scrap lumber, which can be installed more easily,
and cheaply installed than a custom frame. There is no indication anywhere that the claim was intended to cover, or could
cover, a kit or group of parts which could be sold to a builder and assembled into a frame.

Finally, a definition that states that a "frame" is an assembled unit, or is something composed of parts connected together,
tacks the definitions found in standard dictionaries relied upon by Endura. See Meriam-Websters Collegiate Dictionary 462
(10th ed. 2002) ("something composed of parts and fitted together and united") (emphasis added); Websters Encyclopedic
Unabridged Dictionary of the English Language 563 (1989) ("a rigid structure formed of relatively slender pieces joined so
as to surround . . . .") (emphasis added).

BMS's proposed definition also adds the phrase "ready for insertion into a door opening in a wall." Nothing in the claim
language indicates, or even hints, that the frame is ready to be inserted into a wall opening. There is no telling what type of
additional hardware, spacers, fasteners, and lumber might be needed to prepare a hole in the wall, or the frame itself, for
installation. Col. 3, l. 14-17, indicates that in the preferred embodiment a door frame would be ready for placement into a
doors opening, but the claim language is not so limited, and this language will not be added to the definition.

On the other hand, Endura's proposed definition includes the words "and excluding a sill." The claim language sets out
clearly what comprises the frame, namely a top jamb and two side jambs. It would be possible to list dozens of other items
which are not part of the frame, such as the door, the door knob, the hinges, the insulation around the frame, etc., but that
would not add much clarity to the definition. Endura's attorney indicated that inclusion of the language might be helpful in
an anticipated patent dispute, but that matter can be resolved when it arises. Therefore, the court interprets this term as
follows:

"frame" means: "an assembled structure composed of two spaced side jambs connected together at the top by a horizontal
top jamb."
1776
i. "Ear Warmer Frame"

As both 180s and Gordini propose, I construe "ear warmer frame" as "a structure that supports a device worn on or over the ears whose primary function is to keep ears warm." (See id. at 9; Def. Gordini's Response to 180s [sic] Initial Markman Claim Constr. Brief ("Def.'s Response") at 3.)

1777

"Frame Including a Pair of Generally Disposed Side Rails"

The parties' competing definitions of this term are set forth in Table 3.

Table 3 - Parties' Claim Constructions for Claim 92 of the '092 Patent

<table>
<thead>
<tr>
<th>Term, Patent, and Ind. Claim</th>
<th>Pl.'s Interp.</th>
<th>Def.'s Interp.</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame including a pair of generally disposed side rails</td>
<td>Lifetime's interpretation: &quot;A frame may consist only of side rails alone.&quot; (Lifetime's Rep. in Supp. (30) at 12-13.)</td>
<td>Correll's interpretation: &quot;Structure that is composed of parts fitted together and united that may include side rails, but is not composed only of side rails.&quot; (Correll's Mem. in Opp. (22) at 23.)</td>
</tr>
</tbody>
</table>

Much like the term "retaining assembly including a cross brace member," the construction of this term turns on the word including. The parties' arguments are similar to those made in connection with the previous term. Correll contends that use of the word including means that the frame requires both generally parallel side rails and other parts. Lifetime takes the position that although side rails are required, other parts are not.

"Frame" means "a rigid structure formed of relatively slender pieces, joined so as to surround sizable empty spaces or nonstructural panels, and generally used as a major support in buildings or engineering works, machinery, furniture, etc." Webster's at 760.

The specification expressly teaches that the frame may be made of two side rails alone, or it may be made of two end rails alone. The specification reads:

The frame 40 may comprise a first side rail 42 and an opposing second side rail 44. Preferably, the first side rail 42 is disposed substantially parallel the opposing second side rail 44. … The frame 40 may also comprise a first end rail 54 and an opposing second end rail 56. Preferably, the first end rail 54 is disposed substantially parallel to the opposing end rail 56. (Sears Decl., Ex. A, '092 Patent at col. 5, ins. 43-46; id. at col. 6, ins. 22-25.)

The same analysis under Amgen that applied to the retaining assembly element applies here, leading to the conclusion that while the frame must contain either generally parallel side or end rails, other components may be added to the frame, but are not required. 7

--- Footnotes ---

7 Based on the definition of the word frame, Correll argues that the side rails must be "united" by some structure to form a frame. As noted above, the ordinary meaning of the word frame does require that the parts of the frame be joined, but does
not require that the parts be joined by another part of the frame. In the present case, the parts of the frame of the Correll table are joined; they are joined by the table top. Under the ordinary meaning of frame and the teachings of the specification, that is enough.

The specification also demonstrates that the frame does not necessarily have to provide support to the table:

In one presently preferred embodiment of the present invention, the frame 40 is formed of a substantially sturdy, rigid material sufficient to provide structural integrity to the table top 12. For example, the frame 40 may be formed of metal. However, it will be readily appreciated that the frame may be formed of a wide variety of other suitable materials which are consistent with the spirit and scope of the present invention. It will further be appreciated that the size and configuration of the frame 40 will depend, in part, on the size and configuration of the table top 12.

(Id. at col. 7, lines 4-13.)

Based on the above, the court's construction of frame including a pair of generally disposed side rails is: A structure formed of relatively slender pieces or parts, fitted or joined to the table, that may be side rails alone or end rails alone, and other components may also be added, but are not required.

8 In the context of claim 34 of the '331 Patent, the parties again dispute the interpretation of the term "frame," but this time do so as a singular term and without any modifying limitations, as were present above. Because the interpretation of "frame including a pair of generally disposed side rails" of claim 92 of the '092 Patent necessarily provides a construction of the word frame, there is no need to define that word again, or to look again to the intrinsic record for guidance as to its meaning with respect to the '331 Patent.

3 Material fact disputes regarding both accused products would preclude summary judgment on the issue of infringement as to this element. There is a fact question whether both the Icebreaker and Universal have a frame: the Icebreaker's mesh cage and cape lid arguably comprise a frame, and the Universal's cage and support bar arguably serve a frame. Also, the superior portions of both products' frames extend above the flue opening when mounted on the flue. In addition, even if these products do not literally infringe element (a), the evidence suggests that the differences between them and the claimed product are insubstantial.
3. Frangible Portion

The term "frangible portion" appears throughout the '097 patent and the reexamined '097 patent and specifically in asserted claims 11, 24, 25, 27, 32, 34, 35, 39, and 40-42. While used as a single term, this phrase is better defined by its parts. First, Webster's Universal defines "frangible" as, "easily broken; breakable" or, as in Webster's Third, "capable of being broken." Webster's Universal, Stant Ex. 103, p. 761; Webster's Third, Gerdes Ex. 228. Portion is defined, in relevant part, as "a part of a whole." Webster's Universal, Stant Ex. 103, p. 1768.

In claims of the reexamined '097 patent, the patentee describes a fuel cap in which "an impact will fracture said frangible portion of said first flange leaving said housing and said second flange intact to seal said neck." Reexamined '097 patent, col. 1, 11. 58-61. In the dependent claims, the patentee further describes this frangible portion as "positioned to lie between the first and second housing" and formed by a "groove in the axially upper portion of the housing to weaken the axially upper portion of the housing to form the frangible portion of the housing." Id. at col. 2, 11. 43-49. Similarly, in Claims 34, 35, and 42, and their dependent claims, the frangible portion is carefully described as "formed in the housing to lie between the first and second flanges," id. at col. 3, 11. 51-52, or "between the outer cover and the second flange," id. at col. 3, 11. 62-63. These claims, in combination with the specification which describes a "frangible portion" of the first flange designed "to allow the cover to break away due to an impact without breaking the housing itself," evidence a clear intention to use "frangible portion" in its ordinary manner -- that is, to describe a part of the structure that is able to be broken.

Nothing in the claims or specification suggests that the patentee gave the term an extraordinary meaning such as that advanced by Gerdes. The court disagrees with Gerdes' suggestion that the definition should reflect the patentee's intent in including a "frangible portion" in the invention. When it is necessary to do so, the patentee adequately describes the term such that its purpose, that is, the reason it was included and its function in the invention, is clear to the reader of the claims and the specification. Thus, the court does not believe that it was the patentee's intent to have any limitation on the purpose of the "frangible portion" read specifically into the definition of the term itself. Thus, the court finds no reason to do so either. See Int'l Rectifier Corp., 361 F.3d at 1370.

The court also disagrees with Stant's argument that the ordinary meaning of "frangible" requires qualification as "easily breakable." The term "easily" is imprecise and indefinite. If the court adopted Stant's position, people with ordinary skill in the art may read this term very differently depending on how "easily" one determines that the structure must break. For example, nothing in the claims or the specification makes clear the amount of force required to break the structure. Under this definition, a potential competitor would have to determine whether his or her invention breaks too easily, not easily enough, or with just the right amount of ease to constitute an infringement of the claimed fuel cap. This certainly does not provide the potential competitor with the required precise definition that would allow the competitor to know whether he is infringing. See Morton Int'l, Inc. v. Cardinal Chem. Co., 5 F.3d 1464, 1470 (Fed. Cir. 1993).

For these reasons, the court finds that the definition of "frangible portion" is a part of a whole that is capable of being broken.

2. Claim Term Two - "Free"

The term "free" is found in Claims 1-5, 7, 11-13, and 16-18 of the '057 patent, and in Claims 1-5, 7 and 11 of the '704 patent. Plaintiff asks this Court to construe the term as the portion of the rod extending from the base to the extremity of the rod, which is not restrained from moving, and encompassing a rod with either one or two "free" ends. Plaintiff bases its argument on the specific claims contained in the '057 and '704 patents. In addition, plaintiff introduces extrinsic evidence in
the form of the Federal Circuit's November 18, 2003, decision and expert testimony from R. Lee Rawls.

Defendant asks this Court to construe the term "free" as an end of the rod that is unsupported except through the rod itself and therefore is able to move such that when it moves, the rod bends in a bow like fashion. Defendant bases its argument on a dictionary definition from Merriam Webster's Ninth New Collegiate Dictionary, as well as the specific claims and figures in the '704 and '057 patents. Defendant also offers extrinsic evidence in the form of expert testimony from Evan R. Flavell.

In the context of this patent, the term "free" is used to refer to an end of one of the rods. For example, "one end of each of the rods being free," "the free ends of the rods," and "the other end being free." '057 Patent at 7:52, 7:63-64 and 7:66-67 and '704 Patent at 7:33. The specifications of the patents describe a "free end" as the portion of the rod that "extends upward from retainer 36 and base 10." '057 Patent at 3:44-45 and '704 Patent at 4:3-5. The specification further details "[t]he rods are thus free to bend in bow-like fashion, as illustrated in FIGS. 12-22, and produce a force in opposition to the force which bends them." '057 Patent at 3:51-54.

The common definition of "free" is "not hampered or restricted," "not fastened" or "not confined to a particular place." Webster's Ninth New Collegiate Dictionary, at 490 (1990). It does not appear that, in the context of the patent, this definition applies exactly. For example, while the ends of the rods are described as being "free," they are in fact, somewhat restricted by the bolts holding each rod in place, and by the cable attached to the rod. Thus, the common definition must be somewhat altered to define the term "free" as it applies to the rods. The Court finds that a combination of the parties' definitions -- the unsupported portion of the rod that is free to move about relative to the fixed mounting point so that the rod is able to bend in a bow-like fashion -- embodies the meaning of free in this context.

This definition is supported by plaintiff's expert testimony. Mr. Rawls testified that the term "free" means "a portion of the rod extending from the base to the opposite tip of the rods, which is free to move about relative to the fixed mounting point." (Dkt. # 316 at 7). Mr. Rawls emphasizes that this definition recognizes that a rod may have two free ends, and does not require a rod to have one free end and one fixed end. (Dkt. # 316 at 7). This follows the Court's determination, infra, that a rod mounted in cantilevered fashion may also encompass two free ends. Furthermore, the Federal Circuit Court of Appeals has also noted that the language of the claims does not require a fixed end limitation. (See Dkt. # 243, Ex. 1 at 6-7). Accordingly, the Court finds that the proper construction of the term "free" is the unsupported portion of the rod that is free to move about relative to the fixed mounting point so that the rod is able to bend in a bow-like fashion.

1781

c. "free along substantially their entire length"

This term was not defined in the '364 patent specification, but the term was defined by Orr in her argument in support of Amendment A distinguishing prior art, namely, the Santoni patent, the Graham patent, and the Lawson patent. Specifically, Orr stated that the "connection only in the waist area at the side of the garment is vital to the function of the invention." Amendment A at 4, Defendants' Appendix at 53 (emphasis added). This language allowed Orr to successfully distinguish the Graham and the Lawson patents.

The Graham patent included stitching that connected the crotch opening in the crotch area between the legs. Likewise, the Lawson patent had a button that connected the crotch opening in the crotch area between the legs. As a result, the Graham and Lawson patents feature garments that have free edges in the front and in the rear but are connected by stitching or a button in the crotch area between the legs. Orr successfully distinguished the '364 patent by explaining that edges in the '364 patent were different because they are free along substantially their entire length. Amendment A at 11-12, Defendants' Appendix at 60-61.

In addition, when distinguishing the '364 patent from the Graham and Lawson patents, Orr specifically narrowed the '364 patent's scope to exclude all garments that include crotch structures with mechanical closure devices. Orr stated, "[r]ather than simply an openable crotch structure, the Applicant claims a specific garment crotch structure that is adapted to remain closed in normal use and even during strenuous exercise, but still allows manual opening without having to remove the garment and without having to use mechanical enclosure devices such as zippers or . . . buttons." Amendment A at 13, Defendants' Appendix at 62 (emphasis added).
The court construes the term "free along substantially their entire length" to mean that the edges are not connected to the garment along their length except in the waist area of the garment in the front and in the rear at or near the sides of the garment.

1782

The first term in dispute is "a free distal end forming a handle spaced outwardly therefrom." One World asks me to construe the term as meaning "a handle formed at the other end of the arm assembly." Rexon does not dispute this choice of words, but argues that it is an incomplete definition, which ignores language about the spacing of the handle. Rexon's proposed construction defines the distal end in relation to the fixed end of the machine, i.e., as its opposite. This limitation is supported by language in the specification that is cited by both parties. (976 Patent, Col. 4, ll. 3-4) ("a handle 66 at the opposite end of the arm assembly 62"). For this reason, I construe the disputed term as "a handle at the end of the arm assembly opposite the fixed end, and spaced away from the distal end."

1783

6) the term "free edge" means "an edge which is not connected to the hanger body or hook;"

1784

c. "free edge of material"

The court construes the term "free edge of material" to mean that the material that has a free edge is not connected to anything -- i.e., there is no closure mechanism similar to the stitching used in Graham or the button used in Lawson. Accordingly, any of the defendants' garments that has a closure mechanism will be outside the '364 patent's limitations because such a garment will not have a first or second "free edge of material extending from the first [or second] crotch portion front and rear substantially to the waist area at the left [or right] side of the garment." Claim seven, Defendants' Appendix at 10. To interpret this term in any other manner would read on prior art -- Graham and Lawson -- and therefore invalidate the '364 patent. See Harris Corporation, 114 F.3d at 1153.

1785

Aspex contends that "a rearwardly directed free end for securing a magnetic member" means "an unattached end of the auxiliary spectacle frame arm for connecting directly or indirectly to a magnetic member, in a manner such that the connection is not likely to fail or give way." Ps. Br. 16. Aspex also argues--as it did concerning claim 18--that "magnetic member" means "either a permanent magnet or ferromagnetic member, but at least either the first or second magnetic members must be a permanent magnet." Ps. Br. 16. E'Lite posits that the limitation should be construed to mean "a rearwardly directed end portion for securing a magnet." D. Br. 23. As with claim 18, E'Lite maintains that the phrase "magnetic member" need not be construed. For the reasons set out supra at § III(D)(1), the court concludes that it is unnecessary to construe the term "magnetic member."

E'Lite accepts Aspex's construction of "secure" with the exception of "or indirectly." As with claim 18, Aspex provides no support for adding "or indirectly" to its construction of "secure." Even if the addition of "or indirectly" does not alter the meaning of this limitation, it inserts more ambiguity into claim 23 than without it. The court therefore rejects the use of this phrase. Thus the only remaining term at issue in this disputed limitation is "free end."

Aspex argues that its construction is consistent with the ordinary meaning of the word "free" and the disclosure of the specification. Aspex relies on FIG. 7 and the description of the preferred embodiment to support its position that each
auxiliary frame arm 21 has an unattached end that secures a magnetic member 22. E'Lite responds that Aspex's construction of "free end" as "unattached end" makes no sense, because the "free end" is attached to the arm of the auxiliary frame.

E'Lite argues that the '545 patent's description of this limitation is indefinite, and that, other than its appearance in claim 23, there is no mention, description, indication, figure reference, or any other support for the use of "free end" in the specification. In describing the area of the invention where the "free ends" should be, the specification simply refers to the "end portions" of the auxiliary frame's arms. D. App. 8. E'Lite maintains that the best construction of "free end" is "end portion."

The court holds that the best construction of "free end" is "end portion." First, construing "free end" to mean "unattached end," without qualification, is inconsistent with the undeniable requirement that the "free end" be attached to the auxiliary arm. Even with this qualification, however, Aspex's proposed construction is misleading. "Unattached" is the negative of the adjective "attached," which means "(t)acked on, fastened by material union to . . . [or] (j)oined functionally[.]" Oxford English Dictionary (Oxford Univ. Press, 2d ed. 1989); see Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002) ("The ordinary meaning of a claim term may be determined by reviewing a variety of sources, including . . . dictionaries and treatises[.]"). Construing "free end" as "unattached end" could limit the "free end" to the small part of the auxiliary frame arm 21 that is depicted to the left of the magnetic member 22 in FIG. 7. But limiting "free end" in this way is inconsistent with the claim language of claim 23: "and a pair of magnetic members respectively secured in the free ends of said arms." D. App. 9-10. Considering FIG. 7, on which Aspex heavily relies, the magnetic member 22 is secured to the auxiliary frame arms on both the left and the right sides of the magnetic member 22, as depicted in FIG. 7. The right side of the auxiliary frame arm 21 that helps to secure magnetic member 22 is also in contact (i.e., material union) with the primary frame spectacle (part 11). Thus a piece of the auxiliary frame arm that secures the magnetic members (what claim 23 calls the "free ends") can also be materially united or functionally joined to the primary spectacle frame. Construing "free end" as "unattached end" is not necessarily in conflict with claim 23's language, if unattached means "not permanently fixed" (or some form of physical union that is more than mere contact). But "unattached end" also lends support to a reading of the term that is inconsistent with the plain language of claim 23, if unattached means "not materially united" or "not functionally joined." The court rejects construing "free end" as "unattached end" because this term could convey an inaccurate understanding of the invention.

The court holds that "end portion" is the best construction of "free end," because the '545 patent does not use "free ends" at all in the specification, but it does use the phrase "end portion" when describing the part of the invention where the "free ends" would be. See D. App. 8.

Accordingly, the court construes "a rearwardly directed free end for securing a magnetic member" to mean "a rearwardly directed end portion for connecting a magnetic member in a manner such that the connection is not likely to fail or give way."

The parties also disagree on the meaning of "free from play" in claims 15 and 65 of the '486 patent. Initially, Unilin argued that the phrase means those panel separation directions are "free from visible spaces (as viewed by a user from a normal height) so as to prevent free movement in the joint" in the vertical and horizontal disassembly directions. (Unilin Open. Br. 19-20.) In its initial and response briefs, Alloc maintained that "free from play" means that "the joint must have no space in all separation directions in a plane extending in a perpendicular direction from the side edges of the panels." (Alloc Initial Mem. 18.)

At the Markman hearing, Alloc proposed a new five point definition of "free from play":

1. "free from" means "without" Glaxo Group Ltd. v. Ranbaxy Pharm., Inc., 262 F.3d 1333, 1336 (Fed. Cir. 2001);

2. "play" is a dimensional relationship between contact surfaces whereby there is a separation or space, or an ability for the surfaces to move relative to each other;
"free from play means an absence of play at the time panels are installed, and also subsequent to installation following the expansion and shrinkage in accordance with normal use;

ease of displacement along a joined edge is indicative of play; and

the absence of visible gaps.

Given Alloc's advocacy of a new definition of "free from play," the Court allowed the parties to submit post-hearing briefs addressing that definition and to allow Unilin an opportunity to propose a new definition.

In its post-hearing brief, Unilin modified its original proposed definition of "free from play" suggesting that the term be defined as: "no space between the upper contact surfaces and the lower contact surfaces of the coupling parts, as to lock the coupled panels together in the horizontal positions." (Unilin Post Markman Open. Br. 3.) In its response brief, Unilin states "free from play" means "there are no spaces between the contact surfaces so that the panels are locked in the horizontal and vertical directions." (Unilin's Post Markman Resp. Br. 1.)

Unilin states that to a degree, Alloc's proposed construction is consistent with its revised definition. But, Unilin asserts that Alloc is improperly attempting to read in the following limitations:

- an ability for the surfaces to move relative to each other;
- "an absence of play . . . subsequent to installation following the expansion and shrinkage in accordance with normal use;
- ease of displacement along a joined edge is indicative of play; and,
- the absence of visible gaps at the upper surface does not rule out the presence of play.

Unilin maintains that neither the intrinsic nor the extrinsic evidence justify these additional limitations. (Id.)

Unilin states that "an ability for the surfaces to move relative to each other" encompasses movement which is not play, because the definition would include the "sliding" of the panels relative to one another which is contrary to the ordinary meaning of "play" and the teachings of the specification. (Id. at 1-2.) Unilin also asserts that "an absence of play . . . subsequent to installation following the expansion and shrinkage in accordance with normal use" and the "ease of displacement along a joined edge is indicative of play" are tests for play that should not be included in the construction. (Id.) Additionally, Unilin maintains that "an absence of play . . . subsequent to installation following the expansion and shrinkage in accordance with normal use" is an attempt to read in a limitation from a preferred embodiment. (Id. at 3.)

"Free from play" appears in claim 15 as follows: "A floor covering panel according to claim 1, wherein the coupling parts are dimensioned to provide a coupling free from play in all panel separation directions in a plane extending perpendicular to the said side edges when two identical ones of said panel are coupled together." ('486 patent, 15:22-26)(emphasis added.)

Claim 65 includes the term as follows: "said coupling parts being dimensioned to provide a coupling free from play in all panel separation directions in a plane extending perpendicular to the side edges when two identical ones of said panel are coupled together." ('486 patent, 20:23-27)(emphasis added.)

In considering the appropriate definition of "free from play," the Court notes that the '486 patent specification comments that one disadvantage of related inventions is that couplings which allow coupling parts to snap fit into each other does not allow for a 100 percent optimum counteraction against the development of gaps between floor panels because "well-defined plays" have to be provided in order to be sure that the snapping-together is possible. ('486 patent, 1:47-55.) The "brief summary of the invention," provides that "these coupling parts are optimalized in such a manner that they allow that any form of play is counteracted and preferably is excluded." ('486 patent, 2:21-24.)

The description of the second preferred embodiment states that describes "coupling parts which are interlocked free from play in all directions in a plane extending perpendicular to aforementioned edges." ('486 patent, 2:49-51)(emphasis added.) Such description further states: "[d]ue to the fact that the coupling parts provide for an interlocking free from play, as well
as due to the fact that these coupling parts are manufactured in one piece, from the basic material of the floor panels, a perfect connection between adjacent floor panels can always be guaranteed, even with repeated expansion and shrinkage of the floor surface." (‘486 patent, 2:63-66; 3:1-3.) The specification discusses "free from play" in context of the snapping-together, joining, and interlocking of panels. Alloc suggests that "free from play" extends to the panels once they are joined. But, the patent specification does not support Alloc's construction, and therefore, it is not acceptable.

Furthermore, the specification refers to post joinder movement as "expansion and shrinkage," and "floor panels drifting apart, as a result of which undesirable gaps can be formed." (‘486 patent, 1:33-35.) The claims must be read in light of the specification, the "single best guide to the meaning of a disputed term." Aero Prods. Int'l, Inc. v. Intex Recreation Corp., 466 F.3d 1000, 1010 (Fed. Cir. 2006) Alloc's construction of "free from play" as including "an absence of play ... subsequent to installation following the expansion and shrinkage in accordance with normal use" is not supported by the specification and therefore, is rejected. See Phillips, 415 F.3d at 1316 (quoting Merek & Co. v. Teva Pharms. USA, Inc., 347 F.3d 1367, 1371 (Fed. Cir. 2003)). Similarly, Alloc's suggestion that the term "free from play" means "an ability for the surfaces to move relative to each other" is inconsistent with the specification and is rejected. See id.

Alloc contends that Unilin cannot dispute that the absence of visible gaps at the upper surface does not rule out the presence of play, noting that Unilin made that statement in a brief to the European Patent Office. Specifically, in response to opposition proceedings to the European version of its main claim in the ‘486 patent, Unilin stated that "[a]lthough the video does not show visible gaps on the upper surface of the floor covering, play can still be present between the locking surface and the locking groove in the joint." (Alloc Markman Hrg. Ex. Tab U, 22 P 39.) 12 In that same response to the European opposition proceedings, Unilin also stated that the videotape showed that the Alloc panels could be easily displaced with respect to one another as demonstrated by the person straddling the joint between two panels and moving the panels relative to each other by applying a "kicking" force through the sole of his shoe. (Id.) Unilin then stated that "[s]uch ease of displacement is indicative of play." (Id.) Unilin's two comments in its response to the European patent opposition proceedings are extrinsic, not intrinsic, evidence. 13

--- Footnotes ---

12 At the Markman hearing before this Court, counsel for Alloc explained that the videotape was made at the 1996 Domotex trade show, where Alloc's new product was displayed and videotaped. (Decl. of Patrick M. Kuhlman ("Kuhlman") P 4, Tab 17, 67-70.)

13 The Court of Appeals for the Federal Circuit has, on occasion, used statements made in front of foreign patent offices regarding related patents to determine what a person of ordinary skill in the art understands terms to mean, but it has never made them a part of the intrinsic record for claim construction purposes. See Phillips, 415 F.3d at 1317 (defining intrinsic prosecution history to include "the complete record of the proceedings before the PTO and ... the prior art cited during the examination of the patent" and extrinsic evidence to include "all evidence external to the patent and prosecution history" (quotations and citations omitted)); Gillette Co., 405 F.3d at 1374 (referencing statements made regarding a related patent in front of foreign patent offices but not characterizing them as intrinsic prosecution history of the patent at issue); C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 870 n.6 (Fed. Cir. 2004)(Leaving unresolved the question of whether statements the applicants had made during the prosecution of foreign patent applications may limit claims -- the intrinsic record had sufficed to support the claim construction); Tanabe Seiyaku Co., Ltd. v. U.S. Int'l Trade Comm'n, 109 F.3d 726, 733 (Fed. Cir. 1997)"In evaluating infringement under the doctrine of equivalents, 'representation[s] to foreign patent offices should be considered ... when [they] comprise relevant evidence."' (citation omitted)).

--- End Footnotes ---

Chimie v. PPG Indus. Inc., 402 F.3d 1371, 1374 (Fed. Cir. 2005), is cited by Alloc as authority indicating that a test may be included in a construction of a term. Chimie involved the construction of the term "dust-free and non-dusting" in a patent for "essentially spheroidal precipitated silica particulates." Id. PPG, the alleged infringer, contended that the term should be interpreted literally to mean "no dust cloud whatsoever." Id. at 1375. The patent assignee contended that the term should mean "very low-dust." Id.

The appeals court upheld the district court's construction of the disputed term as "a level of dust formation associated with the silica particulates of the '234 patent, as measured in percentage weight according to DIN 53 583, that has a fines content...
value less than or equal to 13 and weight loss by abrasion value less than or equal to 0.5." Id. The appellate court noted that the district court had explained that "DIN 53 583 is an industrial standard provided by the Deutsches Institut fur Normung e.V., a self-governing institution of trade and industry responsible for the preparation of National Standards in Germany, for measuring the fines content and weight loss by abrasion of palletized carbon black used as fillers in the rubber processing industry." Id. In the patent specification, the inventors of the patented device had made specific reference to that standard as a means of measuring the dust qualities of their silica. Id.

Chimie supports the proposition that a test may be included in the definition of a claim term. However, Chimie was based on specific accepted industry test which was discussed in the patent specification.

Chimie is distinguishable. The "test" was an industry standard for dust and was included within the specification. Neither is true of the "tests" suggested by Alloc. Thus, at this juncture, the Court declines to construe "free from play" as including the fourth and fifth prongs proposed by Alloc; that is, "ease of displacement along a joined edge is indicative of play; and, the absence of visible gaps at the upper surface does not rule out the presence of play." The Court construes "free from play" as "there are no spaces between the contact surfaces so that the panels are locked in the horizontal and vertical directions."

Claims 7, 10, 13, 16-21, and 23 call for the ornamental components of the earring to be "free of dependent arms." The phrase was added by amendment during reexamination to distinguish the claimed invention from the Zur patent. The Zur patent teaches a structure extending down from the ends of the ornamental components and which supports the fastening means. During reexamination, Zettl refers to the extending structure disclosed in the Zur patent as "arms" that "depend" from the ends of the ornamental components. (Request for Reexamination, Nov. 13, 1997, at 2). The phrase, "free of dependent arms," therefore, was added to the claims to clarify that the '664 patent calls for fastening means to be located at the ends of the ornamental components themselves and not on any extending structure as that of the Zur patent. (Amendment, Sept. 9, 1998, at 20-21). In light of the '664 patent's reexamination history, the phrase "free of dependent arms," is to be understood as the complete absence of any distinct structures that extend away from the ends of the earring's ornamental components and which serve to support fastening device. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 980 (Fed. Cir. 1995) ("The construction of the patent is confirmed by the avowed understanding of the patentee, expressed by him . . . When his application for the original patent was pending. . .") (internal quotes omitted, citation omitted).

Plaintiffs do not offer a definition for "free passageway," separate from that for "longitudinal gas flow." Defendant's first proffered definition was "an open passageway that extends unblocked along the entire length of the pipe, outside of the microporous material, inside of the outer tube." 51 In connection with Defendant's changed position regarding the need for air flow throughout the entire length of the pipe, Defendant changed the words "the pipe" to "a pipe section." 52 In response to the whole definition, Plaintiffs voiced their concern that the definition may not allow for the placement of spacers that could partially block the free passageway.
The specification explains that a free passageway, of potentially very narrow proportions, exists between the microporous material and the outer tube in order to facilitate the flow of air when reducing pressure. Air is drawn radially across the microporous material into the free passageway, where it travels longitudinally along the outer pipe in the direction of the suction. The patent also teaches the use of spacers to aid in centering the inner tube inside the outer tube, to lock the microporous material in place, and to provide reinforcement. These spacers may partially block the free passageway.

--- Footnotes ---

54 See id. at 3:54-57.
55 Id. at 6:55-61.
56 See Plaintiffs' Markman hearing arguments and expert testimony; Defendant's Markman hearing arguments.

--- End Footnotes ---

As the court understands the patent and the Markman hearing explanations of both parties, if an air molecule encounters a spacer (or, for that matter, some other element of the pipe) that blocks its path when the pressure is being reduced, it will be drawn around that element toward the source of the suction. Accordingly, the passageway may be partially, but not totally, blocked. Defendant's inclusion of the word "unblocked," therefore, is an overstatement.

The court recommends that "free passageway" be construed as the open space that extends along the entire pipe section outside the microporous material and inside the outer tube.

---

2. "A free passageway to allow longitudinal gas flow, whereby low pressure is maintained throughout said annular space."
Plaintiff contends that this term means "an open space that extends along the entire pipe section outside the microporous material and inside the outer tube to allow the movement of air in the annular space lengthwise along an entire pipe section, preserving a low pressure within the annular space." For its part, Technip contends that this term means "that the longitudinal gas flow along an entire pipe section in the free passageway maintains a low pressure throughout the annular space, which includes both the free passageway and the insulating material." In truth, this Court cannot discern a tremendous amount of difference in the two definitions; the real difference is semantics and the fact that Technip wants to put the cart before the horse in the definition and then give no real explanation of the "horse," that is, the free passageway. In light of the specification language (see Doc. 33, Exhibit A, at Columns 1-2 ("In order to cut expenses and improve the standard and durability of heat insulation, there is provided according to the invention a pipe with a heat insulating double casing, which is characterized in that, within a sealed annular space lying between an inner tube and an outer tube being coaxially arranged inside each other, it comprises a self-sustaining plate of an open pore-microporous material, which is flexible enough to be circumferentially wound along the inner tube, and in that there is provided outside said material in said annular space, a free passageway for longitudinal gas flow enabling low pressure to be maintained throughout said annular space."); id. at Column 5 ("According to still another feature of the invention, there is provided with advantage spacers aimed at centering the inner tube inside the outer tube by maintaining an adequate minimal gap between the inner and the outer tube sequentially from one portion to another through the entire length of the pipe. Such spacers typically consist of half-shells held together in position on the inner tube of the pipe."))) as well as the abstract of the invention (see Doc. 33, Exhibit A, ABSTRACT ("A line pipe with a double casing is especially used in transporting oil products. In a preferred embodiment, such a pipe is characterized in that, in a sealed annular space, located between an inner tube and an outer tube both coaxially arranged inside each other, there is included a self-sustaining plate made of open pore-microporous material, which is flexible enough to be externally wound around the inner tube. This plate is preferably less in thickness than said annular space such that a passageway is left free between the former and the outer tube whereby low pressure is maintained.")), this Court finds that the definition favored by the plaintiff, derived as it is from the opinion of the Southern District of Texas in ITP, Inc., supra, is the correct definition of this disputed term. The ITP court's definition...
of "free passageway" as "the open space that extends along the entire pipe section outside the microporous material and inside the outer tube" is simply indisputable in light of the specification language, as well as the abstract, as is its definition of "longitudinal gas flow" as "the movement of air in the annular space lengthwise along an entire pipe section." 2005 U.S. Dist. LEXIS 39078, 2005 WL 3542577, at *8. Accordingly, this Court gives the disputed term that definition suggested by the plaintiff, derived as it is from the ITP, Inc. decision: "The open space that extends along the entire pipe section outside the microporous material and inside the outer tube to allow the movement of air in the annular space lengthwise along an entire pipe section, preserving a low pressure within the annular space." 10

9 According to plaintiff, this is the definition given this term by the district court in the Southern District of Texas. See ITP, Inc., supra, 2005 U.S. Dist. LEXIS 39078, 2005 WL 3542577, at *8 (defining longitudinal gas flow as "the movement of air in the annular space lengthwise along an entire pipe section[]" and free passageway as "the open space that extends along the entire pipe section outside the microporous material and inside the outer tube.").

10 In its brief, Technip identifies as a term in dispute "both coaxially arranged" which it contends means that "both tubes share a single central axis." (Doc. 33, at 4) At the Markman hearing, the plaintiff indicated that this term was not really in dispute since the defendant's proposed definition is very similar to the definition given that term by the ITP, Inc. court. Compare id. with ITP, Inc., 2005 U.S. Dist. LEXIS 39078, 2005 WL 3542577, at *4 ("The 1994 edition of a scientific dictionary defines 'coaxial' as '[s]haring the same axes.' McGraw-Hill Dictionary of Scientific and Technical Terms 394 (5[th] ed. 1994). Similarly, a Webster's desk-reference dictionary defines 'coaxial' as '[h]aving or mounted on a common axis.' Webster's II New Riverside University Dictionary 275 (1984). The term 'arrange' is not defined in the scientific dictionary, but is given the following meaning by the Webster's dictionary: '[t]o put in a specific order or relation.' Id. at 126. Combining the two, 'coaxially arranged' can be defined as associated in such a way as to share a common axis. The common axis in a pipe-in-pipe design is an imaginary line down the center of the inner pipe. Accordingly, the shared axis is 'central.'"). Given the plaintiff's position in this regard and the fact that it appears Technip has simply synthesized into a more cohesive definition the analysis of this term by the ITP, Inc. court, this Court finds that Technip's proposed interpretation of "both coaxially arranged" is the proper interpretation. Accordingly, "both coaxially arranged" means that "both tubes share a single central axis."

10. Free-standing strands

FieldTurf's Proposed Construction: "Portions of the ribbons protruding above the infill"

SCG's Proposed Construction: "A strip of sheet that is divided from an adjoining strip of sheet not attached to or supported by something else"

SCG's Proposed Construction of "free standing": "Protruding without lateral support"

The Court's Claim Construction: "Strands capable of protruding without lateral support"

Looking first to the context of the claim, there is "an upper portion of the ribbons extending above the infill layer and longitudinally split into individual free-standing strands of a selected width to represent grass blades . . . ." The specification explains that "[o]nce all the infill is installed, the upper portion of the ribbons extending above the infill layer are brushed aggressively" such that "[t]he ribbons are longitudinally split by the brushing action along the slits into several individual free-standing strands of a thinner width resembling grass blades." 689 patent, 5:26-31. Both the context of the claim language and the almost identical language from the specification demonstrate that FieldTurf's proposed construction is lacking. Both the claims and specification already state that a portion of the ribbon protrudes above the infill. To give the full phrase "free-standing strands" that same meaning would render the earlier language superfluous. However, FieldTurf makes a better point in its alternative argument that free-standing strand need not be further defined. Particularly with
respect to the "strand," it is simply a shorthand for a particular portion of the ribbon--the "upper portion of the ribs extending above the infill layer and longitudinally split [and] of a selected width to represent grass blades"--and further definition seems unnecessary. Although it is at least arguable that "free-standing" is similarly without need of further explanation, based on the parties' arguments it may be helpful to a jury to state that free-standing means "capable of protruding without lateral support." The claim already provides that the strands are "individual" so "free standing" should provide something more. However, and particularly in light of the specification and invention as a whole, the Court believes that "protruding without lateral support" improperly imports a concept that the strands are wholly isolated from one another. The Court disagrees that the strands must be isolated and thus believes that that the "capable of" language is necessary. Accordingly, the Court construes "free standing strands" as "strands capable of protruding without lateral support."

C. Freeze

Several of the '518 Patent claims describe how the cold UV curing assembly is placed "sufficiently close to where the ink is being jetted onto the surface to freeze dots of the jetted ink on the [substrate] surface." The parties offer slightly different construction of what the term "freeze" should mean in these claims. According to L&P, "freeze dots of the jetted ink" means "exposing ink to a sufficient amount of UV energy to create a film over the wet ink to prevent it from spreading." Vutek's proposed construction reads "exposing ink to a sufficient amount of UV energy to at least partially cure the ink immediately after printing, thereby preventing ink dots from spreading on or wicking into or otherwise moving on the substrate." After reviewing the intrinsic and extrinsic evidence, I conclude that a person of ordinary skill in the art would interpret "freeze" to mean exposing ink to a sufficient amount of UV energy to sufficiently cure the ink such that it will not spread, wick, or otherwise move on the substrate.

The Summary of the Invention section of the specification reads, in pertinent part, "[b]y so mounting the UV curing lights on the printhead carriage, the jetted ink can 'spot cure' the ink, or to cure the ink immediately upon its contacting the substrate. Such spot curing 'freezes the dots' in position and prevents their spreading on or wicking into or otherwise moving on the substrate." Thus, "freezing" refers to a physical state of the dots of ink in which they do not spread, wick, or otherwise move.

Additionally, after reviewing the extrinsic evidence, I find that "freezing" does not necessarily involve creating a film over the wet ink, as L&P suggests. As Whittle explained during the Markman hearing, within a drop of ink, there are many monomers. Once exposed to UV energy, these monomers enter a free radical state in which they begin to stick to one another and create spaghetti-like polymer chains. These polymer chains extend throughout the drop of ink, not just at the surface. Thus, as a drop of cures, the entire drop becomes more viscous, or pasty, rather than just hardening on the exterior. In sum, I conclude that a person of ordinary skill in the art would interpret the phrase "freeze the dots" to mean sufficiently cure the dots of ink such that they will not spread, wick, or otherwise move on the substrate.

f. "Frictionally Held"

The last term in Claim 1 requiring construction is the phrase "frictionally held," which was added by the certificate of correction. 21 This phrase also appears in claim 9, which refers to an "end plug frictionally held." (760 Patent col. 6, ll. 12-13.) The World Wide Plaintiffs assert that this term should be given its ordinary and customary meaning, that is "restrained from motion by frictional force; namely, a force that opposes the relative motion of one body moving with respect to another body with which it is in contact." Relying on the dictionary definition of "frictional force," the World Wide Plaintiffs assert that when a plug is held, it is restrained from motion. This interpretation is supported by the specification, they argue, which discusses the various ways the end plug may be positioned as a friction fit pressed into the distal end, like a cork in a bottle, or alternatively, it may be treated with a solvent so it adheres to the inside wall of the cannula, or it can be put in position and the cannula heated so that it swells and is held into position, or the cannula may be distorted externally to cause it to shrink in the area of the plug and thereby to hold the plug in place. Id. at col. 4, ll. 8-16. They also cite to Figure 2221.
7c, which shows the cannula distortion and is described as "[a] bridge in the cannula wall . . . is deflected inward . . . to frictionally engage the plug and hold the plug yieldably in place until it is pressed outward by the first seed." Id. at col. 5, ll. 22-27 (emphasis added). The World Wide Plaintiffs assert that these are alternatives that one of ordinary skill in the art would recognize as methods for achieving a frictionally held end plug. Regardless of how a tight fit is achieved between the plug and the cannula wall—whether by heat, a distortion of the cannula wall, or treatment of the plug with a solvent—once the tight fit is achieved, the plug is then frictionally held in place.

AnazaoHealth 22 relies on the same paragraph in the specification and argues that the patentees acted as their own lexicographers and expressly narrowed the scope of the phrase "frictionally held" by eliminating from the definition everything except "a friction fit pressed into the distal end of the cannula as a cork in a bottle." Id. at col. 4, ll. 8-9. The alternatives, it contends, are what the patentees expressly disavowed as means of frictionally holding the plug in the cannula (e.g., adhesion, heat, minute distortions in the cannula, surface tension or capillary action). Thus, AnazaoHealth argues that the phrase "frictionally held" should be construed to mean "held in place by a tight fit, as a cork in a bottle, and does not include something being held by adhesion, heat, minute distortion of the cannula, surface tension or capillary action." AnazaoHealth also relies on the prosecution history, in which the patentees distinguish their invention from Mercereau. 23

The patentees described the overflow plug of the Mercereau invention as "not held in place by friction, but rather because it is integral with the coating 480 on the outside of the cannula." (W0481)(emphasis added). They further distinguished Claim 9 from the cited prior art by stating that Mercereau "does not show 'a generally cylindrical end plug frictionally held in the distal end . . .," and Claim 12 because Mercereau "does not show an irregularity to enhance the frictional holding of the plug." (W 0482)(emphasis in original). Finally, they distinguish Claim 16 because the method of Mercereau consisted of filling the distal end of the cannula by dipping the end into a vat to allow lubricious material to enter, rather than forcing the plug into the sharpened distal end of the cannula to frictionally reside there. Id. (emphasis added). Contrary to AnazaoHealth's suggestion, nothing in the prosecution history constitutes a disclaimer by the patentees as to how the plug would be frictionally held in the distal end of the cannula. Rather, if anything, the prosecution history supports Plaintiffs' position that "frictionally held" means more than just held in place like a cork in a bottle, but also includes being held by adhesion, heat, minute distortions to the cannula, or other means. Accordingly, the Court rejects AnazaoHealth's narrow construction. At the same time, the Court does not believe that it is necessary to define "frictional force," as the World Wide Plaintiffs have done, as this term should be well-known to those of ordinary skill in the art and nothing in the Patent or the intrinsic evidence suggests a definition other than the customary and ordinary meaning. Thus, the Court construes "frictionally held" as meaning "restrained from motion by frictional force.

**1793**

A Releasable Needle Holder and Needle Frictionally Held by the Wall of the Syringe Body

The Parties also ask the Court to construe the term "a releasable needle holder and needle frictionally held by the wall of the syringe body" in Claim 22 of the 011 Patent. Both parties agree that the Court's construction should begin with "a releasable needle holder and needle kept in the nose portion of the syringe body." However, the parties disagree on the definition of
"frictionally held by the wall of the syringe body." RTI's proposed construction states "by forces present between the needle holder and wall of the syringe body," and NMT's states "by a force generated along a sliding interface between two cooperating surfaces."

The Court's greatest difficulty in construing this term comes from the parties' failure to explain to the Court how their proposed constructions differ. Friction is defined as "the rubbing of one body against another," or "the force that resists relative motion between two bodies in contact." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 466 (10th ed. 2001). Thus, "frictionally held by the wall of the syringe body" must mean that the body creates a holding force by rubbing against something else. RTI's definition reflects this notion by requiring force between the needle holder and syringe body. The Court's problem is that the specification language from which NMT finds the "sliding interface" makes clear that the "sliding interface" is simply the "needle holder" and "body." For example, Claim 1 language NMT relies on declares "the needle holder having an elongated body … having a cooperating outwardly facing surface configured to cooperate with said inwardly facing surface to produce said … frictional holding force," and "the inwardly facing surface in the wall [of the body] and the cooperating outwardly facing surface on the needle holder are friction surfaces which cooperate to produce said … frictional holding force." Thus, according to NMT's own intrinsic evidence, the "cooperating surfaces" are simply the needle holder and body. Unfortunately neither party deigned to explain exactly how the proposed definitions differ.

The Court finds that the term "a releasable needle holder and needle frictionally held by the wall of the syringe body" means "a releasable needle holder and needle kept in the nose portion by friction with the syringe body." This construction appears to be consistent with both parties arguments, and more importantly with the plain and ordinary meaning of the claim terms. NMT's language requiring a "sliding interface between two cooperating surfaces" appears to simply refer back to the needle holder and body. As such, NMT's language appears to cloud the issue rather than clarify the claim. Indeed, if this claim is truly worth expending the Court's and the parties' time and resources, the parties should have provided the Court with clearer briefing. Moreover, if the parties are truly in agreement, as they appear to be, then they should have resolved this issue themselves without further burdening the Court's time and resources.

1794

b. "from different directions"

The parties agree that the court's construction of the term "from different directions" should begin with the phrase "the 'first light beam' and the 'second light beam' illuminate the 'pattern' at different angles of incidence." The parties do not agree, however, regarding where the definition of the claim should end: ASML believes that "at different angles of incidence" itself offers a sufficient construction of the claim term; Nikon, by contrast, asks the court to detail the kind of different angles of incidence at issue, appending the apparently non-exhaustive example, "which include angles having the same magnitude but different directions." Cf. In the Matter of Certain Microlithographic Machines and Components Thereof, Investigation No. 337-TA-468 at 285 (rejecting a similar, though notably different, Nikon-proffered construction).

As the court reads them, the parties' constructions are not mutually exclusive, whether linguistically or logically. The term "different angles of incidence," if understood as an incorporative category, undoubtedly includes some angles "having the same magnitude but different directions," so what Nikon seeks to add plainly falls within the technological capacity of the invention, if only as an example. But the limitation Nikon seeks to import is unsupported by the claim text and the relevant specification language. See '041 Patent at 3:31-3:50 & 12:13-45. Where claim language concedes to ready explication, the Federal Circuit has long reminded, courts should construe claim terms to mean precisely what they say. See Vitronics, 90 F.3d at 1582. However innocuous (and technologically valid) Nikon's proposed illustration, there is no reason to venture from the plain meaning of the claim terminology here. The claim expressly discusses beams emerging "from different directions"--i.e., from distinct and unshared angles of incidence. Cf. Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1328 (Fed. Cir. 2002) ("We have 'cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification.'") (citation omitted). Nothing in the intrinsic evidence controverts this claim language, and Nikon posits no compelling reason to read into the claim an example (viz., "which include angles having the same magnitude") of something the claim's language already--if implicitly--embraces. Consistent with the intrinsic evidence, the court construes "from different directions" to mean "at distinct and unshared angles of incidence."
The parties next dispute the meaning of the term "front panel." National contends that the term "front panel" has an ordinary and accepted meaning in the instrumentation and test measurement fields. According to National, the term "front panel" means "a graphical user interface that is accessible during execution and comprised of at least one interface element to interactively assign and display values of an input variable and at least one interface element to display values of a resulting output variable." Mathworks urges a more narrow construction. According to Mathworks, the term "front panel" means "a graphical representation of the faceplate of an instrument that is displayed in a window that is separate and distinct from the window containing the associated data flow diagram, and that can only display input and output controls, where there is at least one input control and at least one output control in the front panel, each of which has a corresponding representation in the data flow diagram."

The court adopts neither party's construction. The problem with National's construction is that the definition derives largely from the instrumentation and test measurement fields, and that is not the relevant art. Furthermore, National's construction ignores certain statements made by during prosecution by the prosecuting attorney to the examiner. The problem with Mathworks' definition is that it is divorced from certain claim terms and aspects of the preferred embodiment. In addition, Mathworks makes too much out of the statements made to the examiner.

The claim language refers to the front panel and the data flow diagram as different concepts. The language of the claims implies, but does not necessarily require, the front panel to be separate from the data flow diagram. For instance, dependent claim 2 in the 221 patent claims the method of claim 1 and, in addition, the step of "assembling on the screen a first front panel including the at least one first input variable-icon and the at least one first output variable-icon." If the front panel and the data flow diagram were the same, then dependent claim 2 would be redundant.

To the extent there was any doubt, the inventors confirmed a separateness requirement in the prosecution history of two of the patents. During the prosecution of the 587 patent, the examiner confronted the inventors with various prior art which, according to the examiner, compelled rejection of the then-pending claims.

During prosecution, the inventors were confronted with the Kossiakoff patent as prior art. The examiner rejected all of the pending claims of the 587 patent in part because of Kossiakoff. In doing so, the examiner found that one of ordinary skill in the art would have recognized that the procedure display in the Kossiakoff patent (i.e. the counterpart to the data flow diagram contained in the patents-in-suit) could be used as a display means "responsive to user inputs for displaying at least one input variable . . . and . . . at least one output variable."

In response to the examiner's determination, the inventors' prosecuting attorney distinguished the claims of the 587 patent by asserting, inter alia:

The display the Examiner refers to is the procedure display of the Kossiakoff reference. As mentioned above, it has no input and output variable icon which are displayed on a panel apart from the procedure display. Kossiakoff would have no need for such panel as he was not concerned with emulating an instrument or doing other real time data processing.

(emphasis added).

By this passage, the attorney argued that the claims of the 587 patent were patentable over Kossiakoff on the grounds that the invention set forth in the 587 patent contained a panel that displayed input and output variable icons and that such panel was something apart from the procedure display. This distinction is important. The inventors touted this invention, including its front panel, on the grounds that the system and method of the invention permitted the computer-aided modeling of a process using graphical techniques. This led to easier comprehension by the target group--persons who did not possess specialized skills in computer programming techniques. The inventors noted that "the use of a computer-generated image of a front panel display permits a user to easily understand how data is provided to a system being modeled and how data is provided by the system." The front panel concept was important because it allowed unskilled persons to interface with the virtual instrument through familiar means -- the front panel.
In addition, during prosecution of the 336 application, the examiner rejected all of the pending claims on the grounds that a second piece of prior art, the Dunn patent, showed the step of assembling a panel on the display. National's attorney urged reconsideration of the examiner's rejection and asserted that the chart area noted by the examiner was "used for assembling flow diagrams" and that "it is unrelated to the panel recited in all independent claims in the present application." The court requires that the front panel be separate and apart from the associated data flow diagram. National concedes as much in its reply brief, by urging that the front panel must be "an entity apart from (i.e. other than or besides') the data flow diagram and that it comprises an input variable-icon and an output variable-icon." (National's Reply Brief, p. 34).

Mathworks further urges that the attorney's statements and the specifications compel the conclusion that the front panel and the data flow diagram must be contained in separate windows. The court disagrees. The attorney's remarks made no mention of the term "window." National cannot re-capture what it has disclaimed; however, the court will not hold that National disclaimed more than what its attorneys actually represented to the examiner.

Neither do the specifications require a more restricted construction of the term "front panel." It is true the two do not coexist in the same window in the preferred embodiment set forth in the application. The specifications plainly indicate that, in the embodiment disclosed, the front panel and the data flow diagram reside in separate windows. But the inventors knew how to use the term "window," and used it repeatedly throughout the specifications. The claim language, though, makes no use of the term. Unlike in the case of the inventors' repeated use of very specific data flow semantics, the court is not convinced that the inventors explicitly or implicitly required the front panel to reside in a separate window from the data flow diagram.

Finally, for the same reasons, the claim language does not support, and the court rejects, the additional limitations to the term proposed by Mathworks, namely, that the front panel can only display input and output controls and that it must be a graphical representation of the faceplate of an instrument. The court defines "front panel" as a graphical user interface that is separate and apart from the associated data flow diagram and that displays inputs and output controls, where there is at least one input control and at least one output control in the front panel.

1. front plate

Claim 1 identifies an ice storage receptacle "including a front plate having a discharge opening." Exh. A to Maytag's Pre-Hearing Brief on Markman Claim Construction ('688 patent") col. 9, l.3 (emphasis added). The term "front plate" also appears in claims 5 and 11. 2

2 The relevant portion of claim 5 states:

An ice dispenser, comprising:

a receptacle for storing ice pieces said receptacle having a front plate with a discharge opening;

'688 patent, col. 10, ll. 15-17.

Claim 11 states in relevant part:

An ice dispenser, comprising:

a receptacle for storing ice pieces, said receptacle including a front plate having a discharge opening and a bottom sloped downwardly toward the front;

Id., col. 10, ll. 63-66.
Maytag does not dispute that the '688 patent discloses a horizontally-oriented unit as the preferred embodiment. Maytag argues, however, that the claim is not limited to such an orientation, and that the term "front plate" is relative to the direction of the ice as it moves. In support of this theory, Maytag submits that the plain and ordinary meaning of "front" is "the forward part of a surface," with "forwardly" defined in turn as "a. near, being at, or belonging to the front b. situated in advance." Webster's II New Riverside University Dictionary at 508, 500 (1988). Following this definition, the "front plate" under Maytag's proposed construction is the plate or wall situated in advance of the point at which ice is dispensed.

Whirlpool argues that the plain and ordinary meaning of "front plate" is a plate at the front of the ice receptacle, with "front" defined as "the part or side of anything that faces forward." See Random House Dictionary, 2nd Ed. at 770 (1987) (emphasis added). Whirlpool contends there is no basis for a definition based on the direction of movement in the claims or specification.

The Federal Circuit repeatedly has rejected the argument that the claims of a patent that itself describes only a single embodiment must be interpreted as being limited to that embodiment. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). As clarified by the court: "Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'" Id. (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)); see also Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1306-07 (Fed. Cir. 2003) ("the mere fact that the patent drawings depict a particular embodiment of the patent does not operate to limit the claims to that specific configuration") (internal citation omitted). No such "words or expressions of manifest exclusion or restriction" are present in claims 1, 5 or 11. Rather, each of claims 1, 5 and 11 appears carefully drafted to avoid a horizontal limitation.

Whirlpool argues in its construction brief that if Maytag's proposed construction were to be adopted, the front plate could theoretically double as the "bottom wall." Such a result, according to Whirlpool, would conflict with claim 11, which requires both a "front plate" and a "bottom sloped downwardly toward the front." See '688 patent, col. 10, ll. 65-66. This Court disagrees. Although the preferred embodiment obviously is a box-type structure, the front plate need not be linear. Other structures, such as a modified sphere, could match the description contained in claims 1, 5, and 11, with a "bottom" in the same "side" as the "front plate." When asked during the hearing how he could reconcile Maytag's proposed construction with the language in claim 11, counsel for Maytag responded: "You can still have a front plate in the bottom wall." The key, according to Maytag, is that the front plate remains "in advance" of the flow of ice. The Court finds this argument persuasive.

After considering the parties' arguments and the relevant caselaw, the Court construes "front plate" as the plate situated in advance of the flow of ice from the receptacle. This construction for "front plate" shall carry over to claims 5, 11, which both refer to an ice storage receptacle with a "front plate." See, e.g., Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001) ("a claim term should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent").

The parties agree that terms used in Claim 1 of the '717 Patent have the same meaning in the other claims of the '717 Patent. They dispute the meaning of "front side" and "at said front side" in Claim 6 that reads in full as follows:

A lighting unit comprising: a lamp; a reflector that surrounds said lamp, said reflector having a front side that defines an emission window for exit of light emitted from said lamp, wherein said reflector has lugs at said front side; and a transparent plate located at said front side wherein said the lugs extend above the transparent plate.

Philips argues that "at said front side" means the lugs are positioned at the front or top end of the reflector body closest to the light emission window. Iwasaki asserts that "front side" means "a side at the front end of the reflector body opposite the
back end of the reflector body. "The use of the phrase "at said front side" is most naturally read to mean that there is a single front side; the language would not be understood by a person of ordinary skill in the art to mean "a side at the front end."

The front side is the horizontal plane on the portion of the circumference of the reflector body that faces in the direction that the emitted light is traveling. Put another way, it is the surface of the edge of the rim of the reflector which faces in the same direction the light is traveling. 8

--- Footnotes ---
8 The embodiments reflected in Figures 1, 2, 3 show the lugs (22) positioned on what I have construed to be the front side.
--- End Footnotes ---

1798

B. Claim Construction

This court need only ascertain that the district court's jury instruction containing its claim construction does not amount to a "miscarriage of justice." The trial court concluded that "front side" means "a location on a front side surface of a dumpster." Serio-US complains that the trial court erred in limiting the claim term "front side" to only the front side surface. Serio-US argues that the phrase "front side" means the portion of the container "toward the front." According to Serio-US, the '358 patent does not use the word "side" to refer to a surface, but to refer to a portion of an object.

A review of the intrinsic evidence in the patent shows the district court properly construed the "front side" limitation claim language to mean "a location on a front side surface of a dumpster." Transcript of Record at 910-912, Serio-US Indus., Inc. v. Plastic Recovery Tech., Corp., Nos. 05-1106, 05-1143, 05-1306 (Fed. Cir. argued Jan. 10, 2006) (emphasis added). In claim 8, the patent claims "a pivot shaft circumscribing the locking bar and extending along said front of said container." '358 patent, col. 4, ll. 47-49 (emphasis added). In claim 10, the locking mechanism "according to claim 8, further comprise[s] a hole through said locking bar and said pivot shaft, wherein a lock can be positioned through said hole." '358 patent, col. 4, ll. 53-56 (emphasis added). This claim language does not suggest that the district court's construction would amount to a "miscarriage of justice."

The specification also does not suggest any such miscarriage. According to the specification, the invention positioned "a lock, to lock the pivot bar in place with respect to the lockover arm, allowing the L-shaped lockover arm to be secured atop a lid of the dumpster container." '358 patent, col. 2, ll. 43-46 (emphasis added). Therefore, because the L-shaped lockover arm is secured atop the lid of a dumpster, and because the L-shaped lockover arm is fixed to the pivot shaft that extends along the front of the dumpster, then the claimed front side is the front side surface.

1799

(b) Claim One, Clause Three

Claim 1, clause 3 reads as follows: "a display panel being located on a front surface of said housing proximate said array of actuator buttons[,]" The parties dispute the construction of the term "front surface."

CCL proposes that we construe this term to mean "a forward surface of the housing." In addition to claiming that the term is too ambiguous and indefinite, SCM asserts that it means the "surface on which the actuator buttons appear."

Webster's Third International Dictionary defines "front" as "2: something that confronts or faces forward," or "2b(1): The part or surface of something that seems to look out or be directed forward." Nothing in the specifications is inconsistent with this ordinary meaning. Nor is there any need to narrow the definition to the surface on which the actuator buttons appear, as SCM proposes.
We construe the term "front surface" to mean a forward surface of the housing.

Front Tip

"the plunger head further comprises a tip" ('224 patent, claim 4)

"front tip" ('584 patent, claims 1, 5, 6, 18, 21-24)

The claims of the '584 and '224 patents contain the terms "the plunger head further comprises a tip" and "front tip" (collectively "front tip"). The parties treat these terms as having the same meaning. Thus, the Court addresses these terms collectively. RTI contends that "front tip" means "portion of the plunger closest to the needle." OMI contends that "front tip" means "the smaller diameter portion of the plunger that is forward of the plunger seal." The parties dispute whether "front tip" must be the "smaller diameter portion" of the plunger and whether the "front tip" must be "forward of the plunger seal."

The specification shows that "front tip" is the "portion of the plunger closest to the needle." The specification consistently refers to the tip of the plunger as the part of the plunger that is closest to the needle. The specification states "Head 34 [of the plunger] has a tip portion 40 forming an opening 41 into retraction cavity 38." '224 patent, Col. 7:28-29; see also '224 patent, Col. 11:55-56 (making the same statement); see also '584 patent, Col.8:36-37 (making the same statement); see also '584 patent, Col. 12:62-63 (making the same statement). Also, OMI does not contest that the tip is the portion of the plunger closest to the needle. Accordingly, the Court construes "front tip" as "portion of the plunger closest to the needle."

OMI contends that the "front tip" must be smaller in diameter than the rest of the plunger and be located forward of the plunger seal. OMI argues that various embodiments described in the specification show a tip smaller in diameter than the rest of the plunger and positioned forward of the plunger seal. See '584 patent, figures 1-3, 8, 17-24. OMI also points to the Background of the Art that states "A head end which acts like a piston when installed in a syringe barrel has a reduced diameter front end having an opening and a dislodgeable stopper slidingly mounted in the opening projecting forwardly from the tip" and the Summary of the Invention that states "The nose has a reduced diameter relative to the barrel." '584 patent, Col. 2:32-37; Col. 3:6-7. Finally, OMI argues that because the plunger tip comes in contact with the retainer and the retainer is mounted in the most constricted portion of the barrel where the nose begins to provide high blowout pressure resistance, the tip of the plunger must necessarily have a smaller diameter than the rest of the plunger.

However, none of OMI's references to the patent warrant limiting the "front tip" to being smaller in diameter than the rest of the plunger and positioned forward of the plunger seal. Figures 1-3, 8, and 17-24 of the '584 patent only show possible embodiments of the "front tip," and the specification does not otherwise state that the figures show limiting features of the "front tip." Also, OMI's citations to the Background of the Art and the Summary of the Invention are not persuasive. These excerpts only refer to the barrel having "a reduced diameter" and do not refer to the front tip. Finally, OMI's argument regarding contact with the retainer and high blowout resistance does not mandate that the front tip be smaller in diameter than the rest of the plunger. The tip can be in the narrowed section of the barrel for blowout protection, and at the same time, not be smaller in diameter than the rest of the plunger. Given that OMI is unable to point to any language clearly limiting that the "front tip" must be smaller in diameter than the rest of the plunger and positioned forward of the plunger seal, the Court does not import these limitations into the claims and omits them from the Court's construction.
b. "frozen uniformly"

Even if the ICE-CEL included the identical "opposite direction" flow as that described in the '078 patent, it would not infringe upon claim 16 because the phase change material in the ICE-CEL does not completely freeze as required by the claim.

Paragraph D of claim 16 states that the opposite flow system used in the ICE-BANK provides "generally uniform transfer of heat energy between the liquid in the respective pairs of conduits and the phase change material throughout said tank." The final clause of claim 16 states:

whereby said phase change material may be alternately melted and frozen uniformly throughout the mass of said phase change material as heat is added to and withdrawn from the recirculating liquid in said system.

To accomplish this uniform freezing, the specification of the '078 patent provides for mat tubing to fill the entire volume of the tank "so that no region within the entire tank is more than a short distance away from the mat tubing." The specification further states:

Therefore, ice advantageously builds uniformly on all tubes entirely throughout the whole tank of water. The water level rises in the tank because of the increased specific volume of the ice formed but there is no sideward expansion forces as the ice joins from one spiral layer to the other because the extra water volume has been squeezed upwards previously. The rise in water level provides a measure of the extent of the fusion process. The extra water on top is the last to freeze.

Focussing on these portions of claim 16 and the specification of the '078 patent, it is clear that claim 16 only encompasses systems wherein tubing is placed throughout the entire tank and the phase change material ("PCM") is entirely frozen. The prosecution history of claim 16 likewise mandates this interpretation. When pursuing the '078 patent, Calmac argued to the patent examiner that it "is able to freeze a plastic tank of water to solid ice without rupturing the tank." Amendment to Application for the '078 Patent at 17. Calmac went on to explain that "this is an astonishing result and is entirely unexpected." Id. Calmac emphasized that this system allows ice to build "on all of the tubes throughout the whole tank of water." Id. From this prosecution history, it is clear that claim 16 requires that the PCM freeze completely.

Calmac disputes this interpretation of claim 16. It argues that the patent language only states that the ICE-BANK is able to freeze a plastic tank of water to solid ice. This, it argues, does not mean that the patent excludes partially frozen tank systems from the invention. Calmac's proposed construction of claim 16 alters the true meaning of the claim as indicated through a review of its plain language, the specification, and the prosecution history. Claim 16 is limited to devices which freeze the PCM uniformly and completely. Any other construction of the claim distorts the undisputed patent record.

The ICE-CEL does not infringe upon this limitation of claim 16. First, the ICE-CEL is designed such that portions of the tank contain no coolant tubes. Second, the ICE-CEL is designed so that certain areas of the tank, specifically the sides, the center, and the top, do not freeze. These characteristics of the ICE-CEL are not in dispute. When these characteristics are compared with claim 16, it is evident that the ICE-CEL does not literally infringe upon the '078 patent.

Calmac concedes that the ICE-CEL does not have coolant tubes throughout the tank and that the PCM in the ICE-CEL does not normally freeze entirely. It insists, however, that the ICE-CEL nonetheless literally infringes upon the '078 patent. Although the ICE-CEL is designed to leave portions of the tank unfrozen, if the device is run improperly, all of the PCM in the tank will, in fact, freeze. For this reason, Calmac argues that the ICE-CEL literally infringes its patent. Calmac's argument on this point is frivolous. The PCM in the ICE-CEL may freeze entirely when it is improperly operated; however, it is undisputed that the ICE-CEL is not designed to operate in this manner. In fact, the warranty on the ICE-CEL does not apply if the consumer operates the device in such a way as to achieve 100% freezing. Misuse of a product by a consumer does not by itself transform an essential characteristic of that product. The PCM in the ICE-CEL does not freeze 100% under normal operation; it, therefore, does not literally infringe upon claim 16, which describes a device which "is able to freeze a plastic tank of water to solid ice without rupturing the tank." Amendment to the Application of the '078 Patent at 17.
In the alternative, Calmac argues that the ICE-CEL infringes on the 100% freeze portion of claim 16 under the doctrine of equivalents. Calmac, however, is precluded by prosecution history estoppel from asserting this argument. Initially, the '078 patent was rejected due to the state of the prior art. To overcome this rejection, Calmac argued to the examiner that the thermal storage system described in that claim is unique because it is able to freeze an entire tank of water. Calmac described this ability as an "astonishing result" which was "entirely unexpected." Amendment to the Application of the '078 Patent at 17. Calmac convinced the patent examiner to approve claim 16 by arguing the unique ability of the ICE-BANK to achieve 100% freezing. For this reason, Calmac is now estopped from asserting that claim 16 also includes thermal storage devices wherein the PCM does not freeze entirely. See, e.g., Hughes Aircraft Co., 717 F.2d at 1361.

As discussed above, the ICE-CEL does not literally infringe upon the 100% freezing element of claim 16. Also, Calmac is prevented by prosecution history estoppel from asserting the doctrine of equivalents regarding this element. DB is entitled to summary judgment on the question of infringement. If there is no infringement, then no legal action can proceed against defendant Lake Taylor City Hospital Authority of Norfolk, DB's client.

3. FRUSTO-CONICAL

ConAgra defines "frusto-conical" as "the shape of a cone with its tip cut off" (Filing No. 64). Green did not initially construe "frusto-conical" but defined "substantially frusto-conical" as "the side wall is not parallel, it tapers in a manner that is shaped like the wall of a cone" (Id.).

The Court finds the intrinsic record supports ConAgra's construction of the term. Claim 1 of the '083 patent states the first vessel has a "substantially frusto-conical side wall," and the second vessel has "a frusto-conical side wall."

According to the specification, "frusto-conical" refers to the shape of the vessel's side wall (See the '083 patent, col. 2, l. 54; col. 4, l. 23; col. 4, ll. 50-51). The specification describes the side wall of the first and second vessels as angled (see id., col. 4, ll. 60-63), and states that in the preferred embodiment, the first vessel's side wall is "frusto-conical shaped expanding upwardly such that the upper edge is slightly wider than the base" (Id. at col. 2, ll. 53-55). Figure 3 depicts the side walls of the first and second vessels as the shape of a cone with the tip cut off.

Green's construction of the term is slightly too broad because it defines conical rather than frusto-conical. In contrast, ConAgra's construction appropriately construes both portions of the term, and ConAgra's construction is supported by the specification. Green agrees that frusto-conical means a truncated cone, but Green contends a different construction is appropriate because the patent uses frusto-conical to describe the shape of a wall rather than the shape of a vessel. The Court is not persuaded that this fact requires an alternate construction of the term.

4. Frustoconically Tapered Portion

The parties' proposed constructions are as follows:

Plaintiffs
A portion of an implant whose exterior is conically shaped over a region, but does not come all the way to a point in that region.

Defendant
A portion of the implant body with smoothly tapered sides.

The parties agree that frustoconical means "a truncated cone with its pointed end removed." (Plf's Opening Brief 12 n.3; Def.'s Opening Brief 4.) The parties, however, disagree as to the portion of the implant to which this term refers. Plaintiffs contend it applies to the entire implant, including the threads. Defendant, however, contends that it applies only to the...
internal body of the implant, not the threads.

The language of the claim describes "a frustoconically tapered portion tapering from the major diameter D at the proximal end of the implant to a minor diameter d proximate [to] the distal end of the implant." (Swaroop Decl. Ex. 1, col. 6, ll. 35-38.) Nothing in the language of the claim describes this portion of the implant as having smooth sides. Nor does the claim language specify that this portion refers only to the internal shape of the implant body, excluding the threads.

The specification likewise describes the general shape of the implant, but lacks any reference to the frustoconically tapered portion of the implant as having smooth sides. (Swaroop Decl. Ex. 1, col. 3-4.) Defendant nonetheless relies on Figure 1 to support its contention that the "frustoconically tapered portion" has smooth sides. Specifically, Defendant contends that Figure 1 refers to the "frustoconically tapered portion" as the smooth sides between the threads of the implant. The Court, however, declines to construe this term so narrowly based on the imprecise drawing in Figure 1. As explained above, courts generally do not rely on schematic drawings to limit the scope of a patent to the embodiment depicted in a drawing. See Anchor Wall, 340 F.3d at 1306-7. In addition, Defendant has not given a reasonable explanation for its insistence that a frustocone has "smooth" sides (7/24/09 Transcript 91) nor has Defendant presented compelling expert testimony construing this term in the relevant field as requiring smooth sides.

Moreover, it does not appear that adopting Defendant's proposed construction is consistent with the nature and purpose of the '160 patent. Rather, Defendant's proposed construction seems to be a haphazard attempt to narrow the patent's scope. The '160 patent requires that the implant inserted into the stepped endosseous orifice contain a frustoconically tapered portion, but does not explicitly state nor imply that the precise shape of the internal body of the implant is important, as long as the overall implant contains a frustoconically tapered portion. Indeed, whether the implant is tapered due to its tapered body or its tapered threads the result is the same, the taper fits the proportions of the orifice to accomplish the goal of creating a snug fit with the bone.

Defendant's proposed construction is also inaccurate because it fails to describe the truncated cone that is characteristic of a frustum and thus is overly broad in that it could include a tapered implant that comes to a complete point.

Plaintiffs, on the other hand, have proposed a logical construction for this term that refers to the overall shape of the implant. As described above, the claim language and specification do not contain any language that would limit the term "frustoconically tapered portion" to refer to only the internal body of the implant.

In light of the foregoing, the Court adopts the following construction: A portion of an implant whose exterior is conically shaped over a region, but does not come all the way to a point in that region.

1804

Claim 1; Issue 2 -- Initial Fuel Filter Means

The parties disagree as to the construction of the term "initial fuel filter means for removing water from fuel received from the fuel tank." Plaintiffs assert that one of ordinary skill in the art would understand this term to mean "a water filter comprising a filter head and removable cartridge and equivalents thereof." Mirroring their position with regard to the preamble, Defendants assert that the "initial fuel filter means" consists of a water separation filter, a particulate filter, a fuel pump, and a regulator valve.

The parties essentially are in agreement that this is a means-plus-function limitation, under § 112, P6. As such, the Court must first determine the function identified in this language, and then identify the structure that provides the means for accomplishing this function. Kemeco Sales, Inc. v. Control Papers Co., Inc., 208 F.3d 1352, 1360 (Fed. Cir.2000); IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1429-30 (Fed. Cir. 2000). In terms of defining the function, the language of the claim is not ambiguous; the function is to remove water from fuel that is received from the fuel tank. The parties disagree as to the structure in the specification that provides the means for accomplishing this function.

The Court finds that the structure which corresponds to the function of removing water from the fuel is disclosed in the specification and discussed at col. 3, lines 5-12. It includes a filterhead and a removable cartridge with a drain valve, such
cartridges "being well know in the art." Col. 3, line 14; see also, col. 1, lines 21-23.

While Defendants agree that the initial fuel filter means includes a filterhead and removable cartridge, Defendants assert, as they did regarding issue 1, that the water filter means includes a water separation filter, particle filter, fuel pump, and regulator valve, citing to col. 2, lines 65-68. Once again, however, the language quoted by Defendants is repeatedly and expressly qualified in the specification, which states that the initial fuel filter means "may" include such elements.

Moreover, as Plaintiffs note, it is improper to restrict a means-plus-function limitation by requiring a structure that performs functions different from the function expressly recited in the claim. Creo Prods., Inc. v. Presstek, Inc., 305 F.3d 1337, 1345 (Fed. Cir. 2002). The structure disclosed in the written description is "corresponding" to the claimed means under § 112 only if the structure is clearly linked by the written description or the prosecution history to the function recited in the claim. Unidynamics Corp. v. Automatic Products Int'l, Ltd., 157 F.3d 1311, 1319 (Fed. Cir. 1998); B. Braun Medical, Inc. v. Abbott Laboratories, 124 F.3d 1419, 1424 (Fed. Cir. 1997). None of the additional items listed by Defendants perform the function of removing water from the fuel. The specification states that the fuel pump pressurizes the fuel (col. 3, lines 26-27), while the particulate filter removes unwanted solids from the fuel (col. 3, lines 33-36), and the regulator valve controls the flow rate of the fuel. Col. 3, lines 36-38. In addition, these functions are performed after the water filter removes water from the fuel. Col. 3, lines 20-35. It would be improper to require these additional limitations as part of the initial fuel filter means. See Unidynamics, 157 F.3d at 1319.

As such, the Court finds that the initial fuel filter means is "a water separation filter comprising a filterhead and removable cartridge with a drain valve, or equivalents thereof." Col. 1, lines 21-23; col 3, lines 5-14.

On appeal, Honeywell argues that the district court erred by limiting the "fuel injection system component" limitation to a fuel filter and including no other component of a fuel injection system. In doing so, Honeywell contends that the court imported a limitation from the specification into the claims and thereby improperly limited the scope of the claims to the specification's preferred embodiment. According to Honeywell, nothing in the specification explicitly limits the claim term to a "fuel filter." Honeywell relies on a statement contained in the specification referring to "the metallic components used in prior art systems," '879 Patent, col.1 ll.32-33, to argue that the term "component" was meant to be broad. It also cites the patent's abstract, which summarized the invention using the term "component," and the title of the patent as amended, to further argue that the specification did not limit the "fuel injection system component" to a fuel filter.

In addition, Honeywell points to the prosecution history in assigning error to the district court's construction of the "fuel injection system component" limitation. According to Honeywell, the patentee stated during prosecution that the intended scope of the claims was to include "all fuel components manufactured of the moldable material disclosed and claimed in the specification." Honeywell also notes that the patent examiner issued a restriction requirement during prosecution of the '084 application (which also included claims to "fuel filters") because "the fuel system component [claims] do[] not specifically require that the component be a fuel filter."

Mainly reiterating the points made by the district court in its claim construction decision, ITT/TG responds that the claim term "fuel injection system component" was correctly limited to a fuel filter. ITT/TG also argues, however, that the court erred in its construction of the "electrically conductive fibers" limitation. ITT/TG contends that the court should have construed that term to include only metal fibers with a high aspect ratio, not carbon fibers. According to ITT/TG, the written description compared the properties of metal and carbon fibers, and "disparaged" the use of the latter as an electrically conductive fiber. ITT/TG contends that there was a clear disavowal of carbon fibers from the scope of the claims. Moreover, because the accused quick connects are indisputably made with carbon fibers, ITT/TG asserts that there can be no infringement either literally or under the doctrine of equivalents.

We agree with the district court that the claim term "fuel injection system component" is limited to a fuel filter. In Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005) (en banc), this court recognized that "claims 'must be read in view of the specification, of which they are a part.'" We further stated that "the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Id. (internal citations omitted). Here, the written description uses language that leads us to the conclusion that a fuel filter is the only
"fuel injection system component" that the claims cover, and that a fuel filter was not merely discussed as a preferred embodiment. On at least four occasions, the written description refers to the fuel filter as "this invention" or "the present invention":

This invention relates to a fuel filter for use in the fuel line that delivers fuel to a motor vehicle engine. '879 Patent, col.1 ll.8-9.

According to the present invention, a fuel filter for a motor vehicle is made from a moldable material which may be safely used in vehicles equipped with electronic fuel injection system. Id., col.1 ll.40-43.

This and other advantages of the present invention will become apparent from the following descriptions, with reference to the accompanying drawing, the sole Figure of which is a cross-sectional view of a fuel filter made pursuant to the teachings of the present invention. . . . Id., col.1 ll.43-49.

According to the present invention, an electrically conductive path is provided between the fuel within the inlet cavity 42 [of the fuel filter] and the [vehicle] body 38. Id., col.3 ll.41-43.

The public is entitled to take the patentee at his word and the word was that the invention is a fuel filter.

Moreover, the written description does not indicate that a fuel filter is merely a preferred embodiment of the claimed invention. The fuel filter was the only component of an EFI system that the written description disclosed as having a polymer housing with electrically conductive fibers interlaced therein. The only other fuel component specifically mentioned in the written description, the fuel line, was not required by the patentee to be made of an electrically conductive polymer material, as the claims require. See id., col.1 ll.59-60 (stating that the "fuel line may also be made of a non-conductive material"). The written description's detailed discussion of the prior art problem addressed by the patented invention, viz., leakage of non-metal fuel filters in EFI systems, further supports the conclusion that the fuel filter is not a preferred embodiment, but an only embodiment. Id., col.1 ll.10-25. Given the written description's disclosure, we conclude that the patentee has limited the scope of the '879 patent claims to a fuel filter.

Nor are we persuaded by Honeywell's argument that the patentee confirmed a broader scope of his claims during prosecution. Honeywell relies mainly on the patentee's response to the examiner's indefiniteness rejection in which he stated that the claims cover "all fuel components manufactured of the moldable material disclosed and claimed in the specification." Honeywell places too much weight on that statement, as we find it to be ambiguous and possibly inconsistent with the written description. After all, the only fuel component disclosed and claimed in the patent was a fuel filter. In any event, such a broad and vague statement cannot contradict the clear statements in the specification describing the invention more narrowly.

We also do not assign much weight to the patent examiner's restriction requirement with respect to claims for a "fuel filter" and a "fuel system component" during prosecution of the '084 application. In making the restriction requirement, the examiner did not construe the claim term "fuel system component" or determine its meaning in light of the written description. He merely required that the applicant elect one aspect of his invention for prosecution without applying it to the specification.

Nevertheless, even if we were to agree with Honeywell that the patentee clearly expressed his intention during prosecution to have the "fuel injection system component" limitation include components in addition to a fuel filter, it would not change the result in this case. As we determined above, the written description provides only a fuel filter that is made with polymer housing and electrically conductive fibers interlaced therein. No other fuel injection system component with the claimed limitations is disclosed or suggested. Where, as here, the written description clearly identifies what his invention is, an expression by a patentee during prosecution that he intends his claims to cover more than what his specification discloses is entitled to little weight. See Biogen, Inc. v. Berlex Labs., 318 F.3d 1132, 1140 (Fed. Cir. 2003) (stating that "[r]epresentations during prosecution cannot enlarge the content of the specification").
1. Claim 2: "fuel reservoir"

Claim 2 is construed to mean "the portion of the apparatus for pumping fuel in which fuel is collected and retained apart from the fuel in the fuel tank."

1807

1. Fuel Reservoir

TI Group first argues that the district court's construction of the term "fuel reservoir" is too narrow and is not consistent with the written description of the patent. In particular, the district court construed the term to mean "the portion of the apparatus for pumping fuel in which fuel is collected and retained apart from fuel in the fuel tank." Markman Order at 1. TI Group argues that this definition unnecessarily imports the limitation of retaining fuel apart from the fuel in the fuel tank and is inconsistent with both the term's ordinary and customary meaning and the term's usage in the written description. Instead, TI Group urges that we adopt the broadest dictionary definition as the ordinary and customary meaning of the term "reservoir"--"any receptacle for fluids." 13 The Oxford English Dictionary 703-04 (2d ed. 1989). VDO argues, in response, that the correct construction of "reservoir" is one of the more narrow definitions provided in the dictionary: "a part of some apparatus in which fluid or liquid is contained," id., or "a part of an apparatus in which a liquid is held," Webster's Third New International Dictionary 1931 (1986) ("Webster's").

The dictionary entries for "reservoir" in both The Oxford English Dictionary and Webster's have several definitions that are facially relevant to the claimed invention. Each of the definitions implicates some sort of containment of liquid. Even the definition urged by TI Group, i.e., "any receptacle for fluids," requires that the fluid be retained apart or contained. See 13 The Oxford English Dictionary 320 (2d ed. 1989) (defining "receptacle" as "that which receives and holds a thing; . . . a containing vessel, place, or space" (emphases added)). Thus, TI Group's argument that the district court's construction is unduly narrow is not persuasive. The notion of retaining or containing liquid in the receptacle is a common theme in each of the dictionary definitions. As the district court correctly observed, in the context of this invention, the fuel in the reservoir is contained, or held apart, from the fuel in the fuel tank.

The written description fully supports the ordinary meaning of the term "reservoir" identified by the district court, and there is no indication that TI Group disclaimed or disavowed meaning or acted as its own lexicographer in giving the term another meaning. We therefore affirm the district court's definition of the term "reservoir" as meaning "the portion of the apparatus for pumping fuel in which fuel is collected and retained apart from fuel in the fuel tank."

1808

ii. "full flow"

The term "full flow" also appears in the preamble of each of the asserted independent claims. CFMT argues that the term refers to the inventors' short hand name for a process that includes the characteristics of flowing process fluids past wafers in a process vessel that is hydraulically full. YieldUP counters that the term "full flow" is a CFMT trademark that is not explicitly defined in any part of the patent documents. If the court construes the term, YieldUP contends that it means requiring turbulent plug flow with a high volume turnover rate.

The court does not find that the term "full flow" is an undefined trademark used by CFMT strictly for its marketing purposes. YieldUP markets its own products as "full flow processors" and YieldUP's co-founder and Chief Technology Officer, Suraj Puri, has filed a patent application covering a "Full Flow Method and Apparatus for Cleaning Objects Using Dilute Ammonium Solutions." Therefore, the court finds that the term "full flow" would be understood by one of ordinary skill in the art.

The specification of the '532 patent does not suggest that "full flow" means "plug flow" as YieldUP argues. On the contrary, the two references to "plug flow" in the specification of the '532 patent suggest that if the inventors had meant to refer to
"plug flow" in the patent claims, they knew how to do so, and they would not have used the term "full flow" instead. As advocated by CFMT, the court finds that the term "full flow" is a short-hand name for the method of flowing process fluids past wafers in a vessel that is hydraulically full.

The claim and specification of the 940 patent make clear that the base of the device is a "typical funnel arrangement." 940 pat., col. 2, lines 23-24. While the embodiment in the patent shows a funnel of conical shape, the specification notes that the base "may be of any other shape providing a large open top and small open bottom to facilitate the pouring of fluid into a vessel having a small mouth." Id., col. 2, lines 25-28.

In spite of the variety of shapes a funnel may take, the term "funnel" cannot be re-configured here to cover defendant's devices. The ordinary meaning of the word 5 appears to have been intended by the claim and the definition set forth in the specification. More particularly, the base [10] is required to have a large open top [18] tapering to a narrow pipe-like open bottom [20] for the purpose of directing fluids into a relatively small opening, such as a gas tank orifice. 940 pat., col. 1, lines 19-24. See, e.g., Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1553 (using dictionary to define the claim terms "at" and "to"); American Permahedge, Inc. v. Barcana, Inc., 105 F.3d 1441, 1444 (Fed. Cir. 1997) (relying on dictionary definition to construe the claim term "lateral"). The commonly accepted meaning of the word funnel is intrinsic in claim one - "a large open top tapering downwardly toward a reduced open bottom." 940 pat., col. 4, lines 7-9.

5 Although dictionaries technically are extrinsic evidence, the Court of Appeals for the Federal Circuit has noted that:

judges are free to consult such resources at any time in order to better understand the underlying technology and may also rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents.

Vitronics, 90 F.3d at 1584 n. 6.

The Random House Dictionary 575 (Unabridged 1983) defines a funnel as a "cone-shaped utensil with a tube at the apex, for conducting liquid or other substance through a small opening, as into a bottle, jug, or the like." Other than noting that the shape of the cone need not be conical, the claim and specification follow this standard definition.

A. "A FURRY PET"

Plaintiff argues that the claim term "a furry pet" in claim 1 2 of the '540 Patent means "a pet having fur," while Defendants argue that the claim term means "a pet having fur, examples of which include a cat, a dog, and a horse." The Court believes that Plaintiff's proposed definition is proper, therefore, the Court construes the term "a furry pet" as "a pet having fur."
This disputed phrase appears in Claims 1 and 16 of the '015 Patent. Plaintiff has offered two alternate constructions. Plaintiff's first proposed construction for this phrase is as follows: "a method of making a mechanical surface adhesion bond between electrically conductive elements by applying heat to soften the elements without melting them and pressure to force the softened elements together." Alternatively, Plaintiff proposes this more concise construction: "method of bonding electrically conductive elements together by applying heat and pressure to force the elements together." Defendants, on the other hand, argue that "fusing method of forming a fused joint" means: "method of making a connection between two or more parts resulting from uniting or blending in a whole by melting together."

The first obvious difference in the two proposed constructions centers on the question of whether the joining of the two parts to be connected, in this case the terminal and armature wire, requires heating the parts to the point of melting. Under Defendants' proposed construction, the terminal and armature wire would be heated to the point of melting, which in turn could cause them to become joined. Under Plaintiff's construction, melting is expressly avoided and the parts are merely softened by the application of heat. Also, the parties differ on the issue of whether the application of pressure to the parts being joined is included within the meaning of the disputed phrase.

In support of its proposed construction, Plaintiff points first to the language of the claims themselves. According to Plaintiff, nothing in Claim 1 or Claim 16 indicates that the fusing method claimed requires heating the terminal and the armature wire to the point of melting them together. In response, Defendants point to the language in the claims that describes the application of "heat sufficient to . . . fuse" the armature wire to the terminal. This language, according to Defendants, specifically describes melting because, they argue, "to fuse" means "to bond" and the fusing described in the claims entails the application of only heat to achieve the resulting bond, i.e., to "mak[e] a fused joint." Said another way, under Defendant's interpretation, the "fusing" described in the disputed phrase is a heat-only process that involves bonding parts through the process of melting them together.

However, Defendants' argument appears to be somewhat circular, as it is dependent upon the construction of the term "fuse," and how this term, as well as the concept of "fusing," is understood by a person of ordinary skill in the art of commutator fusing. See On Demand Machine Corp. v. Ingram Industries, Inc., 442 F.3d 1331, 1337 (Fed. Cir. 2006) ("[T]he proper judicial construction of a claim and its terms is from the viewpoint of a person of ordinary skill in the field of the invention; the court must determine how such a person would understand the claim in the context of the particular technology and the description in the specification, with due reference to the prosecution history."). Persons of skill in the art are deemed to read the claim term "not only in the context of the particular claim in which the patent appears, but in the context of the entire patent, including the specification." Phillips, 415 F.3d at 1313. Indeed, the Phillips court noted that the specification may be the "single best guide to the meaning of a disputed term." Id. at 1315.

The specification of the '015 Patent describes the procedure known as "fusing":

- 2236 -
Fusing is a known technique for joining electrically-conductive elements in which a fusing electrode is contacted with one element adjacent the joint so that the fusing electrode forces the elements together. A ground electrode is also contacted with one of the elements, typically at a location remote from the joint, such that an electrical current is passed through the electrodes and at least one of the elements. Heat generated by the electrical current, and the high pressure applied by the fusing electrode, causes a bond to form between the elements.

Nothing in the patent specification indicates that "fusing" requires "melting" of any part to be joined. Nor, according to the specification, does "fusing" appear to be a heat-only process. Rather, the specification describes "fusing" as the joining of electrical conductors through the application of both heat and pressure. This supports Plaintiff's proposed construction of the disputed term.

Similarly, the prosecution history of the '015 Patent and the prior art of a patent discussed during prosecution further support Plaintiff's proposed construction. It appears that the Patent Examiner had considered the term "fusing" to be synonymous with "welding," which, like Defendants' interpretation of the term, would require melting. However, counsel for Joyal explained to the examiner that "fusing" and "welding" were "entirely different joining techniques." Buckingham Decl. 2, Ex. B at J00198. Counsel explained that "fusing" involved joining elements to one another "under the combined influence of heat transferred from the fusing electrode and pressure applied by the fusing electrode." Id. at J00198. Additionally, counsel referred to the prior art Warner '152 patent, 3 which had been cited by the Patent Examiner, and which explained that in "fusing," "the electrode dissipates heat into the assembly to soften the parts without causing them to reach their plastic state. . . . [P]ressure is applied to thereupon force the softened parts together to form the compression joint." Buckingham Decl., Ex. D at col. 1:60-64.

3 United States Patent No. 4,034,152, "Termination System For Fusing Aluminum-Type Lead Wires."

Notwithstanding the above evidence that supports the conclusion that "fusing" or "to fuse" is understood by persons skilled in the art to include the application of both heat and pressure, Defendants argue that the inclusion of "pressure" into the construction of Claim 1 is not permitted under the doctrine of claim differentiation. That doctrine is based on "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1369 (Fed. Cir. 2007) (quoting Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir.1999)). Defendants point to Claim 4, which states as follows: "The method of claim 1, further included applying a compressive force against said terminal by said electrodes." According to Defendants, if the application of pressure was included in the construction of Claim 1, then Claim 4 would be rendered redundant and superfluous. 4

4 Defendants also argue that such a construction would render Claim 4 invalid under 35 U.S.C. § 112, paragraph 4, which requires a dependent claim to "specify a further limitation of the subject matter claimed" in the independent claim. However, the validity of Claim 4 is not at issue here.

Plaintiff responds that the specification makes clear that the application of pressure that is described in Claim 1 is different from the application of pressure set forth in Claim 4, and, therefore, the claims are consistent with the doctrine of claim differentiation. Plaintiff asks the Court, consistent with the doctrine of claim differentiation, to "presume[] a difference in the meaning and scope when different words or phrases are used in separate claims." Comark Comm., Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). According to Plaintiff, Claim 4 refers to an optional subsequent step of pressure being applied, which is in addition to the application of pressure during the fusing described in Claim 1. Indeed, Claim 4 expressly uses the term "further," which in ordinary usage means "additional." Furthermore, the specification of the '015 Patent
explains that under the fusing process pressure is "once again" applied after the insulation on the armature wire is burned off:

Once the electrical insulation has been removed, the mounting arm or pistons of the fusing apparatus, under control of the welding unit, is once again operated to cause the fusing and ground electrodes to apply a compressive force to the tang to fuse the armature wire (under heat and pressure) to the tang. . .

Additionally, Plaintiff points out that if the inventor had intended to exclude the use of pressure in Claim 1, the claim would not have been written to require that electrodes be moved against the terminal "to form a current path," which, according to Plaintiff, necessitates the use of pressure. See discussion in section II.7, infra, regarding construction of a phrase that includes the language "to form a current path." Last, Plaintiff references several different patents that describe fusing and which explain that a second application of physical force may occur as part of the fusing process. See, e.g., Buckingham Decl. at Ex. G, Col. 1:24-26. The Court finds that, particularly in light of the teaching of the specification as well the language of Claim 4 itself, the doctrine of claim differentiation does not preclude a construction of Claim 1 that would include the application of pressure.

Considering the plain language of Claims 1 and 16 as well as the specification of the '015 Patent, the patent prosecution history, and relevant extrinsic evidence, the Court shall construe "fusing method of forming a fused joint" consistent with Plaintiff's proposed construction as follows: "a method of making a mechanical surface adhesion bond between electrically conductive elements by applying heat to soften the elements without melting them and pressure to force the softened elements together."

BACKGROUND

Trilogy owns the '846 and '250 patents, which relate to coaxial cables. A coaxial cable typically has a solid metal inner conductor surrounded by a cylindrical insulating material. The insulating material is covered by a tubular metal outer conductor, known as a "sheath." The asserted claims of the '846 patent relate to a coaxial cable in which the insulating material, specifically a foam dielectric, is "fusion bonded" to the sheath.

Claim 1 of the '846 patent reads (with emphasis added) as follows:

An electrical cable including . . . [a] foamed dielectric insulation . . . the insulation being bonded to the core and being under some radial pressure between the core and the sheath, said insulation filling irregularities in the inside surface of the sheath and being fusion-bonded to the sheath.

Claim 6, the only other asserted claim of the '846 patent, depends from claim 1, and reads:

The electrical cable described in claim 1 characterized by the bond of the foam to the sheath including an outer layer of adhesion-promoting material that bonds the foam insulation to the inside surface of the sheath at a temperature lower than the fusion temperature of the foam.

The '250 patent relates to a method for manufacturing coaxial cables that involves "fusion-bonding" the foam insulation to the sheath. Trilogy asserted only independent claim 1 and dependent claim 8 of the '250 patent. Claim 1 reads (with emphasis added):

The method of making an electrical cable including . . . fusion-bonding the insulation to the inside surface of the cable sheath by heating the sheath.

Times Fiber manufactures coaxial cables that contain a foam dielectric insulation bonded to the sheath with an adhesive. Trilogy sued Times Fiber, asserting that the '846 and '250 patents were infringed by Times Fiber's manufacture and sale of
requires the foam to melt, renders claim 6 meaningless. Trilogy concludes that the district court's claim construction, which

requires a fusion bond to be formed at a temperature lower than the fusion temperature of the foam. Trilogy argues, claim 6 indicates that the fusion bond of claim 1 includes a bond that can be formed at a temperature below the fusion temperature of the foam. Trilogy contends that this interpretation of the claim terms "fusion-bonded" and "fusion-bonding" do not read on its products. The district court construed these claim terms as requiring the foam dielectric insulation to melt onto the sheath. Because Trilogy conceded that the bond in the accused products is not formed by melting the foam, the court held as a matter of law that the accused products did not infringe the patents.

Resolving the infringement claim, the court certified the summary judgment of non-infringement as an appealable final judgment pursuant to Fed. R. Civ. P. 54(b). The court stayed further proceedings on Times Fiber's counterclaims, including its claim for a declaratory judgment of patent invalidity and unenforceability.

Trilogy appeals to this court, challenging the district court's claim construction and arguing that the district court abused its discretion by excluding extrinsic evidence submitted by Trilogy in support of its proffered claim construction. Times Fiber cross-appeals, arguing that the district court erred by failing to give the prior decision of invalidity and unenforceability collateral estoppel effect.

DISCUSSION

We review a district court's grant of summary judgment de novo. Conroy v. Reebok Int'l, Ltd., 14 F.3d 1570, 1575, 29 U.S.P.Q.2d (BNA) 1373, 1377 (Fed. Cir. 1994). Summary judgment is appropriate when no genuine issue as to any material fact exists and the moving party is entitled to judgment as a matter of law. Fed. R. Civ. P. 56(c). Thus, summary judgment may be granted when no "reasonable jury could return a verdict for the nonmoving party." See Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986); Conroy, 14 F.3d at 1575, 29 U.S.P.Q.2d (BNA) at 1377 ("The moving party . . . may discharge its burden by showing the district court that there is an absence of evidence to support the nonmoving party's case."). In determining whether there is a genuine issue of material fact, we view the evidence in the light most favorable to the party opposing the motion, with doubts resolved in favor of the opponent. Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1274, 35 U.S.P.Q.2d (BNA) 1035, 1038 (Fed. Cir. 1995).

A. Infringement

Determining whether a patent claim has been infringed requires a two-step analysis: "First, the claim must be properly construed to determine its scope and meaning. Second, the claim as properly construed must be compared to the accused device or process." Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1576, 27 U.S.P.Q.2d (BNA) 1836, 1839 (Fed. Cir. 1993). Claim construction is a question of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 983-84, 34 U.S.P.Q.2d (BNA) 1321, 1333 (Fed. Cir. 1996) (in banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384, 38 U.S.P.Q.2d (BNA) 1461 (1996). In construing the claims, the court looks to the claim language, the specification, the prosecution history, and, if necessary, extrinsic evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1576 (Fed. Cir. 1996). Application of a properly construed claim to the accused device is a question of fact.

Trilogy argues that the district court erred in its interpretation of the claim terms "fusion-bonded" and "fusion-bonding." Relying on The American Heritage Dictionary of the English Language (1969), the district court stated that the term "fusion" ordinarily means "the act or procedure of liquefying or melting together by heat." Trilogy accepts this definition. However, Trilogy disputes the district court's further conclusion that the terms "fusion-bonded" and "fusion-bonding" as used in the claims necessarily require the foam insulation to melt. Trilogy argues that a fusion bond can also be formed by liquefying or melting a heat-activated adhesive placed between the foam and the sheath and that this fusion bond is also within the meaning of the claims as properly construed.

Trilogy contends that claim 6 of the '846 patent supports its interpretation. Claim 1 recites a cable with a foam insulation that is "fusion-bonded to the sheath." Claim 6, which incorporates all the limitations of claim 1, requires that the bond in claim 1 include an adhesion-promoting material "that bonds . . . at a temperature lower than the fusion temperature of the foam." Thus, Trilogy argues, claim 6 indicates that the fusion bond of claim 1 includes a bond that can be formed at a temperature below the fusion temperature of the foam. Trilogy concludes that the district court's claim construction, which requires the foam to melt, renders claim 6 meaningless.
Contrary to Trilogy's assertion, the district court's interpretation of "fusion-bonded" in claim 1 as requiring the melting of the foam is not inconsistent with use of an adhesion-promoting material in claim 6. Claim 6 depends from claim 1, which requires that the foam be fusion-bonded to the sheath. Claim 6 limits the bond of claim 1 to one that includes an adhesion-promoting material and also requires the adhesion-promoting material to bond at a temperature below the fusion temperature of the foam. However, claim 6 does not require the fusion bond of claim 1 to form below the fusion temperature of the foam. Rather, claim 6 merely requires that the adhesive form a bond below such a temperature. In other words, under the district court's claim construction, claim 6 requires the use of an adhesion-promoting material (that bonds below the fusion temperature of the foam) and further requires the formation of a fusion bond between the foam and the sheath as required by claim 1 (which necessarily occurs at or above the fusion temperature of the foam). Thus, claim 6 of the '846 patent does not compel Trilogy's interpretation of the meaning of claim 1.

Turning to the specification, Trilogy argues that the district court ignored relevant portions of the '846 and '250 specifications that support its proffered claim construction. Specifically, Trilogy argues that the following description demonstrates that a fusion bond can be formed by melting an adhesive below the fusion temperature of the foam:

The foamed insulation can be bonded to the inside of the sheath at [a] lower temperature if an adhesion-promoting material is used. . . .

The advantage of using adhesion-promoting material is that it melts at a lower temperature than that of the foamed insulation.

'846, col. 3, lines 61-74 and '250, col. 4, lines 37-52. Trilogy argues that because the adhesion-promoting material melts, it produces a fusion bond between the foam and the sheath. We disagree. Trilogy does not point to any text in the specification that would lead us to conclude that the use of an adhesion-promoting material results in the foam insulation "being fusion-bonded to the sheath." The specification describes two types of bonds: one formed by melting the foam so that it flows onto and bonds with the sheath and the other in which an adhesion-promoting material is used. The former bond is indisputably one in which the foam is fusion-bonded to the sheath. The latter bond, which uses an adhesion-promoting material, arguably may form a fusion bond between the adhesion-promoting material and the sheath and between the adhesion-promoting material and the foam. For example, other claims which were originally in the patent, but have since been disclaimed, claimed the use of an adhesion-promoting material that is "bonded to both the foam and the metal sheath." Claim 1, on the other hand, does not merely claim the use of a fusion bond, but requires that the foam be fusion-bonded to the sheath.

Any remaining doubt as to whether the use of an adhesion-promoting material alone can form the bond in claim 1 of the '846 patent is dispelled by examination of other limitations in that claim. Claim 1 requires that the "insulation [fill] irregularities in the inside surface of the sheath." Times Fiber argues that this limitation is irreconcilable with Trilogy's proposed claim construction. As explained in the specification of the '846 patent:

The outer layer of the foam-insulated core, when melted by the application of heat to the metallic sheath, flows on to the inner side of the sheath and fills any irregularities in the sheath . . . .

'846, col. 2, lines 3-6, and

The permissible amount of melting depends upon how much the foam is compressed by the sheath. [Compression] causes the foam, when heated to a softening temperature and flowable condition, to flow as necessary to touch all portions of the inside surface of the sheath.

If the sheath is not completely round, then the softened foam will accommodate itself to any lack of circularity. Where the inside surface of the sheath is not completely smooth, the softened foam, when under some compression, flows into the irregularities so as to have contact with the entire inside surface of the sheath.

Trilogy responds that the specification discloses that irregularities are filled by either melting or softening the foam. Trilogy thus asserts that the district court erred by interpreting claim 1 of the '846 patent as requiring melting, as opposed to mere
softening in conjunction with an adhesive. We do not agree. As described in the patent specification and prosecution history, the terms "melting" and "softening" are synonymous. The patent uses the two terms interchangeably. No distinction is drawn between the temperature at which "softening" occurs and the temperature at which "melting" occurs. As the portion of the specification quoted above indicates, the key property of both melting and softening is that the foam enters a flowable condition, i.e., that it melts.

The prosecution history further supports the district court's claim construction. In response to the first office action received during prosecution of the '846 patent, the applicants stated that "the outer part of the foam can be melted and three results can be obtained. . . . Another result is that the softened foam enters into any irregularities caused by roughness of the inside of the sheath." It is clear from this passage that the "softened" foam is melted.

Similarly, claim 1 of the '250 patent claims a method of making a coaxial cable that includes "relieving pressure in the foam and fusion-bonding the insulation to the inside surface of the cable sheath." Again, Trilogy's proposed claim construction, in which the fusion bonding can occur below the melting temperature of the foam, is inconsistent with the step of "relieving pressure in the foam." The specification of the '250 patent states, "by melting the outer layer of foam [insulation] which is compressed against the metallic sheath, the radial compression which extends inward to the center conductor is reduced." Furthermore, the applicant stated during prosecution, "the pressure [on the foam] is then partially relieved by heating the sheath so as to melt the surface of the foam . . . . This bonds the foam to the sheath." After examining the claims, specifications, and prosecution histories of the '846 and '250 patents, we conclude that the district court did not err in its claim construction. Properly construed, the terms "fusion-bonded" and "fusion-bonding" in the asserted claims require the foam to melt and thereby form a bond with the sheath. Thus, since it is uncontested that Times Fiber's products are not made by fusion-bonding the foam to the sheath as we have construed those terms, the district court's finding of a lack of infringement was correct as a matter of law.

Gage

Similar to the above dispute, the parties disagree on whether the "gage" or "gage region" of the drill bit extends around the entire circumference of the drill bit or only encompasses the outermost radius of the bit. Baker Hughes contends "gage," or "gage region," means "area or region extending around the entire circumference on the drill bit and which is located at the maximum or outermost diameter of the drill bit body." ReedHycalog contends "gage" means "the outermost radius of the bit" and "gage region" means "region at the outermost radius of the bit."

Figures in the '249, '715, and '631 Patents distinguish between the "gage," or "gage region," and the junk slots. In particular, Fig. 7 of the '249 and '715 Patents, reproduced in Appendix C and annotated, shows the "gage" is disjoint from the junk slots and fluid courses on drill bit. In addition, Fig. 14A of the '631 Patent, shown in Appendix C and annotated, shows the "gage region" distinct from the junk slots and fluid courses and depicts the "gage region" as the region at the outermost radius of the bit. Thus, "gage" means "the outermost radius of the bit, labeled 207 in Fig. 7 of the '249 and '715 Patents" and "gage region" means "region at the outermost radius of the bit, labeled 322 in Fig. 14A of the '631 Patent."
A structure having a surface that can support one or more game pieces is a structure that includes a playing surface bounded by a rectangular frame or raised periphery, and which is divided into spaces that are arranged in rows and columns that are parallel to the four sides of the frame.

a. Innovention's Proposed Construction

Innovention insists that there is no reason why its intentional use of the broad generic term "game board" as used in the claims should have the highly restricted meaning the defendants propose. It further suggests that the defendants improperly propose to read in features of "four sides" and "rectangular frame" from the '242 patent's preferred embodiments, contrary to principles of claim construction, as well as contrary to the '242 patent's explicit assertion that features of the preferred embodiments are not claim limitations; the specification provides that:

The foregoing embodiments are presented by way of example only; the scope of the present invention is to be limited only by the following claims.

8 Innovention asserts that the construction of "game board" cannot include "the frame or raised periphery" and "divided into spaces that are arranged in rows and columns" features, because these are distinct limitations added by claims that further define "game board", citing (by way of example) claims 14, 23, 25, 30, 39, and 40.

b. Defendants' Proposed Construction

The defendants insist that the very function of the '242 patent depends on the game board having both a playing surface, a bounding frame, and a grid of rows and columns. The defendants point to various claims, including Claim 39, to support its proposed construction that specifies that "spaces" on the "game board" must be laid out in parallel rows and columns, like a chess board or a checker board.

As to the plaintiff's argument that the defendants impermissibly attempt to add features that are added by claims that further define "game board", the defendants urge the Court to reject the plaintiff's attempt to invoke the doctrine of claim differentiation, 9 contending that the doctrine of claim differentiation is overcome when there is powerful evidence to the contrary. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1370 (Fed. Cir. 2007). The Federal Circuit, the defendants insist, has determined that "the written description and prosecution history overcome any presumption arising from the doctrine of claim differentiation." See Kraft Foods, 203 F.3d 1362 at 1368.

9 "[C]laim differentiation...creates a presumption that each claim in a patent has a different scope." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000) (noting that doctrine of claim differentiation creates a rebuttable presumption that each claim in a patent has a different scope).

c. The Court's Construction

The term "game board" appears in many of the '242 patent's claims. Claim 15, which is representative of many of the asserted claims with respect to the term "game board", discloses "A game comprising: a game board having a playing surface and one or more receptacles for holding electronic components...." The parties agree that the claim language itself commands that a "game board" has a "playing surface." Their dispute lies in to what extent the Court should read in other
claim language and features present in a preferred embodiment into the otherwise simple phrase "game board." Indeed, the defendants insist that the 242's "game board" be rectangular, divided into rows and columns, and contain a raised periphery framing the "game board." None of these features, however, are commanded by the generic phrase "game board" or the contextual claim language; the defendants have not convinced the Court that it must go beyond the ordinary meaning of "game board" as disclosed in the claims. If the features the defendants seek to import into "game board" were intrinsically part of the term itself, further claim language would be redundant. 10 The Court agrees with the reasoning supported by the plaintiffs' posited construction: Like in Phillips, the Federal Circuit determined that the use of "steel baffles" means baffles are not inherently made of steel. 415 F.3d 1303, 1312 (Fed. Cir. 2005)(en banc).

10 The defendants' posited definition, which calls for a "frame" and "raised periphery" as well as being "divided into spaces arranged in rows in columns", contains limitations not inherent in the ordinary meaning of "game board" and would also render redundant other claim language.

The language of the claims and the principle of claim differentiation (which has not been rebutted) favors the plaintiffs' construction of the term "game board", albeit slightly modified, based on the claim language that calls for "a game board having a playing surface and a cavity [or one or more receptacles] for holding electronic components." See, e.g., Claims 1 and 15 (emphasis added). The Court determines that "game board" as taught by the '242 patent simply means: "A structure having a playing surface that can support game pieces and electronic components." While the figures of a preferred embodiment of the patent show a rectangular game board, there is nothing in the claim language restricting the game board to that particular shape, even separate language in other claims disclosing "a checkerboard-style game board"; again, the Court relies on the "steel baffles" example of Phillips. Finally, the Court also declines the defendants' invitation to read the preferred embodiment into the claim language.

3. "game piece"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendants' Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>A structure that can be placed on a game board.</td>
<td>At least a mirrored and non-mirrored piece that the player moves from space to space on the surface of the board game during the course of game playing, that is capable of being hit by one of two laser beams emanating from two laser sources permanently mounted to the game board; all game pieces are movable during play.</td>
</tr>
</tbody>
</table>

a. Innoventions' Proposed Construction

Innovention contends that "game piece" is part of the apparatus claims (claims directed to a "board game") and, therefore, the temporal limitations that the defendants would have the Court impose (that is, "moves from space to space" "during the course of game playing", and "movable during play") are inapplicable to a structural item such as "game piece", which is employed in all of the 52 apparatus claims, as well as the two method claims (claims 39 and 40). Innovention asserts that it is illogical to define "game piece" to require "laser sources permanently mounted to the game board." (Indeed, Innovention notes that the defendants are attempting to create a noninfringement argument through their construction of "game piece" because the accused Laser Battle game houses its laser sources in "LaserGun" game pieces.) Innovention again asserts a patentee's mantra: that the defendants improperly try to read limitations from the specification into the claims.
b. Defendants' Proposed Construction

The defendants counter that Innovention uses neither intrinsic nor extrinsic evidence to support its asserted construction of "game piece." The defendants rely on the '242 patent's specification and prosecution history to support their proposed construction: the claims, say defendants, recite game pieces as having a base with a periphery and under surface and, during the prosecution of the '242 patent, Innovention specifically stated that its game pieces differed from prior art cited by the Examiner because some game pieces are mirrored, while others are not mirrored.

c. The Court's Construction

Based on the language of the claims, the specification, and the prosecution history, the Court adopts a slightly modified construction, and defines "game piece" as "A mirrored or non-mirored structure that can be placed on the game board and moved by the players during the course of game playing." The mirrored/non-mirrored feature of "game pieces" was relevant in the prosecution history of the patent and is clearly supported in the claim language. 11

11 The defendants' attempt to incorporate features extrinsic to the "game pieces" themselves is rejected: a person of ordinary skill in the art would not understand "game piece" to be "capable of being hit by one of two lasers emanating from two laser sources permanently mounted to the game board." These limitations are outside the ordinary meaning of the term "game piece" and unlike the mirrored/non-mirrored feature, are not called for by the prosecution history. Moreover, the defendants' proposal that a "game piece" is something the "player moves from space to space" is contradicted by the claim language or the language of the specification both of which permit (in describing the method for playing the game) "game pieces" to be moved either from space to space or rotated in place (so that the player may position the mirror to deflect the laser). See Claim 3 9 ("...alternating turns, each turn comprising moving, either a translation or a rotation, a piece followed by activation of a laser...").

Despite the impediments to a full review, i.e., the sparse record, this court perceives some flaws in the trial court's claim construction that led to the entry of the stipulated judgment of non-infringement. Accordingly, rather than merely remand for development of a complete record, this court offers some analysis to guide the trial court upon remand.

In analyzing the term "gap," the trial court noted that, according to the claim language, the insert is "separated from the tubular frame by a gap" except at its ends, where the insert and the frame were adjoined. The court found no indication that the inventor had given the word "separate" other than its ordinary meaning. In that connection, the trial court consulted Webster's II New Riverside University Dictionary to determine that "separate" meant "set apart from others" and "existing by it self." The dictionary reference also included "void," which means an "open space or a break in continuity." The trial court considered this definition synonymous with "gap." The court further noted that the frame must be "elastically deflectable across the gap to operably engage the insert," which would not be possible if the frame and insert were initially engaged.

The various claims in this patent, however, contain distinctions that cast doubt on the trial court's interpretation of "gap" and its conclusion that all of the disputed claims require a "single continuous space or void." For example, claim 1 features the gap in at least part of an annular shape; claim 15 makes the gap itself annular; claim 18 has no annular requirement. Under this court's case law, the same terms appearing in different claims in the same patent—e.g. "gap" in claims 1 and 15—should have the same meaning "unless it is clear from the specification and prosecution history that the terms have different meanings at different portions of the claims." Fin Control Sys. Pty. Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001); Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) (en banc) ("Claim terms are normally used consistently throughout the patent."). In this case, the claims use the term "gap," but then modify it differently to suggest differences in the geometry of the "gap" in the various claims.
Taking into account the term "annular," "gap" takes on a meaning different from the trial court's construction. Specifically, the modifiers to "gap," such as "annular," produce significant differences in the geometries in each defining claim. These modifiers inform the nature of the gap in each claim and define differently the cross-section of the claimed insert. ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003) ("The context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms.").

This court notes that the adjective "annular" appears only within the claims, not in the patent specification. Nothing in the specification, including the claims, indicates explicitly or implicitly, that the inventor intended to impart a novel meaning to "annular." The record also contains no evidence that "annular" has a peculiar meaning in the field of art encompassed by the '398 patent. This court concludes, therefore, that the ordinary and customary meaning attributed to this term by those of ordinary skill in this art at the time of invention "involves little more than the application of [its] widely accepted meaning." Phillips, 415 F.3d at 1314.

This court has previously recognized that the ordinary and customary meaning of "annular" is "of or relating to an area formed by two concentric circular or curved regions." Int'l Rectifier Corp. v. IXYS Corp., 361 F.3d 1363, 1372-73 (Fed. Cir. 2004) (citing Webster's Third New International Dictionary 88 (1966)). Giving "annular" its proper place in the construction of the claims informs the interpretation of "gap." In claim 1, both the frame and the insert unequivocally have "a circular cross-section," but the gap between them need only form "at least part of an annular shape along a central portion between" the ends. The claim language thus permits non-annularity somewhere along the central portion. Annularity also requires "roughly parallel sides." An embodiment without the annular requirement, therefore, need not have even "roughly" parallel sides. Thus, a claim without the "annular" requirement or with only a partial "annular" requirement could have a gap characterized by intersection of part of the cross-section between insert and frame. In other words, claims 1 and 18 do not require concentricity of the circular insert and frame. Moreover, those claims do not foreclose some contact between the insert and frame.

In claim 18, neither "gap" nor "annular" appear. Instead, the insert has "a substantially circular cross-section" "within the impact portion" of the frame. This impact portion is "inwardly elastically deflectable" to allow contact ("a tight interference fit") between the insert and the impact portion. The term "substantial" implies "approximate," rather than "perfect." Liquid Dynamics Corp. v. Vaughn Co., Inc., 355 F.3d 1361, 1368 (Fed. Cir. 2004). Therefore, in contrast to the insert of claim 1, the insert in this claim need not be perfectly circular. Rather the claim requires only space between the frame and the insert to allow for contact when the impact portion is elastically deflected. Because the bat hits the ball at only a small point of impact, not extending over the entire circumference of the frame, claim 18 also does not foreclose the possibility that contact between the frame and insert occurs, before impact, at some point other than at which it impact occurs. As a result of these considerations, this court defines "gap" for the purposes of claims 1 and 18 of the '398 patent as "a separation." The separation may be localized, so that a cross-section of the bat in the impact region need not possess circular symmetry.

1818

Construction of "gap" and "line segment" at this time is consistent with the Court's "broad powers of case management." The parties dispute whether the defendants' products contain a "gap," and therefore construction of the term may prove dispositive. The "salutary goals of speed and economy" are furthered by construing the term now. Id. at 804.

Other cases support the Court's decision to construe "gap" and "line segment" without further delay. In Exigent Technology, Inc. v. Atrana Solutions, Inc., 442 F.3d 1301 (Fed. Cir. 2006), the plaintiff argued that construction was inappropriate before the close of expert discovery. The Court, rejecting this argument, expressed doubt that the need for additional discovery on claim construction issues can serve as a valid basis for a Rule 56(f) motion. Id. at 1311.

The case for postponing construction is even weaker here than it was in Exigent Technology because the plaintiff has failed to pinpoint a single topic on which it needs discovery. See also The Mass. Inst. of Tech. and Elec. for Imaging, Inc. v. Abacus Software, 462 F.3d 1344 (Fed. Cir. 2006) (affirming in part a district court's claim construction where court stayed discovery until the issuance of its Markman ruling); Network Commerce, Inc. v. Microsoft Corp., 422 F.3d 1353, 1363-64 (Fed. Cir. 2005) ("There is no requirement that the district court construe the claims at any particular time").

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
2 The plaintiff's contention that full-scale discovery is needed prior to claim construction is undercut by its case
management schedule, which proposed that the parties exchange disputed claim terms more than six months before the
close of fact discovery.

The plaintiff next argues against the Court's "piecemeal" construction of claim terms, pointing to the rule that a court must
interpret terms as they are used in the claims. See, e.g., Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005). This
rule speaks to the proper method of interpreting claim terms, instructing a court to consider modifying words and phrases
when construing a particular term. It does not, however, mandate the construction of all disputed terms at once. (In Vivid
Technologies, for example, the parties did not identify all disputed claim terms before the district court's construction.) If the
plaintiff believed that other terms in its patent shed light on the meaning of "gap," it was free to make such arguments, and
indeed, in response to the Court's proposed construction, it has.

The plaintiff also relies on Bayer AG v. Biovail Corp., 279 F.3d 1340 (Fed. Cir. 2002), but that case is inapposite. In Bayer,
the district court held that it had implicitly construed a disputed term in a prior opinion. The Federal Circuit disagreed,
holding that there was no implicit construction of the disputed term and stating that it would be "premature" for it to engage
in claim construction without a lower court construction to review. Id. at 1349. Bayer therefore speaks to the proper timing
for appellate review, not the district court's construction.

The plaintiff's final argument is that it would be inefficient to construe "gap" now because of the possibility that
construction of additional claim terms will be needed at a later stage. The Court believes that it would be more inefficient
for the parties to conduct discovery that the Court's construction might render irrelevant. The Court will revise its
construction if it becomes necessary, but the plaintiff has not explained how such a revision would cause the Court or the
parties undue hardship. Further, the Court believes that such a possibility is unlikely, given the unambiguous usage of the
terms in the patent.

III. Claim Construction

Claim construction begins with the intrinsic evidence of record: the patent's claims, specification, and prosecution history.
Goldenberg v. Cytogen, Inc., 373 F.3d 1158, 1164 (Fed. Cir. 2004); Bell Atlantic Network Servs. v. Covad Commc'ns
Group, Inc., 262 F.3d 1258, 1267 (Fed. Cir. 2001). In construing patent terms, there is a heavy presumption that they carry
their ordinary and customary meanings as would be understood by one of ordinary skill in the art. Goldenberg, 373 F.3d at
1164. Where a claim term has no ordinary and customary meaning, a court must resort to the remaining intrinsic evidence to
obtain the meaning of that term. Id. If ambiguity persists, a court may look to extrinsic evidence, such as expert or inventor
F.3d 701, 706 & n.5 (Fed. Cir. 1997). Where the intrinsic evidence is unambiguous, it is improper for a court to rely on
extrinsic evidence. Id. at 706.

The Court therefore begins with the language of the claims of the '961 patent, which contains one product claim and one
process claim.

The product claim states that the invention comprises three layers that are bonded together along plural concentric lines,
which form a barrier resistant to the egress of fluid out of the periphery of the pad. Col. 9, ll. 16-28. Each concentric line includes at least one line segment and at least one gap, which serves to enhance the flexibility of the pad at the location of the gap. Id. ll. 28-30, 35-36.

The patent also claims the process of producing the invention described in the product claim. Col. 10, ll. 23-59. Dependent claims 26 and 27 describe two methods of forming the line segments: pressure and thermal bonding. Col. 11, ll. 5-12.

The plain language of the claims reveals that the layers of the pad are bonded together along concentric lines, but not at every point along the line. Instead, there are "gaps" in the bonding that enhance the flexibility of the pad. "Line segment," therefore, refers to a space along a concentric line where the pad's layers are bonded together, and "gap" refers to a space along a concentric line where there is no bonding.

Dependent claims 26 and 27, then, teach that the bonding that forms the line segments can be accomplished by pressure and thermal bonding, for example. This reading is consistent with the specification's discussion of several embodiments of the invention, containing line segments formed by various methods of bonding. See, e.g., col. 5, ll. 24-45; col. 7, ll. 45-50; col. 8, ll. 45-48. 4

4 The remaining piece of intrinsic evidence, the patent's prosecution history, has not been submitted nor referenced by either party to support its proposed definitions.

The defendants agree with the Court's proposed construction. 5 The plaintiff objects to the Court's definition, proposing that the Court define "line segment" as "a portion of a plural concentric line at which the top-sheet, fluid absorbent core, and cover sheet are bonded together to form a barrier resistant to the egress of fluid" and "gap" as a "portion of a plural concentric line at which the top-sheet, fluid absorbent core, and cover sheet are not bonded together to form a barrier resistant to the egress of fluid, regardless of how or when such portion is formed."

5 In their summary judgment brief, the defendants argued that "line segment" referred to "compressed portions" and "gap" to "uncompressed portions." When the specification summarizes the invention, however, "pressure" or "compress" are mentioned only once—in a description of "one aspect of the method" of the invention. Col. 2, ll. 44-48. And no form of the words "compress," "pressure," or "density" is mentioned in either independent claim. The Court therefore believes that the defendants' original construction would improperly confine the meaning of claim terms to their usage in a specific embodiment of the invention. See, e.g., Phillips, 415 F.3d at 1323.

The Court rejects the plaintiff's definitions for several reasons. First, the phrase "regardless of how or when such portion is formed" is unnecessary. The Court's definition does not, contrary to the plaintiff's fear, mandate how or when the gap must be formed, but instead only requires that a "gap" lack bonding.

Second, the plaintiff's definitions stem in part from a misreading of the patent. In the plaintiff's view, "line segments" are barriers preventing the egress of fluid, while "gaps" are segments of the pad that are not barriers. The barriers referenced in the claims, however, are the plural concentric lines, which include both line segments and gaps and prevent fluid from exiting the pad. Col. 9, ll. 26-30; col. 10, ll. 45-51. See also col. 2, ll. 40-43 ("The plural concentric lines form a barrier resistant to the egress of fluid out of the periphery of the pad and include at least one gap therein. . ."); Pl.'s Resp. to the Court's May 9, 2007 Letter at 10 (referring to "concentric lines[,] of which the line segments and gaps are part."). In other words, the gaps and the line segments collectively form a "barrier" that prevents fluid from leaking out of the pad. This runs counter to the plaintiff's definition of "gap" as a place where a "barrier" is lacking. 6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
A line segment may, of course, be a "barrier" in the sense that it "serve[s] as a wall across which fluid cannot flow." Col. 6, l. 28. But the patent's claims refer unambiguously to the barrier formed by the concentric lines--the combination of gaps and line segments--that prevents fluid from exiting the pad. The specification is in accord, referring, for example, to the "unbroken portions of the concentric barrier lines," indicating that the concentric barrier lines contain both broken and unbroken portions--gaps and line segments. Id. ll. 26-27.

The plaintiff's remaining objection is that the Court should not define "gap" as a place where there is no bonding because the specification teaches that the layers of the pad may be secured to one another by adhesion. See col. 3, ll. 28-30, 46-50. But the fact that layers of the pad are "secured" by adhesion does not suggest that they are "bonded" within the meaning of the claims. The specification itself illustrates this point when it states that the three layers may be bonded together through pressure and adhesion, implying that adhesion alone would not qualify as "bonding." Col. 5, ll. 39-41.

In fact, the patent mentions "bonding" only once: in reference to the formation of bonded line segments. "Gap" is differentiated from, and juxtaposed with, these bonded line segments. A "gap" is therefore a space defined by the absence of bonding. Interpreting the gaps as containing bonding would contradict the claims, which state that the absence of bonding at the gaps increases the flexibility of the pad. If the gaps do, in fact, contain bonding, then this feature of the invention would be eliminated.

Because "line segment" and "gap" are used unambiguously in the patent, the Court declines to refer to extrinsic evidence. 7

The only piece of extrinsic evidence cited by the parties is the plaintiff's quotation from dictionary definitions of "gap." The Court rejects these definitions to the extent that they are inconsistent with the usage of "gap" in the claims. The Federal Circuit has warned against resorting to non-scientific dictionaries to ascertain the meaning of claim terms, stating that claim construction should focus not on a term's abstract meaning but rather its use in the patent. Bell Atlantic, 262 F.3d at 1267; Phillips, 415 F.3d at 1321.

An appropriate order follows.

ORDER

AND NOW, this 24th day of July, 2007, upon consideration of the parties' submissions on claim construction, and after oral argument on the defendants' motion for summary judgment heard on March 2, 2007, IT IS HEREBY ORDERED that the terms "gap" and "line segment" in the '961 patent are construed as follows:

1. Line Segment: a space along a concentric line where the pad's layers are bonded together;

2. Gap: a space along a concentric line where there is no bonding.

E. Gap

Pall asserts that the term "gap" should be construed by the Court to mean spaces between opposing surfaces of the pleat legs. Cuno argues that limitations on the size and geometric shape of the gap should be included in the asserted patents. This Court disagrees. As already stated, despite the fact that there may appear to be support for this construction in the preferred embodiment, it would be wrong to limit the term gap in such a manner.

The term gap appears in dependent claims 10-13 of the '047 patent. 6 The claim language reads as follows:
10. A filter as claimed in claim 1 wherein gaps between opposing surfaces of the pleats adjoining a radially inner periphery of the filter element have a height of at most approximately a thickness t of each leg of the pleats.

11. A filter as claimed in claim 10 wherein the gaps have a height of at most approximately 1/2 t.

12. A filter as claimed in claim 1 wherein gaps between opposing surfaces of the pleats adjoining a radially outer periphery of the filter element have a height of at most approximately four times a thickness t of each leg of the pleat.

13. A filter as claimed in claim 12 wherein the gaps have a height of at most approximately 2 t.

'047 patent, cols. 26-27, lines 62-67 and 1-7. The Summary of the Invention instructs that the pleating surfaces are "spaced by a gap." '047 patent, col. 2, line 42. The description of preferred embodiments further states that

[a]t the radially inner and outer ends of the pleats 11, small triangular gaps 11f are formed between the opposing internal surfaces 11d of adjoining legs 11a, and at the radially outer ends of the pleats 11, small triangular gaps 11g are formed between the opposing external surfaces 11e of adjoining legs 11a. However, in the present invention, the height of these gaps 11f and 11g as measured along the height of the pleats is preferably extremely small. The height of the gaps 11f adjoining the inner diameter of the filter element 10 is preferably no more than approximately t and more preferably no more than approximately 1/2 t, wherein t is the thickness of the material forming the filter element 10, as shown in FIG. 3. The height of the gaps 11g adjoining the outer diameter of the filter element 10 is preferably no more than approximately 4 t and more preferably no more than approximately 2 t.

'047 patent, col. 4, lines 31-49.

6 The Court notes the term "gap" only appears in dependent claims, which have no material effect on whether there is infringement on the independent claims. Said differently, the independent claims can be infringed regardless of the term gap.
a. Parties' Positions

The parties propose the following constructions for this term which is present in claim 3 of the '631 Patent. The language of claim 3 states that the gap is configured for (1) "receiving air," (2) "dividing said air into two portions," and (3) "directing each [divided] portion through a separate fin structure." Again, Defendants assert there is an exclusive entry requirement by urging the gap is designed to be "the" air intake. Defendants also assert there is an exclusive exit. Plaintiff asserts Defendants argue in terms of individual air molecules, not collective air flows. According to Plaintiff, there is no requirement that the air must be "directed" at the gap.

<table>
<thead>
<tr>
<th>Plaintiff</th>
<th>Defendants</th>
</tr>
</thead>
<tbody>
<tr>
<td>A gap designed to receive air flowing to the second surface, to split the air flow, and to direct portions thereof through separate fin structures</td>
<td>A gap designed to be the air intake and arranged to receive forced air directed at and flowing perpendicular to the second surface, to split the forced air, and to direct all of the forced air through the passages of the fin structures, along paths parallel to the second surface</td>
</tr>
</tbody>
</table>

b. Court's Construction

With respect to the "exclusive entry" and "exclusive exit" requirements, this term does not require the all-or-nothing exclusivity that Defendants propose. Nor is there any requirement that air must flow into the gap at a strictly "perpendicular" angle. As noted above, there is no reason why, for instance, an air source cannot direct a "cone" of air towards the top plate, the vast bulk of which would follow an "angled" path. (Rippel Dec. P 7). Thus, the Court declines to adopt Defendants' proposed construction for this term.

Plaintiff's proposed construction merely restates what is clear from the language of the term itself. Therefore, the Court finds no construction is necessary, and the term shall be given its plain and ordinary meaning.
requirement in question concerns elastics, not absorbents. Therefore, we find the restriction requirement uninformative. We also are unpersuaded by First Quality's argument that since a finished disposable garment has an absorbent it follows that the garment blank subassembly must not have an absorbent component. This reasoning seeks to add a negative limitation that we conclude is not supported by the evidence. However, we disagree with KC's proposed construction that a "garment blank subassembly" is a "precursor element of an unfinished article." The specification states that "a garment blank subassembly...is a type of precursor of the garment." U.S. Patent No. 5,745,922, col. 1, ll. 64-65; U.S. Patent No. 6,098,203, col. 2, ll. 1-2. This definition of the disputed term is unambiguous and is supported by the intrinsic evidence. Thus, we will construe "garment blank subassembly" to mean "a precursor of the garment."

4. "Garment Component"

The term "garment component" is found in both the method and product claims of the patents-in-suit. For example, in Claim 1 of the 779 Patent, a method claim, step (a) of the seam manufacturing process requires "placing the first garment component in an adjacent relationship to the second garment component so as to define a seam." 779 Patent at 6:30-32 (emphasis added). In Claim 20 of the 779 Patent, a product claim, the seam is defined as comprising "a first garment component having an upper and lower surface" and "a second garment component having an upper and lower surface." 779 Patent at 8:10-11, 8:18-19 (emphasis added). The 615 Patent similarly uses the term in Claims 1 and 19, method and product claims, respectively. 615 Patent at 6:31-36, 8:4-5, 8:12-13.

Taltech asks the Court to construe "garment component" to mean "a structural part of a garment, such as a front panel, yoke, rear panel, and sleeve. An interlining is not a garment component." Taltech relies on the specifications and on the opinion of Taltech's expert, Mr. Nienke. Esquel asks the Court to construe "garment component" to mean "any element of an article of clothing," including an interlining, a bonding element or thread. Esquel relies on the patent specifications, on a dictionary definition of "component," and on a technical treatise.

The Court finds Taltech's proposed construction more persuasive. Claim 6 of the 779 Patent and Claim 13 of the 615 Patent state that "... said first garment component comprises a front panel, yoke, and rear panel of a dress shirt and said second garment component comprises a shirt sleeve..." 779 Patent at 7:10-13; 615 Patent at 7:40-42 (emphasis added). The specifications state that "a pucker free garment seam 12" consists of "a first garment component 20, such as a component consisting of a dress shirt front panel 16, yoke 14, and rear panel; a second garment component 22 such as a dress shirt sleeve 12 [sic]; 4 and a bonding element 32." 779 Patent at 5:60-65; 615 Patent at 5:62-67 (emphasis added); see also Fig. 2; 779 Patent at 3:44-47; 615 Patent at 3:45-48 (defining first garment component as comprising a front panel, shirt yoke and rear panel and the second garment component as comprising a shirt sleeve). The examples of a "garment component" identified in the claims and specifications are those that Taltech includes in its proposed construction of the term. Although this is not an exhaustive list of possible garment components, nothing in the intrinsic evidence supports Esquel's broad construction of the term.

4. The patent appears to contain an error in that it should say "13" rather than "12" to refer to the shirt sleeve in the 779 Patent at 5:64 and in the 615 Patent at 5:66. See 779 Patent at 3:46-47 and 615 Patent at 3:48 ("the second garment component comprises a shirt sleeve 13.").

First, a bonding element is not a garment component. The specifications, as outlined above, separately list the bonding element as its own thing, and not as an example of a garment component. 779 Patent at 5:58-65; 615 Patent at 5:60-67; see also 779 Patent at 6:26-56 (Claim 1 separately refers to garment components and bonding elements as distinct objects); 615 Patent at 6:28-67 (same). Nothing in the intrinsic evidence indicates that the terms should be used interchangeably.

Second, an interlining is not a garment component. The specifications of the patents-in-suit state: "Interlinings are known in the art to provide stiffness to garment components." 779 Patent at 5:1-2; 615 Patent at 5:2-3 (emphasis added). This sentence only makes sense if the Court interprets interlinings and garment components to be distinct categories. Esquel's genus and species analogy, see Esquel's Responsive Brief, docket no. 111, at 12 n.6, is not persuasive because there is no evidence in the patent for the proposition that interlinings are a subset of the broader category of garment components. Esquel argues that garment components should specifically include "fusible and non-fusible interlinings...and fusible webs or nets;" however, Esquel's interpretation is unsupported by the intrinsic evidence. Esquel relies on parts of the
specification of the 779 Patent that have no bearing on the construction of the term "garment component." See Esquel's Opening Brief, docket no. 97, at 21 (citing 779 Patent at 3:51-4:3, 4:66-5:1).

Third, thread is not a garment component. Esquel argues to the contrary and relies on the characterization of "components of garments" in a technical treatise that includes interlinings and thread as examples of "components of garments." See Peyton B. Hudson, Guide to Apparel Manufacturing 51-63 (Rev. 2d ed. MEDIA Apparel, Inc. 1989) (docket no. 97, Ex. E). The Court does not rely on extrinsic evidence that is inconsistent with the intrinsic evidence. In this case, the specifications state that "the sewing thread contracts upon being laundered and pulls on opposing garment components at the garment seam which in turn causes the garment components to buckle. . . ." 779 Patent at 1:22-26; 615 Patent at 1:26-29 (emphasis added). Thread acts on the garment components, indicating that it must be a distinct object. The specifications' reference to garment components as coming together at a seam and as buckling are further evidence that a garment component is a fabric panel, not thread.

To interpret the term "garment component," the Court does not rely on the expert testimony provided by Taltech. See Nienke Decl., docket no. 96, P 28. Mr. Nienke's opinion regarding the term "garment component" is merely conclusory. See Phillips, 415 F.3d at 1318 ("[C]onclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court."). The intrinsic evidence is sufficient to support Taltech's proposed construction.

Accordingly, the Court adopts Taltech's proposed construction, with modification, and construes the term "garment component" to mean "a structural part of a garment, such as a front panel, yoke, rear panel, and sleeve. A bonding element, an interlining, and thread are not garment components."

5. "gas flow orifice member"

This claim term appears in claim 1 of the '726 patent as follows:

the interior gas distribution chamber having a gas flow orifice member positioned between a first chamber portion and a second chamber portion to selectively control the flow of the fuel gas from the first chamber portion to the second chamber portion.

(The '726 patent, 11:33-38 (emphasis added)). The term does not appear in the '068 patent.

Travis proposes construing this term to mean "structure to control distribution of fuel gas." Hearth proposes construing this term to mean "a device or obstruction placed in a gas-flow orifice that is positioned between two chamber portions, that effects the volume and rate of gas flow through the orifice." The parties seem to agree that "member" means a device or structure that controls the distribution of fuel gas. The heart of this dispute is that Hearth wants the construction to specify where this device or structure is located and Travis does not want to include such a limitation. Based on the intrinsic evidence, the Court agrees with Hearth and construes the term to mean "a device or obstruction placed in a gas-flow orifice that is positioned between two chamber portions, that effects the volume and rate of gas flow through the orifice."

The claim language specifies the location of the gas flow orifice member; it explicitly refers to the orifice member being between two chambers. To ignore the claim language surrounding this term, and construe the term without any reference to its location, would impermissibly broaden the scope of this term. This clear language belies Travis' argument that including the location in the construction would incorrectly import a limitation from the specification into the claim.

Language in the specification referring to the orifice member also includes its location and describes that location as being between two chambers. In addition, it teaches that the member controls the distribution of the fuel gas by effecting the volume and rate of gas flow. The specification states:

The burner body 78 also includes an orifice member 94 in the intermediate chamber portion 93 so as to control distribution of the fuel gas from the front chamber portion 89 to the rear chamber portion 91. Accordingly, the orifice member 94 effects the volume and rate of gas flow through the selected burner apertures . . . .
A second chamber portion is connected to the first chamber portion by a narrowed gas flow orifice portion positioned between the first and second chamber portions. The orifice portion is selectively sized to control the flow of fuel gas from the first chamber portion to the second chamber portion.

At the claim construction hearing, Travis argued that the orifice need not be positioned between two chambers, but could be an opening in a single chamber. According to Travis, the ordinary and plan meaning of the word "orifice," which means an opening, does not incorporate a location of the orifice. However, as shown above, the surrounding claim language specifies that the member, which is in the orifice, is between two chambers. Every reference to the orifice member in the specification further bolsters this conclusion.

HEN contends that "gas impermeable enclosure" should be construed to mean "a receptacle made of a material which gas cannot pass through." (HEN CC Br. at 16.) HEN contends that the claim itself and the specification support its proposed construction, and that the claim language does not contain any language requiring the enclosure to be completely closed on all sides and gas tight. Minco, on the other hand, argues that "gas impermeable enclosure" should be construed to mean "a gas tight enclosure, into which or out of which gas cannot move or flow, such as a body of silicone surrounded by a small plastic casing." (Minco CC Br. at 16.) Minco argues that according to the specification, the purpose of the gas impermeable enclosure is to provide protection for the cold welds located inside the enclosure from heat or temperature differences. Furthermore, Minco argues that the patent specification describes the gas impermeable enclosure as follows: "The cold joints of the thermocouple 5 are embedded in a gas tight enclosure such as a body of silicone 8 surrounded by a small plastic casing 9. The conductors at the cold joints 7 are V-shaped with the apexes adjacent one another but electrically insulated from one another by the silicone 8." (Minco Ex. A, col. 2, ll. 39-44.) Minco argues that use of the word "embedded" supports the conclusion that the cold welds are encapsulated inside a body of silicone, which is known to be gas tight.

HEN's argument regarding the construction of "gas impermeable enclosure" is predicated on the fact that the enclosure is represented in the specification only by the small plastic casing, (see HEN Ex. A at Figure 1, number 9) which HEN construes as a receptacle that can be open on top. However, we understand the enclosure, based on the specification, as being an enclosure "such as a body of silicone 8 surrounded by a small plastic casing 9," (see HEN Ex. A at col. 2, ll. 40-41), and that this entire enclosure, not just the small plastic casing, must be gas impermeable. Consequently, we reject HEN's use of the word "receptacle" in its proposed construction and its related argument that the enclosure need not be closed on all sides as this is inconsistent with how the applicants understood the term "gas impermeable enclosure" as indicated in the specification. Additionally, HEN's construction of "impermeable" would make more sense if it were used to modify something that was typically two-dimensional, such as a barrier. In such a context, an impermeable barrier means that gas cannot pass through it. However, in the context of this invention, "impermeable" modifies "enclosure," which is something that connotes a three-dimensional element, and an impermeable enclosure means that gas cannot pass into or out of the enclosure. We believe, therefore, that HEN's proposed construction of an impermeable enclosure as a receptacle that is open on the top is not consistent with the understanding of these terms held by an ordinary person skilled in the art. An impermeable enclosure means that gas cannot enter the enclosure from any attitude -- from the bottom, the sides, or the top. Consequently, we construe "gas impermeable enclosure" to mean "an enclosure, into which and out of which gas cannot move or pass." 4

4 The parties have relied in their arguments on extrinsic evidence such as the mechanics of the flow of gases in the area of the enclosure during the immersion of the probe in molten metal and dictionary definitions. However, we need not address this extrinsic evidence as we are able to construe the claim term based on the intrinsic evidence alone. See Phillips, 415 F.3d
at 1319 (stating that courts in their discretion may use extrinsic evidence to determine claim meaning). Moreover, even if we rely on the dictionary definition of impermeable supplied by HEN, this would not support its position because "impermeable" is defined, in part, as "(of substances) not permitting the passage of a fluid through the pores, interstices, etc." See Webster's Encyclopedic Unabridged Dictionary of the English Language (1989). Allowing a substance, such as gas, to enter through the top of the enclosure would not be consistent with this definition.

2) "Gas Mixing Device"

The term "gas mixing device" appears in the '226 patent. MKS contends that this term means "a device that alters the flow pattern of a feed gas as it enters the plasma chamber, so that the feed gas mixes and reacts with the plasma." (D.I. 39 at 24.) Advanced contends that, as used in the claims of the '226 patent, a "gas mixing device" is a "device that creates a gas flow pattern in the plasma channel which enhances the interaction between the feed gas and the plasma." Advanced contends that this definition is mandated by sections of the patent specification which state that "the purpose of the gas mixing device is to create a gas flow pattern in the plasma channel which enhances the interaction between the feed gas and the plasma," and that "[a] gas mixing device enhances the interaction between the feed gases and the plasma thereby improving the dissociation and abatement efficiencies of the plasma source." (D.I. 41 at 37-28 (quoting exhibit J).) Advanced contends that this description is not limited to a specific embodiment of the device.

The Court concludes that an interpretation based more closely on the specification is preferred. Thus, the Court concludes that "gas mixing device" means a "device that creates a gas flow pattern in the plasma channel which enhances the interaction between the feed gas and the plasma."

Background

The '321 patent, entitled "Venting System," describes and claims a system that filters leukocytes from blood, as is done to improve the storage life of donated blood and minimize disease transmission. The claimed system moves and collects the blood, using porous membranes. Claim 39, the only claim now at issue, reads:

39. A method for processing blood or a blood product, comprising:

[1] passing the blood or blood product through a leukocyte depletion medium;

[2] passing gas displaced by the blood or blood product through a gas outlet comprising a porous medium until the blood or blood product contacts the porous medium; and,

[3] passing gas through a gas inlet comprising a porous medium to drive additional blood or blood product through the leukocyte depletion medium.

(Paragraph numbers added.)

The '321 patent describes the system wherein the blood to be treated flows by gravity from a supply container through a leukocyte filter and then to a receiving container. Two membrane filters, the "porous medium" in claim clauses [2] and [3], control the inlet and outlet of gas, which is usually sterile air. The gas aids in moving the blood through the system and in driving all of the blood through the leukocyte filter and into the receptacle. The membranes also serve to exclude bacteria and other contaminants.
The gas inlet, claim clause [3], contains a hydrophobic membrane located upstream of the leukocyte filter. A hydrophobic (or liquophobic) membrane allows passage of gas irrespective of whether liquid also contacts the membrane. Conversely, a hydrophilic membrane allows the gas to pass only until the membrane is contacted and wetted by liquid, upon which the membrane holds the liquid and ceases to allow passage of the gas.

The gas outlet porous medium, claim clause [2], is described in the specification as comprising a hydrophilic membrane located between the receiving container and the outside environment (or connected to a gas recycle system). It allows the gas in the system to escape as it is displaced by the moving blood, preventing the formation of back pressure against the flow of blood through the system. The membrane functions like a valve, whereby the displaced air escapes when the membrane is dry, then seals itself when it is wetted by the blood, preventing both loss of blood and reintroduction of air. The system of the '321 patent is illustrated in Figure 1 of the '321 patent:

In Fig. 1, a typical embodiment, conduits (12) and (15) connect the leukocyte filter (14) to the supply container (11) and the receiving container (17) respectively. The gas inlet (13) is upstream of the leukocyte filter and the gas outlet (16) downstream.

Hemasure stipulated to the validity and enforceability of claim 39, and Pall has not appealed the district court's ruling that claim 45 is not infringed. The only issue on appeal is infringement of claim 39.

--- Footnotes ---

2 In Cardinal Chemical Co. v. Morton Int'l, Inc., 508 U.S. 83, 26 U.S.P.Q.2d (BNA) 1721, 124 L. Ed. 2d 1, 113 S. Ct. 1967 (1993), the Supreme Court mandated that the Federal Circuit review the trial court's decision on the issue of validity, even when ruling on appeal that the patent is not infringed. However, the Court did not require the lower courts to decide validity when the parties did not place validity at issue. Thus the issue of patent validity is not before us.

--- End Footnotes ---

DISCUSSION

Analysis of patent infringement starts with "construction" of the claim, whereby the court establishes the scope and limits of the claim, interprets any technical or other terms whose meaning is at issue, and thereby defines the claim with greater precision than had the patentee. Although the construction of the claim is independent of the device charged with infringement, it is convenient for the court to concentrate on those aspects of the claim whose relation to the accused device is in dispute. On appeal the Federal Circuit is required to construe the claim de novo; thus we do so without deference to the rulings of the trial court. See generally Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 46 U.S.P.Q.2d (BNA) 1169 (Fed. Cir. 1998) (en banc).

A patent claim is construed by examining the claim in the context of the specification, drawing on the specification for an understanding of what is covered by the claim, and looking to the rejections, explanations, and revisions that comprise the record of the patent examination. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2d (BNA) 1321, 1329 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 38 U.S.P.Q.2d (BNA) 1461, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996); Mannesmann Demag Corp. v. Engineered Metal Products Co., Inc., 793 F.2d 1279, 1282, 230 U.S.P.Q. (BNA) 45, 46 (Fed. Cir. 1986). The subject matter of the invention and its delineation in the claims is construed to be understood by persons knowledgeable in the field of the invention. Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1478, 45 U.S.P.Q.2d (BNA) 1429, 1433 (Fed. Cir. 1998); Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2d (BNA) 1126, 1129 (Fed. Cir. 1996). Thus a technical term is taken to have the meaning that it would ordinarily have in the field of the invention, unless it is shown that the inventor used the term with a special meaning and that persons of skill in the field would so understand the usage. Id.

When the district court has held that the "construction" of the claim has also decided the question of infringement, and has granted summary judgment to that effect, we give plenary review to the summary judgment. Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 255, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986); EMI Group North America, Inc. v. Intel Corp., 157 F.3d 887, 891, 48 U.S.P.Q.2d (BNA) 1181, 1184 (Fed. Cir. 1998).
The district court construed the '321 patent claims with an eye to the accused Hemasure system, concentrating on those claim terms whose scope was disputed as applied to the accused system. The Hemasure system, as shown in Hemasure's 510(k) submission to the FDA for the accused product, is pictured as follows:

[SEE PHOTOGRAPH IN ORIGINAL]

In the Hemasure system, blood flows from the "red blood cell bag" through a chamber containing a leukocyte filter and into the "red blood cell storage bag." Air is removed from the red blood cell storage bag by releasing the "air removal clamp" and manually compressing the red blood cell storage bag. Hemasure concedes that its system performs the step of claim clause [1], and that it has a gas inlet porous medium (the "in-line vent filter" in the illustration) as set forth in claim clause [3]. The issue of infringement, and thus the disputed aspect of the claim, relates to the claim clause [2] step of passing displaced gas through a gas outlet porous medium.

The Hemasure system contains a hydrophilic membrane in the filtration chamber immediately downstream of the leukocyte filter (near the upper right corner of the "Leukonet Filter" in the above diagram). This membrane first passes the displaced air out of the chamber as the chamber fills with blood. Then, when the chamber has filled with blood the now-wet membrane prevents the passage of air so that blood in the filtration chamber can be removed by siphoning action at the end of the process. Additional upstream air pressure combined with siphoning action of the downstream blood empty the filtration chamber through the U-shaped chamber, as shown in the illustration. Thus, air and siphoning action clear the filter chamber, permitted by the hydrophilic membrane that closes the outlet to air while the blood is flowing past it.

Pall states that clause [2], properly construed, is met by this part of the Hemasure system. Hemasure states that the "gas outlet" in claim clause [2] refers to the Pall system's external vent of air after the filtered blood is collected. Hemasure states that it is not in accordance with the description of the invention in the '321 specification to construe as the "gas outlet comprising a porous medium" any porous medium located downstream of the leukocyte filter. Pall states that the Hemasure hydrophilic membrane separates air from the blood as it moves into the line leading to the receiving bag, and that this usage is literally within the scope of clause [2], as the district court held, or in any event constitutes infringement under the doctrine of equivalents. Hemasure responds that its membrane serves an entirely different purpose in its system, at a different location, and that the district court clearly erred in its construction of clause [2] so as to find infringement.

The district court construed the clause [2] "gas outlet comprising a porous medium" to mean any "particularized 'hole' covered by a porous membrane" which is located downstream of the leukocyte filter and permits gas to pass through the membrane when dry, but prevents such passage when the membrane is wet by blood. Applying this claim construction, the court held that the Hemasure system contains a gas outlet porous medium as in clause [2], and granted summary judgment of infringement of claim 39.

We deem the district court's claim construction to be unduly broad. The '321 patent explains that the invention is directed to facilitating the air-driven gravity flow of blood through the leukocyte filter, reducing back pressure and minimizing air contact with the blood after the filtration is complete. The specification describes or suggests no role or location of the "gas outlet comprising a porous medium" other than to remove gas at the outlet of the system while retaining the blood and barring reentry of air. We conclude that the correct interpretation of claim clause [2] requires that the gas outlet porous medium be placed so as to serve that purpose.

4 Erbe contends that the term "gas stream" and "inert gas atmosphere" should be construed in reference to one another. While the terms are distinct, I recognize that words are not to be read in a vacuum, but must be read in connection with the

--- Footnotes ---

4 Erbe contends that the term "gas stream" and "inert gas atmosphere" should be construed in reference to one another.
The third disputed claim term "gas stream" is found in Claim 1 as set forth above.

Erbe's Proposed Definition: A stream of gas that exits from the opening at the distal end of the flexible tube and has flow properties (e.g., non laminar and not directed) that allow formation of an inert gas atmosphere between the distal end of the flexible tube and the tissue to be coagulation.

Canady's Proposed Definition: A flow of gas.

(Docket No. 42, p. 3). Canady argues that Erbe tries to read multiple limitations into the term "gas stream" which should not be permitted because the limiting terms appear expressly in other parts of the claim, such that they need not be read into the claim term. Furthermore, Canady argues that reading those limiting terms into the term "gas stream" would render the limiting terms meaningless and superfluous when they appear in the other parts of the claim. (Docket No. 66, p. 23). I agree with Canady. In fact, in its Reply Brief, Erbe agrees that its interpretation of the term "gas stream" may incorporate limitations that appear elsewhere in the claims. (Docket No. 68, p. 12, n.3). A person of ordinary skill in the art would understand that a gas stream to be a flow of gas. Consequently, the claim term "gas stream" is construed to mean a flow of gas.

C. Claim Construction and Infringement Analysis of the Gate Element.

Again, the gate element reads as follows: "a gate in said fence including a frame having a pair of spaced upright support members, a first horizontal brace for spacing the upright support members and length of mesh screen tensioned between said upright support members." See supra at 9. The Court finds that the term "gate" as used in the '769 Patent must be construed to be limited to a gate with additional horizontal members, if any, well below the top of the mesh screen tensioned on the upright members of the gate structure. As noted supra at 13, "a claim term will not carry its ordinary meaning if the intrinsic evidence shows that the patentee distinguished that term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention." CCS Fitness at 1366-67 (citing, inter alia, Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998)). The Court finds that the specification and prosecution history of the '769 Patent require that the meaning of the term "gate" as used in the patent be limited in the fashion stated.

First, regarding the relationship between the claims and the specification, the Federal Circuit has made clear that, "the claims are always construed in light of the specification, of which they are a part." Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001) (citation omitted). "The role of the specification includes presenting a written description of the . . . subject matter of the invention, while the role of the claims is to point out with particularity the subject matter that is patented." Id. (citing 35 U.S.C. § 112, PP1,2). "The claims are directed to the invention that is described in the specification; they do not have meaning removed from the context from which they arose." Id. Therefore, "although the specification need not present every embodiment or permutation of the invention, and the claims are not limited to the preferred embodiment of the invention, neither do the claims enlarge what is patented beyond what the inventor has described as the invention." Id. (internal citation omitted).

The specification of the '769 Patent makes clear that the patented gate must be one whose additional horizontal braces, if any, are well below the top of the mesh screen tensioned on the upright members of the gate structure. The patentees state in their brief description of the invention that, "faced with [the] state of the art, we determined that it should be possible to produce a tension protective fence with a gate presenting the same overall appearance and degree of safety with far superior accessibility for adults but presenting extreme difficulty for a child to defeat the gate and fence." '769 Patent, col. 1, lines 56-60 (emphasis added). After describing the support means for the gate, the patentees then state, "this is all accomplished in cooperation with a gate in the preferred form of frame of a 'U' shape with a bottom bar, side rails and angle bracing rods or gusset plates for reinforcement and a fabric fence material matching the fence extending between the legs of the gate."
'769 Patent, col. 2, lines 7-13. Referring to figure 3 in the detailed description of the invention, the patentees continue, stating that, "the gates G1 and G2 [are] made up, preferably of three frame members including a hinged upright 31, base member 32 and a latched upright 33. . . . The cross brace CB shown in dashed lines might be used for bending strength provided it is on the pool side of the gate and well below the top of the gate fabric." '769 Patent, col. 3, line 58 to col. 4, line 2 (emphasis added). The patentees continue:

To provide uniformity of appearance and freedom from any rigid top cross bar structure on the gate, the U shaped gate is employed as shown in FIG. 3. It is important that the gate have sufficient strength and rigidity to operate properly for years. It also resists any failure if a child attempts to climb it. We have designed such a gate which will not fail if weights equivalent to a 70 pound youngster are applied to the gate.

'769 Patent, col. 4, lines 5-12 (emphasis added). And, concluding the written description, the patentees identify the following three (out of a total of six) features of their invention: (1) "Provides a gate which has a degree of protection of a child climbing it comparable to the fence itself"; (2) "Provides a design of a gate which provides few if any hand holds or foot grips for any child attempting to climb the fence"; and (3) "Provides a pool security gate with no top gate bar." '769 Patent, col. 4., lines 55-67 (emphasis added).

The language in the specification identified above does not require a construction of the gate element as restrictive as that proposed by Baby Guard -- i.e., that the claimed gate must be limited to the preferred embodiment of a U-shaped gate. But, in light of the patentees' written and graphic description of the invention, the gate element cannot be construed to cover gates with a top horizontal bar.

In addition, the prosecution history of the '769 Patent further supports this construction of the gate element. On February 10, 1997, the PTO examiner rejected, on various bases, all twenty-one claims originally included in the patentees' application of November 13, 1996. See Defendant's Mot., Ex. 9. The examiner rejected claims 1 and 17 (the predecessor to claim 15 in suit), among others, on the basis that they were anticipated by the prior art under 35 U.S.C. § 102(b). See id. at 2-3. The examiner stated that the gate shown in the figures of an identified prior art fence "is supported by a U-shaped frame and attached to the fence by support means." See id. (emphasis added). The necessary implication of the examiner's statement here is that he understood both the prior art gate and the gate claimed in the patentees' application to be limited to a U-shaped gate.

On April 2, 1997, the patentees filed an amendment to their application in response to the examiner's February 10 rejection. Addressing the examiner's rejection of claims 1 and 17, among others, as anticipated by the prior art, the patentees stated, inter alia, that the prior art gate referenced by the examiner in the February 10 rejection "is not a gate and not U-shaped, but rectangular." See Defendant's Mot., Ex. 10 at 4 (emphasis added). The necessary implication of the patentees' statement is that, while the prior art gate was not U-shaped in their view, the gate they were claiming in their application was, and hence the examiner wrongly determined that their invention was unpatentable as anticipated by the prior art the examiner had referenced.

On April 16, 1997, after the patentees filed the April 2 amendment, the patentees attended an interview with the examiner. See Defendant's Mot., Ex. 5. The examiner's interview summary record states that the claims discussed were claims 1, 4, 6, 17 (the predecessor to claim 15), 18 and 21. See id. The record further states that, "the examiner stated that the poles being inserted into the ground at an angle to the vertical and the use of U-shaped support for the gate with the U opening upwardly would not be shown by the art of record." See id. (emphasis added). In response to this interview, the patentees submitted a second amendment to their application on April 18, 1997. See Defendant's Mot., Ex. 11.

In the April 18 amendment, the patentees stated that the examiner's interview summary record "appears as correct and the applicant's agree with the examiner's conclusion." See id. at 5. In response to the interview, the patentees also made two additional amendments to the claims that are relevant to the instant analysis. First, the patentees amended the gate element of claim 1 by inserting the word "first" before the phrase "horizontal brace". See id. at 1. This amendment plainly recognizes that the claimed invention gate is not limited to gates with only three members: two upright members and one horizontal brace. The necessary inference is that second or even more additional horizontal braces are contemplated by claim 1, and claim 1 is therefore not properly construed as limited only to the preferred, three-member, U-shaped embodiment, as Baby Guard argues.

- 2258 -
Second, the patentees amended dependent claim 6, which depends from dependent claim 4, which in turn depends from claim 1. In the April 18 amendment, the patentees added the phrase "opening upwardly", emphasized in the quotation below, to the then existing language of claim 6, so that claim 6 as allowed by the examiner reads as follows:

A lightweight fence and gate as claimed in Claim 4 wherein said gate includes a generally U-shaped frame opening upwardly with said first horizontal brace secured to the lower ends of said upright support members and a second horizontal brace secured to said upright support members on the pool side of said mesh at a height well below the top of said gate.

See id. (emphasis original). This exchange between the examiner and the patentees, particularly in light of the specification, makes clear that the examiner suggested, and the patentees added, this amendment to claim 6 acknowledging that claim 1, from which claim 6 ultimately depends, would not countenance a U-shaped frame "opening downwardly", because such a gate would in fact be arch-like, i.e., it would have a top horizontal bar.

In light of the specification and the prosecution history of the '769 Patent, the gate element of claim 1 cannot be construed to cover gates with top horizontal members. The term "gate" in the gate element must be construed to be limited to gates whose additional horizontal members, if any, are positioned well below the upper edge of the mesh screen tensioned on the gate frame. Therefore, the gate element, properly construed, covers not only U-shaped gates, but also gates with additional horizontal members, so long as such members are well below the upper edge of the tensioned screen. The invention gate, however, does not and cannot cover rectangular gates, gates in the shape of an inverted U, or any other gate with a top horizontal bar.

B. Claim 11 and Claim 17: "Gathering Chamber"

The parties next dispute the meaning of the phrase "gathering chamber" in claims eleven and seventeen of the '843 patent.

14 In claim seventeen of the '843 patent, the parties actually dispute the meaning of the phrase "defining a gathering chamber". In proposing definitions for the phrase "defining a gathering chamber", each party has combined its proposed construction of "gathering chamber" with a dictionary definition of "defining." Johnson, however, also argues that the "'defining' needs no construction" because the parties' "proposed definitions" of defining "are not any plainer than the word 'defining' itself." The court agrees with Johnson. The Federal Circuit Court of Appeals has noted that courts "regularly forgo detailed dictionary analysis if the term is . . . commonplace." C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 863 (Fed.Cir. 2004). The court concludes that the term "defining" is commonplace and therefore the court can forgo a detailed analysis of "defining." The court will focus on interpreting the phrase "gathering chamber" as used in claims eleven and seventeen of the '843 patent. For claim seventeen, the court will add the word "defining" to the definition of "gathering chamber".

Johnson argues that "gathering chamber" means "the space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly against the surface of the shroud." Johnson supports this construction with two arguments. First, Johnson argues that the prosecution history reveals that Ametek "acted as his own lexicographer and provided [this] explicit definition for the term 'gathering chamber'". Second, Johnson argues that Ametek disclaimed claim scope during the prosecution of the '843 patent "by amending the claim to state that the gathering chamber is formed specifically between the ends of the vanes and the shroud . . . and by distinguishing the Japanese . . . patent with respect to the configuration of the vanes and the shroud".

Ametek responds that Johnson's definition "adds extraneous limitations on the claims." Specifically, Ametek argues that Johnson's construction of gathering chamber "(1) totally ignore[s] the word 'gathering', and (2) defines "the term 'chamber' as to its location and position, which are otherwise treated in the claim itself and not identified as requiring construction."
Ametek instead argues that "gathering chamber" means "an enclosed space for accumulation of working air" and that this
definition is "in accordance with common dictionary definitions, [and] consistent with the meaning adduced from the patent
specification and drawings."

The court concludes that although Ametek did not act as its own lexicographer, Ametek did disavow claim scope in its
negotiations with the USPTO examiner. Accordingly, the meaning of the disputed phrase is "the space or cavity formed
between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly
against the surface of the shroud."

1. Prosecution History

a. Acting As One's Own Lexicographer

Johnson first argues that the prosecution history reveals that Ametek acted as its own lexicographer and defined "gathering
chamber" to mean "the space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing
ends of the vanes are not positioned directly against the surface of the shroud."

As noted earlier, a patent applicant can act as its own lexicographer during the prosecution of a patent by giving a claim
term "a meaning 'inconsistent with its ordinary meaning'". Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1378
(Fed.Cir. 2005). The applicant seeking to give a claim term a meaning other than its ordinary meaning must do so "with
reasonable clarity, deliberateness, and precision . . . . so as to give one of ordinary skill in the art notice of the change." In re
Paulsen, 30 F.3d 1475, 1480 (Fed.Cir. 1994) (concluding the "patent does not clearly redefine the term 'computer' such that
one of ordinary skill in the art would deem it to be different from its common meaning").

The court concludes that the '843 patent does not clearly redefine the term "gathering chamber" such that one of ordinary
skill in the art would deem it to have other than its ordinary meaning. Johnson points to Ametek's efforts to distinguish the
'843 patent from the Japanese prior art as evidence that Ametek acted its own lexicographer by giving "gathering chamber"
a definition different from its ordinary definition. However, a party seeking to redefine a claim term must do so with
"reasonable clarity, deliberateness, and precision". In re Paulsen, 30 F.3d 1475, 1480 (Fed.Cir. 1994). The court's review of
the prosecution history reveals no clear, deliberate or precise attempt to give "gathering chamber" a specific definition other
than its ordinary meaning.

b. Disavowal of Claim Scope

Johnson next argues that the prosecution history of the '843 patent reveals that Ametek narrowed the definition of "gathering
chamber" by specifically disavowing claim scope. Specifically, Johnson argues that Ametek narrowed the scope of
"gathering chamber" when it emphasized the differences between the '843 patent and the Japanese patent.

As explained earlier, a patent's prosecution history may, in some instances, reveal that the patent holder "disclaimed or
disavowed subject matter" thereby "narrowing the scope of claim terms." Superguide Corp. v. DirectTV Enters., 358 F.3d
870 (Fed.Cir. 2004) (quoting ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1091 (Fed.Cir. 2003)). A patent applicant
cannot construe a claim term "one way in order to obtain [its] allowance" before the USPTO and "in a different way against
accused infringers." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed.Cir. 1995).

After the USPTO examiner rejected the '843 patent as anticipated by the Japanese patent, Ametek requested permission to
amend proposed claim eighteen (issued claim seventeen). Ametek requested "entry of an amendment . . . which sets forth
that the outer rim of the bracket conjunction with the shroud forms a gathering chamber between the ends of the vanes and
the shroud" (emphasis added). Ametek explained that the Japanese patent did not have a gathering chamber with these
characteristics. Specifically, Ametek wrote to the USPTO,

Such feature is clearly not present in the [Japanese patent] inasmuch as the trailing ends of the vanes are positioned
directly against the surface of the shroud and therefore a gathering chamber as defined in the present [proposed] claim
[eighteen (issued claim seventeen)] of the '843 application] is simply not present [in the Japanese patent].
(emphasis added). In other words, according to Ametek's statements to the USPTO, the gathering chamber in the '843 patent was a specific type of gathering chamber which did not exist in the Japanese patent and could only exist where the "vanes are [not] positioned directly against the surface of the shroud".

The court concludes that in distinguishing the '843 patent from the Japanese patent on the basis of this specific type of gathering chamber, Ametek disavowed the ordinary scope that the term "gathering chamber" might otherwise have. Accordingly, the court adopts a definition of the "gathering chamber" that is in keeping with Ametek's statements to the USPTO: "space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly against the surface of the shroud."

Accordingly, (1) in claim eleven of the '843 patent "gathering chamber" means "space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly against the surface of the shroud", and (2) in claim seventeen of the '843 patent "defining a gathering chamber" means "defining a space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly against the surface of the shroud."

2. Claim Language

Defining "gathering chamber" as "a space or cavity formed between the trailing ends of the vanes and the shroud wherein the trailing ends of the vanes are not positioned directly against the surface of the shroud" is consistent with the way that the claims use the claim term.

Paragraph six of claim eleven states that the "bypass motor assembly" comprises, inter alia, an "end bracket" with a downwardly sloping shoulder and each said vane [blade] has a trailing end extending radially along said sloping shoulder, said trailing ends and said shroud forming a gathering chamber therebetween where the working air collects prior to exiting from said at least one exhaust aperture.

'843 patent, Col.8, Ll. 29-34 (emphasis added). Paragraph one of claim seventeen similarly states that the end bracket is comprised of, an outer rim surrounding said shoulder and adapted to support the shroud, said plurality of vanes extending almost to said outer rim, each one of said plurality of vanes having a trailing end, said plurality of trailing ends and the supported shroud defining a gathering chamber therebetween.

'843 patent, Col. 10, Ll. 15-20 (emphasis added). The court's construction of the phrase fits is consistent with the way in which the claims describe the '843 patent.

3. Drawings 15

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

15 Because the court has concluded that it can determine the meaning of the disputed terms through examination of the intrinsic evidence, the court need not turn to extrinsic evidence. See Phillips Petroleum Co. v. Huntsman Polymers Corp., 157 F.3d 866, 870 (Fed.Cir. 1998) (noting if "intrinsic evidence unambiguously delineates the scope of the patent, resort to extrinsic evidence . . . is unnecessary").

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Furthermore, the '843 patent drawings are consistent with this construction of the disputed claim term. Exhibit 3 illustrates that the gathering chamber (68) is the space between the sidewall of the shroud (96) and the trailing end (58) of the vanes (52). Furthermore, the trailing ends (58) of the vanes (52) "are not positioned directly against the surface of the shroud" (28). Accordingly, Ametek's "use of the disputed term[]" in the drawings "is consistent with the meaning given to [the term] by the court." Rexnord Corp. v. The Laitram Corp., 274 F.3d 1336, 1342 (Fed.Cir. 2001).
2. Disputed constructions

a. "Gauge"

The first claim term of the '196 patent for which the parties dispute the proper construction is "gauge," as used in claims 1 and 8 of the '196 patent. Ideal does not propose an alternative construction for this claim term, because Ideal believes it to be unambiguous and well known to one of ordinary skill in the art. The claim term and Rivard's proposed construction are shown below in the following chart.

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Rivard's Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gauge</td>
<td>A size measurement of needles determined by the outer diameter of the needle. The smaller the gauge number the larger the needle outer diameter.</td>
</tr>
</tbody>
</table>

i. Arguments of the parties. In support of its construction, Rivard argues that "gauge" refers to the outer diameter of the needle, despite Ideal's contention that it refers to the diameter of the inside or lumen of the needle. Rivard points out that the patent specification explicitly states that the outer diameter dictates the gauge of the needle. Rivard asserts, further, that this definition was recited by the examiner in rejecting the pertinent claims and that the patentee acquiesced in this definition. Rivard argues, further, that extrinsic evidence from the American Society of Testing Materials (ASTM), defining gauge by outer diameter and minimum wall thickness, confirms the correctness of its construction.

Ideal argues that Rivard's construction ignores claim language, which claims "a gauge of needle cannula having an outer diameter and a lumen with a lumen diameter." In light of this language, Ideal argues that Rivard is improperly "reading out" the lumen diameter as a determinant of the gauge of a needle, based solely on language of the specification disclosing an embodiment whereby "the outer diameter of the needle determines gauge." Ideal also asserts that, in prosecuting the '196 patent, the patentee provided illustrations of lumen diameter and outer diameter of various gauges of needles. Ideal contends that Rivard's extrinsic evidence is simply irrelevant under applicable law.

ii. Analysis. Starting, as always, with the words of the claim term presently at issue, see Nystrom, 424 F.3d at 1142 (courts must "begin [their] claim construction analysis with the words of the claim"), the court notes that claim 1 of the '196 patent does claim, inter alia, a needle assembly "which includes a gauge of needle cannula having an outer diameter and a lumen with a lumen diameter," and further, that "the outer diameter is greater than an outer diameter of a standard needle cannula and the lumen diameter is identical to a lumen diameter of the standard needle cannula between 14 and 27 gauge." The '196 patent, claim 1 (emphasis added). Similarly, claim 8 of the '196 patent claims, in pertinent part, a needle assembly "wherein the needle cannula is of a gauge, has an outer diameter, and a lumen with a lumen diameter and wherein the outer diameter is greater than the outer diameter of a standard needle cannula and the lumen diameter is identical to the lumen diameter of the standard needle cannula between 14 and 27 gauge." The '196 patent, claim 8. Thus, the words of the patent claims at issue make clear that comparisons are made between the claimed needle and a prior art needle in terms of both the outer diameter and the lumen diameter of a needle of a particular gauge. These words, therefore, strongly suggest that "gauge" should be construed to include both outside diameter and lumen diameter.

Other intrinsic evidence from the specification of the '196 patent supports such a construction. See Aquatex, 419 F.3d at 1380 ("Where . . . the disputed claim term is technical or a term of art, [t]he best source for understanding [it] is the specification from which it arose, informed, as needed, by the prosecution history.") (quoting Phillips, 415 F.3d at 1315); Phillips, 415 F.3d at 1314 (the specification is not only "highly relevant" to claim construction, "[u]sually, it is dispositive," and "is the single best guide to the meaning of a disputed term"). Specifically, the Detailed Description states, in part, the following:
In the case of the 16 gauge embodiment of the needle of the present invention, the sidewalls 17 flanking (opposite each other) the lumen 18 have a combined thickness which is greater than 0.46 mm (0.018 inch), preferably a combined thickness of 0.64 mm (0.025 inch) and the diameter of the lumen 18 is about 1.19 mm (0.047 inch). Thus, the outer diameter of needle 12 is about 1.8 mm (0.072 inch). Preferably, the needle cannula of the present invention has a circular cross-section. In contrast, a 16 gauge prior art needle has an outside diameter of about 1.65 mm (0.065 inch) and a lumen diameter of about 1.19 mm (0.047 inch). Therefore, the combined thickness of the sidewalls flanking (opposite each other) the lumen of the prior art needle is about 0.46 mm (0.018 inch), which is somewhat more likely to break.

The '196 patent, Col. 4, l. 55, to Col. 5, l. 2. This portion of the Detailed Description, again, makes comparisons between a prior art needle and the claimed needle ostensibly of the same "gauge" on the basis of outer diameter, lumen diameter, and indeed, thickness of the sidewall, further supporting Ideal's contention that "gauge" should be defined in terms of both inner and outer diameter.

The fly in the ointment, as Rivard contends, is another portion of the Detailed Description, which states the following:

[T]he needle cannula of the present invention includes, but is not limited to, gauges between 14 and 27. It should be understood that because the sidewall of the needle cannula of the present invention is thicker than the sidewall of prior art needle cannulas and the outer diameter of the needle cannula determines the gauge, a 16 gauge needle cannula of the present invention has an outer diameter similar to the outer diameter of a 15 gauge needle cannula.

The '196 patent, Detailed Description, Col. 5, ll. 18-26 (emphasis added). This portion of the specification, thus, appears to define "gauge" solely in terms of the outer diameter of a needle. Ideal contends that this language merely discloses an embodiment, i.e., an embodiment of a 16 gauge needle that has an outer diameter similar to the outer diameter of a 15 gauge prior art needle cannula, but an inside diameter similar to the inside diameter of a 16 gauge prior art needle cannula. While Ideal's description of this language as merely part of the disclosure of an embodiment is not entirely satisfactory, it is clear that this language comes on the heels of the extensive comparison, quoted above, of the claimed needle in a 16 gauge embodiment with a prior art 16 gauge needle in which the comparisons are made on the basis of both inside and outer diameters, so that the reference solely to outer diameter determining gauge quoted just above simply illustrates one factor in the comparison of the claimed needle and the prior art, for the specific purpose of showing that the outer diameter of a 16 gauge embodiment of the claimed needle is similar to the outer diameter of a 15 gauge prior art needle. The court does not find the language on which Rivard relies to be dispositive of the question of whether the gauge of a needle is determined solely from its outer diameter or on the basis of its inside diameter and outer diameter, because it does not amount to the patentee acting as its own lexicographer, see Phillips, 415 F.3d at 1316 (where the specification reveals a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess, then the patentee's definition must govern), nor does it amount to a statement of the understanding of one of ordinary skill in the art concerning determination of the gauge of a needle.

Turning to the prosecution history to see whether it reveals that the inventor limited the meaning of "gauge" to outside diameter in the course of prosecuting the patent, see Research Plastics, 421 F.3d at 1296 (citing Phillips, 415 F.3d at 1317-18), the court finds that the examiner did reject application claims 16 and 23, which recited "the outer diameter is greater than an outer diameter of a standard needle cannula of identical gauge" on the ground that "[i]t is unclear how a cannula of a particular gauge can have a larger outer diameter than a cannula of identical gauge, given Applicant's disclosure on Page 9, lines 25 and 26, which recites that 'the outer diameter of the needle cannula determines the gauge.'" Joint Appendix at 745, Exhibit 1004 (Office Action of July 14, 2003). The examiner noted that "[t]hese statements appear to be contradictory and therefore make the claim language indefinite." Id. The patentee responded by deleting the "of identical gauge" language from application claims 16 and 23. Id. at 735 & 739. The court also finds, however, that the patentee subsequently asserted, in its October 28, 2004, appeal, that a needle gauge has an outer diameter and a lumen with a lumen diameter, see id. at 594, and also submitted the exhibit of technical notes for fabrication of syringe needles discussed above defining the dimensions of needles of various gauges in terms of outer diameter, inner diameter, and wall thickness. See id. at 787.

Taken together, the intrinsic evidence of the patent claims, specification, and prosecution history convince the court that needle gauge is determined from the inner or lumen diameter as well as the outer diameter. In the alternative, the court reads the claims and specifications to show that the patentee acted as its own lexicographer in defining "gauge" in terms of inner or lumen diameter as well as outer diameter. See Phillips, 415 F.3d at 1316 (where the specification reveals a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess, then the patentee's
axis of rotation parallel to each cylinder's axis of rotation. The wheel drives rotation of each cylinder about its respective axes. Figure 3 also depicts a wheel at the end of a motor shaft located outside the circle of cylinders, having an arrangement of vertically-oriented cylinders (for holding reagent containers) capable of independent rotation about their respective axes. Such extrinsic evidence is far from sufficient to impose such a definition over the patentee's definition of "gauge" in terms of both inside diameter and outer diameter in the intrinsic evidence of the '196 patent.

iii. The court's construction. In light of the foregoing, the court construes "gauge" as used in claims 1 and 8 of the '196 patent to mean "a size measurement of needles determined by the outer diameter and the inner or lumen diameter."

1831

The parties' primary dispute regarding the '349 patent is the meaning of the term "gear" in claim 9, which is the only claim in that patent asserted against the redesigned Architect. As a general matter, the parties agree that a gear is "a toothed machine part, such as a wheel or cylinder, that meshes with another toothed part, to transmit motion or to change speed or direction." (D.I. 296.) However, Abbott contends that the court should construe the term to "exclude [] a sprocket and/or a chain." (Id.) Abbott argues that during prosecution, Bayer limited the invention of the '349 patent to the specific gear structure recited in order to secure an allowable claim. Bayer disagrees, and argues that it disclaimed nothing with regard to claim 9. Unfortunately, neither the claim language itself nor the specification is particularly instructive as to the proper construction of "gear." Therefore, the court must look to the prosecution history for guidance. Phillips, 415 F.3d at 1314-17.

As mentioned above, the prosecution history of a patent serves an important public-notice function because it is a written record of both the inventor's understanding of the invention, and the limitations the inventor may have placed on the invention in order to distinguish it from prior art. See id. at 1317. In other words, courts "refer to the prosecution history, when it is of record, to discern the applicant's express acquiescence with or distinction of the prior art as further indication of the scope of the claims." Chimie, 402 F.3d at 1377. "As a basic principle of claim interpretation, prosecution disclaimer promotes the public notice function of the intrinsic evidence and protects the public's reliance on definitive statements made during prosecution." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). Nevertheless, there is "a 'heavy presumption' that claim terms carry their full ordinary and customary meaning." Id. at 1323. Thus, the doctrine of prosecution disclaimer may not be invoked "where the alleged disavowal of claim scope is ambiguous." Id. at 1324. Rather, the "heavy presumption" can be overcome only if "the patentee unequivocally imparted a novel meaning to those terms or expressly relinquished claim scope during prosecution." Id. at 1323. "Consequently, for prosecution disclaimer to attach, [Federal Circuit] precedent requires that the alleged disavowing actions or statements made during prosecution be both clear and unmistakable." Id. at 1325-26.

In the case of the '349 patent, the original application was submitted with twelve claims of two types. Application claims 1, 3-5, 8-9, and 11 more-or-less described the physical arrangement of the reagent containers and the various axes of rotation, but did not describe the gear structure for driving the rotation of the containers. Application claims 2, 6-7, 10, and 12, on the other hand, included the gear structure not present in the other claims. (D.I. 301 at A281-86.) Among the latter set, application claims 6, 7, and 10 described a "ring gear" for driving the satellite gears, whereas application claims 2 and 12 described a "circular gear" for driving the satellite gears.

2 Application claim 12 was issued as claim 9 in the '349 patent.
axis, however it is oriented such that it is in tangential contact with only one cylinder at a time. Thus, as the circle of cylinders rotates about a central axis, only the cylinder in contact with the wheel is rotated. The other cylinders remain stationary. (See id. at A 1712.) In response to the examiner's rejection, Bayer argued:

Claims 1, 6, 8, and 12 recite the capability of simultaneously rotating the agitating assemblies and their respective reagent containers. In addition, these claims recite the structure for accomplishing this. For example, Claim 6 recites a ring gear, concentric with the primary vertical axis of rotation for the reagent tray and coupled to an agitating motor, in driving engagement with each of the satellite gears. In contrast, Forrest provides a motor 103 having a rubber wheel 101 or gear on a motor shaft 102. The rubber wheel is provided at a tangential location proximate a ring of reagent containers. Each container is spun, one at a time, as it passes the rubber wheel or gear.

(Id. at A307-08 (emphasis in original).)

In spite of Bayer's arguments, the examiner remained unconvinced and again rejected all twelve claims in a June 2001 office action. The examiner explained that Forrest incorporates by reference a European patent, which discloses additional motors for use with each cylinder, thereby enabling simultaneous rotation of the cylinders. (Id. at A327.) Subsequently, counsel for Bayer conducted an interview with the examiner and her supervisor. Bayer summarized that interview as follows:

Examiner Bex also indicated during this telephone call that the rejection of Claim 6 under 35 U.S.C. § 103(a) [obviousness] was being withdrawn on the basis that the cited prior art failed to disclose, teach or suggest, alone or in combination, a reagent transport apparatus in which each of plural agitating assemblies comprise a satellite gear in communication with a first reagent container holder and concentric with the vertical axis of rotation of the respective agitating assembly, and a ring gear, concentric with the vertical axis of rotation of a reagent tray, in driving engagement with each of the satellite gears, whereby rotation of the ring gear results in the rotation of each of the satellite gears about their respective axes of rotation. Thus, Claim 6 was indicated by Examiner Bex as being allowable. Claim 7 is also considered allowable as being dependent from Claim 6.

In general, Examiner Bex indicated that the remaining independent claims would also be allowable if similar limitations with respect to the satellite and ring gears were incorporated therein. For instance, the Examiner indicated that claim 12 would be allowable if the physical relationship between the satellite gear and inner reagent container were more specifically defined.

(D.I. 301 at A340-41.)

With respect to application claim 12, Bayer amended it in the manner directed by the examiner during the interview. Importantly, that amendment did not change any of the pre-existing claim language describing the relationship between the circular gear and the satellite gears. (Id. at A347-48.) Thus, it is apparent that Bayer believed the gear structure of application claim 12 (i.e., the circular gear/satellite gear combination) to be equally as distinguishable from the prior art as the gear structure of application claim 6 (i.e. the ring gear/satellite gear combination). Moreover, after the interview, the application claims without gear structures were still rejected by the examiner as anticipated by Forrest. Therefore, it must have been Bayer's understanding that the gear structure, and not the simultaneous rotation of the containers about their respective axes, distinguished Forrest. In fact, Bayer went on to argue that the application claims without gear structures were distinguishable because simultaneous rotation in Forrest requires multiple motors, whereas the application claims only required one motor for that task. However, the examiner never accepted that argument. Instead, Bayer cancelled the claims not reciting the allowable gear structure, or amended them to include such a structure, in order to avoid the examiner's rejections:

Examiner Bex indicated that she had reviewed the claims in light of the previously applied references and the newly cited references… and had come to the conclusion that at least the subject matter of independent claim 6 was allowable. In particular, Examiner Bex indicated that the references failed to anticipate the specific gear structure of claim 6.

…

In light of this conclusion, and without prejudice to pursuing claims of differing scope in one or more continuing
applications, claims 1-2, 10, and 13 are canceled herewith, and limitations similar to the gear structure recited in claims 6, 10 or 12 are incorporated into each of independent claims 8 and 14. The dependency of claims 3-5 has been amended to refer to claim 6.

(Id. at 372-73 (emphasis added).) 3 Once again, Bayer demonstrated its understanding that the recited gear structure of application claims 6, 10, or 12 was crucial to patentability. Also noteworthy is the fact that Bayer believed, as is demonstrated by the emphasized language above, that the circular gear/satellite gear structure of application claim 12 distinguished the prior art to the same extent as the ring gear/satellite gear structure of application claims 6 and 10.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 Application claims 2 and 10 recited gear structure, but they were canceled nonetheless. However, the important point to note is that no claims without the gear structure remained.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Finally, after the examiner allowed the claims reciting gear structures, both the examiner and Bayer wrote informative explanations of the reasons for allowance. The examiner commented as follows:

While the configuration of two sets of containers, both concentric about a primary axis of rotation and positioned on a rotatable tray is well-known in the art, none of the prior art specifically recite the use of a plurality of satellite gears in mechanical communication with each of the agitating assemblies holding one set of the containers. The satellite gears being concentric with the secondary axis of rotation. Additionally, the prior art fails to disclose a ring gear, concentric with the primary vertical axis of rotation, which is in mechanical communication with each of the respective satellite gears, such that rotation between the reagent tray and ring gear results in the simultaneous rotation of each of the satellite gears about their secondary vertical axis.

(Id. at A383.) Bayer then responded:

Thus, it is [Bayer's] interpretation of the reasons for allowance that the point of novelty with respect to the cited and applied art lies in the claimed arrangement of satellite gears and a ring gear for simultaneous rotation of each of the satellite gears about a respective secondary axis of rotation.

...

The purpose of the Interview, from the perspective of [Bayer], was to discuss the possible allowability of the present claims if specific structural elements (e.g., the ring gear and the satellite gears) were added to the independent claim not already reciting such elements. Given the urgency in prosecuting the present application…., a decision was made to preserve for another day the question of whether claims without such structural elements were distinguishable from the cited art.

...

In sum, it was asserted by [Bayer] that, with the selective inclusion of specific structural elements relating to a ring gear and satellite gears, the application would be allowable over the cited art.

(Id. at A386-88 (emphasis in original).) Thus, both the examiner and Bayer agreed that the specific gear structure recited in the issued claims was the reason for allowance. Once again, no distinction was drawn between the ring gear/satellite gear structure and the circular gear/satellite gear structure.

Bayer also filed patent application 10/156,849 ("the '849 application"), which is a continuation of the '349 patent. The recited gear structure in the '849 application claims and the recited gear structure in the '349 patent claims are nearly identical. And, similar to the '349 patent, the '849 application describes a circular gear/satellite gear structure in independent claim 1, and a ring gear/satellite gear structure in independent claim 7. Significantly, all of the claims in the '849 application were rejected in an October 2002 office action as being anticipated by U.S. Patent No. 3,151,073 ("the '073 patent") to Anthon, without regard to which gear structure (i.e., circular or ring) was employed.
Anthon describes a "centrifuging apparatus" having a chain disposed around the periphery of a ring of sprockets with which the chain is engaged. The chain is driven by another sprocket tangentially engaged with the outer side of the chain. Thus, when the drive sprocket rotates, it causes the chain to drive the rotation of each sprocket in the ring about its respective axis. (D.I. 301 at A509.) In rejecting the claims of the '849 application, the examiner explained the operation of Anthon in her own words:

Anthon teaches a circular ring gear 78 concentric with the primary vertical axis of rotation and coupled with the agitating motor, wherein the circular gear is rotatable by the motor and in communication with each of the satellite gears such that rotation of the circular gear about the primary axis of rotation causes each of the satellite gears to rotate about their [sic] respective secondary vertical axis simultaneously.

(D.I. 298 at A2182.) Bayer responded with the following argument:

As for both claims 1 and 7, a gear concentric with the primary vertical axis of rotation and coupled to an agitating motor is recited. The American Heritage Dictionary of the English Language, Fourth Edition, Copyright 2000, defines "gear" as "a toothed machine part, such as a wheel or cylinder, that meshes with another toothed part, such as a wheel or cylinder, that meshes with another toothed part to transmit motion or to change speed or direction." The same dictionary defines "chain" as "a connected, flexible series of links, typically of metal, used especially for holding objects together or restraining or for transmitting mechanical power." The roller chain 78 of Anthon can in no way be regarded as the same element as the recited gear.

(D.I. 301 at A448.) Thus, Bayer clearly and unmistakably distinguished chains from gears, at least insofar as the claims of the '849 application are concerned. However, "the prosecution history of a related patent can be relevant if, for example, it addresses a limitation in common with the patent in suit." Advanced Cardiovascular Sys., Inc. v. Medtronic, Inc., 265 F.3d 1294, 1305 (Fed. Cir. 2001). Thus, courts "presume, unless otherwise compelled, that the same claim term in the same patent or related patents carries the same construed meaning." Omega, 334 F.3d at 1334. Since the '849 application is a continuation of the '349 patent, and since there is no indication that Bayer intended "gear" to have a different meaning in the later application, the term must be construed identically in both. Consequently, the court's construction of "gear" in the '349 patent must exclude chains.

The more difficult question is whether the court's construction must also exclude sprockets. Although neither the prosecution history of the '349 patent, nor the prosecution history of the '849 application contain an explicit disclaimer of sprockets, Abbott contends that Bayer's citation to the dictionary definition of "gear" was sufficient to act as a disclaimer. More specifically, Abbott argues that since a sprocket meshes with a chain, and not with another toothed part, sprockets do not fit within Bayer's dictionary definition of "gear." Bayer responds by pointing to several sources that refer to sprockets as gears. Bayer also directs the court's attention to the last sentence of its response to the rejection in light of Anthon, in which Bayer merely distinguished chains, not sprockets. This last point is dispositive. Excluding sprockets from the definition of "gear" requires the court to infer that Bayer explicitly relinquished sprockets because it defined "gear" as "a toothed machine part… that meshes with another toothed part," whereas sprockets mesh with chains (which allegedly have no teeth). In the court's view, that inference is too tenuous to amount to a clear and unmistakable surrender of subject matter. Thus, the term "gear" will be construed as "a toothed machine part, such as a wheel or cylinder, that meshes with another toothed part, to transmit motion or to change speed or direction, and which excludes a chain."
1. Intrinsic Evidence

a. Claim Language

The Court first considers the intrinsic evidence to determine the proper meaning and scope of the disputed terms "liquid," "gel," and "liquid containing pack" as used in the Sereboff patent. In analyzing the intrinsic evidence, the Court first considers the language of all the claims, both asserted and nonasserted. See Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995). Although the words in a claim are usually given their ordinary and customary meaning, a patentee may act as a lexicographer, giving the claim language a meaning different from the ordinary and customary usage of the words. See Vitronics, 90 F.3d at 1582. In this case, Fellowes essentially argues that all "gels" are subsumed within the term "liquid," and that "liquid" is specially defined by the written description of the Sereboff patent to include 3M's elastomeric gel. (See Def.'s Mem. in Opp'n at 6-7, 10.) 3M offers an interpretation in which the term "liquid" includes only "liquid gels," while "solid gels" are not included within the term "liquid." (See Pl.'s Mem. in Supp. at 5-7, 15.)

The Court first examines the relationship between independent claim 1, which includes the term "liquid," and dependent claims 3 and 20, which include the term "gel." A dependent claim can only further define (i.e., add narrowing limitations to) an independent claim; it cannot substitute one element for another specified in the independent claim. See Manual of Patent Examining Practice § 608.01(n) (7th ed. 1998). This convention of patent practice means only that "liquid" and "gel" cannot be mutually exclusive, for that would improperly substitute "gel" in dependent claims 3 and 20 for "liquid" in independent claim 1. Moreover, under the doctrine of claim differentiation, different claims are presumed to have different scopes. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). This suggests that the term "liquid" in claim 1 is broader than the term "gel" in claims 3 and 20. For example, "liquid" in claim 1 includes water, which is not a "gel" within the scope of claims 3 and 20. These observations, however, while helpful in construing the claim language, do not resolve the dispute over whether all "gels" are completely subsumed under the term "liquid."

b. Written Description

Accordingly, the Court turns to the Sereboff patent's written description, which is also sometimes referred to as the patent specification. For the patentee to use terms in a claim differently from their ordinary meaning, the special definition of the claim term must be clearly enunciated in the written description or prosecution history of the patent. See Vitronics, 90 F.3d at 1582. Fellowes argues that the written description clearly indicates that the term "liquid" includes elastomeric gels because the written description of the Sereboff patent includes a reference to U.S. Patent Number 5,173,963 ("the Greenberg patent"), which discloses an elastomeric nonflowing gel. (See Def.'s Mem. in Opp'n at 6-7.) This argument is without merit.

The Sereboff patent's mere reference to the Greenberg patent fails to satisfy the Vitronics requirement of providing a clear and explicit special definition of any special usage of a claim term. First, the Greenberg patent is discussed only in the "Background of the Invention" section of the Sereboff patent, and is mentioned only in the context of identifying possibly relevant prior art, not to identify the actual subject matter of Sereboff's claimed invention. (See Sereboff patent at column 1, lines 35-41.) Moreover, the Sereboff patent fails to identify nonflowing elastomeric gels as being the important feature of the Greenberg patent for which reference to the Greenberg patent is made. (See id.) Furthermore, the Sereboff patent fails to incorporate the subject matter of the Greenberg patent by reference, such that the disclosure in the Greenberg patent is not considered to be part of the disclosure of the Sereboff patent. See In re Howarth, 654 F.2d 103, 107 (C.C.P.A. 1981) (requiring a patent applicant to either "set forth the information in his specification or incorporate it by reference to a reasonably accessible source"); In re De Seversky, 474 F.2d 671, 673 (C.C.P.A. 1973) (refusing incorporation where no "incorporation-by-reference" language existed in the application); Manual of Patent Application Practice and Procedure § 608.01(p) (7th ed. 1998) ("Mere reference to another application, patent, or publication is not an incorporation of anything therein into the application containing such reference for the purpose of the disclosure required by 35 U.S.C. 112, first paragraph."). For these reasons, the Court finds that the Sereboff patent's mere reference to the Greenberg patent does not provide a special definition of the term "liquid" that includes elastomeric gels.

Other portions of the Sereboff patent's written description must also be considered in interpreting the term "liquid." Fellowes argues for attaching a special meaning to "liquid" based on the following portion of the Sereboff patent's written description:
As is seen in FIG. 3, pack 30 includes a substantially liquid type composition 34 which may be in the form of a liquid having a viscosity approximating the viscosity of water, or may include a gel composition contained therein having a viscosity substantially above that of water.

(Sereboff patent at column 3, lines 53-68, emphasis in original.) The Court finds that this explicit language is sufficiently clear to constitute a special definition of the claim term "liquid." Under this special definition, the "liquid" of claim 1 of the Sereboff patent includes both a substance at about the viscosity of water and also gels having a viscosity substantially above that of water. (See id.) The written description of the Sereboff patent does not impose an upper bound on the viscosity of gels considered to be within the special definition of the claim term "liquid." (See id.) Thus, the written description of the Sereboff patent indicates that the term "liquid" appears to include all "gels" that can be regarded as having a viscosity.

c. Prosecution History

Having decided, based on its written description, that the Sereboff patent created special definitions of the terms "liquid" and "gel" at the time the patent application was filed, the Court next turns to the prosecution history to determine if this understanding of the meaning of "liquid" and "gel" was later modified during prosecution of the Sereboff patent application before the U.S. Patent & Trademark Office. Both claim amendments and mere arguments for patentability, along with other aspects of the prosecution history, must be examined to determine the meaning of terms in the claims. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). The patentee cannot treat the claim as a "nose of wax," having one meaning during prosecution, and yet another altogether during litigation. See Semmed, Inc. v. Richard-Allan Med. Indus., 888 F.2d 815, 819 n.8 (Fed. Cir. 1989) (citing White v. Dunbar, 119 U.S. 47, 51-52, 30 L. Ed. 303, 7 S. Ct. 72 (1886)).

During prosecution of the Sereboff patent application, the claims were rejected as being obvious based on U.S. Patent Number 5,228,665 ("the Garcia patent," disclosing a foam slab wrist rest) in view of U.S. Patent Number 4,896,388 ("the Bard patent," disclosing a pillow using both a compressible filling and a water filling). In arguing for patentability, Sereboff stated:

Unlike the Garcia system, the inventive concept of the [Sereboff] Application is not directed to a support system which provides firmness sufficient to restrict the movement of a user's wrists, nor to one which urges the user's wrists to maintain a fixed desirable position. Rather, it is directed to accommodating the free movement of the user's wrists and palms by the use of a fluid support mechanism which resiliently conforms to the contours of the user's wrists and palms, even while they are moving.

(Witt Decl. Ex. 7 at 47 ("Sereboff prosecution history").) (emphasis added) The Court finds that these explicit arguments during prosecution of the Sereboff patent created two additional constraints on the claims. First, the support mechanism must be fluid. (See id.) Second, the support mechanism must dynamically conform to the user's wrists while they are moving. (See id.) The first constraint provides additional insight into the proper interpretation of the claim terms "liquid" and "gel," i.e., the support mechanism must be "fluid." The second constraint does not affect the Court's literal infringement analysis.

4 A patent cannot be obtained for subject matter sought to be patented that is deemed "obvious" by the patent examiner. See 35 U.S.C. § 103.

The term "fluid" limits the "gels" included within the claim term "liquid" to only those gels that flow. Gels that do not flow are not "liquid," as that term was defined by the Sereboff patent application and further limited by Sereboff during prosecution. Stated differently, use of the term "fluid" during prosecution of the Sereboff patent allows the Court to conclude that the term "gel" is not subsumed within the term "liquid." The intrinsic evidence indicates that the term "liquid" in independent claim 1 limits the "gels" in claims 3 and 20 to only those gels that flow; nonflowing gels are not within the scope of the Sereboff patent claims.
2. Extrinsic Evidence

When the intrinsic evidence does not resolve a disputed claim term, the Court may also receive extrinsic evidence to aid in claim interpretation. See Markman, 52 F.3d at 980; Vitronics, 90 F.3d at 1583. In this case, the intrinsic evidence clearly limits the claimed "liquid" to include only those gels that flow. However, an examination of the extrinsic evidence provided by Fellowes' own expert, Dr. Larson, confirms the above claim construction based on the intrinsic evidence.

Dr. Larson submitted an expert report in which he stated that "both the ordinary and scientific meanings [of 'liquid'] describe it as a substance that flows. . . . The term 'liquid' can refer to substances that flow or deform reversibly only when modestly large forces are imposed." (Larson Decl. P 3.) "If a gel is flowable, then the network structure must be capable of being broken down under a load or force, and to reform itself once that load is removed. Block copolymer formulations possess this property. . . ." (Id. P 10.) "The [3M] block copolymer formulation . . . fits within the range of gel possibilities envisioned by Sereboff." (Id. P 12.) "The [term] . . . liquid . . . as used in claim 1 of the Sereboff patent [is] intended to exclude substances like foam rubber that cannot deform irreversibly or 'flow,' but instead spring back into a predetermined shape after the deforming force is removed." (Id. P 17.) This terminology is also "intended to exclude nonflowable elastic substances. . . ." (Id. P 19.)

These statements by Dr. Larson clearly limit the claimed "liquid" to only those substances that flow. Dr. Larson admits that "nonflowable elastic substances" are not included within the scope of the Sereboff patent claims. (Id. P 19.) Thus, if the 3M gel is either nonflowable or elastic, it does not infringe the Sereboff patent. Dr. Larson also sheds further light on the meaning of "flow" and "flowable." If the 3M gel "springs back into a predetermined shape after [a] deforming force is removed," it does not flow and does not infringe the Sereboff patent. (See id. P 17.) Moreover, if the 3M gel is incapable of reforming itself after being broken down, then it does not infringe. (See id. P 10.) (emphasis added). The Court interprets the words "reforming itself," based on their plain meaning, to mean "reforming on its own accord" rather than "capable of being reformed." Thus, if reforming the 3M gel back to its predetermined shape (after the gel is broken down) requires an externally applied force, then the 3M gel does not infringe. 5 In summary, the Court finds that the extrinsic evidence offered by Fellowes also indicates that the claimed "liquid" must flow. The Court further finds that the claimed "liquid" must be inelastic, and it must be capable of reforming itself back into a predetermined shape after being broken down.

5 Although Dr. Larson states that block copolymer formulations are able to reform themselves, he does not state that all block copolymer formulations act this way, or that the accused 3M elastomeric gel acts this way. (See id. P 10.)

--- Footnotes ---

1. The parties agree that resort to dictionaries is useful to determine the meaning of the term "geometry." As the district court correctly stated, "[t]he ordinary meaning of 'geometry' in the context of the claims is a figure characterized by points, lines, or planes." Ormco Corp. v. Align Tech., Inc., No. SA-CV-03-16-GLT, slip op. at 3, 2005 U.S. Dist. LEXIS 43398 (C.D. Cal. Feb. 24, 2005) (citing Webster's New World Dictionary Third College Edition 564 (1988)). In other words, geometry means "configuration" or "shape." 6 Unlike the district court, we think that objects of different thicknesses plainly have different "configurations" or "shapes." Furthermore, the specification indicates that "[i]n a broadest sense, the methods of the present invention can employ any of the known positioners, retainers, or other removable appliances which are known for finishing and maintaining teeth positions in connection with conventional orthodontic treatment." '611 patent, col. 9, ll. 25-29. Thus, we conclude that the Truax devices satisfy the "geometries" limitation of claim 1.
"Generally Adjacent"

In claims 48, 50, 54, and 56 of the '404 Patent, the parties dispute the terms "cross brace member" (which the court has previously constructed), "generally adjacent," "connected to the table top," and "lip." The parties' proposed constructions of generally adjacent are set forth in Table 5.

<table>
<thead>
<tr>
<th>Term, Patent, and Ind. Claim</th>
<th>Pl.'s Interp.</th>
<th>Def.'s Interp.</th>
</tr>
</thead>
<tbody>
<tr>
<td>generally … adjacent</td>
<td>Lifetime's Interpretation: &quot;adjacent&quot; means in contact with. (Lifetime's Mem. in Opp. (originally document 26 in 1:03CV0013TC) at 7-8.)</td>
<td>FDL's Interpretation: &quot;adjacent&quot; means lying near, not distant, close, but not necessarily touching.&quot; (FDL's Rep. Mem. in Supp. (48) at 4-5.)</td>
</tr>
</tbody>
</table>

The ordinary meaning of the claim term "generally" is "usually, commonly; ordinarily; and "for the most part." Webster's at 795. "Adjacent" means "lying near, close, or contiguous; adjoining; neighboring." Id. at 25. "Adjoin" means "to be close to or in contact with." "Adjoining" means "being in contact at some point or line; located next to another; bordering," and "neighboring" means "situated or living near." Id. at 1286. In the context of the '404 Patent, the support pedestal (table leg) in the collapsed position would be close to, near, bordering, or in contact with the mounting surface (underside) of the table.

The specification is not helpful in refining this construction because it simply repeats the term adjacent, without clarification:

Preferably, a pair of securing members 152 are disposed in relation to the mounting surface 14 for releasably securing a respective support pedestal 18, 20 in the collapsed position adjacent the mounting surface 14.

(FDL's Motion for Invalidity (originally document 24 in 1:03CV0013TC) Ex. 1, '404 Patent at col. 11, Ins. 23-26.)

Lifetime argues that United States Patent No. 5,921,623 to Nye (the "'623 Patent"), which has been assigned to Lifetime, makes clear that the table legs of the '404 Patent, when in the collapsed position, are in contact with the underside of the table. (Sears Decl. (originally document 27 in 1:03CV0013TC), Ex. A, '623 Patent.) Lifetime is correct that in the '623 Patent, when the table legs are collapsed, they are near, but not in contact with, the underside of the table. According to Lifetime, then, because the Examiner considered the '623 Patent during the prosecution of the '404 Patent, the reason for allowance of the '404 Patent was that the table legs of the '404 Patent were in contact with the underside of the table.
10 One embodiment of the '404 Patent also appears to have a similar arrangement that allows the pedestals to lie flat when in the collapsed position. (FDL's Motion for Invalidity (originally document 24 in 1:03CV0013TC) Ex. 1, '404 Patent at col. 14, Ins. 50-54; id. at Fig. 4.) This embodiment, however, does nothing to advance Lifetime's interpretation of the term generally adjacent, and in fact, if anything, it lends support for a definition of "adjacent" that means "close to" or "near."

But Lifetime's argument does not take into account that the '404 Patent disclosed an element not shown in any of the claims of the '623 Patent--depressions in the table top. This means that the Examiner had at least one additional element in the '404 Patent, not present in the '623 Patent, that could explain why she allowed the '404 Patent.

In short, there is nothing in the claim language nor in the specification that requires the pedestals actually touch or come in contact with the mounting surface of the table. In fact, the claim language mandates a directly opposite conclusion: The pedestals may be "close to" or "near" and still be "adjacent" within the meaning of claims 48, 50, 54 and 56. Moreover, the modifier "generally" suggests even more leeway when interpreting "adjacent." Specifically, the pedestals may be "close to" or "near" the mounting surface of the table "for the most part," meaning that they can be farther away in some instances.

Accordingly, "generally adjacent" means that the pedestals are located or situated close to, near, bordering, or in contact with the underside of the table.

--- Footnotes ---

11 The Honorable Gary L. Taylor of the United States District court for the Central District of California arrived at the same interpretation of "generally adjacent" in another case involving the '404 Patent. Lifetime Products, Inc. v. Alton Indus., Inc., No. SA CV-02-350-GLT(ANx) slip op. at 7-8 (C.D. Cal. Apr. 21, 2004). This provides additional support for the court's interpretation of generally adjacent.

--- End Footnotes ---

D. Generally Arcuate Segments

ICU's Construction
Naturally separated divisions, portions or sections of the walls that are bent, curved like a bow or arc-sharped

RyMed's Construction
Segments wherein the inner and outer surfaces of the wall are curved in the same direction.

The term "generally arcuate segments" appears in independent claim 1 of the '204 Patent. ICU contends that the Court should adopt the construction used in the Braun case because it reflects the plain meanings of "arcuate" and "segment." (D.I. 118, at 21.) ICU also contends that RyMed's proposed construction ignores or excludes dependent claim language which further defines the disputed term, (D.I. 172, at 18), and that RyMed's proposed construction contains limitations not warranted by the claim language or Common Specification. (Id. at 21.)

RyMed contends that ICU's construction is "confusing, redundant, and inconsistent with the intrinsic evidence." (D.I. 116, at 28.) RyMed further contends that Figure 9 is the only support in the Common Specification for the term "generally arcuate segments," and that a prosecution history disclaimer should apply to prevent ICU from arguing that additional support exists in the Common Specification. (See D.I. 116, at 29 ("ICU is... estopped by its statements in the prosecution history from arguing that a seal such as the O-ring based seal of Figure 13 has 'arcuate segments.'").)

As an initial matter, the Court finds that prosecution history disclaimer is inapplicable. In order for the Court to find a prosecution history disclaimer, the patentee must have limited the meaning of a claim term by making a "clear and unmistakable disavowal" of claim scope during prosecution. Purdue Pharma, L.P. v. Endo Pharm., Inc., 438 F.3d 1123, 1136
(Fed. Cir. 2006). During the prosecution of the '204 Patent, the Examiner rejected the term "arcuate segments" for lack of support in the specification. (D.I. 117, Ex. 23, at 49.) The patentee replied, "Figure 9 clearly discloses a seal element 36a having the arcuate segments." (Id.) Because it is not apparent whether the patentee meant Figure 9 as one of multiple examples of "arcuate segments," or as the only example of them, no "clear and unmistakable disavowal" was made. See Sandisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1287 (Fed. Cir. 2005)("[t]here is no 'clear and unmistakable' disclaimer if a prosecution argument is subject to more than one reasonable interpretation"). The fact that the patentee had the opportunity to cite Figure 13 in support of "generally arcuate segments," but chose not to, does not change the foregoing analysis.

As ICU points out in their Opening Brief, both parties are in relative agreement as to the meaning of "arcuate." (Compare D.I. 118, at 21 (ICU construing "arcuate" as "bent, curved like a bow, or arc-shaped") with D.I. 232, at 72:20-21 (RyMed stating "arcuate means curved like a bow. Bow means something bent into a simple curve.").) However, the parties dispute whether or not RyMed's proposed limitation concerning "the inner and outer surfaces of the wall" is appropriate. In the Court's view, this limitation is unwarranted. Even if RyMed were correct that the Figure 9 embodiment is the only support for "generally arcuate segments" in the Common Specification- which is a contested point- they provide no justification for reading a limitation about the inner surface walls into Figure 9.

ICU relies in large part on the Braun construction of "generally arcuate segments." In Braun, the parties stipulated to the construction, and it was based on dictionary definitions, a now-disfavored practice. Accordingly, it is unclear how persuasive an authority Braun is on the construction of this term. However, if prosecution history disclaimer does not apply and the proposed RyMed limitation is not accepted, ICU's proposed construction is more persuasive. Thus, the Court concludes that "generally arcuate segments" means "naturally separated divisions, portions or sections of the walls that are bent, curved like a bow or arc-shaped."

1837

The issue here is: how circular is "generally circular"? ASM argues that no construction is necessary, because no construction could improve upon the claim language "a generally circular configuration."

Genus correctly points out that "when a word of degree is used the district court must determine whether the patent's specification provides some standard for measuring that degree." Exxon Research and Engineering Co. v. United States, 265 F.3d 1371, 1381 (Fed. Cir. 2001) (quoting Seattle Box Co. v. Indus. Crating & Packaging, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984)). In Exxon, an issue was whether the term "substantial absence of slug flow" was indefinite because the specification did not provide any empirical standard for determining when the process could be said to be substantially lacking in slug flow. Id. The Federal Circuit found that one of ordinary skill in the art would understand from the specification that the reason slug flow should be avoided is that it may interfere with reactor efficiency. Id.

Whether there is a "substantial absence of slug flow" therefore can be determined with reference to whether reactor efficiency is materially affected. If there is no slug flow or such minimal slug flow that the slug flow has no appreciable impact on reactor efficiency, then there is a "substantial absence of slug flow" within the meaning of the claims. In this setting, as in other, mathematical precision is not required - only a reasonable degree of particularity and definiteness. (Id.) See also Modine Manufacturing Co. v. United States International Trade Commission, 75 F.3d 1545, 1550-54 (Fed. Cir. 1996) (construing "relatively small" in light of the specification, the other claims, and the prosecution history); Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 821 (Fed. Cir. 1988) (claim language such as "approach each other," "close to," "substantially equal," and "closely approximate" are "ubiquitous in patent claims" and "when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention, and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the courts.")

The claim language at issue requires that the gas flow apertures are placed "in a generally circular configuration having a radius substantially equivalent to a radius of" the substrate. ('165 patent 5:47-6:1, 6:22-25.) The substrate itself is either circular (claim 1) or substantially circular (claim 6). (Id. 5:36, 6:19.) The reason for using a generally circular configuration of apertures that substantially matches the size of the substrate is not specifically set forth in the specification. Genus points to the following language from the prosecution history, however:
As described by the present application, creation and maintenance of the stagnation point gas flow can only be achieved by having and maintaining a uniform gas flow velocity vector perpendicular to the entire surface of the susceptor. This is accomplished by the present invention by providing the gas injector with apertures having a circular configuration corresponding to the circular configuration of the substrate. The pending claims have been amended to further clarify and point out this important distinction.

('165 Prosecution History at 98.) Thus, the prosecution history identifies a purpose of the generally circular configuration of the gas flow apertures as enabling the creation and maintenance of the stagnation point gas flow by having and maintaining a uniform gas flow velocity vector perpendicular to the entire surface of the susceptor.

Genus argues, however, that this language defines "generally circular" as "circular." This argument is not persuasive. The inventors were simply using a shorthand version of the claim language to describe the creation and maintenance of the stagnation point flow. Importantly, the actual claim language at the time the inventors used that language called for a "generally circular configuration," just as it does now. (Id. at 96.)

Genus also points to ASM's position in prior litigation, in which it argued that the "generally circular" language means that "the gas injection apertures are distributed in a configuration which appears generally like a circle with apertures distributed within the circle," and that "any variance from circular cannot be such as to prevent commercially acceptable thickness uniformity in the deposition." (Reines Decl., Ex. A, March 10, 1997 Joint Claims Chart from ASM v. Applied Materials at 2.) Uniform deposition of material on the substrate is, of course, a major goal of the invention, as noted in the summary of the invention section of the '165 patent. ('165 patent 2:3-11.) Thus, ASM's statement in the Applied Materials case is consistent with the language Genus cites from the prosecution history. Accordingly, it appears that the "generally circular configuration" of the gas flow apertures is one of the features of the invention that leads to uniform deposition of material on the substrate.

Thus, where there is a question as to whether a configuration is "generally circular" or not, the person of ordinary skill in the art can look to see whether the gas flow is initially directed perpendicularly across the entire surface of the substrate, and whether there is commercially acceptable uniformity of deposition of material on the substrate. Where all the other features of the invention exist, but these features do not exist, then one would know that the configuration of the gas flow apertures is too far from circular to be thought of as "generally circular." Thus, the term is not too indefinite to be construed.

Whether or not an apparatus has a generally circular configuration of gas flow apertures, however, is really a matter of infringement, not of claim construction. The Court agrees with ASM that there is no better way to define "generally circular" than to simply say "generally circular." Accordingly, the Court declines to construe the term.

E. "being generally concentric to"

The parties dispute the meaning of the term "being generally concentric to" as it appears in claims 37, 41, and 45 of the '748 Patent. Synovis contends that no construction is necessary, but if the Court decides to construe the term, it should be construed as "generally sharing a common axis or center." (Joint Statement at 19.) Gore, on the other hand, asserts that the Court should construe "being generally concentric to" as "having a common center (as circles one within another)." (Id.) The Court concludes that the term "being generally concentric to" is properly construed as a "having a common center (as circles one within another)."

3. "Longitudinally disposed bands, wherein each band defines a generally continuous wave having a spatial frequency along a line segment parallel to the longitudinal axis."
Consistent with the claim language and its ordinary meaning, the specification 4 and the prosecution history, 5 the court construes this limitation to mean that "the stent has multiple elongated surfaces that run parallel to the stent's long axis, each of these surfaces having the undulating appearance of a continuous wave."

4 Claim 1 requires that there be a plurality of links between bands. (406 patent, col. 5, l. 32) The specification requires that the bands undulate through approximately two cycles before there is a circumferential link and that there be a plurality of periodic links. (406 patent, col. 4, ll. 7-10, 15-17) Nowhere in the patent does it direct one of ordinary skill in the art how to construct a stent that meets these criteria without the bands running the length of the stent. Figures 3(a) and (b), showing a "portion of a stent with two bands between two circumferential links," cannot mean that a band is only what is shown, as what is depicted does not have a plurality of links. (See also '406 patent, col. 2, ll. 52-59 (describing Fig. 1(c) and (d) as an "axially flexible stent in accordance with present invention").) This construction does not read into the independent claim the limitations for its dependent claims, as none of the dependent claims cited by Cordis requires that the bands run the length of the stent. (See '406 patent, claim 10 and claim 17 (requiring that the bands be capped at the ends of the stent); Id., claim 3 (requiring that the band change in spatial frequency along its length)).

5 D.I. 230, Ex. 37 at 11637; Id., Ex. 34.

NAC assigns error to the district court's construction of the claim limitation "generally convex," which precludes any concavity in the inner walls of the base portion. NAC argues that, contrary to the court's finding, the applicant did not disclaim inner walls with any concavity during prosecution. According to NAC, the statement in the prosecution history relied upon by the court to support a disclaimer merely reflected the applicant's distinction of the generally convex inner walls of the claimed invention from the inner walls of the prior art, which were "concave in [their] entirety."

NAC also contends that the district court's construction, which defines the "generally convex" limitation differently for the outer and inner walls of the base portion, is prohibited. CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1159 (Fed. Cir. 1997) (instructing that terms should be construed consistently throughout the claims). Moreover, NAC asserts that under the court's construction, the claims do not read on the patent's preferred embodiments, shown in figures 14 and 15, which show base portions with concave inner walls. See Nat'l Steel Car, Ltd. v. Canadian Pac. Ry., Ltd., 357 F.3d 1319, 1337 (Fed. Cir. 2004) (stating that claim interpretations "that do not read on the preferred embodiments are rarely, if ever, correct and would require highly persuasive evidentiary support.").

Finally, NAC finds error in the district court's construction which requires a majority of points on the inner wall to be convex. According to NAC, the term "generally" is a word of approximation that should not be limited to a strict numerical boundary such as a majority of points. Instead, NAC contends that, applying "ordinary English," the court should have construed the term "generally" as "on the whole," or "in a general manner."

Plastipak responds to NAC's points by arguing that the district court's construction of the "generally convex" limitation, excluding any concavity in the inner walls of the base portion, was required by the applicant's disclaimer during
prosecution. Like the district court, appellees read the applicant's prosecution statement as distinguishing the inner walls of the claimed invention from the corresponding structure in the Dechenne patent on the basis of not even being "slightly concave," instead of being entirely concave.

Regarding NAC's argument that the "generally convex" limitation should not be construed inconsistently, Plastipak again contends that the applicant's argument during prosecution required that result. Plastipak also disputes NAC's assertion that the district court's construction reads out preferred embodiments. According to Plastipak, the specification only discloses one "particularly preferred embodiment," shown in figure 12, and the inner walls of that embodiment are within the court's construction of "generally convex." Nonetheless, Plastipak cites case law supporting the proposition that claim construction does not always include all of the embodiments disclosed in a specification. See Elekta Instrument S.A. v. O.U.R. Scientific Int'l, Inc., 214 F.3d 1302, 1308 (Fed. Cir. 2000).

Finally, Plastipak defends the district court's construction of the term "generally" to require a majority of points. Plastipak argues that that construction was supported by the Oxford English Dictionary Online. Moreover, Plastipak asserts that construing "generally" to require a majority of points is not inconsistent with NAC's proposed construction of the term, "on the whole."

We agree with the district court's conclusion that the applicant, through argument during the prosecution, disclaimed inner walls of the base portion having any concavity. Cognizant of the high standard required in order to show a prosecution disclaimer, e.g., Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-26 (Fed. Cir. 2003), we conclude that that standard has been met here. To overcome an obviousness rejection, the applicant distinguished his invention from the Dechenne patent on the basis of the latter disclosing inner walls that are "slightly concave." The inescapable consequence of such an argument is that the scope of applicant's claims cannot cover inner walls that are "slightly concave." Moreover, it logically follows, as the district court also concluded, that the scope of applicant's claims is also limited to inner walls of the base portion with no concavity.

We are not persuaded by NAC's argument that the applicant intended only to distinguish his invention from the prior art on the basis that the inner walls in the prior art bottles are entirely concave. Although the inner walls disclosed in the Dechenne and Jakobsen patents may be viewed as entirely concave, 3 that is not what the applicant argued during prosecution to gain allowance for his claims. The applicant stressed the difference in the extent of the concavity between the Dechenne and Jakobsen patents, noting that Dechenne is "slightly concave," whereas Jakobsen is "clearly concave in its entirety." Such a distinction would have been unnecessary if the only point that the applicant intended to make was that both prior art patents disclosed inner walls that are entirely concave.

We also reject NAC's argument that the district court erred in its construction of the "generally convex" limitation because the limitation is construed differently as it relates to the inner and outer walls of the base portion. Although the same limitation, i.e., "generally convex," appearing in different parts of the same claim is typically given the same construction, the applicant's argument during prosecution has warranted a departure from that general rule. As explained above, the "generally convex" limitation normally allows for some concave points on the walls of the base portion as long as the majority of points are convex, and, indeed that is how the court construed the limitation for the outer walls of the base portion. As we have also explained above, however, the "generally convex" limitation for the inner walls of the base portion cannot be given the same construction as the outer walls because the applicant disclaimed any concavity for the inner walls, but not the outer walls.

We find even less persuasive NAC's argument that the district court's construction would read out of the claims the preferred embodiments shown in figures 14 and 15. First, figures 14 and 15 show bottles with inner walls in the base portion that appear to have no convex points. Regardless how the term "generally" is construed, it requires that there be at least some convex points in the inner wall. Thus, even if some concavity in the inner walls is permitted, figures 14 and 15 would still
not fall within the scope of the claims. Secondly, as appellees note, we have previously explained that limitations may be construed to exclude a preferred embodiment if the prosecution history compels such a result. Elekta Instruments S. A., 214 F.3d at 1308. For the reasons explained above, in this case, it does. As the district court recognized, the fact that claims do not cover certain embodiments disclosed in the patent is compelled when narrowing amendments are made in order to gain allowance over prior art.

Finally, the district court did not err in construing the term "generally" to mean a majority of points. As NAC properly recognizes, terms of approximation such as "generally" need not be construed with mathematical precision. See, e.g., Anchor Wall Sys. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1311 (Fed. Cir. 2003). We do not believe, however, that the district court's construction imposes any "mathematical precision," as NAC asserts. In merely requiring a majority of points to be convex, the court articulated a common-sense understanding of the term confirmed by a dictionary. Moreover, we find the court's construction more fitting to the technology at issue here than NAC's proposed construction of "on the whole."

D Generally convex

Taylor contends that generally convex claims a lower portion that bulges outward. Divisional patent 410 describes the mounting member from a perspective below the mounting member. Independent claim 1 of patent 410 describes the lower portion as "having a generally convex outer surface . . . and facing in a direction away from said upper portion." The specification in patent 410 is identical to the specification in patent 449.

The specification does not use the term generally convex to describe the lower portion. However, the specification uses the term concave to describe the lower portion. 449 patent, col. 4, ll. 19-30. Based on the meaning of convex and on the absence of concave in the specification, the Court holds that one of ordinary skill in the art would believe that concave and convex describe the same structure but from a different perspective and that the same limitations apply to each term.

Independent claims 15, 26, 33, 37 and 38 of patent 449 state that the arcuate lower portion is "generally concave in cross section," the arcuate lower portion "forms a generally concave section," and that the "arcuate cross section is generally concave in cross section." These claims reveal that the meaning of generally concave and thus generally convex must lie within the meaning of arcuate. The ordinary meaning of arcuate is curved like a bow or arched. Taylor's proposed construction of convex as bulging outward is broader than curved like a bow or arched.

The correct construction of generally convex is consistent with the dictionary meaning of convex, which is curved outward like the exterior of a sphere. This construction of convex is within the meaning of arcuate. Consequently, the Court holds that the correct construction of generally convex is a shape that curves outward similar to the exterior of a sphere. 7

7 The modifier "generally" allows for slight deviations from mathematical boundaries. Anchor Wall Systems, Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-1311 (Fed. Cir. 2003). Consequently, the Court construes generally convex to claim a lower portion that is similar to the exterior of a sphere.

Ameritex argues that, like arcuate, generally convex must not be construed to include a structure with flat sections. However, as explained above, neither the claims nor the specification reveal a requirement that the claimed lower portion is
void of flat sections, and the prosecution history does not reveal a disclaimer of lower portions with flat sections to avoid reading on prior art.

1842
gen generally corresponding to

Plaintiff again argues that this term is unambiguous and requires no definition. Defendants propose the following definition: "exactly equal to or less than."

Defendants' definition is too narrow and places an improper emphasis on "exactly." The patent specifications teach that the "end of the ring metal and sheet of paper coincide" and that "sheets of paper whose length exceed that of the ring metal could also be stored in the binder." (729 patent at col. 4, ll. 16, 18-20.) Figure 3 demonstrates that the end of the paper coincides with the end of the device. "Generally corresponding to" covers each of these possibilities.

The Court agrees with Plaintiff. The term is unambiguous and is readily comprehensible to the finder of fact.

1843
e. "Generally Cylindrical End Plug"

All three parties have proposed constructions for this phrase. AnazaoHealth asks the Court to construe this as a separate ejectable member of predetermined dimensions comprised of material other than bone wax that is in the shape of a cylinder (i.e. the surface traced by a straight line moving parallel to a fixed straight line and intersecting a fixed planar closed curve), including end surfaces at a ninety (90) degree angle to the side of the plug, and placed into the distal end of the needle.

The World Wide Plaintiffs have broken the phrase into two constituent parts: "generally cylindrical" - "an object or material having the general form or properties of a cylinder" and "end plug" - "an object or material used to fill or seal an opening and positioned toward an extreme portion of the object it is filling." The Terwilliger Plaintiffs propose a construction of "a piece of material having the general form of a cylinder used to fill an opening and positioned at the distal end of the object it is filling."

Initially, the Court has construed "plug" in Claim 1 as "an object or material used to fill or seal an opening," 28 and will incorporate that construction into "generally cylindrical end plug."

28 See Discussion at 35-46, supra.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

As for the phrase "generally cylindrical," the Court rejects Defendant's proposed construction for several reasons. It gives no effect to "generally" and improperly reads this term out of the Claim. See Innova/Pure Water, 381 F.3d at 1119 (holding that "[w]hile not an absolute rule, all claim terms are presumed to have meaning in a claim"). In the context of claim construction, use of the adverb "generally" is to account for "some amount of deviation from exact." See Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1311 (Fed. Cir. 2003); see also Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 908 (Fed. Cir. 2005) (holding that "generally" is a term of approximation).

Additionally, Defendant's proposal would exclude several of the embodiments of the invention disclosed in the specification and depicted in the drawings. For example, Figures 1 and 2 show end plugs and spacers that are described as of "cylindrical
shape," although they possess rounded ends and are clearly not perfectly cylindrical. This provides an indication of how the patentees used the term "cylindrical" in the Patent. Because the end plug resides inside the cannula, its shape is necessarily constrained by the internal bore of the needle cannula, which is circular when viewed as a cross-section. Thus, the end plug should be "generally cylindrical" to fit within the cannula, but there is nothing in the claim or specification that would require the degree of precision set forth in Defendant's proposed construction. The Court finds that "cylindrical" was intended by the Patentees to have its ordinary meaning, that is, "having the form or properties of a cylinder." Webster's at 565. As used in this Claim, it is the shape that is critical and, thus, the Court construes "cylindrical" to mean "having the form or shape of a cylinder."

Claim 9 also refers to an "end plug," as opposed to simply "a plug" as in Claim 1. The World Wide Plaintiffs maintain that in the context of Claim 9 "end plug" can be construed in the same manner as "plug" since the Claim provides that it is to be held in the distal end, which has been construed as "the tip or point of the needle cannula." The Terwilliger Plaintiffs ask the Court to add a limitation to the construction of "end plug" as "a piece of material used to fill an opening and positioned at the distal end of the object it is filling." The Court finds that in the context of Claim 9, this additional language is redundant of what is already in the claim.

Accordingly, the Court construes the phrase "a generally cylindrical end plug" to mean "an object or material generally having the form or shape of a cylinder used to fill or seal an opening."

C. "Generally Cylindrical Shape"

The parties also offer competing definitions of the term "cylindrical," and of the resultant meaning of the phrase "generally cylindrical." The Court "may… rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents." Vitronics, 90 F.3d at 1584, n.6. Defendant argues that "cylinder" means "a solid body described by the rotation of a parallelogram round one of its sides [such that] the ends of [the body] are equal and parallel circles." (Defendants' Markman Brief at 14) That definition is derived from a non-authoritative dictionary, however, published by Dorset & Baber. At oral argument, defendant did not contest plaintiff's assertion that a respected authority on dictionaries, Kenneth Kister, has dismissed defendant's chosen dictionary as a mediocre, inferior work which is especially shallow on technical terms. (See Appendix to Plaintiff McNeil's Pre-Markman Hearing Responsive Brief at A855 - A857)

Plaintiff cites a definition derived from Webster's Third New International Dictionary (1961), published by Merriam-Webster. Kister states that it is "a great dictionary," and that its "coverage of the vocabulary of modern science is one of the dictionary's most impressive strengths." (App. Pl. Brief at A861) The definition given by Webster's Third New International is "the surface traced by any straight line moving parallel to a fixed line and intersecting a fixed curve." Webster's at 565. Unlike defendant's proffered definition, plaintiff's definition would not limit the term to objects with curving sides and perfectly circular cross-sections; rather, objects under this definition could have rectangular cross-sections, and curved or straight sides that were conjoined at angles. See Markman Hearing on Patent Claim Construction, testimony of Dr. Larry Augsburger, transcript at 85- 86. The Court recognizes the authoritative status of this dictionary, and accepts this definition as the plain, ordinary meaning of the term "cylinder."

Unlike the term "seam," "cylinder" is not given a particular definition or limitation in the specification or the prosecution history. Defendant argues that the specification does not disclose any shape other than an oblong tube with a circular cross-section as being appropriate for the medicament or the retaining mechanism for preparing the medicament. Defendant also draws the Court's attention to the patent drawings depicting an uncoated caplet which is used for the medicaments, and which is described as having a "cylindrical" center portion. See '524 patent, Figures 9 and 10.

The drawings in the patent reveal that a circular cross-section is one possible form for a cylinder, as that term is used in the patent, but neither the drawings nor the specification actually define "cylindrical" in a particular manner, or limit the term to the particular form that is used as an example in the drawings. "Where a specification does not require a limitation, that limitation should not be read from the specification into the claims." Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed.Cir. 1988) (citing Lemelson v. United States, 752 F.2d 1538, 1551-52 (Fed.Cir. 1985)).
At the Markman hearing in this case, defendant also offered, as extrinsic evidence, the testimony of Dr. Banker in support of its definition of "cylindrical." Banker testified that someone of ordinary skill in the pharmaceutical arts would understand the term "cylindrical" to refer to an object that is shaped like a right cylinder, i.e. a tube with a perfectly circular cross-section. Banker testified that such persons would analogize the right cylinders found in a typical pharmaceutical laboratory to the medicament claimed in the '524 patent, and, conforming to their understanding of the "capsule" shape that is being simulated, would therefore believe that the medicament claimed in the '524 patent must have a perfectly or nearly circular cross-section.

The Court may rely on expert testimony in order to come to a proper understanding of the meaning of technical or specialized terms in the claims. See Vitronics, 90 F.3d at 1584. In this case, the word "cylindrical" is not an unambiguous word in everyday speech, but rather a technical term from geometry, and Dr. Banker's testimony is helpful to the Court in understanding what a person of ordinary skill in the art of pharmaceutics would understand the term "cylindrical" to mean. Claim 1 does not disclose a strictly cylindrical shape, however - it discloses a caplet with a "generally cylindrical shape." Unlike "cylindrical," "generally" is not a technical term of art for which the Court must seek the guidance of extrinsic evidence. Defendant argues that, in its ordinary meaning, "generally" means "reproducing the details of the model almost, but not quite, perfectly", so that a medicament with a "generally cylindrical shape" must have a "cylindrical, although perhaps not perfectly circular, cross-section." Defendant argues that any shape which does not have an almost perfectly cross-section cannot be "generally cylindrical" because it is, by definition, "distinctly non-cylindrical."

Defendant's argument places too limited a gloss on the word "generally," which, according to Webster's Third New International Dictionary, means "in a general manner; in a reasonably inclusive manner: in disregard of specific instances and with regard to an overall picture; on the whole." Webster's at 945. "Generally" cannot be limited to mean "almost perfectly," as defendant would have the Court read it.

Dr. Banker suggested in his testimony that, in the context of the '524 patent, the phrase "generally cylindrical" follows defendant's proposed definition and means, in essence, "having a circular cross-section". Markman Hearing, transcript at 153, 165-166. The Court notes that Banker premised this definition on his understanding that a person skilled in the art would read that phrase together with the phrase "simulated capsule-like medicament" and would, therefore, understand that the thing being imitated was a capsule, which Banker took to mean a medicament with a perfectly circular cross-section. Banker appears not to have offered a definition of the phrase "generally cylindrical" in isolation, but rather to have limited it to the implication drawn from another phrase in the claims. 3 The phrase "simulated capsule-like medicament" has its own definition, however, and the word "generally" does not take on a different meaning merely by virtue of appearing in the same claim as a separate phrase describing the same medicament. "Generally" is not defined in the specification or the prosecution history to mean anything other than "generally", and so it does not mean "almost perfectly" - it means "generally," as defined by Webster's.

--- Footnotes ---

3 In other words, Banker seems not to have actually been addressing the specific meaning of the phrase "generally cylindrical" when he was asked about that particular phrase - his answer reflected his view that the phrase was, as he put it, "defined" by, and interchangeable with, the phrase "simulated capsule-like medicament." Markman Hearing, transcript at 153.

--- End Footnotes ---

The Court notes that Banker testified that something which was "generally cylindrical" would have to be "something that, if not 100 percent cylindrical, be very close to a cylinder." Markman hearing, transcript at 153. To the extent that Dr. Banker's testimony would conflict with the broader understanding of the phrase "generally cylindrical", the Court notes that when patent documents are unambiguous, expert testimony regarding the construction of claim terms is entitled to no weight at all, see Vitronics, 90 F.3d at 1584, and that expert testimony "on the proper construction of a disputed claim term... may only be relied upon if the patent documents, taken as a whole, are insufficient to enable the court to construe disputed claim terms. Such instances will rarely, if ever, occur." Id. at 1585. In this case, the term "generally" is unambiguous, and the Court will not give any weight to Banker's contradictory testimony. 4
Moreover, plaintiff presented the testimony of Dr. Augsburger, who stated that in his view, based upon nearly forty years of experience, the phrase "generally cylindrical shape" would be understood by an ordinary person in the field of pharmaceutics to have the broader meaning ascribed by plaintiff. See Markman Hearing, transcript at 82 - 83. Given that the expert testimony is inconsistent, the Court will accept the view that accords with its understanding of the meaning of the modifier "generally."

The Court agrees with defendant that "generally cylindrical" cannot be defined so broadly as to include shapes that are distinctly non-cylindrical, but at the least, shapes which are generally cylindrical must include shapes which are within the plain, ordinary, dictionary definition of the term "cylinder." Even accepting Dr. Banker's definition of the term "cylindrical" to mean a right cylinder for the purposes of the '524 patent, the addition of the modifier "generally" cannot limit the phrase to objects which have almost perfectly circular cross-sections. A generally cylindrical object resembles a cylinder "in a general manner; in disregard of specific[s]… and with regard to the whole picture; on the whole." Plaintiff's proffered definition of "cylinder" would encompass defendant's definition, but would also include objects with elliptical or parabolic cross-sections. These latter shapes would resemble a right cylinder on the whole, in disregard of the specific nature of the curve of the exterior surface of the medicament, and without almost perfectly imitating that curve. In light of Banker's testimony about the proper understanding of the term "cylindrical," therefore, the Court will accept plaintiff's proffered definition of the term "cylinder" as the correct construction of the phrase "generally cylindrical shape" for purpose of Claim 1.

IV. CONCLUSION

The Court concludes that the disputed terms have the following meanings:

1. "Simulated capsule-like medicament" shall mean "a medicinal form that imitates, resembles, or suggests in form or appearance a gelatin shell enclosing medicine."

2. "Partially overlapping said first gelatinous coating and forming a seam" shall mean "extending over and covering part of, but not all of, the first gelatinous coating in a manner such that there is a transition of color and a transition of thickness."

3. "Generally cylindrical shape" shall mean "shape formed by a straight line moving parallel to a fixed line and intersecting a fixed curve."

3. "A Thickness Generally Equal to Circumferentially Adjacent Areas"

a. Construction

Hallmark contends that this limitation should be interpreted to mean that "the thickness of the pleat and the thickness of the adjacent areas of the rim are such that a smooth and unbroken surface is provided. All evidence of the folds or pleats particularly on surfaces without an overcoat should have disappeared." Hallmark argues this construction is required by the need to turn to the specification to define the term "generally."

The proper test in construing a potentially vague limitation is that "if the claims, read in the light of the specification, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir.) (cites omitted), cert. dismissed, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985). As James River argues, the specifications provide both quantitative and qualitative measures to define the phrase "generally equal." These comparisons use physical measurements and photomicrographs of plate cross sections.
The quantitative comparisons examine the thickness of the rim pleats and the thickness of the bottom wall. The '140 patent's Figure 8 shows a cross section of a non-integrated fold, and the specification states the thickness is 0.028 inches. Figure 9 shows a cross section of an integrated fold, and the thickness is 0.017 inches. As the paperboard blank is 0.016 inches, the specification reveals that the invention's fold is 6.25% thicker than the bottom wall, while the prior art fold is 62.5% thicker than the bottom wall. Thus, the specification teaches a quantitative comparison of the thickness of the folds compared to either the blank or the center of the plate. 4

4 There is an assumption that the thickness of the bottom wall is equal to that of the blank. As the bottom wall is not subjected to pressure, and as both measure 0.016", this assumption appears to be valid. Moreover, any error likely to be introduced by this assumption will only work against James River. If the bottom wall is compressed in an accused plate, there all likely be greater variation between the thicknesses of the rim pleats and the bottom wall, thus potentially allowing the accused plate to escape infringement.

The problem with the quantitative comparison taught by the specification is that it does not match the claim limitation. The specification contains no clear measurements of rim areas circumferentially adjacent to the pleats. The only measurements given are the pleat thickness, the blank thickness, and the bottom wall thickness. Moreover, the non-pleat rim areas are subjected to pressure and compressed, so one cannot assume they are equal to the blank areas in thickness.

There is no reason why the rim pleats and the adjacent areas cannot be quantitatively compared. They simply were not in the specification. As the claim language is clear, there is no need to import an additional comparison from the specification. E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir.), cert. denied, 488 U.S. 986, 102 L. Ed. 2d 572, 109 S. Ct. 542 (1988). However, the specification does indicate the usefulness of being able to quantitatively compare the rim pleats. The only question is: how much variation is allowable between the pleats and circumferentially adjacent areas? In the '140 specification, the preferred embodiment had a 6.25% variation between the pleat and the bottom wall, while the prior art had a 82.5% variation. PX-001 at 11-12; James River Response Brief in Opposition at 17. Thus, making allowance for the compression of the circumferentially adjacent areas, a 25% variation between the pleats and the adjacent areas will be considered generally equal. This will still represent a substantial improvement over the prior art.

In addition, the specification teaches a qualitative comparison of rim smoothness, which will ensure James River's invention is limited to its claim. The '140 specification teaches a comparison between the paperboard surfaces of the prior art and the invention's preferred embodiment. As the specification states, the invention plate shown in Fig. 9 has an "essentially smooth and continuous" surface at both the top and bottom of the pleat, while the prior art plate in Fig. 6 has "discontinuity of surfaces. PX-1. Co. 12, lines 57-85. Admittedly, once again, the claim language refers to the equality between rim pleats and adjacent areas, while the specification compares the rim pleats to the prior art plates, instead of the invention's adjacent areas. Here, however, the smoothness of the rim pleats extends into the beginning of the adjacent areas, so that the entire rim area is smooth.

These comparisons allow a claim interpretation in accord with the limitation's natural language. The physical measurements verify that thicknesses along the rim are similar, and the qualitative comparisons verify that the pleat surfaces are smooth and that there is a smooth transition to the adjacent areas. Both of these comparisons must indicate that the claim limitation reads on the accused plates to show infringement.

(a) Claim One, Clause Two

Claim 1, clause 2 reads as follows: "A generally flat rectangular housing containing operating electronics and an array of calculator actuating buttons[]." The phrase "generally flat" is in dispute.

(1) Indefiniteness
SCM claims that the term "generally" is too ambiguous, and therefore the patent fails for indefiniteness. A patent is presumed valid. 35 U.S.C. § 282. A party attempting to invalidate a patent for indefiniteness must do so by clear and convincing evidence. Al-Site Corp. v. VSI Int'l Inc., 174 F.3d 1308, 1323 (Fed. Cir. 1999).

The Patent Act requires that the "specification shall conclude with one or more claims particularly pointing out and distinctly claiming subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2. This requirement places future inventors on notice concerning the scope of the patent. Rengo Co. v. Molins Mach. Co., 657 F.2d 535, 551 (3d Cir. 1981). Whether a patent is invalid because it is indefinite is an issue of law. Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1376 (Fed. Cir. 2001) ("We adhere to the principle that determination of claim indefiniteness is a legal conclusion that is drawn from the court's performance of its duty as the construer of patent claims.")

A patent is sufficiently definite "[i]f one skilled in the art would understand the bounds of the claim when read in light of the specification...." Exxon Research & Engineering Co., 265 F.3d at 1375 (citation omitted). A patent is not indefinite "merely because it poses a difficult issue of claim construction." Id. The amount of necessary detail depends upon the invention and the prior art. Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir. 1985).

While the Federal Circuit has not specifically addressed whether the term "generally" is too indefinite to maintain the validity of a patent, courts have discussed the viability of words connoting approximations and have often found them sufficiently definite. For example, the use of the term "substantially" does not necessarily render a claim indefinite because the term and others like it are "ubiquitous" in patent claims. Andrew Corp. v. Gabriel Elec., Inc., 847 F.2d 819, 821 (Fed. Cir. 1988); see also Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001) ("We note that like the term 'about,' the term 'substantially' is a descriptive term commonly used in patent claims to avoid a strict numerical boundary to the specified parameter.") (quotation omitted). But see Amgen Inc. v. Chugai Pharm. Co., 927 F.2d 1200, 1218 (Fed. Cir. 1991) (finding the use of the word "about" in the claim was too indefinite, but noting it was not a per se rule).

SCM has not shown by clear and convincing evidence that the term "generally" as used in Claim 1 is too indefinite for "one skilled in' the art." We conclude that SCM has not met its burden to invalidate the '085 patent on indefiniteness grounds.

(2) Construction of Disputed Term

CCL contends that the ordinary and customary meaning of "generally flat" is something that need not be perfectly flat. SCM proposes that we construe this term to mean "at least as flat as a Prod Art Co. calculator model No. SC-82." This proposed construction is derived from a statement the inventor of the '085 patent made when he was questioned about this disputed term with reference to another calculator.

We conclude that the term "generally" is sufficiently clear given its ordinary meaning. Webster's Third International Dictionary defines generally to mean "on the whole." It is also defined as "in a general manner." In turn, "general" is defined as "marked by broad overall character without being limited, modified or checked by narrow precise considerations." Id. Thus, in the context of this claim, generally flat means "housing that is flat on the whole."

Additionally, while the claims and specifications do not explicitly provide a definition of "generally flat," in light of the function of the invention, certain limitations are at least implied and would be known to one skilled in the art. The invention has a "generally flat" housing, but it also contains a lid structure that has a "flat cover." Claim 1(b). That "flat cover" must pivot rearwardly to form a stand, which supports the calculator in a tilted position. Claim 1(e). If the housing is not flat as a whole, it would inhibit the functioning of the invention because the flat cover could not properly cover the display and subsequently pivot to form a stand. Thus, the claims and the function of the invention help to define this disputed term.

The specifications also support this construction of the disputed term. They provide that the lid structure is supposed to protectively cover the display panel. Col. 2: 28-29; Col 2: 61-65. As explained above, if the front housing is too curved, the flat cover would not properly protect the display panel. The specifications also indicate that after the lid rotates backwards, it is in essentially a perpendicular orientation and forms a stand to support the calculator on a horizontal surface. Col. 2:34-38. If the housing is not "generally flat," (flat as a whole), but is more rounded, the calculator, even with the stand, may be unsteady when used on a horizontal surface.
Accordingly, we construe the term "generally flat" to mean a housing that is flat on the whole, but not necessarily exactly or perfectly flat.

Applying the above standards, the Court observes that the plain language of the claim calls for a "generally flat aft keel." The term "flat" is generally understood to mean horizontal. See Spaulding v. Guardian Light Company, 170 F. Supp. 679 (N.D. Ill. 1958); Illinois Tool Works, Inc. v. The Rawlplug Co., Inc., 1991 U.S. Dist. LEXIS 11035, 21 U.S.P.Q.2D (BNA) 2036 (N.D. Ill. 1991) (rejecting infringement claim—finding accused drill tip cannot be considered "generally flat" in that it had eight separate surfaces). While the term "generally flat" is imprecise, the term "generally," modifies the term "flat" context, means "mostly." 1 Thus, the Court construes the plain language of the claim to call for an aft keel that is mostly horizontal.

This interpretation is consistent with the drawings and specifications of the '202 Patent. The Summary of the Invention section of the Patent states, inter alia: "A further object [of the present invention] is to provide a broad flat keel having a width of about ten percent of the boat's beam" (Doc. No. 1, Ex. A., column 2, lines 33-34). The drawings depict a flat keel (See Figure 2a of the Patent, as described in Column 2, lines 60-64). And, although the specifications do mention a "substantially flat or concaved keel portion" (Column 4, Line 24) [emphasis added], this is not inconsistent with a keel that is mostly horizontal. "Concave," as defined in The American Heritage Dictionary, means "curved, like the inner surface of a sphere." Thus, a "slightly concave" aft keel (claim 10) to be generally flat, that is, mostly horizontal, but slightly curved.

Defendants argue that the Court should also consider the prosecution history of the patent, and Plaintiff makes certain representations based on a purported reissue application. Neither side, however, has properly presented these documents to the Court. Defendants attach as an exhibit to their brief unauthenticated copies of documents which they argue represent the prosecution history of the Patent. Such fugitive documents are not identified or supported by any affidavit, attesting to their authenticity. Worse yet, Plaintiff quotes extensively from a Notice of Allowance purportedly issued by the Patent Office, a copy of which is apparently not even in the record. (The Court was unable to locate the document referred to and no record citation was provided.) (See Doc. No. 48, p. 12, fn 6). Assuming, however, that both Plaintiff and Defendants representations of the prosecution history are true, it does not alter the result reached by the Court.

The principal question in this case is whether the term "generally flat aft keel," properly construed, encompasses a twelve degree V-shaped aft keel such as the one found in Regal's FasTrac hull design. The district court construed "generally flat" to mean "mostly horizontal." Schoell argued that, although deeper V-shapes may not be flat, a twelve degree V-shape was sufficiently shallow to be "generally flat." Rejecting Schoell's position, the court noted that Schoell's written description distinguished between flat-bottomed hulls and V-shaped hulls. The court concluded that, although "generally flat" need not mean "dead flat," a V-shaped keel could not be considered "generally flat" in light of the distinctions made by Schoell.
On appeal to this court, Schoell argues that the trial court erred by interpreting the term "generally flat" too narrowly. Schoell contends that the trial court did not recognize that the claim language, written description, and prosecution history show that "generally flat" embraces configurations that are not perfectly flat. Schoell further argues that Regal has admitted, in a sales training videotape referring to the aft keel as "flatter" than the adjacent planing portions, that "flat" is a relative, not absolute, term.

Contrary to Schoell's contentions on appeal, the trial court's interpretation of "generally flat" was not limited to completely flat surfaces. As the trial court recognized, the word "generally" modifies "flat" and, in this context, means "mostly." This definition is supported by the written description, which in one instance describes the aft keel as "substantially flat or concaved." The trial court acknowledged that a "slightly concave" aft keel, as claimed in dependent claim 10, is not completely flat and is within the scope of the independent claims requiring a "generally flat" aft keel.

The trial court also interpreted "flat" to mean "horizontal." Although that interpretation might not apply in some cases, since, for example, a vertical surface may be flat but not horizontal, we think it is understood that flat and horizontal are synonymous as applied to the keel of a boat in an upright, stationary position. Also, the court's reference to other reported decisions construing the term "flat" in other contexts is at most harmless error since the court relied on the ordinary meaning and not on any special meaning given to the term in the patents at issue in those cases. In any event, we find the phrase "mostly horizontal" to provide little more guidance than "generally flat" in determining whether a twelve degree V-shaped keel is within the scope of the claims. Thus, we must look further into the record to resolve that question.

Throughout the claims, written description, and prosecution history of the '202 patent, Schoell distinguished between V-shaped keels and generally or substantially flat keels. In describing his boat hull in the written description portion of the patent, Schoell carefully differentiated between the V-shape of the forward keel and the substantially flat surface area of the aft keel. In the claims of the '202 patent, Schoell required a V-shaped forward keel and a generally flat aft keel. Furthermore, during prosecution of his application, Schoell responded to the examiner's rejection of his initially filed claims as obvious over an earlier Schoell patent, U.S. Patent No. 4,193,370 (the "'370 patent"), asserting that "Schoell shows no stepped offset and shows no generally flat aft keel." Joint App. at 339. The '370 patent, however, describes a V-shaped aft keel with a dead rise angle between twelve and eighteen degrees. Thus, not only did Schoell differentiate between a V-shaped keel and a generally flat keel, he essentially conceded that a twelve degree V-shaped keel cannot be a generally flat keel as claimed in the '202 patent.

For our purposes, we need not decide whether a shallow V-shaped keel can meet the "generally flat" claim limitation, or, if so, how shallow it must be. Regal's aft keel has a twelve degree dead rise V-shape, but a portion of its forward keel also has a twelve degree V-shape. Because Schoell so clearly distinguished between the two keel shapes, a twelve degree V-shape cannot be both V-shaped and generally flat. If Regal's forward keel satisfies the "V-shaped forward keel" limitation, Regal's aft keel cannot satisfy the "generally flat aft keel" limitation. Conversely, if Regal's aft keel satisfies Schoell's aft keel limitation, Regal's forward keel cannot satisfy Schoell's forward keel limitation. Thus, it is impossible for Regal's FasTrac hull to literally infringe the claims of the '202 patent.

Schoell's response to this conclusion is that the claims do not require the forward keel to be V-shaped the entire length from the bow to the stepped offset. According to Schoell, Regal's twelve degree V-shaped aft keel can satisfy the "generally flat" limitation, and the portion of the forward keel with a deeper V-shape, the portion closest to the bow, can satisfy the "V-shaped" limitation. The claim language itself belies this theory. Claim 1 unequivocally requires a "forward hull including . . . a V-shaped keel extending from the bow to the stepped offset." The language of claim 17--"the forward hull including an arcuate bow . . . and a V-shaped forward keel trailing therefrom"--is not as explicit, but the application of the adjective "V-shaped" to the forward keel rather than to a portion of the forward keel suggests that the entire forward keel must be V-shaped.

Schoell finally argues in his reply brief that, because Figure 2a of the '202 patent depicts a forward hull similar to Regal's with a V-shape that is deeper at the bow and flattens as it approaches the step, Regal's forward hull must meet the V-shaped claim limitation. This argument, however, ignores the clear distinction between the V-shape of the forward keel and the flat surface of the aft keel in the '202 patent. Regal does not dispute that its forward keel is V-shaped, but Schoell overlooks the other half of Regal's position--if Regal's forward keel is V-shaped, its aft keel cannot be generally flat.
Lastly, we find no merit in Schoell's argument that "flat" is a relative term and that an aft keel that is flatter than the adjacent hull sections qualifies as "generally flat." The genesis of Schoell's argument is a sales training videotape produced by Regal that describes the allegedly infringing Regal hull:

As you can notice, we [have] got the 24 degree dead rise here at the bottom of the hull and more notably right at the keel we've a little flatter sectional surface. That is the step-pad. It's approximately again 12 degrees [and] it provides for lift as the boat wants to come out of the water and at the same time giving stability at high end speeds.

Joint App. at 670 (emphasis added). Nothing in the '202 patent or its prosecution history, however, indicates that "generally flat" is to be measured relative to adjoining areas. It is undisputed that Regal's aft keel is flatter than the adjacent planing portions of the hull, but by no means does this lead to the conclusion that Regal's aft keel is "generally flat" within the meaning of the claims.

For the above reasons, we affirm the district court's grant of Regal's motion for summary judgment with respect to literal infringement.

1849

4. Claim 1, 22, 24, 26--"generally flush with the exterior"

Claim 1 is representative of this term in context and states:

carrier means for supporting a light, a control, an instrument or the like within said interior space, said carrier means including a rigid support and mounting means for mounting said support within said opening such that said support is generally flush with the exterior of said bottom wall portion.

The Special Master recommends construing the term "generally flush with the exterior" to mean that the parts are flush, when assembled, within the normal tolerances accorded such parts in the field of the invention, and are flush, as a rule, in ordinary practice. Thus, two parts are not "generally flush" if the parts, as a rule, in ordinary practice, are not flush within normal tolerances accorded such parts in the field of the invention, when assembled. Plaintiff contends that the Special Master defined "generally" improperly by focusing on frequency or occurrence, rather than mechanical structure. Rather, Plaintiff argues use of the word generally limits the term "flush" by describing the degree of flushness and concluding otherwise ignores inclusion of the word "generally."

It is apparent that inclusion of the word "generally" indicates something other than perfectly or precisely flush. The specification states that the "overall styling and appearance of the rearview mirror case assembly is significantly improved by the integration of the carrier modules such that they are mounted generally flush with the bottom wall of the case and are essentially hidden from view when the mirror is viewed from the normal driving position." '336 patent, col. 3, lines 26-31. Plaintiff suggests that "generally flush" references the part of the specification which states that the carrier module is "essentially hidden from view when the mirror is viewed from the normal driving position." This construction, however, does not explain what generally flush means if not precisely flush, and conflates two separate criteria for the carrier module. The carrier module could be generally flush and not essentially hidden or vice versa; therefore, these two elements need to be read as separate limitations and not one as a further explanation of the other.

One possible definition for 'generally' is mostly, but that does not make sense in this case. Schoell v. Regal Marine Ind., Inc., 247 F.2d 1202, 1207 (Fed. Cir. 2001). Something cannot be mostly flush, as in substantially, largely, but not wholly flush. That would require at least part of the mechanism to be precisely flush which contradicts the language of the claim.

Since generally is not a scientific term and has not been given any meaning in the claim or specification, the Court may rely on a standard dictionary for guidance as to its meaning. Wenger Mfg., Inc. v. Coating Machinery Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001) (using Webster's New World Dictionary to define term "circulate"). "A dictionary is not prohibited extrinsic evidence, and is an available resource of claim construction. Although a dictionary definition may not enlarge the scope of a term when the specification and the prosecution history show that the inventor, or recognized usage in the field of the invention, have given the term a limited or specialized meaning, a dictionary is often useful to aid the court in
determining the correct meaning to be ascribed to a term as it was used." Vanguard Products Corp., 234 F.3d at 1372 (internal citations omitted) (finding no error in district court's reliance on dictionary to define "integral"). The Court, therefore, finds "generally" means, "1. popularly; widely; 2.a. as a rule; usually; b. for the most part; 3. without reference to particular instances or details; not specifically." AMERICAN HERITAGE DICTIONARY 755 (3rd ed. 1996). The definition for "usual" is, "1. commonly encountered, experienced, or observed; 2. regularly or customarily used; 3. in conformity with regular practice or procedure; habitually happens." Id. at 1967. Synonyms for usual include habitual and customary. Id.

Use of the term flush alone would allow for normally recognized tolerances since nothing in the specification requires a precise fit for the mirror assembly. However, the word "generally" cannot be ignored. Use of the word "generally" does not refer to degree of flushness beyond what is within regular practice in the field. "Generally" indicates that the support is flush as judged by regular practice. Therefore, the carrier module is "generally flush" if when assembled it is flush within normal tolerances in the field and is flush as a rule, in conformity with regular practice.

II. "Generally Frustoconically Shaped Pylon"

The key disagreement between the parties is whether a "generally frustoconically shaped pylon" can have a shape other than that of a right circular cone that has had the top part cut off. 4 The Defendants contend that it cannot. The Plaintiff asserts that the pylon can have a base in the shape of any closed plane, such as a circle, rectangle, hexagon, cruciform, oval, or an irregularly shaped closed plane.

Beginning with the claims themselves, the Court notes that the phrase at issue consists of two adverbs ("generally" and "frustoconically") and one adjective ("shaped"), all of which modify the noun "pylon." The language of the claims, quoted above, does not define these terms either individually or collectively. As determined above, the Court must construe this term through the eyes of an individual having a high school education.

The main difficulty presented by the phrase "a generally frustoconically shaped pylon" is that the ordinary meanings of the noun "pylon" do not fit neatly into the claimed invention, a floating dock. EZ Dock argued that "looking up a word in a dictionary should be straightforward," (EZ Dock Reply Brief at 3), and provided definitions from Webster's Third New International Dictionary of the English Language for several words or word roots used in the phrase in question. Significantly, however, EZ Dock did not include that dictionary's definition for "pylon," and in fact provided no definition for "pylon." Webster's Third New International Dictionary defines it as follows:

1 a: a usually massive gateway often with flanking towers--compare PROPYLN b: an ancient Egyptian gateway building having a truncated pyramidal form; broadly: two such truncated pyramids with a gateway between c: a monumental mass placed so as to flank an entranceway (as an approach to a bridge 2: a tower (as of steelwork) for supporting either end of a wire (as for a telegraph line) over a long span 3 a: a post, tower, or other projection marking a prescribed course of flight for an airplane b: a structure for supporting the propeller on the side of a rigid airship or for attaching an auxiliary fuel tank, a bomb, or other external stores carried by an airplane.

From the foregoing, it is evident that the ordinary meanings of the term "pylon" do not make sense in the context of a floating dock. 5 The Court therefore turns to the specification and prosecution history for assistance in determining what the patentee meant by the term "pylon."
5 Inserting one of the several alternate definitions of "pylon" into Independent Claim 8 of the '055 patent produces the following results:

A floating dock, comprising:

   a docking member with top, bottom and side surfaces defining a hollow cavity and a generally frustoconically shaped
   massive gateway, often with flanking towers within the cavity extending from the top surface to the bottom surface.

A floating dock, comprising:

   a docking member with top, bottom and side surfaces defining a hollow cavity and a generally frustoconically shaped
   ancient Egyptian gateway building having a truncated pyramidal form within the cavity extending from the top surface to
   the bottom surface.

A floating dock, comprising:

   a docking member with top, bottom and side surfaces defining a hollow cavity and a generally frustoconically shaped
   monumental mass placed so as to flank an entranceway within the cavity extending from the top surface to the bottom
   surface.

A floating dock, comprising:

   a docking member with top, bottom and side surfaces defining a hollow cavity and a generally frustoconically shaped
   tower (as of steelwork) for supporting either end of a wire (as for a telegraph line) over a long span within the cavity
   extending from the top surface to the bottom surface.

A floating dock, comprising:

   a docking member with top, bottom and side surfaces defining a hollow cavity and a generally frustoconically shaped
   post, tower, or other projection marking a prescribed course of flight for an airplane within the cavity extending from the top
   surface to the bottom surface.

"Claims must be read in view of the specification, of which they are a part." Markman, 52 F.3d at 979. The specification
may show that the patent "uses the words in a manner clearly inconsistent with the ordinary meaning reflected, for example,
in a dictionary definition. In such a case, the inconsistent dictionary definition must be rejected." Texas Digital Sys., Inc. v.
Telegenix, Inc., 308 F.3d 1193, 1204 (Fed. Cir. 2002). An inventor may act as his own lexicographer and use the
specification to supply new meanings for terms, either explicitly or implicitly. Electro Scientific Indus., Inc. v. Dynamic
Details, Inc., 307 F.3d 1343, 1347 (Fed. Cir. 2002). When construing claims, however, a court must not add limitations that

Here, the inventors did not explicitly act as lexicographers in their specification by defining the phrase "generally
frustoconically shaped pylon" or any of its component parts. The specification's discussion of "pylons" is the following:

Each docking member 12 is desirably generally hollow. The thickness of the wall of the docking member 12 can vary
with need but should desirably be in the range of 0.19 to 0.63 inches, with a wall thickness of approximately 0.25 inches
being preferred. Within the hollow cavity of the docking member 12, elongate struts stretch from the bottom surface to the
top surface. These struts provide additional structural support for the docking member 12 as well as prevent sagging of the
deck when pressure is applied (as when a person walks upon the deck).

The struts can be of any suitable formation. In the preferred embodiment, portions of the bottom surface extent upwardly
into the interior of the docking member 12 towards the top surface to form a series of tapered generally frustoconically
shaped pylons 30. The struts desirably include pylons with an arcuate top connected by slightly taller and wider pylons. In the preferred embodiment, two generally parallel strips of pylons run along the length of the bottom surface of the docking member 12. When the docking member 12 is positioned on the water, air is trapped within the pylons 30, thereby allowing the docking member 12 to remain afloat in the event that it becomes damaged and water begins to enter the cavity. (Mitchell Aff. Ex. 1 (‘055 patent) at col. 3 ll. 3-27 (emphasis added).)

Thus, implicitly, a "generally frustoconically shaped pylon" is a form of strut, a structure intended to provide support within the hollow cavity of the docking member. 7

6 Nothing in the PTO's August 2001 Re-examination Certificate modifies these paragraphs.

7 The patent also includes two figures - Figures 2 and 3 - that pertain to the "pylons" labeled in the specification as element 30.

The prosecution history of the '055 patent is the next category of relevant intrinsic evidence. A patent's prosecution history also provides relevant information about the scope and meaning of claim terms. Markman, 52 F.3d at 980. Arguments and amendments made during the prosecution of the patent application, and other aspects of the prosecution history, are relevant in determining the meaning of terms in the claims. See Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). The definition for a disputed claim term might appear in the prosecution history. See Honeywell, Inc. v. Victor Co. of Japan, Ltd., 298 F.3d 1317, 1323 (Fed. Cir. 2002) (observing that it is well settled that an inventor may define a claim term in the prosecution history).

EZ Dock cites to a May 11, 1993 Amendment submitted to the PTO in support of its argument that the applicants defined "pylon" to mean "conical." The Amendment indicated that the applicants had "amended page 6 of the specification to state that the pylons formed by the docking members are generally frustoconically shaped." (Mitchell Aff. Ex. 10 at 3.) The Amendment also stated, "Webster's New Collegiate Dictionary, Copyright 1979 by G. & C. Merriam Co., defines a pylon as a structure that is 'conical.'" 8 (Id.) The Amendment concluded with the assertion that, therefore, the words "generally frustoconically shaped," added to page 6 of the specification "are equivalent to the word they are describing in the specification [i.e., pylon] . . . and do not represent new matter." The PTO allowed this amendment.

8 In point of fact, no such definition appears in that edition of Webster's New Collegiate Dictionary. The only definition for "pylon" in that edition which contains the word "conical" states that a "pylon" can mean "a conical marker used on a road (as for directing traffic)."

From the foregoing, the Court determines that the inventors defined the term "pylon" to mean "a structure that is 'conical.'" To construe the phrase at issue, therefore, it must determine what an individual who has completed high school would understand "a structure that is 'conical'" to be. The Defendants argue that a conical structure must be shaped like a right circular cone and must have a circular base. Placing it in the parlance of teenagers, the Defendants contend that the pylon in question must look like an icecream cone. 9

9 The Defendants argue, with no supporting evidence, that a "typical high school educated person would not think of a shape with a noncircular base as a cone." Noting that a pyramid has a noncircular base, the Defendants go on to argue, again without a supporting factual basis, that "[a] typical high school educated person would not think of a pyramid as a cone." The Court rejects this line of argument as speculative.
When one compares that argument to the '055 patent, however, problems arise. The specification refers to a preferred embodiment having strips of pylons, and Figure 2 of the patent shows two parallel strips of openings on the bottom surface of a docking member. Each strip consists of a pattern of alternating rectangular openings and oblong openings. The drawings of a patent are relevant intrinsic evidence that the Court may consider in construing claims. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324 (Fed. Cir. 2002). The Defendants offer no compelling explanation as to what those strips shown in Figure 2 represent if not the strips of pylons discussed in the specification, as seen from the bottom. Viewing the patent as a whole, it is evident that the '055 patent contemplates "pylons" which have something other than perfectly round bases.

"A claim construction that excludes from its scope a preferred embodiment 'is rarely, if ever, correct and would require highly persuasive evidentiary support." Bowers v. Baystate Techs., Inc., 302 F.3d 1334, 1345 (Fed. Cir. 2002) (quoting Vitronics, 90 F.3d at 1583). The Defendants contend that EZ Dock's proposed construction of a "pylon" as a "conical" structure having a base in the shape of any closed plane (not just a circle) would encompass Heinrich's flange, found in the prior art in United States Patent No. 4,365,577. The Court has carefully reviewed the Heinrich patent and finds the Defendants' arguments to be unpersuasive. The Defendants have not presented the "highly persuasive evidentiary support" necessary to warrant their narrow proposed interpretation of the phrase at issue.

The Court concludes that, in the context of the '055 patent, a "pylon" is a conical structure; that is, it is a structure having a closed plane base and a surface formed by line segments joining every point of the boundary of the base to a common vertex. Having determined what a pylon is, the Court turns to the modifying adjective and adverbs, "generally frustoconically shaped."

EZ Dock argues that the presence of the term "generally" in the phrase "generally frustoconically shaped pylon" means that "the shape of the pylon of the floating dock is not specifically, totally, or only frustoconical in shape." (EZ Dock Initial Markman Brief at 13 (emphasis in original).) According to EZ Dock, the pylon may have some characteristics of a frustoconical shape, but also have other characteristics which are not frustoconical. "Frustoconical" means "of the shape of a frustrum of a cone." In the context of a cone, a "frustrum" is ordinarily "the part of a solid . . . between two parallel planes cutting the solid, especially the section between the base and a plane parallel to the base," American Heritage Dictionary of the English Language (4th ed. 2000), or "the basal part of a solid cone . . . formed by cutting off the top by a plane parallel to the base," Merriam Webster's Collegiate Dictionary (10th ed. 2002). The top of a frustrum, therefore, is ordinarily parallel to its base and is flat.

The specification and Figure 3 from the '055 patent provide some insight into what a "generally frustoconically shaped pylon" includes. The specification indicates that it is desirable for the pylons to have an arcuate top; i.e., a top that is "curved like a bow," Merriam Webster's Collegiate Dictionary (10th ed. 2002), or "having the form of a bow; curved," American Heritage Dictionary of the English Language (4th ed. 2000). The arcuate top is illustrated in Figure 3. Upon consideration of the intrinsic evidence and Federal Circuit cases construing the term "generally," the Court concludes that a "generally frustoconically shaped pylon" is a structure that, for the most part, is in the shape of the frustrum of a solid having (1) a closed plane base and (2) a surface formed by line segments joining every point of the boundary of the base to a common vertex.

3. "Said end portion is formed into a generally hemispherical shape." Consistent with the claim language and its ordinary meaning, 14 and the specification, 15 the Court construes "said end portion is formed into a generally hemispherical shape" to mean that "the tubular body ends are formed, for the most part, by spherical segments."
Ethicon contends that the phrase "generally hexagonal" means a staple pocket with "six major faces," similar to those shown in Figures 1, 2 or 3 of the patent. U.S. Surgical contends that the inventor's lexicography establishes that "generally hexagonal" means "octagonal." U.S. Surgical also contends that the claim term includes a limitation on both the shape (octagon) and the length of the parallel sides (conforming to the staple size).

Ethicon argues that "generally hexagonal" as used in the claim does not mean a mathematically precise hexagon. Ethicon notes that the patent labels the prior art staple pockets as "generally rectangular" (Col. 1, lines 32-33), even though they are illustrated as having more than four sides (see Figures 2-a and 3-a). The patent improvement of adding the four tapered sides resulted in a pocket shape described as "generally hexagonal" because there are six major sides easily seen. The two smaller parallel sides are very tiny (as wide as a human hair, as long as .011 inches). The viewer thus perceives a "generally hexagonal" shape. (The Patent Examiner's reasons for allowance of the claims concludes that "the prior art does not disclose a pocket having a hexagonal shape as claimed" which also lends some support to Ethicon's argument. See Doc. 52, Exhibit 2, File Wrapper for the '823 Patent, at p. 20.)

U.S. Surgical responds that the specification and all figures clearly describe an octagon. The patent's claimed improvement avoids the close tolerances of the prior art end pockets, as illustrated in Figures 2-a and 3-a. Those prior art pockets actually had 12 sides, and so were not "rectangular" as described in the patent. U.S. Surgical posits that to accept Ethicon's definition would result in an unbounded claim: a pocket could have many more than six sides and still be "generally" hexagonal, and infringe the patent.
reconcile this contradiction is to construe the drafter's use of "hexagon" to mean "octagon."

U.S. Surgical's argument contravenes two basic claim construction principles. First, as noted above, the Court may not limit construction of a claim term to the preferred embodiment or the specification, absent express language so limiting the claim. There is nothing in the specification expressly limiting the invention to an eight-sided pocket. Second, U.S. Surgical's proposal fails to explain the drafter's use of "rectangular" and "generally rectangular" to describe prior art staple pockets that are clearly not four-sided rectangles. This phrasing supports Ethicon's proposed construction, that it is the "major" faces of the pocket that are being described in the phrases "generally rectangular" and "generally hexagonal."

As to the question of the length of the parallel sides: Ethicon rejects U.S. Surgical's construction requiring the parallel sides to approximate the length and width of the unformed staple. The prior art descriptions in both the specification (Col. 1, lines 26-31) and the preamble of Claim 1 (Col. 4, lines 3-8) describe the two sets of parallel sides as conforming to the size of the staple. Ethicon argues that adding the tapered sides necessarily modifies the relationship between the size of the staple and the size of the parallel sides. Ethicon also notes that U.S. Surgical's construction would exclude the preferred embodiment, which explicitly states: "Of course, the length of the first parallel sides and tapered sides may have any dimension required to fit the surgical staple." (Col. 3, lines 18-20.)

U.S. Surgical responds that a Jepson claim preamble acts as a claim limitation unless expressly modified by terms describing the improvement. Claim 1's preamble limits the length of the first parallel sides ("generally corresponding to the length of said unformed staples"). There is nothing in the improvement language stating that the length of those parallel sides would change, only that the tapered sides are added.

U.S. Surgical's proposed construction is unduly restrictive. It is true that the body of Claim 1 describing the improvement of tapered sides does not expressly modify the length of the first parallel sides after the tapered sides are added to the pocket. But the specification and the Figures clearly show that the staple is generally longer than the first parallel side. Indeed, that appears to be the essence of the "self-guiding feature" of the invention. Moreover, U.S. Surgical's construction would directly contradict the explicit description of the preferred embodiment, which is rarely if ever a proper construction of a claim.

The Court therefore construes the term "a generally hexagonal shape" to mean that the staple pocket is perceived by a viewer to have six major sides that can have varying lengths. This construction does not imply that "major" has any functional meaning, but is limited to a visual perception of the pocket's general shape.

1. "Spatially aligned so as to be generally in phase with one another."

Consistent with the claim language and its ordinary meaning 11 and the specification, 12 the court construes this limitation to mean "the bands generally undulate at the same rate, so as to run parallel to each other."

End Footnotes

11 D.I. 230, Ex. 41 (defining "align" as "to arrange in a line or so as to be parallel"); D.I. 280, Ex. 10 (defining "in phase" as "in a synchronized or correlated manner").

12 '406 patent, col. 4, ll. 10-15.
The parties submit two varying constructions of this claim language. Alltrade asserts that this claim language teaches an elliptical shank. Alltrade contends that "oblong" means "something deviating from a square or circular form through elongation." Such a shape includes an ellipse, but also includes other elongated shapes deviating from a square, such as a rectangle. Alltrade further asserts that the ordinary meaning given to "major axis" according to Webster's Dictionary is "the axis passing through the foci of an ellipse." Opposition, Ex. F. Webster's similarly defines "minor axis" as "the chord of an ellipse passing through the center perpendicular to the major axis." Id. Therefore, Alltrade's construction would interpret this claim limitation as requiring an elliptical cross-section.

Olympia's proposed construction is broader. Olympia asserts that a "major axis" may exist in several shapes that are not elliptical. Reply, at 6. As an example, Olympia argues that an "egg-shape" might have a major and minor axis, but is not elliptical. Olympia's construction requires that the cross-section define orthogonal major and minor axes and that "at least one convex arcuate surface is provided on edge(s) of the shank along the major axis to enable comfortable gripping of the shank while enabling application of significant pulling forces on the shank without resulting pain, discomfort or injury to the hand of the user." Motion, at 10. Therefore, Olympia's construction includes an elliptical cross-section, as well as many other possible rounded-corner cross-sections. Reply, at 7. At oral argument Olympia also asserted that "oblong" required the cross-section to have a "stretchable" appearance. Olympia also asserted that any "stretchable" cross-section having a major and minor axis would be oblong for the purposes of this claim. The Court notes that under this construction, the word "oblong" is without meaning. A cross-section with a major and minor axis encompasses all non-symmetrical cross shapes such as a circle or hexagonal cross-section. If that construction is given to major and minor axis, the word oblong does not have meaning. In this Claim language, major and minor axis modify the term "generally oblong" and that term must be given meaning under claim construction principles.

In construing this Claim, the Court finds the Claim language at issue unambiguous. The Court finds that Alltrade's construction is consistent with the intrinsic evidence as well as the ordinary meaning of the terms "generally oblong," as well as the mathematical terms major and minor axis. The Court therefore holds that the cross-section taught by Claim 19 is elliptical.

2 The Court notes that the parties submitted the declarations of J. Michael McCarthy and Ralph Engdahl in support of their respective claim constructions. The Court did not rely on expert testimony to interpret the patent claims as the Court finds that the claims are unambiguous in the light of the intrinsic evidence. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576 (Fed. Cir. 1996). At oral argument, Olympia asserted that the Court may have improperly relied on the proposed claim construction of its expert and therefore improperly relied on extrinsic evidence. The claim construction principle guiding courts to rely on intrinsic evidence certainly does not prohibit reading the parties’ proposed constructions and argument directing the Court to intrinsic evidence supporting that construction.

The disputed phrase "generally oblong cross section" must be read in the context of the entire claim as part of "an elongate shank having a generally oblong cross section … said shank having a major axis within said common plane greater than a minor axis along a direction transverse to said common plane." Id. at col. 8, ll. 37-38, 48-50. Simplified, this means that the cross section of the shank is "generally oblong" with a major axis in the plane of the hook, shank, and chisel, and a minor axis transverse or perpendicular to that plane. "Generally" is understood to mean "in a general manner" or "in disregard of specific instances and with regard to an overall picture" or "on the whole." Webster's Third New International Dictionary 945 (3d. ed 1993). "Oblong" is understood to mean "deviating from a square or circular form through elongation." Id. at 1557. "Generally oblong" is therefore a shape that is longer in one direction than the other, but not necessarily true to a specific geometrical shape, i.e., not a perfect oval or rectangle.
The district court interpreted the phrase in conjunction with the terms "major axis" and "minor axis," as used in the particular geometrical shape of an ellipse. When defined in reference to an ellipse, a "major axis" is "the axis passing through the foci of an ellipse," id. at 1363, and a "minor axis" is "the chord of an ellipse passing through the center perpendicular to the major axis," id. at 1440. We do not think this strict geometrical meaning should be assigned to the claims. The terms "major axis" and "minor axis" in the claim serve to orient the "generally oblong" shape with respect to the common plane of the hook, shank, and chisel. In the claim, "major axis" and "minor axis" are simply used to refer to the dimensions of the shape where a "major axis" is the longer dimensional cross section and the "minor axis" is the shorter dimensional cross section. The terms are used this way in the specification, which for example, refers to the minor axis as the "smaller of the dimensional cross sections." ‘553 patent, col. 4, ll. 43-44. The terms are used to denote the relative dimensions of the orthogonal cross sections.

Interestingly, the terms "ellipse" and "elliptical" do not appear in the patent claims or specification. "Oblong" appears in the specification only once when the patentee states that "by providing an oblong or oval cross sectional dimension for the shank, as opposed to a sheet of flat metal or hex cross section shank, the user can apply significantly greater forces to the shank without incurring discomfort or pain, or possible injury." '553 patent, col. 6, ll. 27-32. Because the patentee requires an arcuate surface on the edge of the shank along the major axis to provide the comfortable grip described in the patent, a rectangular shaped cross section, like that of a flat bar, is not included in claim 19. The cross sectional shapes covered by the claim could be similar to ovals or rounded rectangles, or other geometrical shapes that have been elongated or stretched.

The use of the terms "major axis" and "minor axis" does not limit the shank to only elliptical cross sections. However, the use of the terms does limit the orientation of the shank with respect to the common plane of the tool and limits the shank cross section to a shape that has a longer dimension in the direction of the common plane and a shorter dimension transverse or perpendicular to the common plane of the tool. The district court therefore erred when it defined the shank cross section to be elliptical. This error, however, is harmless to the denial of the preliminary injunction motion.

a. "Generally Parallel"

Claims 38 and 50 of the '015 patent as well as claims 30 and 43 of the '713 patent require "a bottom face which is generally parallel to the top face." '015 patent, col. 18, ll. 22-23; id. at col. 16, ll. 42-43; '713 patent, col. 14, ll. 20-21; id. at col. 15, ll. 53-54 (emphasis added). Because "[parallelism] is a mathematical concept that is either true or false," Anchor, 252 F. Supp. 2d at 853, the district court interpreted "generally parallel" to be limited to the ordinary meaning of "parallel." Id. at 852. This was error.

While the term "generally parallel," as the district court noted, is mathematically imprecise, we note that words of approximation, such as "generally" and "substantially," are descriptive terms "commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001) (quoting Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1217 (Fed. Cir. 1995)); see, e.g., Andrew Corp v. Gabriel Elecs. Inc., 847 F.2d 819, 821-22 (Fed. Cir. 1988) (noting that terms such as "approach each other," "close to," "substantially equal," and "closely approximate" are ubiquitously used in patent claims and that such usages, when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the courts). And, while ideally, all terms in a disputed claim would be definitively bounded and clear, such is rarely the case in the art of claim drafting. In this case, exact parallelism is sufficient, but not necessary, to meet the limitation of the claim term "generally parallel."

It is undisputed in this case that ordinarily, "parallel" means "everywhere equal distant." Anchor, 252 F. Supp. 2d at 852 (citing Merriam-Webster Collegiate Dictionary 842 (10th ed. 1998)). Additionally, the relevant definition of "generally" is "in disregard of specific instances and with regard to an overall picture; on the whole, as a rule." Webster's Third New International Dictionary 945. Because the claim language itself expressly ties the adverb "generally" to the adjective "parallel," the ordinary meaning of the phrase "generally parallel" envisions some amount of deviation from exactly parallel. It is the claim limitation, as a whole, that must be considered in claim construction. Apex, 325 F.3d at 1374.
The written description does not specify any special definition for the terms "generally," "parallel," or the phrase "generally parallel." See, e.g., '015 patent, col. 5, ll. 5-6 ("The top surface 26 generally lies parallel to the bottom surface 28."); '713 patent, col. 5, ll. 10-11 (same). Moreover, nothing in the prosecution history of the '015 patent family clearly limits the scope of "generally parallel" such that the adverb "generally" does not broaden the meaning of parallel. Accordingly, we hold that the phrase "generally parallel" envisions some amount of deviation from exactly parallel.

1857

B. "Generally Parallel"

The claims also require that the top sizer have "a generally parallel pair of opposed sides and a generally parallel pair of opposed ends" Exh. 510, col. 7, lines 7-9. A&E argues that the term parallel is an absolute term that describes two lines or surfaces which are always equidistant and never meet, and that the modifier "generally," therefore, cannot be reconciled with the term parallel. Additionally, A&E argues that its sides and ends are not "parallel" because they are tapered, meaning that each side is angled at one half of one degree. Finally, A&E argues that because the ends of its hanger are semi-circular, its ends are not parallel.

The task of determining the construction of the term "generally parallel" has been eased by a recent Federal Circuit decision involving that exact term. See Anchor Wall Sys., Inc., v. Rockwood Retaining Walls, Inc., 340 F.3d 1298 (Fed. Cir. 2003). In Anchor Wall Systems, the district court had held "that modifiers, no matter how strong, cannot alter the meaning of a claim term describing a mathematical concept so that the concept would be false if read to describe the accused device." Id. at 1310 (quoting Anchor Wall Sys., Inc., v. Rockwood Retaining Walls, Inc., 252 F. Supp. 2d 838, 852 (D. Minn. 2002)). Accordingly, the district court effectively ignored the adverb "generally" and held that "[parallelism] is a mathematical concept that is either true or false." Id. (quoting Anchor Wall Sys., 252 F. Supp. 2d at 853). The Federal Circuit, however, reversed that holding, finding that although, in the purest sense, "generally parallel" is a mathematical misnomer, the use of "words of approximation, such as 'generally' and 'substantially' are descriptive terms 'commonly used in patent claims to avoid strict numerical boundaries to the specified parameter.'" Id. at 1310-11 (quoting Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001) (internal quotations omitted)). Accordingly, the court found that "the phrase 'generally parallel' envisions some amount of deviation from exactly parallel." Id. at 1311.

The holding in Anchor Wall Systems is particularly applicable in this case where the term "generally parallel" has a meaning to those skilled in the relevant art of injection molding (the method of manufacturing for the plastic hangers). As was made abundantly clear at trial, drafting or tapering (molding the plastics with a slight angle) is a commonly utilized technique to make it easier to remove the plastic from the mold within which it is made, and it is readily understood as such by those skilled in the relevant art. Indeed, except when absolute parallelism is required, a slight draft is common and properly expressed as "generally parallel."

A&E argues, nonetheless, that the term "generally parallel" does not provide sufficient guidance as to the scope of the claims, thus rendering the claims indefinite. However, the term "generally parallel" does not exist in a vacuum. As explained by the former Production Manager of Spotless, the term "generally parallel" would arise in the field of injection molding:

if you wanted to specify something that was precisely parallel, you would go to some pain, some length to say this has to be exactly parallel. Otherwise the term generally parallel or substantially parallel would allow for there to be draft angles so that the features were not exactly parallel.

Tr. at 595-596.

The term "generally parallel" is, therefore, construed to encompass a deviation from exactly parallel that is commonly provided in order to assist in removing the plastic from the mold. Here, the draft angle of one half of one degree 16 in the A&E top sizer existed to facilitate its removal from the mold. See Tr. at 773-73. Accordingly, A&E's hanger, the sides of which contain a draft angle of one half of one degree literally infringes the "generally parallel" limitation. 17
16 For context, if the height of the top sizer is one inch, an angle of one half of one degree would cause each side of the top sizer to be out of parallel by approximately 8 thousandths of an inch. See Tr. at 369. Accordingly to the expert testimony, the width of a human hair is approximately 4 thousandths of an inch. See id. at 973.

17 A&E argues that the ends of its top sizer are not generally parallel because the ends of its top sizer are semi-circular. This argument confuses the parallel limitation with the planar limitation discussed below. As Spotless correctly points out, in ordinary usage, two non-flat surfaces can be parallel so long as they are equidistant - or in this case approximately equidistant. See Tr. at 369.

1858

Additionally, the parties dispute several terms in relation to the '322 patent's mention of "rows of gathers," "fold lines," and "generally parallel," in various claims. 6 Perfect Fit's contentions, to which Louisville Bedding objects, center around Claim 29's description of one step as "attaching to said piece of material elastic material for pulling said piece of material into a plurality of rows of gathers extending in a longitudinal direction of the skirt means and having fold lines running generally parallel to each other in said downward direction, perpendicular to said longitudinal direction." Perfect Fit again argues that the elastic material must extend substantially over the height of the sidewall, asserting that it would not otherwise accomplish its function of pulling the material into rows of gathers. Moreover, the defendant contends that (1) the rows of gathers must themselves be spaced substantially over the width of the skirt and (2) the rows of gathers must be straight and discrete (this latter contention focused on the term "generally," which precedes "parallel" but not "perpendicular" in the claim).

6 During Louisville Bedding's presentation, which preceded that of Perfect Fit, the plaintiff called attention to and took issue with various proposed interpretations of claim terms offered by the defendant in answers to interrogatories; rather than attempting to compose a glossary for every disputed word in the patent, the court will focus on the thrust of Perfect Fit's contentions in its actual presentation. This is in accordance with Judge Simpson's view of claim construction as ascertaining each element of a claim, as it exists in dynamic operation with all the other elements of the claim.

The court finds the language of Claim 29 to be unambiguous; therefore we decline to adopt the defendant's additions. There is no need to read into the claim language the requirement that the elastic material be spaced substantially over the height of the sidewall. 7 Additionally, the court accords "generally parallel" its plain meaning; in the context of gathers, there is no requirement that they be "mathematically" parallel, nor does the omission of "generally" from the notation that they are oriented perpendicularly to the longitudinal direction require the fold lines of the gathers to be precisely straight or mathematical. 8

7 The specification, as noted by the plaintiff, states that virtually any number of rows of elastic cords may be used; if the defendant is concerned that this language will be construed to include a product which has only one such row, the concern is alleviated by requirement of rows (plural) of gathers which are perpendicular to the longitudinal direction of the skirt.

8 The defendant made much of the fact that the drawings of the patent show mathematically parallel fold lines. The court notes that this may be more a consequence of the medium utilized for the illustration (presumably, a computer-generated graphic).
In contrast to the asserted claims just discussed that only recite "connecting elements," independent claim 12 and dependent claims 13-15, 17, 18, and 20 of the '154 patent specifically claim "a plurality of generally parallel connecting elements." '154 patent, col. 9, l. 25 - col. 10, l. 17. The court construed the phrase "generally parallel connecting elements" to require the described connecting elements to run generally parallel both to each other and to the stent's longitudinal axis. Adv. Cardiovascular I, slip op. at 25-27. Based on this construction, the court granted summary judgment of no literal infringement of claims 12-15, 17, 18, and 20 of the '154 patent because it found that the connecting elements on the opposite sides of the NIR stent are not generally parallel to each other because they curve in opposite directions. Adv. Cardiovascular III, slip op. at 8. The court also noted that the connecting elements of the NIR stent are not parallel to the stent's longitudinal axis because, while the longitudinal axis is straight, the connecting elements are curved. Id. at 9. The court also granted summary judgment of no infringement under the doctrine of equivalents, finding that ACS had failed to present any evidence to support its contention that non-parallel connecting elements are insubstantially different from the claimed generally parallel connecting elements. Id. 10-12.

ACS argues that claims 12-15, 17, 18, and 20 of the '154 patent only require the connecting elements to be generally parallel to each other, not to the stent's longitudinal axis. ACS asserts that, under this construction, the NIR stent's connecting elements meet the "generally parallel" limitation because, while curved, they are still parallel to each other. Scimed responds by arguing that the district court properly construed "generally parallel connecting elements" to require the connecting elements be parallel both to each other and to the stent's longitudinal axis. Relying upon this construction, Scimed asserts that the NIR stent cannot infringe because its connecting elements are curved, making them non-parallel to each other and to the stent's longitudinal axis.

We conclude that the district court erred in construing claims 12-15, 17, 18, and 20 of the '154 patent as requiring connecting elements that run parallel to the longitudinal axis of the stent. These claims simply recite "generally parallel connecting elements." See, e.g., id. at col. 9, l. 25. The claims contain no language explicitly requiring the connecting elements to be parallel to the longitudinal axis of the stent. In addition, as noted above in Part II, there is no support for such a construction in the '154 patent's specification or drawings.

Scimed, however, points to the prosecution history. It argues that the inventors distinguished their invention over the disclosure of the Palmaz '417 patent on the ground that the Palmaz '417 patent disclosed connecting members that were not parallel to the longitudinal axis of the stent. The prosecution history does not support this argument.

It is important to recognize exactly what the inventors stated with respect to the Palmaz '417 patent and their invention, as disclosed in the '986 application:

The '417 Palmaz patent discloses connector members 100 which are preferably disposed in a "non-parallel" relationship with respect to the longitudinal axis of adjacent grafts or prosthesis 70. . . . As seen in Figures 7-10 of Palmaz, each of the connector members 100 and 102 are disposed in a non-parallel relationship with respect to the longitudinal axis of the adjacent prosthesis 70.

* * *

The independent claims of the present invention recite "a plurality of generally parallel connecting elements" which clearly distinguish over the preferred "non-parallel" connecting members 100 of the '417 Palmaz patent.

Figures 7, 9, and 10 from the Palmaz '417 patent are as follows:

GET DRAWING SHEET 3 OF 3.
axis of what would be the "stent" in Palmaz, which is designated by the number 70'. See Palmaz '417 patent col. 12, ll. 15-17 (stating that "graft or prosthesis, 70' is illustrated as including three grafts, or prostheses, 70, flexibly connected to one another by connecting members 100"). Rather, they argued that connecting members 100 and 102 were in a non-parallel relationship with "graft" or "prosthesis" elements 70. In other words, the inventors were not saying that their invention was distinguished from the Palmaz '417 patent because Palmaz had connecting members that were not parallel to the longitudinal axis of the stent, which, by inference, their invention did. Rather, they were saying that their invention, unlike the Palmaz '417 patent, see connecting members 100 and 102 in Figures 7, 9, and 10 above, had connecting members that were in parallel alignment with the longitudinal axis of prosthesis 70. Thus, the inventors neither stated nor suggested during prosecution that their invention was limited to a stent in which the connecting members were in parallel alignment with the longitudinal axis of the stent. 7

7 After the statements cited above were made, the examiner responded that "there is no limitation of the claim which requires the connector members to be parallel to the longitudinal axis of the stent; only that the connector members are 'generally parallel'." This response by the examiner further supports our conclusion that the inventors were not defining "generally parallel connecting elements" to mean connecting elements that are parallel to the stent's longitudinal axis.

1. Generally parallel to the longitudinal axis

I conclude that the term "generally parallel to the longitudinal axis" as used in claims 28, 53 and 57-59 of the '978 patent does not need construction because its plain and ordinary meaning is easily discernible from the claim language. Nothing in the claim language or the specification requires a special definition. Therefore, the plain and ordinary meaning controls. Northern Telecom Ltd., 215 F.3d at 1295. Nonetheless, I note that defendant's proposed construction would not fit into the ordinary meaning of the term.

Defendant contends that a proper construction of the term should include the limitation "without rotation in a direction perpendicular to that axis." It is helpful to read the term in context, which includes the following language:

one of said mount frame and said snowplow frame having first and second arms and the other of said mount frame and snowplow frame having first and second receivers, said first and second receivers receiving said first and second arms, respectively upon relative movement therebetween in a direction generally parallel to the longitudinal axis of the vehicle.

E.g., '978 pat., col. 10, ins. 15-21; col. 14, ins. 8-14. "Generally parallel to the longitudinal axis" describes the direction of movement between the first and second arms and first and second receivers of two different frames that are being connected. The specification provides an example of this purpose of this movement:
For both attaching the snowplow assembly 12 to and detaching the snowplow assembly 12 from the mount assembly 14 a force should be applied to the lift frame 22, such as on traverse element 44, in the direction of the mount assembly 14 as latch lever 160 is rotated. Such movement facilitates alignment of the latch pins 102, 104 with the holes 94 in the arms 92. Id., col. 7, Ins. 21-27. Thus, the movement in a direction "generally parallel to the longitudinal axis" of the vehicle is to facilitate alignment of the latch pins with the holes in the arms so that the mount frame and snowplow frame can be connected.

Neither the claim language nor the specification permits the inference that "generally parallel to the longitudinal axis" means "without rotation in a direction perpendicular to that axis." First, the claim language uses the word "generally" which leaves open the possibility that the movement will occur in a direction other than perfectly parallel to the longitudinal axis. Second, it would defeat the purpose of the invention to construe the term as excluding any movement in a direction perpendicular to the longitudinal axis of the vehicle. In aligning the latch pins with the arm holes, it is possible that if the arm holes were slightly below the latch pin alignment, force on the snowplow assembly could tilt the arms upward, that is, perpendicular to the longitudinal axis of the vehicle, while moving the arms into the receivers to align the holes with the pins. Finally, defendant fails to point to any language that prohibits perpendicular movement. Thus, the claim language is broad enough to include some movement in a direction perpendicular to the longitudinal axis of the vehicle. Defendant's proposed meaning would prevent such movement, making it improper.

A. Claim Construction

When a claim is construed, claim terms should generally be given their "ordinary and customary meaning." Phillips v. AWH Corp., 415 F.3d 1303, 1312-14 (Fed. Cir. 2005). The meaning of a claim is determined by using intrinsic evidence, which includes the claims, the specification, and the prosecution history and by using extrinsic evidence, which includes dictionaries. Id. at 1319. However, extrinsic evidence in determining the meaning of a claim may be less reliable than intrinsic evidence: "extrinsic evidence may be useful to the court, but it is unlikely to result in a reliable interpretation of patent claim scope unless considered in the context of intrinsic evidence." Id. This court has cautioned that "heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification." Id. at 1321.

In the present case, the proper claim construction based on the teachings in Phillips begins with the claim language. First, the claim language itself limits and describes "surface" by including the language "generally planar." Mr. Byrne argues that a "generally planar surface" exists on the accused device because "a plurality of points on the surface of the wire edge guide lie in a plane." However, as Black & Decker points out, the claims do not cover a "surface that has two or more points in a plane," but recite only a "generally planar surface." Further, the '815 patent teaches that the purpose of the "generally planar surface" is as a flail stabilizer, and this flail stabilizing purpose is achieved when the surface itself is "generally planar." Thus, based on the language of the claims, the "surface" claimed in the '815 patent must be "generally planar" itself and not merely have points lying in a plane.

Second, the specification of the '815 patent further supports the claim language that the surface itself is "generally planar." In Figure 2, the "circumferential lip" (21) is depicted as a solid, two-dimensional surface. The exact lip width is uncertain, since it is determined relative to an undefined feed increment. Specifically, the written description describes the ideal lip width as being "less than the feed increment of the trimmer head so that the flail tip would wear away before that portion of the flail traveling adjacent the lip would wear through." However, the solid, two-dimensional surface of Figure 2 is sufficient to support the conclusion that the surface must be "generally planar" itself and not merely lie in a plane. In other words, the surface must be flat and continuous and not de minimis.

Finally, the prosecution history described the circumferential lip as "two-dimensional in nature" and disclaimed a "narrow" circumferential lip in an affidavit to overcome the Bartholomew patent. Thus, the claim language "generally planar surface" of the "circumferential lip" should be construed as referring to a two-dimensional surface that is not narrow but has a width less than the feed increment of the trimmer head and is itself generally planar.
The district court erred in construing "surface" because it gave too much preliminary weight to dictionary definitions without relying on intrinsic evidence, as cautioned against in Phillips. The court should have applied the teachings of Phillips and should have considered the claims, the specification, the prosecution history, and if necessary the dictionary when it construed the claims.

Mr. Byrne complains that the district court erred by considering the accused device when construing the claims. However, there is a distinction between performing claim construction and deciding what should be construed. A court may consider the accused device to determine what part of the claim must be construed. Exigent Tech. v. Atrana Solutions, Inc., 442 F.3d 1301, 1309 n.10 (Fed. Cir. 2006). But, the court cannot construe claims based on the accused device. Id. The district court in this case did not err when it considered the accused device to determine that it should construe the claim term "generally planar surface."

A. "Generally polyhedron shaped"

Plaintiff argues that the claim term "generally polyhedron shaped" requires only that the enclosure be substantially or approximately polyhedron shaped. Plaintiff asserts that the phrase should be interpreted with reference to the enclosure in an empty state, rather than in a filled state. The enclosure is meant to be filled with flexible material, plaintiff argues, and the use of the term "generally" contemplates that the enclosure's shape is malleable and will change as it is used. Thus, the polyhedron's faces need not be straight, but can be curved.

Plaintiff refers the Court to the '986 patent specification, which describes the flexible enclosure as having "a general polyhedron shape formed by the substantially planar surfaces 47-52." Patent, col. 3, lines 56-57. The specification also explains that the material utilized within the enclosure must be able to "withstand repeated cycles of compression . . . and expansion of the pad structure." Patent, col. 4, lines 6-16. Finally, plaintiff notes that the prosecution history refers to a device patented by Mengshoel that the patent examiner described as "of a generally polyhedron shape [although it] is not an exact polyhedron due to it's [sic] curved shape." Pros. History, page 2, para. 3. Plaintiff claims that the Mengshoel reference shows that the patent examiner recognized that a polyhedron could encompass curved regions, as long as the overall shape is still a polyhedron.

Defendant argues that the shape of the enclosure must be determined when the enclosure is filled, not empty. Defendant argues that a polyhedron by definition has straight sides and flat faces and claims that the word "generally" was intended only to provide for slight deviation from a mathematically perfect polyhedron and cannot be used to "entirely vitiate" the meaning of "polyhedron shaped." Joint Memorandum regarding Claim Construction at 6-7. Defendant asserts that the Mengshoel reference indicates how the patent examiner viewed a polyhedron, but not what the patentee understood the term to mean.

The claim language refers to "a generally polyhedron shaped enclosure," and describes the properties of that enclosure, including the following: "the flexible enclosure being substantially filled with a flexible, resilient material." Patent, claim 12, col. 8, lines 9, 29-30.

Claims "must be read in view of the specification, of which they are a part." Vitrionics, 90 F.3d at 1582 (citations omitted). The specification, like claim 12, refers to a "flexible enclosure" which is "substantially filled, and preferably completely filled, with a flexible, resilient material." Patent, col. 3, lines 59-60. The specification also states that the pad material "exerts a force which separates upper and lower legs . . . and thus relieves stress upon knee." Patent, col. 3, lines 62-64. An empty enclosure could not perform this function. It is "entirely proper to consider the functions of an invention in seeking to determine the meaning of particular claim language." Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1318 (Fed. Cir. 2005), citing Renishaw PLC v. Marposs Societa per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998).

The Court finds that the claim's references to the enclosure contemplate the enclosure in a substantially filled state, not in an empty state. The intended function described in the specification supports this conclusion. Accordingly, the Court will interpret the language of claim 12 with reference to the enclosure in a filled state, rather than an empty one.
The claim's language, specification, and prosecution history do not make clear the definition of polyhedron. Accordingly, the Court will consult a dictionary to determine the ordinary and customary meaning of "polyhedron." A polyhedron is "a solid formed by plane faces." Webster's Ninth New Collegiate Dictionary (1983). A plane is defined as "a: a surface of such nature that a straight line joining two of its points lies wholly in the surface; b: a flat or level surface." Id. A polyhedron thus by definition must contain plane faces— that is, flat or level faces. "Generally" and "substantially" are words of approximation, "descriptive terms" used to "avoid a strict numerical boundary to the specified parameter." Anchor Wall Systems, Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-11 (Fed. Cir. 2003), quoting Ecolab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1367 (Fed. Cir. 2001).

The Court finds that a "generally polyhedron shaped enclosure" means that the overall shape of the enclosure, when in a substantially filled state, must be that of a polyhedron, and the faces of the polyhedron need not be strictly or perfectly flat or planar, but must be generally flat or planar.

1864

Generally predetermined acceptable limit

This term is used in Claim 30 of the '977 patent, which is dependent on Claim 29. Claim 29 provides, in essence, a means for restricting angular distortion of the housing (caused by wet compression) to a "generally predetermined acceptable limit that prevents damage to the compressor." Claim 30 relates to the apparatus described in Claim 29 and contains the following:

\[ \text{wherein said means for controlling angular distortion of the housing comprises means for insuring a sufficiently uniform distribution of liquid water in the working fluid to limit angular deformation of the housing to a generally predetermined acceptable limit that prevents damage to the axial-flow multistage compressor.} \]

This apparatus is described in the specifications at column 18 of the '977 patent. Here, it is explained that the amount of deformation can be measured in relation to the particular mass flow increment, thus allowing the operator to control deformation within a generally predetermined acceptable limit. The "generally predetermined acceptable limit" therefore refers to a limit of angular deformation which has been generally recognized by the manufacturer or operator in advance of operating the turbine, against which the actual deformation caused by wet compression is measured in order to prevent damage to the compressor.

Defendants' contention that the amount of acceptable distortion must have been specifically determined by calculation or measurement is not supported by the evidence.

The Court therefore construes this term to mean:

A boundary, generally recognized or appreciated by the manufacturer or operator in advance of operating the gas turbine.

1865

DISCUSSION

Norgren filed a complaint with the ITC in which it alleged violations of section 337 in the importation into the United States, the sale for importation, and the sale within the United States after importation of certain SMC connecting structures that allegedly infringe claims 1-5, 7, and 9 of the '392 patent. The ALJ held an administrative trial, received post-hearing briefing from the parties, and then issued an initial determination in which he concluded that there was no violation of section 337. More specifically, the ALJ found that the accused SMC connecting structures do not infringe the asserted claims because they do not meet the claim limitation of "a four-sided generally rectangular clamp adapted, in its operative clamping position, to engage, in parallel relationship with one another, the pair of ported flanges." The ALJ also determined that the asserted claims of the '392 patent are nonobvious. The ITC decided not to review the initial determination and
terminated the investigation with a finding of no violation.

Norgren appeals, challenging the ALJ's claim construction. Both the ITC (as appellee) and SMC (as intervenors) respond that the ALJ's finding of noninfringement was correct because the underlying claim construction was correct. SMC also argues that the ALJ erred in concluding that the asserted claims are not invalid for obviousness. We have jurisdiction under 28 U.S.C. § 1295(a)(6).

We review claim construction de novo. Gemstar-TV Guide Int'l, Inc. v. Int'l Trade Comm'n, 383 F.3d 1352, 1360 (Fed. Cir. 2004); see also Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1455-56 (Fed. Cir. 1998) (en banc). Independent claim 1 of the '392 patent recites as follows:

1. Connecting structure for contiguously connecting together a pair of fluid-flow elements, each fluid flow element including a generally rectangular ported flange so as to define a pair of ported flanges associated with the fluid-flow elements, said connecting structure comprising:

   a four-sided, generally rectangular clamp adapted, in its operative clamping position, to engage, in parallel relationship with one another, the pair of ported flanges, one of said sides of the clamp being pivotally mounted so that said one side can be pivoted out of said operative clamping position in order to permit reception of said flanges into the clamp and then pivoted back into said operative clamping position,

   sealing means for establishing fluid-tight communication between the respective ports formed in said flanges, and

   locking means for releasably locking said one side in said operative clamping position, in which position the clamp urges the flanges towards one another thereby establishing together with said sealing means, said fluid-tight communication between said ports.

Because this claim recites a "clamp adapted . . . to engage . . . the pair of ported flanges," the parties agree that we must construe "generally rectangular ported flange," which appears in the preamble of claim 1, insofar as the flange is configured to permit engagement by the clamp. The ALJ explained, "whether or not the flange on an FRL must have two or four . . . rims is the salient issue to be determined." The ALJ stated:

the word "flange," as used in the claims of the '392 patent, is the structure that is received into the claimed clamp, and further that "a generally rectangular ported flange" is a flange of rectangular shape with projections on all four sides and a hole in the middle that is used as a port.

The ALJ further explained:

In view of the fact that the clamp must be four-sided, and the clamp is specially adapted to engage the generally rectangular ported flanges of the FRLs, it is reasonable to conclude that each rectangular flange is engaged on all four of its sides by the four-sided clamp. Thus, the clamp is adapted to engage flanges with four projecting rims.

Norgren argues that the ALJ's claim construction is erroneous for requiring that each flange has projections (or projecting rims) on all four sides. 1 We agree.

1 In its briefs, Norgren also maintained that the ALJ's claim construction incorrectly requires that the entire flange be received into the clamp. At oral argument, however, counsel for Norgren and counsel for SMC conceded that for the SMC accused structures, flanges do not extend beyond the clamp. Oral Argument Tr. 9:07-11:46 (Norgren), 35:08-36:47 (SMC). In other words, the accused SMC connecting structures permit reception of two flanges entirely into the clamp. Accordingly, we do not address this issue.

Nothing in the claims, written description or prosecution history requires four projecting rims. The claims of the '392 patent...
do not recite the terms "rim" or "projection." Indeed the term "rim" does not appear anywhere in the '392 patent. The specification refers to two items as projections--the hook attached to the rectangular spacer and a ridge in another embodiment of the u-shaped member--neither of which are present on the flanges or relate to the flanges in any way. See '392 patent col.2 l.62, col.3 l.1, col.4 l.19. It is true that the figures of the '392 patent depict a preferred embodiment that includes two flanges, each with four projecting rims. See id. figs.3 & 4. But these figures are the full extent to which the patent refers to flanges with four projecting rims. Thus under the well-established prohibition on importing limitations from the specification into the claims, see Phillips v. AWH Corp., 415 F.3d 1303, 1320, 1323, the "generally rectangular ported flange" of the asserted claims of the '392 patent is not limited to a flange having four projecting rims.

1866

17. "Generally sinusoidally-shaped." Consistent with its ordinary meaning and the prosecution history, 38 the court construes this phrase to mean "a repeating pattern, formed by substantially straight segments connected by bends or curves, that generally resembles a sine wave because it does not double back on itself."

1867

The dispute at the Markman hearing in this case centered on the meaning of the phrase "generally smooth and planar" in relation to the exterior surfaces opposite the projections. Since plaintiff did not define the terms in its specification, the court will rely on their ordinary meanings. Plaintiff urges the court to rely on its hypothetical claim construction, "to make the case more comprehensible for the Court and Jury." The court finds that reliance on the hypothetical is unnecessary and inappropriate, as the court and jury may rely on the ordinary meaning of the terms.

Webster's Dictionary defines the word "generally" as, "1. For the most part: WIDELY. 2. As a rule: USUALLY; 3. In disregard of particular instances and details."

"Smooth" is defined as "1. Having a surface free from roughness, irregularities, or projections: EVEN."

"Planar" is defined as "1. Of, pertaining to, or located on a plane. 2. Flat."

Having heard the arguments and reviewed the briefs of the parties in addition to studying the specification and prosecution history, 1 the undersigned construes the disputed portions of the claims as follows:

. "Generally smooth" is construed to mean having a surface which is for the most part free from roughness, irregularities, or projections.

. The word "generally" is construed to modify "planar," since one of the exterior surfaces on plaintiff's clip (identified in DX-1 as ref. 38) has a curve on one side. The court notes, however, that plaintiff's arguments regarding the examiner's comments (at prosecution history, pp. 76, 78-79) about curvature and concave surfaces do not bear on the claims because those comments were made in regard to the projections/protrusions (i.e. ref. 50) and not the exterior surfaces opposite the projections.

. "Generally planar" is construed to include irregular deviations from a mostly flat surface, such as the curve on the end of ref. 38 where it meets ref. 50. See Arvin v. Industries, Inc. v. Berns Air King Corp., 525 F.2d 182 (7th Cir. 1975) (ruling that use of the word "generally" to modify "planar" does not negate the meaning of planar, but allows for some deviation from a perfectly flat surface).
6. Generally Tear Drop Shape

Claim 7 of the '456 patent provides: "said positioning ring has a generally tear drop shape." Defendants propose the following construction, "having a globular form at the bottom, tapering to a point at the top" and present little if any argument in support of this proposal. (Defs.' Br. at 47-48.) Plaintiff counters with substituting "point at top" with "narrower portion at the top." (Pl.'s Reply Br. at 39.) Plaintiff points out that Figure 5-A, (App. at i), which illustrates an embodiment of the positioning ring, indicates that the positioning ring does not have a point at the top. Thus, defendants' construction would impermissibly exclude the preferred embodiment. See Vitronics, 90 F.3d at 1583-84. Neither party presents, nor could this Court find, a dictionary definition of "tear drop" which indicates whether the ordinary meaning of the word must include a pointed top. The claim itself also indicates that the shape is "generally tear drop." I therefore conclude that plaintiff has presented the construction which is consistent with the claim language and specification. Thus, the claim is not limited by a pointed top as described by defendants. Thus the proper construction for "generally tear drop shape" is: having a globular form at the bottom, tapering to a narrower portion at the top.

B. Whether the "Fluted" Devices Have a Uniform Stem Wall Thickness

Claim 1(b) of the '663 patent discloses an intramedullary rod with a sidewall "having a first, generally uniform smaller wall thickness defining the stem, and a second, larger wall thickness defining the head." The court has defined the phrase "first, generally uniform smaller wall thickness defining the stem" to mean "the wall thickness of the stem is thinner than the wall thickness of the head and that thickness does not vary significantly; the thinner wall and the uniformity define the stem as distinct from the head." Several of Synthes's devices have a "fluted" stem portion, meaning that the outer circumference of the stem resembles that of the bit of a Phillips head screwdriver, rather than being perfectly cylindrical. 13 The fluted devices are as follows 1) all 240 mm length versions of the "standard" PFN rod, 2) all 235 mm length versions of the "short" TFN rod, and 3) the 11 and 12 mm versions of the "long" TFN rod. (TX 17; TX 13; TX 3, respectively).
This analogy is not perfect. The fluted devices have six outer "points" along the circumference of the stem, where a Phillips screwdriver has only four.

Synthes claims that the fluted versions of the TFN and PFN do not practice claim 1(b) of the '663 patent. The court agrees. The fluted rods perform three functions not achieved by more traditional cylindrical rods: 1) reduced stiffness, 2) improved endosteal blood supply, and 3) decreased rotation of the rod within the bone canal. (Tr. 634:25-635:15, 1642:14-1643:8).

More importantly, the fluted stem walls do not have a generally uniform thickness; rather, their thickness varies significantly. The 235 mm length TFN rods have variances in stem wall thickness ranging from 50% (between 2.7 mm and 1.8 mm) to 140% (3.25 mm to 1.35 mm). (TX 2, 45; Tr. 446:4-16; Pretrial Stip. 6.63). The 11 mm and 12 mm versions of the long TFN rod have variances in stem wall thickness ranging from 25% (3.2 mm to 2.55 mm) to 55% (3.25 mm to 2.1 mm). (TX 3, 45; Pretrial Stip. 6.68). An examination of the 240 mm version of the PFN shows that its circumferential variance in stem wall thickness is similar to that of the 11 mm and 12 mm versions of the long TFN. The foregoing variances demonstrate that the stem wall thickness of the fluted versions of the TFN and PFN are not uniformly thick along their circumference so as to practice claim 1(b) of the '663 patent. (Tr. 1642:3-13, TX 45). Further, the fluted versions of the PFN and TFN vary in stem wall thickness along their length. Each of the devices has a fluted and non-fluted portion of the stem. In particular, the variation in wall thickness between the unfluted and fluted portions along the length of the stem of the fluted TFN and PFN rods is between 25% and 140%. This variation is significant and inconsistent with claim 1(b) of the '663 patent. (Tr. 445:19-447:18). Thus, the fluted TFN and PFN rods do not infringe that patent.

1871

a. Magistrate Judge's Ruling

The magistrate judge determined that "generally V-shaped" ribs means two diagonal lines that extend at an angle but in opposite directions like the "over-all" features of the letter "V," but does not require that the lines come to a point like the letter "V." R&R at 17. The magistrate judge construed the term by looking at the language of the claim and the common meaning of the word "generally." Id. at 16-17. When comparing the language of Claim 1, which describes the ribs on the lid to be "disposed diagonally to form side-by-side V-shaped ribs," and Claim 6, which describes the ribs on the bottom to be "in diagonal orientations forming side-by-side generally V-shaped ribs," the magistrate judge gave the word "generally" significance. Id. at 17. Since "generally" is expressly tied to the adjective "V-shaped," the magistrate judge stated that there can be some deviation from a precise "V" so the diagonal lines need not come to a point. Id.

b. The Defendants' Objections

The defendants argue that the magistrate judge's construction of "generally V-shaped ribs" cannot be accepted because it is so broad as to leave no indication as to the limit of what constitutes a "V" shape. Defs. Objections at 12. Instead, the defendants request the court to adopt the interpretation that "generally V-shaped ribs" must meet at a point on the bucket with a modification to the apex where the bottom tip is chopped off. Id. The defendants argue that Figure 9 shows a modified apex at the top and the bottom of the bucket. Id. Thus, they assert that "generally V-shaped ribs" should be construed as requiring the ribs to touch in a modified apex. Id. at 13.

c. This Court's Construction

As an initial matter, the court notes that "[w]ords of approximation, such as 'generally' and 'substantially,' are descriptive terms commonly used in patent claims to avoid a strict numerical boundary to the specified parameter." Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-11 (Fed. Cir. 2003)(internal quotations omitted)(discussing that "the claim language itself expressly ties the adverb 'generally' to the adjective 'parallel,' the ordinary meaning of the phrase 'generally parallel' envisages some amount of deviation from exactly parallel. It is the claim limitation, as a whole that must be considered in claim construction."). Thus, the addition of the word "generally" to Claim 6 thus must be given significance. Because the adverb "generally" is expressly tied to the adjective "V-shaped," the use of the term "generally" in Claim 6 indicates a deviation from a precise "V."
In addition, the intrinsic evidence does not support the defendants' construction that "generally V-shaped ribs" are required to touch in a modified apex. Instead, contrary to the defendants' position, the intrinsic evidence strongly suggests a difference between the ribs on the bottom of the bucket and the ribs on the curved flange section at the top of the bucket.

Specifically, the ribs on the bottom of the bucket, introduced in Claim 5 and described in Claim 6, are stated to be "diagonal orientations forming side-by-side generally V-shaped ribs." '493 patent at Col. 7:16-17 (emphasis added). In contrast, the ribs on the curved flange on the top of the bucket were not described in the claims, but were described in the specification as "a plurality of diagonal ribs" being "disposed in a V-shaped arrangement having a modified apex at the ends of each rib." '493 patent at Col. 4:53-54. The phrase "generally V-shaped ribs," as used in Claim 6 to describe the ribs on the bottom of the bucket, is, to state the obvious, different from the term "a modified apex," which is used to describe the ribs on the curved flange on the top of the bucket. Indeed, the language in the specification expressly states that the diagonally oriented ribs on the bottom of the bucket are merely "similar" to the ribs on the top of the bucket, not identical. '493 patent at Col. 5:1-2.

As noted by the plaintiffs, if the inventor had intended to describe the ribs at the top of the bucket in the same way as those on the bottom of the bucket, he would have done so. Moreover, as evidenced from the prosecution history, the description of the ribs on the bottom of the bucket does not include the term "modified apex," which is used for the top of the bucket. Instead, the ribs on the bottom of the bucket are described as being "separated" at the apex. Def. Appx. Exh. 11, P 001804:7-9.

The court also is not persuaded by the defendants' assertion that Figure 9, which shows the ribs on the bottom of the bucket and the ribs on the curved flange of the top of the bucket, requires that a "modified apex" definition controls because the claim language cannot be confined to one particular embodiment when the specification indicates that multiple embodiments are possible. KCJ, 223 F.3d at 1356; '493 patent at Fig. 9.

Further, while the defendants assert that the magistrate judge's construction of "generally V-shaped ribs" is too broad, the court should consider adopting a narrower meaning only "where there is an equal choice between a broader and narrower meaning of a claim, and there is an enabling disclosure that indicates that the applicant is at least entitled to a claim having the narrower meaning." Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996). This principle is not implicated with respect to the construction of the term "generally V-shaped ribs" because the use of the word "generally" coupled with the language in the specification does not indicate a narrower meaning should be adopted.

Finally, the court finds that, contrary to the defendants' assertion, the issue as to how far apart the diagonal lines will need to be on a bucket to be "generally V-shaped" is a question of infringement, not of claim construction, because it would need to be determined in reference to an accused device. Miken Composites, 515 F.3d at 1336.

The court concludes that "generally V-shaped ribs" means two diagonal lines that extend at an angle but in opposite directions like the "over-all" features of the letter "V," and does not require that the lines come to a point like the letter "V."
Plaintiff contends that the specification, prior art and expert testimony from the defendants' expert support its view that the extension is from the plane of the eye and not the top surface of the cutting head assembly. The language of the claim itself, however, indicates that the extension comes from the top surface of the cutting head assembly. A description denoting the plane of the eye is not included in the claim.

Nor is the plane of the eye included in that portion of the written description highlighted by plaintiff. Rather, the specification of the '456 patent reads: "the drive means 80 are thereby permitted to enter the cutting head assembly 50 through the top surface 56' and are thus, generally vertically disposed. It is believed that this feature results in less interference with the surgical field and facilitates finer handling by the surgeon than is offered by conventionally known microkeratomes. Specifically, known microkeratomes have typically provided for horizontally disposed drive means." Col. 13, ln. 64-Col. 14, ln. 4. Thus, the written description supports the construction that the extension comes from the top surface of the cutting head assembly, not the plane of the eye. The prior art citation merely indicates that the inventor changed the horizontal direction to a vertical direction.

Plaintiff points to the following deposition testimony of Dr. Steinert, the defense expert:

Q. Do you understand what's meant by "generally vertical orientation"?
A. Yes.

Q. What does that mean to you?
A. Going up and down.

Q. With respect to the eye or with -
A. Well, the way it's used, yes, it ends up being that way, but what it really would refer to is orientation relative to the head and how it passes across the ring.

(Dep. at 117-18, Pl.'s Ex. 14.) Thus, Dr. Steinert testified that the extension from the plane of the eye is mere happenstance, but that the term refers to the extension from the cutting head assembly. I therefore conclude that neither the intrinsic nor extrinsic evidence demonstrates that the ordinary meaning of the claim language is varied. Thus, the defendants' construction of the term is correct, and "generally vertical orientation" shall be construed as: over and perpendicular to the top surface of the cutting head assembly.
C. Generated Shapes

"Generated shapes" is used in Claim 1 and Claim 3. In Claim 1 it is used in claiming a method of producing "the appearance of smoothed edges are given to the generated shapes." 272 patent, col. 6 ll. 29-30. In Claim 3 it is used in claiming an "apparatus for producing on the photoreceptor an image of generated shapes made up of spots." Id., col. 6 ll. 33-34. The dispute about the construction of "generated shapes "centers on whether "generated shapes" are limited to characters. Hewlett argues that "generated shapes" should not be limited to characters but should include all shapes brought into being on the photoreceptor. Pitney argues that the term has already been defined and limited to characters by the Federal Circuit.

In its opinion in this case, the Federal Circuit stated "generated shapes' are, of course, the letters, numbers or other characters formed with fewer jaggies than under the prior art methods." Pitney III, 182 F.3d at 1305. Pitney argues that this definition is now the law of the case. The law of the case doctrine was judicially created to ensure judicial efficiency and to prevent the possibility of endless litigation. Central Soya Co. v. Geo. A. Hormel & Co., 723 F.2d 1573, 1580 (Fed. Cir. 1983). The doctrine applies not only to issues discussed and decided but also those decided by necessary implication. W.L. Gore & Assoc., Inc. v. Garlock, Inc., 842 F.2d 1275, 1278-79 (Fed. Cir. 1988) (citing Smith Int'l, Inc. v. Hughes Tool Co., 759 F.2d 1572, 1577 (Fed. Cir. 1985)). Thus, although the Federal Circuit did not specifically address the question of whether the "generated shapes" could be shapes other than characters, it did define it in construing what "spots of different sizes" meant. In order to construe "spots of different sizes," the court had to consider what "generated shapes" the spots of different sizes were producing. In so doing, it limited the claim to " . . . letters, numbers or other characters. . ." Pitney III, 182 F.3d at 1305. The definition is thus the law of the case. 3

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 Under its newly-cited precedent, Hewlett admitted at oral argument on April 24, 2001 that generated shapes should be limited to letters, numbers or other characters because it was so limited in the patent specification. See Netword, 242 F.3d at 1351.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

In allowing the 272 claims, the PTO specifically stated that several patents disclosing half-tone reproducing devices disclosed "patently different technology" than the 272 patent. 4 PB Ex. 19, at 1 ("a half-tone reproducing device, as compared to that of a character generator which actually produces an image of generated shapes (or characters) made up of spots, is a patently different technology and is not quite concerned with generating shapes using spots of different sizes.")

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Half-toning uses spots of different sizes to allow the eye to see the pattern of dots as a continuous tone image. PB Mem. on Claim Construction at 17. The focus of half-toning is on reproducing images by varying tone or shade. Id. at 18.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

The PTO's conclusion supports the Federal Circuit's construction and indicates that the construction remains the same after reexamination.

Based on the Federal Circuit's construction of the term and the PTO's support of that construction, "generated shapes" are letters, numbers, or other characters formed with fewer jaggies than under the prior art methods. 5

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 Hewlett indicated that there was a dispute between the parties regarding the necessity of a character generator in creating "generated shapes." Pitney did not address this dispute and seems to have conceded that "generated shapes" need not come from a character generator. The court thus finds that "generated shapes" are not limited to characters that originate from a character generator.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
1. "geographically dispersed"

The suggested construction for this phrase submitted by the parties changed from the initial written submissions and during the course of the Markman hearing. In its written submissions, plaintiff asserted that the term be construed to mean "in different geographic locations." During the Markman hearing, plaintiff suggested they would agree to a construction which states: "in different geographic locations, either within a building or in different buildings." Plaintiff claimed that the phrase "either within a building or in different buildings" was taken directly from the prosecution history. (Pl.'s Resp. Br., fn. 5, p. 6; Hr'g., pp. 81, 85.) Defendants initially requested that the disputed term be assigned its ordinary meaning.

After considering plaintiff's second proposal, defendants took issue only with the use of the word "different" being used to give meaning to "dispersed." Defendants continued to argue that the word "dispersed" would be more informative to a jury and more readily understandable. (Defs.' Br., p. 15; Hr'g., p. 84.) Defendants further argued that while plaintiff cited to the prosecution history to supply meaning for its suggested construction, it failed to cite the prosecution history accurately. On this point, we agree with defendants, and indeed, in its brief, plaintiff cited to instances in the prosecution history where the inventors explained "geographically dispersed" using the terms "disparate," in one instance, and "separate" in another. (Pl.'s Br., p. 14.) Conversely, plaintiff has not cited to any reference in the prosecution history that uses the word "different."

After discussion on this point, plaintiff indicated that it would agree to a claim construction that uses the word "separate" in place of "different." (Hr'g., p. 88.) Defendants similarly conceded they would accept "disparate" in place of "dispersed." (Id., p. 89.) Neither side would accept the alternate definition offered by the other. Consequently, the Court adopts the following construction: "in separate geographic locations, either within a building or in different buildings." This construction is closest to the prosecution history (which both sides have asked the Court to rely upon) and provides a simple and clear meaning for the disputed claim term.

48[e]. said contributions management device being optionally geographically remote from a plurality of said electronic contributions accepting devices

Each contributions accepting device may be, but need not be, located in a geographically remote location from the contributions management device. In this context, "geographically remote" means in a different area, separated significantly in space.

1. "Gesture Action" (’053 patent, claims 1, 6, 20, 22) The patented inventions may be briefly described as methods for creating realistic computer animations of characters. The first term in dispute is "gesture action." Plaintiff's proposed construction is "a defined movement of joints over time which symbolizes or emphasizes an idea, sentiment or attitude." Defendant's proposed construction is "body part undulation executed under the control of a set of coupled frequency and range signals."

Plaintiff principally objects to the word "undulation" in defendant's construction on the ground that the '053 patent describes at least one gesture action, the "casual pose," that does not entail any undulation. See transcript, 12/18/06 ("Tr."), at 9; '053 patent, 6:54-7:14. Plaintiff argues that the casual pose is "driven primarily by noise," see '053 patent at 7:11-14; '132 patent at 7:14-17, so that an observer viewing a figure in the "casual pose" would perceive movement that was random, rather than undulatory, see Tr. at 50-51. However, plaintiff's expert, Dr. Norman I. Badler, admitted that it would be "very unlikely" for the casual pose not to entail at least some undulation, see Tr. at 104-05; moreover, as defendant's expert Dr. Kellogg S. Booth noted, "the noise function[] constitute[s] undulation," see Tr. at 119; see also Tr. at 122, 147. More broadly, the Court
agrees with Dr. Booth's testimony that neither the fact that certain gesture actions such as the casual pose entail less undulation than others, nor the fact that any gesture action can be "stopped" before undulation takes place, changes the fact that the essential nature of gesture actions is to provide for undulation. See Tr. at 109-10, 117-19, 146-49.

Plaintiff also objects to the phrase "executed under the control of a set of coupled frequency and range signals" in defendant's construction. Defendant's use of this phrase is supported, however, by the specification of the '053 patent (and the corresponding specification of the '132 patent) that introduces the phrase "gesture action" in the following terms:

The programmer/user can specify a sequence and/or combination of different gesture actions. Each action is implemented as a set of coupled frequency and range of pseudorandom time-varying signals set to each limb. The transition from one action to the next is smooth and life-like.

'053 patent at 2:47-52 (emphasis added); see also '132 patent at 2:51-56. Defendant's construction largely tracks this language. Although plaintiff's expert, Dr. Badler, testified that the phrase "[e]ach action" in the above-quoted passage does not necessarily refer to a "gesture action," see Tr. at 36, and that the word "of," following the word "range," is an error and should be the word "or," see Tr. at 37, 40, the Court does not credit this testimony, finding it much more likely that the language means what it says.

Further, defendant's entire construction is supported by the deposition testimony of Dr. Kenneth Perlin, the inventor of the '053 and '132 patents, who testified that the '799 application (which underlies both patents) does not anywhere describe how to create a "gesture action" that is not a "body part undulation executed under the control of a set of coupled frequency and range signals." Declaration of Dr. Kellogg S. Booth dated November 12, 2006 ("Booth Decl."), Ex. 6 ("Perlin Dep.") at 101. Plaintiff argues that Dr. Perlin recanted this testimony by testifying later in his deposition that he thought he "could create a . . . gesture which is effectively a pose" with "[n]o time varying behavior," and that "this [would] describe how to create a gesture action that is not a set of coupled frequency and range values." Declaration of Paul D. Ackerman dated November 30, 2006 ("Ackerman Decl."), Ex. A at 281 (emphasis added). But this later testimony does not amount to a recantation because it says only what Dr. Perlin could create or describe now, and not what he did create or describe in the patents.

Accordingly, the Court adopts defendant's proposed construction of "gesture action."

1878

H. Element 8: "The Annular Surface Having An Axial Length Extending For A Given Distance Along The Length Of The Hub"

Element 8 requires "the annular surface having an axial length extending for a given distance along the length of the hub." Papst argues that the Court should not limit the "given distance" to any particular distance. Sunon asserts that the Court should limit the "given distance" to a distance of "at least one-third of the axial length of the hub." The Court agrees with Sunon.

Because the term "a given distance" is ambiguous, the Court may turn to the specification for guidance as to how to construe the term. An examination of the written description and drawings is necessary to determine whether the patentee has disclaimed subject matter or has otherwise limited the scope of the claims. Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1343 (Fed. Cir. 2001). The specification of the '015 patent unequivocally requires the distance to be "at least one-third of the hub length" in order for the invention to work as intended. In the Summary of the Invention, the patentee stated:

According to the present invention, this problem [of increasing air flow efficiency] is solved in that the axial length of the conical annular surface amounts to at least 1/3 of the hub length and in that with respect to the axial median plane, the scroll plate is asymmetrical in the corner areas and is constructed cylindrically over a longer distance from the axial median plane to the inlet side than to the outlet side.

It has been discovered that these measures lead to a considerable improvement in the performance, without having to modify the external dimensions of the axial-flow fans. It has also been found that the improved action does not occur to any noticeable extent, i.e., occurs only barely, unless the axial length of the conical ring surface corresponds to at least one third
of the total hub length. Only the combination of the two features mentioned above leads to the surprising improvement.

The requirement that the distance be "at least one-third of the hub length" is not, as Papst argues, simply a best mode. Rather, it is an essential feature of the invention, the purpose of which is to maximize the efficiency of air flow. '015 patent, col. 1, l. 47-49 ("The task of the present invention is therefore to provide an axial-flow fan, which has a higher efficiency than the known fans of this type."). The invention will not fulfill this purpose if the "given length" is less than one-third the length of the hub. "When the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1347 (Fed. Cir. 2004), quoting SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001). This is particularly true where, as here, the patentee made the broad, unequivocal statement in the "Summary of the Invention." Microsoft, 357 F.3d at 1348 ("Those statements, some of which are found in the 'Summary of the Invention' portion of the specification, are not limited to describing a preferred embodiment, but more broadly describe the overall invention of the [patent]."). In this case, the patentee limited the scope of his invention to a particular length of the "given distance" by unequivocally stating that the invention will not work as intended with a distance less than one-third the distance of the length of the hub.

The prosecution history is not to the contrary. After the '015 patent issued, the patentee filed for a continuation and a broadening amendment. As originally issued, Claim 29 required the distance to be "one-third the length of the hub." In the broadening amendment, Papst sought to replace the "one-third" requirement with the phrase "a given distance." The examiner allowed the broadening amendment, and Claim 29 reissued with the broader claim language. The fact that the PTO allowed the broadening amendment, however, is not dispositive. It simply means that prosecution history estoppel does not bar a broad construction of "any given distance." But prosecution history is not the only means by which the patentee may limit the scope of his claims--limiting the claim scope via disclaimers in the specification is another. As the Court discussed, that is what happened here.

Accordingly, the Court construes Element 8 to mean that the axial length (in a direction parallel to the axis of rotation) of the "annular surface" of the impeller hub defined by the reduced diameter portion corresponds to at least one-third of the total hub length.
Furthermore, there are no dimensional limitations in the specification or the drawings.

Plaintiff argues that a trocar of a "given" diameter in combination with an "endoscopic" clip applier means a 10/11 millimeter trocar and a clip applier capable of applying medium/large clips. The words of a claim must be given their ordinary meaning unless it appears that the inventor used the terms differently. "Although a patentee can be his own lexicographer, as we have repeatedly said, the words of a claim 'will be given their ordinary meaning, unless it appears that the inventor used them differently.'" Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 951 (Fed. Cir. 1993); see also Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387 (Fed. Cir. 1992).

The '249 patent contains no special definitions of the words "given" or "endoscopic." Therefore in construing Claim 36, the words "given" and "endoscopic" should be given their ordinary meaning. Thus, "a tubular cannula having a given internal diameter" would mean a tubular cannula having an assumed or hypothetical internal diameter, i.e. one of no fixed or specific diameter. See Webster's Third New International Dictionary. Likewise, "endoscopic" would mean any device capable of being used with an endoscope, an instrument for visualizing the interior of a hollow organ or body cavity. "Endoscopic" would not connote any size limitation, except perhaps the general limitation of a size sufficiently small to be able to be inserted into an orifice or incision in the human body.

Plaintiff argues that notwithstanding the absence of any special definitions of these words in the patent, one skilled in the art would understand that "given internal diameter" and "endoscopic," as used in Claim 36 signify that the cannula referred to in the claim is a 10/11 millimeter cannula and that the surgical clips referred to in the claim are medium/large surgical clips, since these are the standard in the field of endoscopic surgery. This argument is unavailing because it is undisputed that medium sized surgical clips are used in endoscopic surgery and are thus, "endoscopic." In fact plaintiff itself markets an endoscopic clip applier designed for use with medium sized surgical clips. 4 Plaintiff's contention that one skilled in the art would understand that Claim 36 includes the limitations of a 10/11 millimeter trocar and a medium/large surgical clip does not present a genuine issue of material fact. The Court likewise finds no merit in plaintiff's argument that testimony regarding the intent of the inventors or spatial relationships depicted in the unscaled patent drawings raise genuine issues of fact regarding size limitations in Claim 36.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 It is also undisputed that there are minor variations in the sizes of trocar cannulas and surgical clips within categories made by various manufacturers and that there is no precise or uniform standard dimension for a medium or medium/large surgical clip.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Plaintiff further argues that part of the prosecution history of the '249 patent includes representations regarding the dimensions of the trocar cannula and surgical clips which supply the limitations it wishes to read into Claim 36. Plaintiff refers to the remarks section of its Response to Office Action, Dated April 30, 1992 in which its patent counsel summarized an interview with the patent examiners. The remarks include, inter alia, the following description of a demonstration of plaintiff's device at the interview:

As was demonstrated at the interview, applicant's commercial embodiment of applicant's device is not only automatic, but can apply medium/large clips having about a 5.33 millimeter width between the outer surfaces of their legs. This permits the instrument to be used with a trocar having a cannula with an internal diameter of about 10 millimeters.

"It is elementary that resort must be had in the first instance to the words of the claim which define the metes and bounds of the invention." Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed. Cir. 1984). Limitations not found in the language of a claim cannot be read into the claim. E.I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430 (Fed. Cir. 1988), cert. denied, 488 U.S. 986, 102 L. Ed. 2d 572, 109 S. Ct. 542 (1988). Limitations appearing in the patent specification cannot be read into the claims. Id. Nor is it permissible to inject into claims limitations referred to in the prosecution history. Intervet America, Inc. v. Kee-Vet Labs, Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989).

While limitations contained in the specification or prosecution history may be used where necessary to interpret what the patentee meant by a word or phrase in a claim, see e.g., Minnesota Mining & Mfg. v. Johnson & Johnson, 976 F.2d 1559
(Fed. Cir. 1992), there is no warrant for resorting to the prosecution history for such a purpose in this case. The words of
Claim 36 are plain, they do not include any dimensional limitations on the size of the trocar or the surgical clip. The absence
of limitations and the use of the word "given" when referring to the internal diameter of the cannula reflect a conscious
intent by the drafter of this claim to make it as broad as possible so as to include a trocar of any size in combination with a
clip applier having jaws of any size. In oral argument on this motion, counsel for plaintiff admitted that Claim 36 was so
intended:

There could be, the reason the claim is not written with specific numerical dimensions, art does change. Things may be
available later on with the advent of better suturing, when you are coming out of the abdomen, you can use larger trocars,
and then we could use larger jaws, larger clips, etc.

Likewise, in opposing defendant's motion for summary judgment of non-infringement, plaintiff said with respect to Claim
36:

In construing a patent claim, the focus must be on the language of the claim itself. That is crucial because it is the claim --
rather than statements in the prosecution history or the patent specification -- that defines the metes and bounds of the
invention…

If, as is the case here, the claim was drafted so as to obtain the broadest coverage with the fewest "limitations" on the
scope of coverage, it is entitled to be so construed.

offered in support of this proposition the declaration of John P. Milnamow, its outside patent counsel who prosecuted the
application for the '249 Patent. Mr. Milnamow stated:

Thus, not only is this prosecution history consistent with my intent and the objective construction which a facial reading
of Claim 36 compels, but it reinforces my intention to have this particular claim contain as broad coverage as possible. The
only objective limitations in the claim are the jaws, which extend outwardly from the shaft and must be wide enough to
receive the clip but narrow enough to be entered into a trocar without compressing, and the single trigger… It was my intent
and it remains my professional opinion that any endoscopic multiple clip applier having these characteristics infringes this
claim. (Emphasis in the original).

Milnamow Declaration, Appendix to Ethicon's Memorandum in Opposition to Richard-Allan's Motion For Summary
Judgment, Doc. 48.

The prosecution history plaintiff relies on to import limitations into Claim 36 consists only of a description of a
demonstration of a device. There is no suggestion in the description that plaintiff's patent lawyers represented to the patent
examiners that plaintiff intended that the claims of the patent would be limited to the dimensions of the device
demonstrated. Even if the Court were persuaded that it was proper to consider this part of the prosecution history to interpret
Claim 36, it would add nothing of value to the interpretation and would raise no genuine issue of fact relating to the
existence of dimensional limitations in that claim.

Plaintiff solved the problem of designing an endoscopic automatic multiple clip applier for medium/large clips with jaws
narrow enough to fit through a 10/11 millimeter trocar cannula with the jaws in the open position. It did so by incorporating
a design feature in the jaws which plaintiff refers to as a "primary heel." The claims of the '249 patent relating to the jaw and
other specific aspects of the Ethicon device may well be valid and enforceable. In this case, however, Ethicon has elected to
assert only the broadest claim in its patent, Claim 36 which, by its own admission fails for obviousness in the absence of
size limitations which do not appear in the claim and which the Court concludes cannot properly be read into the claim.
Accordingly, defendant's motion for summary judgment on the issue of obviousness is well taken.
Claim terms are given their ordinary meaning to one skilled in the art unless it appears from the patent and prosecution history that the terms were used differently by the inventors. Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387, 21 U.S.P.Q.2d (BNA) 1383, 1386 (Fed. Cir. 1992). In this case, the claims specified that the trocar used to practice the invention was of a "given internal diameter." The patentee now argues that one skilled in the art would understand the phrase "given internal diameter" to be limited to 10/11 millimeters; he asks us to accept that construction in order to avoid undisclosed prior art. We cannot do that. Neither can we accept the patentee's equally unsupported position that the phrase "endoscopic multiple applier" is limited to a clip applier that applies medium/large size clips. This meaning is unsupported by the claims, specification and prosecution history. Nowhere in the claims, specifications or the prosecution history was there any elaboration of size encompassed within those phrases. Furthermore, Ethicon submits no substantial extrinsic evidence to support its position.

We understand the tension between, on the one hand, drafting a claim as broadly as possible and, on the other hand, limiting the claim's breadth so that the claim is valid. In this case, Claim 36 of the '249 patent is drafted so broadly as to cover the prior art, making the claim invalid. The fact that the Patent and Trademark Office ("PTO") granted the patent does not undercut the claim's obviousness. The PTO was not informed of U.S. Surgical's "Long Surgiclip" and, had they been aware, they might well have reached the same conclusion.

Under a proper construction of the claim language in this case, Claim 36 of the '249 patent is invalid as obvious. Therefore, the district court's grant of summary judgment is affirmed.

a. GLASS FIBERS: Intrinsic Evidence

The competing asserted meanings for "glass fibers" are "glass threads or filaments or pieces thereof" (Plastpro) and "bundles of filaments" (Therma-Tru). Because it is "the most significant source of the legally operative meaning of disputed claim language," Vitronics, 90 F.3d at 1582, the Court turns first to the intrinsic evidence of record. All the independent claims of the '540 patent require that the outside of the door skins be "essentially devoid of glass fibers for a predetermined depth of at least 0.005 inch." The specification uses the terms "fibrous glass reinforcement" and "glass fibers." (McQuillen Dec., Exh. A, col. 2, ll. 43, 68.). "Fibrous glass reinforcement" describes one of the components of the sheet molding compound, or resin, compressed to form the door skins. (Id., ll. 41-44.). In another portion of the specification, the disputed term is used in the following manner:

The elimination of glass fibers from the surface of the exterior side provides the present structure with several advantages. First, it allows the fine grain texture to be placed in the surface to a defined depth without exposing glass fibers. The [sic] prevent wicking and other inherent fibrous glass problems from occurring. At the same time, it allows the fibrous glass reinforcement to be distributed closer to the centroid of the skin. This results in a door structure which reduces deflection.

(Id., col. 3, ll. 16-24.) (emphasis added).

The specification does not expressly or impliedly define "glass fibers." Furthermore, there is no indication in the specification that the patentee ascribed a special meaning to the term. Nor does the prosecution history reveal any special meaning of the term. In fact, the fiber-free claim limitation does not appear in the '400 application in any form. The rejected '549 CIP application included the fiber-free claim limitation, but with no special meaning attached to the term. As recently as 2002, the Patent Office challenged the fiber-free limitation for obviousness. Therma-Tru's response echoed the language of the fiber-free claim limitation and does not assist the Court in its construction of the term. The Court therefore cannot agree with Therma-Tru that the plain language of the specification alone resolves the claim construction question.

As the intrinsic evidence of record -- the claim language, the specification, and the prosecution history -- does not indicate that Therma-Tru ascribed a particular meaning to the claim term, "glass fibers" must take on the ordinary meaning to one skilled in the art. Digital Biometrics, 149 F.3d at 1344. For this inquiry, the Court consults dictionaries, encyclopedias, and treatises.
b. GLASS FIBERS: Ordinary Meaning in the Relevant Art

In support of its construction of "glass fibers" as "glass threads or filaments or pieces thereof," Plastpro directs the Court to both general and technical dictionaries, as well as trade encyclopedias and engineering manuals available at the time the '540 patent issued. A general dictionary defines "fiber" as "a filament; any threadlike part of a substance." See Exh. N, WEBSTER'S NEW UNIVERSAL UNABRIDGED DICTIONARY 680. "Filament" is in turn defined as "a thread; a fiber." See id. at 684. A scientific/technical dictionary defines "glass fiber" as "[a] glass thread less than a thousandth of an inch thick, used loosely or in woven form as a . . . reinforcing material in laminated plastics." See Exh. O, MCGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNICAL TERMS 685. Finally, one scientific dictionary essentially defines "fiber" and "filament" as synonyms of one another. See Exh. P, THE CONDENSED CHEMICAL DICTIONARY 388 (defining "filament" as "a continuous fiber"). An engineering manual on materials states that standard glass fiber is spun as "single glass filaments . . . collected into strands that are manufactured into many forms of reinforcement." See Exh. Q, MATERIALS HANDBOOK 385.

In support of its construction of "glass fibers" to include "pieces of filaments," Plastpro cites to a handbook on reinforced plastics in which it is noted that "chopped fiber lengths" are used as reinforcement in sheet molding compounds such as are at issue in this case. See Exh. T, HANDBOOK OF TECHNOLOGY AND ENGINEERING OF REINFORCED PLASTICS/COMPOSITES 216.

The above objective sources clearly support construction of "glass fibers" as threads, filaments, or pieces of filaments. However, as discussed below, Therma-Tru urges that the plain meaning of the term is "bundles of filaments" or, if not, then the Court should look beyond the demonstrated plain meaning of the term to find a definition more suited to the practical functioning of glass fibers in the invention.

In support of its "ordinary meaning" position, Therma-Tru argues that, because the '540 patent specification implicitly defines "glass fibers" as "bundles of filaments," Plastpro erroneously relies on extrinsic evidence to support its construction. 7 Therma-Tru contends that an implicit definition is discernible from the '540 patent's fiber-free limitation as "glass threads or filaments or pieces thereof." Although the claim construction in Pease does not bind this Court, the Court has considered the underlying reasoning for the Michigan district court's construction of the same claim limitation disputed in this case. In Pease the court adopted the recommendations of a Special Master who reviewed the intrinsic and extrinsic evidence in the case. The court found that the Master's recommended construction comported with the form in which such fibers are used in the industry. See Exh. W at 3; Exh. X at 20.

The above objective sources clearly support construction of "glass fibers" as threads, filaments, or pieces of filaments. However, as discussed below, Therma-Tru urges that the plain meaning of the term is "bundles of filaments" or, if not, then the Court should look beyond the demonstrated plain meaning of the term to find a definition more suited to the practical functioning of glass fibers in the invention.

In support of its "ordinary meaning" position, Therma-Tru argues that, because the '540 patent specification implicitly defines "glass fibers" as "bundles of filaments," Plastpro erroneously relies on extrinsic evidence to support its construction. 7 Therma-Tru contends that an implicit definition is discernible from the '540 patent's repeated use of the term "glass fibers." It also argues that the prosecution history reinforces its proposed construction. Therefore, it is Therma-Tru's position that the Court need go no further than the intrinsic evidence in the record to construe the fiber-free claim limitation.

7 However, Therma-Tru itself offers extrinsic evidence almost exclusively to support its construction of "glass fibers." See Def.'s Opp. Br., at 13-17.
Therma-Tru further argues that general and technical dictionaries do not consistently define a "fiber" as a "filament." Therma-Tru is correct that differing dictionary definitions must be reconciled with reference to the patent itself, but it does not offer a contemporaneous objective source to support its construction. Rather, Therma-Tru relies on the testimony of several experts.

For example, Kenneth West, a Therma-Tru employee involved in the production of fiberglass doors, concluded in his Technical Expert Report that "if individual filaments are used in the SMC manufacturing process, the resulting door skins would be unacceptable in appearance and strength." (Dec. of Sangeeta Shah, Exh. D, at 16.). Mr. West further noted:

The functional characteristics of the '540 'glass fibers' clarify the patentee's intent in defining 'glass fibers' to constitute a bundle of filaments and not a single filament. The use of fine grain texturing at the surface to a defined depth does prevent surface exposure of bundles of filaments, i.e., glass fibers. However, surface texturing cannot eliminate single break away filaments from being exposed at the surface. Moreover, the existence of these single glass filaments at the exterior surface does not affect any of the functional reasons identified in the '540 patent for suppression of glass fibers, i.e., to avoid wicking, provide reinforcement, a high quality surface appearance, and ease in handling.

(Id. at 17.)(emphasis in original).

Robert R. Jackson, Director of Research and Development at Therma-Tru, testified that a fiber is a "bundle of filaments." (Id., Exh. F, at 28.). John M. Maxel, an expert for Therma-Tru in this litigation, also testified that a "fiber" is a "bundle of filaments," and acknowledged that while a bundle consists of approximately 200 filaments, as few as 100 filaments would also constitute a bundle. (Id., Exh. G, at 18 11. 20-23; at 21-22.). Therma-Tru also offers the testimony of John E. Thorn, the inventor, who testified that the intent of the patent was to suppress the majority of the fibers (which he referred to as "clusters of filaments") from the top .005 inch of the door skin. (Id., Exh. H, at 27, ll. 7-16.)

As a threshold issue of the correct legal standard to apply to Therma-Tru's evidence, the Court notes that the Federal Circuit clearly favors "objective resources" such as dictionaries, encyclopedias, and treatises over expert testimony on claim construction:

Dictionaries, encyclopedias, and treatises, publicly available at the time the patent is issued, are objective resources that serve as reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art. Such references are unbiased reflections of common understanding not influenced by expert testimony or events subsequent to the fixing of the intrinsic record by the grant of the patent, not colored by the motives of the parties, and not inspired by litigation.

Texas Digital Sys., 308 F.3d at 1202-03.

These objective sources are preferred over the expert testimony of attorneys, technical experts, and even the inventors themselves. Vitronics, 90 F.3d at 1585. Given that "opinion testimony on claim construction should be treated with the utmost caution, for it is no better than opinion testimony on the meaning of statutory terms," id., the Court places emphasis on contemporaneous objective resources over opinion testimony to discern the ordinary meaning to one skilled in the art.

As to its "practical functioning" position, Therma-Tru does not convincingly show that the ordinary meaning of glass fibers is inconsistent with the practical function of glass fibers in the invention. The Court addresses each of Therma-Tru's "functional" arguments that Plastpro's proposed construction contradicts the "implicit definition" of the term.

1. Individual Filaments Are Not Available to Purchase

Therma-Tru contends that "glass fibers" must mean "bundles of filaments" because one cannot purchase single glass threads. However, this is irrelevant to the Court's inquiry into the proper meaning of "glass fibers" as used in the invention. Indeed, the form in which a raw material is marketed and sold may have little resemblance to the form it assumes once incorporated in a patented product or process. Furthermore, there is evidence in the record that bundles or rovings of glass fibers may "filamentize," or break down into individual threads, during the compression molding process, which further suggests that the relevant inquiry is not the form the fiberglass takes at the time of purchase, but the form it assumes when
used in the molding process. See McQuillen Dec., Exh. M P 41 (distinguishing "hard" glass from "soft" glass and noting that, when combined with the SMC resin, the latter "tend[s] to separate into individual filaments."); see also id., Exh. Q, MATERIALS HANDBOOK 385 (noting that "fibers spun as single glass filaments . . . are collected into strands that are manufactured into many forms of reinforcement," thus implying that the manufactured form may vary widely from the ultimate reinforcing form.).

2. Individual Filaments Do Not Perform the Required Reinforcement

Therma-Tru next contends that individual filaments cannot adequately reinforce the door skins. Its essential argument is that single filaments "would cause the SMC compound to fall apart during molding." (Def.'s Opp. Br., at 16.). However, construing "glass fibers" to mean filaments does not contravene the reinforcing function attributed to "glass fibers" in the specification. The description of the glass fibers' function in the specification is as follows: "The elimination of glass fibers from the surface of the exterior side . . . allows the fibrous glass reinforcement to be distributed closer to the centroid of the skin. This results in a door structure which reduces deflection." (McQuillen Dec., Exh. A, col. 3, ll. 16-24.). The McGraw-Hill Dictionary of Scientific and Technical Terms, a source available at the time the '540 patent issued, notes that a glass fiber may be "used loosely or in woven form . . . as a reinforcing material." (Id., Exh. O, at 685.). Therefore, to one skilled in the art, the ordinary meaning of "glass fiber" in the reinforcement context must include individual filaments.

3. Individual Filaments Do Not Solve the "Wicking" Problem

Therma-Tru argues that the wicking problem only arises if bundles of filaments occur at the surface of the skins; because single filaments are incapable of wicking stain, the '540 patent thus implicitly defines fibers to mean bundles. In support, Therma-Tru points only to the patent itself and a general definition of wicking in support of its position. However, the statements of Therma-Tru's experts make clear that the precise quantity of filaments required to make a wicking-resistant bundle is not clear.

On the one hand, Therma-Tru's Kenneth West testified that "[a] bundle of filaments includes approximately 200 glass filaments." (Shah Dec., Exh. D at 16.). Burr L. Leach, a Therma-Tru expert in prior litigation, stated that a fiber consists of approximately 264 filaments. (Id., Exh. E, at 95, ll. 11-15.). John M. Maxel, Therma-Tru's expert in this litigation, testified that a fiber consists of approximately 200 filaments, but that even 100 filaments could also constitute a fiber. (Id., Exh. G, at 21-22.). Maxel emphasized that defining a fiber in terms of filaments is "not black and white." (Id. at 22.).

Significantly, West testified that as few as three filaments could cause a wicking problem. (McQuillen Reply Dec., Exh. D, at 59, ll. 23-25.). If as few as three filaments can cause wicking (and none of the cited experts suggests that three filaments would constitute a "bundle"), it cannot be that "the wicking problem only arises if bundles of filaments occur at the surface of the skins." Therefore, it would be consistent with the specification to construe "glass fibers" as "threads" or "filaments" or "pieces thereof" because, if not suppressed to a certain depth below the surface, even a few filaments can cause a wicking problem.

Because the ordinary meaning of the term to one skilled in the art is not inconsistent with the intrinsic evidence, Vitronics, 90 F.3d at 1584 n.6, the Court finds that "glass fibers" should be interpreted as "glass threads or filaments or pieces thereof.

B. The "glass mat-faced" claims

USG argues that the district court misconstrued the meaning of the limitation "glass mat-faced" and that when properly construed the "faced" claims 8 could not be infringed by USG's fiberglass gypsum board.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

8 Claims 1, 2, and 5 of the '496 patent and claims 1 and 2 of the '900 patent can be classified as "faced" claims.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
Claim 1 of the '496 patent is representative of these claims:

An exterior insulation system for a building comprising a glass mat-faced gypsum support surface, insulating material having an inner surface and an outer surface, the inner surface of which is adhered to said support surface by an adhesive material, the insulating material being substantially free of channels penetrating therethrough and between said inner and outer surface, and an exterior finishing material overlying the outer surface of said insulating material. (Emphasis added.)

USG asserts that "glass mat faced" means that the surface of the board facing out from the studs to which insulation is applied is an exposed, non-gypsum covered glass mat. The district court, however, adopted Georgia-Pacific's construction that the term "glass mat-faced" means "glass mat surface reinforcing material." Because USG's board is reinforced with fiberglass mats the court upheld the jury's finding that the "faced" claims were infringed.

USG argues that during prosecution of a different patent application in which claims were rejected in light of the Pilgrim patent, U.S. Patent No. 4,378,405, Georgia-Pacific surrendered any interpretation of the term "faced" that would include a completely embedded or coated fiberglass mat. The prosecution history statement relied on by USG was made by Georgia-Pacific nine months after the glass mat-faced claims of the '496 patent issued. There Georgia-Pacific stated:

The Pilgrim patent does not disclose glass mat-faced gypsum board. To the contrary, this patent discloses a gypsum board in which the glass mat is covered by a thin layer of gypsum (emphasis original).

USG argues that Georgia-Pacific used the term "faced" to distinguish its board from prior art fiberglass mat-reinforced boards based upon the difference between leaving the fiberglass mat on the working surface exposed versus completely embedding it.

Georgia-Pacific argues that this post-issuance statement is extrinsic evidence and should be rejected because the intrinsic evidence alone resolves any ambiguity of this disputed claim term.

The specification of the patent in suit is the best guide to the meaning of a disputed term. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2d (BNA) 1573, 1576-77 (Fed. Cir. 1996); see also Bell & Howell Document Management Prod. Co. v. Altek Sys., 132 F.3d 701, 705, 45 U.S.P.Q.2d (BNA) 1033, 1037 (Fed. Cir. 1997) ("When construing a claim, a court should look first to the intrinsic evidence, i.e., the claims themselves, the written description portion of the specification, and the prosecution history.) Additionally, when intrinsic evidence is unambiguous, it is improper for the court to rely on extrinsic evidence to contradict the meaning of the claims. See Pitney Bowes, Inc., v. Hewlett-Packard Co., 182 F.3d 1298, 1308-9, 51 U.S.P.Q.2d (BNA) 1161, 1167-68 (Fed. Cir. 1999).

The '496 patent states at col. 9, lines 39-43:

Although improvements in an EISystem can be realized by the use of a gypsum core which has but one of its surfaces faced with fibrous mat as described herein, it is preferred that both surfaces of the core be faced with substantially the same fibrous material . . . .

Because the '496 patent refers explicitly to both surfaces of the board being faced, "faced" cannot mean only the surface facing out from the studs as is necessary for USG to prevail. Furthermore, in the prosecution of the '496 patent Georgia-Pacific's patentee declared to the PTO: "One of the glass fiber mat-reinforced surfaces was substantially gypsum-free and the opposite surface was substantially gypsum covered." Thus, the glass mat-faced term was represented to mean both surfaces of the board one of which was described as covered with gypsum. For these reasons we are convinced that the district court properly construed the "faced" claims.

We also note that for Georgia-Pacific to be bound by the statement made to the PTO in connection with a later prosecution of a different patent, the statement would have to be one that the examiner relied upon in allowing the claims in the patent at issue. See Mannesmann Demag Corp. v. Engineered Metal Prods. Co., 793 F.2d 1279, 1284-85, 230 U.S.P.Q. (BNA) 45, 48 (Fed. Cir. 1986) ("In cases where a patentee's amendments were not required in response to an examiner's rejection or critical to the allowance of the claims, no estoppel has been found.")
Vanderlande challenges the ITC's construction of the claim limitation "glide surface surrounding said [slat] wall." Vanderlande contends that this claim limitation refers to an inner surface of a diverter shoe that contacts the outer surface of the slat on all sides. So construed, Vanderlande does not infringe claims 1 and 4, as it is undisputed that the inner surface of the Mark 2 Posisorter's diverter shoe only contacts the outer surface of the slat on three sides, and does not contact the top of the slat. The ITC rejected Vanderlande's argument as to contact, determining that the limitation at issue actually did not require any contact at all:

The term "glide surface" in claim 1 [and incorporated by reference in claim 4] is merely a two-dimensional surface and does not imply any points of contact or non-contact between the inner surface of the diverter shoe and the outer surface of the slat wall. Points of contact or non-contact between the glide surface and the slat wall are not claimed features of this element of claim 1. . . . All that matters to being a "glide surface," really, is whether the inner surface of the Mark 2 Posisorter shoe (i) moves over or along the surface of the slat in a smooth, effortless manner without pivoting or rolling; and (ii) is two-dimensional. There is no factual dispute that the Mark 2 Posisorter shoe's inner surface possesses these characteristics. Ergo, the inner surface of the Mark 2 Posisorter constitutes a "glide surface" as that term is used in claim 1.

We review the ITC's claim construction de novo. Honeywell, 341 F.3d at 1338. We seek to determine what a person of ordinary skill in the art would understand the claims to mean "in light of the intrinsic evidence of record, including the written description, the drawings, and the prosecution history, if in evidence." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324 (Fed. Cir. 2002). While extrinsic evidence can shed useful light on the relevant art -- and thus better allow a court to place itself in the shoes of a person of ordinary skill in the art -- the "intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Indeed, a "court should look first to the intrinsic evidence of record," id., to determine if the patentee "expressly defined terms used in the claims or . . . defined terms by implication," Dow Chem. Co. v. Sumitomo Chem. Co., Ltd., 257 F.3d 1364, 1373 (Fed. Cir. 2001).

The critical term in the limitation "glide surface surrounding said [slat] wall" is "glide surface," as the parties agree that the ITC correctly construed "surrounding" to mean "to extend on all sides; to encircle; to enclose on all sides to cut off communication or retreat." ALJ Op. at 69. The written description's most detailed discussion of the term "glide surface" is in the context of the explanation of the preferred embodiment:

Each diverting shoe 28 includes a support member 44 and a diverting member 46 mounted to the support member (FIG. 2). Support member 44 includes a glide portion 48 having a continuous glide surface 50 having substantially the same configuration as the outer surface of slat 22 for gliding movement along the slat. . . . Continuous surface 50 includes a channel 58 surrounding projection 42 of the slat such that the projection rides within the channel (FIGS. 8, 9, and 11). Continuous surface 50 additionally includes a support rib 60 which engages top wall 30 of the slat to support an upper wall 62 of the support member. Continuous surface 50 additionally includes an enlarged radius forward upper corner 64 and an enlarged radius lower rear corner 66, in which enlarged radius corners 38 and 40 of the slat, respectively, ride. This arrangement provides bearing engagement between the enlarged radius corners of the slat and the corresponding corners of surface 50 to resist reaction forces tending to rotate the shoes about the axis of elongation of the slat. . . .

'510 patent, col. 3, ll. 26-51. As this passage and the accompanying drawings make plain, "contiguous glide surface 50" is the inner surface of the diverter shoe.

In the preferred embodiment, the glide surface contacts the outer surface of the slat at various points; these points of contact resist the reaction forces that are generated when the diverter shoe pushes an item across the slat. At the upper-left corner and the bottom-right corner of the slat, the slat engages the glide surface's "enlarged radius forward upper corner 64 and . . . enlarged radius lower rear corner 66." Id. at col. 3, ll. 44-45. In the drawings of the preferred embodiment, both the upper-right and bottom-left corners of the slat also appear to make contact with the glide surface. On the top of the slat, the slat
engages the glide surface's "support rib 60." Id. at col. 3, l. 41. On the bottom of the slat, a projection off the slat rides within the glide surface's "channel 58." Id. at col. 3, l. 38. The above-referenced parts of the glide surface are depicted (without the slat) in figure 8:3

Footnotes

3 Support rib 60 is visible but not numbered in this figure; the support rib is numbered in figure 9, set out supra.

End Footnotes

But in the preferred embodiment, the glide surface also has regions that do not contact the slat. Indeed, regions of noncontact are found on every side of the slat, as can be discerned on close inspection of figure 2:

GET DRAWING SHEET 1 OF 6.

Vanderlande acknowledges that the glide surface in the preferred embodiment has regions that do not contact the slat, but emphasizes that the glide surface includes at least some contact with every side of the slat. Vanderlande's argument is accurate with respect to the preferred embodiment, which includes not only midsection contact points on the top and bottom of the slat, but also contact points at the corners of the slat.

But the "Summary of the Invention" (quoted at length supra) expressly contemplates other embodiments, stating that the invention includes embodiments with contact "between at least one edge [i.e., corner] of each slat and an engaging portion of the glide surface of the diverter shoe." Id. at col. 1, ll. 65-66 (emphasis added). Moreover, while the "Summary of the Invention" describes a midsection contact point on the bottom of the slat, it does not describe a midsection contact point on the top of the slat. In short, the "Summary of the Invention" teaches that the invention embraces glide surfaces that do not contact the slat on all sides, e.g., a glide surface with contact points only on the bottom of the slat and one corner of the slat. While such glide surfaces may not be optimal -- indeed, the "Summary of the Invention" emphasizes that it is preferable to have bearing means at "diagonally opposite slat edges in order to better resist reaction forces about the axis of the slat," id. at col. 2, ll. 1-2 -- they do fall within the disclosure of the invention, indicating that the patent requires a broader meaning of "glide surface" than the one pressed by Vanderlande.

Vanderlande argues that statements of Siemens/Rapistan to the European Patent Office ("EPO") during the prosecution of a European counterpart to the '510 patent support Vanderlande's contention that a glide surface must contact the slat on all sides. In the prosecution to which Vanderlande refers, the EPO initially rejected the patent application in view of a prior-art reference, a shoe sorter that used "skids" to stabilize the shoe on the slat. Siemens/Rapistan argued to the EPO examiner that if the skids themselves were considered to be the "glide surface," the glide surface would not "surround" the slat as required by the Siemens/Rapistan application:

In Claim 1 of the present [European] application, the slat is defined by a wall which has an upper portion defining the conveying surface, and the wall is surrounded by a glide surface of the diverter shoe. This does not appear to be the case in [the prior art reference]. In annex 1 of the official communication, the Examiner indicated that the planar upper portion [i.e., the top wall of the slat] . . . is surrounded by the skids, but this does not appear to be the case, because the planar upper portion is above the skids.

ALJ Op. at 65 (citations omitted). As the ALJ properly determined, the "distinctions in [Siemens/Rapistan's] counterargument to the EPO have nothing to do with whether or where the 'glide surface' contacts the slat." Id. at 68.

The extrinsic evidence likewise fails to show that those skilled in the relevant art would understand a "glide surface" as having contact on all sides. At the evidentiary hearing before the ALJ, the expert witness for Siemens/Rapistan and the inventors named on the '510 patent testified that the term "glide surface" had no independent meaning in the art of sortation systems. Vanderlande did not present any evidence to the ITC that the term "glide surface" had any meaning in this art. Instead, Vanderlande argued to the ITC, and contends on appeal, that the term has an "ordinary meaning" that requires contact. The linchpin of Vanderlande's argument is a definition of the noun form of "glide" found in a general-usage
dictionary: "a device for facilitating the movement of something; esp: a circular usu. metal button attached to the bottom of furniture legs to provide a smooth surface." Merriam Webster's Collegiate Dictionary (10th ed. 1998). Vanderlande places particular weight on the illustrative example of the button on the bottom of a furniture leg, emphasizing that the furniture-leg button completely contacts both the furniture leg and the floor.

4 On appeal, Vanderlande asserts that it has found "over 200 patents using the term ['glide surface'] to describe a low friction contact surface" and discovered similar results using an Internet search engine. Vanderlande does not state, however, whether these patents and Internet findings are specific to the art of sortation systems. In any event, Vanderlande did not present this evidence to the ITC, and we thus hold any argument based on this evidence to be waived.

Vanderlande's reliance on this illustrative example from a general-usage-dictionary definition is unpersuasive, for several reasons. First, Vanderlande misapprehends the proper role of general-usage (as opposed to technical, art-specific) dictionaries in claim construction. Claims are to be construed from the vantage point of a person skilled in the relevant art. To the extent that this artisan would understand a claim term to have the same meaning in the art as that term has in common, lay usage, a general-usage dictionary can be a helpful aid to claim construction. But where evidence -- such as expert testimony credited by the factfinder, or technical dictionaries -- demonstrates that artisans would attach a special meaning to a claim term, or, as here, would attach no meaning at all to that claim term (independent of the specification), general-usage dictionaries are rendered irrelevant with respect to that term; a general-usage dictionary cannot overcome credible art-specific evidence of the meaning or lack of meaning of a claim term. Cf. Dow Chem., 257 F.3d at 1373 ("We have previously cautioned against the use of non-scientific dictionaries, 'lest dictionary definitions . . . be converted into technical terms of art having legal, not linguistic significance.'" (quoting Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1478 (Fed. Cir. 1998))). As the ITC properly determined in this case: Vanderlande's effort to attribute to the term "glide surface" the ordinary dictionary definition of the word "glide" alone is misplaced. Vanderlande did not present any evidence outside of the dictionary definition of the word "glide" to show that "glide surface" has an ordinary meaning in the material handling industry or in the sortation industry. By contrast, [Siemens/Rapistan] demonstrated, through its expert witnesses having personal experience in the material handling and diverter sortation field, that "glide surface" does not have an ordinary meaning, and the [ITC] Staff agreed with this view.

ALJ Op. at 61 (citations omitted).

Second, even if general-usage dictionaries could be useful in circumstances like these, the definition of the noun "glide" cited by Vanderlande -- "a device for facilitating the movement of something" -- concerns only one word in a two-word claim term and is vague, abstract, and fails to connote a particular structure. Indeed, Vanderlande does not even rely on the definition itself, but rather on an extrapolation from the illustrative example of the furniture-leg button. Vanderlande's argument rests on a long series of tenuous assumptions: the word "glide" in the claim term "glide surface" is based on the noun form, not the verb form; the characteristics of the illustrative example of the furniture-leg button necessarily obtain with respect to all glides; therefore every "glide surface" must have the characteristics of the furniture-leg button; therefore a glide surface surrounding a three-dimensional structure -- like a conveyor-belt slat -- must contact this structure on all sides just as the button contacts the floor. Vanderlande's shaky syllogism cannot overcome the uncontroverted testimony regarding the lack of ordinary meaning of "glide surface" in the art of sortation systems.

Third, in any event Vanderlande's dictionary argument is entirely eclipsed by the '510 patent's written description, which provides detailed, art-specific examples of glide surfaces, not only in the preferred embodiment but also in the express contemplation of other embodiments, including embodiments in which the glide surface does not contact every side of the slat. See Dow Chem., 257 F.3d at 1373 (stating that "any definition found in or ascertained by a reading of the intrinsic evidence may not be contradicted by any meaning found in dictionaries"). As noted above, the "intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics, 90 F.3d at 1582, and this is particularly true where, as here, the written description provides definite and readily discernible guidance as to the intended meaning of a structural claim term. Indeed, it is doubtful whether any extrinsic evidence could contradict or overpower the meaning evident from the written description here, and certainly Vanderlande's furniture-leg button cannot do so.
Vanderlande argues that its construction of "glide surface" is buttressed by the content of a mediation statement prepared by Siemens/Rapistan in connection with the mediation of a prior litigation. The content of this mediation statement, which would be inadmissible in a patent suit in federal district court, see Federal Rule of Evidence 408 ("Evidence of conduct or statements made in compromise negotiations is . . . not admissible."), was at most a theory advanced in a proceeding to mediate a separate litigation, upon which we place little--if any--weight in claim construction, cf. Beckson Marine, Inc. v. NFM, Inc., 292 F.3d 718, 726 (Fed. Cir. 2002) ("Litigation theories -- to the extent not expressed in claim language, the patent specification, or the prosecution history -- do not affect claim scope."). In any event, we have considered the mediation statement (which the parties marked as confidential) and believe it is ambiguous with regard to the claim-construction issue at hand. We conclude that a "glide surface" is a diverter shoe's inner surface that has some contact, but not necessarily complete contact, with the outer surface of the slat, and that need not contact all sides of the slat. We note that our construction of "glide surface" is different from the ITC's construction, which did not require any contact at all. We believe the ITC's definition was overly broad. Indeed, the ITC's definition could conceivably embrace "no-contact" technologies far beyond the patent's disclosure, such as a glide surface that rides above the slat on air currents, or a glide surface that is magnetized to repel the outer surface of the slat.

Returning to the claim limitation as a whole, we conclude that "glide surface surrounding said [slat] wall" refers to a glide surface (as just defined) that completely encircles the slat. This construction embraces Vanderlande's Mark 2 Posisorter, whose diverter shoe's inner surface has some contact, but not complete contact, with the outer surface of the slat, and which completely encircles the slat.

The district court's misconstruction of the "glide" limitation flows from its misunderstanding of the claim language, "gliding along a support," which according to the district court requires that the glide "moves the user in a certain course," see Mattox, 2004 WL 1638202, at *7. As the decision on infringement makes clear, the district court understood "in a certain course" to mean along a path directed by a guide. Put differently, the district court believed that claim 1 defines the "glide" using language that requires the glide to travel along a directional support that limits nonlinear movement, e. g., a "guide track." See, e. g., the '961 patent, Figure 8. This is incorrect.

The claim language, "gliding along a support," plainly includes traveling over a floor. Consequently, the district court erred when it read out of claim 1 embodiments of the glide structure that "glide[] on the floor." See Mattox, 2004 WL 1638202, at *11. Absent statements in the intrinsic record to the contrary, where claim language is plainly susceptible to an interpretation that includes the described embodiments, that interpretation is the better interpretation. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996) (reasoning that an interpretation that excludes a preferred embodiment is unlikely to be correct).

Such is the case here. A glide that travels along a support surface which can be a floor is depicted in the '961 patent. See, e. g., the '961 patent, Figures 1, 4, 5, 6, & 7. Clearly, as the depicted glide moves along the support surface, it is not subject to the constraints of a "guide track." See id. Moreover, in one embodiment, item 114, which is described as elastic tubing, see the '961 patent, col. 5, l. 38, is not present, see id., col. 9, ll. 50-52. In such an embodiment the only feature controlling the course of the gliding motion is the ability and decisionmaking of the user.

Based on its misapprehension of the claim meaning, the district court erroneously held that the "glide" limitation could not be met. Because the accused device contains "a glide for supporting arms of a user in a forward kneeling position and gliding along a support," the accused device meets the "glide" limitation of the '961 patent. As the district court understood, a glide is a device for facilitating the movement of something. As set forth in the record, the glide of the accused device is clearly capable of supporting the arms of a user in the operation of the device. The user can keep both arms parallel or otherwise. Furthermore, the glide in the accused device facilitates "gliding along a support" because it permits the user to travel over a floor.
Variations of the term "global alignment" appear in three '832 patent claims. In their claim construction memoranda, the parties have not brought the terms of their "global alignment"-related dispute into firm relief, leaving it to the court to divine both the meaning of the claim terms and the contours of the parties' dispute. As the term is used repeatedly in the '832 patent, "global alignment" offers a kind of technological counterpoint to "field-by-field" alignment. Where "field-by-field" alignment denotes the process through which individual substrate sub-areas are aligned for exposure, "global" alignment denotes the alignment (i.e., positioning relative to the mask pattern) of the entire substrate form. In this vein, reading "global" to connote "entire" comports with both the plain meaning of the term and the intrinsic evidence.

By reference to the use of prior art, the specifications teach that "with this system an alignment mark provided in the substrate and an alignment mark provided in the mask outside the mask pattern are imaged on each other and the mutual positions of the marks are determined." See '832 Patent at 2:9-12. "Initially," the specifications add, "two and possibly several further substrate alignment marks outside the substrate area which must be repetitively illuminated with the mask pattern are aligned . . . . This alignment is known as the global alignment." Id. at 2:20-25; see also Exh. 2 at 264 (April 5, 1993, prelim. am.) ("Global alignment means that two or more alignment marks at the edge of the substrate are aligned relative to corresponding marks on the reticle."); '832 File History, Am., March 20, 1998, p. 4. Against this intrinsic evidence, Nikon's contention that this tardily-added claim requires the court to confine the relevant type of alignment to that of sub-area components is unconvincing. "Global alignment," the claim notes, is "realized" through

imaging mask alignment marks and substrate alignment marks onto each other by the projection system; observing the extent of overlap between an alignment mark image and the alignment mark on which the image must be formed; displacing along a first, X axis and a second, Y axis of a three-axes system of coordinates and rotation about the third, Z axis of the system of coordinates of the mask pattern and the substrate relative to each other until a sufficient degree of overlap is obtained; positioning each individual sub-area with respect to the mask pattern by displacing the substrate and the mask pattern relative to each other from the global-aligned position while measuring the displacement along at least one of said X and Y axis, the rotation about the Z axis and tilts about the X and Y axis of the substrate; and using all measuring results to realize the ultimate positioning of the relevant sub-area in an X-Y plane with respect to the mask pattern.

See '832 Patent at Claim 1. This claim is as cumbrous as it is long, and it is at least slightly misleading to imply, as the claim does, that "global alignment" involves all five of the steps listed. Global alignment, in fact, is "realized" in the first three steps--a fact suggested, albeit inexactly, in the articulation of step four: ". . . positioning each individual sub-area with respect to the mask pattern by displacing the substrate and the mask pattern relative to each other from the global-aligned position . . . ." Id. The position could not be already "global-aligned," of course, if the process of global alignment were not complete. Nothing in this claim language necessarily posits sub-area-specific alignment as the definitive aspect of "global" alignment; rather, the claim sloppily adds two field-by-field steps to a recitation of a distinct realization process. It is poor claim drafting, but it does not change the meaning of the predicate "global alignment" term.

Throughout the patent, the term "global alignment" refers to the positioning of the entire substrate, not to "each individual sub-area" on that substrate. See Vitronics, 90 F.3d at 1583. This is what global alignment has long meant to those of ordinary skill in the art, regardless of the cognomen affixed to the step-by-step process articulated in the claim. Consistent
with conventional usage and the intrinsic record, the court construes "global alignment" to mean "the initial positioning of the entire substrate according to substrate alignment marks," "globally aligning" to mean "the process or act of positioning of the entire substrate according to substrate alignment marks," and "globally positioned" to mean "situated or located by reference to the entire substrate."

I. Claim Construction

Eisenberg contends that the district court failed to construe the claims pursuant to Markman prior to consideration of the JMOL motion. Alimed responds that Eisenberg has not identified any disputed claim interpretation issue that could affect the invalidity verdict. Claim construction is a question of law which we review de novo. See Cybor, 138 F.3d at 1456, 46 U.S.P.Q.2D (BNA) at 1174.

The '507 patent is representative and provides:

1. A glove for preventing injury to the thumb's ulnar collateral ligament comprising:

   a hand covering having a thumb portion,

   said thumb portion having a retainer means disposed at least in part on the radial side of said thumb portion, said retainer means being inflexible in the radial direction, and when the wearer's thumb is in place in said thumb portion of said glove, said retainer means is disposed to extend over the thumb's metacarpal phalangeal joint and is of sufficient length to also extend over substantial portions of the adjacent bones which form the joint so as to generally immobilize the bones with respect to the joint in the radial direction whereby radial movement of the thumb which might injure the ulnar collateral ligament of the thumb is prevented.

2. The glove of claim 1 wherein said retainer means comprises a trough, said trough disposed on the radial side of said thumb portion and extending from the approximate tip of said thumb portion to the wrist area.

3. The glove of claim 2 wherein said trough has a hollow section, which said section fits around said radial side of said thumb portion.

   * * *

6. The glove of claim 1 wherein said retainer means fits around the entire thumb portion.

col. 4, ll. 26-47, 54-55.

A. Glove

In considering Eisenberg's post-trial motions the district court noted that it had previously construed the term "glove" as a matter of law, adopting Eisenberg's definition of "glove" as encompassing splint-like devices. See Eisenberg III, slip op. at 11. This claim construction was set forth in the district court's Memorandum and Order denying Alimed's summary judgment motion. See Eisenberg v. Alimed, Inc., Civil Action No. 91-12413-NG, slip op. at 8 (D. Mass. Sept. 29, 1994) (Eisenberg I). Thereafter, the court instructed the jury that the term "glove," as used in the patent claims "may encompass splint-like devices." Eisenberg alleges no error by the district court in construing the term "glove."

1. "Glue"
Atmel's sole argument in support of its contention that the glue layer must, in addition, adhere well to the exposed material to the tungsten. "335 Patent at col. 2:30-33. Thus, the specification supports Atmel's construction with respect to adherence.

As to how the term "glue layer" should be construed with respect to its adherence to other materials, Agere argues that the term "glue layer" should be construed as "a layer, composed of one or more materials, that promotes adhesion between an underlying dielectric region and a subsequently-deposited tungsten layer." Atmel argues that the term "glue layer" should be construed as "a layer of material of a single composition that adheres well to the dielectric layer, to the tungsten layer that is subsequently deposited, and to the exposed material at the bottom of the contact hole." There are two essential differences between the parties' constructions: (1) Agere contends the glue layer may contain more than one material, while Atmel contends the glue layer must be composed of only a single material; and (2) Atmel contends that the glue layer must adhere well to the exposed material at the bottom of the contact hole, in addition to adhering well to the dielectric and the tungsten, while Agere contends the glue layer need only promote adhesion between the dielectric and the tungsten.

As to the composition of the glue layer, Claim 1 itself expressly states that "said glue layer comprises at least one member selected from the group consisting of conducting nitrides." '335 Patent at col. 6:4-6 (emphasis added). Similarly, the specification states that "the glue layer comprises at least one material selected from the group consisting of A1 and conducting nitrides such as TiN." Id. at col. 3:67 through col. 4:1 (emphasis added). This language clearly implies that the glue layer may consist of multiple materials. Moreover, there is nothing in the claim language itself or the other intrinsic evidence stating, or even implying, that the glue layer must be comprised of only a single material. The Court also notes that Atmel has failed to set forth any argument in support of its contention that the term glue layer should be construed as "a layer of material of a single composition." See Defendant Atmel Corporation's Post-Hearing Submission Regarding Claim Construction ("Def.'s Post-Hearing Brief") at 7-9. In addition, claim 1 states that "said glue layer comprises at least one member selected from the group consisting of conducting nitrides." '335 Patent at col. 6:4-6 (emphasis added), and both parties have jointly stipulated that the term "comprises" as it appears in the '335 patent means "includes at least the following but does not exclude others," Joint Statement of Claim Terms at 1.

As to how the term glue layer should be construed with respect to its adherence to other materials, Agere argues that the specification reveals that the patentee intended the term to have a particular meaning. The specification states: "A glue layer is a layer of material deposited prior to the tungsten and which has good adhesion both to the underlying dielectric layer and to the tungsten." '335 Patent at col. 2:30-33. Thus, the specification supports Atmel's construction with respect to adherence.

Atmel's sole argument in support of its contention that the glue layer must, in addition, adhere well to the exposed material
at the bottom of the contact hole is based upon a statement made by the patent applicants during the prosecution history. After an initial rejection of claim 1 on July 20, 1987, a second rejection on February 20, 1988, and a third rejection on August 11, 1988, the patent applicants (in an Amendment After Final Rejection dated February 15, 1989) sought to amend claim 1 to add the following (after the words "CHARACTERIZED IN THAT"): "a portion of said glue layer overlies said exposed underlying material and said tungsten contacts said portion of said glue layer that overlies said underlying material and ...." Exhibit AG 006890 from 12/05/02 Hearing. Referring to this proposed amended language, the patent applicants attempted to overcome the previous rejections and distinguish their purported invention from a prior art reference by contending that the prior art reference "does not state that the [glue layer] is deposited through a hole onto an underlying material (e.g. substrate) and, consequently, shows no appreciation for the requirement that the [glue layer] must adhere well to the substrate, as well as the dielectric." Exhibit AG 006891 from 12/05/02 Hearing. However, this effort to amend claim 1 in order to avoid the prior art was unsuccessful because the Patent and Trademark Office considered the Amendment After Final Rejection, determined that the proposed amendment was insufficient to overcome the previous rejections, concluded that the proposed amendment would raise new issues not related to the reasons for the previous rejections, and did not enter the amendment. See Exhibit AG 006899 from 12/05/02 Hearing. Thus, the proposed amendment was never added to claim 1 and the applicants' explanation for how this amended language would distinguish their invention from the prior art does not bear on our task, which is to construe the language of claim 1 as it appears in the final issued patent.

Accordingly, the Court construes "glue layer" to mean "a layer, composed of one or more materials, which is deposited prior to the tungsten and which has good adhesion both to the underlying dielectric layer and to the tungsten."  

On October 16, 2006 the court filed a Markman decision in this case, construing claim terms of U.S. Patent No. 5,758,328 ("the '328 patent). Plaintiff, Source Search Technologies, LLC ("SST"), now moves pursuant to Local Rule 7.1(i) for reconsideration of that portion of the Markman Opinion that holds that "Goods and Services" is construed to mean "standardized articles of trade and performances of work for another." The court reached this conclusion by citing Defendants' contended definition and noting that "SST has not objected to Defendants' contention, and therefore, it will be accepted." (Opinion, at 28-29).

A motion for reconsideration shall be accompanied by a brief "setting forth concisely the matter or controlling decisions which the party believes the Judge or Magistrate Judge has overlooked." Local Rule 7.1(i) Ciba-Geigy Corp. v. Alza Corp., No. 91-5286, 1993 U.S. Dist. LEXIS 3971 1993 WL 90412, at 2-3 (D.N.J. Mar. 25, 1993). Such a motion is not to be used to simply reargue the same issues already rejected, or to voice disagreement with the court's decision on the merits.

It is readily apparent that SST has established the basis for reconsideration. The court, adopting Defendants' definition of goods and services, overlooked that SST strenuously disputed that definition. Defendants contended, based on their construction of the language of the patent, for a narrow definition of that term, namely, that goods or services must be standardized. SST, on the other hand, contended that goods and services needed no construction and that "the '328 patent merely stated that in order to ensure that there was no confusion about what is being requested by a buyer, either the descriptions of the products had to be standardized, or the products had to be described with text to be clear."

This difference of opinion was expressed in the parties' submissions and at the Markman hearing. Yet the court overlooked it in its Markman Opinion. Therefore, SST's motion for reconsideration will be granted.

The parties submitted everything they had to say on this issue prior to the Markman hearing; they argued the question at the hearing (a transcript of which the court has); they had the opportunity to give added emphasis to their views in connection with the motion for reconsideration. Therefore the court will conduct its reconsideration on the record before it without a further hearing.

The term "goods and services" is used constantly throughout the claims of the '328 patent. For example, claim 1 begins:

A computerized system for forming a computer based network of network members inclusive of network buyers and or network vendors for processing requests for quotation for goods and services through at least one central processing unit. . .
It is Defendants' position that the specification explicitly disclaims a broad reading of goods and services, i.e., that goods and services means any goods and services. They point to the following language:

"The present invention is a computerized quotation system forming a computer based communications network for processing requests for quotations for goods and services from respective buyers or vendors who broadcast such requests to network members of the computerized system. There is no central pricing database to limit the number of buyers and vendors of goods and services or to limit the number of goods and services which can be processed. However, the goods and services must be standadized items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering to buyers. Fig. 1 shows the system of this invention as configured using the Internet as the communications network."

('328 patent, col. 3, ll. 55-67) (emphasis added).

This is pretty unambiguous language: "... the goods and services must be standardized items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering to buyers." The cases have distinguished between the terms "must" and "may" or "can" as used in patents. The word "must" is mandatory language; whereas "may" and "can" are permissive terms. See BBA Nonwovens Simpsonville, Inc. v. Superior Nonwovens, LLC, 303 F. 3d 1332, 1340 (Fed. Cir. 2002).

SST asserts that the paragraph of the specification that follows the paragraph upon which Defendants rely completes the teaching on the subject. It includes the statement:

"Standardization of product or service descriptions is essential to avoid confusion unless a more text oriented specification is appropriate for the product or service type."

('328 patent, col. 4, ll. 9-16) (emphasis added).

It is SST’s contention that the specification provides two options for identifying the goods and services for which a quotation is sought: i) requesting a quote for a standardized product or service, or ii) requesting a quote for a product or service for which a text oriented specification is appropriate. This would open up the request for goods and services to any product or service, standardized or not.

If one follows the pertinent language of the specification which incorporates all the language upon which the parties rely ('328 patent, col. 3, l. 55 to col. 4, l. 12), it becomes clear that Defendants' interpretation is the correct one.

It starts with the paragraph containing the language, "However, the goods and services must be standard items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering buyers." ('328 patent col. 3, ll. 63-65). The next paragraph describes how network members can use the computerized system. Once again there is a reference to standardized goods or services: "The programming … which enables network members to interact with the network would include information sufficient for network members to identify standard goods or services that they wish to identify in a request for quotation." ('328 patent col. 4, ll. 4-9) (emphasis added).

The next sentence, the sentence upon which SST relies, simply suggests how the network member can identify the standard goods or services that are the subject of his request: "Standardization of product or service descriptions is essential to avoid confusion unless a more text oriented specification is appropriate to the product or service type." ('328 patent col. 4, ll. 9-12). This sentence in no way suggests that the particular product for which a "text oriented specification is appropriate" is not to be standardized.

This conclusion is illustrated by Figure 8 of the '328 patent to which SST refers. The quote given in Figure 8 is for 5000 "TYPE J RESSISTOR[S] 5%." Thus a text oriented specification is provided, namely 5000 and 5%. Nevertheless, the underlying product - the Type J resistor - is a standardized item.

Having corrected the deficiency of the October 16, 2006 opinion by considering the matter it previously overlooked, the
court arrives at the same conclusion it arrived at in that opinion. It reaffirms its holding that "Goods and Services" is construed to mean "standardized articles of trade and performances of work for another." The court will file an order implementing this opinion.

3. "Gradually tapering"

For "gradually tapering," Plaintiff argues that no construction is necessary, but suggests that should the Court find otherwise, the construction should be "becoming smaller by steps or degrees." For their proposed construction, Defendants suggest "gradually tapering" means "steadily diminishing by fine degrees as the entire external boundary is approached from the center." 11

The parties essentially agree on the "tapering" portion of the term, namely that the nipple cover will proceed in some manner from thicker to thinner material. Instead, the primary dispute in the parties' constructions boils down to each side's view on the proper construction of the term "gradually." Defendants argue that "the specification, the figures, and the prosecution history all indicate that the outer surface of the nipple cover must form a continuous curvature." Defs.' Claim Constr. Br. 21. In the specification, Defendants point to the following phrase discussing the gradual tapering of the nipple cover: "[t]he edges of the device will gradually taper to be thinner near the edges . . . [which] will allow the nipple cover to blend with the breast surface . . . for a continuous smoothness." '606 patent col. 2 ll. 36-39. In the prosecution history, Defendants also point to the inclusion of the 'continuous curvature' language discussed in connection with the gradual tapering of the nipple cover in noting that "Plaintiff emphasized a 'curvature of outer surface [that] is [a] substantially continuous curvature from [the] centre to [the] periphery.'" Defs.' Claim Constr. Br. 22. Based on the dictionary definition of the term 'continuous,' Defendants argue that the patent's references to the 'continuous' nature of the curve means the claims mandate the nipple cover's curvature need be "without a break or irregularity." Defs.' Claim Constr. Br. 22. Defendants chose the "steadily diminishing" language in their proposed construction to reflect the idea that the continuous curvature should be without breaks or irregularities.

In response, Plaintiff objects to the "steadily diminishing" language (and Defendant's continuous curvature argument) as impermissibly trying to read a limitation into the claims that does not exist. Plaintiff notes that despite the reference to the continuous curvature language in prior applications of the patent, the 'continuous curvature' language ultimately was not included in the issued patent's claims, thereby indicating the curvature need not necessarily taper without breaks or irregularities. The Court agrees.

All claim construction begins with the words of the claims. See Teleflex, 299 F.3d at 1324. The only reference to the term "gradually tapering" comes in Claim 1: "the nipple cover having a first thickness . . . and a second thickness [,. . . and the thickness of the nipple cover gradually tapering from the first thickness to the second thickness." 606 patent col. 4 ll. 20-24. As noted by Plaintiff, there is no reference in the claims to a continuous curvature, or a tapering such that it be free from irregularities.

Similarly, there is also no support in the specification mandating a continuous curvature free from irregularities. As quoted above, Defendant is correct that the specification does reference a "continuous smoothness." However, the 'continuous smoothness' is meant to reference the transition from the edge of the nipple cover to the surface of the breast, not the gradual tapering of the thickness at the center of the nipple cover to the second thickness at the periphery. All the specification discusses in relation to the "gradually tapering" term is that the nipple cover should taper off to be thinner at the edges. There is no discussion in the specification indicating the gradual tapering must be of a continuous smoothness, or that the
tapering must steadily diminish to this thinness at the edge of the cover.

The dictionary defines 'gradually' as "taking place, changing, moving, etc., by small degrees or little by little." DICTIONARY.COM, http://dictionary.reference.com/browse/gradually. This definition stands in stark contrast to the dictionary meanings of "continuous" or "steadily," both of which indicate an unfaultering, constant, regular progression. Had the patent wished to claim a steady progression free from irregularities, the drafter could have used either of these terms, yet chose "gradually." Giving the terms their ordinary meaning, as the Court must, "gradually" means only that the change takes place "little by little," not necessarily that it is unwavering, constant, or free from irregularity. Defendants' arguments and proposed construction including "steadily diminishing" suggests a progression to the thinness at the outer edge of the nipple cover that is unwavering, and such a construction finds no support in the patent's specification and claims. Accordingly, the Court must reject Defendants' proposed language of "steadily diminishing" as attempting to impermissibly import a limitation into the claims.

Footnotes:
12 The definitions of the root term "steady" include "free from change, variation, or interruption; uniform; continuous," and "constant, regular, or habitual." DICTIONARY.COM, http://dictionary.reference.com/browse/steadily. As noted above, the term "continuous," at least as it pertains to curvature, means "of or relating to a line or curve that extends without a break or irregularity."

Instead, the Court adopts Plaintiff's proposed construction as the construction of the Court: "becoming smaller by steps or degrees." Such a construction reflects the definitions of the terms "gradually" and "tapering," and also incorporates the specification's discussion of the nipple cover's progression from one thickness near the center to a thinner thickness near the edge of the cover without mandating that the progression be entirely free from irregularity.

1891

1. "Prosthesis" and "Graft" 1

Footnotes:
1 The term "prosthesis" is found in the preamble of independent claim 1 of the '458 Patent and in each of the dependent claims of that patent. The term "prosthesis" also is found in the preamble to independent claims 1, 15, 17 and 23 of the '158 Patent and in each of the dependent claims of that patent. The term "prosthesis" also is found in the bodies of dependent claim 22 and independent claim 23 of the '158 Patent.

The term "graft" is found in the preamble of independent claim 1 of the '073 Patent and is found in the preamble of independent claims 1, 20, 21 and 23 of the '736 Patent. It also is found in each of the dependent claims of those patents.

Footnotes:
The Court also considers the claim language in light of the specification of which it is a part. See Markman, 52 F.3d at 979.

In general, these terms are used only in the preambles to independent claims. (See ‘458 Patent, claim 1; ‘073 Patent, claim 1; ‘736 Patent, claims 1, 20, 22; and ‘158 Patent, claims 1, 15, and 17.) These terms also are used in dependent claims, prior to the introduction of additional limitations. (See, e.g., ‘458 Patent, claim 2 (“The prosthesis as defined in claim 1, wherein said bifurcated base structure is circumferentially reinforced at locations along its length by a plurality of separate spaced apart wires.”) The bodies of the independent claims, which use the terms solely in their preamble, set out a complete invention that is not dependent upon the preamble term for life, meaning or vitality. Further, because the bodies of these independent claims do not use the terms "prosthesis" or "graft," they do not "derive antecedent basis from the preamble." See Eaton, 323 F.3d at 1339.

Cook argues that because the terms "prosthesis" and "graft" are used in dependent claims, the terms in those claims must derive their antecedent basis from the independent claims. The Court does not find this argument persuasive, as it effectively negates the principle that a preamble term may serve merely as a label for the invention as a whole. Thus, the Court concludes that with respect to claim 1 of the ‘458 Patent, claim 1 of the ‘073 Patent, claims 1, 20 and 22 of the ‘736 Patent, and claims 1 and 15 of the ‘158 Patent, the terms "prosthesis" and "graft," are labels for the invention as a whole and need not be construed.

However, independent claim 21 of the ‘736 patent, and independent claim 23 and dependent claim 22 of the ‘158 Patent, which depends from independent claim 17 of that patent, use the terms "prosthesis" or "graft" in both the preamble and the body of the claims. In the Catalina Mktg. case, supra, the district court determined that a term used solely in a preamble of one claim and in the preamble and body of another claim should be construed as a limitation in both claims. The Federal Circuit reversed. With respect to the claim that used the term only in the preamble, the court held that the term was not a limitation because: "the applicant did not rely on this phrase to define its invention nor is the phrase essential to understand limitations or terms in the claim body[;]" the specification did show that the term provided additional structure for the invention described in the body of the claim; the inventors had not relied on the term to distinguish over prior art; and because if the disputed phrase was deleted from the preamble, it would not affect the fact that the claim body defined a structurally complete invention. Catalina Mktg., 289 F.3d at 810. As to the claim where the term was used both in the preamble and the body, the Federal Circuit affirmed the district court's construction of the term as a limitation, because the term as used in the body derived antecedent basis from the preamble. Id. at 810-11. In this case, in those claims where the inventors chose to use the terms "prosthesis" and "graft," in the preamble and the bodies of claims, the Court concludes that the preamble does provide an antecedent basis for the terms as used in the body and, therefore, acts as a limitation for those terms.

Defendants assert that the Court should construe the terms "prosthesis" and "graft" to mean an intraluminal device. Plaintiffs argue that the terms should be construed more broadly and can encompass a device comprised in part of a traditional vascular graft. Gore also argues the Court should construe these terms as "multi-component" devices "used as a unit." 2

The claim language demonstrates that the claimed "prosthesis" or "graft" is comprised of several components, i.e. a bifurcated base graft structure and a second graft structure, or a first graft body and a second graft body. The Court, therefore, concludes it is not necessary to include "multi-component" in its construction of these terms.

The Court first looks to the language of the claims. Claim 21 of the '736 Patent refers to overlapping or attaching one portion of the "graft" to the second portion of the "graft," while it is inside of a vessel. ('736 Patent, col. 7, ll. 36-38.) As is discussed in more detail below, Claims 22 and 23 of the '158 Patent refer to the "prosthesis" being placed in a vessel. Thus, the language of these claims support Defendants' position that the terms should be construed to be limited to intraluminal devices.

The Court also considers the claim language in light of the specification of which it is a part. See Markman, 52 F.3d at 979.
The specification shows that the inventors use the term "graft" as shorthand for "intraluminal graft." For example, in the "Field of the Invention" section, the inventors state that "[t]he present invention relates to an intraluminal graft for use in treatment of aneurysms or occlusive disease." ('458 Patent, col. 1, ll. 10-11.) In the section entitled "Background Art," the inventors state that "[i]t is known to use "stents and intraluminal grafts of various designs for the treatment of aneurysms … ." (Id., col. 1, ll. 15-16.) The inventors discuss the prior art intraluminal grafts and then state that "[s]uch intraluminal grafts are inserted through the femoral artery into the aorta in a catheter. Upon release of the graft from the catheter it expands to the size of the aorta[.] … There are a number of problems associated with such known grafts." (Id., col. 1, ll. 27-33 (emphasis added).) The inventors conclude by stating that "[t]he present invention is directed to an alternative form of intraluminal graft which provides an alternative to known grafts." (Id., col. 1, ll. 40-42 (emphasis added).) See Honeywell Int'l, Inc. v. ITT Indus., 452 F.3d 1312, 1318 (Fed. Cir. 2006) ("On at least four occasions the written description refers to the fuel filter as 'this invention' or 'the present invention.'").

--- Footnotes ---

3 Because the patents-in-suit share a common specification, for ease of reference, the Court's citations to the specification in this Order are to the '458 Patent. The only time the term "prosthesis" appears in the specification is in the title of an article cited in the section of the specification describing the Background Art. (See, e.g., '458 Patent, col. 1, ll. 22-24.) Defendants urge the Court to adopt their construction of the term "prosthesis," primarily based upon the language in the specification that refers to "the invention" as an "intraluminal graft." That is, Defendants essentially equate the term "prosthesis," as used in the preamble to claims of the '458 and '158 Patents, to the term "graft," as used in the preambles to claims of the '736 Patent and '073 Patent. Plaintiffs do not seem to seriously dispute this proposition and do not articulate a clear difference between the two terms, other than to argue that the term "graft" should include a requirement that it be formed in part of plastic or polymer.

--- End Footnotes ---

Similarly, in the section entitled "Disclosure of the Invention," the inventors state that "[i]ii another aspect the invention relates to a method for positioning an intraluminal graft as defined above … causing an intraluminal graft as defined above to be carried through the catheter on an inflatable balloon until the graft extends into the vessel from the proximal end of the catheter … ." (Id., col. 1, ll. 54-59 (emphasis added).) In addition, in the section entitled "Best Mode of Carrying Out the Invention," the inventors use the terms "intraluminal graft 10" and "graft 10" interchangeably. (See, e.g., id. at col. 5, ll. 11, 17, 21, 26-27, 58-67, col. 6, ll. 1-10.) Finally, the specification is rife with references to the "intraluminal graft" or, the shorthand "graft", as "the invention" or "this invention." (See, e.g., id., col. 1, ll. 11-12, 40-41, 45-46, col. 3, ll. 33, 39-40, 45, col. 4, ll. 5-6, 20, 32, 55-56.)

Finally, each of the alternative embodiments described in the specification refer to devices that contain wires, which all parties agree are a feature of intraluminal grafts. None of the alternative embodiments, however, describe a traditional vascular graft. Nor do any of the figures disclose a traditional vascular graft. These facts further support Defendants' argument that the terms "prosthesis" and "graft" should be limited to intraluminal devices. (See, e.g., '458 Patent, col. 3, ll. 26-32 & Figs. 1-7.)

Plaintiffs rely on declarations submitted during the prosecution history to support their position that the terms "prosthesis" and "graft" should not be so limited. (See Schneider Decl., Exs. 4-8.) These declarations describe a surgery that Dr. White performed, on October 6, 1993, in which he overlapped an intraluminal graft with a traditional vascular graft, using what Plaintiffs describe as the "Sydney Trombone Technique." With respect to the term "prosthesis," Plaintiffs also rely on the fact that a dictionary definition of the term "prosthesis," which comports with their proposed construction, is attached to the Declaration of Dr. Ian Gordon. (See Schneider Decl., Ex. 7.) However, a fair read of Dr. Gordon's declaration supports Defendants' position. In that declaration, Dr. Gordon did not refer back to the traditional vascular graft when he explained the meaning of the term "prosthesis." He referred back to the endovascular grafts. (Schneider Decl., Ex. 7 at 2 ("[E]ach endovascular graft is a prosthesis... ") (emphasis added).) Thus, although the language of the claims, read without reference to the specification, might be broad enough to encompass a non-intraluminal prosthesis or graft, when the Court reads the claims in light of the specification, it concludes that a person of ordinary skill in the art would understand that the inventors used the terms "prosthesis" and "graft" in these claims to claim intraluminal devices. See SciMed Life Sys., Inc., 242 F.3d at 1341.
The language of claim 21 of the '736 Patent, and the language of claims 22 and 23 of the '158 Patent also support Gore's position that the "prosthesis" or "graft" should be construed to require that the device is used in a unitary fashion. For example, dependent claim 22 of the '158 Patent teaches that "the prosthesis is adapted to be placed in a lumen of a first vessel that intersects with a second vessel...." ('158 Patent, col. 8, II. 1-2.) Similarly, independent claim 23 reads as follows:

A prosthesis comprising:

a bifurcated base graft structure which defines a common flow lumen and a pair of connector legs which define divergent flow lumens from the common flow lumen; and

a second graft structure which is adapted to overlap and be attached to one of the flow lumens of said bifurcated base structure [sic] to form a continuous extension of that lumen;

wherein at least one of the bifurcated base graft structure and the second graft structure comprises a first end and a second end, and wherein at least one of the first and second ends is provided with a wire structure which has a plurality of apices extending beyond at least a portion of the corresponding end such that the wire structure apices extend across a lumen of a first vessel that opens into a second vessel in which the prosthesis is being placed without occluding the lumen of said first vessel.

(Id., col. 8, II. 17-36 (emphasis added.)) Independent claim 21 of the '736 Patent contains language that is similar to the "wherein clause" of claim 23 of the '158 Patent. (See '736 Patent, col. 8, II. 3-13 ("wherein the graft is adapted to be placed in a lumen of a first vessel that intersects with a second vessel; and wherein at least one of the said inlet end of said first graft body and said outlet end of said second graft body that is adjacent to a junction between the first vessel and the second vessel is reinforced with a wire member which has a plurality of apices extending beyond at least a portion of said respective end adjacent to said junction, and said plurality of apices extend across said junction so that the graft does not occlude the lumen of the second vessel") (emphasis added.).)

The inventors specifically define the term vessel in the specification as "blood vessels or like ducts such as the bile duct and the ureter." (See '458 Patent, col. 1, II. 18-20.) Thus, the claim language emphasized above, when combined with the inventors' explicit definition of vessel, supports a conclusion that the inventors intended that both portions of the "prosthesis" or "graft" described in these claims would be used in a unitary fashion. This claim language therefore undercuts Plaintiffs' argument that the "prosthesis" or "graft" claimed could be comprised, in part, of a device that already had been implanted in a patient.

Accordingly, the Court construes the terms "graft," as used in claim 21 of the '736 Patent, and the term "prosthesis," as used in claims 17, 22 and 23 of the '158 Patent, to mean: "An intraluminal device that is used in unitary fashion to substitute, repair or replace a missing or defective part of a vessel."
A lengthy discussion of the graft body that distinguishes the graft body from the wires and suggests that the wires may be integrated with the graft body or attached to it by some other means. Again, this discussion supports a view that the graft body is separate and distinct from the wires. (See id., col. 2, ll. 62-67, col. 3, ll. 1-25.) Finally, when they discuss the prior art, the inventors note that intraluminal grafts previously had been formed of a "sleeve, in which is disposed a plurality of self-expanding wire stents." (Id., col. 1, ll. 20-22.) These references further reinforce the view that the "graft body," or sleeve, is separate from the wires or wire-stents.

Accordingly, the Court construes the term "graft body" to mean: "an artificial device formed of plastic or fabric for use inside of a vessel."

A. "the granules comprising a thermoplastic and a thermoset plastic"

1. The Parties' Proposed Constructions

At the outset, the parties agree that "the granules include both a thermoplastic component and thermoset plastic component" and that "the claim does not disclose a limitation on the relative amounts of the two components." 2 (D.I. 59 at 1-2; D.I. 78 at 5.) However, Safas proposes that I construe this claim term to mean that the granules may comprise either a combination of discrete thermoplastic particulates and discrete thermosetting particulates mixed together into a matrix, or that each granule may have both a thermoplastic and thermoset plastic component. (D.I. 78 at 5.) Safas argues that because the claim language employs the plural term "granules," and not other language such as "each granule comprising," those skilled in the art would "readily understand that claim 1 includes both a combination of discrete thermoplastic particulates and discrete thermosetting particulates which are mixed to form the granules,' and each granule having a thermoplastic and thermoset plastic component." (Id. at 6.) Safas also supports its proposed construction by referring to language in the specification of the '895 patent and the prosecution history. (Id.)

2. The Court's Construction

I construe "the granules comprising a thermoplastic component and a thermoset plastic component" to mean that each individual granule must contain both a thermoplastic component and a thermoset plastic component. (D.I. 80 at 10.) Etura argues that Safas' proposed construction is inconsistent with the plain language of the claims, the specification of the '895 patent, and the prosecution history. (Id. at 8-9.)
3 Etura argues that I should construe the thermoplastic/thermoset plastic limitation as requiring a granule possessing the performance benefits described in the '895 patent and that is predominantly thermoset in nature. (D.I. 80 at 13.) Specifically, Etura asks me to construe the limitation as requiring "more thermoplastic material than what Safas argues occurs naturally in all thermoset plastic." (Id.) I decline to do so, as I am confident that the claim construction provided herein addresses Etura's concerns without imposing a quantitative limitation on the amount of thermoplastic material that must be present in each granule. Indeed, the parties have agreed that the claim does not disclose a limitation on the relative amounts of the thermoplastic and thermoset plastic components. (D.I. 59 at 1-2; D.I. 78 at 5.)

GO BACK

1894

(b) "Granules Of A Coarse, Permeable Material"

The phrase "granules of a coarse, permeable material" appears in claims 1 and 6; "granules" are further limited in claims 2, 3, 4, and 10. The claims do not say what size the granules may be, just that they be small enough to fit in the tumbling chamber. Likewise, the coarseness and permeability are not specifically defined. Each of these qualities will be addressed.

Golden Trade cites to its experts and argues that a "granule" is "a small particle," that the specification calls for "granules of pumice or similar material," ( '213 patent, col. 1, l. 63-64), and that pumice stones are typically 1/2" to 1 1/2" in size. Lee counters that the expert statements are conclusory, that no statement in the patent actually defines the size of the granules, and that Golden Trade's use of the size of pumice stones is irrelevant. In addition, Lee cites testimony by the inventor Ricci (albeit regarding permeability) that tennis balls could be used in the '213 process, and testimony by Golden Trade's expert, a chemist for the other plaintiff, Greater Texas, that granules can be a "particle of any size" and "there's no limitation on the large size or on the small size." (Desai Dep. at 101.)

During prosecution, the Examiner rejected the claims under 35 U.S.C. § 112 because the use of "granules of coarse permeable material" was "unduly broad, insufficiently defined and beyond the scope of enablement." (Office Action of Oct. 6, 1987 at 2, in Pros. Hist., Tab G.) In attempting to narrow the phrase, Ricci admitted that it read on "foam crumbs" and asserted that determining the ratio of granules to fabric or granules to bleach "to achieve a desired effect on a given fabric chamber. Likewise, the coarseness and permeability are not specifically defined. Each of these qualities will be addressed.

Normally, words in a patent are given their ordinary usage unless defined differently by the patentee. Carroll Touch, Inc. v. Electro Mechanical Sys., 15 F.3d 1573, 1577 (Fed. Cir. 1993). "Granule" comes from the Latin word for "grain" and means "[a] small grain or pellet." Webster's II New Riverside University Dictionary 544 (1984). We can not tell from the prosecution history if the admission that the phrase at issue reads on "foam crumbs" was directed to the granules' size, coarseness, or permeability, and, if it was directed to size, whether the crumbs might be too large or too small. The prior art disclosed "small sized abrasive particles," pumice stones, an artificial pumice rolling member, and zeolites (very small crystalline structures). (Amendment of Nov. 16, 1987 at 8, in Pros. Hist., Tab I.) There seems to be no doubt that small sized particles are included. The conclusion as to the upper boundary is harder. Pumice stones may be 0.8" to 2", (see Ricci Decl. of Oct. 16, 1987, in Pros. Hist., Tab K ("2 to 5 cm")), a size which seems to be larger than a "small grain or pellet." Because the amendment only discusses ratios of granules to fabrics and bleach, it would seem that even a large "granule" would be suitable so long as there would be enough fabric or bleach to create the random faded effect on the fabric. The size of a granule would be limited by practicalities such as the size of the tumbling machine and the machine's opening, as well as by the size of the fabric being processed. (If the granules were larger than the fabric being processed, the granules would not randomly contact the fabric to create the random faded effect, and uniform fading would occur.) This upper boundary may be limited in claims 2 and 10 to the normal size of pumice stones, but given the broad statement during prosecution as to the knowledge of those skilled in the art, it would seem that the boundary is variable in the broader claims 1 and 6. This interpretation, coupled with Greater Texas' witness's admission that granules can be of any size, leads to the conclusion that a granule can be as small as a grain and as large as the practicalities of the tumbling machine and the fabric being processed allow. The nature of the granules would be limited to material which was coarse and permeable and would include pumice, paper, foam and sponge as well as PVC pipe, diamonds, synthetics and selica gel, clay, salt and crushed powder pellets.
As for permeability and coarseness, Ricci says that "everything is permeable" to some extent. (Ricci Dep. at 923.) Defining coarseness is harder because it depends on what one of ordinary skill in the art would deem sufficient in relation to permeability. (See '213 patent, col. 2, l. 7-9 ("sufficient roughness with a texture such as will permit high absorption of a powerful bleaching agent").) Obviously, coarseness of pumice, (claim 2), pumice stones, ( '213 patent, col. 3, l. 43), coarse, paper-based material, (claim 3), and "foam," (Amendment of Nov. 16, 1987 at 7, in Pros. Hist., Tab 1), are included. Claim 4 limits claim 1's recitation of granules to those that "produce a dual fading action that is a mechanical action" due to the "coarse surface" and a "chemical action" due to the bleach within the granules. If claim 1 is read at its broadest, it would seem that the granules do not have to produce a mechanical or chemical action, just that they have to be coarse and be able to produce a random faded effect (although it is hard to say how such an effect is produced without mechanical and chemical action). Another factor contributing to the dual fading action is the "mechanical properties of the cloth." ( '213 patent, col. 3, l. 13-14 (emphasis added.) Thus the coarseness, in the sense of roughness, requirement is minimal, resting on what one of ordinary skill in the art would look for in relation to permeability and the mechanical properties of the fabric being processed. As the permeability goes up, the required coarseness decreases.

1895

C. "graphic print"

a. Parties' Positions

The parties propose similar constructions for "graphic print" as they do for the term "photographic print." "Graphic print" is present in claim 21 of the '632 Patent. Again, the primary dispute is whether the claim term should include images generated through ink printing.

Plaintiff

Plain meaning

Alternatively, "a reproduction relating to a written or pictorial representation, or other display generated by a computer or an imaging device"

Defendants

An enlarged positive image on light-sensitive material of a graphic made from a film negative or plate and that is not made using ink printing.

Plaintiff's construction is based on the dictionary definitions of both "graphic" and "print." Dkt. No. 104 at 30-31. Both parties offer the same arguments for their respective proposed constructions for "graphic print" as they offered for "photographic print." See, e.g., Dkt. No. 104 at 30; Dkt. No. 110 at 15 (the "constructions [of photographic print' and 'graphic print'] depend equally upon the same portions of the intrinsic record.").

b. Court's Construction

Claim 21 of the '632 Patent states:

21. A floor tile for use as a flooring surface in a commercial merchandising display comprising:

an enlarged graphic print of photographic quality having oppositely disposed first and second major faces; and

a transparent protective coating on said first major face defining a barrier to prevent injury to said photographic print from foot traffic and other objects passing over said floor tile.

There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987); see also, Nystrom v. Trex Company, Inc., 424 F.3d 1136, 1143 (Fed. Cir. 2005) (citing Tandon). However, different terms in separate claims may be construed to cover the same subject matter where the written description and prosecution history indicate that such a reading
is proper. Tandon, 831 F.2d at 1023-1024. This is one of those cases. The parties do not articulate a substantive difference between "graphic print" and "photographic print," and the Court cannot discern any distinction after consideration of the claim language. Furthermore, the remaining intrinsic evidence indicates that a parallel construction is appropriate. Finally, as previously discussed, the evidence demonstrates that patentee has surrendered ink printing. See supra Part (B)(b).

Therefore, the Court construes the term "graphic print" to mean "a print of a graphic created by conventional photographic processes rather than by ink printing."

1896

2. graspable object(s)

The term "graspable object(s)" appears in claims 1 - 24 of the '874 patent, claims 1 - 20 of the '786 patent, and claims 1 - 8 of the '754 patent. The parties have discussed the term "graspable object" in tandem with the term "object," and have not placed much emphasis on the term "graspable." The plaintiff proposes a construction of "an object that is capable of being grasped by a human hand." The defendant proposes "a block," with the further caveat that a "graspable object' does not include keyboards, mice, pens, wands, instruments for writing or hand signing on graphic tablets or touch screens, or other devices not specifically adapted for a child's use." For the above reasons, the court concludes that the term "graspable object" means "a physical thing (or item) that is capable of being grasped in a human hand."

1897

B. Grate

The term "grate" is recited three times in Claim 1 and describes either tables or a shelf, i.e., side grate tables/lower grate shelf. Plaintiff proposes the following construction of the term "grate": "framework of parallel or crossed bars used as a partition, guard or the like, such as to allow for spillage to fall therethrough." Defendant proposes: "a framework of parallel support members (not necessarily steel and not necessarily rigid)."

Again, the Court must begin with the language of Claim 1 of the patent. The term "grate" is used three separate times and precedes the terms "tables" and "shelf." The illustrations in the patent clearly show the three items, Items 214, 216, and 166 in Figures 1 and 2, as grates and not solid flat surfaces. Defendant argues that his proposed claim construction of "grate" "allows spillage to fall therethrough." (Def. Response at 6.) The spillage issue is addressed and described in various portions in the specification. (Col. 2, ll. 59-60; Col. 2, ll. 40-45; Col. 9, ll. 34-35.)

Additionally, Defendant objects to the description of the material necessary to create the grate, i.e., steel. (See Claim 9, "pair of side grate tables and said lower grate shelf are comprised of steel.") As noted above, Plaintiff does not specify in its preferred claim construction the material of which the grate is composed. The issue, therefore, is the description of the grate. Plaintiff proposes a "framework of parallel or crossed bars used as a partition"; Defendant proposes a "framework of parallel support members." Column 6, lines 5 through 8, of the specification provide that the lower grate shelf is comprised "of a framework of parallel bars or wires fashioned from steel." Column 7, lines 32 through 37, describe the side grate tables as frameworks of parallel bars or wires fashioned from steel. These consistent descriptions in the specification are the basis of the Court's construction of the term "grate":

A framework of parallel or crossed bars or wires such as to allow for spillage to fall therethrough.

1898

1. The Term "Gravel"

The meaning of the term "gravel" as it is used throughout the '784 patent claims is critical to determining whether LAPP's
product infringes Python's '784 patent. The term gravel is used a total of 204 times throughout the patent. As discussed above, when construing patent claims, the court must consider the claims themselves, the specification, and the prosecution history of the patent. If an analysis of this intrinsic evidence resolves the ambiguity in the disputed claim term, the court should not rely on extrinsic evidence. However, if the term cannot be defined by referring to this intrinsic evidence, the court can refer to extrinsic evidence to aid in its determination of the meaning of the claim terms. The Federal Circuit has noted that prior art documents and dictionaries are more objective types of extrinsic evidence than opinion testimony, "whether by an attorney or artisan in the field of technology to which the patent is directed." Vitronics Corp. v. Conceptronic Inc., 90 F.3d 1576, 1585 (Fed. Cir. 1996).

a. The Claims

LAPP contends that although the word gravel is used continuously throughout the patent claims and specification, it is never defined. Case law instructs that although an inventor is free to use terms in a manner other than their ordinary meaning, if the special definition of the term is not clearly stated in the patent specification or patent history, the term will be interpreted as having its ordinary and customary meaning. See Markman, 52 F.3d at 979; Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1578 (Fed. Cir.)("A technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and the prosecution history that the inventor used the term with a different meaning.")(citations omitted), cert. denied, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996).

Looking to the words of the claims themselves, no express definition of the word gravel is provided. Python contends that when the claims are read in view of the specification of which they are apart, as required by case law, a definition of gravel is found. Column 6, lines 19-22 of the specification reads: "The gravel is sufficiently heavy that it will fall back to the floor of the aquarium while sediment is carried away with the water discharged through the elongated hose." Python contends that this sentence defines the term gravel by reference to its weight. This sentence, however, is a small part of the entire specification that describes in detail the basic function of a preferred embodiment of the claims. In other words, this sentence is merely one part of the complete description of how the claims, read together, function to clean the aquarium tank; it does not define the word gravel. This statement does not say what gravel "is," it says what it "does." A definition, on the other hand, is a "statement of what a thing is." See Webster's New World Dictionary of the American Language, Second College Edition, 1984 Simon and Schuster, p. 370. Therefore, Python's attempt to transform the sentence in its specification into a definition of the term gravel fails.

b. The Specification

The specification may act as a sort of dictionary when it expressly defines terms used in the claims or when it defines terms by implication. Vitronics, 90 F.3d at 1582. Additionally, the fact that a patent specification emphasizes a limitation from its beginning to its end supports a finding that such limitation is part of the claimed invention. Gentex Corp. v. Donnelly Corp., 69 F.3d 527, 529-30 (Fed. Cir. 1995).

As discussed above, the specification does not define the disputed term gravel. Rather the specification repeatedly uses the term to explain the function of the claims and limits the scope of the patent to an invention or device that lifts gravel into the gravel tube, churns it, and then allows the gravel to fall back into the tank. Once the court defines the term gravel, the scope of the patent will be clear and a device that falls outside the patent's scope will not be considered an infringing device.

c. Prosecution History

In interpreting the disputed terms, the court may also consider the prosecution history of the patent, which may include representations made by the applicant regarding the scope of the claims. In the instant case, the applicant (Reyneirs) did not, at any time during the prosecution of the patent, assign any special meaning to the term gravel. The term, although it was used throughout the claims and specification, was neither expressly nor impliedly defined in the patent. Since gravel is not otherwise defined by the patent, the assumption would be that the term gravel is to be given the "meaning that it would be given by persons experienced in the field of the invention." Hoechst, 78 F.3d at 1578.

d. Extrinsic Evidence
The intrinsic evidence analyzed above does not aid the court in defining the disputed term in the instant patent. What is clear from the above analysis is that the term gravel should be assigned its ordinary and customary meaning in construing the patent at issue. To presumably aid the court in determining the ordinary and customary meaning of the term, the parties submitted numerous dictionary definitions as well as declarations that purport to define the term gravel. Python argues that the definition includes sand. To support its contention, Python submitted the Declaration of Lance Reyneirs, the original holder of the '784 patent. Reyneirs states in his declaration that:

as one skilled in the art of constructing aquariums, I understand the term "gravel" as used in this patent to teach the use of natural aggregate material typically and historically, used in lining the bottom of aquariums. . . . "Gravel" as used in the '784 patent is understood by the great majority of aquarium hobbyists to include aggregate materials ranging in size from coarse sand to pebbles to small chunks of rock. A typical natural aquarium gravel setup will include aggregate material of varying sized, almost always including coarse sand.

Reyneirs' 2nd Decl., P37.

Additionally, Python attached the Declaration of Ralph Speice, who has been an active tropical and marine fish aquarium hobbyist for over 50 years, and has served as monthly contributing editor for "Fresh Water and Marine Aquarium" magazine since 1978. Mr. Speice essentially restates the same definition given by Mr. Reyneirs to describe the term gravel. Python also submitted the definition of gravel obtained from the 1991 version of Random House Webster's College Dictionary, which defines gravel as "small stones and pebbles or a mixture of these with sand."

LAPP submitted its own declarations and dictionary definitions 3 that support their position that sand is not included in the definition of gravel. LAPP also cited to the 1996 Annual Book of ASTM (American Society of Testing Materials) Standards, which defines gravel as particles of rock that will pass a 3 inch (75 mm) sieve and be retained on a No. 4 (4.75 mm) U.S. Standard sieve. Sand is defined as particles of rock that will pass a No. 4 (4.75 mm) sieve and be retained on a No. 200 (75 [mu] m) U.S. Standard sieve. Under these Standards, most sand would be able to pass through the 1.33 mm slots in the claw of the accused device and be churned in the gravel tube. In the 1996 Annual Book of ASTM Standards, the scope of the standards are set out as follows:

[These ASTM Standards are part of a] system for classifying mineral and organo-mineral soils for engineering purposes based on laboratory determination of particle size characteristics, liquid limit, and plasticity index and is used throughout the United States and in many other countries when precise classification is required.

Pradel Decl., P 15, Ex. F.4

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

3 The dictionary definitions include Webster's New World Dictionary, Third College Edition, which defines gravel as a "loose mixture of pebbles and rock fragments coarser than sand;" The American Heritage College Dictionary, Third Edition, which defines gravel as "an unconsolidated mixture of rock fragments or pebbles;" and Webster's New World Dictionary of American Language, which defines gravel as "a loose mixture of pebbles and rock fragments coarser than sand."

4 Daniel E. Pradel holds a Doctorate Degree in Civil Engineering from the University of Tokyo and a Certificate of Postdoctoral Studies in Geotechnical Engineering from UCLA. Attached to his declaration is a copy of the 1996 Annual Book of ASTM Standards, Volume 4.08. The definitions of gravel and sand are found in section 3.1.1 and 3.1.2, respectively.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - 

The Federal Circuit has noted that if a court relies on extrinsic evidence:

dictionaries . . . are more objective and reliable guides. Unlike expert testimony, these sources are accessible to the public in advance of litigation. They are to be preferred over opinion testimony, whether by an attorney or artisan in the field of technology to which the patent is directed. Indeed, opinion testimony on claim construction should be treated with the utmost caution, for it is no better than opinion testimony on the meaning of statutory terms.
Given the intrinsic and extrinsic evidence in the instant case, this Court adopts the ASTM definitions and construes the term "gravel" as having a minimum particle size of 4.75 mm.

Python objects to the district court's construction of the following claim language from claims 1 and 10, respectively:

- means for causing sufficient flow of water through the gravel tube . . . [so] that gravel adjacent the bottom of the aquarium tank will be churned in the gravel tube . . . [but] being insufficient to cause gravel churned in the gravel tube to [be] pulled into the elongated flexible hose;

- the step[] of . . . causing a flow of water from the bottom of the aquarium upwardly through the gravel tube . . . sufficient to lift gravel into the gravel tube and to churn [it] . . . and . . . insufficient to cause the gravel to be pulled from the gravel tube into the hose

(collectively, the "churn limitation").

The court determined that it could construe the churn limitation based on only the intrinsic evidence, and held that this functional limitation requires that an infringing device "draw[] gravel into a gravel tube where it is churned, cleaned and released back into the tank." Python defines the recited function more narrowly and argues that the churning limitation is only a "test of flow sufficiency," which does not require that the gravel actually be drawn into the tube and churned during the device's operation. During prosecution, however, Python defined the function more broadly when it deliberately added the churn limitation in response to the examiner's initial rejection of the claims as obvious over a reference that disclosed churning gravel at the bottom of the tank. Python stated:

> In the operation of the apparatus shown in [the cited reference], as water is forced into the aquarium tank through hose 24, the water flow into the tank will churn up the bottom of the aquarium, and solid material that had previously settled to the bottom of the tank will be dispersed throughout the tank . . . An additional advantage of applicant's apparatus is that the gravel at the bottom of the tank is thoroughly churned in the gravel tube until it is completely cleaned . . . [The reference] does not illustrate the use of a gravel tube structure so as to provide for a churning of the gravel in a gravel tube. . . . There is no suggestion in the prior art of churning gravel in the gravel tube and pulling sediment from the churned gravel and discharging that sediment along with waste water into a drain.

September 27, 1985, Amendment (emphasis added). This limitation requires, therefore, that the accused device perform the function of churning the gravel in the gravel tube.

Because the parties disputed the meaning of the ordinary word "gravel," the court supplied the definition. See Fromson v. Anitec Printing Plates, Inc., 132 F.3d 1437, 1441-42, 45 U.S.P.Q.2D (BNA) 1269, 1271 (Fed. Cir. 1997) ("When technical or scientific terms in the claims require definition or explanation or understanding in the course of deciding whether the claims are infringed, it is the judicial duty to do so."). Based on its review of the written description and prosecution history, the court determined that "the term gravel should be assigned its ordinary and customary meaning in construing the patent at issue." See Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1443, 43 U.S.P.Q.2D (BNA) 1837, 1840 (Fed. Cir. 1997) ("Claim terms are given their ordinary and customary meaning in the field of the invention, unless a special definition is clearly stated in the specification."); Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2D (BNA) 1126, 1129 (Fed. Cir. 1996) ("A technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and the prosecution history that the inventor used the term with a different meaning.").

Python argues that the inventor supplanted the ordinary and customary definition with a definition in the written description. See Intellicall, Inc., v. Phonometrics, Inc., 952 F.2d 1384, 1388, 21 U.S.P.Q.2D (BNA) 1383, 1386 (Fed. Cir. 1992). (An inventor may "be his own lexicographer and . . . give terms uncommon meanings."). The written description of the '784
The gravel is sufficiently heavy that it will fall back to the floor of the aquarium while sediment is carried away with the water discharged through the elongated hose 14." Col. 6, ll. 19-22. Python maintains that this language defines the word "gravel" as any material small enough to enter and heavy enough to fall from the gravel tube during operation. This definition is broader than the ordinary and customary one.

For a word to take on a new definition, however, the inventor's intent to redefine the word must be readily apparent from the written description. See Multiform Desicants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1477, 45 U.S.P.Q.2D (BNA) 1429, 1432 (Fed. Cir. 1998) ("When the meaning of a term is sufficiently clear in the patent specification, that meaning shall apply."); York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996) ("Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning."). The '784 patent's written description is not sufficiently explicit to endow the term "gravel" with the broader definition suggested by Python. Therefore, the court correctly construed the term "gravel" based on its ordinary and customary meaning to one skilled in the art.

On this record, there is no genuine issue of material fact about the ordinary and customary meaning of the word "gravel" to one skilled in the art. See Johnston v. IV AC Corp., 885 F.2d 1574, 1579, 12 U.S.P.Q.2D (BNA) 1382, 1385 (Fed. Cir. 1989) ("[A] mere dispute over the meaning of a term does not itself create an issue of fact. This is true even where the meaning cannot be determined without resort to the specification, the prosecution history or other extrinsic evidence provided upon consideration of the entirety of such evidence the court concludes that there is no genuine underlying issue of material fact."). The ASTM Standards provides the only meaningful distinction between the words "gravel" and "sand." It would be unreasonable to disregard this distinction, as well as to disregard the other dictionary definitions and common sense, to adopt Python's litigation-induced definition of "gravel" which is supported by only one dictionary. Therefore, the court's claim construction stands.

1. "grazing angle" of the '710 Patent and "an angle" of the '551 Patent

The first element of claim 1 and claim 24 of the '710 patent use the phrase "grazing angle" to depict the angle at which the invention focuses a beam of light at the surface being inspected. '710 at 13:9, 14:63. In claim 1 and 3 of the '551 patent (a continuation of the '710 patent application) the phrase "an angle" is used to describe a similar function. '551 at 13:12, 13:28. The parties contest the meaning of these phrases. KLA asserts that "grazing angle" as used in the '710 patent and "an angle" as used in the '551 patent refers to any angle other than an angle normal to the surface being inspected. D.I. 340 at 11; D.I. 409 at 27. ADE argues that "grazing angle" is commonly understood to one of ordinary skill in the art to refer to an angle close to the surface being inspected and would limit the meaning of "grazing angle" to an angle between 0 and 10 degrees of the surface. D.I. 314 at 10-12. As to the phrase "an angle" ADE argues in their Opening Brief (D.I. 314) that this phrase must be interpreted in the same manner with regard to the '551 patent as explained above regarding the '710 patent and, then, argues in its Responsive Brief (D.I. 398) that the phrase "an angle" encompasses 90 degrees or normal incidence. D.I. 314 at 15; D.I. 398 at 15.
This court construes the phrase "grazing angle" as used in the '710 patent and the phrase "an angle" as used in the '551 patent to mean any angle other than an angle normal to the surface being inspected. This meaning is consistent with that taught in the written description and depicted in the drawings of the '710 and '551 patents. Figures 2, 3, 6, 7A, and 7B of the '710 and '510 patents depict either explicitly or implicitly an angle or angles for the focused beam of light other than an angle normal to the surface being inspected. For example, Figure 6, reproduced below to the left of Figure 3, uses the mathematical expression \( w / \cos \theta \) to describe the magnitude of the long axis of the ellipse (or the spot of light used to scan the surface being inspected) with \( \theta \) representing the angle shown in Figure 3, reproduced below, and \( w \) representing the minimum width (or length of the short axis of the spot). '710 at 9:53-60; '551 at 9:53-60.

The angle \( \theta \) depicted in Figure 3 and used in the above equation is the angle between 150, or a line normal to the surface being inspected, and the directed beam of light used to scan the surface. Thus, as angle \( \theta \) approaches 90 degrees, or normal, the magnitude of the long axis of the ellipse gets smaller. If this angle approaches 0, or the surface, this axis gets bigger, but if angle \( \theta \) is 90 degrees, normal to the surface, this equation becomes meaningless. A person of ordinary skill in the art would readily understand this mathematical equation and its significance in relation to the patented invention.

The written description of the '710 and '551 patents do not limit "grazing angle" or "an angle" (angle \( \theta \) in Figure 3) to any particular angle or angular range other than a normal angle. ADE, however, argues that the "grazing angle" has a commonly understood meaning in the art referring to an angle of incidence close to the surface being inspected. Furthermore, ADE asserts the inventors understood this meaning and used the phrase accordingly. ADE may or may not be correct in their argument that the inventors had a general understanding of the common art meaning of the phrases "grazing angle" and "an angle" at the time of filing the '710 and '551 patents. The inventors' supposed understanding is unimportant in the present case given that the inventors specifically provided a description for "grazing angle" and "an angle" in the '710 and '551 patents so that a person of ordinary skill in the art could read the patent and determine what angle was necessary to generate varying magnitudes for the "spot's" or ellipse's long axis and, thus, use that angle to change the dimensions of the ellipse as needed to effectuate a scan.

The parties heavily contest the meaning of "said chemically embossed portion has an emboss depth greater than the emboss depth of any portion of said mechanically embossed portion" as found in claims 1 and 9 of the '008 patent and the slight variation of this phrase as found in claim 11 of the '008 patent ("the relative depth language of the '008 patent").

Mannington argues that as used in claims 1, 9, and 11 the relative depth phrase "means that the maximum chemical emboss depth is greater than the maximum mechanical emboss depth." D.I. 326 at 27. In support, Mannington asserts that those skilled in the art understand that emboss depth:

\[ \text{... refers to the difference between the unembossed surface and the deepest part of the embossed surface. Accordingly, the emboss depth of a chemical embossment is the difference, caused solely by the chemical embossing, between the unembossed surface and the deepest part of the embossed surface in the given area. Likewise, the emboss depth of a mechanical embossment is the difference, caused solely by the mechanical embossing, between the unembossed surface and the deepest part of the embossed surface in the given area.} \]

Id. at 28 (emphasis in original).

Moreover, argues Mannington, citing Tate Access Floors, Inc. v. Interface Architectural Resources, Inc., 279 F.3d 1357, 1370, (Fed. Cir. 2002), "a" and "an" as used in patent law and the contested phrases mean one or more of a specified item. Id. at 29. Thus, when the claim language "chemically embossed portion has an emboss depth greater than the emboss depth
of any portion of said mechanically embossed portion" is read with these definitions in mind, it is clear that the inventors intended that only one "portion" of the chemically embossed area be deeper than the deepest mechanically embossed area when measured from the surface to the bottom of the respective embossed areas. Id.

Armstrong argues, on the other hand, that the language "must be interpreted to exclude any product which includes any mechanical embossment deeper than a chemically embossed portion, as measured from the top unembossed surface of the product, whether that chemically embossed portion comprises the joint or grout lines or whether a second chemically embossed portion exists on the 'raised areas.'" D.I. 324 at 26. This construction Armstrong asserts is mandated by the prosecution history.

In particular, Armstrong argues, that Mannington, to distinguish prior art, "included the 'key' limitation: '… wherein said chemically embossed portion of said foam layer has an embossed depth greater than the embossed depth of any portion of said mechanically embossed portion." D.I. 324 at 26 (emphasis in original). In support of this newly added phrase, Armstrong alleges that Mannington pointed to the specification "which states '… in any event, the portion of the foam layer which has been overlaid with the design layer having the (chemical) retarder composition is not mechanically embossed. And, the portions or areas of the foam layer beneath the areas or portions of the wear layer that are embossed are generally slightly embossed.'" Id. at 27 (emphasis in original). Moreover asserts Armstrong, Mannington continued with this line of reasoning in an interview conducted with the examiner to distinguish other prior art references. Id. Consistently with Armstrong, Domco asserts, in a nutshell, that the phrase should be interpreted such that no mechanically embossing is found in the chemically embossed areas. D.I. 142 at 20-27.

Having construed, supra, the phrases "a chemically embossed portion" and "a mechanically embossed portion" as used in the '008 patent much of the mental labor involved in construing the relative depth language of the '008 patent is complete. To reiterate summarily, "a mechanically embossed portion" was construed such that mechanical embossing does not occur in the chemically embossed areas and "a chemically embossed portion" was construed to correspond to those areas where a "regulator," "inhibitor," "retarder," or similar chemical compound was applied to create a recessed textural appearance. This being the case, therefore, the phrase "said chemically embossed portion has an emboss depth greater than the emboss depth of any portion of said mechanically embossed portion" as found in claims 1 and 9 of the '008 patent and the slight variation of this phrase as found in claim 11 of the '008 patent must be construed consistent with the internal logic of the patent and its prosecution history to mean that mechanical embossing does not occur in the chemically embossed areas and that the mechanically emboss depth of those areas mechanically embossed does not exceed the depth of those areas that are chemically embossed when this depth is measured from the unembossed surface plane.

1902

Excess Weight on Bit

Claims in the '930 and '631 Patents include the following "excess weight on bit" limitations: "a weight on bit greater than the selected weight"; "a weight on bit in excess of that required"; "a weight on bit greater than the selected weight"; and a "greater weight on bit" than that required to cause the cutter to cut the formation at the selected depth of cut. Baker Hughes contends these similar terms require the "amount of weight applied along the centerline of the drill bit body" to be "greater" or "larger than the weight required" for the cutter to cut into the formation at a selected depth of cut, but not more weight than one may normally expect or encounter. ReedHycalog contends the excess weight on bit terms do not have an upper bound and mean "regardless of the weight that is applied to the bit." Baker Hughes argues the claim language does not contain words of infinite scope and a claim construction that allows an infinite amount of weight on the drill bit is nonsensical.

ReedHycalog cites two portions of the '631 Patent specification, the Abstract and Summary of the Invention sections, to support its constructions. These state the claimed invention acts to control the torque on bit, depth of cut, and volume of formation cut per bit rotation, "regardless" of the amount of weight on bit. '631 Patent Abstract, col. 4:8-13.

A person of ordinary skill in the art would not conclude the '930 and '631 Patents disclose a drill bit capable of operation when an infinite amount of weight is applied to the bit. Moreover, a person of ordinary skill in the art would not interpret "regardless of the amount of weight on bit" and similar phrases to mean the drill bit can control the depth of cut, volume of
formation material cut per but rotation, and torque on bit for all excess weights. Further, the claims and specifications do not support a construction that allows for an infinite amount of weight on bit. Thus, the Court construes the excess weight on bit terms to require the weight to be neither abnormal nor unusual. 23

23 Ref. No. 25 of Appendix B contains the disputed terms and their constructions.

1903

a. Greatest Elevation

The parties dispute the construction of the term "greatest elevation" in Plaintiff's patent. Defendant argues that the term "greatest elevation" applies to the entire sole or insole and, therefore, a device with a greater elevation at some point other than under the big toe joint would not be covered by Plaintiff's patent. Plaintiff replies that the limitation of the "greatest elevation" is in comparison to other portions of the forefoot, and not in relation to the midfoot. Plaintiff urges that the claim language "greatest elevation" be construed to refer comparatively to only the forefront portion of the insole, not to refer to the entire insole or any other part of the sole. In other words, theoretically, a portion of the sole not covered by the elements of Claim 1 (i.e., not the forefoot, the rearfoot, or the angulation) could be of greater elevation than the forefoot portion, and the device would still remain within the terms of the 882 patent. This is the logical, commonsense interpretation of the claim language. Dr. Talarico's patent describes a forefoot portion of the sole, designated in Figure 7 on Sheet 4 of the 882 patent, and a rearfoot portion. Claim 1 states, "...said inclined surface compensates the forefoot... giving the... big toe joint... the greatest elevation..." Comp., Ex. 1, 882 patent, col. 10, ln. 26-30. The Court finds that "greatest elevation" is a comparative term referring only to the forefoot portion of the sole as designated by Figure 7 on Sheet 4 of the 882 patent, which cuts diagonally into and does not include, for example, the portion of the sole designated in the 663 patent as the midfoot portion, where there is an "additional lift to the metatarsal by use of a supportive arch." Black Aff., Ex. 1, 663 patent, Abstract.

1904

d. Grip Means

With respect to the grip means, claim 2 provides in pertinent part:

A system according to claim 1, wherein said spring means includes grip means for gripping the wall of said element within said coupling.

The '243 patent, claim 2.

The use of the word "means" creates the presumption that § 112, P 6 applies. The language in claim 2 fails to recite sufficient structure to overcome the presumption that § 112, P 6 applies. The proper construction of the grip means is as a means-plus-function element. The grip means are "cutout tabs" in the body of the leaf springs, angled away from the surface of the spring to cut into the wall of the trough element. See id. at col. 4: 4-15.

1905

a. The disputed term in Claim 23: "Grooves"

i. Claim language. The first term that the court must construe is found in Claim 23 of the "product" patent, the '909 patent. The only disputed term in this claim is "grooves." Claim 23, with the disputed term italicized, states the following:
23. A plastic washing machine basket comprising: a substantially circular base wall having a peripheral portion; and an
annular plastic sidewall extending upward from the peripheral portion of said base wall to a terminal edge, said sidewall
having inner and outer surfaces, grooves formed in said inner surface of said sidewall, a plurality of spaced apertures
extending through said sidewall, said apertures located within said grooves.

The '909 patent, Claim 23 (emphasis added).

ii. The parties' definitions and arguments. The parties' proffered definitions of this term are shown below, with bold font
indicating differences between their definitions. Also, the authority on which each party relies for its definition is shown just
below that party's definition.

Maytag contends that its construction is correct, because it reflects the "plain and ordinary meaning" of "grooves" in the
context of Claim 23 and the '909 patent generally. Maytag points out that the claim language contains no limitations on the
shape of the "grooves," so that nothing departs from the ordinary meaning of "groove" as "a narrow depression, channel, or
trough in a surface." This construction is reinforced, Maytag contends, by looking to other claims--which, among other
things, refer to "teardrop-shaped grooves," making clear that the patentee knew the difference between a simple groove and
a groove with a specified shape. Maytag contends that this definition is also reinforced by the specification--which likewise
makes clear that a particular shape of the groove is specified when one is intended. Finally, Maytag contends that its
definition is reinforced by extrinsic sources, such as dictionary definitions. In contrast, Maytag contends that Electrolux's
construction is in error, because the term "grooves" does not refer to any projection on a corresponding surface, and Claim
23 of the "product" patent says nothing about how the grooves are made.

In response, Electrolux contends that the '909 patent refers throughout to teardrop-shaped recessed portions formed in the
interior sidewall. Electrolux also contends that the '909 patent nowhere limits the "groove" to a particular width or
narrowness and always refers to the "groove" as recessed into the surface of the sidewall, not merely made as part of the
sidewall. Electrolux also points out that the patent language upon occasion refers to the "groove" as "teardrop-shaped" and
as having both a broader portion and a narrower portion, not simply as "narrow." Thus, Electrolux argues that claim
differentiation bars Maytag from expressly including a "narrow" limitation as part of the general definition of "groove." To
do so, Electrolux argues, would render some of the language of other claims mere surplusage.

In rebuttal, Maytag contends that Electrolux is redefining "groove" to mean "any depression," which is far too broad.
Instead, Maytag argues that the specification and figures all show the "grooves" to be narrow, whether or not they are
"teardrop-shaped." The connotation of all of the dictionary definitions, Maytag contends, is that a "groove" is an
"elgongated" and "narrow" depression. Maytag reiterates its contention that Electrolux is also improperly importing from the
specification the location and method of creating the grooves into the construction of "grooves." In rebuttal, Electrolux
contends that Maytag is improperly importing a "narrow" limitation into "grooves" in Claim 23, while ignoring the express
teachings of the specification with regard to how the "grooves" are formed.
In its surrebuttal, Maytag asserts that it is not defining "grooves" as "narrow," but defining "grooves" as "narrow depressions," because the ordinary meaning of "groove" connotes a "narrow depression," such as a "channel" or "trough." Maytag also reiterates that Electrolux is improperly importing the method of producing the washing machine basket into the "product" patent, when the Examiner required separation of the "product" and "process" claims into separate patents. In its surrebuttal, Electrolux asserts that how the structure of the "groove" is formed is important to understanding the patentee's use of the term in the claims.

At the oral arguments, Electrolux identified the construction of "grooves" as a matter deserving further argument. Electrolux contended that it is improper to import a "narrow" limitation into the definition of "grooves" when there is no such limitation in any claim or portion of the specification. Electrolux points out that the patentee used "narrow" in reference to other parts of the "groove," for example, in Claims 10 and 16, and inclusion of such a limitation would exclude other embodiments. Moreover, Electrolux asserted that reading a "narrow" limitation into "grooves" was expressly rejected by the Federal Circuit Court of Appeals in Beckson Marine, Inc. v. NFM, Inc., 292 F.3d 718, 724 (Fed. Cir. 2002). In response, Maytag asserted that Electrolux's construction would turn a "groove" into any depression, while "narrow depression" is the ordinary meaning of "groove" and is the meaning supported by the claim terms and specification in this case. Indeed, Maytag asserts that Beckson is not controlling, precisely because it involved use of the term "groove" in an entirely different context.

iii. Analysis. Beginning with the words of the claim, Nystrom, 424 F.3d at 1142; Biagro, 423 F.3d at 1302, it is readily apparent that Claim 23 states that the "sidewall [has] grooves formed in said inner surface of said sidewall," see the '909 patent, Claim 23 (emphasis added), but it does not state or incorporate the process whereby the grooves are "formed" into the meaning of "grooves." Also, although the claim language does specify the location of the "grooves," that is, "in said inner surface of said sidewall," id., that language does not define "grooves," because "grooves" must necessarily be in something. Thus, while Claim 23, taken as a whole, requires a plastic washing machine basket with "grooves" in the sidewall, the claim does not in any way narrow the meaning of "grooves" to mean only "grooves" that are "formed by a corresponding projection on the mold core," as Electrolux suggests, nor is the location of the "grooves" part of the definition of "grooves," although for purposes of the claim limitation in Claim 23, the "grooves" are claimed to be "in said inner surface of said sidewall."

Neither Claim 23, nor any other claim, nor the specification of the '909 patent suggests that "groove" is a "technical [term] or term of art," so it does not appear that the specification is necessarily the only source for understanding the meaning of "grooves." See Aquatex, 419 F.3d at 1380 (quoting Phillips, 415 F.3d at 1315, for the proposition that the specification is "the best source" for understanding a claim term, where the term is "technical or a term of art"). Clearly, no part of the specification to which the parties have pointed the court suggests that the patentee was its own "lexicographer" as to the meaning of "grooves," so that there is no "governing" definition for "grooves" to be found in the specification. Compare Phillips, 415 F.3d at 1316 (the patentee may act as lexicographer, and when the patentee does so, its definition must govern). Also, although the specification remains of "central importance" to determining the proper construction of the term, id., and may even be "dispositive" in some cases, Phillips, 415 F.3d at 1314, the court finds that this specification is helpful primarily to show that the patentee used "grooves" in the "ordinary" sense.

Specifically, most of the references to "grooves" in the specification that are cited by the parties show that, when a specific shape for the "groove" is intended, e.g., "teardrop-shaped," the patentee specified that shape. See the '909 patent, col. 2, 11. 3-10 (Summary Of The Invention referring to "teardrop-shaped grooves"); col. 3, 11, 17-23 (Detailed Description Of The Invention also referring to "teardrop-shaped grooves"); col. 3, 11. 61-64 (same). In other circumstances, the patentee left the shape of the "groove" unspecified. See id., col. 4, 11. 36-53 (referring simply to "grooves"). Undeniably, the specification refers to "teardrop-shaped projections 132" that extend from the "mold core 90" in order to form beveled apertures 44 and the teardrop-shaped grooves 50 in basket 2," id., col. 5, 11. 43-56; see also id. col. 6, 11. 60-67, but this part of the specification does not define "grooves" or make the process whereby the "grooves" are created part of the definition of "grooves." Thus, specifications of particular shapes for the "grooves" in the patent specification and the claims, such as those cited above and in unasserted Claim 29 which expressly claims "grooves [that] are teardrop-shaped," see the '909 patent, Claim 29 suggest that "groove," when standing alone, must have its "ordinary" meaning. See Nystrom, 424 F.3d at 1143 (different words in separate claims suggest differences in meaning). Otherwise, the express definitions of shape in other parts of the specification or other claims would be "superfluous." Merck, 395 F.3d at 1372 (terms must not be interpreted in such a way as to make any other terms superfluous).
Similarly, the claimed limitation on certain "grooves" as having "narrowed end portions," versus "enlarged end portions," as in Claims 10 and 16, does not exclude a definition of "grooves" as "narrow depressions," as Electrolux contended at oral arguments. Specification of the relative widths of the "end portions" of the "grooves" again suggests only that, when a specific (or relative) shape was intended for "end portions" of a "groove," such specific shape was claimed, but that, for any other portion of the "groove," the term was intended to have its ordinary meaning.

Finding nothing dispositive in the claim language itself or the specification of the '909 patent concerning the meaning of "groove" in Claim 23, the court turns to extrinsic evidence, such as standard dictionaries, for guidance on "the widely accepted meaning of [this] commonly understood word[]." Phillips, 415 F.3d at 1314. At this point, the parties' dispute is between "a narrow depression, channel, or trough," as Maytag defines the term, and "a depression, channel, or trough," as Electrolux would have it. Plainly, a "groove" may be a kind of "depression," but not every "depression" is a "groove." For example, MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY (10th ed. 1995) defines "depression" as "a depressed place or part: HOLLOW," id. (definition 3 of "depression n"), while it defines "groove" as "a long narrow channel or depression." Id. (definition 1 of "groove n") (emphasis added); see also Plaintiff's Markman Appendix, Exhibit C (definition 2 a of "groove n" from WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY (no date shown), stating "a long narrow hollow or channel made artificially in a surface") (emphasis added). By relying on such a dictionary limitation on the shape of the pertinent "depression" Maytag is not improperly redefining "groove" in the patent as a "narrow groove," as Electrolux contends, but properly defining the kind of "depression" referred to by "groove" as a "narrow depression." Nor is it appropriate to conclude, as Electrolux contends, from a single part of the specification stating that the "teardrop-shaped grooves 50 generally taper along their length, in both width and depth," see id. col. 3, lines 17-19, that the patentee intended to eschew a definition of a "groove," standing alone, as a "narrow depression." Rather, "tapering" suggests a specific kind of "narrow depression" in the particular circumstance referred to in this part of the specification, i.e., "a narrow depression" that "become[s] progressively smaller toward one end." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY (10th ed. 1995) (definition 1 of "taper vb"). Similarly, the references to "narrowed end portions" and "enlarged end portions," for example, in Claims 10 and 16, suggest only that the "narrow depression" has "end portions" that are relatively "enlarged" or "narrowed."

Nor is the court persuaded by Electrolux's contention that the Federal Circuit Court of Appeals rejected the ordinary meaning of "grooves" as "narrow depressions" in Beckson Marine, Inc. v. NFM, Inc., 292 F.3d 718, 724 (Fed. Cir. 2002). Rather, in Beckson, the court held that, in the context of the patent at issue, "the ordinary meaning of 'groove' is not limited to long and narrow U-shaped entities, but encompasses as well other structures that drain water." Beckson, 292 F.3d at 724. This conclusion was based, in part, on use of "the broad term 'draining structures,'" which the court concluded "suggests that the applicant did not limit the claim term 'groove' to a specific width or length." Id. "In fact," the court held, "the written description does not require long and narrow grooves at any point." Id. This court doubts that the construction of "grooves" in Beckson, concerning a completely different patent, could, in any way, be dispositive of the meaning of "grooves" in the '909 patent, which relates to a completely different device. Moreover, in the '909 patent, there is no broader generic term, such as "draining structures," associated with "groove" that would suggest that the patentee did not intend any limitation on width or length. Instead, in the context of all of the evidence bearing on the question here, the court concludes that, while the applicant may not have intended to limit the claim term "groove" to a specific width or length, the patentee did intend to use the term in the sense of a depression that was narrow in width relative to its length, i.e., a "narrow depression." For example, a fair inference from the more specific specifications of the "grooves" as "teardrop-shaped" or as "narrowed and "enlarged" end portions is that the "grooves" are relatively narrower in width than length, that is, that they are "elongated" or "narrow" depressions.

In short, the court concludes that the proper construction of "groove" for purposes of the '909 patent is Maytag's definition, "a narrow depression, channel or trough in a surface."

1906

7. Groove

The term "groove" appears specifically in asserted Claims 25, 32, 41, and 42. With this term, the parties agree that nothing in the specification or prosecution history suggests that the patentee intended to use the term other than according to its
ordinary definition. The dispute is instead, what is included in this definition. A "groove" may be defined as a "long narrow cut or indentation in a surface," Webster's Universal, Stant Ex. 103, p. 842, or as "a long narrow hollow or channel in a surface," Webster's Third, Gerdes Ex. 229, or even as "[a] channel or hollow, cut by artificial means, in metal, wood etc." as the court noted in Beckson Marine Inc. v. NFM, Inc., 292 F.3d 718, 723-24 (Fed. Cir. 2002).

While the court agrees with the parties that nothing in the claims, specification, or prosecution history suggests deviating from one of these ordinary meanings, the court also does not see any evidence that the definition should be limited as to width, length, or means of cutting. Like the court in Beckson Marine, this court has reviewed the evidence bearing on the meaning of the term as it is used in the patent. Nothing in that evidence limits the groove to only those indentations or cuts that are long and narrow and created by artificial means. Therefore, the court finds that the definition asserted by Gerdes, although technically a dictionary definition of the term, is too restrictive based on the use of the term in this particular patent. See Waner, 331 F.3d at 854. For this reason, the court finds that the definition of "groove" is more properly any channel, hollow, cut, or indentation in a surface.

5. "Groove." Consistent with the specification and claims, "groove" shall be given its ordinary dictionary meaning. Therefore, "groove" shall mean "a narrow furrow or channel." 5

--------- Footnotes ---------

5 The American Heritage Dictionary 578, (2d ed. 1982).

--------- End Footnotes ---------

7. "{G}roove-like constrictions:" 7 "A longitudinal groove wherein the lateral defining surface opposite the lower band surface of the spring strips is circular." This construction is consistent with the only embodiments disclosed by the '512 patent. (col. 6:58-62; col. 7:24-25; col. 7:56-59) A construction requiring a circular lateral defining surface is supported by the prosecution history. During prosecution, the examiner rejected original claim 12 (now claim 9) under 35 U.S.C. § 112 as indefinite.(Id. at JA01077) In response, the applicant cited the description of the groove-like constrictions in Figure 6. (Id. at JA01106) With respect to Figure 6, the specification explains that "the two lateral defining surfaces of the constrictions are embodied spherically . . . ." (col. 6:16-19) Finally, spherical must be understood to mean circular, as the lateral surface cannot be spherical in cross section. (See D.I. 165 at JA01216)

--------- Footnotes ---------

7 '512 patent, claims 9 and 13.

--------- End Footnotes ---------

3. "{G}rooves" 4 and "{C}hannels:" 5 "Regions within the cable that are substantially physically separated from other regions within the cable by a pair separator, i.e., they are formed by, but need not be part of, the separator." This construction is consistent with the claims as well as the specification. (col. 5:4-5; col. 7:26-29) The parties agree that the '095 and '999 patents use these two limitations interchangeably. Despite an ordinary meaning describing these limitations as "narrow" regions, the court declines to incorporate this limiting term into its construction in view of the relatively broad grooves displayed by figure 5. Moreover, although formed by the pair separator, the "grooves" and "channels" are discrete from, and not physical attributes of, the pair separator. (See figure 5 (depicting a preferred embodiment which has
"grooves" formed by arranging the pair separator, yet grooves do not appear to be components of the pair separator)

1910

Element [c]-a ground mechanism is also disputed. Thomas and Betts interprets this element to be "an elongated ground rod sunk into the ground" while Senior Industries suggests the proper interpretation to be "a structure (such as a rod or pipe-possibly including several elements) which makes an electrical connection with the earth (i.e., the "ground"), such that dangerous voltages cannot build up in the electrical power system." The proposed constructions are really not in conflict. Senior Industries interpretation is more descriptive and clearly tracks the language in the specification. For example, the specification states the following:

Whether the utility box has an overhead feed or an underground feed, the metal box itself must be electrically connected to ground G through a suitable grounding system. For example, a conduit 16 holds a large size grounding wire 18 which is connected through a clamp 20 to an elongated grounding rod 22 sunk into the ground G.

(the '960 patent, col. 3, lines 51-57 (Ex. A.)).

This passage from the patent specification confirms that the inventor intended the terms to be accorded their ordinary meaning. Furthermore, an examination of the prosecution history supports the notion that the ground mechanism is not limited to a ground rod, as the amendments that were made to Claim 1 include the change in the original words "ground rod" to "ground mechanism". This substitution of the broader term "mechanism" for the narrower term "rod" confirms that the inventors intent was to cover grounding mechanisms, and not just grounding rods. (See Exhibit H; 7/12/90 Amendment C, pp. 1 and 4). As such, the proper construction of element [c] is "a ground mechanism which makes an electrical connection with earth" and is not limited to a sunken ground rod.

1911

Forward Movement of the Needle

"needle holding portion is grounded inside the nose adjacent to the first open end by a barrier limiting forward motion of the elongated needle holder inside a front portion of the nose prior to or during retraction" 10 ('224 patent, claim 1)
11 RTI contends "a barrier disposed in the front end portion of the body that limits forward motion of the needle holding portion and the retractive needle relative to the body as the plunger is depressed inside the barrel during injection and retraction" means "a structure located near the front end of the body that serves to limit forward movement of the needle holder prior to or during retraction." OMI contends the term means "a structure located near the front end of the body that serves to prevent any forward movement of the needle holder prior to or during retraction."

"the needle holding portion is grounded on the annular shoulder" 12 ('224 patent, claim 52)

12 RTI contends "the needle holding portion is grounded on the annular shoulder" means "the needle holder abuts a structure of reduced diameter within the syringe body." OMI contends the term means "the needle holder is prevented from moving forward by a structure of reduced diameter within the syringe body prior to or during retraction."

The claims of the '224 patent contain the above "forward movement of the needle" terms. The parties dispute whether "limiting," "limits," and "grounded" mean the needle holder's forward movement is merely limited or if the needle holder is entirely prevented by an obstruction.

The prosecution history shows that the needle holder does not move forward once grounded. "'[A] clear and unmistakable disavowal of scope during prosecution' may affect the construction of a claim term." Lucent Techs., Inc. v. Gateway, Inc., 525 F.3d 1200, 1211 (Fed. Cir. 2008) (citations omitted). The applicant stated "If needle (3) can still move forwardly during retraction, it does not appear to be 'grounded inside the nose' and a patient could be expected to experience pain as the needle moves forward in relation to the needle assembly (9) as the plunger is fully depressed during retraction." Def.'s Br. (Docket No. 89) Ex. 11, Amendment and Resp., 36. The applicant later stated "Pressly et al. '629 does not disclose a syringe having a needle retraction mechanism grounded inside the nose adjacent to the first open end as recited in claim 58." Def.'s Br. (Docket No. 89) Ex. 11, Amendment and Resp., 38. Thus, the applicant established that when the needle is grounded, it cannot move forward, and the applicant expressed clear disavowal when he distinguishing from the prior art that the needle assembly, which includes the needle holder, cannot move forward during retraction if it is grounded inside the nose.

The specification supports construing "limit" and "grounded" as "prevent any forward movement." The Summary of the Invention states "The front of the needle holder is grounded in the nose portion against forward movement." '224 patent, Col. 4:6-7 (emphasis added). The Detailed Description of the Preferred Embodiment is consistent with the Summary of the Invention. The Detailed Description of the Preferred Embodiment states "Since the front portion 26 of the needle holder is grounded or bottomed inside front 76 of nose 16 at annular shoulder 77, no amount of pressure will allow needle holder 22 or needle 28 to move forward." '224 patent, Col. 8:27-30. Thus, the specification supports that the needle holder does not advance forward at all when grounded.

RTI contends that because dependent claim 52 (dependent on claim 50, which depends on claim 43) already contains the limitation "grounded on the annular shoulder," OMI's construction, which equates "limiting" (found in claim 43) with "grounded" would render claim 52 meaningless. '224 patent, Col. 24:9-10. However, OMI's construction is consistent with claim 52. The presumption created by claim differentiation requires "only that at least one limitation must differ." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000) (citation omitted). Claim 52 specifies that contact between the needle holder and the annular ring prevents forward movement of the needle holder. Contact between the needle holder and the annular ring is the required difference between claim 43 and claim 52 under the doctrine of claim differentiation. Thus, claim 43 and claim 52 may both prevent forward movement of the needle holder. Furthermore, any presumption created by claim differentiation is rebutted by the specification and prosecution history discussed supra. Thus, OMI's construction properly equates "limit" to "grounded."
RTI also contends that the original claim 30, which was cancelled prior to issuance, used the language "prevents forward motion of the retractable needle during retraction." Pl.'s Br. (Docket No. 79) Ex. 6, Amendment in Resp. to Non-Final Office Action, 38. RTI concludes from this that the applicant actually used the word "prevent" when he wanted to convey the meaning of "prevent"; thus, the applicant did not intend for other words, like "limit" and "grounded," to carry the meaning of "prevent." However, original claim 30 was cancelled, and RTI does not present evidence on the reason for cancellation. Thus, the intentions of the applicant and the examiner regarding the cancellation are unknown. This drastically reduces the persuasive value of original claim 30 because RTI only hypothesizes why the applicant used "prevent" in claim 30 and such a hypothesis alone does not establish clear disavowal. Accordingly, the "prevent" language in original claim 30 does not contradict RTI's proposed language "prevent any forward movement of the needle holder."

Accordingly, the Court construes "needle holding portion is grounded inside the nose adjacent to the first open end by a barrier limiting forward motion of the elongated needle holder inside a front portion of the nose prior to or during retraction" as "the needle holder abuts an obstruction in the nose of the syringe which prevents any forward movement by the needle holder prior to or during retraction," "a barrier disposed in the front end portion of the body that limits forward motion of the needle holding portion and the retractable needle relative to the body as the plunger is depressed inside the barrel during injection and retraction" as "a structure located near the front end of the body that serves to prevent any forward movement of the needle holder prior to or during retraction," and "the needle holding portion is grounded on the annular shoulder" as "the needle holder is prevented from moving forward by a structure of reduced diameter within the syringe body prior to or during retraction." 13

13 RTI did not include "prior to or during retraction" in its claim construction for "the needle holding portion is grounded on the annular shoulder." However, RTI did not state an objection to OMI's use of this language. Thus, the Court includes "prior to or during retraction" in the Court's construction as language that is not in dispute.

2. Arguments

Energizer argues that the plain meaning of Claim 1 indicates that it does not cover razors having more than three blades. Gillette argues that the Quattro contains a group of three blades meeting the terms of the claims in the 777 patent, and that the addition of the fourth blade does not avoid infringement.

Claim 1 requires a "safety razor blade unit comprising . . . a group of first, second, and third blades." The term "first" used as an adjective in this context indicates an item that is "before all others with respect to time, order, rank, importance, etc., used as the ordinal number of one." Random House Webster's College Dictionary 501 (1992). The term "second," when used as an adjective in this context, indicates an item that is "next after the first; being the ordinal number for two." Id. at 1210. Similarly, the term "third" in this context indicates an item that is "next after the second; being the ordinal number for three." Id. at 1387.

Claim 1 governs the spatial and sequential placement of the three blades. Claim 1 states that the first blade in the group of three is a "first blade defining a blade edge nearest the guard having a negative exposure not less than -.02 mm." The third blade is a "third blade defining a blade edge nearest the cap having a positive exposure not greater than +.02 mm." Thus, the "first blade" in the group of three is defined as the one "nearest the guard" with a certain negative exposure. The "third blade" is defined as the one "nearest the cap" with a certain positive exposure. The "second" blade has "a blade edge not less than the exposure of the first blade and not greater than the exposure of the third blade." Thus, the three blades with "progressive geometry" must be in the proper sequence of exposures within the blade unit. The addition of fourth blade in the middle between the first and second blade or the second and third blade is inconsistent with the plain language of "first," "second," and "third" because the blade "nearest the cap" would really be the "fourth" blade in the sequence.
Gillette insists that the use of the word "comprising" in Claim 1 indicates that it covers a razor with a group of three blades arrayed in the specific geometry of the 777 Patent, even if that razor unit includes additional intervening blades. Cf. Cybor Corp. v. FAS Techs., 138 F.3d 1448, 1459 (Fed. Cir. 1998) (construing the limitation "to" in the term "by first pumping means to second pumping means" not to preclude the fluid passing through intervening components). It is true that "comprising" is "generally understood to signify that the claims do not exclude the presence in the accused apparatus or method of factors in addition to those explicitly recited." Smith & Nephew, Inc. v. Ethicon, Inc., 276 F.3d 1304, 1311 (Fed. Cir. 2001) (citing Vivid Techs., Inc. v. American Science & Eng'g, Inc., 200 F.3d 795, 811 (Fed. Cir. 1999)). See also Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997) ("'Comprising' is a term of art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim.") (citation omitted).

But "comprising" is not a "weasel word with which to abrogate claim limitations." See Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1379-80 (Fed. Cir. 1998). While the term "comprising" does not exclude additional unrecited elements, the term could not be used to "affect the scope of the particular structure recited within the method claim's step." Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271 (Fed. Cir. 1986) (holding that a step which recites engaging "eight cube pieces as a composite cube" does not read on a step which engages more than eight cube pieces despite the use of the transitional term "comprising").

Here, Claim 1 provides for a safety razor blade comprising: (1) a cap; (2) a guard; and (3) "a group of first, second, and third blades." While the use of the word "comprising" indicates that certain elements may be added (e.g., the wires in the Quattro blade unit) without vitiating a claim of infringement, any placement of another blade in the middle would contradict the plainly defined configuration of the "group of first, second and third blades in the blade unit" mandated by Claim 1. No amount of creative numbering (like Gillette's designating the middle blades as 2a and 2b) can avoid the plain language regarding blade configuration in Claim 1 that excludes from its literal scope the possibility that the accused razor unit contain four blades. See N. Telecom Ltd. v. Samsung Elecs. Co. Ltd., 215 F.3d 1281, 1296-97 (Fed. Cir. 2000) ("If a patent requires A, and the accused device uses A and B, infringement will be avoided only if the patent's definition of A excludes the possibility of B . . . ."). This interpretation of the plain language in the claim is consistent with the specification, which Defendant asserts uses the words "three," "third" or "tertiary" in 30 different places. Nothing cited in the prosecution history speaks to the contrary. Therefore, Gillette is unlikely to prevail on its argument that Schick's accused Quattro razor meets all the limitations in Claim 1 or 10. 2

--- Footnotes ---

2 As Gillette has not demonstrated a likelihood of success on literal infringement, the Court need not turn to the other factors in the test for a preliminary injunction in a patent case.

--- End Footnotes ---

1913

Applying this case law, this court must determine, on this preliminary record, whether the language "comprising . . . a group of first, second, and third blades" in the '777 patent can encompass four-bladed safety razors (such as the QUATTRO(R)) or is limited to solely three-bladed safety razors. As explained below, this court discerns that claim 1 uses the "open" claim terms "comprising" and "group of," in addition to other language, to encompass subject matter beyond a razor with only three blades. Moreover, the specification's focus on blade exposures and express reference to "blade units with a plurality of blades," '777 patent, col. 1, II. 3-6, shows as well that this invention covers razors with more than three blades.

The objective of the invention of the '777 patent is to reduce drag forces in safety razors with more than two blades. See id. at col. 1, II. 24-37. The '777 patent accomplishes this objective by progressively increasing the blade exposure and the blade span. Id. at col. 1, II. 37-59. Indeed, the specification specifically acknowledges that it is not the three blades themselves which solve the prior art problem of detrimental drag forces, but instead the arrangement of three blades in a particular spatial configuration, stating "the novel aspects of the present invention residing in the provision of three blades set in the blade unit set in particular dispositions with respect to each other and the guard and the cap." Id. at col. 3, II. 16-19 (emphasis added). The written description likewise discusses these parameters with respect to the relative positioning of
each of the three blades at length at column 1, line 60 through column 2, line 40. These principles of progressive blade exposure and progressive blade span could apply equally to four or five blades. Such a geometric arrangement of three, four, or even more blades will achieve a closer shave and, at the same time, minimize excess drag. It may be that a four-bladed safety razor is a less preferred embodiment. A four-bladed razor costs more to build, requires more parts, and adds more frictional drag compared to the three-bladed version. Nevertheless, a patentee typically claims broadly enough to cover less preferred embodiments as well as more preferred embodiments, precisely to block competitors from marketing less than optimal versions of the claimed invention.

Indeed, the language of claim 1 of the '777 patent encompasses more than only three-bladed razors. At the outset, the open language of claim 1 embraces technology that may add features to devices otherwise within the claim definition. Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271 (Fed. Cir. 1986). The claim uses two terms to show this open-ended meaning. The word "comprising" transitioning from the preamble to the body signals that the entire claim is presumptively open-ended. Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001); Innovad Inc. v. Microsoft Corp., 260 F.3d 1326, 1333 (Fed. Cir. 2001). Because the patentee invoked this open-ended treatment in claim 1 of the '777 patent, the scope of claim 1 encompasses all safety razors satisfying the elements set forth in the claim. The addition of elements not recited in the claim cannot defeat infringement. See Crystal Semiconductor, 246 F.3d at 1348 ("The transition 'comprising' creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements. KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2002).")

The claim element identifying the blades likewise uses another presumptively "open" claim term -"group of." '777 patent, col. 4, l. 6. At the outset, the language "group of" does not place any limits or closed implications on the elements following this broad designation. Claim drafters often use the term "group of" to signal a Markush group. A Markush group lists specified alternatives in a patent claim, typically in the form: a member selected from the group consisting of A, B, and C. See Manual of Patent Examining Procedure § 803.2 (2004). A Markush group by its nature is closed. If an applicant tries to claim a Markush group without the word "consisting," the PTO will insist upon the addition of this word to ensure a closed meaning. Thus, in order to "close" a Markush group, the PTO insists on the transition phrase "group consisting of." See Abbott Labs. v. Baxter Pharm. Prods., Inc., 334 F.3d 1274, 1280 (Fed. Cir. 2003). Without the word "consisting" the simple phrase "group of" is presumptively open. If intending to limit the claimed invention to a three-bladed razor, the patent drafter would not have used the words "group of." Rather, the drafter would have used the words "group consisting of," or the simple formulation "and first, second, and third blades." Because the drafter chose to use the open term "group of," additional members in the element "group of … blades" will not defeat infringement. In other words, a razor with two "second blades," as in the QUATTRO(R), will still fall within the literal language of the claim.

The element at issue requires:

a group of first, second, and third blades with parallel sharpened edges located between the guard and cap, the first blade defining a blade edge nearest the guard having a negative exposure not less than -0.2 mm, and the third blade defining a blade edge nearest the cap having a positive exposure of not greater than +0.2 mm, said second blade defining a blade edge having an exposure not less than the exposure of the first blade and not greater than the exposure of the third blade.

'777 patent, col. 4, II. 5-14 (emphases added). This element clearly defines a "group of blades" as a subset of the total number of blades in the razor, and specifically identifies which blades of the razor are the "first, second, and third" blades of the subset. The first blade in the group is the blade "nearest the guard," or leading blade. The third blade in the group is the blade "nearest the cap," or trailing blade. The second blade is defined by its exposure, and must "have an exposure not less than the exposure of the first blade and not greater than the exposure of the third blade." Given that the first and third blades must define the leading and trailing blades, respectively, and in light of the specification's discussion ion of a progressive blade exposure, the second blade must also be located between the first and third blades. See id. col. 1, I. 60 - col. 2, I. 40 (discussing a progressive blade exposure from a first blade to a second and third blades). Thus, any blade in between the first and third blades and with an exposure greater than that of the first blade and less than that of the third blade is a "second" blade in the claimed subset of blades. The accused QUATTRO(R) device, in fact, has two "second blades" because both of the middle blades in the accused device meet the definition of the "second blade" set forth in the claim. Any subset of three blades in a blade unit meeting these definitions is a "group of blades "as defined by the clear language of the claim. This claim is not ambiguous. In fact, the patentee underscored this open-ended claim meaning by using both the open-ended transition phrase "comprising" for all elements of claim 1 as discussed above, and the open-ended claim term "group of" for
The district court adopted Energizer's argument that the numerous (approximately thirty) references to "three," "third," and "in the art would construe the claims of the '777 patent to encompass razors with more than three blades. This blatant admission by this same defendant before the EPO clearly supports this court's holding that those skilled in the art would construe the claims of the '777 patent to encompass razors with more than three blades.

The prosecution of patents related to the '777 patent also supports reading claim 1 as an open claim. The defendant itself endorsed an open interpretation of "comprising" when it argued to the European Patent Office (EPO) that a virtually identical claim in Gillette's European counterpart to the '777 patent would not exclude an arrangement with four or more blades. This blatant admission by this same defendant before the EPO clearly supports this court's holding that those skilled in the art would construe the claims of the '777 patent to encompass razors with more than three blades.

The district court adopted Energizer's argument that the numerous (approximately thirty) references to "three," "third" and
"tertiary" in the specification limit the scope of the claims. Gillette, 2004 U.S. Dist. LEXIS 28656, slip op. at 14. However, "words or expressions of manifest exclusion" or "explicit "disclaimers in the specification are necessary to disavow claim scope. Housey Pharm., Inc. v. Astrazeneca UK Ltd., 366 F.3d 1348, 1352 (Fed. Cir. 2004); Liebel-Flarsheim v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). Despite the numerous cites to three-bladed razors plucked from the written description, no statement in the patent surrenders or excludes a four-bladed razor. Neither the district court nor Energizer refers to the "manifest" or "explicit" exclusion test. This patent and its prosecution record fall far short of any kind of disclaimer or disavowal. Not only did the patentee claim the invention with two open-ended terms ("comprising" and "group of"), but the specification expressly teaches that the invention encompasses a "plurality of blades." This court declines to import limitations to the claims from the specification absent a "manifest" or "explicit" exclusion. Id. The patentee did not disclaim razors with more than three blades at all, let alone "manifestly," or "explicitly." Rather the patentee opened its teachings of the invention in the specification with an express statement that the "invention" covers "blade units with a plurality of blades." '777 patent, col. 1, ll. 3-6. The applicant did not "manifestly" or "explicitly" disclaim blade units with a plurality of blades by expressly defining the invention in those exact terms. More important, the language of the claim itself, with its open transition phrases and use of ordinals to distinguish but not limit claim elements, shows that the invention embraces "a plurality of blades."

III

Based on the preliminary record before this court, the district court erred in limiting the claims of the '777 patent to encompass safety razors with solely three blades. Accordingly, this court vacates the district court's denial of a preliminary injunction on the grounds of Gillette's failure to show a likelihood of success on the merits of its claim. However, because the claim construction set forth in this opinion is preliminary and based upon an incomplete record, the district court will have every opportunity to review and revisit this claim construction during development of a full record. Indeed, this court recognizes the difficulty imposed on a trial court to construe claim terms based upon a preliminary "likelihood" record. See, e.g., CVI/Beta Ventures, Inc. v. Tura, LP, 112 F.3d 1146, 1160 n.7 (Fed. Cir. 1997) (reversing its own earlier "likelihood" claim construction of terms that were appealed after a complete record); Bayer AG v. Biovail Corp., 279 F.3d 1340, 1349 (Fed. Cir. 2002) (holding that it was premature for this court to engage in its own claim construction where the district court had not performed a comprehensive claim construction based on a complete record); Metallics Sys. Co. v. Cooper, 100 F.3d 938 (Fed. Cir. 1996) (declining to construe patent claims on appeal from a denial of a preliminary injunction).

ARCHER, Senior Circuit Judge, dissenting.

Because the majority exalts form over substance in reaching its conclusion, specifically elevating claiming conventions over the clear teachings of the specification of U.S. Patent No. 6,212,777 ("the '777 patent"), I dissent.

In construing a claim, we first look to the words of the claims, and these words are generally given their ordinary and customary meaning. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Our search for the proper meaning of claim terms does not stop there, however, because a patentee may choose to "use terms in a manner other than their ordinary meaning." Id. Such a redefinition or limitation of a claim term need not be explicit. "In other words, the specification may define claim terms 'by implication' such that the meaning may be 'found in or ascertained by a reading of the patent documents.'" Bell Atl. Network Servs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001) (quoting Vitronics, 90 F.3d at 1582); see Astrazeneca v. Mutual Pharm. Co., Inc., 384 F.3d 1333, 1340 (Fed. Cir. 2004) (explaining that a patent applicant need not expressly state "my invention does not include X" to indicate his exclusion of X from the scope of his patent). Thus, "the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Vitronics, 90 F.3d at 1582 (emphasis added). The majority eschews this teaching in our case law, instead focusing primarily on the ordinary and customary meaning of the claim terms.
The construction of claim 1 of the '777 patent hinges on how the terms "comprising" and "group of" are construed. The majority follows claiming conventions and ascribes an open meaning to these terms. In doing this, the majority ignores the overwhelming teaching of the specification that the invention of the '777 patent is a razor limited to three blades arranged in the described claim configuration. 1

1 The blade configuration refers to the described progressive and variable blade spans and blade exposures and the three blades' location relative to each other.

Claim 1 reads "comprising a guard, a cap, and a group of first, second, and third blades"; it does not read "a group of blades comprising first, second, and third blades." In this claim, the transition term "comprising" refers only to the total number of elements in the complete razor, allowing for a razor with additional elements besides the guard, the cap, and the three blade unit. See Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1379 (Fed. Cir. 1998); Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271 (Fed. Cir. 1986) (holding that a step which recites engaging "eight cube pieces as a composite cube" does not read on a step which engages more than eight cube pieces, despite the use of the transitional term "comprising"). For example, claim 1 could include a safety razor with an additional guard or cap or some other element altogether. Because the transition term "comprising" is not a weasel word with which to abrogate claim limitations," Spectrum Int'l, 164 F.3d at 1379-80, or to impermissibly expand a claim's scope, claim 1 should not be construed as permitting a group with more than three blades simply because claim 1 contains the open transition term "comprising" in its preamble when the entire specification points to the invention as being only a three-bladed razor with progressive blade exposure and span.

The dependent claims themselves demonstrate that the blade unit of the invention contains only three blades-including a single second blade. Specifically, whenever the second blade is referred to individually, it is referred to singularly ("the edge of the second blade," claim 6, II. 2-3, claim 7, line 2; "the exposure of the second blade," claim 10, line 2). Similarly, the dependent claims' use of the term "span" (singular) whenever the distance between the first and second blades and second and third blades is mentioned evidences that there can only be a single second blade: "a span between the edges of the first and second blades," claim 5, line 2 (emphasis added); "a span between the edge of the third blade and the edge of the second blade," claim 6, II. 2-3 (emphasis added); "a span between the edge of the second blade and the edge of the first blade," claim 7, II. 2-3 (emphasis added); "a span between the edges of the first and second blades and between the edges of the second and third blades," claim 8, II. 2-3 (emphasis added); and "the span between edges of the second and third blades," claim 9, line 2 (emphasis added). A blade unit including more than one second blade would contain "spans" (plural) between "the second blade" and the first or third blade - one between the first or third blade and the first second blade and one between that same first or third blade and the second second blade. There simply could not be a single span between a first or third blade and two second blades. The majority states that the use of "a span" for describing the distance between the edges of the first and second blades and that between the edges of the second and third blades suggests that there can be more than one span for each. In other words, there can be a first span between the edge of the first blade and the edge of the first second blade and a second span between the edge of the first blade and the edge of the second second blade. Such an interpretation of "a span" is not consistent with the remainder of the claim language, however. Claims 5 and 8 state that this span is "substantially equal to 1.5 mm." In a razor having two second blades as proposed by the majority, the first and second blades would have to be virtually in the same spot to satisfy this claim language (a configuration the majority does not even claim the specification supports), as the edge of each second blade would have to be substantially 1.5 mm from the edge of the first blade. 2 Thus, there can only be a single span between the edge of the first blade and the edge of the second blade and a single span between the edge of the third blade and the edge of the second blade. The majority's claim construction effectively replaces "span" with "spans"; this is not what is claimed.

2 The same analysis applies to the distance between the edges of the third and second blades as described in claim 8.
The specification similarly limits the invention to a blade unit having only three blades. The written description begins with an explanation of how two-bladed safety razors have dominated the wet shaving industry. "Safety razors having blade units with two blades have in recent years been sold in very large numbers and are generally acknowledged to give a better quality shave, especially in terms of closeness, than single bladed razors." '777 patent, col. 1, II. 34-37. The specification then explains that a blade unit with more than two blades can provide a closer shave but notes that such a multi-bladed razor is not desirable for other reasons:

Closeness of a shave obtained is only one parameter by which razor users judge the performance of a razor. Adding extra blades can have a serious detrimental influence on other blade unit characteristics, most notably the drag forces experienced when the blade unit is moved over the skin, with the consequence that the overall performance of the blade unit can be markedly inferior despite a closer shave being obtainable.

Id. at col. 1, II. 24-29. The specification then discloses that the inventors have discovered a particular blade geometry for a three-bladed razor so as to overcome the traditional shortcomings of razors having more than two blades. Specifically, the inventors found that adding a third blade positioned between the other two blades in a particular configuration improved closeness while adding only minimal drag:

It has been found that with a blade unit comprising three blades, the frictional drag forces can be kept at an acceptable level while allowing an improved shaving efficiency, by setting the blades relative to each other and to guard and cap surfaces positioned in front of and behind the blade edges, according to a particular geometrical disposition.

Id. at col. 1, II. 32-37. As such, with the exception of the three-bladed razor having the claimed geometry, the specification actually discourages, or teaches away from, razors that have more than two blades. In this regard, the specification expressly cautions that "adding extra blades [more than two] can have a serious detrimental influence on … blade unit characteristics." Id. at col. 1, II. 25-27. The general summary or description of the invention thus describes a three-bladed razor with a certain blade configuration and criticizes other blade units having more than two blades.

We have construed claims to be limited to one type of device where the written description has emphasized features of that device and criticized other similar devices. See Astrazeneca, 384 F.3d at 1340 (citing SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1340-45 (Fed. Cir. 2001) (construing claims to be limited to catheters with coaxial lumens where written description emphasized coaxial lumens as a feature of the invention and criticized catheters using other types of lumens)). Here, the inventors expressly state that using more than two blades in a safety razor is problematic. '777 patent, col. 1, II. 24-31. They then explain that these problems are overcome by a three-bladed razor having blades arranged with progressive blade spans and blade exposures. Id. at col. 1, II. 32-37. This discussion, which expressly emphasizes certain features of the invention (a three-blade unit with the blades arranged in the described geometry) and implicitly criticizes other similar devices (blade units having more than two blades not having the same features), suggests the claims should be narrowly construed.

In my view, therefore, the term "comprising" should not be read as encompassing a blade unit having more than three blades. This is made clear by the claims themselves and by the written description as described below. The traditional open claiming term "comprising" thus applies to the limitations of the razor as a whole, that is, the cap, the guard, and the blade unit and permits other elements included in the razor. However, it does not permit the expansion of the number of blades in the blade unit itself.

Turning to the term "group of," the written description makes clear that this term is not used as an open claiming term as Gillette argues. The term "group of" occurs only once in the written description when the patentee is describing the invention as a whole in the background section of the patent. The group is specifically described as three blades:

Thus, in accordance with the present invention there is provided a safety razor blade unit comprising a guard, a cap and a group of three blades with parallel sharpened edges located between the guard and cap, the first blade defining the edge nearest the guard having an exposure not greater than zero, and the third blade defining the blade nearest the cap having an exposure not less than zero.

'777 patent, col. 1, II. 37-44 (emphasis added).
While not referring again to the "group of "blades, the patentee consistently and frequently refers to his invention as a three-bladed safety 3 razor. For example, when the written description speaks of the "blade unit" of the invention, 4 the only type of blade unit identified is one having three blades: "blade unit comprising … a group of three blades," '777 patent, col. 1, II. 39-40; "three-bladed blade unit," id. at col. 1, line 54; "three-bladed safety razor blade unit," id. at col. 2, line 50; and "three blades set in the blade unit," id. at col. 3, II. 17-18. When explaining the basic structure of the invention, the specification discloses "the novel aspects of the present invention reside in the provision of three blades set in the blade unit set in particular dispositions with respect to each other and the guard and cap." (Id. at col. 3, II. 16-19) (emphasis added). By stating that the unit (group) of three blades (disposed in the described manner) confers novelty to the invention disclosed in the '777 patent, the patentee clearly shows that he regards the invention to be a safety razor with a blade unit having exactly three blades with progressive exposure and span.

3 It was represented to the district court, and noted in its opinion, that the word "three," "third," or "tertiary" is used in thirty different places in the mere three-column-long specification of the '777 patent. Gillette, 2004 U.S. Dist. LEXIS 28656, No. 03-11514-PBS, slip op. at 14. Additionally, nowhere in the specification is the possibility of a four-bladed razor even suggested. This supports a finding that the claims should be interpreted as limited to razors having only three blades. See Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1348 (Fed. Cir. 2004) (noting that the specification referred to transmitting data over a phone line roughly two dozen times and never suggested transmitting data through the use of a packet switched network).

4 The patentee uses the term "blade unit" to describe the carrier of the blades of the invention. See '777 patent, col. 2, II. 63-64 and representation thereof in Figs. 1 and 2.

The majority contends that a three-bladed razor is merely a preferred embodiment of the invention of the '777 patent, as opposed to the invention. However, the specification is replete with instances where the patentee described the invention as a razor having three blades with the described blade geometry. To this end, the specification states "with a three-bladed safety razor blade unit having the blades disposed as specified herein we have found an enhanced overall shaving performance in comparison to a two-bladed razor," (id. at col. 2, II. 50-53) (emphasis added) (located immediately prior to the patentee's statement that "some specific embodiments of the invention are described below"); "it is ensured that an enhanced shaving efficiency is secured due to there being three sharpened blades," (id. at col. 4, II. 2-3 (emphasis added) (the final sentence of the written description which explains that "with the embodiments of the invention" this result is reached); "in accordance with the present invention there is provided a safety razor blade unit comprising a guard, a cap and a group of three blades," id. at col. 1, II. 37-40 (emphasis added) (located in the background section of the patent). These statements are directed to the invention as a whole and suggest that three blades is a part of the invention, not merely a preferred embodiment. We have held that a claim term was properly construed in accordance with a limitation that was "repeatedly and consistently" described in the specification where "those statements, some of which [were] found in the 'Summary of the Invention' portion of the specification, [were] not limited to describing a preferred embodiment, but more broadly describe the overall inventions of [the] patent[]." Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d at 1346-48 (stating "the claims must be interpreted in light of the specification … which repeatedly and consistently describes the local and remote systems of the claimed inventions as communicating directly over a telephone line" and holding that communications were restricted to being over a telephone line and excluded the use of a packet-switched network). Such is the case here.

That a three-bladed razor is not merely a preferred embodiment of the invention of the '777 patent is further evidenced by the fact that the specification addresses only changes in the blade exposure and blade span, not the number of blades. Specifically, the '777 patent states:

A steadily increasing blade exposure has been found most effective. Therefore, the value of the exposure of the secondary blade is ideally approximately half way between the exposure values for the primary and tertiary blades, and very satisfactory test results have been obtained with all three blade edges lying in a common plane. In most embodiments a secondary blade exposure substantially equal to zero will be very satisfactory. We recommend that the tertiary blade exposure be a positive value equal in magnitude to the negative exposure of the primary blade.
The span $S_1$ of the primary blade 11 is from 0.5 to 1.5 mm and is preferably substantially equal to 0.70 mm. The span $S_2$ of the secondary blade 12 and the span $S_3$ of the tertiary blade 13 have the values in the range of 1.0 to 2.0 mm. They are shown [in FIG. 1] equal with a value substantially equal to 1.50 mm. The edge of the tertiary blade is at a distance $S_4$ substantially equal to 1.80 mm in front of the cap.

A more favourable blade arrangement is shown in FIG. 2. The span $S_1$, $S_2$, $S_3$ and $S_4$ are the same as those mentioned above for FIG. 1. The primary blade in this embodiment has an exposure of -0.04 mm, the exposure of the secondary blade 12 zero, the edges of all three blades lying in a common plane $P$ as in FIG. 1, and the exposure of the tertiary blade 13 is +0.06 mm. Thus, there is a progressive increase in blade exposure from the leading blade 11 to the trailing blade 13.

The consistent factor throughout these passages and the patent's drawings is the presence of three blades arranged with progressive blade exposures and blade spans. It is the value of the blade exposure and span that the inventors could vary, not number of blades in the configuration. Thus, a three-bladed razor is not merely a preferred embodiment of the invention; rather, it is the invention. Indeed, nowhere in the specification is the blade unit of the invention expressly described as having multiple blades in excess of three.

5 In this embodiment the blade spans may also vary -- i.e., within the same range as that describing the embodiment shown in FIG. 1 ("The spans $S_1$, $S_2$, $S_3$, and $S_4$ are the same as those mentioned above for FIG. 1"). Id. at col. 3, II, 43-44.
7 Indeed, given the majority's claim construction, which would allow for a second second blade, the district court on remand will now have to determine validity issues including that under 35 U.S.C. § 112 P1.

8 See also supra at 6 (quoting the '777 patent at col. 2, PP. 50-53 and col. 4, II. 2-3).

9 The majority is correct that the use of the terms "first," "second," and "third" in a claim does not necessarily impart a sequential meaning to the items being claimed. However, here the balance of the language in claim 1 clearly demonstrates that the inventor intended a sequential relationship by saying that the second blade is located between the first and third blades. '777 patent, col. 4, II. 7-11 ("The first blade defining a blade edge nearest the guard … and the third blade defining a blade edge nearest the cap.").

In sum, the patent specification 1) repeatedly and consistently teaches that the safety razor of the invention is one having three blades; 2) teaches preferred embodiments which vary the configuration of the blades but in no way changes the number of blades of the invention; and 3) discourages the use of more than two blades in a blade unit except for the three-bladed blade unit having the claimed geometry. I believe these teachings together clearly demonstrate that the inventors did not regard a blade unit with four blades arranged in the described geometry as their invention. Therefore, "comprising" and "group of" should not be construed to include a safety razor having more than three blades.

The only support in the specification for the majority's position that "comprising" and "group of" should be given their conventional meaning is the following sentence: "This invention is concerned with safety razors, and relates in particular to safety razors having blade units with a plurality of blades defining parallel sharpened edges arranged to pass in turn over a skin surface being shaved." Id. at col. 1, II. 3-6 (emphasis added). This single, broad statement, not repeated or endorsed elsewhere in the patent's written description, cannot be read to expand the invention beyond what is explicitly described throughout the specification. In particular, it cannot rewrite the statements that the novelty of the invention "resides in the provision of three blades set in the blade unit," id. at col. 3, II. 16-18, and that the goal of "an enhanced shaving efficiency is secured due to there being three sharpened blades," id. at col. 4, II. 2-3. The majority relies on this one instance of the use of the word "plurality" and conveniently ignores the repeated statements in the specification that the blade unit is composed of three blades.

Finally, the majority's claim construction ignores the notice function of the specification. As the Supreme Court stated almost two hundred years ago, an object of the specification is, to put the public in possession of what the party claims as his own invention, so as to ascertain if he claims any thing that is in common use, or is already known, and to guard against prejudice or injury from the use of an invention which the party may otherwise innocently suppose not to be patented. It is, therefore, for the purpose of warning an innocent purchaser or other person using a machine, of his infringement of the patent; and at the same time of taking from the inventor the means of practising upon the credulity or the fears of other persons, by pretending that his invention is more than what it really is, or different from its ostensible objects, that the patentee is required to distinguish his invention in his specification.

Evans v. Eaton, 20 U.S. 356, 434, 5 L. Ed. 472 (1822) (emphases added). Anyone reading the '777 patent would be left with the indelible impression that the patentee had invented a three-bladed, and only three-bladed, safety razor with blades having the described variable blade span and blade exposure. Only with a crystal ball could a competitor in the safety-razor
industry have concluded that the '777 patent could cover a four-bladed razor.

II.

Certainly, claiming conventions demonstrate that claim terms such as "comprising" and "group of" are traditionally viewed as open claim terms. However, here, the specification makes abundantly clear that the invention of the '777 patent was a razor having three blades, no more, arranged in the described geometry. For this reason, I would affirm the district court's claim construction and its denial of Gillette's motion for a preliminary injunction.

a. "Guard" and "cap"

Claim 1 requires a "safety razor blade unit comprising a guard, a cap, and a group of first, second, and third blades." 777 Patent col.4 11.5-6 (emphasis added).

Schick asserts that the term "guard" as used in the 777 Patent means "a blade unit element positioned in front of the blade edges." (Defs.' Opp'n to Pl.'s Markman Br. 9.) Gillette agrees with this construction. (Pl.'s Reply to Pl.'s Markman Br. 6.)

Schick asserts that the term "cap" as used in the 777 Patent means "a blade unit element positioned behind the blade edges" and includes "any lubricating strip incorporated in such element." (Defs.' Markman Br. 12.) While initially disagreeing, Gillette now concedes this construction. (See Pl.'s Reply to Pl.'s Markman Br. 6; Markman & Summ. J. Hr'g Tr. 19:11-18, Oct. 20, 2005.)

The Court adopts these constructions of the terms "guard" and "cap" as well. While the "ordinary and customary meaning" is not readily apparent from the terms or the claims, the specification as noted by Schick:

refers to "guard and cap surfaces positioned in front of and behind the blade edges." 777 Patent at 1:35-36. Both Figures in the patent show the blade unit element denominated "cap" positioned behind the blade unit elements denominated "blades having parallel sharpened edges." 777 Patent at 3:4; 3:7-8; and Figs. 1 & 2. . . . Both Figures in the patent show the blade unit element denominated "guard" positioned in front of the blade unit elements denominated "blades having parallel sharpened edges." 777 Patent at 3:4; 3:7-8; and Figs. 1 & 2.

(Defs.' Opp'n to Pl.'s Markman Br. 9.) Also noted by Schick, "the specification states that as shown the cap comprises lubricating strip 4 mounted on a frame.' (Id. (quoting 777 Patent col.3 11.4-5).) Therefore, as used in the 777 Patent, the term "cap" means "a blade unit element positioned behind the blade edges" and includes "any lubricating strip incorporated in such element," and the term "guard" means "a blade unit element positioned in front of the blade edges."

K. "guide ions through"

Claim 1(e), which describes the working of the invention's ion guide, states: "means for applying essentially an AC-only voltage between the rod means of said first rod set so that said first rod set may guide ions through said first space." Claim 14(c) similarly states: "placing an essentially AC-only RF voltage between the rod means of said first set so that said first rod set acts to guide ions therethrough." RF stands for "radio frequency and is another way of describing an alternating current. The parties dispute the proper construction of "guide ions through." 2

2 The parties treat "guide ions through" and "guide ions therethrough," for purposes of this construction, interchangeably.
Micromass contends that the ordinary meaning of "through" is "a function word that indicate[s] movement into at one side or point and out at another and especially the opposite side of" or "to indicate passage from one end or boundary to another." Thus, it concludes that "guide ions through" requires that the first rod set (1) guide ions all the way from the beginning to the end of the first space, (2) without ever trapping or storing them for a period of time. Micromass argues that this construction is supported by an argument MDS made to distinguish its claimed invention from one of the ion trap references it presented on reexamination.

AB/Sciex contends that "guide ions through" means only what it says -- ions must be guided through the first space by the ion guide. It argues that Micromass's construction creates two claim limitations unsupported by the claims themselves. Those two limitations are (1) the requirement that all ions enter and exit the ion guide, and (2) that the ions must be guided without ever trapping or storing them for any period of time. AB/Sciex argues that the first of these requirements is rebutted by the specification, which notes that the maximum percentage of ions transmitted through the ion guide using various orifice sizes and pressures was 90%. See 736 Patent at Col. 7, ln. 10-66. The second of these requirements, AB/Sciex argues, has no basis in the plain meaning of the claims and is not required by statements MDS made during the prosecution history.

Reading the claims alone, it is apparent that the term "guide ions through" does not require the successful transmission of all ions or limit the amount of time permitted to do so. It is uncontested that "through" is defined as "indicate[s] movement into at one side or point and out at another and especially the opposite side of." Webster's Ninth New Collegiate Dictionary 1230 (1991). No part of this definition, however, requires the transmission of all ions or sets any restriction on how long the movement of ions can take. Indeed, the only limitation on ions guided through the ion guide is the fact that "ions" is plural and therefore there must be two or more.

Lacking textual support for its two limitations in the claims themselves, Micromass points to statements made by MDS in distinguishing the ion trap references during reexamination. While discussing the Schaaf article, MDS described the working of an ion trap by stating, "with an ion trap, ions of a selected range of mass to charge ratios are trapped or stored for a period of time (which can be quite lengthy) due to electric fields generated with electrodes." Request for Reexamination at 6. In contrast, MDS argued that the claimed invention had an entirely different structure than an ion trap and stated that the "first rod set receives essentially only an AC voltage so that ions are guided through the first vacuum chamber without being trapped there." Id. at 7. Micromass argues that this statement is an admission that the ion guide does not trap ions for any length of time and that this admission must narrow the court's construction of "guide ions through." Understood in context, the distinction drawn by MDS was not that ion guides do not trap ions for any length of time and ion traps do. Rather, MDS argued that ion traps are designed to trap the ions of interest for further analysis, while the ion guide is designed to transmit the ions of interest for further analysis. Moreover, MDS did not state that all ions are guided through the first vacuum chamber without being trapped there, it only said that ions are guided without being trapped in the first vacuum chamber. Thus, it is inappropriate to find in this statement an admission that the claim's limitation that the invention "guide[s] ions through" requires that all ions be guided through. The court finds that MDS did not disclaim a broad interpretation of "guide ions through" by distinguishing the ion trap reference in the Schaaf article.

The court will therefore adopt AB/Sciex's proposed construction that the term "guide ions through" means simply that ions must be guided through the first space by the AC-only voltage between the rod means. The court will not adopt a more narrow construction of the phrase to require either that all ions be transmitted through the ion guide or that the ion guide not trap or hold any ions for any length of time.

1917

A. Guide Means, Guide Assembly and Guide Element

Defendants argue that the terms "guide means," "guide assembly" and "guide element" are subject to a means-plus-function analysis under § 112, P 6. Plaintiff disputes the application of such an analysis. As highlighted by the joint submission at oral argument, the disputed claim limitations in which "guide means" appear read: 3 "said positioning ring including guide means formed on an upper surface thereof in a generally arcuate path," (Claim 1(b) of the '456 patent), "said retaining and
positioning means including guide means formed thereon which are structured and disposed to guide said cutting head assembly along a generally arcuate path during movement of said cutting head assembly over said retaining and positioning means," (Claim 48(c) of the '456 patent), and "said positioning ring including guide means formed thereon in a generally arcuate path." (Claim 30(b) of the '009 patent).

3 The phrase also appears in Claims 2, 3, 6, 8, 12, 29, 46, 47, and 50-52 of the '456 patent, and Claim 14 of the '009 patent.

As highlighted by the joint submission at oral argument, the disputed claim limitations in which "guide assembly" appears read: 4 "said positioning ring including a guide assembly defining a generally arcuate path," (Claims 3(b), 9(b), 10(b), and 15(b) of the '649 patent), and "said positioning ring including a guide assembly defining a generally arcuate path, said guide assembly including a channel member and a post member." (Claim 14(b) of the '649 patent). The disputed claim limitation in which "guide element" appears reads: "a positioning ring including a cavity adapted to receive a cornea, an aperture for exposing a portion of the cornea of the eye, and a guide element; . . . said guide element guiding said head across said aperture making the lamellar incision in the cornea." (Claim 14 of the '553 patent).

4 The phrase also appears in Claim 43 of the '009 patent, and Claims 1, and 11-13 of the '649 patent.

Defendants propose that the guiding function in all three terms should be construed as: "directing and facilitating the movement of the cutting head assembly in an arcuate path." (Court Reference Sheet at 1.) They propose that the corresponding function should be comprised of: "a channel, including a toothed track formed thereon, extending in an arcuate path on the upper surface of the positioning ring, and a rigid upstanding member generally opposite the toothed track." (Id.) Plaintiff proposes that: "The term 'guide means' and 'guide assembly' as used in the asserted claims mean a structure on or operably connected to a positioning ring that defines the arcuate path of the microkeratome cutting head during movement across the positioning ring. The 'guide element' of the '553 patent is not limited to an arcuate path but otherwise has the same definition." (Id. at 2.)

I begin with examining the term "guide means." Defendants start with the premise that because the word "means" is included in the term, there is a presumption that § 112, P 6 is invoked. Defendants argue that guide means is the same as "means for guiding" and as such is a means-plus-function clause. Defendants stress that plaintiff's proposed construction consists of only the most generic identification of structure and not the mandatory definite structure. They contend that plaintiff's definition would not only encompass any structure, or a limitless range of structures, but is defined purely by what it does: directing a path. Defendants turn to Valmont Industries, Inc. v. Reinke Manufacturing Company, Inc., 983 F.2d 1039, 1042 (Fed. Cir. 1993), and argue that plaintiff's proposed construction would allow the claim limitation to encompass all conceivable means for performing the function, which as discussed by the court in Valmont, is the harm that Congress sought to avoid when enacting § 112, P 6.

Plaintiff acknowledges that the term includes the word "means" and therefore there is a presumption that § 112, P 6 is invoked; however, it contends that the presumption is rebutted because sufficient structure is recited to perform the function, and there is no function linked to the word means. Plaintiff compares "guide means" to the "detent mechanism" which was in dispute in Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996) and the "second baffle means" term at issue in Envirco Corporation v. Clestra Cleanroom, Inc., 209 F.3d 1360 (Fed. Cir. 200). In Greenberg, the Court determined that "the fact that a particular mechanism - here "detent mechanism" - is defined in functional terms" is not sufficient to bring the claim within the ambit of § 112, P 6. Greenberg, 91 F.3d at 1583. The Court acknowledged that many devices are named for the function they perform, e.g., "filter," "brake," "clamp," "screwdriver," or "lock." See id. The Court, relying purely on dictionary definitions, concluded that detent fell into this category of terms and noted the following:

It is true that the term "detent" does not call to mind a single well-defined structure, but the same could be said of other
that directs the motion of something. 5 Plaintiff proposes that the term be defined as "a structure . . . that defines the arcuate
to guide the cutting head assembly. Three of the four dictionaries offered essentially define the term "guide" as some object
each identified claim (or subsection thereof) indicates by the language itself that the function served by the "guide means" is
of the same patent.)” (citing Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995)). Specifically,
the term guide means as used in the identified claims recite the function of guiding. See Georgia-Pacific Corp. v. U.S.
Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 2000) (“a claim term cannot be given a different meaning in the various claims
of the same patent.”) (citing Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995)). Specifically,
each identified claim (or subsection thereof) indicates by the language itself that the function served by the "guide means" is
to guide the cutting head assembly. Three of the four dictionaries offered essentially define the term "guide" as some object
that directs the motion of something. 5 Plaintiff proposes that the term be defined as "a structure . . . that defines the arcuate

See id. (recognizing the following technical and non-technical dictionary definitions: "a mechanism that temporarily keeps one
part in a certain position relative to that of another, and can be released by applying force to one of the parts"; "a part of
a mechanism (as a catch, pawl, dog, or click) that locks or unlocks a movement”, "[a] catch or checking device, the removal
of which allows machinery to work such as the detent which regulates the striking of a clock”) (citations omitted). The
Court held that "detent mechanism" was not subject to a mean-plus-function analysis. See id. at 1584. In Environco, the court
began with the presumption that "second baffle means" was governed by § 112, P 6. The court noted that "baffle" is defined in
the dictionary as "a device (as a plate, wall or screen) to deflect, check, or regulate flow." Environco, 209 F.3d at 1365. The
court concluded that this definition conveyed a structure that rebutted the presumption that the means-plus-function analysis
was invoked. See id. Defendants distinguish a baffle from a guide on the ground that a baffle is defined by a definitive range
of structures, namely, a plate, wall or screen.

Plaintiff provides the following dictionary definitions for "guide: "a device by which another object is led in its proper
course," Dorland's Illustrated Medical Dictionary (25th ed. 1974), "a contrivance for directing motion of something; esp:
such a contrivance (as in a tool) having a directing edge, surface, or channel," and a "grooved director for a surgical probe
or knife," Webster's Third New International Dictionary at 1009 (1993), "a device for steadying or directing the motion of
something," Webster's Ninth New Collegiate Dictionary at 341 (1987), and "a device that acts to regulate or direct a motion
or operation," The American Heritage Dictionary at 581 (2d College ed. 1985). Plaintiff contends that these definitions
support its view that the term "guide means" connotes sufficient structure. Plaintiff further argues that the guide means
include the further structural limit of a guide in an arcuate path. Defendants counter that the direction the guide moves
cannot be considered a "structure."

Defendants counter that plaintiff's own experts support defendants' conclusion that plaintiff's proposed definition
encompasses only a generic structure. Dr. Akin provides in his report that: "Despite the appearance of the word "means," the
term "guide means" as used in the '456 and '009 patents would be considered structure to a person of ordinary skill in the
art. The structure being a device by [sic] which directs an object in its proper path." (J.E. Akin, Ph.D., PE, Markman Report
at 17 (September 26, 2001),Defs.' Ex. I ("Akin Report")) (emphasis added). Defendants characterize this statement as a
functional description of the structure in that the generic structural term "device" is followed by the function of directing an
object in its proper path. Dr. Slade provides in his report that: "The term "guide" was a well recognized structural term to
persons of ordinary skill in the art and was widely used to refer to the range of structures that provide for retention and
direction of a cutting head assembly as it moves across the opening in the positioning ring." (Rebuttal Report of Stephen G.
Slade, M.D. at 5, Defs.' Ex. J ("Slade Report").) Defendants contend that Dr. Slade describes guide means in terms of what
it does and offers a limitless structure instead of providing "sufficiently definite" structure.

As noted by plaintiff the Court of Appeals for the Federal Circuit has specifically rejected the argument that a term must fall
within § 112, P 6 if it is defined in functional terms. See Personalized Media, 161 F.3d at 705 (“neither the fact that a
'detector' is defined in terms of its function, nor the fact that the term 'detector' does not connote a precise physical structure
in the minds of those of skill in the art detracts from the definiteness of structure”) (citing Greenberg, 91 F.3d at 1583). At
the same time, the Court of Appeals has also determined that a device that is described in terms of what it does and not in
terms of its structure can at times include any conceivable device, and in those circumstances § 112, P 6 must apply. See
Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1214 (Fed. Cir. 1998) ("the claimed 'lever moving element' is
described in terms of its function not its mechanical structure. If we accepted [the] argument that we should not apply
section 112, P 6, a 'moving element' could be any device that can cause the lever to move. [The] claim, however, cannot be
construed so broadly to cover every conceivable way or means to perform the function of moving a lever, and there is no
structure recited in the limitation that would save it from application of section 112, P 6.").

The term guide means as used in the identified claims recite the function of guiding. See Georgia-Pacific Corp. v. U.S.
Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 2000) ("a claim term cannot be given a different meaning in the various claims
of the same patent."") (citing Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995)). Specifically,
each identified claim (or subsection thereof) indicates by the language itself that the function served by the "guide means" is
to guide the cutting head assembly. Three of the four dictionaries offered essentially define the term "guide" as some object
that directs the motion of something. 5 Plaintiff proposes that the term be defined as "a structure . . . that defines the arcuate
path of the . . . cutting head. . . ." While use of the word "define" in this context is quite creative, it is clear that plaintiff is really admitting that the guide means performs the function of directing that arcuate path. I therefore conclude that plaintiff's argument that the presumption is overcome because no function is recited in the specified claims fails.

5 The fourth definition uses the language of leading an object as opposed to directing an object.

The inquiry, of course, does not end there, since plaintiff can still avoid application of § 112, P 6 as long as the term includes sufficient structure. As plaintiff relies heavily on dictionaries, I begin by analyzing those definitions. In so doing, I conclude that not a single definition includes any definitive structure. For instance, the Court in Enviroco was presented with a definition of "second baffle means" which provided the structure of a "plate, wall or screen." Enviroco, 209 F.3d at 1365. Likewise, the Court in Greenberg was offered a definition of "detent mechanism" which provided examples in the shape of a "catch, pawl, dog, or click." Greenberg, 91 F.3d at 1583. The definitions advanced here offer the generic shapes of a "contrivance," a "tool" with a "directed edge, surface or channel," a "grooved director," or simply a "device." Such examples fail to conjure a non-generic form. The definitions offered by plaintiff's experts fail to indicate otherwise. Plaintiff's own construction fails to include sufficient structure. Rather, plaintiff suggests that the term should be defined as "a structure that accomplishes defining (which as previously discussed is the equivalent of directing) a particular path. Plaintiff's insistence that defining an arcuate path provides structure is not convincing to this Court. As suggested by defendants, the direction in which a device moves does not provide structure. Rather, the indicated path is more properly a function of such device. I therefore conclude that the term does not connote sufficient structure to escape the application of a means-plus-function analysis.

Before continuing with an analysis of the function and corresponding structure of "guide means," I will address whether the means-plus-function analysis shall apply for the terms "guide assembly" and "guide element." I start by highlighting that plaintiff makes no distinction between the term "guide means" and "guide assembly" in its proposed construction. The claim language and context for these two terms are nearly identical. Essentially, the patentee replaced the term "guide means" with the term "guide assembly" in the '649 patent which was filed after this lawsuit was initiated. The only real difference is that certain claims in the latter patent include the addition of the structure of a channel member and a post member. It is true that because the word "means" is not used in the claims, there is a presumption that § 112, P 6 does not apply. That presumption is, however, rebuttable. I have already concluded that the use of the term "defining the arcuate path" as used in plaintiff's proposed construction while innovative, is akin to "directing an arcuate path." The same logic applies to the claim language in the '649 patent. While I cannot dispute that this language offers structure not included in the other claims, it is equally significant that this claim was written after this lawsuit was filed, and plaintiff was well aware of the drafting weaknesses of the earlier and related patents. The fact that additional structure was added to the term and the word "means" was replaced with the word "assembly" does not dissuade me from concluding that the term "guide assembly" is subject to a means-plus-function analysis for the same reasons that the term "guide means" is subject to that analysis.

As to the term "guide element," again, while the term "means" is not used, and therefore a presumption exists that a means-plus-function analysis does not apply, the term clearly denotes a function of guiding the head. Moreover, no structure is offered in the claim. For these reasons, and for the same reasons that the terms "guide means" and "guide assembly" are subject to § 112, P 6, I conclude that the term "guide element" is also subject to § 112, P 6.

Having so concluded, I must now determine the functions linked to those related terms. Defendants propose the following function for each term: "directing and facilitating the movement of the cutting head assembly in an arcuate path." The only flaw I find in this proposal is the word "facilitating." The Court of Appeals for the Federal Circuit has been clear that the function must come from the claim language itself. See Generation II, 263 F.3d at 1363; Micro Chem., 194 F.3d at 1258. Defendants, it appears, have imported the word "facilitating" from the following language in the written description of the '456 patent: "In any event however, the guide means 40 will be disposed on the positioning ring 32 so as to guide and facilitate movement of the cutting head assembly 50 . . . ." Col. 7, Ins. 32-34. I conclude that the plain language of the actual claims provide for the function of directing the movement of the cutting head assembly in an arcuate path. See, e.g. Claim 48(c) of the '456 patent. The function for the term "guide element" varies in that its function is not to guide the cutting head in an arcuate path, but to guide the head across the aperture making a lamellar incision. See Claim 14 of the '553 patent.
Thus, the guide element does not have a function of guiding in an arcuate path.

The next step is to determine the corresponding structures. As previously provided, defendants propose the following structure: "a channel, including a toothed track formed thereon, extending in an arcuate path on the upper surface of the positioning ring, and a rigid upstanding member generally opposite the toothed track." (Court Reference Sheet at 1.) In the event that this Court employs a means-plus-function analysis, plaintiff proposes the following structure: "a channel member, with or without a toothed track, or a rigid upstanding member such as a post, or both, or other equivalent structures." (Pl's Reply Br. at 15.) Thus, the two key questions are whether the structure includes a toothed track and whether the structure includes a rigid upstanding member. Plaintiff argues that the toothed track is part of the most preferred embodiment and the rigid upstanding member is part of the preferred embodiment; accordingly, under Micro Chem., 194 F.3d at 1258-59, neither structure should be included in the corresponding structure. Plaintiff takes the position that the function is accomplished by either the channel member (which need not have a toothed track) or the rigid upstanding member. The Court of Appeals in Micro Chem. noted that in determining the structure linked to the identified function, no structure should be incorporated from the written description beyond what is necessary to perform the function as stated in the claim. See id. The Court did not hold that structure which is part of a preferred embodiment can never be part of the "corresponding structure" of a means-plus-function claim. Defendants direct the Court to Kahn, 135 F.3d at 1476, in which the Court of Appeals noted that the corresponding structure includes that which is clearly linked or associated in the specification. In B. Braun Medical v. Abbott Lab., 124 F.3d 1419, 1425 (Fed. Cir. 1997), the Court explained that once § 112, ¶ 6 is invoked, the patentee must detail in the specification an adequate disclosure showing what is meant by that language; "if an applicant fails to set forth an adequate disclosure, the applicant has in effect failed to particularly point out and distinctly claim the invention as required by the second paragraph of section 112." Accordingly, this Court concludes that if the only structure identified in the specification to perform the determined function is part of the preferred embodiment, such structure must be part of the "corresponding structure," or else the patentee has failed to claim any structure. See Mitek Surgical Prod., Inc. v. Arthrex, Inc., 230 F.3d 1383, 2000 U.S. App. LEXIS 30336, 2000 WL 217637, at *2-3 (Fed. Cir. 2000) (per curiam) (unpublished) (affirming decision of district court that limited claim to preferred embodiment because it was the only embodiment; determining that disclosures in prior art were irrelevant because structure in prior art may only be used to limit and not broaden the scope of means-plus-function structures).

As stated above, plaintiff takes the position that the function of the guide means is accomplished by either the rigid upstanding member or the channel member (which may or may not include a toothed track); both structures, according to plaintiff, are not needed. I begin with the possible inclusion of a rigid upstanding member and note that the "guide assembly" as defined in Claim 14(b) of the '649 patent specifically includes a "post member." 6 The specification of the '456 patent reads:

The guide means 40 further comprise a rigid upstanding member 44 disposed on the retaining and positioning means 30, and generally opposite the toothed track 43. . . . From the explanation which follows, it will become clear that channel member 42 and rigid upstanding member 44 permit the cutting head assembly 50 of this invention to become effectively guided. . . . It will also be appreciated that in assembled form, upstanding member 44 acts as additional guide means for enabling the cutting head assembly 50 to be driven along an arcuate path.

Col. 8, Ins. 11-13, 18-22; Col 9, Ins. 40-44. These highlighted passages do not even describe a preferred embodiment of the rigid upstanding member. Rather, the specification indicates that the rigid upstanding member is a necessary element of guiding the cutting head and is positioned generally opposite the toothed track. Plaintiff's argument that the rigid upstanding member is merely additional guide means and therefore not necessary to perform the function is unavailing. As pointed out by defendants, the word "additional" does not mean "alternative." I therefore conclude that the rigid upstanding member is part of the corresponding structure.

6 In determining whether the corresponding structure includes a rigid upstanding member, this Court found Figures 5A, 5B and 5C of the '456 patent useful. (App. at i.)

The following language from the specification of the '456 patent directs this Court's determination of whether the toothed
track is part of the corresponding structure. 7

Referring to FIGS. 5-A and 5-C, in the preferred embodiment, guide means 40 are seen to comprise a channel member 41, 42 . . . As depicted in FIG. 5-A, channel member 41 may comprise an elongated "C" shaped structure or even an inverted "L" shaped structure. . . . As illustrated in FIGS. 5-B and 5-C however, in the most preferred embodiment channel member 42 is formed by interconnection of two separate elements, namely, an upwardly and arcuately extending sidewall 36 formed on positioning ring 32, and a toothed track 43 which is interconnected with sidewall 36. . . . Thus, guide means 40 in the form of a generally "C" shaped channel member 42 is comprised by the combined structure of sidewall 36 and toothed track 43. . . . With respect to the embodiment shown in FIG. 5-A, it is contemplated that a toothed track may also be mounted to an upper surface of positioning ring 32 or to an upper surface of channel member 41. It will be appreciated that toothed track 43 cooperated with drive means 80 (see FIGS. 7 and 11) so as to drive the cutting head assembly 50 across positioning ring 32.

Col. 7, Ins. 36-38, 42-45, 47-52; Col. 8, Ins. 1-10 (emphasis added).

7 In determining whether the corresponding structure includes a toothed track, this Court found Figures 5A, 5B, 5C, 7 and 11 of the '456 patent useful. (App. at i, ii and v.)

Thus, the specification does appear to disclose a channel member without a toothed track as depicted in Figure 5A. The problem, however, is that the specification does not in any way explain how that embodiment could actually direct the cutting head assembly. The specification only details how a channel member with a toothed track can perform the guide means function. The patentee describes only a toothed track which mates with the propulsion shaft 125 to guide the cutting head assembly in an arcuate path. The teeth of the channel (with the power transmitted thereto) are the core of the guiding process. Without it, there is no structure that can effectively guide the cutting head assembly. This Court is well aware of the mandate not to import excess limitations from the specification. See, e.g., Wenger Mfg., Inc. v. Coating Machinery Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001). I am equally mindful, however, that in construing a means-plus-function claim, the inventor is limited to the structure disclosed in the patent, see Kahn v. Gen. Motors Corp., 135 F.3d 1472, 1476 (Fed. Cir. 1998), and must sufficiently disclose such structure or the invention fails to comport with § 112, P 2, see B. Braun Med., Inc. v. Abbott Lab., 124 F.3d 1419, 1425 (Fed. Cir. 1997).

Plaintiff also attempts to invoke the doctrine of claim differentiation to support its position that the toothed track is not part of the corresponding structure. Under this judicially created doctrine, it is presumed that each claim in the patent is different in scope. See Intermatic Inc. v. Lamson & Sessions Co., 273 F.3d 1355, 1364 (Fed. Cir. 2001); Wegner, 239 F.3d at 1233. At the same time, "claim differentiation is not a 'hard and fast rule of construction,' and cannot be relied upon to 'broaden claims beyond their correct scope.'" Wegner, 239 F.3d at 1233 (quoting Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000)). See also Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) (rejecting argument that "means for joining" limitation could not include a "cross member" because that limitation was recited in a dependent claim; "[a] means-plus-function limitation is not made open-ended by the presence of another claim specifically claiming the disclosed structure which underlies the means clause or an equivalent of that structure.") (alteration in original). Thus, the stringencies of a means-plus-function limitation cannot be escaped merely by adding a dependent claim that recites the corresponding structure disclosed in the specification. See Wegner, 239 F.3d at 1234. Plaintiff contends that because the toothed track is claimed in dependent Claims 44 and 45 of the '456 patent, the toothed track may not be imported into the corresponding structure of the independent claims. I conclude that this argument runs counter to the case law from the Court of Appeals for the Federal Circuit which clearly indicates that a dependent claim cannot be relied upon to avoid the strictness of a means-plus-function limitation.

I therefore conclude that the corresponding structure is also comprised of a channel member with a toothed track mounted or formed thereon. Defendants propose that the construction further require that the channel extend in an arcuate path on the upper surface of the positioning ring. The specification of the '456 patent provides: "guide means 40 are seen to comprise a channel member 41, 42, which extends along a length of at least one side of positioning ring 32 and preferably, on an upper surface of positioning ring 32." Col. 7, Ins. 37-40. Thus, the description requires only that the channel member extend along
at least one side of positioning ring; it need not be on the upper surface thereof. The specification further provides: "It will also be appreciated . . . that channel member 41, 42 extends across ring 32 in an arcuate or semi-circular path." Col. 7, lns. 40-42.

Lastly, I turn to the corresponding structure for guide element. While the claim language of the term "guide element" indicates a varied function from that of guide means and guide assembly, the specification does not mention this means-plus-function claim term. I must therefore conclude that plaintiff has failed to set forth an adequate disclosure, and has, in effect failed to particularly point out and distinctly claim the invention as required by the second paragraph of section 112. See B. Braun Medical, 124 F.3d at 1425.

In summary, this Court has made the following conclusions with respect to the guide terms. Each term, guide means, guide assembly and guide element, are subject to § 112, P 6. The functions for guide means and guide assembly are the same: directing the movement of the cutting head assembly in an arcuate path. The corresponding structure includes a channel member with a toothed track that is formed or mounted thereon and extends in an arcuate or semi-circular path along at least one side of positioning ring and a rigid upstanding member, such as a post, that is positioned generally opposite the toothed track. As depicted in Figures 5A, 5B and 5C the guide means includes both a channel member and a rigid upstanding member; these embodiments clearly demonstrate that both structural elements perform the function of directing the cutting head assembly. This Court therefore rejects plaintiff's argument that either element can alone perform the function of directing the movement of the cutting head assembly in an arcuate path. As to the term guide element, because the inventor did not disclose any corresponding structure in the specification, the patentee failed to claim this portion of the invention.

1918

"Guide Means for Conducting…Wash Liquid" in Claim 16

One of claim 16's many elements is this:

- guide means for conducting a portion of wash liquid containing said concentrated soil particles from said pump chamber to said soil container.

Despite Whirlpool's protestations at W. Mem. 22, the term "guide" cannot be viewed as sufficient structure (if it is indeed structure at all) to remove that language from the ambit of Paragraph 6. 29 As Laitram Corp. v. Rexnord Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991)(emphasis in original) said of a similarly deficient description, "the recited alleged structure tells only what the [claim element] does, not what it is structurally."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

29 Nor does the phrase "from said pump chamber to said soil container" add enough to that de minimis description, by indicating the location of the means, to alter the analysis.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

When the claim is read in terms of the specification as Paragraph 6 directs, it is clear that the corresponding structure comprises annular guide chamber 52, first and second upstanding annular walls 46 and 50, upper edge 47 of first wall 46 and aperture 51 (col. 6, ll. 45-51). 30 That being so, only one other refinement needs to be looked at next: W. Mem. 23 (emphasis in original) asks that this Court "expressly find that the claimed functions does not require 'conducting a portion of wash liquid…from the entire perimeter of the pump chamber."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

30 W. Mem. 22 admits that "guide chamber 52" is "the structure which performs this function" but suggests that it does not have to be annular because, though labeled as such, "there is nothing in the specification which requires such a geometry as necessary to perform the conducting function…." But Paragraph 6 does not ask a court to evaluate the structure in the specification and to determine, as an engineer might, the effectiveness of any particular configuration. It rather commands
that the claim element be limited to the structure as described in the specification.

On that score the specification says (col. 6, ll. 45-50):

As the wash liquid swirls upwardly in a clockwise direction, the concentrated soil particles accumulated on the interior of first upstanding annular wall 46 flow over the upper edge 47 with a portion of the wash liquid. Wash liquid accumulates in annular guide chamber 52....

In light of that language and the depictions of the structure in the patent's Exhibits, Whirlpool has essentially invited this Court to repeal the laws of physics--principally but not solely the principle that water seeks its own level. Because upper edge 47 (like the first wall) is both annular by definition and in the same horizontal plane throughout, the flow over that edge is also 360 [degrees] in scope.

The parties agreed that this element required construction; they continue to disagree on the proper construction to give it. In its post-hearing brief, Fitness Quest has limited its proposed construction somewhat; its construction remains, however, substantially more detailed than that offered by Monti. See Appendix B.

The parties devoted substantial time at the hearing to the question of whether this element -- whether in its original form or in either of the proposed constructions offered by the parties -- was a functional or a structural element. Fitness Quest contended that "guide member" was structural language without an accompanying structural description; Monti contended that Fitness Quest was attempting to read the element as a means-plus-function element, even though "guide member" in itself does not appear to be a means-plus-function element.

"Means-plus-function claiming applies only to purely functional limitations that do not provide the structure that performs the recited function." Phillips, 415 F.3d at 1311 (citation omitted). As in Phillips, "guide member" is not a "purely functional placeholder in which structure is filled in by the specification." Id. "Guide member," while perhaps not ideally specific, plainly is intended to identify a structure, not a means for achieving a particular goal.

Monti further complains that Fitness Quest's proposed construction of the term reads into Claim 15 -- an independent claim -- the adjustability limitations from the dependent claim, Claim 16. Transcript 118. Fitness Quest contends that its construction does not go so far as Claim 16's limitation as to how the guide member and force producing assembly are attached -- that is, in an adjustable fashion. Doc. 43 at 6-7.
Plainly, if Fitness Quest were understood to be importing elements of Claim 16 into Claim 15, that would be improper. "[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Phillips, 415 F.3d at 1315 (citation omitted). By the same token, the constructions offered by both parties include functional language, which both parties apparently deemed necessary to an intelligible construction of the element.

The construction offered by Monti comes closer to a proper construction of "guide member" than the construction offered by Fitness Quest, as it is more limited and more reflective of both the meaning of "guide member," as used throughout the patent and its use in the specific context of Claim 15. Problematic in Monti's construction, among other language, however, is the word "part." As Fitness Quest noted, "part" is a generic -- usually singular -- word that provides little information concerning the referenced term beyond that it is a single (non-multi-part) piece within the referenced device. Transcript 112-13. This Court agrees that more specificity -- without unduly constricting the claim language -- is desirable in construing this term.

For these reasons, the Court has determined that the following language, taken with modification from the construction proposed by Monti, will most appropriately construe the meaning intended to be conveyed by the term "guide member:" "a structure that guides the directional movement of the user as the user performs the exercise."

B. The '056 Patent

Landers assigns error to the district court for giving the limitation "guide tracks," as it appears in claim 1, the same construction as it did in claim 2. According to Landers, the guide tracks in claim 1 guide a nozzle blaster down the well casing, whereas the guide tracks in claim 2 guide a ball cutter. Landers contends that because the claims cover different inventions, the limitation "guide tracks" should also be construed differently. Landers also argues that the court erred in finding no infringement of claim 1 under the doctrine of equivalents. Landers asserts that the court, in making that finding, improperly assumed that claim 1 would be invalid for obviousness if the scope of the term "guide tracks" was broad enough to cover the accused device's pin and groove structure.

We do not agree with Landers that the district court erred by not construing the "guide tracks" limitation differently for claims 1 and 2. In fact, our case law explicitly states that "the meaning of a term in a claim must be defined in a manner that is consistent with its appearance in other claims in the same patent." CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1159 (Fed. Cir. 1997). Indeed, Landers provides no persuasive reasoning, nor can we discern from the patent ourselves, why the guide tracks used to guide a nozzle blaster, as required by claim 1, cannot also guide a motor for movement of the ball cutter, as required by claim 2.

We do, however, conclude that the district court clearly erred in finding that a pin and groove structure would not meet the "guide tracks" limitation under the doctrine of equivalents. The court's error stems from its not construing the "guide tracks" term before concluding that the accused device's pin and groove structure does not meet that limitation, either literally or equivalently. The court's rationale for proceeding in such a manner appears to be that claim construction was unnecessary because any construction in favor of Landers on "guide tracks" would invalidate the claim. As we explained in Nazomi Communications, Inc. v. ARM Holdings, PLC, 403 F.3d 1364 (Fed. Cir. 2005), however, this rationale is critically flawed.

4 Although Nazomi issued after the district court rendered its decision on appeal, the case law expounded upon in Nazomi was established prior to its issuance.

In Nazomi, the district court adopted a narrower claim interpretation in order to preserve the claim's validity. Id. at 1367-68. We criticized this approach of focusing on validity, and, in the process, glossing over the intrinsic evidence that must inform the court's claim construction. Id. at 1368. Pertinent to this appeal, we advised that "it is essential to understand the claims
before their breath is limited for purposes of preserving validity. "Otherwise the construing court has put the validity cart before the claim construction horse." Id., at 1368-69. Here, the court clearly did not construe the term. Thus, it should not have proceeded to narrow the limitation's construction for purposes of preserving validity. To borrow the Nazomi court's adage, there is a validity cart, but no claim construction horse.

Indeed, the flaw in the district court's analysis is further exposed by the possibility that there is only one sustainable construction for claim 1. Under such a circumstance it would be inappropriate for the district court to construe the claim to preserve its validity. See Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999) (claims should not be interpreted to preserve their validity if such an interpretation is contrary to the claim's language and the written description). Only after the court completes its claim construction analysis, which it has not done here, can it determine whether competing interpretations of "guide tracks" even exist, and only then is it permissible for the court to choose an interpretation that may preserve the claim's validity.

Accordingly, we vacate the district court's finding of noninfringement, both literally and under the doctrine of equivalents, of claim 1 of the '056 patent and remand for the court to give the "guide tracks" limitation its ordinary and customary meaning consistent with the intrinsic evidence. Moreover, the limitation "guide tracks" is not indefinable merely because the patent specification and the prosecution history do not provide a "clear description" of the term, as the district court appears to conclude. Final Decision, slip op. at 35.

b. "a guide tube having a distal end"

i. "guide tube"

It is not clear whether the parties dispute the construction of the term "guide tube." Perouse, in its opening brief, construed "guide tube" to mean "a hollow cylinder through which a guide can pass." (Perouse Opening Br. 23-24.) Gore did not construe "guide tube" in its opening brief but stated that the term "may not be in dispute." (Gore Opening Br. 26 n. 12.) In its reply brief, Gore alleged that the parties were in agreement that "guide tube" was to be construed as "a tubular structure with a central lumen." (Gore Reply Br. 27.) Similarly, Perouse asserted in its reply brief that Gore agreed with Perouse's proposed construction. (Perouse Reply Br. 13-14.) At the Markman hearing, Gore again stated that the parties did not dispute the construction of "guide tube." (See Oct. 23, 2007 Tr. 78:10-24.) Perouse, however, asserted that there was a disagreement concerning whether the claim language required a lumen positioned exactly in the center of the tube or whether it permitted a guide tube with an off-center lumen.

The Court finds that the lumen need not be positioned exactly in the geometric center of the guide tube. There is no indication in the specification that the precise positioning of the lumen is important, and neither expert contends that a person of ordinary skill would interpret "guide tube" to include this limitation. Gore did not brief this issue. At the Markman hearing, Gore's only argument in support of the limitation was that the specification and drawings consistently depict a tube with a lumen that is centered within the tube. This argument merely proposes importing a limitation from the specification into the claims, which is improper. See Phillips, 415 F.3d at 1323-24. The Court rejects this limitation.

The Court does not believe there is any other difference between the constructions proposed by the parties, and construes "guide tube" to mean "a hollow cylinder or tubular structure through which a guide can pass." This is the ordinary meaning of the term as understood by a person of ordinary skill in the art at the relevant time, and is supported by the intrinsic evidence. For example, the specification discloses that "the tool is threaded onto a guide, inserted through the skin, and conveyed endoluminally as far as the desired location." (787 patent col.3 11.32-35.) This construction is further confirmed by extrinsic evidence, including dictionary definitions and patents for similar devices. (Golds Opening Decl. PP 63-67.)

The Court construes "a guide tube" to mean "a hollow cylinder or tubular structure through which a guide can pass."

ii. "distal end"

The parties provide identical constructions of "distal end," as it appears in the phrase, "guide tube having a distal end."
The parties construe this phrase as "the extremity of the guide tube away from the operator." (Perouse Opening Br. 22; Gore Proposed Order 2.) The Court agrees and adopts this construction.

Accordingly, the Court construes "a guide tube having a distal end" to mean "a hollow cylinder or tubular structure through which a guide can pass, having an extremity away from the operator."

1922

1. "guide wire tube" or "guide wire tube" 2

2 The claims in the '358 patent uses the term "guide wire", while the claims in the '057 patent uses the term "guidewire." The parties agree that "guide wire" and "guidewire" are identical. For claim construction purposes, "guide wire" will be used as reference to both terms.

3. "guide wire tube" or "guide wire tube" 2

2 The claims in the '358 patent uses the term "guide wire", while the claims in the '057 patent uses the term "guidewire." The parties agree that "guide wire" and "guidewire" are identical. For claim construction purposes, "guide wire" refers to both terms.
The plaintiffs raise two arguments in support of their construction: (1) under SciMed, the sole embodiment is the crux of the invention and the claims should be construed accordingly, and (2) claim 2 of the '358 patent adds the limitation that the outer diameter reduces or tapers, and therefore the doctrine of claim differentiation creates a presumption that this limitation is not in claim 1.

The court is not persuaded by the plaintiffs' argument that the claims should be construed according to the sole disclosed embodiment. See Cordis Order at 8-10. The plaintiffs' claim differentiation argument, however, has more merit. Claim 2, which depends from claim 1, adds the sole limitation that "the outer diameter of the distal portion of the guide wire tube is smaller than the outer diameter of the proximal portion of the guide wire tube." '358 Patent at 38-41. A construction of the term "guide wire tube" that requires the outer diameter to taper would render claim 2 meaningless.

The language in claim 2 that is directed to the outer surface of the guide wire tube is very similar to the language in claim 1 that refers to the guide wire lumen (which is created by the inner surface of the guide wire tube). Claim 1 states that "the lumen having a first diameter for the distal portion of the guide wire tube and a second diameter larger than the first diameter for the proximal portion of the guide wire tube." '358 Patent at 7:16-21. Both the plaintiffs' and defendants' proposed constructions, which require the inner diameter to taper, would render this express language of claim 1 superfluous. The patentee expressed the concept of "reduced or tapered" guide wire tube walls, both inner and outer, by using the language directed to the diameters of the distal and proximal portions. See '358 Patent at 2:60-61. Accordingly, "guide wire tube" means "a tube for passage of a guide wire."

7. Element (f)

Element (f) of Claim 1 requires "Guiding and transporting the ejected product from between the mold parts through the guide conduit." '998 patent at Col. 6 ll. 14-16. Turn-Key argues that this element must be construed according to its plain language and defines "guiding" as directing the product's path of travel through the conduit and "transporting" as causing the product to move through the conduit. Joint Statement at 14; Pl's Opening Brief 16-18. Defendants conversely argue that Element (f) requires that each ejected plastic product has its path determined by and is conveyed by the guide conduit until the plastic product has exited the mold completely. In addition, Defendants argue that the ejected plastic product does not interact with any other structure for guiding or conveying it from between the primary mold parts, besides the guide conduit. Joint Statement at 41; Crest's Responsive Brief 17-19; KM, MC & Concord's Brief at 10-11.

The Court construes the term "guiding" according to its ordinary and customary meaning, thus signifying the act of directing, Random House Webster's College Dictionary at 577, and "transporting" in its ordinary and customary meaning, thus signifying the act of carrying. Id. at 1368. The dictionary defines "through" as "in at one end, side, or surface and out at the other." Id. at 1341. The Court therefore construes Element (f) to require the directing and carrying of the ejected plastic product from the space separating the mold parts to the end or to an exit of the guide conduit. The Court finds Defendants' construction requiring that the carrying and directing of the product be accomplished by the conduit itself to be unsupported by the plain language of the claim. The Court's construction does not render "guide" in Element (d) meaningless because, as previously noted, Element (d) merely introduces the conduit and incorporates into its definition the role that it plays in directing the travel of the ejected molded plastic product-none of the parties contest the fact that the conduit plays some kind of role in directing the movement of the product.

The Court's construction also does not render "guiding" in Element (f) meaningless because the construction still requires that the product be directed in its travel from the space between the mold parts to the end or to an exit of the conduit. The claim language does not disclose the method by which the carrying and directing of the product is to be accomplished and as such, the Court declines to require that the product not interact with anything other than the guide conduit during the process described in this claim.
B. Manner in Which Eggs Are Transferred

Plaintiffs request the Court to construe the guiding steps in claim 24 to require "(1) transfer by lifting of eggs to holding stations; (2) transfer by lifting of eggs from the holding station to the spaced-apart locations; and (3) transfer by lifting of more eggs to the holding stations." 50 In addition, they "request the Court to find specifically that travel of eggs between the 'holding stations' and the 'spaced-apart locations' is not via conveyor belt or other physically connected pathway but rather by 'picking and placing.'" 51 The Court declines to impose a "lifting" or "picking and placing" requirement on claim 24.

Although the specification discloses a preferred embodiment in which eggs are advanced by a "pick and place" mechanism, the specification provides no basis for reading the particular limitations of the preferred embodiment into claim 24. On the contrary, the specification expressly states that "other variations and modifications will be apparent to those skilled in the art." 505 Pat., col. 8, ln. 67-68. As discussed above, 52 unless the specification provides some basis for reading the particular limitations of the preferred embodiment into the claim, references to the embodiment are not claim limitations. See Laitram, 863 F.2d at 865, 9 U.S.P.Q.2D (BNA) at 1299.

Plaintiffs also argue that "use of the term 'holding station' requires that the eggs be held or temporarily stored at the holding station" after each guiding step. 53 Again, Plaintiffs' argument finds no support in the claim language, the specification, or the prosecution history. The Court therefore construes the guiding steps in claim 24 in accordance with the plain meaning of their language:

"guiding said eggs from said weighing stations first to a plurality of egg holding stations located downstream of said guide means" means carrying eggs to holding stations,

"and then to a plurality of locations longitudinally spaced-apart from and substantially horizontally co-planar with said holding stations," means carrying eggs from the holding stations to the spaced-apart locations.

"guiding further eggs to said plurality of holding stations," means carrying more eggs to the holding stations.
"guiding steps"

Based upon its claim construction, the district court instructed the jury, in relevant part, that the guiding steps of claim 24 "are defined as follows: (1) Carrying eggs to holding stations; (2) Carrying eggs from the holding stations to the spaced apart location; and (3) Carrying more eggs to the holding stations." At trial, Diamond did not object to either the district court's construction of "guiding steps" or to the jury instructions about that term. Following the jury verdict of non-infringement, the district court denied Diamond's JMOL motion. In its denial, the district court acknowledged that its interpretation of guiding steps left undetermined whether the claim requires sequential performance of the steps. Then the trial court reasoned that the jury reasonably could have determined from the testimony presented that sequential performance is a necessary characteristic of the "guiding steps." The district court's instructions to the jury did not require sequential performance. In essence, the district court allowed the jury to add an additional limitation to the district court's construction of "guiding steps." In this, the district court erred. Claim construction is a question of law and is not the province of the jury. Markman, 52 F.3d at 979.

This error takes on significance in this appeal because the jury found that the Moba Omnia does not infringe. The record before us discloses no alternative basis upon which a reasonable jury could find that the Moba Omnia does not infringe, other than that the Moba Omnia does not satisfy the guiding steps limitation. Thus, by allowing the jury to import an additional limitation into the claims, the district court fundamentally altered the verdict.

Because Diamond did not object to the district court's claim construction or instructions to the jury, FPS contends that Diamond has waived its right to argue the interpretation of "guiding steps" on appeal. The doctrine of waiver as applied to claim construction prevents a party from offering a new claim construction on appeal. Interactive Gift Express v. CompuServe Inc., 256 F.3d 1323, 1346, 59 USPQ2d 1401, 1418 (Fed. Cir. 2001). Moreover, a party's objection to a jury instruction is waived unless that party objects to the instruction before the jury retires to consider the verdict. Fed. R. Civ. P. 51. In this case, however, waiver does not bar Diamond's argument. Diamond does not now contest the district court's instruction to the jury on the meaning of "guiding steps." Essentially Diamond does not wish to alter the district court's claim construction on appeal, but seeks enforcement of the trial court's claim construction.

Diamond has argued consistently, in its JMOL motions and in its argument on appeal here, that "neither the language of the claim itself nor the Court's order defining this language requires that the 'guiding steps' occur separately." Thus, Diamond has consistently protested the error that this court currently reviews on appeal. Thus, this court will not apply waiver to prevent Diamond from protecting the original breadth of the binding claim construction presented by the district court to the jury from post facto imposition of an additional limitation. Interactive Gift Express, 256 F.3d at 1346. Application of waiver in this case would essentially render unreviewable the district court's error. In sum, Diamond has not waived its argument that the guiding steps may be performed simultaneously.

Nowhere does the plain language of claim 24 require separate and consecutive performance of the various guiding steps. Rather, such a construction is contrary to the teachings of the '505 patent. For example, the specification explicitly describes simultaneous performance of guiding steps two and three. '505 patent, col. 5, l. 54 to col. 6, l. 3. Moreover, simultaneous performance of the guiding steps is consistent with operating at a significant rate of speed, a stated object of the invention. '505 patent, col. 2, ll. 3-7. The prosecution history is also consistent with this claim construction. Hence, this court, like the district court as well, construes the guiding steps to include simultaneous performance.

1927

c. "With a gun barrel cleaning device having a first end and a second end which comprises the steps of"

Michaels argues that the phrase "gun barrel cleaning device" has its ordinary meaning and refers to a flexible tool that has an end that is dropped into and pulled through a barrel to accomplish multiple cleaning functions in one pass. Michaels also argues that it does not require a fabric sheath that may be sectioned and capable of assembly and disassembly. Col 3, lines 64-67; Col 5, lines 17-52; Col 7, lines 45-57; Col 8, lines 33-36; Col 9, lines 10-14; Col 9, line 53 to Col 10, line 11; Fig. 4.

Clean Gun counters that this phrase requires a single, elongated, non-sectioned member, at least part of which is a tubular sheath. The device does not require assembly or disassembly and has no exposed fittings, connections, clamps, wires, push
rod tips or other metal parts. See Figs. 10 and 10A; Col 1, line 36 to Col 2, line 41; Col 2, line 62 to Col 13, line 63; Col 4, lines 9-25, 30-44, 43-60; Col 5, lines 38-52; Col 5, line 56 to Col 6, line 2; Col 6, lines 58-63; Col 7, lines 46-57; Col 9, lines 14-40.

First, to support its proposed construction that the patents must eliminate assembly and disassembly, Clean Gun points to a criticism in the patent specification of gun cleaning devices that are sectional:

All cleaning devices in use today require assembly, changing of fittings, and/or changing of cloths or patches prior to and during their use. This is always an inconvenience and it can prove to be a detrimental disadvantage under tense circumstances, tight time constraints, bad visibility or severe environmental conditions.

Col 3, lines 55-58; see also Col 1, lines 60-62 (criticizing sectional devices that require assembly and disassembly as "time-consuming and complex to use.").

Clean Gun's reliance on the patent's criticism of assembly and disassembly alone is not an express disclaimer and warrants no limitation. However, the patent also expresses that an "object of the invention is to provide a gun barrel cleaning device which eliminates assembly, disassembly, changing of parts, changing of patches, etc." Col 4, lines 22-25. In light of this objective, particularly when read with the criticism, this court concludes that the gun barrel cleaning device must be capable of cleaning the gun barrel as a single unit. It does not require any additional steps of taking sections apart and replacing various cleaning sections during the cleaning process.

This claim construction does not foreclose connecting sections. Rather, there is an advantage to having connections for assembly and disassembly prior to or after cleaning a gun barrel. For example, a user may want to eliminate certain cleaning steps or replace or clean certain cleaning segments. Thus, when in use, the gun barrel cleaning device must be connected as one unit to allow the user to clean a gun barrel in one pass, without any other cleaning steps which require assembly and disassembly. When the user is not cleaning a gun barrel, sections may freely be assembled or disassembled by using connectors.

This conclusion is supported by the patent's example of Figure 4. Figure 4 is the only figure in the patent showing a device with exterior metal couplings capable of assembly and disassembly. As discussed above, the restriction requirements on the '589 Patent do not limit the method claim to a particular device. The specification describes Figure 4 as a "second preferred embodiment." Col 9, lines 10-11. Figure 4 plainly has threaded connections which permit assembly and disassembly. Col 9, lines 10-13.

This conclusion is further supported by inconsistent specifications on exposed metal parts. At one place, the specification recites that an "object of the invention" is to provide a utensil that "is light weight, easily carried under field conditions, and which reduces or eliminates the metal parts typically used in a cleaning device." Col 4, lines 17-20 (emphasis added). To "reduce" is not the same as to "eliminate." Yet, at another place, the specification also states that an "object of the invention" is to "eliminate[] the possibility of metal to metal contact with the gun barrel itself." Col 4, lines 9-11. The specification also states that the method claims can be accomplished by all the various devices depicted in Figures 1, 4, 10, and 13. Col 9, line 52. Figure 4 shows a device with connectors and exposed metal parts. The function of protecting the gun barrel may be accomplished by aligning the brush "with the length of the gun barrel cleaning device" as required by the asserted claims. This prevents misalignment of metal parts which cause damage to the inside of the gun barrel.

As Clean Gun has demonstrated, it may be possible for metal connectors to nick the edge of the gun barrel when first being dropped into the gun barrel. However, the specification speaks to reducing or eliminating damage to the inside of the gun barrel during the cleaning process, not while inserting the device into the gun barrel. Accordingly, the phrase "gun barrel cleaning device" consists of a device that is designed such that there may be connecting metal parts (Fig. 4), but the connectors cannot be readily exposed during the gun cleaning process.

Second, Clean Gun relies on language describing the brush enclosed in a tubular sheath as a way to eliminate metal-to-metal contact. Clean Gun believes that all of the device claims in the two asserted patents require the brush to be inside the sheath. The patent does detail a "preferred embodiment" of a brush inserted into a sheath so that only the soft bristles extend through the sheath. Col 9, lines 15-37. Additionally, the patent summarizes the beneficial results of this aspect of the invention: "The gun cleaning device can also be made such that no metal components (other than the intended industry
standard, soft, phosphor-bronze bristles) can touch the inside surface of the gun barrel, which eliminates scratching, scarring, or uneven abrasion of the crown of the gun barrel, the riflings or other barrel metals.” Col 6, lines 58-63.

As discussed above, this court is unwilling to read into its claim construction any nonlimiting language such as "preferred" or "can also." Additionally, Figure 4 does not have a tubular sheath. Accordingly, the gun barrel cleaning device is not limited to a tubular sheath.

1928

III.

Bigio's challenge to the Board's determination that the toothbrush references are analogous art requires this court to review the Board's construction of the disputed claim term "hair brush." Cf. In re Paulsen, 30 F.3d 1475, 1479 (Fed. Cir. 1997) ("To properly compare the [prior art] reference with the claims at issue, [this court] must construe the [disputed] term . . . to ascertain its scope and meaning.").

As discussed above, the PTO gives a disputed claim term its broadest reasonable interpretation during patent prosecution. Hyatt, 211 F.3d at 1372. The "broadest reasonable interpretation" rule recognizes that "before a patent is granted the claims are readily amended as part of the examination process." Burlington Indus. v. Quigg, 822 F.2d 1581, 1583 (Fed. Cir. 1987). Thus, a patent applicant has the opportunity and responsibility to remove any ambiguity in claim term meaning by amending the application. In re Prater, 56 C.C.P.A. 1381, 415 F.2d 1393, 1404-05 (CCPA 1969). Additionally, the broadest reasonable interpretation rule "serves the public interest by reducing the possibility that claims, finally allowed, will be given broader scope than is justified." In re Am. Acad. of Sci. Tech. Ctr., 367 F.3d 1359, 1364 (Fed. Cir. 2004) (quoting In re Yamamoto, 740 F.2d 1569, 1571-72 (Fed. Cir. 1984)).

In this case, the Board construed the term "hair brush" to include "not only brushes that may be used for human hair on [a] scalp, but also brushes that may be used for hairs on other parts of animal bodies (e.g. human facial hair, human eyebrow hair, or pet hair)." Bigio, 2004 Pat. App. LEXIS 70 at *4. At the outset, the word "hair" preceding "brush" throughout the body of the claim does not alone limit the claim to brushes for scalp hair. At best, the word "hair" carries the meaning that the claimed invention involves brushing some kind of hair. The claim, however, does not specify or limit the claim to any particular kind of hair.

In examining the term "hair brush," the Board correctly declined to import from the specification a limitation that would apply the term only to hairbrushes for the scalp. The application in this case, specifically the "Objects of the Invention," discusses an "anatomically correct hairbrush" for brushing scalp hair. ’747 application at p. 1, ll. 14-15, ll. 16-18; p. 2, ll. 4-6, ll. 7-8. Nevertheless, this court counsels the PTO to avoid the temptation to limit broad claim terms solely on the basis of specification passages. In re Zletz, 893 F.2d 319, 321 (Fed. Cir. 1989). Absent claim language carrying a narrow meaning, the PTO should only limit the claim based on the specification or prosecution history when those sources expressly disclaim the broader definition. See, e.g., Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906-09 (Fed. Cir. 2004) (explaining requirement for an express disclaimer in either the specification or prosecution history).

In this case, the term "hair brush" alone does not specify the kind of hair to be groomed by the claimed invention. Thus, the term may reasonably encompass not only scalp hair brushes but also facial hair brushes. The Board correctly declined to accept Bigio's invitation to narrow the interpretation only to scalp hair by importing a limitation from the specification. Moreover, the Board's interpretation does not strain the bounds of the "broadest reasonable interpretation" of the term "hair brush." Indeed that term may reasonably encompass more than a grooming device for scalp hair. This court therefore affirms the Board's interpretation of "hair brush."

1929

b. "Half Maximum Fan Speed"
The limitation "half maximum fan speed" is found in Claim 1 of the '290 patent. ’290 patent, col.6, l.18. Relying on the ordinary meaning of the words, Delta contended that "half maximum" refers to fifty percent of the highest speed of the fan. Defs.’ Mem. at 15. Control countered that one skilled in the art would not so limit the phrase and directed the Court to the written description for a more functional definition. Pl.’s Mem. at 7.

It is well-established that a patentee is free to use terms in a manner inconsistent with their ordinary meaning as long as the special definition is apparent from the specification or prosecution history. Vitronics, 90 F.3d at 1582-83; Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578 (Fed. Cir. 1996). During the Markman hearing, counsel for Control argued that "it would be clear to those skilled in the art reading the patent that this is not a precise value . . . a half maximum is not a number, it is not a speed, it is a range of speeds." Markman Hr'g Tr. at 13:8-13. Control directed the Court to column 4, line 33 of the ’290 patent to support its argument that "the thrust of the entire specification supporting that claim and the half max is that the minimum represents . . . a value which is not on some arbitrary scale from the fan stopping to the fan going full blast, but is at a point that meets those balancing functions." Id. at 15:22 to 16:2. The "balancing functions" refers to the invention's goal of providing optimum cooling with low acoustical noise.

The patent teaches that "it is highly desirable to maintain a predetermined fan speed, e.g. approximately half maximum speed, when air temperature is below the preselected threshold." ’290 patent, col.4, ll.33-36. The preselected threshold refers to the temperature above which the fan speed increases. The summary of the invention states that the predetermined fan speed is the minimum speed needed to provide "adequate cooling of the electronic equipment under typical or nominal conditions." Id. col.2, ll.1-3. Thus, according to Control, "half maximum" does not refer to a number, but rather identifies the minimum speed necessary to achieve adequate cooling under normal conditions. Markman Hr'g Tr. at 15:12-18; Pl.’s Mem. at 8 (asserting that half maximum must be defined functionally to reflect a balance between acoustical noise and cooling).

Control's construction, however, provides no limit to the "half maximum fan speed" limitation. If "half maximum" were defined as the minimum speed necessary to achieve adequate cooling, then "fan speed" could vary widely depending on the environment, the electrical components, and any number of other factors not incorporated into the patent. Such a broad construction is not only contrary to the plain meaning of the limitation but also contradicts the prosecution history. During prosecution of the patent, Control was forced to amend its original limitation of "preselected minimum" to avoid prior art. Katz Decl. Ex. B at C00059. "To further aid in distinguishing from [the prior art], each of the independent claims has been amended to recite that the fixed level corresponds to 'one-half maximum fan speed' . . ." Id. at C00047. Control cannot now reclaim what it willingly abandoned to obtain the patent.

During claim construction, the Court acknowledged that "half maximum" is not a precise figure. Specifically, the Court accepted Control's argument that the highest rated speed of a fan varies. In addition, the Court recognized that the written description teaches "approximately," not exactly, half maximum. ’290 patent, col.4, l.34. Ultimately, the Court ruled that "half maximum speed means roughly fifty percent of the highest rated speed of the fan having in mind that fans supplied by different manufacturers may differ as to their highest rated fan speed." Markman Hr'g Tr. at 26:10-13.

1930

I. Half-Shells

Claims 1 and 11 of the '875 patent describe the housing of the fluorescent lamp as "including two separable, identical half shells." (App. To Def's Markman Br. Ex. A at Col. 4, L. 26 and Col. 5, L.L. 24-25)(emphasis added). Claim 10 of the '227 patent describes "a self-supporting elongated housing having two separable half-shells, both half-shells being identically shaped." (App. To Def's Markman Br. Ex. B at Col. 5, L.L. 6-7)(emphasis added). Additionally, Claim 11 of the '227 patent discloses "a self-supporting elongated housing having two separable half-shells, said half-shells being joined along a junction plane and said plug being arranged in said junction plane of said half-shells." (Id. at Col. 6, L.L. 5-8)(emphasis added).

APP contends that "half-shells" are equal halves of a hard outside cover. Lampi has not proffered its own definition of "half-shells." Rather, counsel for plaintiff generally asserted that "half" does not mean equal. With respect to "shell," Lampi also asserted that there is no basis to interpret it as a hard outside cover.
Neither of these objections to APP's interpretation is well-founded, particularly since Lampi failed to provide an alternative definition. First, and most obviously, the ordinary and customary meaning of "half" is one of two equal or corresponding parts into which a thing is divided. Nothing in the patent suggests otherwise. Indeed, Claims 4 and 15 of the '875 patent use the term "corresponding" to describe the two shells which meet along a junction plane to form the housing. (See App. To Def.'s Markman Br. Ex. A at Col. 4, L. 39 and Col. 6, L. 9). Moreover, counsel for Lampi conceded that, at least mathematically, halves are more often than not equal to one another. We will not quibble with his analysis. Contrary to APP's assertions, however, "equal" or "corresponding" does not necessarily mean exactly alike or the same. If that were the case, there would be no reason to modify "half-shells" with the term "identical" discussed in part II of this Opinion.

As to "shell," we find no basis for Lampi's objection to interpreting it as a hard outside covering. The ordinary, and indeed only, meaning of "shell" in this context is a hard outer cover or structure that forms a firm framework or covering. For confirmation of this definition, we need look no further than the claims themselves which are riddled with references to the housing. Specifically, Claims 3 and 14 of the '875 patent and Claim 5 of the '227 patent describe the half-shells as "injection molded parts made of plastic." (See App. To Def.'s Markman Br. Ex. A at Col. 4, L.L. 32-33 and Col. 6, L.L. 2-3; Ex. B at Col. 4, L. 53). These half-shells form a self-supporting elongated housing which supports the fluorescent tube and electrical components. (See App. To Def.'s Markman Br. Ex. B at Col. 5, L.L. 5-19 and Col. 6, L.L. 5-20). The electrical plug then extends outward to support the housing and fluorescent tube in a "self-supporting manner when inserted into an electrical outlet." (Id.). Because the shells are made of plastic, and because they form a housing which supports the inner components of the lamp, it is reasonable to interpret "shell" as a hard or firm outside covering.

Accordingly, we adopt APP's interpretation and define "half-shells" as two equal or corresponding parts forming a hard or firm outer covering into which the housing of the fluorescent lamp is divided.
the fluorescent lamp installed during fabrication, and . . . repaired if necessary[]." '227 patent, col. 2, ll. 14-18. Thus, the specification indicates that the housing must have at least two half-shells, but that it may have other parts as well.

Our interpretation is also supported by comparison to claim 1. Like claim 11, claim 1 claims, in part, a "housing . . . having" various listed structures. Claim 8, which depends from claim 1, reads: "The lamp according to claim 1 wherein said housing comprises two separable half-shells." Because claim 8, a dependent claim, must be narrower than claim 1, from which it depends, the term "having" in claim 1 must be open. That interpretation of the term "having" in claim 1 supports the conclusion that the patentee intended to use the same language in claim 11 in the same manner.

Therefore, we conclude that the district court erred in ruling that half-shells must be the only two elements that form the housing in claim 11. The proper interpretation of the "housing having two half-shells" limitation is a "housing having at least two equal or corresponding parts forming a hard or firm outer covering into which the housing of the fluorescent lamp is divided." Because the district court erred in construing that limitation, we vacate that portion of the judgment and remand for the court to consider whether the 5544 model infringes under the claim construction set forth above.

Kapusta asserts that the district court erred in construing the claim term "hand-grip size case" to require the limitations that the case be "no smaller than the width of an adult palm, no smaller than 1 inch in width, and of a rectangular shape." Kapusta contends that the court should have given the term its ordinary and customary meaning of "a case that is suited to a grip by the hand," and the court should not have added limitations for which there is no support in the intrinsic record. With respect to the "of a rectangular shape" limitation, Kapusta argues that the district court imported a limitation from the preferred embodiment of the specification into the claims. Furthermore, Kapusta argues that the district court erred by finding the term at issue to be ambiguous and then importing unnecessary limitations in order to preserve the patent's validity.

Gale counters that the added definitions of the term "hand-grip size case" are in the specification. Specifically, the figures portray the case to be of hand-grip size and of a rectangular shape. Furthermore, the specification notes that the case has a "top wall," which suggests a rectangular-shaped case. Gale also argues that the extrinsic evidence, including two prior art references introduced during litigation and expert testimony, disclose that a hand-grip size case does not encompass all portable devices smaller than Kapusta's device. According to Gale, the term at issue is ambiguous because it has an expansive meaning subject to different interpretations and thus, in light of the prior art introduced during litigation, it must be construed narrowly to preserve its validity.

We agree with Kapusta that the district court erred in its claim construction by including extraneous limitations. The court should have given the term "hand-grip size case" its ordinary and customary meaning. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (explaining that unless the intrinsic evidence compels a contrary result, a claim term should be given its ordinary and customary meaning). The ordinary and customary meaning of "hand-grip size case" is a case of a size that can be gripped in a normal hand. We see no reason to depart from that ordinary and customary meaning or to add dimensions to the term, as there is no support for the district court's limitations in the intrinsic record.

Starting with the claim language itself, we see no evidence from this source to support the court's size limitations. The claim states that the test circuit is mounted in "a hand-grip size case," implying that the case is capable of being gripped in the hand of a normal person, and not of a size with specific dimensions. The straightforward mechanical technology of the invention and the understandable claim language give that meaning to this term. See Phillips, 415 F.3d at 1314 ("In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words."). "Hand-grip" means what it says, i.e., capable of being gripped by the normal hand. The claim language does not imply a departure from that meaning.

The specification also does not suggest any reason to deviate from the ordinary and customary meaning by imparting dimensions to the term. The specification consistently refers to the instrument as serving "in the hands of an operator." '663 patent, col. 1, ll. 63-65, col. 2, ll. 34-36. However, nowhere does the specification explicitly or implicitly ascribe numerical limitations to the case embodying the instrument. In fact, when mentioning the hand-grip size case, the specification states
only that the case is "of preferred hand-grip size," suggesting that the dimensions of the case being of hand-grip size, while preferred, are not inflexible. The specification further mentions that the operator will "grasp the primary instrument," yet that description does not suggest any specific numerical dimensions of the case. '663 patent, col. 6, II. 22-25. In the few instances where the specification alludes to either the "hand-grip size case" or to grasping the instrument, it does not reference any dimensions. Because numerical dimensions are absent in the specification, it was improper for the district court to construe the claim term with the lower limit dimensions.

The district court stated that it established the size dimensions of the "hand-grip size case" from "a preferred embodiment described in the specifications and shown in the drawings. . . ." Claim Construction Order, at 5. It further appears to have determined the meaning of the "of a rectangular" shape limitation solely from figures 4-7 because that is the only place in the patent that suggests such a shape. However, we cannot accept the district court's analysis because case law is well established that, while a specification should be used to interpret the meaning of a claim, it should not be used to import unnecessary limitations into the claims. See Phillips, 415 F.3d at 1323. In particular, we have acknowledged that claims must not necessarily be restricted to those embodiments disclosed in the specification, even if a patent describes only a single embodiment. As we stated in Phillips, "although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments . . . In particular, we have expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." Id.

Here, the district court expressly ascertained the size limitations from a preferred embodiment and improperly construed the term to incorporate those limitations. The specification states that the figures are shown "for illustrative purposes" and thus the figures do not restrict the scope of the claims to that which is shown in the drawings. See '663 patent, col. 3, II. 66-67. The specification also states that figures 4, 5, and 6 depict "one of the featured companion test instruments," further suggesting that the scope of the claims should not be restricted exclusively to those figures. Id. at col. 5, II. 3-5. Because the specification does not indicate that the embodiment depicted in the figures is meant to be the only embodiment, and in fact implies otherwise, the claim term should not be limited to specific dimensions established from the figures.

The prosecution history also does not provide support for the addition of dimensions to the "hand-grip size case." On appeal from a rejection by the examiner, the Board of Patent Appeals and Interferences ("BPAI") rejected applicant's broad argument that the invention is distinguished over the prior art because it is "portable," but added that "there is no teaching or suggestion in [the references cited upon which the rejection was made] of a hand grip size case and therefore we will not sustain this rejection . . ." Applicant thereafter amended claims from being only portable to incorporate the language specifying "a hand-grip size case in which said test circuit is mounted" to put the claims in condition for allowance. The BPAI implied that the invention was distinguishable over the cited prior art by the inclusion of a "hand-grip size case," but the BPAI did not ascribe any lower size dimensions to the case.

Moreover, with regard to the "of a rectangular" shape limitation, although figures 4-7 show the instrument as housed in a rectangular-shaped case, the specification never suggests that this shape is critical to the operation of the invention. An important object of the invention is to have the portable test instrument serve "in the hands of an operator." '663 patent, col. 1, II. 61-64. There is no reason why this objective could not be accomplished equally as well with a non-rectangular shaped case. As long as the instrument can serve "in the hands of an operator," it fulfills the objective of the patent, irrespective of the specific shape of the case. The specification does not assign any significance to the shape of the case, and there is otherwise no indication in the intrinsic evidence that the invention must be limited to the rectangular shape depicted in some of the figures.

Gale further contends that in addition to the figures, the reference in the specification to securing a connector to the "top wall" of the case implies that the case is rectangular. See '663 patent, col. 5, II. 32-34. We find this argument unpersuasive. Securing the connector on the "top wall" does not compel the use of only a rectangular shape because other shapes could include a top wall.

Finally, the court's finding that the term is ambiguous and should be construed to sustain its validity is without basis. The term "hand-grip size case" is not ambiguous. Although the term may be of a nonspecific size and shape, that does not render the claim term ambiguous. Because the term is not ambiguous, the district court should not have applied the doctrine of construing claims to preserve their validity. Construing claims to sustain their validity has been limited to those cases in which "the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous."
Phillips, 415 F.3d at 1327 (quoting Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 911 (Fed. Cir. 2004)). We have not applied the doctrine broadly and have "certainly not endorsed a regime in which validity analysis is a regular component of claim construction." Phillips, 415 F.3d at 1327. This is not one of those limited cases where the term cannot be construed using other available tools. Had the district court limited its construction to the ordinary and customary meaning, it would not have had to resort to construing the claim term more narrowly to preserve its validity.

In sum, we do not accept the limitations that the district court added to the term "hand-grip size case." We see no basis for incorporating specific dimensions and a specific shape into the claim construction. Because we disagree with the court's claim construction, we vacate the district court's finding of noninfringement of the '663 patent to the extent that it was based on an erroneous claim construction of the term "hand-grip size case." That term, as indicated above, simply means a case of a size that can be gripped in a normal hand. While we might, on the basis of that meaning, make our own judgment on the question of infringement, based on the record, the better practice is to have the district court make that factual determination on remand. We therefore remand for the court to redetermine whether Gale's Products meet the limitation as we have construed it.

1933

O. "wireless handheld computing device"

Term wireless handheld computing device

Ameranth's Definition a mobile computing device which is suitable for in-hand use and is capable of wirelessly communicating with other computing devices

Term wireless handheld computing device

Defendants' Definition
Defendants do not believe that a construction is required for this term.

If the Court concludes that a construction is required, the term should be construed as "a palm sized wireless computing device"

The disputed term is located in each of the asserted independent claims: "transmitting said second menu to a wireless handheld computing device." Based on the limited briefing, the parties appear to dispute whether the handheld computing device must be palm-sized. Although a hand-held device does not necessarily need to be palm-sized, it must be sized to be held in one's hand. The court therefore construes the term to mean "a wireless computing device that is sized to be held in one's hand."

GO BACK

1934

1. "handheld module including a display, manual controls, and system circuitry for processing signals for display"

Plaintiffs' construction: a module that by design is operated while its components (i.e. a display, manual controls and system circuitry for processing signals for display) are held in one hand

Defendant's construction: a compact assembly designed to be carried in one hand that includes a display, manual controls, and system circuitry for processing signals for display
The parties' dispute regarding the meaning of this phrase boils down to a dispute about the meaning of "handheld." Defendant contends that "handheld" means a device that can be carried in one hand, while plaintiffs argue that "handheld" devices must be operable when held in one hand. In support of its position, defendant contends that the patent specification make clear that the term "handheld" denotes a machine that is easily portable. Plaintiffs rely on dictionary definitions and materials relating to the prosecution of an allegedly related patent in support of their argument that the common understanding of the term "handheld" relates to a user's ability to operate the device while it is held in one hand, not the portability of the device.

The meaning of "handheld" is not readily apparent from the claims themselves, which shed little light on how a user would interact with the device. Therefore, I turn to the patent specification to determine the meaning of the term as it is used in the '101 and '566 patents. The "Background Art" portion of the '566 patent offers persuasive evidence that "handheld" in the context of the '101 and '566 patents refers to a class of devices that are relatively portable in contrast to traditional, cart-mounted devices. This portion of the patent specification explains that "modern ultrasound devices generally fall into two classes of devices." '566 pat., col. 1, lns. 24-25. The first class of devices is described as "large, immobile," id. at lns. 26-27, "high-end," id. at ln. 40, devices that "are arguably portable" but "are limited by their ability to be transported easily." id. at lns. 29-30. The second class of devices is described as "systems designed for handheld use," id. at ln. 47, with displays in "specialized modules" or "laptop computers," id. at ln. 55. The specification goes on to discuss in detail the advantages of the invention's light weight and easy portability. Id. at col. 6, lns. 3-4, 9-10.

Next, the specification of the '566 patent cites U.S. Patent No. 5,839,422 (the "Chiang patent") as representative of the "handheld" devices that use a laptop computer display. Id. at 56. The Chiang patent discloses a ultrasound system in which a laptop is connected to a hand-held scanner. It is clear from the Chiang patent that the full device it discloses is not intended to be operated while held in one hand, although it includes a handheld scanhead. Therefore, the reference in the '566 specification to the device disclosed in the Chiang patent also suggests that, in the context of the '566 and '101 patents, "handheld" is the nomenclature given to devices that can be carried in one hand.

In contrast, all of plaintiffs' arguments rely on extrinsic evidence. Plaintiffs' primary argument is that dictionary definitions provide the proper definition of the term "handheld." Although dictionary definitions may be helpful to understanding claim terms in some cases, the Court of Appeals for the Federal Circuit has cautioned explicitly against over-reliance on them. Phillips, 415 F.3d at 1319. In this case, the patent specification provides insight into the meaning of the term "handheld" as it is used in the '101 and '566 patents and it is not appropriate to replace these specific definitions with those gleaned from a non-technical dictionary. Id. Plaintiffs' other arguments regarding statements included in defendant's internal marketing materials and a narrow reading of the Chiang patent are similarly unpersuasive. Therefore, I will adopt defendant's construction of the term "handheld."

**Court's construction:** a compact assembly designed to be carried in one hand that includes a display, manual controls, and system circuitry for processing signals for display.

1935

**B. "Handheld unit dimensioned for handheld grasping"**

The plain meaning of this term is that the unit is designed to be of a size permitting it to be easily grasped and held in the hand of a human operator.

1936

1. Claim 1 ("handle")

Claim 1 (and all dependent claims) of the '050 Patent uses the term "handle" as follows: "a housing including a first handle and a second handle movable with respect to the first handle," and "a clamp member extending distally of the distal portion of the outer tube and pivotable between an open position and a clamped position by movement of the second handle.
between first and second positions..." See '050 Patent, Claim 1 (emphasis added). Plaintiff proposes the following construction: "The part of the instrument designed to be grasped by the hand," while defendant proposes: "A part of the housing that can be grasped by the hand by inserting one or more fingers through an opening therein." The plaintiff's proposed instruction that "handle" be construed as "the part of the instrument designed to be grasped by the hand," comports with the agreed ordinary and customary meaning of "handle" as "a part that is designed esp. to be grasped by the hand or that may be grasped by the hand," see Def. Claim Construction Br. [Doc. # 40] at 10, and there is a heavy presumption in claim construction that claim terms carry their "ordinary and customary meanings." Phillips, 415 F.3d at 1312-13 (internal quotation and citation omitted).

While defendant's argument that this ordinary meaning cannot be adopted given various distinctions drawn by the patentee between "handle" and various other terms n2 may correctly reflect that the patentee did not intend that these other terms be given the identical construction as "handle," in the Court's view, adopting defendant's proposed construction to avoid this result is neither necessary nor appropriate. Claim terms will "take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327. No such indication of intent to deviate from the ordinary meaning of "handle" appears either in the Claim 1 itself or in the specifications. See '050 Patent, Claim 1, 10:47-50, 11:63-66, 14:9-12.

n2 See Def. Claim Construction Br. at 10-12 (comparing "handle" with, inter alia, "stationary gripping member" described at '050 Patent, 4:35-41, 6:20-26).

Moreover, it is improper for a court to "import" limitations into a claim from the specifications. See e.g., N. Am. Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1348 (Fed. Cir. 2005) ("Unless required by the specification, limitations that do not otherwise appear in the claims should not be imported into the claims."); Seachange Int'l, Inc. v. C-COR Inc., 413 F.3d 1361, 1376 (Fed. Cir. 2005) ("It is improper to import a limitation into a claim where the limitation has no basis in the intrinsic record."); Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 906 (Fed. Cir. 2005) ("The court must take care in its analysis, when locating in the written description the context for a disputed term, not to import a limitation from that written description."). Defendant's proposed limitation that the construction require that the "handle" contain an opening into which fingers can be inserted appears in neither the claim itself, nor the specifications, and thus there is no basis for "importing" that limitation into the claim construction.

A. Canady's '675 Patent

On July 15, 1991, Dr. Jerome Canady filed a patent application entitled "Surgical Coagulation Device." After several amendments to the initial application, the PTO approved the application and issued the '675 patent to Jerome Canady on May 4, 1993. The '675 patent is related to a coagulation device that controls or prevents blood flow in tissue for various types of incisional surgical procedures using an endoscope. Specifically, the '675 patent discloses a coagulation device using ionizable gas, such as argon, and radiofrequency current ("RF current") to cause blood coagulation (stoppage of bleeding) in the tissue. Using this device allows the ionizable gas to conduct the RF current in a gas stream to the tissue where the RF current causes blood in blood vessels of the tissue to "blow away." As a result, the blood vessels coagulate thus ceasing blood flow in the tissue. In addition, the coagulation device causes blood coagulation without physical contact between the device and tissue.

To perform this type of procedure, the '675 patent discloses a flexible tube passing through an endoscope which includes a flexible wire for conducting RF current. The flexible tube allows the ionizable gas to flow through the tube and endoscope. At the tip of the flexible tube and wire, the ionizable gas is discharged creating a gas stream that conducts the RF current from the flexible wire to the tissue which causes blood coagulation. In the '675 patent, claim 1 states the patented invention as follows:

1. A surgical tissue coagulator comprising an elongate, biocompatible, flexible tube having an open distal end and a proximal end, the tube having an external diameter of less than about 5 mm and being insertable into and maneuverable within a surgical endoscope;
means for connecting the proximal end of said tube with a source of an inert, ionizable gas so that a stream of said gas can flow through said tube and exit the distal end of said tube;

a flexible wire within said tube for conducting radio frequency current, the wire having a distal end for position adjacent the distal end of said tube, and means at the distal end of said wire for discharging an arc of radiofrequency energy away from the distal end of said wire within said stream of inert gas exiting the distal end of said tube so as to form an ionized gas stream which is capable of coagulating tissue during endoscopic surgery within a patient, the wire having a proximal end opposite the distal end of the wire, and means for connecting the proximal end of the wire with a source of radiofrequency energy; and

a handle attached to said tube adjacent the proximal end of the tube for maneuvering said tube within said endoscope while said handle is outside said endoscope. (Col. 4, Line 67 to Col. 5, Line 25) (emphasis added).

Figure 2 of the '675 patent, as shown below, illustrates a preferred embodiment of the claimed invention. The preferred embodiment is used for endoscopic surgical procedures where a tube is inserted and passed through an endoscope to conduct the RF current and carry the ionizable gas.

IV. CLAIM INTERPRETATION

In construing patent claims, the court must consider (1) the claim itself, (2) the specification, and (3) the prosecution history of the patent application (if introduced). Vitronics Corp. v. ConceptorInc., Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Words in a claim must be given their plain meaning unless another definition is specified. In re Zletz, 893 F.2d 319, 321-22 (Fed. Cir. 1989). The court, however, can neither narrow nor broaden the scope of the claim to give the patent owner something different than what he intended. E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988). The appropriate starting point is with the specific language of the claims, Phonometrics, Inc. v. Northern Telecom Inc., 133 F.3d 1459, 1464 (Fed. Cir. 1998), and all words in a claim must be considered. In re Wilson, 57 C.C.P.A. 1029, 424 F.2d 1382, 1385 (C.C.P.A. 1970).

In claim 1 of the '675 patent, the "handle" element is recited as "a handle attached to said tube adjacent the proximal end of the tube for maneuvering said tube within said endoscope while said handle is outside said endoscope." (Col. 5, Lines 21-24) According to claim 1, the recited "handle" has the purpose of "maneuvering" a tube within an endoscope. This purpose of "maneuvering" is clearly supported in the specification. More particularly, in the detailed description of the specification of the '675 patent, a preferred embodiment of the claimed invention discloses the "handle" as "a handle (18) [which] is provided for maneuvering tube (10) within an endoscope (16) (shown in Fig. 2) while handle (18) is outside the endoscope." (Col. 3, Lines 2-5).

Canady contends that the prosecution history of the '675 patent application shows the novelty of the '675 patent is related to the use of an "ionizable gas" and in particular, argon gas, for endoscopic electrosurgery. Canady further asserts that the claimed "handle" element should be interpreted to cover any "handle" element which is positioned outside of an endoscope.
This contention is unavailing because the court cannot interpret the claimed "handle" element to cover all "handle" elements positioned outside of an endoscope, but must interpret the explicit language of the claims which clearly recites a "handle" being further limited by its function of "maneuvering" a tube within an endoscope. See In re Wilson, 424 F.2d at 1385 (noting that the court cannot ignore the specific language in a claim). Furthermore, the court must construe patent claims consistently with the specification and the preferred embodiment. See Vitronics, 90 F.3d at 1583; See also In re Barr, 58 C.C.P.A. 1388, 444 F.2d 588, 592-93 (C.C.P.A. 1971) (noting that the court should give the claims the broadest reasonable interpretation consistent with the specification). Here, both the claim language and the specification describe a "handle" as having the purpose of "maneuvering" a tube within an endoscope. Moreover, adopting the ordinary meaning of the term "handle" dictates the court's conclusion that the claimed "handle" is "a part to be held or operated with the hand." In re Zletz, 893 F.2d at 321-22. The clear language of the claim further compels the court's conclusion that the claimed "handle" is further limited by its function "for maneuvering" a tube within an endoscope. Accordingly, the court concludes that the claimed "handle" of the '675 patent is limited by its recited function of "maneuvering" a tube within an endoscope. Armed with this claim construction, the court proceeds to determine the validity of the '675 patent and ascertain whether ERBE's APC Probes infringe claims 1 and 11-16 of the '675 patent.

1938

C. "Handle Component"

Pedicraft argues that the claim limitation "a handle component mounted to . . . at least one side rail," as used in Claims 10 and 18, should be construed to mean "a portion of the side rail positioning mechanism to be actuated by hand." Dkt. 65, pp. 17-18. This construction, according to Pedicraft, is supported by Claim 10, which purportedly "recites that the handle component is provided to actuate other components of the side rail positioning mechanism." Id. at 18. Moreover, the specification, file history, detailed description and Figure 4 of the '855 Patent all allegedly support Pedicraft's position that the handle component is actually that portion of the side rail that is actuated by hand. Id. at 18.

Stryker, on the other hand, proposes a simple definition of "handle component" as merely a "grip." Pedicraft argues that this definition is too restrictive and would improperly limit the handle to a "stationary grip structure" without consideration for the claimed actuating role played by the handle component, which is both evidenced in Claim 10 as well as the patent specification and prosecution history. Pedicraft points out that Mr. Lockwood testified that a handle component, in the context of the '855 Patent, would be understood to provide for handle actuation as opposed to a stationary grip, and Dr. Dyro purportedly also stated that a stationary grip would not perform the claimed hand actuation. Dkt. 62, pp. 51-52; Dkt. 63, pp. 43-44. In essence, Pedicraft interprets the "grip" to be a "subcomponent of the overall handle component," or in other words, the "handle component" is actually an assemblage of parts used to actuate the side rail positioning mechanism between a lock and release position. Id.

Stryker, on the other hand, supports its "grip mounted to the side rail" construction of "handle component" by arguing that the specification of the '855 Patent actually refers to the handle component as a "handle grip." '855 Patent, Cols. 5-6. Additionally, Stryker claims Dr. Dyro did in fact refer to the handle component as a "grip" during his Markman testimony. Dkt. 63, pp. 40-41. It argues that Pedicraft's proffered "actuation" definition is vague and unclear, and in fact the actuation function appears separately in the '855 Patent after the term "handle component" is used. Stryker therefore urges the Court to adopt a clearer definition of "handle component" as simply a "grip."

The Court again agrees that Stryker's proposed construction comports with both logic and the '855 Patent itself. The patent refers to the "handle component" as comprising a "handle grip," and then only later explains that this component operates to "rotate the lock spindle from a lock position to a release position." '855 Patent, Cols. 5-6; Claim 10, Col. 9; Dkt. 66, pg. 34. The handle component itself, however, is simply a handle grip used to rotate the spindle, as opposed to some vague assemblage of parts comprising some unstructured actuation function. Stryker's construction of "handle component" is
therefore the most logical and will be adopted by this Court.

1939

D. "HANDLE PORTION"

The next term to construe is "handle portion," which appears in claim 1 of the '540 Patent. Plaintiff argues that the meaning of the term is "portion of the grooming tool having a hand-grip portion and a head portion." Plaintiff asserts that this proposed definition is based on the specification of the '540 Patent, which states that the "handle portion 22 includes a hand-grip portion 26 and a head portion 28." ('540 Patent, doc. # 1-3, p.7 col.2 ll.58-60). Defendants argue that the meaning of "handle portion" is "the portion of the tool that does not include the pet engageable portion." Defendants assert that this construction is also based on the language of the '540 Patent, which states, "the only essential components of the pet grooming tool 20 are the handle portion 22 and the pet engageable portion 24." ('540 Patent, doc. # 1-3, p.8 col.3 ll.56-58).

Plaintiff argues that "Defendants' definition does not indicate what a handle portion is. Rather, it merely indicates what it is not." (Pl.'s Opening Brief, doc. # 101, p.8). Plaintiff also argues that Defendants cannot claim that the only two components of the patented tool are the handle portion and the pet engageable portion. This is because the cited claim terms are listed under the term "comprising," which is an open-ended term that does not exclude unlisted elements. See Mars, Inc. v. H.J. Heinz Co., L.P., 377 F.3d 1369, 1376-77 (Fed. Cir. 2004). The Court agrees with Plaintiff's arguments and rejects Defendants' proposed definition, "the portion of the tool that does not include the pet engageable portion."

Defendants, challenging Plaintiff's definition, argue that the definition is "ambiguous" and "does not account for all the components found in the claimed invention." (Defs.' Opening Brief, doc. # 100, p.12). The Court agrees with Defendants that Plaintiff's definition is somewhat ambiguous, specifically because Plaintiff's proposed definition includes the term "head portion," which would require further definition.

The Court will reject both of the definitions initially proposed by the Parties, and instead adopt a definition that gives the words of the claim their "ordinary and customary meaning." Phillips, 415 F.3d at 1312 (internal quotations omitted). "Handle portion" is a term that is sufficiently common and identifiable, and the claim term is apparently not afforded a special meaning of any type in the pet grooming industry. The Court has determined that the "ordinary and customary meaning" of "handle portion" is "portion of the grooming tool that the user holds and that secures the pet engageable portion," and the Court will construe the term as such. This "ordinary and customary" meaning was readily apparent, so the Court need not consider other intrinsic or extrinsic evidence.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 This definition was informally proposed by Defendants in the September 18, 2009 Markman hearing, and is similar to the everyday description of "handle portion" given by Plaintiff at the same hearing.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

1940

(b) "a hanger extending downward from each side of said primary frame members;"

Boler interprets element (b) as "a structure or a thing, attached to the frame members, that extends toward a lower place." Watson, on the other hand, defines this term as "a structure or a thing extending toward a lower place." Boler contends that its interpretation is more appropriate because it advises one ordinarily skilled in the art what the "structure or thing" is attached to, i.e. the frame members. The court agrees with Boler and therefore defines element (b) as "a structure or a thing, attached to the frame members, that extends toward a lower place."
Hard Facing

Claims in the '631 Patent contain the terms "an exterior hard facing," "a hard facing," and "a hard facing material." ReedHycalog contends "hard facing" is limited to nickel carbide or tungsten carbide. Baker contends "hard facing" means "a material that resists being worn away by abrasion during drilling" and lists 10 materials as examples of hard facing.

The '631 Patent does not define "hard facing" and offers little guidance. Claim 7 of the '631 Patent claims a drill bit "wherein the bit body comprises steel and the at least one bearing surface of at least one of the plurality of blade structures includes an exterior hard facing." Id. at col. 30:11-14. Claim 8, a dependent claim, claims the same drill bit "wherein the exterior hard facing comprises tungsten carbide particles." Id. at col. 30:15-16. Therefore, as delineated above, it is presumed under the doctrine of claim differentiation that "hard facing" is not limited to tungsten carbide particles.

Claim 11 claims a drill bit "wherein the wear-resistant exterior comprises at least one of the group consisting of carbide, tungsten carbide, synthetic diamond, natural diamond, polycrystalline diamond, thermally stable polycrystalline diamond, cubic boron nitride, and hard facing material." Id. at col. 30:25-30. While this claim appears to list separate materials, claim 8 indicates "hard facing" can contain tungsten carbide, one of the materials listed in claim 11. Id. at col. 30:15-16. Therefore, the claim 11 list does not exclude the other listed materials from the construction of "hard facing."

The specification also does not define the term. It lists "hard facing" as a type wear-resistant feature apart from embedded-diamonds, thermally stable PDCs, PDCs, weldings, and weldments. Id. at col. 20:40-44. However, the specification does not limit "hard facing" to any type of material or state that "hard facing" cannot comprise the other listed wear-resistant materials.

Logic dictates that "hard facing" is a material harder than the material it is applied to. As such, "hard facing" includes those materials listed in the specification, in addition to other materials, when those materials are harder than the surface they are applied to. Thus, "hard facing" and "hard facing material" mean "wear-resistant material that is harder than the material onto which it is applied." 27

27 Ref. No. 32 of Appendix B contains the disputed terms and their constructions.
Court that Genus' device contains, in addition to the gas showerhead, a separate outer ring containing gas flow holes that point outward at a 45-degree angle.

The language of the claims, however, does not require that the gas flow apertures be parallel to the substrate. In claim 1, the apparatus must be capable of directing the gas flow perpendicular to the substrate. ('165 patent 5:37-39.) Claim 1 describes the apparatus as "comprising a member having a plurality of gas flow apertures passing therethrough for maintaining said flow of gas perpendicular to said substrate . . . said member being disposed parallel to said circular substrate[.]") (Id. 5:39-42.) Thus, the member containing the apertures must be disposed parallel to the substrate, but there is no requirement that the apertures themselves be parallel to the substrate. An aperture through a solid substance is a three-dimensional hole, containing an input, a tunnel through the solid substance, and an output. The apparatus must be capable of directing the gas flow perpendicular to the substrate, which would seem to require that the output of the gas flow apertures be disposed parallel to the substrate, but there is no requirement that the input of the gas flow apertures also be parallel to the substrate. As Genus points out in another part of their argument, apertures that are in a "Y" formation may start out at an angle, but nonetheless direct the gas downwards perpendicular to the substrate.

Claim 6 contains similar language requiring that there be an apparatus comprising "gas flow means having a plurality of apertures passing therethrough and disposed parallel to said substantially circular substrate, said plurality of apertures forming a generally circular configuration[.]") (Id. 6:17-23.) This language at first appears to be ambiguous, as it is not immediately clear whether the gas flow means must be disposed parallel to the substrate, or whether the gas flow apertures are disposed parallel to the substrate. When this language was added to the claim, however, the inventors stated that the language was added "to positively recite and claim the features of the gas flow means or apparatus as being disposed parallel to the surface of the substrate," which clarifies that it is the gas flow means that must be parallel to the substrate. ('165 Prosecution History at 0053.)

In claim 6, as in claim 1, the gas flow must be directed perpendicular to the substrate ('165 patent 6:26-29), which suggests that perhaps the outputs of the gas flow apertures also must be parallel to the substrate. Again, however, there is no requirement that the input of the gas flow apertures be parallel to the substrate.

Thus, Genus' argument that "all of the apertures are disposed parallel to said substantially circular substrate" is not well taken. Even if one assumes that by using the phrase "all of the apertures," Genus intended to refer only to the gas flow apertures, Genus' argument does not distinguish between the input and output of the gas flow apertures.

ASM appears to be arguing for the possibilities that: (1) gas may also flow into the chamber from some source other than the gas flow apertures in the showerhead; and (2) that some of the gas flow apertures need not be parallel to the substrate. Claims 1 and 6 both require an apparatus "comprising" a substrate and either "an apparatus for directing a flow of gas" (claim 1) or a "gas flow means" with certain characteristics. ('165 patent 5:34-37; 6:17-20.) The parties agree that the term "comprising" is an open term which creates a presumption "that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements." Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). There is no argument here to rebut that presumption. Thus, the use of the term "comprising" does not preclude an apparatus that also uses an additional gas flow apparatus or means that is not parallel to the substrate or in which the outputs of the gas flow apertures in that additional gas flow apparatus are not parallel to the substrate.

Determining whether the claims permit any of the gas flow apertures to be non-parallel to the substrate requires that the Court determine what the inventors meant by the term "having." The Federal Circuit has stated that the term "having" can make a claim open, but does not convey the open-ended meaning as strongly as the term "comprising." Crystal Semiconductor, 246 F.3d at 1348. Use of the term "having" does not create a presumption that the body of the claim is open. Id. The Court must examine the claim in its full context in order to determine whether the use of the term "having" limits the claim to its recited elements. Id.

The claims do not expressly require that the either the input side or the output side of the apertures be parallel to the substrate. What is required is that the apparatus containing the apertures be parallel to the substrate, and that the gas flow be perpendicular to the substrate. Whether this can be accomplished with some additional number of gas flow apertures that are not parallel to the substrate and/or are not contained in the showerhead seems to be to a question of fact that is better reserved for briefing on infringement. At this juncture, as a matter of claim construction, the Court finds that the term
"having" does not preclude the possibility that the apparatus may have gas flow apertures other than those described in the
claims. As the gas flow apertures described in the claims are associated with the performance of particular processes,
however, any additional gas flow apertures must not be necessary to perform the processes described in the claims, and also
must not interfere with those processes.

1943

1. The '041 Patent

It is undisputed that the plaintiff's latch mechanism is comprised of the following basic parts: a container body, a lid with a
latch bar, an elongated "tongue" structure, a "tooth" located on the distal, or top, end of the tongue, and a lower ridge which
extends outwardly opposite the tongue. The tooth and lower ridge together form the upper and lower boundaries of a recess
or indentation into which the latch bar structure of the lid fits to lock the container in a closed configuration. To open, or
disengage, the latch mechanism, the user must manually flex or bias the distal end of the elongated tongue in a backward
direction so that the tooth of the tongue structure can clear the latch bar of the lid.

According to the parties, the relevant portion of claim 4 of the '041 patent involves the following language:

said latch comprises an elongate tongue . . . having a ridge extending outwardly opposite said rear surface across said
tongue generally parallel to and in a spaced relation to said tooth . . . .

'041 patent (emphasis added).

In its papers, Rubbermaid asserts that the key word set forth in claim 4 is the word "having," and thus requests the court to
interpret that term. "Having" is not specifically defined in the claim, the patent, or the prosecution history. Consequently,
and because "common words, unless the context suggests otherwise, should be interpreted according to their ordinary
meaning," Desper Products, Inc. v. QSound Labs, Inc., 157 F.3d 1325, 1335 (Fed. Cir. 1998), defendant urges the court to
consult, and ultimately adopt, the dictionary definition of the term.

"Having" is the present participle of the verb "have." As defined by Webster's Collegiate Dictionary, "have" is defined as "to
hold, include, or contain as a part or whole." Webster's Collegiate Dictionary 533 (10th ed. 1999); accord Webster's Third
New Int'l Dictionary 1039 (1986)(defining "have" as "contain, include"). Plaintiff does not dispute this definition of the
word "having," and does not offer an alternate definition of the word. Therefore, because there is no indication that plaintiff
intended to assign to the term "having" any meaning other than its plain and ordinary meaning, and further because plaintiff
has raised no objection to the court's construction of the term in that manner, the court adopts the dictionary definition of the
term. Thus, the court concludes that the term "having," as it is used in claim 4 of the '041 patent, means "to hold, include, or
contain as a part or whole."

According the term "having" its plain and ordinary meaning, defendant argues, requires the court to construe claim 4 as
limited to latch mechanisms with tongues which contain or include a lower ridge. More specifically, defendant contends
that, because claim 4 specifically claims a latch mechanism with a "tongue . . . having a ridge," that ridge must necessarily
be a part of the tongue structure. The court agrees, and therefore construes claim 4 of the '041 patent as claiming latch
mechanisms with ridges that are a part of the tongue structure.

1944

II. "Having [a]"

Plaintiff's proposed construction: "having only"

Defendant's proposed construction: "having at least"
The transitional phrase "having" appears in all independent claims of the patents-in-suit and is used to define the panels of the invention. The parties agree that "having" must be interpreted in light of the specification to determine whether open or closed language is intended, see Lampi Corp. V. American Power Products, Inc., 228 F.3d 1365, 1376 (Fed. Cir. 2000), but they disagree on where this will lead us. Plaintiff advances a closed construction, contending that the term "having" is meant not only to exclude additional elements, but also to restrict the number of named elements. In other words, the panels must have only one main plateau, one spliced plateau, one jogged portion and cannot have any additional plateaus, jogged portions or anything else. Defendant contends that the term is meant to be open, meaning that the recited elements of a main plateau, spliced plateau and jogged portion are only part of the invention and that the claim does not exclude additional, unrecited elements. See, e.g., Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997) (use of an open term like "comprising" means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim).

The transitional phrase "having" can make a claim open but it is not presumed to do so (in contrast to "comprising," which is presumptively open). Crystal Semiconductor Corp. v. TriTech Microelectronics Intern., Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). To determine whether the term is meant to be open or closed, the court must look for clues in the claims or in the specification. Lampi Corp. v. American Power Products, Inc., 228 F.3d 1365, 1376 (Fed. Cir. 2000). For example, in Enzo Biochem, Inc. v. Appliera Corp., 2006 U.S. Dist. LEXIS 74570, 2006 WL 2927500, *9 (D. Conn. 2006), the court noted that the patentee had used the term "having" differently from the term "comprising." Specifically, in the claims using the word "comprising," the patentee had used language such as "at least one of," which signaled that it intended "comprising" to have an open meaning. In contrast, the patentee did not modify the term "having," which was always stated in the form "a compound having the structure." From this observable dichotomy, the court determined that the two terms had different constructions, with "comprising" being an open term and "having" being a closed term. Id.

Citing Enzo, plaintiff argues that the patentee's use of the open term "comprising" in the same claim containing the word "having" is evidence that the terms should be construed differently. In contrast to the patent in Enzo, however, here the patent does not use the phrase "comprising at least one of" or any other modifier signifying that the term has a meaning different from "having." Contrary to plaintiff's argument, the mere fact that the term "comprising" is used to describe the wall joint and the term "having" is used to describe the elements of the panels is not strong proof that the patentee intended the terms to have different constructions. To the contrary, the patentee's word choice in the specification suggests that it intended the word "having" to have an open construction. Lines 17-20 at Col. 4 of the '564 patent read:

"The word 'includes' is a patent law term of art meaning 'comprising'; it is an 'open ended' term allowing other elements to be included in the meaning of a term. The First Years, Inc. v. Munchkin, Inc., 575 F. Supp.2d 984, 998 (W.D. Wis. 2008); see also SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1284 (Fed. Cir. 2005) ("includes" means "comprising"); Medicem S.A. v. Rolabo, S.L., 353 F.3d 928, 933 (Fed. Cir. 2003) ("comprising" is "open ended" term). The use of "includes" in the specification suggests that the patentee contemplated an invention that did not exclude a panel having elements other than a main plateau, spliced plateau and jogged portion, or a panel having multiple spliced plateaus and jogged portions. Absent evidence to the contrary, I presume that the patentee had this same intent when drafting the claims.

In addition, in the disputed portions of Claim 1, the word "having" is followed by "a." The word "a" can have "its normal singular meaning" or can mean "one or more," depending on how the patentee uses the term. See, e.g., North American Vaccine Inc. v. American Cyanamid Co., 7 F.3d 1571, 1575-76 (Fed. Cir. 1993). Here, it appears that when the patentee wanted to limit the elements to no more than one of each, he used the phrase "a single," as he did in claims 5 and 19, which refer to a splicer comprised of "a single plate" of rigid material. The use of the simple article "a" after the word "having" in Claim 1 as opposed to "a single" suggests that the patentee did not intend to similarly limit Claim 1.

Finally, as defendant points out, it would seem that in order to join a plurality of first and second panels to form the cargo body described in Claim 15 and achieve the goal of a smooth-walled interior, each panel except the first and last in a multipanel cargo body would have to have a main plateau, two spliced plateaus, and two jogged portions. (At first blush, Claim 15 might seem to account for this by defining a "cargo body" comprised of pairs of first and second panels with a joint between each adjacent pair of first and second panels, but a closer reading suggests that Claim 15 merely is explaining how to join a plurality of first and second panels to form a cargo body.) Because of the timing of the briefing schedule,
plaintiff did not have an opportunity to respond to this argument, so I am not relying on it to find that the term "having" is an open term. Nonetheless, it does support the notion that as used in this patent, the term "having" means "having at least."

Court's construction: "having a" means "having at least one."

C. "the first and second legs having a compliant area, thus allowing the hanger to accommodate various size of transmission lines"

For the following reasons, this court construes the claim term "the first and second legs having a compliant area" in claims 1, 15, 31, 32, and 37-38 of the '543 patent to be clear on its face.

Beverly advocates limiting the construction of the term "compliant area" to a structure equivalent to flexible spring fingers based on the absence in the specification of any teaching of the claim's reference to the "first and second legs having a compliant area." (Def. Mem. at 3.) Beverly relies on the specification's teaching of the compliant area [110] as existing between the mounting [100] and retaining section [102] at the opposite end of the hanger from the legs [14, 12] and the extended section [104], (see fig. 1, supra), as compared to the relevant claims' suggesting that the first and second legs having their own compliant area. According to Beverly, the disputed claims are broader than suggested in the teachings of the specification and so the claims would be invalid unless given Beverly's proposed construction.

Andrew first characterizes this argument as another attempt by Beverly improperly to limit the claims to the patent's preferred embodiments. Andrew also asserts that Beverly has misconstrued the preferred embodiments themselves by failing to understand that the hanger legs' compliant area is the area between the mounting and retention section and that the claims do "not require that the legs themselves have a compliant area, but rather that structure (e.g. a compliant area) be present in the overall device to enable the legs to be compressed toward each other and expand away from each other by spring force" and thus accommodate various sizes of lines. (Pl. Reply at 9-10.)

While the grammar in the claims is not the epitome of clarity, the prosecution history of the '543 patent leads the court to conclude that the disputed term is clear on its face; the "first and second legs having a compliant area" refers to compliant area 110 between the retention section and the mounting section. As relevant here, the Patent and Trademark Office ("PTO") rejected the claims 1-3, 6, 11-13, 15-18, 31, and 32 as being unpatentable over the "Thoen" invention. Thoen teaches:

stackable transmission hangers comprising a transmission line retention section (12) having a first and second legs (24). The first and second legs include a locking fastener (28) configured to lock against an attachment surface (not numbered). A mounting section (34, 134) extends from the transmission line retention section including a lip (34) to be received in a square mounting hole (134) disposed on a second hanger. The retention section includes the first and second areas of resistance (the interior area of legs 24).

(Pros. Hist., Paske 84.) The Thoen invention did not make reference to any compliant area at all. During the prosecution of the '543 patent, Andrew on May 14, 2001 amended the claims in which the disputed terms appear to add in the language "having a compliant area" to overcome the patent examiner's rejection. (Pros. Hist., Paske 92-100.) In its application explaining the amendments, Andrew stated that "Claims 1, 15, 31 and 32 have been amended to clarify that each of the first and second legs includes a compliant area, which enables the hanger to accommodate various sizes of transmission lines [Claims 37 and 38 were added as new]." (Id. at 102.) The amended language of "having a compliant area" could only refer to compliant area 110. The patent examiner rejected the claims because they were obvious given the prior art, which mentioned no compliant area, and so Andrew added the language of "having a compliant area" to explain that the legs worked in conjunction with the compliant area 110 to accommodate various sizes of transmission wire in order to overcome the patent examiner's rejection. The court also notes that the initial application included compliant area 110; that the later amended language reuses the term "compliant area" suggests that the applicant was referring to the original compliant area 110. Additionally, the specification describes only one compliant area--compliant area 110--and makes no reference at all to separate compliant area in the legs.

Furthermore, Beverly's proposed construction improperly imports a preferred embodiment of spring fingers into the
invention, see Phillips, 415 F.3d at 1323, and the proposed construction undermines the principles of claim differentiation by rendering meaningless the dependent claims' requiring of spring fingers, such as claim 9. See Curtiss-Wright Flow Control Corp., 438 F.3d at 1380. The court finds that the disputed claim phrase requires no construction and can be given its ordinary meaning.

2. "Recessed Protrusion"

The parties dispute the proper construction of the words "recessed protrusion," in claim 1. In particular, claim 1 recites a "fastening means having a recessed protrusion protruding from the base . . . ." '693 Patent, col. 4, ll. 45-47. PLC asserts that the words "recessed protrusion" should be construed as an "annular projection downwardly extending from the base." PLC Brief at 7. Bidco asserts that PLC is reading additional limitations into the claim and that the words "recessed protrusion" should be construed according to their plain meaning. See Joint Claim Construction and Prehearing Statement at 4. The Court concludes that the words "recessed protrusion" carry their plain meaning, with the caveat that the recessed protrusion must protrude toward the support surface.

In support of the assertion that the recessed protrusion must be "annular" and extend "downwardly," PLC points to the specification and the prosecution history. First, PLC points out that the specification states that "[t]he single aperture 8e may be countersunk 8f in order to allow the head of the screw 8b to rest flush and level with the upper surface of the base 8a." PLC Brief at 8 (quoting '693 patent, col. 3, ll. 59-61). PLC notes that the definition of "countersink" is a "hole with the top part elongated so a screw or bolt head will lie flush with or below the surface." Id. (quoting Webster's II New Riverside University Dictionary, 1994 at 319). PLC goes on to quote the specification as explaining that the countersink "allows the elongated flooring planks, 2, 3 and 4 [in figures 2, 4 and 5] to lie flat on the supporting members." Id. (quoting '693 patent, col. 4, ll. 3-8). According to PLC, the recessed protrusion could only achieve this function if it were both annular and downwardly extending.

PLC points further to the prosecution history, in which the patentee amended claim 1 to add the "recessed protrusion" in response to the patent examiner's rejection of claim 1 on the ground of anticipation. See PLC Brief, Ex. B, August 24, 2001 Response Under 37 C.F.R. § 1.111 at 3-4. In discussing the recessed protrusion, the patentee stated as follows:

The recessed protrusion has a recess so that when a screw or nail is placed in the recessed protrusion, the head of the screw or nail will lay flush on the base of the clip. This will enable another tongue and groove board to be slid over the clip easily without damaging the board. If there were no recess the screw or nail will scratch and damage the board and will also make it harder for installation.

Another advantage of the recessed protrusion is that when a screw or nail is placed in the recessed protrusion to engage a support surface, the protruding part of the recessed protrusion extending from the bottom of the clip (see FIG. 7 of the present application), the protruding part can also engage the support surface to prevent the clip from moving around.

Id.

The Court is not persuaded that the use of the word "countersink" in the specification requires that the "recessed protrusion" must be either "annular" or "extend downwardly from the base." First, nothing in the dictionary definition of "countersink" requires a downward orientation. Moreover, even if it did, the word "countersink" is not used in claim 1 and the words that are used -- "recessed protrusion" -- do not indicate a downward direction or orientation. It is improper for the Court to import limitations from the specification that are not found in the claims themselves. See Comark Communications v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) (holding that "[i]t is axiomatic that limitations from the specification should not be read into the claims"). Second, the reference to countersinking in the specification also does not provide a basis for concluding that the protrusion must be annular. As PLC conceded at oral argument, a protrusion of any shape can accomplish the function of allowing the flooring planks to lie flat, so long as the protrusion is sufficiently large.

The Court also does not find anything in the prosecution history that supports the conclusion that the "recessed protrusion" must be annular or extend downwardly. First, PLC has not pointed to any specific reference to the shape of the protrusion in
the prosecution history or anything else in the prosecution history that would require an "annular" protrusion.

Nor does the amendment cited by Defendant persuade the Court that the recessed protrusion must be "downwardly extending from the base." Such a construction would impose a limitation with respect to the orientation of the entire assemblage that the Court does not find in the prosecution history.

It is true that the inventor described the recessed protrusion as being in the "bottom" of the clip such that a board can slide easily "over a clip." See PLC Brief, Ex. B, August 24, 2001 Response Under 37 C.F.R. § 1.111 at 3-4. This language indicates that the recessed protrusion extends toward the support surface. Otherwise, a board could not slide "over" the clip as described in the patent prosecution. Therefore, the Court concludes that the words "recessed protrusion" carry their ordinary meaning, with the additional requirement that the recessed protrusion must protrude toward the support surface.

3. "Having a Recessed Protrusion"

The parties dispute the meaning of the words, "having a recessed protrusion," in claim 1. See '693 patent, col. 4, ll. 45-46. PLC asserts that this term must be construed to mean that "the recessed protrusion is preexistent to application of the fastening means." PLC Claim Construction Brief at 9. Bidco, on the other hand, argues that PLC's construction adds an improper temporal limitation and should be rejected. The Court concludes that PLC is correct.

PLC argues that the language in this term must be construed to limit the claim to a device with a preexisting recessed protrusion because otherwise, the claim will be invalid as anticipated by prior art, namely, United States Patent No. 2,317,428 ("the '428 patent" or "the Anderson clip"). In particular, PLC points to an embodiment of the Anderson clip which it argues has all of the elements of claim 1 of the '693 patent. Id. (citing '428 patent, col. 1, ll. 1-5 and Figures 1 and 2). PLC asserts that the only differences between the clip shown in Figures 1 and 2 of the '428 patent and the accused device are: 1) the Anderson clip contains additional parts 16 and 19; and 2) the aperture of the Anderson clip is round instead of oblong. According to PLC, these differences do not, however, place the accused device outside the scope of claim 1 of the '693 patent because an "aperture" can be either round or oblong, and because claim 1 of the '693 patent uses the open-ended term "comprising" -- thus signifying that the claim will read on devices with additional elements.

Bidco counters that the Anderson clip does not anticipate the device claimed in the '693 patent because the design of the Anderson clip is "so fundamentally different that it accomplishes the exact opposite of the purpose of the '693 patent." Bidco Reply Brief at 10. In particular, Bidco argues that an important feature of the claimed device is the "open-ended extension of the free-end of the clip into the tongue and groove of the planking," id., which allows planks to "expand and contract longitudinally according to weather and atmospheric condition." Id. (quoting '693 patent, col. 1, ll. 65-67). In contrast, Bidco asserts, the additional planes 16 and 19, shown in Figures 1 and 2 of the '428 patent, "restrict[] movement of the tongue and groove planking." Id. at 11. Moreover, Bidco argues, because of these additional elements, the Anderson clip does not meet the limitation in claim 1 requiring a free end "extending in a single plane and sized to engage a groove." Id. (quoting '693 patent, col. 4, ll. 48-51).

"A prior art reference anticipates a patent claim if the reference discloses . . . all of the limitations of the claim." EMI Group N. Am., Inc. v. Cypress Semiconductor Corp., 268 F.3d 1342, 1350 (Fed. Cir. 2001). A device which would "literally infringe if later anticipates if earlier." Bristol-Myers Squibb Co. v. Ben Venue Labs., 246 F.3d 1368, 1378 (Fed. Cir. 2001). Here, the Court must determine whether the Anderson clip would anticipate the device claimed in claim 1 of the '693 patent if claim 1 were construed to read on devices in which the recessed protrusion is creating during assembly rather than when the clip is manufactured. If so, the Court must address whether this conclusion justifies adopting PLC's proposed construction to preserve the validity of the claim.

The critical issue in determining the significance of the Anderson clip is whether the additional elements 16 and 19 take the device outside of the scope of claim 1 of the '693 patent. If they do, the Anderson clip does not anticipate the '693 patent regardless of how the Court construes the claim term "having a recessed protrusion." In addressing this issue, the Court finds instructive cases in which the Federal Circuit has held that statements made in the specification may disclaim embodiments found in the prior art and limit the scope of a claim. See Scimed Life Sys., Inc. v. Advanced Cardio. Sys., 242 F.3d 1337, 1340-1342 (Fed. Cir. 2001). In these cases, the Federal Circuit has explained that "[w]here the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be
considered broad enough to encompass the feature in question." Id.

The specification of the '693 patent emphasizes the ability of the claimed device to keep the planks secure "while permitting the planks to expand and contract at rates different than the joists themselves." '693 patent, Abstract. This is described as one of the objects of the invention and is recognized as an important feature of prior art by Erwin. See '693 patent, col. 4, ll. 40-44, 62-67. The Court concludes that these statements in the specification effect a disclaimer of embodiments that do not allow the planks to expand and contract longitudinally, such as the Anderson clip, even though the open-ended term "comprising" in claim 1 might otherwise encompass the Anderson clip. See Cultor Corp. v. A.E. Staley Mfg. Co., 224 F.3d 1328 (Fed. Cir. 2000) (holding that written description implicitly limited subject matter of patent and therefore, that asserted claims did not read on accused device even though claim by itself might otherwise have been read to encompass accused device).

This conclusion finds further support in the use of the term "free end portion" in claim 1 to describe the part of the clip labeled 8d in Figure 1 of the '693 patent. '693 patent, col. 4, ll. 48-49. Based on the plain meaning of the word "free," the Court construes this term as limiting the claim to include only a device that does not have additional surfaces attached to element 8d, such as elements 16 and 19 in the Anderson clip, that prevent expansion and contraction of the planks that are secured by the clip. Although the word "comprising" does not exclude additional, unrecited elements, it is not "a weasel word with which to abrogate claim limitations." Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1379 (Fed. Cir. 1998). As a result, the Court finds that the Anderson clip does not anticipate the claimed device.

The Court, however, concludes nonetheless that the words "having a recessed protrusion" mean that the recessed protrusion exists prior to installation. First, the word "having" is a static term. It does not encompass a clip that does not "have" a recessed protrusion in its unassembled state. Nor is there any suggestion in the specification that the inventor intended to claim a device in which the "recessed protrusion" was not present in the unassembled device but rather, was created only at installation. Had the inventor wished to claim such a device, he could have used method claims to do so. However, as Bidco correctly points out, there are no method claims in the '693 patent. Further, statements made by the inventor in the prosecution make clear that the recessed protrusion exists before installation rather than being created by installation. In particular, in the amendment quoted above, the inventor stated, that "[t]he recessed protrusion has a recess so that when a screw or nail is placed in the recessed protrusion, the head of the screw or nail will lay flush on the base of the clip . . . . See PLC Brief, Ex. B, August 24, 2001 Response Under 37 C.F.R. § 1.111 at 3-4 (emphasis added). Thus, both the words of the claim and the prosecution history support the conclusion that the recessed protrusion is preexistent to application of the fastening means.

Said outlet duct being configured to radially expand said airflow to a low velocity and said return duct being configured for low radial flow return velocity to said high pressure compressor

Key to both phrases above is the term "low velocity." While a person or ordinary skill in the art arguably would understand that the air flow exiting the low pressure compressor is at a very high velocity, the parties disagree as to how the outlet and return ducts in the '499 Patent are designed to slow the velocity. Thus, the Court will construe the term "low velocity" first.

Low velocity

Claim 1 specifies that the outlet duct of the low pressure compressor is configured to radially expand air flow "to a low velocity" and the return duct is configured for "low radial flow return velocity," Rice contends that the term "low velocity" should be construed to mean "a decreased air flow velocity." Rolls-Royce, on the other hand, wants a specific numerical value and contends that the low velocity term means air flow velocity "less than approximately 200 ft./sec."

Notably, the claim language is not "to a lower velocity" or "to a reduced velocity." Rice, however, points out that dependant claim 9 includes the specific numerical limitation of less than approximately 200 ft./sec. Rolls-Royce counters that claim 9 specifies "said low velocity of less than approximately 200 ft./sec." which indicates that the prior use of low velocity was meant as "less than approximately 200 ft./sec." Rolls-Royce further identifies in the specification where Rice described the preferred embodiment as having air flow velocity of about 200 ft./sec. See Def's Br. 33-35.
However, there is no indication in the descriptive passages cited by Rolls-Royce that a velocity less than approximately 200 ft./sec. is critical to the invention. While the reduction in velocity is identified as being advantageous to "reduce inlet pressure loss" (col. 8, line 27), nowhere does the specification indicate that the velocity of 200 ft./sec. is in and of itself a necessary parameter to be met in order to realize the gas generator of the invention. Rather, the specification indicates that the low pressure loss benefit resulting from a lower air flow velocity between the low and high pressure compressors is made possible by the additional radial space made available by the increased pitch-line radius, r, as a consequence of the intercooler. See col. 8, lines 28-38. The description in the '499 patent specification of the air flow velocity is unlike the situation identified in Toro Co. v. White Consolidated Industries, Inc., 199 F.3d 1295 (Fed. Cir. 1999), wherein the specification described the advantages of a unitary structure of a ring permanently attached to a cover as being important to the invention.

Rolls-Royce also relies upon the prosecution history for support of its proposed construction of "low velocity." Specifically, Rolls-Royce identifies that the July 7, 1989 Amendment added the "low velocity" recitation to the claims and argues that Rice's remarks indicate that a low velocity of less than 200 ft/sec. was needed. Examination of Rice's remarks indicate that Hull was being distinguished on the basis of an absence of an external counterflow intercooler. Rice first points out that the compressed air being cooled in Hull's heat exchanger 16 and the coolant flow in the same direction. Rice then offered that Hull did not have a low pressure drop heat exchanger and ducting, which are realized by the claimed counterflow externally mounted intercooler. Amendment 8.

When Rice turned to the DuPont prior art, Rice again argued that a counterflow externally mounted intercooler was absent just as in Hull. Rice also pointed out that the discharge of the axial flow fan 18 of DuPont was directly to heat exchanger 26 and would be high. Similarly, the velocity to downstream heat exchanger 28 would be high "because there is very little change in the cross-sectional flow area shown." Amendment 9. Rice's remarks indicate nothing more than the prior art did not include the ducting that would radially expand the air flow to a lower velocity. His remarks do not indicate that either Hull or DuPont were being distinguished on the basis of the specific air flow velocity through the heat exchanger and ducting of each. The import of Rice's remarks do not extend beyond the requirement that the ducting radially expand the air flow to slow it to a lesser velocity. The remarks clearly do not amount to a clear disclaimer of air flow velocities through the intercooler and associated ducting above 200 ft./sec. Thus, the Court adopts Rice's construction for "low velocity" as being "a decreased air flow velocity."

Having adopted Rice's construction of low velocity, the Court turns to the disputed term "to radially expand." Rice proposes the construction "to cause air flowing away from the axis of the shafting to increase in volume." Rice argues that a person of ordinary skill in the art would understand that "radially expand" means something expands as it moves away from the axis, in contrast to "axial" which indicates a direction along the axis. Rolls-Royce, on the other hand, proposes the construction "to increase the cross-sectional flow area in a direction generally perpendicular to the axis of the gas generator."

However, the embodiment disclosed in figure 7a of the '499 patent depicts a duct that "radially expands" the air flow from the low pressure compressor. The air flowing radially through the duct in figure 7a is not perpendicular to the axis of the gas generator. Further, the specification describes how the direction of the flow with respect to the radial position can be "curved backwards" and vary in angle to accommodate different structures. Col. 14, lines 44-50. Nothing requires that the expansion occur only when the air is flowing perpendicular to the axis. Thus, the Court adopts Rice's plain meaning "to cause air flowing away from the axis of the shafting to increase in volume."

The parties previously requested no construction for the term "outlet duct;" therefore, the Court will not construe that term. The Court previously construed "return duct" to mean "conduit for conveying air back from the externally mounted intercooler."

In sum, the Court construes the disputed term, "said outlet duct being configured to radially expand said air flow to a low velocity" to mean "said outlet duct shaped and positioned to cause air flowing away from the axis of the shafting to increase in volume resulting in a decreased air flow velocity."

The Court construes the disputed term, "said return duct being configured for low radial flow return velocity to said high pressure compressor" to mean "the conduit conveying air back from the externally mounted intercooler being shaped and positioned to result in a velocity of air flowing toward the axis of the shafting that is lower than the velocity of that air when
The parties dispute whether satisfaction of the relationship of \( \text{AHPC} \propto \frac{\text{ALPC}}{(\text{TLPC}/\text{THPC})} \) is to be of \( \text{AHPC} \propto \frac{\text{ALPC}}{(\text{TLPC}/\text{THPC})} \) and the specified operating conditions of the intercooler. If the low pressure compressor is sized (i.e., matched to the inlet of the high pressure compressor) based on the relationship illustrated embodiment, the pitch line radius \( r_3 \) of the high pressure compressor remains constant and the pitch line radius \( r \) constant RPM, there is the necessity to size the pitch line radii of the compressors according to the change in density. In the high pressure compressor, the density of the cooled air is increased accordingly to Boyle's Law. Because of the disclosure explains that, because the air from the low pressure compressor is cooled before being admitted to the inlet of the high pressure compressor, and inversely proportional to the absolute temperature ratio between the high temperature air flow discharged from the low pressure compressor compared to the low temperature air flow from the intercooler passing to the inlet area of the high pressure compressor

To the extent the parties seek construction term-by-term, the Court finds that approach to be confusing and unnecessary and declines to do so. Rather, the claim language in dispute clearly expresses a relationship between two specified structures: the inlet flow area of the high pressure compressor (AHPc) and the outlet flow area of the low pressure compressor (ALPO). As depicted in the specification in Fig. 2, the pitch line radius \( r \) establishes the flow area of the low pressure compressor 24 outlet (ALPc). The pitch line radius \( r_3 \) establishes, as shown in Fig. 4, the flow area of the high pressure compressor 44 inlet (Alin). See col. 8, lines 51-53. The specified relationship is expressed in terms of a direct proportioning of the flow areas. Thus, a direct proportioning exists of the pitch line radii, \( r \) and \( r_3 \), [i.e., as the outlet flow area of the low pressure compressor gets larger (\( r \) gets bigger), the inlet flow area of the high pressure compressor gets correspondingly larger (\( r_3 \) gets bigger) in accordance with some constant ratio].

However, because of the intercooler, the proportioning constant between (AHPc) and (ALPc) also includes an additional proportioning factor established by the ratio of the absolute temperature of the high temperature air flow discharged from the low pressure compressor (TLPC) and the low temperature air flow from the intercooler passing to the inlet area of the high pressure compressor (THPc). This temperature ratio is expressed as (TLPC/THPc). However, the relationship of the inlet flow area of the high pressure compressor (AHPc) and the outlet flow area of the low pressure compressor (ALPO) changes in inverse proportion to the temperature ratio (TLPC/THPc). That is, as the ratio of (TLPC/THPc) gets larger, the inlet flow area of the high pressure compressor (AHPc) gets smaller.

The claim limitation can be expressed mathematically as:

\[
\text{AHPc} \propto \frac{\text{ALPC}}{(\text{TLPC}/\text{THPC})} \propto \frac{\text{ALPO}}{\text{AHPc}} \propto (\text{TLPC}/\text{THPC})
\]

Thus, as the intercooler provides more cooling of the air flow from the outlet of the low pressure compressor, which is at a temperature TLPC, the temperature of the air flow from the intercooler passing to the inlet area of the high pressure compressor (THPc) is further reduced relative to temperature air flow discharged from the low pressure compressor (TLPC). Accordingly, the denominator of the ratio gets smaller and the ratio gets correspondingly larger. The consequence is that, because the inlet flow area of the high pressure compressor (AHPc) changes in inverse proportion to this ratio, the inlet flow area of the high pressure compressor (AHPc) gets smaller.

This claim language was added during the reexamination prosecution of the '499 patent. In his statement to the examiner, Rice identified support in the specification to be found at column 9, beginning with line 1. As to the patentability of the amended claim, Rice characterized the limitation as expressing a power producing system wherein "the inlet flow area to the high pressure compressor is matched to the conditions of the air flow exiting the low pressure compressor," which was said to be "governed by Boyle's Law." Statement 4. Rice also notes that other factors could be changed to satisfy Boyle's Law, such as changing the speed of the compressor could be used, although "a change in speed is not used to obtain the desired substantial matching to satisfy Boyle's Law." Statement 5. Rice was specific that "matching of the low and high pressure compressors is uniquely obtained by satisfying the area and temperature relationships recited in the amended claims." Id. Indeed, the disclosure in column 9 cited in support of the claim amendment describes the matching of the flow areas according to Boyle's Law based upon the low and high pressure compressors running at a constant RPM.

The disclosure explains that, because the air from the low pressure compressor is cooled before being admitted to the inlet of the high pressure compressor, the density of the cooled air is increased accordingly to Boyle's Law. Because of the constant RPM, there is the necessity to size the pitch line radii of the compressors according to the change in density. In the illustrated embodiment, the pitch line radius \( r_3 \) of the high pressure compressor remains constant and the pitch line radius \( r \) of the low pressure compressor is sized (i.e., matched to the inlet of the high pressure compressor) based on the relationship of \( \text{AHPc} \propto \frac{\text{ALPC}}{(\text{TLPC}/\text{THPC})} \) and the specified operating conditions of the intercooler.

The parties dispute whether satisfaction of the relationship of \( \text{AHPc} \propto \frac{\text{ALPC}}{(\text{TLPC}/\text{THPC})} \) is to be
evaluated while the system is producing power (Rice) or whether it is evaluated as a design rule (RR). Claim 1 is clearly directed to apparatus and not a method. Thus, the focus is on the structure of the power producing system and not on any sequence of steps conducted by a system in producing power or attaining a particular operating condition. More specifically, the claim limitation concerns defining the relationship of the structures of the low and high pressure compressors as to the size of the outlet and inlet flow areas, respectively. The structure is thereby established and does not change during operation of the system while producing power.

Rice argues that the subject claim limitation embraces a dynamic operating environment because the specification presents a thermodynamic analysis of the invention. See Pl.'s Br. 39. However, the thermodynamic analysis "of this invention" and for "optimum efficiency" presented in column 16, line 1, through column 23, line 3, is premised on the intercooler being sized to effect a specified exit temperature under specified environmental conditions for a particular approach temperature. See col. 16, lines 54-57. This supports Rolls-Royce's argument that the relationship of AHPC cc ALPC / (UP c/TuPc) is a design rule applied to obtain low and high pressure compressor structures optimized for a predetermined operating condition of the intercooler.

The Court construes the claim limitation to mean "a design rule applied to optimize the cross-sectional area of the air flow inlet of the high pressure compressor in relation to the cross-sectional area of the air flow outlet of the low pressure compressor for a predetermined operating condition of the intercooler (1) by having the areas increase or decrease together on a constant ratio basis between them and (2) by having the cross-sectional area of the air flow inlet of the high pressure compressor also increase or decrease in opposite to the ratio of the absolute temperature of the air flow at the cross-sectional area of the air flow outlet of the low pressure divided by the absolute temperature of the air flow at the cross-sectional area of the air flow inlet of the high pressure compressor (i.e., the area increases as the ratio gets smaller and decreases as the ratio gets larger), which can be expressed mathematically as: AHPC \[\text{proportional}\] ALPC / (TLPC/THPC)."

1948

3) Said portion having been subject to work-hardening.

The third element of Claim 1 is that "said portion (has) been subjected to work-hardening." Defendants contend that the teaching of the specification is that work-hardening of at least about 30% must be applied to material in the pseudoelastic state to attain the claimed work-hardened pseudoelastic state and the claimed elasticity, whereas the only evidence presented at the hearing established that the degree of work-hardening in Defendants' process was no more than 10%.

The language of the claim, however, clearly contains no reference to work-hardening of at least 30% to attain the claimed work-hardened pseudoelastic state or claimed elasticity. Literally, even minimal work-hardening is covered. Claim 1 of the '112 patent, in marked contrast, which is not in issue at this stage of the proceedings, does contain a 30% work-hardening limitation and certain examples within the '955 specification do refer to 30% work-hardening. In no respect, however, does the evidence suggest that the patentees ever argued that 30% work-hardening was necessary to avoid prior art or that any prior art disclosed material in a work-hardened pseudoelastic metallurgical state in which work-hardening was less than 30%. Indeed, Plaintiffs have shown that, in a Second Preliminary Amendment in the '955 file history, they deleted all reference in Claim 1 to 30% work-hardening, stating that the claim as amended claimed a portion "subjected generally to work-hardening." Plaintiffs further declared in the amendment that their "examples of work-hardening, including preferred percentages whenever added, are illustrative only and should not be a limitation of the claim." It is an accepted rule of claim construction that the presence of a limitation in some claims, which is absent from other claims, will support the interpretation that the latter claims did not have a limitation. Specialty Composites, 845 F.2d at 987. The Court interprets this limitation to require only that frames have been subjected to minimal work-hardening. Accordingly, the Court finds that Plaintiffs are likely to succeed at trial in showing Defendants' frames contravene the third element of Claim 1.

1949

5) Said portion having greater than 3% elasticity over a temperature range from -20 [degrees] C. to +40 [degrees] C.
The fifth element of Claim 1 requires that the NiTi SMA portion of the frame "have greater than 3% elasticity over a temperature range from -20 [degrees] C. to +40 [degrees] C." Plaintiffs contend that this element means that at every temperature within the indicated range, the frame portion will recover at least 3% of its original shape after being subjected to stress and then released. Thus, if a frame portion were stretched 4% beyond its original shape and upon release recovered more than 3% of its original shape, the "3% elasticity" element would be met despite the 1% residual strain. Defendants assert that this particular element requires that the frame portion show complete recovery, i.e. a return to origin, after a strain greater than 3%.

The Court considers first the language of the claim itself. North American Vaccine, 7 F.3d at 1575. It is true that Random House Dictionary, cited by Defendants, defines "elasticity" as "the capacity of a material to recover its original form upon the removal of a force," a definition that in general was affirmed by Defendants NiTi SMA expert Dr. Schety, their engineering expert Mr. Bjorge, and indeed to some extent by Plaintiffs' NiTi SMA expert Professor Beshers. Nonetheless interpretation of a claim term by reference to dictionary definitions without first acknowledging its use in the specification or prosecution history is inappropriate. See Hormone Research, 904 F.2d at 1563. Indeed, in selecting language for a patent claim, the patentee is not confined to dictionary definitions of the terms used. "Patent law," as previously observed, "allows the inventor to be his own lexicographer." Fromson v. Advance Offset Plate, Inc., 720 F.2d 1565, 1569 (Fed. Cir. 1983). Terms, however, must be construed "in connection with the other parts of the patent instrument and with circumstances surrounding the inception of the patent application." Id. At the same time, if a patent applicant wishes to give claimed terms an uncommon meaning, "he must set out his uncommon definition in some manner within the patent disclosure." Hoganas, 9 F.3d at 951; Intellicall, 952 F.2d at 1385.

To begin, it should be noted that Professor Beshers agreed only as to the definition of elasticity in its elementary concept. He specifically clarified that the elementary definition of elasticity put forth by Defendants was not applicable in the context of the NiTi-based SMA eyeglass frames defined in the patent. In that regard, he was careful to define elasticity as recovery of at least 3% of the original shape of the framed portion when subjected to an appropriate load and released. Moreover, language in the specification favorable to Plaintiffs' interpretation appears at the very first sentence in the section entitled "Summary of the Invention" which reads: "It is the purpose of the instant invention to provide eyeglass frames which (1) are highly resistant to permanent deformation, or "kinking," over the full range of ambient temperatures . . . ."

The stated purpose, it may be noted, is not to provide frames that are "totally" resistant to permanent deformation, which is the clear implication of the definition that Defendants contend for, i.e. that any material with a strain over 3% must spring back to origin. The purpose of the patent is to provide frames "highly," which is to say "largely," "greatly," or "to a considerable degree" resistant. Plaintiffs' interpretation would thus seem more sensible than Defendants, i.e. over the ambient temperature range, Plaintiffs' frame components will more likely than conventional frames resist permanent deformation when subjected to a reasonable range of stresses. The components, in other words, will recover at least 3% of their original shape, possibly more depending on the temperature.

Defendants point out, however, that in disclosing how to achieve "the desired very high elasticity property," the patent equates "optimized elasticity" properties with Figure 2H of the patent which shows full recovery of the frame upon release of the stress. In addition, Defendants cite the following sentence which appears at Column 6, lines 1 through 4, of the patent: "Thus, throughout the temperature region of interest for eyeglass frames, the component acts completely elastically up to strains of 6% or more. This is many times the range achieved with traditional metal frame materials." Defendants argue that this establishes that elasticity must mean complete recovery of the stretched materials to their original size or length at all indicated temperatures.

As used within the patent, however, the term "elasticity" and its variants suggest otherwise. Thus the first example given in the patent "show(s) complete elastic springback at room temperature," which certainly implies that at other temperatures elasticity may be less than complete. See Read Corp. v. Portec, Inc., 970 F.2d 816, 823 (Fed. Cir. 1992) At the same time, the temple described in the first example is said to have "greater than 6% elasticity over a temperature range of -20 [degrees] C. to +40 [degrees] C." Presumably "complete elastic springback" and "6% elasticity" have different meanings, otherwise the term "complete" elastic springback could have been used to refer to elasticity over the entire temperature range.

The second example given in the patent describes a temple that exhibits "3.7% elastic springback and imparts 3.8% shape-memory recovery when heated." The third example lies between the first two and is said to yield "5.0% elastic springback.
and imparts 2.25% shaped memory recovery." These two examples obviously do not exhibit "complete elastic springback," since they have respectively 3.8% and 2.25% shape-memory recovery, residual deformations to be recovered by applying heat. Again, however, the initial recovery in these two examples is described as "elastic." Figure 2G of the patent is in accord. It shows an 8% elongation springing back to a 3% elongation (i.e. 5% elasticity), with the residual 3% returning to origin by means of "heat recovery."

Finally, as noted in Specialty Composite, "a review of other claims in the same patent can aid in deciding the scope of a particular claim." 845 F.2d at 986. The fact that Claim 5 of the '955 patent describes a component that combines "a minimum of 3% heat recoverable memory . . . and at least 3% elasticity," further indicates that "elasticity" means something other than "full elastic recovery."

Defendants nonetheless suggest that when Plaintiffs were trying to distinguish their claimed frames from prior art in order to persuade the PTO to allow their application, they defined "greater than 3% elasticity" to mean that, at strains greater than 3%, the material would return to zero. They cite in particular Plaintiffs' discussion of the so-called Mercier article. 5 That article, however, reported test results of a shape-memory alloy material that exhibited a substantial permanent deformation when tested at a single temperature (100 [degrees] C.), which is outside the temperature range required in Claim 1 (-20 [degrees] C. to +40 [degrees] C.). In addition, the Mercier article does not disclose the level of elasticity, nor indeed any other appropriate features of its material, at any temperature other than 100 [degrees] C., a fact that the PTO examiner apparently found significant, since he was unwilling to infer that similar properties would obtain at different temperatures, especially those within the range of Claim 1 of the '955 patent. In other words, the residual strain vel non of the Mercier material was ultimately irrelevant to the PTO reexamination of the '955 patent. Even so, the Court concludes that Plaintiffs' statements regarding the Mercier material amounted to no more than a suggestion that, even at the presumably optimal temperature at which it was tested, the material exhibited permanent deformation and that a frame component made of the material would become permanently deformed or kinked. "Every statement made by the patentee during prosecution to distinguish a prior art reference does not create a separate estoppel. Arguments must be reviewed in context." Read Corp., 970 F.2d at 824. Defendants' estoppel argument finds little favor in this Court. Reviewed in context, nothing Plaintiffs said in the reexamination process suggests a limitation of Claim 1 or disavowal of any subject matter of Patent '955.

Having construed the 3% elasticity element of the claim consistently with Plaintiffs' view, the Court has no difficulty in concluding that each of Defendant's frame components exhibits at least 3% elasticity over the required temperature range. Professor Beshers, on behalf of Plaintiffs, performed tensile tests on Defendants' frames at -20 [degrees] C., 0 [degrees] C., room temperature, and +40 [degrees] C. to determine whether they satisfied this element of Claim 1, and concluded that they did. Defendants, on the other hand, presented no tests or evidence by way of rebuttal.

--- Footnotes ---

5 The "Mercier article" was cited as prior art in the Request for Reexamination for the '955 patent. Its full citation is Mercier, O. & Torok, E., Mechanical Properties of the Cold-Worked Martensitic NiTi Type Alloys, Journal de Physique, Dec. 1982, at C4-267.

--- End Footnotes ---

1950

a. "said faceplate having a longitudinal axis and having returns extending from the sides of each face plate that are angled to allow the faceplate to expand under extreme heat."

Universal contends that the phrase should be interpreted to require (1) opposing faceplate returns that extend from the central faceplate; and (2) that the opposing faceplate returns extend from the faceplate at an approximately 90[degree] angle from the faceplate, where the angle is formed between the faceplate and each return. JVI contends that the phrase should be interpreted as two face plate returns extending from opposing ends of the face plate at an angle that allows the faceplate to expand when exposed to extreme heat (such as welding) without causing significant distress to the concrete in which the flange connector is embedded.
As both parties recognize, unlike Claim 1, Claim 6 does not state that the faceplate returns extend at approximately a 90[degree] degree angle from the faceplate, but defines the angle in terms of a function, specifically an angle that allows the faceplate to expand under extreme heat. JVI argues that the language allows for a broader construction of the angle, any angle that is sufficient to allow such expansion. Universal contends that the specification, including the summary of the invention and the description of the preferred embodiment, does not support such an interpretation because the only angle disclosed to perform the function is a 90[degree] degree angle. Because only a single description of the invention is discussed, Universal contends that the description amounts to a limitation to the scope of the claim. Honeywell, 452 F.3d at 1318.

JVI contends that the phrase should be given its plain and ordinary meaning. Heat generated by welding causes the faceplates of flange connectors to expand. When conventional flange connectors are embedded in concrete, the faceplates cannot expand without causing significant distress to the concrete. Thus, JVI contends that its definition clarifies that the returns are angled to allow the faceplate to expand without causing distress. JVI contends any other limitation proposed by Universal is not supported by the claim language. The preferred embodiment described should not be imported as a limitation to the claim.

The Court agrees with JVI's interpretation. Claim 6, unlike Claim 1, does not name a specific angle but defines the angle in terms of function. Universal's proposed language would result in a narrower interpretation of the claim than its language requires. See Pilant Corp. v. MSC Marketing & Technology, Inc., 416 F.Supp.2d 632, 639-40 (N.D. Ill. 2006).

1951

3. Head Opening

The head opening is defined consistently and clearly throughout the '828 patent specification and claims as an opening which allows the user to enter and exit the inner cavity. ( '828 Patent, col. 1, lines 11-13; col. 2, lines 39-42; figs. 1, 2, 5, and 6; claims 7, 11, and 12.) In its brief on claim construction, Mont-Bell further defines the head opening as "the opening which receives the head of the user." (Plaintiff's Brief on Claim Construction ("Pl.'s Br. Cl. Const.") at 4.) Mountain Hardwear responds that this aspect of the definition is not set forth in the '828 patent. (Def.'s Opp'n at 3.) That the head opening receives the head of the user rather than the user's feet is self-evident. Given that, it is unnecessary to expand the existing definition of head opening.

1952

C. A Head Portion (6i)

The head portion describes a feature of the female fastener. It is referred to in col. 3, ll 19-21 as follows:

head portion adapted to span the seat shell aperture thereby preventing the fastener from passing through the seat shell aperture

and col. 7, l 41

. . .such that head spans aperture.

This phrase is to be construed as follows:

The upper part of the female fastener fashioned in a manner to prevent it from passing through the seat shell.
As we alluded to above, the crux of Zebo's argument is that the '835 patent covers only those trolling motor-autopilot systems that include a compass or other directional indicator physically attached to the trolling motor. Zebo arrives at this conclusion by following the route: (1) Zebo considers the "heading lock" invention of the '835 patent to be concerned only with the direction and orientation of the trolling motor rather than the boat; and (2) therefore, the heading lock--which, according to claim 1, includes a heading detector "disposed to transmit . . . heading signals"--must be physically attached to the trolling motor. Because the accused AutoGuide systems undisputedly contain a directional indicator (a "heading detector") in a foot pedal--attached to the trolling motor via wires rather than mechanically--Zebo argues that Johnson's infringement claim must fail.

While Zebo recognizes that claim 1, the broadest claim at issue, does not explicitly require that the "heading detector" be mechanically coupled to the trolling motor, it nonetheless suggests that a proper interpretation of the terms "heading signal" and "coupled" in the language of claim 1 compels such a limited claim scope. In doing so, Zebo points out that Figure 1 of the '835 patent, and at least some of the language in the written description, suggest that the preferred embodiment of the invention includes a compass mechanically attached to the trolling motor. This case, then, presents the question of when it is permissible to narrow the scope of broad claim language by reference to embodiments described and depicted in the balance of the specification.

We begin, as with all claim interpretation analyses, with the language of the claims. See Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120; Abtco, Inc. v. Exitron Corp., 122 F.3d 1019, 1023, 43 U.S.P.Q.2D (BNA) 1545, 1548 (Fed. Cir. 1997); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995). The general rule is, of course, that terms in the claim are to be given their ordinary and accustomed meaning. See Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121; York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996). General descriptive terms will ordinarily be given their full meaning; modifiers will not be added to broad terms standing alone. See, e.g., Virginia Panel Corp. v. MAC Panel Co., 133 F.3d 860, 865-66, 45 U.S.P.Q.2D (BNA) 1225, 1229 (Fed. Cir. 1997) (unmodified term "reciprocating" not limited to linear reciprocation); Bell Communications, 55 F.3d at 621-22, 34 U.S.P.Q.2D (BNA) at 1821 (unmodified term "associating" not limited to explicit association); Specialty Composites v. Cabot Corp., 845 F.2d 981, 987, 6 U.S.P.Q.2D (BNA) 1601, 1606 (Fed. Cir. 1988) (unmodified term "plasticizer" given full range of ordinary and accustomed meaning). In short, a court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms. See, e.g., Nike Inc. v. Wolverine World Wide, Inc., 43 F.3d 644, 646, 33 U.S.P.Q.2D (BNA) 1038, 1039 (Fed. Cir. 1994); E.I. Du Pont De Nemours & Co. v. Phillips Petroleum, 849 F.2d 1430, 1433, 7 U.S.P.Q.2D (BNA) 1129, 1131 (Fed. Cir. 1988); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 U.S.P.Q. (BNA) 473, 477 (Fed. Cir. 1984).

In order to overcome this heavy presumption in favor of the ordinary meaning of claim language, it is clear that "a party wishing to use statements in the written description to confine or otherwise affect a patent's scope must, at the very least, point to a term or terms in the claim with which to draw in those statements." Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1121. That is, claim terms cannot be narrowed by reference to the written description or prosecution history unless the language of the claims invites reference to those sources. See, e.g., McCarty v. Lehigh Valley R.R., 160 U.S. 110, 116, 40 L. Ed. 358, 16 S. Ct. 240 (1895) ("If we once begin to include elements not mentioned in the claim in order to limit such claim . . ., we should never know where to stop."); Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121. In other words, there must be a textual reference in the actual language of the claim with which to associate a proffered claim construction.

Our case law demonstrates two situations where a sufficient reason exists to require the entry of a definition of a claim term other than its ordinary and accustomed meaning. The first arises if the patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term. See In re Paulsen, 30 F.3d 1475, 1480, 31 U.S.P.Q.2D (BNA) 1671, 1674 (Fed. Cir. 1994); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387-88, 21 U.S.P.Q.2D (BNA) 1383, 1386 (Fed. Cir. 1992); Lear Siegler, Inc. v. Aeroquip Corp., 733 F.2d 881, 888-89, 221 U.S.P.Q. (BNA) 1025, 1031 (Fed. Cir. 1984). The second is where the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used. See Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1554, 42 U.S.P.Q.2D (BNA) 1737, 1741 (Fed. Cir. 1997) (looking past claim language because of lack of clarity), overruled on other grounds by Cybor Corp. v. FAS Techs., Inc., 138
F.3d 1448, 46 U.S.P.Q.2D (BNA) 1169 (Fed. Cir. 1998) (en banc); J.T. Eaton & Co. v. Atlantic Paste & Glue Co., 106 F.3d 1563, 1568, 41 U.S.P.Q.2D (BNA) 1641, 1646 (Fed. Cir. 1997) (Because "[the disputed claim term] is a term with no previous meaning to those of ordinary skill in the prior art[,] its meaning, then, must be found [elsewhere] in the patent."); North Am. Vaccine, Inc. v. American Cyanamid Co., 7 F.3d 1571, 1576, 28 U.S.P.Q.2D (BNA) 1333, 1336 (Fed. Cir. 1993) (using the specification for guidance "when the meaning of a claim term is in doubt"); E.l. Du Pont De Nemours, 849 F.2d at 1433, 7 U.S.P.Q.2D (BNA) at 1131 (Fed. Cir. 1988) (the written description can supply understanding of unclear claim terms, but should never trump the clear meaning of claim terms). Cf. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998) ("In this case, the [disputed] term has a clear and well-defined meaning. This term is not so amorphous that one of skill in the art can only reconcile the claim language with the inventor's disclosure by recourse to the specification."). In these two circumstances, a term or terms used in the claim invites--or indeed, requires--reference to intrinsic, or in some cases, extrinsic, evidence, see Vitronics Corp. v. Conceptron, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996) (reference to extrinsic evidence is proper when intrinsic evidence cannot resolve ambiguity in claim language), to determine the scope of the claim language.

B

Here, Zebco's primary claim interpretation argument is that the term "heading" in the phrase "heading signal" refers only to the direction of the trolling motor, thus requiring that the heading detector, "being disposed to transmit said heading signals," must be affixed to the trolling motor. Zebco, of course, recognizes that the ordinary and accustomed meaning of "heading" connotes only direction, rather than being limited to the direction of the trolling motor. Thus Zebco argues, as it must, for a more limited scope of "heading," to overcome the presumption in favor of the ordinary--and, in this case, broader--meaning.

Because Zebco does not suggest that the phrase "heading signal" lacks clarity as it is used in the claim, in order to establish a reason to import a narrow definition of the term, it must instead argue that the term "heading" has been given a particular meaning by the patentee. To this end, Zebco argues that language throughout the written description and prosecution history of the '835 patent demonstrates that "heading" in the context of the '835 patent is limited to the direction of the trolling motor. We find this unpersuasive, as did the district court. First, the written description does not describe "with reasonable clarity, deliberateness, and precision" the definition of "heading" proposed by Zebco. See In re Paulsen, 30 F.3d at 1480, 31 U.S.P.Q.2D (BNA) at 1674. Indeed, the many uses of the term throughout the '835 patent are consistent with a broader definition, one encompassing the directions of both the boat and the trolling motor unit. Compare, e.g., '835 patent, col. 3, lines 58-62 ("The electronic steering system of the present invention continues to monitor the current heading of the thrust motor" (emphasis added)) with '835 patent, col. 7, lines 37-39 ("Heading detector 204 continuously monitors the current heading of the boat" (emphasis added)). Varied use of a disputed term in the written description demonstrates the breadth of the term rather than providing a limited definition. See, e.g., Enercon GMBH v. International Trade Comm'n, 151 F.3d 1376, 1385, 47 U.S.P.Q.2D (BNA) 1725, 1731-32 (Fed. Cir. 1998) (refusing to limit a term used "interchangeably" in the written description to only one of the uses of the term). That the term "heading" is used at various points in the written description to refer to both the direction of the trolling motor and the boat is simply not "a special and particular definition created by the patent applicant," Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121, and is thus an insufficient reason to limit the scope of the term.

Contrary to Zebco's arguments, Laitram Corp. v. Morehouse Industries, Inc., 143 F.3d 1456, 46 U.S.P.Q.2D (BNA) 1609 (Fed. Cir. 1998), is inapposite. The court there held that a narrow interpretation of a disputed term was compelled because of statements in the written description that made clear that "the asserted claims will bear only one interpretation: that the 'driving surface' limitation is limited to flat driving surfaces," and that the "'driving surface' limitation . . . requires flat driving surfaces." Id. at 1463, 46 U.S.P.Q.2D (BNA) at 1614-15 (emphasis added). Here, of course, there is no such unambiguous language in the written description; nothing suggests that "heading" is required to be the heading of the trolling motor. Cf. id.

Zebco also argues that the patentee ascribed a special meaning to the term "heading" in the prosecution history. See, e.g., Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378, 49 U.S.P.Q.2D (BNA) 1065, 1068-69 (Fed. Cir. 1998) (explicit meanings given to claim terms in order to overcome prior art will limit those terms accordingly); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995); Standard Oil Co. v. American Cyanamid Co. 774 F.2d 448, 452, 227 U.S.P.Q. (BNA) 293, 296 (Fed. Cir. 1985). In particular, Zebco argues that the applicant's statement, in a June 17, 1992 amendment to the '586 application, that "the heading signal . . . is dependent solely
on the heading of the motor, and totally independent of the orientation of the vessel" is a clear definition of "heading signal" as being limited to the direction of the thrust motor. However, Zebco overlooks the fact that the claims referred to in that passage, claims 4 and 14 of the '586 application, expressly included an additional limitation: that the compass be "in a substantially fixed relationship to said propulsion device," (claim 4) or likewise "in a predetermined relationship with said propulsion device" (claim 14). The argument referenced by Zebco was unquestionably focused on the requirement, in those claims, that the compass be attached to the trolling motor. The patentee's suggestion that, where the "substantially fixed relationship" or "in a predetermined relationship" claim limitation was present, the feedback signal (i.e., the heading signal) was dependent on the heading of the motor sheds no light on the meaning of "heading signal" in claims where that very limitation is not present. Rather, this exchange is an example of how carefully-crafted arguments in support of patentability can avoid creating ambiguous or adverse prosecution history. By stating clearly and particularly that the context of his remarks was in regards to claims 4 and 14, the applicant ensured that those of ordinary skill in the art--as well as courts, if need be--could evaluate the import and scope of his statements. Thus, because this argument was plainly limited to claims including a "fixed" or "predetermined" relationship between the compass and the trolling motor, it cannot be said to be a clear statement limiting the scope of "heading signal" in general. Zebco thus has not shown that sufficient reasons exist to import a limited definition of this term into the clear language of the claim.

We therefore agree with the district court that the ordinary and accustomed meaning of "heading signal" controls.

1954

1. Heat-Activatable Adhesive Layer

Avery's proposed definition of heat-activatable adhesive layer is: "An adhesive or thermoplastic film generally having a lower melting point than the other layers of the laminate." Whitlam proposed: "A layer of heat-activatable adhesive or thermoplastic film material with a thickness between 0.1 and 10.0 mils inclusive that may have a lower melting point than any other film layers in the thermal transfer laminate." The only real difference between the two definitions is the inclusion of the thickness limitations in Whitlam's definition. These limitations come directly from the specifications of the '486 and '722 patents. In column 3, line 14 of both patents, the general dimensions of the heat-activatable layer are given: "The thickness of heat activatable adhesive layers 118 and 230 range from about 0.1 to 10 mils." In this case the proposed definition includes a limitation from the specification, which the Federal Circuit has consistently held to be unacceptable. See e.g. Intervet America, Inc. v. Kee-Vet Laboratories, Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989)("limitations appearing in the specification will not be read into claims, and . . . interpreting what is meant by a word in a claim 'is not to be confused with adding an extraneous limitation appearing in the specification, which is improper'"). Therefore the Court adopts the following definition of heat-activatable adhesive layer: "An adhesive or thermoplastic film generally having a lower melting point than the other layers of the laminate."

1955

D. "Heat Conductive Cylinder"

Ramsey contends that "heat conductive cylinder" should be defined as "a solid cylindrical object formed of heat conductive material." Ramsey argues that any fragmentation of the cylinder would compromise the efficiency of the heat transfer. It also notes that the claims must be read to require a single cylinder and not an assembly of parts: "a heat conductive cylinder" in Claim 1 and "braking pads, one on each side of the cylinder" in dependent Claim 2. '255 Patent, 5:13 and 5:25 (emphasis added).

Warn contends that a "heat conductive cylinder" should be construed as "any cylindrical part or assembly of parts whether solid or hollow made from a heat conducting material." In particular, Warn argues that Ramsey's limitation that the cylinder must be solid, namely made from one piece, is not addressed anywhere in the patent or the prosecution history. Warn agrees that an objective of the invention is to better dissipate the generated heat but argues that there is no limitation that only the most efficient design to do so is claimed.
As quoted above from the specification, the stator is an extension of the drum so that the head is conducted from the end faces through the stator material to the drum's outer surface and out to the atmosphere. Patent, 2:18-21, 4:42-45.

In differentiating the '255 invention from the '646 invention, the '255 specification states:

The brake pads [of the '646] are heat insulators and thus the heat created between the shoes and pads is retained within the mechanism. Under severe loads this can be a problem and an objective herein is to facilitate heat dissipation with an improved design over that of the '646 disclosed embodiment.

Ramsey contends that the prosecution history is additional evidence that the heat conductive cylinder is a solid metallic object functioning to transfer heat efficiently. Heuser Decl., Ex. B at 4:18-24, 7:2-7.

Again, it is clear from the '255 patent itself, as well as the cited prosecution history, that efficient heat dissipation is a primary objective of the invention. If the inventors intended to cover a cylinder assembled from multiple sections, they could have so claimed. Further, using Warn's definition, there is no limitation on any gap between the assembly of parts forming the cylinder. The gap could be so large that the heat conducting properties are lost. I also note the claim language of "a heat conductive cylinder," rather than language allowing an assembly of parts. Patent, 5:13-14.

At first I was concerned with Ramsey's proposed definition of a "solid" cylindrical object because in the claim, "said cylinder further having a center opening and a brake shaft extended through said center opening." Patent, 5:21-22. The core must be hollow. But I now realize that the center opening is already provided for later in the claim.

I conclude that the cylinder must be a single piece from end to end and not an assembly of parts with gaps in the interior. Thus, I define "heat conductive cylinder" as "a solid cylindrical object formed of heat conductive material."
This court finds that a similar analysis applies in construing the third limitation -- "a heater mounted in the [radial center of the] base to heat liquid contained in the reservoir." Black & Decker focuses on the first half of the limitation and argues that this limitation merely requires that the accused device have a heater mounted in the base. Under such a proposed interpretation, it is irrelevant whether the heater is actually "in" the reservoir or underneath it -- either way, the heater is in the base. This court does not disagree with Black & Decker's proposed interpretation of the first half of the limitation, standing alone. However, this court believes that Black & Decker ignores the second half of this third limitation; namely, the requirement that the heater mounted in the base must "heat liquid contained in the boiling liquid reservoir." For the same reasons stated above, this court finds that the third limitation should be construed to require a heater that heats the liquid while it sits in the reservoir. Once again, Black & Decker chose to insert the phrase "boiling liquid" when referring to the reservoir. In sum, when taken together, the two limitations reinforce the same basic point. The Black & Decker patent is limited to a heating system that heats the liquid while in the reservoir.

--- Footnotes ---

7 After the parties filed their summary judgment briefs in this case, the Federal Circuit issued a ruling in a similar case -- The Rival Co. v. Sunbeam Corp., 1999 U.S. App. LEXIS 2768, 1998 WL 96416, *6-7 (Fed. Cir. Feb. 23, 1999) -- in which it affirmed the district court's finding of no infringement based on, among other things, a finding that Sunbeam's food steamers lacked a "boiling water reservoir." The parties here filed supplemental briefs concerning the effect of this opinion. Because Rival involved a different (albeit similar) patent and because the Federal Circuit's opinion is not citable as precedent, this court did not consider the Rival opinion in this ruling.

--- End Footnotes ---
by heating the cylinders with the natural gas burner to an operable temperature range of 400 to 950 degrees Fahrenheit (204 to 510 degrees centigrade)." (Kowalski Patent, Col. 16, at 39-41.)

Here, then, just as in Gentry, the "entirety of the specification clearly indicates that the invention is of a much narrower scope," Cooper Cameron Corp., 291 F.3d at 1323, than what is claimed in Claims 1 and 67. The specifications do not support the broad claim language of "heating"; accordingly these claims are deemed invalid on this ground. See Gentry Gallery, 134 F.3d at 1479.

1959

ORDER GRANTING MOTION FOR CLARIFICATION AND RECONSIDERATION OF CLAIMS CONSTRUCTION ORDER

Before the Court is the motion of William R. Kowalski ("Kowalski") and Hawaii International Seafood ("HISI") to clarify and reconsider the Court's claims construction order filed on October 17, 2007, in the above-captioned cases. Specifically, Kowalski and HISI request the Court to (1) clarify that the word "heating," as used in Claims 1 and 67 of the Kowalski Patent, is not limited to a specific numerical temperature range, and (2) to vacate the finding of invalidity of those claims. After careful consideration of the motion, the supporting and opposing memoranda, and the relevant case law, the motion for clarification and reconsideration is hereby GRANTED.

DISCUSSION

On August 31, 2007, the Court held a Markman hearing to construe certain claims of U.S. Patent 5,972,401, titled "Process for Manufacturing Tasteless Super-Purified Smoke for Treating Seafood to be Frozen and Thawed," originally awarded to Kowalski on October 26, 1999 (hereinafter "Kowalski Patent"). During claims construction, HISI and Kowalski urged that the word "heating" in Claims 1 and 67 of the Kowalski Patent not be given the specific numerical temperature limitation requested by Plaintiff and Counterclaim Defendant Tuna Processors, Inc., and by Defendants Mommy Gina Tuna Resources, King Tuna, Inc., Joaquin Lu, Seafriend, Richard Friend, Citra Mina Corporation, and Integral Seafood LLC (collectively, "TPI"). The Court ruled that the specifications, which "disclose[d] an operable temperature range of 204[degree] to 510[degree] C," did not support the broad language of the claim of "heating." (Claims Construction Order 19.) On this basis, the Court invalidated Claims 1 and 67 for violating the written description requirement of 35 U.S.C. § 112. It is this portion of the Claims Construction Order for which HISI and Kowalski request clarification and reconsideration.

Motions for reconsideration may only be brought if there has been (1) "[d]iscovery of new material facts not previously available," "[i]ntervening changes in law," or (3) a "[m]anifest error of law or fact." Local Rule 60.1. Here, Kowalski and HISI assert that the Court made a manifest error of law by invalidating the claims during the claims construction process. Kowalski and HISI agree with the Court's implied finding that "heating" is broadly defined in Claims 1 and 67, but contend that the Court overstepped its bounds in taking the next step of invalidating those claims based on the specifications' failure to describe such a broad claim. The Court agrees.

Each claim of a patent is presumed to be valid. 35 U.S.C. § 282; Abbott Labs. v. Syntron Bioresearch, Inc., 334 F.3d 1343, 1357 (Fed. Cir. 2003). Patents may be held invalid for failure to meet the written description requirement of 35 U.S.C. § 112 when narrow specifications fail to support a broad claim. Gentry Gallery, Inc. v. Berkline Corporation, 134 F.3d 1473, 1479 (Fed. Cir. 1998). However, invalidity under § 112 is a question of fact. Cordis Corp. v. Medtronic Ave., Inc., 339 F.3d 1352, 1364. To obtain a finding of invalidity under § 112 prior to trial, a party "must submit such clear and convincing evidence of invalidity such that no reasonable jury could find otherwise." Eli Lilly & Co. v. Barr Labs., 251 F.3d 955, 962 (Fed. Cir. 2001).

Here, in addressing the validity issue in the context of claims construction, the Court did not allow the parties the same opportunity to present facts that would have been afforded them in a summary judgment proceeding. In addition, the Court did not take into consideration whether invalidity had been demonstrated by clear and convincing evidence.

TPI argues that the Court's finding of invalidity was nonetheless appropriate because sua sponte summary judgment can be proper where no material dispute of facts exists, and there has been adequate time to develop necessary facts. (TPI Mem.
Opp. (citing Fuller v. City of Oakland, 47 F.3d 1522, 1533 (9th Cir. 1995).) Here, however, the Court does not believe that the parties were given adequate time to develop necessary facts, or to make the sorts of arguments that would have been raised in a summary judgment proceeding. In addition, TPI was never forced to prove invalidity with clear and convincing evidence. C.F. Fin Control Sys. Pty., Ltd. v. OAM Inc., 265 F.3d 1311, 1312 (Fed. Cir. 2001) (stating that "the district court's sua sponte grant of summary judgment of invalidity and unenforceability was procedurally improper because it did not provide the parties with adequate notice or an opportunity for FCS to present evidence and argument in opposition to the motion"). Accordingly, the Court hereby VACATES that portion of its Claims Construction Order that found Claims 1 and 67 of the Kowalski Patent to be invalid under § 112.

Kowalski and HISI have also requested that the Court clarify that it has construed the word "heating," as used in Claims 1 and 67 of the Kowalski Patent, as not limited to any specific numerical range. This is correct. While the Court continues to believe that the specifications of the Kowalski Patent describe a process significantly more limited than the "heating" claimed in Claims 1 and 67, these limitations may not be read into the broad claim. See Conoco, Inc. v Energy & Envtl., 460 F.3d 1349, 1358 (Fed. Cir. 2006) (affirming that "when a claim term is expressed in general descriptive words, we will not ordinarily limit the term to a numerical range that may appear in the written description or in other claims") (quoting Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998)). If TPI wishes to challenge the validity of this claim based on the failure to adequately describe "heating" in the specifications, TPI may do so at the proper time. For the moment, however, the Court CLARIFIES that the word "heating," as used in Claims 1 and 67 of the Kowalski Patent, is not limited to any specific temperature range.

CONCLUSION

The Court's Claims Construction Order for the Yamaoka and Kowalski Patents, filed on September 17, 2007, is hereby reconsidered and amended such that (1) the portion of the order invalidating the Kowalski Patent's Claims 1 and 67 is VACATED; and, (2) the Court clarifies that "heating," as used in Claims 1 and 67 is not limited to any specific numerical temperature range.

1960

4. Temperature Range of the Heating Step of Processing

Defendants argue that the claims at issue require that the heating stage of the process must occur at a temperature between 25 [degree] C and a specified upper limit. Howmedica asserts that the claims do not specify an upper temperature limit for the heating stage.

'934 Patent, claims 23, 50; '814 Patent, claim 7; '308 Patent, claim 24: "said material . . . heated . . . at a temperature . . . greater than 25 [degree] C" 

'814 Patent, claim 19: "annealing said material . . . at a temperature greater than 25 [degree] C"

'308 Patent, claims 1, 12: "heating the [polyethylene material/polymer]"

'308 Patent, claims 5, 16: "method as set forth in claim [1/12], wherein the temperature is greater than 25 [degree] C"

'020 Patent, claims 10, 11, 12: "medical implant comprising an ultra-high molecular weight polyethylene . . . annealed at a temperature greater than 25 [degree] C"

Howmedica proposes that the phrase "at a temperature [. . .] greater than 25 [degree] C" requires no interpretation. Defendants argue that the Court should interpret this phrase as "at a temperature of greater than 25 [degree] C but less than 140 [degree] C." Defendants refer to the summary of the invention and the preferred embodiment in the specification to narrow the scope of the claim. They observe that the process described in the specification does not include situations wherein the material is heated at a temperature greater than its melting point. The Court rejects defendants' argument.

a. "heating" / "heating at a . . . temperature greater than 25 [degree] C"
Related dependent claims do not support defendants' proposed limitation of the ordinary meaning of the terms "heating" and heating "at a temperature [. . .] greater than 25 [degree] C" in independent claims 23 and 50 of the '934 Patent. Dependant claims 30 and 53 of the '934 Patent are for "[t]he medical implant . . . wherein said heating has an upper temperature limit of the melting point of the . . . material." '934 Patent, claims 30, 53. 10 Dependent claims 32 and 54 are for "[t]he medical implant . . . wherein said heating has an upper limit not exceeding the distortion temperature of the . . . material." '934 Patent, claims 32, 54. In contrast, independent claims 23 and 50 of the '934 Patent do not specify any upper temperature limit on the heating process. The express upper temperature limits in the four dependent claims imply that heating "at a temperature . . . greater than 25 [degree] C," without any express upper limits, includes processes whereby the material is heated above its melting or distortion point, approximately 140 [degree] C. See Phillips, 415 F.3d at 1314-15 (express limitations in dependent claims should not be read into independent claims). The Court finds that the heating processes described by claims 23 and 50 of the '934 Patent are not limited to an upper temperature of 140 [degree] C.

10 The description of the preferred embodiments indicates that the melting point or distortion temperature of ultra-high molecular weight polyethylene is "about 140 [degree] C." See, e.g., '934 Patent, 5:55-58; 6:66-7:02.

ii. '814 Patent, claim 7

Limitations on a related dependant claim also imply that "heated . . . at a temperature . . . greater than 25 C" in claim 7 of the 814 Patent does not disclose an upper limit on the heating of the polymer. Dependent claim 10 of the '814 Patent is for "[t]he device . . . wherein the polyethylene material is heated to a temperature between 25 [degree] C and the melting point of said polymer," which implies that independent claim 7 of the '814 Patent is not so limited because it specifies no upper temperature limitation. See Phillips, 415 F.3d at 1314-15. The Court finds that claim 7 of the '814 Patent does not place an upper temperature limit of 140 [degree] C on the heating process.

iii. '308 Patent, claims 1, 5, 12, 16, 24

Likewise, limitations on a related dependant claim imply that the disputed claims of the 308 Patent do not disclose an upper limit on the heating of the polymer. Dependent claims 9 and 20 of the '308 Patent are for "the method . . . wherein the polyethylene material is heated to a temperature . . . between 25 [degree] C and the melting point of said polymer." '308 Patent, claims 9 and 20. The limitations established in all of these dependent claims lead the Court to find that independent claims 1 and 12 of the '308 Patent, which only specify "heating the polyethylene material," may include processes whereby the material is heated above 140 [degree] C. See Phillips, 415 F.3d at 1314-15. Claims 5 and 16 of the '308 Patent limit the invention described in claims 1 and 12 to processes "wherein the temperature is greater than 25 [degree] C," but do not specify any upper limit. '308 Patent, claims 5, 16. Applying the doctrine of claim differentiation, the Court finds that claims 5 and 16 include processes that involve heating the polymer to a temperature greater than 140 [degree] C.

Claim 24 of the '308 Patent specifies that the material is heated at a "temperature of greater than 25 [degree] C." '308 Patent, claim 24. Reading the language of claim 24 consistently with claims 5 and 16, the Court finds that claim 24 of the '308 Patent is not limited to heating at a temperature of less than 140 [degree] C.

b. "annealed at a temperature of greater than 25 [degree] C"

i. '020 Patent, claims 10, 11, 12

The language of the '020 Patent claims is less clear because the context does not clarify the definition of the claims at issue. Also, the '020 Patent claims differ from those of the other patents because they use the word "anneal" rather than "heat." The Court will not base its interpretation of these claims on its construction of the '934, '814, and '308 Patents, and will look to the specification to define the term "anneal" in the '020 Patent claims. The '020 Patent specification only describes an annealing process which takes place at a temperature between 25 [degree] C and 140 [degree] C. This confirms the Court's
understanding of the plain language definition of the term "anneal," which is method of changing a material's physical properties by heating a material to a point below its melting point and then cooling that material. The Court will interpret "annealed at a temperature of greater than 25 [degree] C" in claims 10, 11, and 12 of the '020 Patent to mean exactly that: "annealed at a temperature of greater than 25 [degree] C" and less than the melting point of that material -- approximately 140 [degree] C.

ii. '814 Patent, claim 19

Claim 19 of the '814 Patent similarly states that the method of treatment consists of "annealing said material . . . at a temperature greater than 25 [degree] C," unlike the other disputed claims of that patent, which disclose the "heating" of the material. Looking towards the ordinary meaning and the specification, the Court finds that claim 19 of the '814 Patent describes a process of heating the material to a temperature between 25 [degree] C and 140 [degree] C.

c. Prosecution History

The Court rejects Defendants' resort to the prosecution histories of the '934, '471, and '485 Patents because the prosecution history does not demonstrate that Howmedica limited the upper temperature of the heating stage in response to the examiner's objections. In amending its '934 Patent, Howmedica did not add an upper temperature limit; Howmedica lowered the lower temperature limit. In his objection to the '471 and '934 Patent claims, the examiner was objecting to the claims' highly imprecise temperature and duration language, not to the lack of an upper temperature limit of 140 [degree] C.

GO BACK

1961

5. What is the proper Construction of the Phrase "heating said substantially uniform mixture within said die" in the '092 Patent?

Claim 1 of the '092 patent contains the phrase: "heating said substantially uniform mixture within said die to a temperature substantially above the softening temperature of said binder material but to a temperature less than the softening temperature of said primary material[]." KXI contends this phrase means that at least a portion of the mixture is heated above the softening temperature of the binder while the mixture is in the die. Culligan contends this phrase means that the heating must be applied to the mixture while it is in the die. Culligan contends the claim limitation cannot be met by an extruder that heats the mixture solely by applying heat to the extruder barrel.

In support of its construction, Culligan cites several passages from the best mode section of the '092 patent's specification. Culligan cites column 8, lines 58-65 of the '092 patent, which reads in relevant part:

The barrel of the extruder is modified to operate at ambient room temperature or to provide mild preheating . . . and the powder is transported through the barrel at a temperature below the softening point of the binder resin. Heat resulting from friction within the barrel can, if desired, be removed by the circulation of coolant through both the screw and barrel.

Culligan cites column 4, lines 44-48 of the '092 patent, which reads in relevant part:

It is important that the feed material 38 entering the die 26 remain flowable. For that reason, the preheating which occurs within the extruder barrel 12 should not closely approach the softening point of the binder material. However, preheating is useful because it reduces the amount of additional heat that must be supplied within the die 26.

Culligan argues these passages define the phrase "heating . . . within the die" to require the entire mixture be heated above the softening temperature of the binder in the die, and not in the barrel.

Culligan also argues that plaintiffs are estopped by the prosecution history of the '948 patent from arguing that "heating . . . within the die" does not require that all of the mixture be heated to a temperature substantially above the softening point of the binder in the die. KXI responds that it is improper to consider the '948 patent's prosecution history in this context. KXI argues that furthermore it has not treated the phrase "heating . . . within said die" in claim 1 of the '092 patent the same as the phrase "means in said die for heating . . . ." KXI also points out that the '092 patent claim containing this phrase is not in
means-plus-function language, and is therefore not limited to the specification, as is the related phrase in the '948 patent.

The '948 patent was filed as a continuation-in-part of the co-pending '092 patent. Claim 1 of the '948 patent contains the phrase: "means in said die adjacent to the inlet end thereof for heating said particulate mixture within said die cavity to a temperature substantially above the softening temperature of said binder material but less than the softening temperature of said primary material." Claim 1 of the '092 patent contains the phrase: "heating said substantially uniform mixture within said die to a temperature substantially above the softening temperature of said binder material but to a temperature less than the softening temperature of said primary material[.]" Both of these limitations concern the heating phase of the extrusion process described in the patents.

During the prosecution of the '948 patent, the patentee made statements distinguishing the extruder disclosed by the Zavasnik patent based upon where heating occurs. The patentee argued the "heating of the material" occurs in the extrusion die, and not in the "non-heated extruder barrel." The court finds these statements are relevant to interpreting the meaning of the '092 patent claim limitation at issue.

The court finds the plain meaning of the words of the claim limitation at issue disclose heating the mixture to a temperature above the softening temperature of the binder in the die, and not in the barrel. Furthermore, the court finds the words of the claim and the best mode descriptions relied upon by Culligan are consistent with the statements made during the prosecution of the '948 patent.

The court finds that the '092 patent teaches heating the mixture to a temperature above the softening temperature of the binder material in the die, and not in the barrel. In reaching this conclusion, the court relies upon (1) the plain meaning of the words of the claim; (2) passages from the best mode section of the patent specification cited by Culligan; and (3) the '948 patent's prosecution history. Accordingly, the court construes the phrase "heating said substantially uniform mixture within said die to a temperature substantially above the softening temperature of said binder material" in the '092 patent to mean that the substantially uniform mixture is heated to a temperature substantially above the softening temperature of the binder while the mixture is in the die. This claim limitation precludes heating the mixture to a temperature substantially above the softening temperature of the binder material while the mixture is in the barrel, but it does not preclude preheating the mixture in the barrel.

Claims 1-3, 5-7, and 15 of the '061 patent include a "heating station" limitation. The district court adopted Ventana's construction of the term "heating station" as to the number-of-slides limitation and provided a "glossary" to the jury that defined "heating station" as "a slide support and heating element capable of directly heating at least one microscope slide, but designed to hold and heat a number of slides by conductive heating, e.g., direct contact of a heated surface to a portion of the microscope slide to be heated." (J.A. at 30 (emphasis added).)

Ventana urges on appeal that the district court's construction of "heating station" correctly requires each heating station to "hold and heat a number of slides." Under this construction, Ventana argues that the jury's verdict of infringement of claim 1 of the '061 patent is not supported by substantial evidence because each heating station of the accused devices holds and heats only a single slide. CytoLogix contends that the district court's construction of "heating station" is inconsistent with the plain language of the claims; that the correct construction covers devices in which only a single slide can be accommodated by each heating station; and that the evidence requires a verdict of infringement under this construction.

n6 CytoLogix also argues that substantial evidence supports the jury's verdict even under the district court's claim construction.

CytoLogix is correct that the district court's claim construction conflicts with the plain language of the claims. Claim 1 of the '061 patent recites a "heating station adapted to support at least one microscope slide," meaning that a heating station
that supports only one slide falls within the scope of the claim. '061 patent, col. 11, ll. 2-3. Furthermore, claim 2 recites "[a] microscope slide stainer as claimed in claim 1 wherein each of the heating stations supports a single microscope slide." Id. at col. 11, ll. 6-8. Claim 2 would be rendered meaningless if each heating station had to support multiple slides. An interpretation of one claim that renders another claim meaningless is disfavored. In re Cruciferous Sprout Litig., 301 F.3d 1343, 1349 (Fed. Cir. 2002). There is nothing in the specification that suggests a different construction. See Phillips, 415 F.3d at 1314.

Ventana points to the prosecution history of the '061 patent as support for the district court's claim construction. It argues that CytoLogix disclaimed individual slide heating. Ventana misreads the prosecution history. A precursor claim to issued claim 1 had claimed "electronic control for heating the individual heating surfaces" of the heating stations. (J.A. at 2748.) The examiner rejected the claim under 35 U.S.C. § 112 because the specification did not enable one skilled in the art to make or use the claimed "electric [sic] control for heating the individual heating surface." (J.A. at 2756.) CytoLogix amended the claim such that it recited "electronic control for the heating stations" rather than the "individual heating surfaces." (J.A. at 2839.) CytoLogix also explained in its response that "claims 1-9 were rejected under 35 U.S.C. § 112, second paragraph, with respect to the recitation of individual heating surfaces heated or controlled individually. That feature is no longer recited in the claims." (J.A. at 2841.) The exchange during prosecution had nothing to do with the number of slides a heating station may accommodate; it only established that if a heating station accommodates more than one slide, all of the slides on that heating station must be heated as a group and not individually.

Thus, the claim term "heating station" is not limited to a device that holds and heats a number of slides. The term "heating station" is properly construed to mean "a slide support and heating element capable of directly heating at least one microscope slide by conductive heating, e.g., direct contact of a heating surface to a portion of the microscope slide to be heated."

Although the district court erroneously construed "heating station," a new trial is not required because the district court's instruction to the jury did not constitute prejudicial error. "To warrant a new trial . . . the erroneous jury instruction [must have been] in fact prejudicial. When the error in a jury instruction could not have changed the result, the erroneous instruction is harmless." Ecolab Inc. v. Paraclice, Inc., 285 F.3d 1362, 1374 (Fed. Cir. 2002) (internal quotation marks omitted); see also Seachange Intl, Inc. v. C-COR Inc., 413 F.3d 1361, 1381 (Fed. Cir. 2005); Weinar v. Rollform Inc., 744 F.2d 797, 808 (Fed. Cir. 1984). Prejudicial error only exists if "there was sufficient evidence at trial to support a finding of [non-]infringement under a correct instruction." Ecolab, 285 F.3d at 1374. Although infringement under the district court's erroneous claim construction was debatable, infringement under the proper construction was not. n7 This was so because there was no dispute that the heating stations of the accused devices supported and heated at least one slide. We sustain the jury's verdict of infringement concluding that the "heating station" limitation of claims 1-3, 5-7, and 15 of the '061 patent is satisfied.

n7 See also Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1560 (Fed. Cir. 1995) (jury verdict reversed where insufficient evidence to support verdict under correct construction).
customary meaning of the word and in such a manner that it can apply generally to any vertical dimension.

For the foregoing reasons, I conclude that the term "height" should be construed to mean "the distance between the bottom and top surfaces of an object or between the lowest and highest points of a cognizable portion of an object."

1964

**d. "Held in Spaced Relation" or "Spaced Relation"**

The last term in Claim 3 that the parties have identified as requiring construction is "held in spaced relation" or just "spaced relation." Claim 3 states "the seeds being held in spaced relation by the biodegradable material." ('760 Patent col. 5, ll. 56-57.) The World Wide Plaintiffs propose a construction of "set apart a particular distance from one another." AnazaoHealth has proposed "fixed in place with respect to other radioactive sources by the biodegradable material." The Court adopts the construction proposed by Plaintiffs.

The most critical aspect of the invention is its ability to improve the positioning of the radioactive seeds in the body upon implantation. Thus, the "spaced relation" of the seeds vis-a-vis one another - that is, the distance between the seeds - is extremely important. Had the patentees intended "spaced relation" to have no spatial relationship, they could have simply used the word separated. The dictionary defines "spacer" as "one that spaces," "a device or piece for holding two members at a given distance from each other." The Court finds that one of ordinary skill in the art would construe "held in spaced relation," as meaning that the seeds were "set apart a particular distance from one another."

1965

**II. Literal Infringement**

A literal infringement analysis requires two separate steps. First, the asserted claims must be interpreted by the court as a matter of law to determine their meaning and scope. In the second step, the trier of fact determines whether the claims as thus construed read on the accused product. To establish literal infringement, every limitation set forth in a claim must be found in an accused product, exactly. Infringement, both literal and under the doctrine of equivalents, is an issue of fact.

--- Footnotes ---

1 In Markman v. Westview Instruments, Inc., the Supreme Court confirmed that "the construction of a patent, including terms of art within its claim, is exclusively with the province of the court." 134 L. Ed. 2d 577, 116 S. Ct. 1384, 1387 (1996).

--- End Footnotes ---

Defendant's argument that there is no literal infringement is simple:

Defendant's product does not literally infringe the single independent claim of the '076 patent because the plastic glove member of the accused structure is not "hemispherical" nor is the fabric stretched across the front of the plastic member in "spaced relationship" with the inner surface. Since the product of defendant does not meet these limitations of the claim, there is no literal infringement.

(Def. Mem. at 15.)

**Defendant's product (Pl. Ex. MC) is plainly not "hemispherical."** 2 Plaintiff argues, however, that examination of the specification and prosecution history, see Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (in
banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996), shows that defendant's "conclusion that 'hemispherical' means one-half of a full sphere...is patently incorrect." (Pl. Mem. at 19.)

2 In a geometrical sense, a "sphere" is defined as "a body or space bounded by one surface all points of which are equally distant from a point within that constitutes its center." Webster's Third New International Dictionary of the English Language Unabridged at 2193 (1986). A "hemisphere," in the geometrical sense, is "either of two half spheres formed by a plane through a sphere's center." Id. at 1055.

It is true, of course, that:

Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history.

Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Here, the only definition "by implication," id., that can be found in the specification of the '076 patent must be derived from the drawings, most particularly Figure 2, which shows a rigid glove that is less than a hemisphere, but is, nevertheless, a part of a sphere. 3 The rigid glove component of defendant's product, on the other hand, is not part of a sphere, having a perceptibly flattened surface. Therefore, this Court holds that there has been no literal infringement of Claim 1 of Bai's '076 patent as the rigid plastic member of defendant's product cannot be considered to be hemispherical in shape.

3 "It is beyond question that each of Figures 1-4 in the '076 patent show a glove that is concave and substantially symmetrical about its center." (Plaintiff's Reply Mem. at 6.)(emphasis in original).

The plaintiff proposes "the contact lens has functional wettability, dehydration resistance, deposition resistance, and comfort, rendering the lens suitable for extended wear." The defendants propose "clinical performance, resulting from the lens having a sufficiently high proportion of HAM units to silicon units on the lens surface, that is a significant improvement over the clinical performance of the untreated lens body."

The plaintiff's construction comes from the specification describing examples of clinical performance. See '327 Patent, 1:63-2:6. The plaintiff contends that the defendants' construction improperly incorporates structural limitations into a functional limitation. The defendants argue that the "high degree of clinical performance" is based on the structural invention, and, therefore, the structure must be included in the definition.

The defendants also dispute the inclusion of "extended wear" in the plaintiff's proposed construction. According to the defendants, the specification does not require clinical performance to have extended wear capabilities and if the patentee wanted to limit the claim term to "extended wear," he could have explicitly done so.

The defendants attempt to import limitations from the preferred embodiment. A "high degree of clinical performance" is the benefit achieved by the structure disclosed in the '327 patent. This does not mean that the Court's construction must include the structure as suggested by the defendants. Furthermore, throughout the specification, "clinical performance" is associated with the ability to wear the lenses for a long period of time. See '327 Patent, 2:1-6, 6:6:35-39, 6:45-50. Accordingly, the
Court construes the term to mean "a contact lens that has functional wettability, dehydration resistance, deposition resistance, and comfort, rendering the lens suitable for extended wear."

1967

8. "material having a high electrical resistance"

This phrase is found in Claims 1 and 16. Plaintiff argues that this phrase should be construed as "a metal, alloy or other material, such as tungsten, molybdenum or Elkonite (copper-tungsten alloy) having a higher electrical resistance than copper." Defendants assert that the phrase need not be construed, and the Court agrees. Because the Court sees no ambiguity as to the meaning of the phrase "material having a high electrical resistance" and because its ordinary and customary meaning is clear to one skilled in the art, the Court declines to construe the phrase as it is used in the '015 Patent.

1968

"high intensity mixing"

The parties do not dispute the construction of the limitation "high intensity mixing". Mikron contends that the term should be construed to mean "the process employed to distribute solid and liquid components with the express purpose of dispensing them in a polymer (or plastic resin). Marley contends that the limitation should be construed to mean "the process employed to distribute solid and liquid components with the express purpose of dispensing them in a polymer resin." This construction is supported by the ordinary and accustomed meaning of the term and the patent specification. Accordingly, high intensity mixing is construed to mean "the process employed to distribute solid and liquid components with the express purpose of dispensing them in a polymer resin".

1969

A. Construction of "high strength adhesive" and "bond strength sufficient to resist peeling of the fabric from the substrate"

This Court views the terms "high-strength adhesive" and "bond strength sufficient to resist peeling of the fabric from the substrate" as inextricably linked. The summary judgment record demonstrates that one ordinarily skilled in the art would not attribute an independent definition to "high-strength adhesive," but rather would understand the term in the context of the adhesive's performance. Indeed, the record contains no basis on which to construe "high-strength adhesive" independently. On the contrary, American Seating's adhesives expert, Dr. Hartshorn, reports that "there is no accepted definition of the term high-strength adhesive." (Def.'s Ex. 136.) Instead, he says, a functional definition applies: "[t]he adhesive must be sufficiently strong for the application and may be referred to as 'high strength' simply because it has the level of performance required." (Id.) The Court agrees that a functional definition is proper here. This is also consistent with the Federal Circuit Court's 2004 decision addressing the construction of "high strength adhesive." See American Seating Co. v. USSC Group, Inc., 91 Fed. Appx. 669, 676-77 (2004) (acknowledging, at least implicitly, that "high strength adhesive" in the '931 Patent had to be understood in terms of the bond strength the adhesive created). In the '931 Patent, the required performance of the "high strength adhesive" is to create "a bond strength sufficient to resist peeling of the fabric from the substrate." (Def.'s Ex. 1.)

The question then becomes how to construe "bond strength sufficient to resist peeling of the fabric from the substrate." American Seating proposed construction states, "The bond strength of the high strength adhesive must deter or discourage peeling by a vandal during a trip normally undertaken on intra-city public transportation." American Seating's proposed construction lacks objectivity. It hinges on the necessarily subjective experience of a hypothetical vandal on a "normal" trip taken on public transportation within an undefined city. American Seating's proposed construction is too vague to serve the public notice function a patent provides. See Markman, 517 U.S. at 373 (quoting McClain v. Ortmayer, 141 U.S. 419, 424, 12 S. Ct. 76, 35 L. Ed. 800, 1891 Dec. Comm'r Pat. 532 (1891) ("[A] patent must describe the exact scope of an invention . . . to secure to [the patentee] all to which he is entitled, [and] to apprise the public of what is still open to
With regard to the first issue, the district court erred as to both patents. Because the patents contain slightly different adhesive is sufficient to prevent a person from being able to manually peel the fabric from the substrate."

As to all claims at issue, the Court adopts Kustom's proposed construction for "bond strength sufficient to resist peeling of the fabric from the substrate." Kustom's proposed construction comports with the patent language, prosecution history and other record evidence. The American Seating's adhesives expert, Dr. Hartshorn, concedes that he has no expertise in vandal psychology and no experience in determining what might deter or discourage a vandal from performing an act of vandalism. (Hartshorn dep., Pl.'s Ex. 13, 181-84.) The tests Dr. Hartshorn applied to formulate his report could not reliably measure the nebulous likelihood that a vandal would be deterred or discouraged by the strength of the adhesive bond. (See Def.'s Ex. 136.)

Nor does Plaintiff's proposed construction comport with the intrinsic evidence. Nothing in the language of the claims or specifications suggests that the subjective perseverance of an urban vandal dictates the scope of the claims. The patent itself contains not a word about the psychology of vandalism or the sociology of public transportation use. On the contrary, the patent speaks throughout in terms of bond strength and peel strength, terms relevant to engineering, not social science. Indeed, Claims 2 and 11 of the '931 Patent refer to a specific peel strength. (Def.'s Ex. 1, Col. 6, 35-38; Col. 8, 37-40.) Though the language of the disputed claims does not make reference to specific peel strengths, the language does focus on bond or peel strength, not the perseverance of a reasonably aggressive vandal. Indeed, if the subjective thinking of a vandal underpinned the construction of the claim terms, it is difficult to see how the claims could survive the obviousness and indefiniteness challenges Kustom raises in its motion for summary judgment of invalidity. (docket # 52.)

Kustom proposes to construe "bond strength sufficient to resist peeling of the fabric from the substrate" to mean: "The bond strength of the high strength adhesive is sufficient to prevent a person from being able to manually peel the fabric from the substrate." Kustom's proposed construction offers a more objective framework consistent with the language of the '931 Patent itself. The patent makes numerous references to bond and peel strength. Claims 1, 2, 3, 6, 7, 8, 10 and 12 all speak of bond strength, peel strength, or both. (Def.'s Ex. 1.) The Summary of the Invention explicitly refers to bond strength and peel strength. (Id.) The Detailed Description of Preferred Embodiment describes a minimum bond strength to be illustrated by a minimum peel strength: "As a minimum standard, it is desired that the fabric to substrate bond exhibit a peel (stripping) strength after being fully cured . . . exceeding the tensile strength of the fabric or a minimum bond strength of at least twenty-five (25) pounds per inch width of fabric." (Id.) Both parties have acknowledged that bond strength and peel strength are familiar terms in the art of engineering. Indeed, there is a standard test used in the industry to determine bond and peel strength, the American Society of Testing and Materials ("ASTM") Standard D 903 protocol, known as the "Standard Test Method for Peel or Stripping Strength for Adhesive Bonds" (the "ASTM peel test"). The record shows that one of ordinary skill in the relevant art here -- would have no basis to address these questions using recognized tools in the discipline. American Seating's adhesives expert, Dr. Hartshorn, concedes that he has no expertise in vandal psychology and no experience in determining what might deter or discourage a vandal from performing an act of vandalism. In application, the proposed construction would first require one to determine how persevering a typical vandal would be -- to posit, in effect, a "reasonably aggressive vandal." Next, one would need to decide what a normal intra-city trip might be. In any given city, and among different cities, "normal" travel could mean a multitude of different things. The range of putative vandals and potential intra-city trips defies quantifying. Certainly, one skilled in the art of engineering -- the relevant art here -- would have no basis to address these questions using recognized tools in the discipline. American Seating's adhesives expert, Dr. Hartshorn, concedes that he has no expertise in vandal psychology and no experience in determining what might deter or discourage a vandal from performing an act of vandalism. (Hartshorn dep., Pl.'s Ex. 13, 181-84.)

The prosecution history of the patent also weighs in favor of Kustom's proposed construction. In responding to an earlier Patent Office challenge of Claims 1, 3, 4 and 6 in the '931 Patent, American Seating described a seat insert with fabric attached to the substrate "by means of a high strength adhesive that bonds the fabric directly to the substrate with such strength that the upholstery cannot be peeled from the substrate." (Def.'s Ex. 71) (emphasis added.) American Seating's own description in its response to the Patent Office closely aligns with Kustom's proposed construction.

Kustom's proposed construction comports with the patent language, prosecution history and other record evidence. The Court adopts Kustom's proposed construction for "bond strength sufficient to resist peeling of the fabric from the substrate." As to all claims at issue, the Court construes "high strength adhesive" to mean "An adhesive providing a bond strength sufficient to prevent a person from being able to manually peel the fabric from the substrate," and construes "a bond strength sufficient to resist peeling of the fabric from the substrate" to mean "The bond strength of the high strength adhesive is sufficient to prevent a person from being able to manually peel the fabric from the substrate."
language we will treat them separately.

Claim 1 of the '539 patent requires:

a layer of high strength adhesive interposed between the pile fabric and the substrate, the adhesive at least partially permeating the backing of the fabric without materially impairing the visual appearance of the fabric from the other side, the adhesive bonding the fabric to the substrate with a bond strength sufficient to resist peeling of the fabric from the substrate, the bond strength being such that if upright fibers are grasped in an effort to peel the fabric from the substrate, the fibers will break before the backing will peel from the substrate.

The district court concluded that the claim term "high strength adhesive" was explained in the specification to mean an adhesive with "a stripping strength exceeding 25 pounds per square inch." Contrary to the district judge's holding, however, the language of the claim itself is sufficient to set forth the bonding requirement of the adhesive. The claim states that the adhesive bonds the "fabric to the substrate with a bond strength sufficient to resist peeling of the fabric from the substrate, the bond strength being such that if upright fibers are grasped in an effort to peel the fabric from the substrate, the fibers will break before the backing will peel from the substrate."

The district court stated that using the breaking of fibers as a measure of bond strength "is not a reasonable definition when the carpet is weak, because one cannot legitimately describe an adhesive used in that context as a "high strength adhesive." Claim 1, however, sets forth the bonding requirements of the adhesive by requiring that it be greater than the tensile strength of the fibers. There is nothing improper about defining the requisite strength of the adhesive by reference to the material that is being bonded, and in light of that definition in the claim, it would be improper to import another, narrower definition based on the notion that the definition in the claim would include some adhesives that would not normally be considered "high strength."

The district court also remarked that the functional definition of "high strength adhesive" lacked utility because "the invention would not be useful if the carpeting readily disintegrated, even though the pulling of the substrate would be avoided." We reject that conclusion because the specification makes clear that the benefit of the invention is that when individual fibers break before the fabric backing separates from the substrate it is more difficult to vandalize the seat. '539 patent, col. 2, ll. 57-63; col. 3, ll. 3-6.

The district court's adoption of the 25-pound per inch requirement was unwarranted for three additional reasons. First, the specification described the 25-pound per inch peeling strength as preferred and desired, not as a necessary feature of the claimed invention. See '539 patent, col. 2, ll. 31-34 ("Preferably, the fabric to substrate bond either exceeds the tensile strength of the fabric itself or has a peeling strength of at least twenty-five pounds per inch width of fabric."); '539 patent, col. 4, l. 66 to col. 5, l. 4 ("As a minimum standard, it is desired that the fabric to substrate bond exhibit a peel (stripping) strength after being fully cured ... exceeding the tensile strength of the fabric or a minimum bond strength of at least twenty-five (25) pounds per inch width of the fabric."). While the specification taught that that level of strength was desirable in the preferred embodiment, there is nothing in the specification to indicate that it was meant to be incorporated into the claims as an absolute limitation.

Second, and more importantly, the references in the specification to the strength of the adhesive bond were both couched in alternative form; that is, both described the desired bond strength as being either 25 pounds per inch of fabric width, or greater than the tensile strength of the pile fibers. Thus, even if the language of the specification is imported into the claim, and even if the language of preference is treated as language of absolute requirement, the language on which the district court relied does not support the court's conclusion that a "high strength adhesive" must have a peel strength of at least 25 pounds per inch of fabric width.

Finally, claim 3 of the '539 patent, which was dependent on claims 1 and 2, added the requirement that the "bond strength of the fabric to the substrate is at least twenty-five (25) pounds per inch width of fabric" as an alternative means of satisfying the "high strength adhesive" limitation. The absence of that alternative means from the definition of bond strength in claim 1 is a strong indication that claim 1 should not be construed to incorporate that limitation by implication and thereby exclude any adhesive with a bond strength of less than 25 pounds per inch of fabric width. See Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 972 (Fed. Cir. 1999) ("normally . . . limitations stated in dependent claims are not to be read into the independent claim from which they depend"). For all these reasons, we conclude that it was error for the district court...
court to interpret the term "high strength adhesive" in claim 1 of the '539 patent to mean an adhesive having a bond strength of at least 25 pounds per inch.

Interpreting claim 1 of the '931 patent presents more of a challenge because the claim language simply states that the bond should be sufficient to "resist peeling." The relevant claim language reads:

a layer of high strength adhesive interposed between the vertical pile fabric and the substrate and affixing the vertical pile fabric to the substrate, the adhesive bonding the fabric to the substrate with a bond strength that is sufficient to resist peeling of the fabric from the substrate.

As in the case of the '539 patent, the district court held that the claim language was ambiguous and that in light of the specification, the claim had to be limited to adhesives with a bond strength greater than 25 pounds per inch of fabric width.

Although the language of the '931 patent is broader than that of the '539 patent, there is still no justification for importing the 25-pound bond strength limitation from the specification into the claims. The specification of the two patents is identical, and the 25-pound strength requirement is expressed in the '931 patent, as in the '539 patent, as a preferred or desired feature, and as only an alternative measure of bond strength. In addition, as in the case of the '539 patent, a separate claim of the '931 patent (claim 2) recites the requirement that the bond strength be at least 25 pound per inch of fabric width. As a matter of claim construction, it was therefore improper for the district court to interpret the term "high strength adhesive" in the '931 patent to be limited to an adhesive with a bond strength greater than 25 pounds per inch.

The USSG Group is correct that the requirement that the bond strength only be "sufficient to resist peeling of the fabric from the substrate" is a minimal requirement that renders the claim broad. But we conclude that the claim was intended to be broad. While the breadth of the claim might create an issue as to validity, it does not create an issue as to its construction. It was thus error for the district court to construe the claim to incorporate 25-pound bond strength as a limitation.

Next, the Court must interpret the term "high pressure" as it is used in Claim 10 of the 669 patent, which claims "[a] method of loading a tubular replacement syringe into a high pressure power injector for injecting fluid into an animal." (Doc. No. 30, Exh. 1; 669 patent, col. 10, lines 17-18)(emphasis added). As the following analysis demonstrates, the term "high pressure" must be construed in its context as an adjective of the term "power injector." Therefore, the Court will construe the entire term "high pressure power injector" as an adjective.

The language of Claim 10 does not define the term "high pressure." However, when describing the syringe to be loaded into the injector, the claim does state that the syringe must be "capable of withstanding, . . . an operating pressure of at least 100 psi [pounds per square inch]." (Doc. No. 30, Exh. 1; 669 patent, col. 10, lines 32-34). Based on this language, L-F argues that the term "high pressure" means operating at pressures of at least 100 psi. (Doc. No. 164, p. 20).

While the claim language relied on by L-F may be relevant to the Court's overall analysis of the term "high pressure", it cannot, standing alone, define the term "high pressure." The claim language does not clearly delineate the pressure range to be attributed to the term "high pressure". As a result, the Court must interpret the claim language in light of the specification and prosecution history to ascertain the meaning of "high pressure."

When discussing injection pressures, the specification for the 669 patent states that:

For applications such as the injection of contrasting fluid for CT scanning, pressure may typically be in the range of from 25 to 300 psi, while in some angiographic injection applications the pressure may range to 1200 psi or higher.

669 patent, col. 12, line 24-27

(Doc. No. 30, Exh. 1). In other words, an injector operates at a pressure range of 25-300 psi for CT applications and
operates at a pressure range up to 1200 psi or higher for angiographic applications. Thus, by determining which applications the injector in Claim 10 is capable of performing, the Court can infer the meaning of "high pressure power injector" as it is used in Claim 10.

The claim language does not indicate whether the injector disclosed in Claim 10 is capable of CT applications, angiographic applications, or both CT and angiographic applications. Thus, the Court must look to the specification and prosecution history for guidance on this issue. The specification for the 669 patent indicates that the injector described in the specification can be used for angiographic and/or CT applications:

FIG. 1 is a perspective view of an angiographic CT injector embodying principles of the present invention.

669 patent, col. 5, lines 21-22

* * *

Referring to FIG. 1, an angiographic injector 10 according to another preferred embodiment of the present invention is illustrated, configured for CT applications.

669 patent, col. 6, lines 12-14

(Doc. No. 30, Exh. 1). The question then becomes whether the injector described in Claim 10, like the injector described in the specification, is capable of both CT and angiographic application, only CT applications, or only angiographic applications.

The specification goes on to state that the fluid used in the injector "may be of relatively high pressure in the range, usually over 200 psi." (Doc. No. 30, Exh. 1; 669 patent, col. 12, lines 22-23). The implication of this statement is that pressures over 200 psi are considered high, therefore a "high pressure power injector", as in Claim 10, would be an injector that operates at pressures of 200 psi or higher, which would include both CT applications and angiographic applications.

The conclusion that "high pressure power injector" refers to an injector that is capable of performing both CT and angiographic applications is also supported by the prosecution history of the 669 patent. L-F offered the following statements to the PTO Examiner during prosecution of the 669 patent:

Claim 95 relates specifically to high pressure power injectors, as for example the injectors used in angiography, with CAT equipment and the like. For such uses, applicants' front loading injector is totally new. The front loading feature is embodied in the simple operator motion of inserting the syringe into the injector by a rearward axial motion and twisting the syringe a fraction of a turn (as for example the quarter turn of the embodiment described in the specification).

(Doc. No. 84, Exh. 3(B) at MED 002326). (emphasis added). At first glance, it is unclear whether "with CAT equipment and the like" is a phrase modifying the term angiography or whether it is part of a series of injector applications with "angiography" being the first in the series, with "with CAT equipment" being the second in the series, and with "the like" being the third in the series. However, a reading of the full prosecution history reveals that this statement, although grammatically incorrect, involves a series of injector applications. Therefore, Claim 95 related to "high pressure power injectors" such as those used in angiography and those used with CT equipment.

14 Claim 95 issued as claim 10 of the 669 patent.

15 The terms CT and CAT are synonymous.

16 When discussing Claim 91 (issued as claim 1 of the 669 patent), L-F states that "claim 91 relates to the advantage of the present invention by which the efficiency of the use of a power injector, such as used in angiography and with CAT scanning equipment, is enhanced." When distinguishing this "present invention" from prior art devices, L-F states that "the prior art devices provided for angiography and CAT scan uses do not have this capability." From these statements, the Court
infers that "used. . . with CAT scanning equipment" is the equivalent of "CAT scan uses". (Doc. No. 84, Exhibit 3(B) at MED 002324-002325)(emphasis added).

It should be noted that the individual independent claims of the 669 patent refer to an injector as a "high pressure power injector", a "power injector", or simply an "injector." 17 Nothing in the language of the various claims indicates whether the use of these different terms is intended to describe injectors capable of different applications. Medrad would argue that the use of these different terms indicates that the injector is intended to perform different applications. However, there is nothing in the specifications or prosecution history to support this conclusion. In fact, the prosecution history supports the opposite conclusion, that there is no difference in the terms. During patent prosecution, L-F stated the following to the PTO Examiner:

Applicants' invention relates to relatively high pressure power injectors . . . In order to focus more clearly on the particular features of the present invention and the advantages it provides, applicants have replaced the claims with seven independent claims, each relating to a particular unique problem and unique advantageous solution provided by the invention.

(Doc. No. 84, Exhibit 3(B) at MED 002324)(emphasis added). L-F then went on to discuss the seven independent claims referred to in this excerpt, which were apparently related to "high pressure power injectors." Those claims, 91, 93, 95, 100, 101, 103, and 105, issued as independent claims 1, 6, 10, 19, 20, 22, and 24 respectively. The issued claims refer to an injector as a "power injector" (claims 1, 19, 22 ), a "high power pressure injector" (claims 10, 20, 24), and an "injector" (claim 6). The inference to be drawn is that the terms "power injector", "high power pressure injector", and "injector" all refer to the same type of injector, i.e., a "high pressure power injector." This conclusion is consistent with the principle that "claims that are written in different words may ultimately cover substantially the same subject matter." Multiform Desiccants, 133 F.3d at 1480

17 The independent claims of the 669 patent are 1, 6, 10, 19, 20, 22, 24, 31, and 36.

Accordingly, based on all the intrinsic evidence, the Court concludes that the "high [sic] power pressure injector" described in Claim 10 of the 669 patent is capable of performing angiographic as well as CT applications. As such, it operates at pressures ranging from 25 psi to in excess of 1200 psi.

Crown's proposed construction is "[t]he hinge segment referred to in claim 1 of the '728 patent: The region of metal that undergoes bending as a result of angular displacement of the frangible panel during normal use by a user." 109 Rexam's proposed construction is "[a] line between the first end and the second end of the primary score." 110

109 D.I. 325 at 12.

110 Id.

The court adopts Rexam's proposed construction.
Claim 7 of the '728 patent recites "[t]he end member of claim 1, wherein, at least a portion of the second score groove passes through the hinge line generally transverse to a hinge line passing between the first end and the second end of the primary score groove." 111

The parties agree that this claim contains a drafting error as there is no antecedent basis for "the hinge line" first recited therein. Rexam argues that the drafting error was using "a" and "the" in the wrong order with respect to "hinge line," i.e., that claim 7 was meant to read "[t]he end member of claim 1, wherein, at least a portion of the second score groove passes through [a] hinge line generally transverse to [the] hinge line passing between the first end and the second end of the primary score groove." Crown argues that the drafting error was the recitation of "the hinge line" and that that language in claim 7 was referring back to the "hinge segment" of claim 1 from which claim 7 depends.

Reading other claims of the '728 patent demonstrates that Crown is incorrect and that the "hinge line" recited in claim 7 does not refer back to the "hinge segment" of claim 1 and, therefore, should not be given the same construction as "hinge segment."

Like claim 1, unasserted independent claim 10 recites a can end having a "hinge segment." Like claim 7, unasserted claim 15 (which depends from claim 10) recites "[t]he end member of claim 10, wherein, at least a portion of the second score groove passes through a hinge line generally transverse to a hinge line passing between the first end and the second end of the primary score."

The repetition of "hinge line" in claim 15 lends support to Rexam's argument that the "hinge line" recited in claim 7 was not a mistake other than the error in drafting "the hinge line" in that claim rather than "a hinge line" as in claim 15. Additional evidence that the inventors intended that "hinge segment" is not the same as "hinge line" is found in unasserted independent claim 18 of the '728 patent where both terms are used: "a second end separated from said first end by a hinge segment, the hinge segment with a hinge line area." This likewise indicates that Crown is incorrect in its assertion that "the hinge line" of claim 7 is referring to, and means the same thing as, the "hinge segment" recited in claim 1.

Given that Crown offers no alternative proposed construction should the court disagree with its contention that the "hinge line" refers to the "hinge segment," its construction must necessarily be rejected. The court also determines that the claim language and specification supports Rexam's proposed construction.

Claim 7 of the '728 patent states that the hinge line "pass[es] between the first end and the second end of the primary score
groove.” 114 Describing the embodiment illustrated by figure 6, the specification states that “the tail portion 25 terminates in the end wall 12 beyond the score 22, and at least slightly transecting the line defining the hinge segment 26.” 115 Figure 6 illustrates the tail portion 25 of the anti-fracture score 24 ending at a dashed line which, although not given a separately-numbered designation, could be understood to illustrate the hinge line. The embodiment illustrated in figure 7 also has the same dashed line and that figure is described wherein “a tail portion 25 . . . not only transects the line defining the hinge segment 26, but also extends and encircles the second end 30.” 116

Therefore, the court adopts Rexam's proposed construction: "a line between the first end and the second end of the primary score." 101

Crown's proposed construction is "[t]he region of metal that undergoes bending as a result of angular displacement of the frangible panel during normal use.” 100 Rexam's proposed construction is "[t]he segment of metal between the first end and the second end of the primary score that stays attached to the central panel of the can end under normal opening conditions.” 101

The court adopts Rexam's proposed construction.

Crown argues that Rexam's proposed construction "seeks to redefine the 'hinge segment' to ignore what it is, and instead to define it by where it might be (or might not) be located: 'the segment of metal between the first end and the second end of the primary score.'" 102 Crown maintains that "Rexam's proposal to define the hinge segment without regard to what it does and without regard to where it is actually located should be rejected." 103 The court disagrees. In making this argument, Crown truncates Rexam's definition which reads in full, "the segment of metal between the first end and the second end of the primary score that stays attached to the central panel of the can end under normal opening conditions.” The non-italicized portion of Rexam's proposed construction indicates where the hinge section is located. The italicized portion of that construction describes what the hinge segment does, i.e., it is the segment of metal that remains attached to the central panel when the can is opened. Furthermore, Rexam's definition of "hinge segment" is supported by language of the score line patents' claims and common specification.
Claim 1 of the '230 patent recites:

a primary score groove in the central panel wall defining an outer perimeter of the frangible panel segment, the score groove having a first end adjacent the vent region, and a second end joined to the first end by a curvilinear segment of the score groove, the first end and the second end being separated by a generally linear hinge segment of the central panel wall, said hinge segment being non-frangible to integrally connect the frangible panel segment to an adjacent area of the panel.

104

Claim 13 of the '230 patent recites:

a frangible panel formed in the panel wall and being defined by a curvilinear score groove and a hinge segment, the score groove having a thickness residual and having a first end and a second end, said hinge segment having a length defined by a generally straight line between said first end and said second end.

105

Claim 1 of the '728 patent recites:

a primary score groove in the central panel wall defining an outer perimeter of the frangible panel segment, the score groove having a first end adjacent to the vent region and a second end, the first end and the second end being separated by a generally linear hinge segment of the central panel wall, said hinge segment integrally connecting to the frangible panel segment to an adjacent area of the panel.

106

Taken together, a plain reading of the claim language supports Rexam's proposed construction. The hinge segment is a generally linear part of the central panel between the first and second ends of a score groove and which remains attached to the central panel.

The score line patents' common specification supports that reading of the claim language. The "Summary of the Invention" section recites:

The score groove has a first end adjacent to the vent region and a second end joined to the first by a curvilinear segment of the score groove, whereby the first and the second end is separated by a generally linear hinge segment of the central panel wall. The hinge segment is non-frangible to integrally connect the frangible panel segment to an adjacent area of the panel.

107
The score line patents' common specification also describes an embodiment in which:

The central panel wall 12 has a displaceable tear panel 20 defined by a curvilinear frangible score 22 with an adjacent anti-fracture score 24 on the tear panel 20, and a non-frangible hinge segment 26. The hinge segment 26 is defined by a generally straight line between a first end 28 and a second end 30 of the frangible score 22.

Because Rexam's proposed construction is supported by the intrinsic evidence, the court adopts its construction: "the segment of metal between the first end and the second end of the primary score that stays attached to the central panel of the can end under normal opening conditions."

a. Claim Construction: "Hinged Joint"

Defendant argues that the "hinged joint" refers to the "hinge" shown in Figure 8C. Figure 8C depicts a "coupler embodiment[] for coupling the curtain to the head" where "the head is formed in two sections which interface at a hinge" and "the sections join at jaws to clamp the curtain, thereby securing it to the head." This is the only reference in the patent, other than in claim 1, to a "hinge."

Plaintiff counters that the "hinged joint" refers to "joint 56" of Figures 3A and 5A. Figure 3A depicts a curtain mount embodiment with a "body, a spring, a plunger, [and] a head," where "[t]he plunger and head preferably interface at a universal joint such that the curtain mount can be installed at a variety of angles relative to the ceiling." The patent also describes "joint 56" as "a swivel joint."
In the context of this patent, Plaintiff's construction of "hinged joint" makes more sense. Although the only reference in the patent outside of claim 1 to a "hinge" is in the context of the jaws/curtain clamping mechanism of Figure 8C, the hinge in that figure clearly does not permit the curtain coupling mechanism to "interface[e] with the elongated portion" of the curtain mount. Instead, that hinge allows one jaw of the coupling mechanism itself to interface with the other jaw. "Joint 56" is the only depiction in the patent of a joint that allows the coupling mechanism to interface with the elongated portion of the curtain mount, as described in the claim. Claim 1 also describes the "hinged joint" as "pivotable," a characteristic of the depicted "universal" or "swivel" "joint 56." Although Plaintiff likely picked the wrong word in "hinged," the claim's meaning is clear after consulting the remainder of the patent. 69 The patentee is his own lexicographer, and may define and use terms as necessary. 70 In this case, the word "hinge" can only refer to the pivotable socket that accomplishes the task of linking the head and pole, as depicted in Figure 56. The "hinged joint" of claim 1 may encompass the "universal" or "swivel" "joint 56," depicted in Figures 3A and 5A.

3. "Holding A Helical Array of Regularly Disposed Bristles"

Plaintiffs urge a tripartite construction of "holding a helical array of regularly disposed bristles." First, they argue that the phrase requires that the portions of the bristles at the surface of the brush must display a visible helical pattern along the main portion of the brush. Second, the distribution of the bristles must be substantially constant, within manufacturing tolerances, along the main portion of the brush and, third, the bristles must be sufficiently spaced between turns and within each turn to allow for interpenetration of the bristles of one turn of the helix into the following turn as the brush is pulled through the wiper. (D.I. 272 at 23) Defendants argue that "holding a helical array" refers only to bristles gripped by a twisted wire that are in a helical or spiral arrangement. With respect to the term "regularly disposed bristles," defendants argue that it means "bristles that appear to be distributed substantially uniformly along the length of the brush."

a. "Holding a helical array"

The '622 patent does not support a construction of "holding a helical array" that requires the bristles at the surface of the brush to display a visible helical pattern. The phrase merely requires that the bristles be held in a helical array by the twisted metal core of the brush. A review of the claim language confirms this.

In claim 1, the phrase "holding a helical array" modifies "from a twisted wire." Thus, it is the twisted wire that holds the helical array of bristles. There is no indication that this array must be visible to the naked eye from the surface of the brush. 3 Although plaintiffs argue that "the combination of [the] words 'helical' and 'array,' by definition, require a visible pattern," nothing about the combination of the two words dictates such a conclusion. (D.I. 272 at 23) The claim language requires only that the twisted wire core hold a helical array, regardless of whether or not the tips of the bristles form separate spiral rows on the brush surface.

3 The specification refers to the invention as "comprising a central core formed from a twisted wire holding a helical array"
of regularly disposed bristles . . . " ('622 patent, col. 2, ins. 22-24) (emphasis added). (See also '622 patent, col. 3, ins. 26-28) There simply is no language intimating that the helical array be visibly apparent.

Plaintiffs also equate "helical" with "twisted" and contend that the term "helical array" would be superfluous and repetitive if construed to mean the manner in which the twisted core holds the bristles. "To twist," however, means "to unite by winding" whereas "helix" refers more specifically to "something spiral in form as: . . . b. a coil formed by winding wire around a uniform tube" or "a space curve with turns of constant slope from the base and constant distance from the axis." Webster's Third New Int'l Dictionary 1051, 2473 (Unabridged ed. 1993) (emphasis added). "Twisted" thus refers to the manner by which the two wire strands of the core are united while "helical" refers to the specific manner in which the core bristles must be arrayed around (and held by) the core. Although plaintiffs cite both the specification and the prosecution history for support of their construction of "holding a helical array," nothing in either source indicates that this array must be visible on the surface of the brush. Accordingly, the court shall construe "holding a helical array" to mean that the bristles held by the core must be disposed in the form of a helix.

b. "Regularly disposed bristles"

As an initial matter, claim 1 does not equate "regularly disposed" with "manufacturing tolerances." There is nothing in the claim, the specification, or the prosecution history to suggest that the court should not accord "regularly disposed" its ordinary meaning of "harmonious in form, structure or arrangement." Webster's at 1913. There is a "heavy presumption in favor of the ordinary meaning of claim language," Johnson Worldwide Assocs., 175 F.3d 985 at 989, and it is well established that a claim term should be given its ordinary meaning unless the specification or prosecution history provide a special meaning or definition. See Kegel Co. v. AMF Bowling, Inc., 127 F.3d 1420, 1427 (Fed. Cir. 1997). Neither the specification nor the prosecution history provide a special definition for "regularly disposed." Indeed, the specification supports construing "regularly disposed" according to its ordinary meaning. For instance, it describes the bristles as "disposed in regular bundles" within the rake-shaped device prior to their insertion in the metal core. ( '622 patent, col. 5, ins. 1-4) There is no mention of manufacturing tolerances or any other specific criteria for the "regular disposition" of the bundles prior to their insertion in the core.

Specifically, plaintiffs cite portions of the specification addressing the "flattening" problem associated with conventional mascara brushes. In these brushes, the densely packed and "substantially juxtaposed" bristles flatten each other in the direction of the core as the brush is drawn through the wiper. The density of the bristles (i.e., their large number) and the "substantially juxtaposed" manner of their arrangement produces the clumping problem that the present invention attempts to remedy. The '622 patent proposes to remedy this clumping problem by interspacing the bristles "at a far greater distance from each other by using a number of bristles which is approximately 35% to 80% less than that of a conventional mascara brush." ( '622 patent, col. 2, ins. 17-20) As the specification explains, "because of being relatively sparse, the bristles of one turn cannot, by bending over as they pass through the wiper lip, also produce the bending over of the bristles of the following turn; on the contrary, they interpenetrate between the bristles of this following turn . . . ." ( '622 patent, col. 2, ins. 43-48) (emphasis added). In other words, the specification attributes interpenetration to the "sparsity" of the bristles, not to their "regular disposition" around the core. "Sparse" is defined as "of few and scattered elements; having spaces between the component units; not thickly grown or settled; thinly scattered." Webster's 2184. "Sparse" denotes elements that are scattered and not disposed closely to one another. It is thus distinct from a "harmonious or even" arrangement or distribution of elements.

Accordingly, the court shall not construe "regularly disposed" to require interpenetration. The court shall construe the term "regularly disposed" to mean evenly or harmoniously distributed along the length of the brush.
4 Plaintiffs also urge that the term "regularly disposed" applies only to the main portion of the brush and not to the end of the brush. Nothing in claim 1 so limits the term. Although the specification envisions "a greater bristle population density for the bristles" at the free end of the brush ('622 patent, col. 3, Ins. 8-9), it does not contemplate that these bristles be disposed in an irregular or uneven manner.

GO BACK

A. Holding Station and Spaced-Apart Locations

Plaintiffs argue that "holding stations and spaced-apart locations must be interpreted as structures located at two separate and distinct positions from which eggs are lifted." 46 Neither the claim, the specification, nor the prosecution history supports a construction that requires the "holding station" or the "spaced-apart locations" to be physical structures. The claim does not use the terms "holding station" and "spaced-apart locations" in an uncommon way; 47 the specification indicates that the inventor intended the terms to be spatial references; 48 and the prosecution history confirms that the examiner understood that the phrase "holding station" refers to a first location from which eggs are lifted simultaneously with eggs at a second downstream location. 49 The Court therefore declines to adopt Plaintiffs' proposed construction of the terms "holding station" and "spaced apart locations."

46 Pls.' Resp. to Def.'s Mem. Defining Disputed Claim Terms at 39.

47 The ordinary meaning of the term "station" is "the place or position in which something or someone stands or is assigned to stand or remain." Webster's at 1861 (defining "station," def. 2). The most relevant definition of the term "holding" as applied to dynamic systems such as a system for continuously transferring eggs is "maintaining position." Id. at 1078 (defining "hold," def. vii. a). The ordinary meaning of the term "location" is "a position or site occupied or available for occupancy." Id. at 1128 (defining "location," def. 2.a).

48 The specification describes the advancement of the eggs with language such as: the eggs are fed "into the holding stations"; advancing bars engage the eggs "in the holding stations"; and the eggs are moved "into pick-up positions." '505 Patent, col. 5, ln. 58-68.

49 In rejecting dependent claim 28, later incorporated, inter alia, in amended and allowed claim 24, the examiner commented "the claim requires eggs to be advanced from the egg holding stations to a second location spaced from the egg holding stations. . . . It appears that Applicant intended to claim the transfer of eggs from the eggs holding station to a subsequent downstream second location and, upon a subsequent egg arriving at the egg holding station, the lifting means simultaneously engages both eggs in the egg holding means and the second location." Application No. 06/452, 451, Examiner's Communication, Paper No. 3, mailed May 31, 1984 at 2-3.

"holding station"

The district court correctly construed the "holding station" of claim 24 of the '505 patent as "a first location in space to which an egg is moved and at which the egg may maintain position until the egg is lifted simultaneously with an egg at a 'spaced-apart location.'" Nonetheless, FPS argues that the district court's construction requires that an egg cease motion before the lift to the overhead conveyor. The claims simply do not require a specific temporal limitation associated with the term "holding." Indeed the specification states that the holding station positions an egg relative to the overhead conveyor for pick-up to the overhead conveyor. See, e.g., '505 patent, col. 2, ll. 44-58, col. 6, ll. 4-8. The specification actually speaks of eggs that are "held" as they move. Id. at col. 5, ll. 2-6 ("The disks each include a plurality of peripheral recesses which are disposed in horizontal alignment so as to receive and hold eggs advanced along the guide bars as they are transferred to the holding stations."). Moreover, the ordinary meaning of "to hold" is "to keep in position, guide, control, or manage." The Oxford English Dictionary (2d ed. 1989). This meaning also imposes no requirement that an object remain stationary.

Moreover, as this court has repeatedly counseled, the best indicator of claim meaning is its usage in context as understood by one of skill in the art at the time of invention. Markman, 52 F.3d at 986. In this instance, the context is the swift and safe movement of eggs. As indicated by the specification, the process holds the egg at the same time it moves the egg, thus achieving the dual goals of precision and speed. The process may hold and move an egg at the same time. In sum, the district court correctly construed the term "holding." The term "holding station" also does not require lack of motion.

5. Construction of "holding the sample in a non-flowing manner within the sample chamber"

The parties next dispute the construction of the phrase "holding the sample in a non-flowing manner within the sample chamber", found in Claim 16. Plaintiffs assert that the term means "the sample remains within the sample chamber during measurement rather than flowing through the sensor during measurement as it would in a flow cell" and Defendant contends that it means "the sample is at rest in the sample chamber during the test." Defendant notes that the patent examiner required the inclusion of the term "non-flowing" before the PTO would allow the patent, and that the inclusion of this term was significant. The plain and ordinary meaning of "non-flowing" manner indicates that the sample must be stopped, rather than moving. In the preferred embodiment portion of the specification, the patent states, "The sensor can also be used in conjunction with a flowing sample stream. In this configuration, the sample stream is made to flow through a sample chamber. The flow is stopped periodically and the concentration of the analyte is determined by electrochemical method, such as coulometry. After the measurement, the flow is resumed, thereby removing the sample from the sensor." ('164 Patent, 11:40-43). 14 In another section, the patent states, "As the fluid flow was stopped and current was allowed to flow between the electrodes…" ('164 Patent, 23:9-14). As the specification indicates, it is important to the proper functioning of the sensor that the sample be at least temporarily immobilized during measurement. Accordingly, the Court construes the term to mean "the sample is not moving in the sample chamber during the measurement."

14 The preferred embodiment continues, "[a]lternatively, sample may flow through the chamber at a very slow rate, such that all of the analyte is electrolyzed in transit, yielding a current dependent only upon analyte concentration and flow rate." ('164 Patent, 11:44-46). However, since this description of the sample as flowing at a very slow rate is directly at odds with the plain and ordinary meaning of non-flowing", the Court finds that this language does not describe those claims which contain a "non-flowing" limitation, such as Claim 16.
Plaintiffs interpret the phrase "holding the two retaining mechanisms together" to mean "supporting, or keeping from falling, the two parts that hold the lenses together, whether rims or other mechanisms such as screws or pins." Defendant, of course, offers its now familiar objections.

Consistent with its means-plus function finding, the court finds that the phrase "holding the two retaining mechanisms together" means "supporting, or keeping from falling, the rims together.

1980

5. Holding Unit for Receiving and Holding the Wafer in a Measuring Position During Measurements (Claims 1 and 21)

Plaintiff argues "holding unit for receiving and holding the wafer in a measuring position during measurements" is not subject to means-plus-function construction, and should be construed as "an assembly that receives and holds wafers in position while they are being measured." In the alternative, plaintiff argues the structures corresponding to the above-quoted function, specifically, "receiving and holding wafers in position while they are being measured," are "gripper 42" and "protruding surfaces 84" or, alternatively, "piston 160" and "measurement support 168." 7

--- Footnotes ---
7 Plaintiff stated its alternative position at the claim construction hearing.
--- End Footnotes ---

Defendant argues the term is subject to means-plus-function construction, the function is "receiving the wafer and holding the wafer in a fixed position during multiple measurements," and the corresponding structure is "gripping system 34" or, alternatively, "gripping unit 132." 8

--- Footnotes ---
8 Defendant first identified "gripping unit 132" as a corresponding structure in its claim construction brief. (See Def.'s Claim Construction Brief, filed June 29, 2006, at 24:8-9.)
--- End Footnotes ---

The Court, for the reasons stated by defendant, finds the term is subject to means-plus-function construction. The Court, for the reasons stated by plaintiff, finds the function performed by the means is "receiving and holding the wafer in position while it is being measured." The Court further finds the corresponding structures are "gripper 42," "vacuum pad 44," and "protruding surfaces 84," and equivalents thereof, or alternatively, "piston 160," "vacuum pad 152," and "measurement support 168," and equivalents thereof. 9

--- Footnotes ---
9 Although the Court adopts the corresponding structures proposed by plaintiff, the Court has added "vacuum pad 44" and "vacuum pad 152." See '689 Patent, col. 3, II. 39-41 ("Once the wafer 25 is in the wafer collecting position, as shown in Fig. 4, gripper 42 lowers vacuum pad 44 to grab the wafer 25."); id., col. 5, II. 26-29 ("Once the wafer support 150 has the wafer in a predefined position, the vacuum pad 152, which is controlled by piston 160, moves toward the wafer and grabs it by applying a vacuum.").
--- End Footnotes ---

GO BACK
The parties' motions require the Court to construe the term "hole" in claim 1 of the '678 patent. The '678 patent, which relates to implant devices used to align and support the spine, has one independent claim and six dependent claims. The invention of the '678 patent is polyaxial: it has a ball-and-socket joint that allows for flexibility in connecting the screw to the rod. Claim 1 of the '678 patent requires that the invention have "two holes for receiving a [metal] rod." The defendant argues that Alphatec's pedicle screws do not have two holes for receiving the rod but instead have U-shaped slits; its position is there can be no infringement of an invention which expressly requires holes because the terms are not synonymous. Here, the question at issue is whether "holes" is a general term that includes "slits."

The plaintiffs' position is that the term "holes for receiving a rod" should be construed to mean "openings in the sides of the receiver for receiving a rod." Those openings need not be circumscribed (closed) according to the preferred embodiment in the specification of the patent-in-suit. The preferred embodiment, as seen in Figure 3 of the patent, shows holes open to the top of the receiver. (U.S. Patent No. 5,207,678 fig.3 (filed May 4, 1993)). To accept the defendant's proposition that the claim term "holes" requires a circumscribed opening would mean that the preferred embodiment shown in the patent lies outside the patent's claim language, which the Federal Circuit warns is "rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc. 90 F.3d 1576, 1583 (Fed. Cir. 1996). 1 No disclosed embodiment of the '678 patent features a receiver member with a closed hole. Rather, the example of the hole that receives the rod is a non-circumscribed opening - it is open to the top of the receiver, making "it easier to place the rod into the receiver." (Biedermann's Feb. 9, 2007 Opposition to Defendant's Motion for Summary Judgment of Non-Infringement, at 3) (hereinafter, "Biedermann Feb. 9 Memorandum").

1 The defendant cites Vitronics to oppose an argument plaintiffs made in their brief that "common usage" of the term "holes" supports its proposed construction. Its argument is that according to Vitronics, extrinsic evidence may not be used to alter the meaning of the claims. See, 90 F.3d at 1583. However, in view of the clear intrinsic evidence in the present case - the claim language and specification - the Court does not rely on extrinsic evidence to construe the term.

The fact that broader independent claim 1 uses "holes" and narrower dependent claim 2 uses "slits" further resolves the question in favor of the plaintiffs. Indeed, if claim 1 prohibited slits, as the defendant argues, then claim 2 could not be dependent from it. See, e.g., In re Abele, 684 F.2d 902, 907 (C.C.P.A. 1982) (dependent claim includes all the limitations of the independent claim). Dependent claim 2 more narrowly specifies the features that receive the rod - they are "slits (12, 13)." This indicates that the term "holes" in broader claim 1 encompasses slits. Therefore, the Court defines the term "hole" to mean "an opening," and that term includes a U-shaped "slit."

The defendant also contends that the prosecution history of the '678 patent demonstrates that any meaning for "holes" that encompasses a slit (or slot) was expressly disclaimed. (Alphatec's Jan. 12, 2007 Memorandum in Support of Summary Judgment of Non-Infringement, at 6-7). For example, original claim 3 included the phrase "two mutually opposite slits" for receiving the rod but that claim was rejected. 2 The defendant's argument is that during the prosecution of the patent the plaintiffs substituted original claims 1-8, which used the language of "slits," with claim 9 (issued claim 1), which for the first time uses the term "holes," and that such alleged substitution constitutes plaintiffs' subject matter disclaimer of the prior use of the term slits.

2 The '678 patent application as originally filed on January 7, 1992 contained original claims 1-8. The applicants added claims 9-15 in a Preliminary Amendment filed in March 1992. In an Office Action dated April 13, 1992, the Examiner rejected original claims 1-8 but overlooked claims 9-15. In response to the Examiner's rejection, in October 1992, the applicants canceled original application claims 1-8 and resubmitted original claims 9-15, which ultimately became claims 1-7 of the issued patent. These claims were allowed without comment by the Examiner on October 30, 1992. (Biedermann Feb. 9 Memorandum, at 4).
The Federal Circuit has cautioned against excessive reliance on prosecution history for claim construction purposes because the prosecution history "often lacks the clarity of the specification and this is less useful for claim construction purposes." Phillips v. AWH Corp., 415 F.3d 1303, 1317 (Fed. Cir. 2005). The Federal Circuit requires that a prosecution history disclaimer of claim scope "must be both clear and unmistakable." Sorensen v. ITC, 427 F.3d 1375, 1379 (Fed. Cir. 2005) (citation omitted). "This may occur, for example, when the patentee explicitly characterizes an aspect of his invention in a specific manner to overcome prior art." Purdue Pharma L.P. v. Endo Pharm. Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006).

Here, the prosecution history shows that plaintiff made no such waiver. The application leading to the '678 patent was originally filed in January 1992, with 8 claims. A few months later, in March 1992, a preliminary amendment was filed adding application claims 9-15 (Biedermann Feb. 9 Memorandum, at 4). This amendment was filed before the Examiner had issued any Office Action, and before the Examiner had rejected any claims. Application claims 9 - 15 had numerous wording differences compared to application claims 1 - 8, but were directed to the same subject matter. Application claims 9 - 15 were an additional claim set, not amendments to existing claims, and ultimately became claims 1- 7 of the issued patent.

On May 1, 1992, the Examiner issued an Office Action, rejecting or objecting to application claims 1 - 8 based on certain references, and for other reasons; however, the Examiner overlooked application claims 9 - 15 at that time. In a later telephone interview, the Examiner indicated that he had found the preliminary amendment and would re-issue the Office Action to address application claims 9 - 15. (Alphatec Ex. F, at 4). When the Examiner did not re-issue the Office Action, the plaintiff resubmitted application claims 9 - 15 in an amendment, and they were allowed without comment by the Examiner. (Alphatec Exs. F and G). At no point were application claims 9 - 15 ever narrowed or revised. There was never any argument or discussion concerning "holes" during this exchange, nor at any time in the prosecution history, nor is there any definition of the term set forth in the prosecution history.

The defendants assert that "[t]he prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwell Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir.), cert denied, 516 U.S. 987, 116 S. Ct. 515, 133 L. Ed. 2d 424 (1995). In Southwell, the patentee distinguished over prior art by amending the claims and arguing that a particular feature in the claims distinguished over a two-step process disclosed in the prior art. See id. at 1576. The argument was made in response to the Examiner's inquiry into the scope of that particular claim feature. Id. Because of that argument, the Federal Circuit concluded that the patentee had "necessarily disclaimed coverage of a two-step process." Id.

In contrast, here, the term "holes" was at no time mentioned or discussed during prosecution of the '678 patent, was never argued as a point of distinction over any prior art, and it was not contended that any prior art lacked holes for receiving a rod. Indeed, application claim 9 containing the term "holes" -- which issued without change as claim 1 -- was first submitted before any rejections were made. This conclusively establishes that the term was not intended to address any rejection. Moreover, the Examiner never indicated that "holes" was the basis for allowing any claims. "[T]he alleged disavowing statements [must] be both so clear as to show reasonable clarity and deliberateness, . . . and so unmistakable as to be unambiguous evidence of disclaimer." Harvest Tech. Corp. v. Cytomedix, Inc., 2004 U.S. Dist. LEXIS 18003 at *15 (D. Mass. Sept. 9, 2004) (quoting Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325 (Fed. Cir. 2003). Here, no disavowing statements were made, so there is no way the prosecution history can be construed to rise to the "clear and unmistakable" level required for disclaimer. In short, the plaintiffs never disclaimed any subject matter with respect to "holes.

Thus, in addition to construing holes as openings which include U-shaped slits, the Court rules as a matter of law that the prosecution history of the '678 patent reflects that the plaintiff made no disclaimer of claim scope with respect to the term "holes."
The dispositive issue of claim construction here is whether claims one and seven of the '760 patent are limited to a stud with a hole drilled prior to inserting the stud into the header or whether the claims encompass products without such a pre-drilled hole.

Defendant Steeler asserts that the claim term "having at least one hole formed therein" in claims one and seven unambiguously requires that a hole be pre-drilled into the stud and, thus, excludes any devices where the hole is made by a self-tapping screw after the stud is inserted into the header. Steeler contends that, even though the preferred embodiment discloses a preferred method of assembly where the hole is formed after the stud and header are assembled, the claims should be limited to a device with a pre-drilled hole, because the scope of Sliptrack's right to exclude is governed by the language of the claims, as interpreted by the prosecution history, and not by the written description.

For its argument, in addition to the claim language, Steeler relies heavily on the patent's prosecution history. Specifically, Steeler points to the amendment to the patent application, wherein, to address the examiner's indefiniteness rejection, applicant revised the claim from providing that the stud was aligned with the vertical slot to providing that the hole "is aligned with said vertical slot." See Amendment to '760 Patent Application, Barnard Decl., Exh. D. In addition, Steeler points to the applicant's remarks in the amendment where he stated that "the hole serves as a reference point on the stud which is used to align the stud and the slot." See Amendment to '760 Patent Application, Barnard Decl., Exh. D. The thrust of Steeler's argument is that in order for the "hole formed therein" to serve as a reference point when aligning the stud with the vertical slot, the hole must be formed in the stud prior to inserting it into the header and, thus, it must therefore be pre-drilled.

In response, Sliptrack contends the claim language makes clear that, as ultimately assembled, the stud must have a "hole formed therein," but does not mandate any particular process for when such a hole shall be formed. Sliptrack does not see any inconsistency with this position and the text requiring that the "hole is aligned with said vertical slot" and argues that in either case, pre or post-drilled, the hole formed in the stud will be aligned with the slots when the device is assembled. Finally, Sliptrack contends that it would be improper to construe the claim to require a pre-drilled hole, because such a construction would read out the preferred method of assembly, which describes a self-tapping screw to form the hole after the stud is inserted into the header. Sliptrack does not address Steeler's argument regarding the remarks made during the prosecution history that the hole will serve as a "reference point" when aligning the stud with the vertical slot.

The court begins claim construction analysis with the words of the claim. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). The claim language defines the bound of claims scope. Bell Communications Research, Inc. v. Vitalink Communications, Corp., 55 F.3d 615, 619-20 (Fed. Cir. 1995). The words used in the claims are interpreted in light of the intrinsic evidence of record, including the written description, the drawings and the prosecution history, if in evidence. Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323 (Fed. Cir. 2001). The intrinsic evidence may provide context and clarification about the meaning of the claim terms. York Products, Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996). "Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics, 90 F.3d at 1582.

This case presents an interesting question and a somewhat difficult resolution. The court agrees with Plaintiff Sliptrack that the claims and the written description, read alone, do not appear to require a pre-drilled hole. The claims at issue, one and seven, provide that the stud will have at least "one hole formed therein proximal to said top end" and that the header shall be "positioned so that said hole is aligned with said vertical slot." See '760 patent, Barnard Decl., Exh. C. A fair reading of this language supports Sliptrack's argument that, as ultimately assembled, the stud will have a hole aligned with the vertical slot. The court agrees that this text, on its face, does not mandate that the hole be pre-drilled. If the claims and the written description were the only evidence the court was relying upon to interpret the claims, Sliptrack likely would prevail. That is not the case, however. In addition to the claims and the written description, the court must also consider the prosecution history, which, here, is dispositive.

As the Federal Circuit has made clear, "arguments and amendments made during prosecution of a patent application must be examined to determine the meaning of the claims." Rheox, 276 F.3d at 1325 (citing Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 15765 (Fed. Cir. 1995)) (emphasis added). "The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Id.; see also Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1326 (Fed. Cir. 2002).
When initially submitted, all nine claims in the application for the '760 patent were rejected for indefiniteness and, specifically, the examiner questioned "how is the stud aligned with the vertical slot." See Action by PTO, Barnard Decl. Exh. C. To overcome this rejection, applicant revised his claims to include specific language that there would be a hole formed and positioned so that the hole is aligned with the vertical slot. See Amendment to '760 Patent Application, Barnard Decl., Exh. D (emphasis added). Counsel for applicant then explicitly remarked that this change answered the examiner's question "by adding hole 22 proximal to top end 40 of the stud as an element of the claims. The hole serves as a reference point on the stud which is used to align the stud and the slot." See Amendment to '760 Patent Application, Barnard Decl., Exh. D (emphasis added).

From this amendment and the remarks therewith, the court cannot escape the conclusion that the claim was narrowed to require that a hole be pre-drilled in the stud prior to inserting the stud into the header. As originally drafted, claim one provided that the stud was aligned with the vertical slot, but then was amended to require that the hole be aligned with the vertical slot. In order for the hole to be aligned with the vertical slot and to serve as a "reference point" on the stud when used to align the stud and the slot, the hole, by definition, would have to be formed prior to inserting the stud into the header. Quite simply, the hole cannot serve as a reference point if it does not exist.

While the court is aware that such a construction will read out the preferred method of assembly, which discloses a method where the hole is formed by a self-tapping screw after the stud is inserted into the header, this result, while perhaps unusual, is nevertheless permissible. See Rheox, 276 F.3d at 1327; see also Elekta Instrument S.A. v. O.U.R. Scientific In'l, Inc., 214 F.3d 1302, 1308 (Fed. Cir. 2000). Because it is rare that a construction reading out the preferred embodiment will be the correct construction, the Federal Circuit has noted that such a construction requires "highly persuasive evidentiary support." Id. Sliptrack asserts that prosecution history is not the type of "highly persuasive evidence" sufficient to support such a construction. Sliptrack is incorrect, however, and the Federal Circuit has stated just the opposite. Id. ("Where the prosecution history requires a claim construction that excludes some but not all of the preferred embodiments, such a construction is permissible and meets the standard of highly persuasive evidentiary support"). Indeed, it is difficult to imagine evidence more "highly persuasive" than Sliptrack's remarks in its Amendment stating that the hole will be used as a reference point to align the stud with the vertical slot. Sliptrack relinquished its right to exclude products without a pre-drilled hole when it amended its claim and provided this explanation to the PTO to overcome the indefiniteness rejection.

Sliptrack vigorously defended its position at the summary judgment hearing by asking the court to distinguish "product" patents and "process" (or method) patents, arguing that the '760 patent is for a product, not a process and, thus, the order or method of assembly is not at issue, and it is not relevant when the hole in the stud is formed. Instead, Sliptrack asserted, in construing the claim, the court must look at the final product, which, by necessity, must include a "hole formed therein" and that such hole always will be aligned with the slots as long as the product is properly assembled.

Sliptrack's argument is persuasive and is supported by the written description, which provides two possible methods of assembly, one using a self-tapping screw after the stud is inserted into the header and one where the hole is pre-drilled. Presumably, the applicant would not have provided two "possible" methods of assembly if the patent itself was for a particular process or method. Despite what may have been intended by the inventor in theory, however, the court must rely on the objective, intrinsic evidence in the record. See Rheox, 276 F.3d at 1327 ("Reading the written description alone, this argument might be effective, but in light of the prosecution history, which was generated after the written description was drafted, it is apparent that Rheox relinquished any coverage of TSP."). Sliptrack simply cannot escape the prosecution history of the '760 patent, where, though perhaps unintentionally, counsel added an element of method or process by amending the claim in the manner he did and by noting that the hole would serve as a "reference point."

The PTO examiner initially rejected patentee's claims for indefiniteness. To address the examiner's concern, overcome the rejection, and get the application approved, counsel amended the claims as set forth above and filed the relevant remarks therewith. While there may have existed an alternative approach to address the examiner's concerns, this was the way prosecution counsel chose to confront the rejection. The court must construe the claims accordingly and cannot undo, by ignoring the prosecution history, what may have been an unintentional result by counsel. In addition to a patent's definitional function, the Supreme Court and the Federal Circuit have consistently recognized the paramount importance of a patent's public notice function, and "the public has a right to rely on such definitive statements made during prosecution." Rheox, 276 F.3d at 1325 (quoting Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1347 (Fed. Cir. 1998)); see also Warner-Jenkinson Co., Inc. v. Hilton Davis Chem. Co., 520 U.S. 17, 137 L. Ed. 2d 146, 117 S. Ct. 1040, (1997); Vectra Fitness v. TNWK Corp., 162 F.3d 1379, 1384 (Fed. Cir. 1998) ("The public is entitled to rely upon the public record of a
Agere argues that the term "holes" should be construed as "hollow places in a solid body or mass." Atmel argues that the term "holes" should be construed as "contact holes, that is, openings in the first dielectric layer that expose the silicon surface (i.e., the silicon substrate) or the conducting material at the silicon surface." The essential difference between the parties' constructions is that Atmel contends the term "holes" only applies to openings in the first dielectric layer, which openings would necessarily expose the silicon surface of the wafer, or the conducting material at the silicon surface of the wafer. Thus, Atmel apparently contends that the term "holes" would not apply to openings in dielectric layers that are positioned above the first dielectric layer (which would expose some previously-created metal contact rather than exposing the silicon surface of the wafer or the conducting material at the silicon surface of the wafer). The Court concludes that Agere's proposed construction is the proper construction for the following reasons.

Agere's proposed construction comports with the ordinary meaning of the term "hole." According to the "Random House Dictionary of the English Language," one of the definitions of the word "hole" (and the definition most appropriate to this context) is "a hollow place in a solid body or mass; a cavity." See Random House Dictionary of the English Language 911 (2d ed. 1987). Moreover, Atmel's construction would incorporate into claim 1 a restriction that is set forth in the subsequent dependent claims. Dependent claim 2 is directed toward "[a] method as recited in claim 1" in which the underlying material exposed by the "holes" in the dielectric layer is specified as being the silicon surface of the wafer, and dependent claim 3 is directed toward "[a] method as recited in claim 1" in which the underlying material exposed by the "holes" in the dielectric layer is specified as being a metallic silicide. See '335 Patent at col. 6:7-10. Thus, dependent claims 2 and 3 illustrate that where the patentee intended to specify or limit the type of material exposed by the "holes," the patentee did so explicitly. Therefore, since claim 1 does not on its face specify or limit the type of material exposed by the "holes," it would be inappropriate to limit the term "holes" as applying only to openings in the first dielectric layer which expose the silicon surface of the wafer or the conducting material at the silicon surface of the wafer. Indeed, "it is settled law that when a patent claim does not contain a certain limitation and another claim does, that limitation cannot be read into the former claim in determining either validity or infringement." SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1122 (Fed. Cir. 1985).

There is a heavy presumption that a claim term carries its ordinary and customary meaning. CCS Fitness, 288 F.3d at 1366. In order to deviate from the ordinary and customary meaning, Atmel must show that the intrinsic evidence establishes that the patentee demonstrated an intent to do so either by setting forth some other specific definition of the disputed claim term, or by distinguishing the term from prior art. See Interactive Gift, 256 F.3d at 1331. However, an examination of the specification only provides further support for Agere's proposed construction. In addition to contemplating that "the glue layer film may be deposited, through openings in the dielectric, directly on the silicon or on a conducting material, such as a silicide, overlying the silicon," '335 Patent at col. 3:7-10, the specification notes that the deposition process may be used for other purposes, such as "to form interconnects," 1 '335 Patent at col. 5:3-6, and that "the use of A1 [tungsten] is particularly suited for upper levels in multilevel metallization schemes where junction spiking is not a consideration," '335 Patent at col. 5:14-16 (emphasis added). Thus, it appears that the patentee specifically contemplated using the deposition process to fill not only openings in the first dielectric layer, but also openings in layers other than the first dielectric layer.

--- Footnotes ---

1 Atmel argues that the term "interconnect" does not refer to openings in upper-level dielectric layers, but rather refers to a structure that connects two points on the same level to one another. However, the specification makes clear that, at least according to the patentee, the term "interconnect" means "the lines and windows used to connect devices," and, according to the patentee, the term "window," in turn, can be used to mean either (1) only "the openings to the source, gate, or drain electrodes" (i.e., openings in the first dielectric layer), in which case "opening[s] between levels in multilevel metal structures" are distinguished as "vias," or (2) both "the openings to the source, gate, or drain electrodes" and "the opening[s] between levels in multilevel metal structures," in which case the terms "windows" and "vias" are interchangeable. See '335 Patent at col. 5:3-6.
In summary, Agere's proposed construction of the term "holes" comports with the ordinary meaning of the word, the claim language, and the remaining intrinsic evidence. Accordingly, the Court construes the term "holes" as "hollow places in a solid body or mass."

1984
C. Hollow

"Hollow" appears in several asserted claims of the '324 Patent. Claims 9 and 13, quoted above, provide examples. After describing the process to obtain whole [beta] - glucan--extracting non-glucan components without disrupting a cell wall--the '324 Patent's specification states: "These hollow, three-dimensional particles are conducive to a high water holding capacity, in that they become filled with water upon hydration." '324 Patent, col. 4, ll. 11-13. The '324 Patent's use of "hollow" is consistent with the term's common meaning of having an empty space within. See Webster's Third New International Dictionary 1080 (2002). The Court construes the term accordingly. See Phillips, 415 F.3d at 1314.

1985

1986

1. hollow tubular housing

P&M argues that one of ordinary skill in the art of airbrushes would understand this term to mean "an unfilled, or non-solid, approximately tube-shaped body." (Pls. Opening Mem. at 12.) Rose Art argues that someone of ordinary skill in the art would understand "tubular housing" to "describe a hollow cylindrical body that encases the reservoir pen." (Def. Pre-Markman Hr'g Br. at 16-17.) Nothing in the plain language of claim 1 limits the meaning of this term to "a hollow cylindrical body that encases the reservoir pen." Moreover, this construction of the term is at odds with the patent specification. The words hollow and tubular cannot be construed as cylindrical because figs. 1 and 4 of the '886 patent show that the housing is tapered on both ends and is, therefore, not cylindrical. There is also nothing in the language of the claim or the specifications which requires the housing to completely encase the reservoir pen. In fact, adoption of Rose Art's proposed construction would exclude the fig. 8 preferred embodiment from the patent claims. Although figs. 1 and 4 of the '886 patent illustrate an embodiment in which the reservoir pen appears to be completely encased within the housing, fig. 8 of the '886 patent illustrates an embodiment in which the housing does not encase the pen in its entirety. In fig. 8, approximately one-half of the reservoir pen protrudes from the open end of the housing opposite the nozzle.

Rose Art contends that fig. 8 is not within the scope of claims of the '886 patent because several of the dependent claims of the patent, namely claims 2 through 5, 7 and 8 clearly claim a different embodiment of the patent. However, dependent claims 6 and 9 speak only to the fig. 8 embodiment of the patent and the specification of the patent specifically describes the fig. 8 embodiment. ('886 patent, col. 3, ll. 12 - 26.) The Court will not construe the '886 patent to exclude the fig. 8 embodiment since it is specifically claimed by the language of the patent and specifically described by the patent specification. Claim construction that would exclude a preferred embodiment "is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics Corp., 90 F.3d at 1583-84. Accordingly, the Court construes the term "hollow tubular housing" as "an unfilled, or non-solid, approximately tube-shaped body." Since the entirety of the intrinsic evidence with regard to this term is not ambiguous, the Court did not consider the extrinsic evidence submitted by the
The parties dispute the meaning of the term "homogenization" as it appears in claims 1, 25, 32 and 34. The parties agree that the inventor, John Lawton, acted as his own lexicographer and defined the meaning of the term within the patent. They disagree on the scope of Lawton's definition. Imagecube finds the complete definition of homogenization in the opening sentence of the '875 patent's "Description of Preferred Embodiments," which reads:

The term "homogenized" or "homogenization", for the purposes of this disclosure, will refer to the formation of an alloy between the substances which are homogenized.

('875 Patent, Col. 2, ll. 59-61.) Imagecube therefore asks me to construe the term homogenized to mean "forming an alloy."

Defendants argue that Lawton narrowed the definition of homogenization later in the specification. Discussing one embodiment of the invention, in which the components to be alloyed consist of polymers, Lawton stated:

The components may consist of polymers, which can be dispersed together and alloyed by the application of radiation . . . The homogenization to form an alloy between polymers is a non-polymerization interaction, and polymerization techniques (free radical, condensation, and like mechanisms between monomers and/or oligomers and optionally initiators) are excluded from the definition of "homogenization" as used herein.

('875 Patent, Col. 3, ll. 38-45) (emphasis added). Shortly thereafter, discussing another embodiment of the invention in which the components to be alloyed consist of metals or ceramics, Lawton stated:

The components may consist of metal or ceramics which, when contacted with appropriate imaging radiation of appropriate intensity, form a metal or ceramic alloy having properties distinguishable from the properties of the components . . . It will thus be understood that homogenization, in the case of metals and ceramics, is different from conventional sintering techniques, wherein powders are heated to essentially fuse or bond the particulates at their outermost points of contact into a solid mass. This also distinguishes the homogenization process of the invention from selective laser sintering (SLS) techniques. Thus, it will be understood that "homogenization "for purposes of the invention requires intimate mixing of at least two components with resultant formation of an alloy between the components, which cannot be achieved using conventional sintering techniques.

(1d., Col. 3, ll. 51-55; Col. 4, ll.3-13) (emphasis added). Defendants therefore ask me to construe homogenization as a process that requires intimate mixing of at least two components with the resultant formation of an alloy between the components, but excluding polymerization techniques.

To a certain degree, the process of construing the meaning of a claim, particularly when the inventor has acted as his own lexicographer, is not unlike the process of interpreting a work of fiction such as a novel. Much has been written about the proper methodology for each. The difference between the two is that for the patents, there is no doctrine of deconstruction, so that, for some, the interpretation turns in large part on each reader. Yet the only permissible perspective is that of the person of ordinary skill in the art. Nonetheless, the process of determining what a person of ordinary skill in the art would understand the words to mean is not unlike the process of reaching accepted reading of works of poetry or novels: one marshals the evidence, including the language, context, rules of the genre and historical circumstances, to determine the meaning and scope of the text's language.

Just as in literature, where a novel may contain significant evidence to support more than one interpretation of the language, so too in certain patents the process of claim construction will yield evidence (not necessarily of equal weight) supporting more than one possible meaning to the person of ordinary skill in the art. This is just such a case. The inventor, acting as his own lexicographer, offered a general definition of homogenization, which he subsequently limited in the specification. This leans in favor of a narrow construction of the term. Yet he limited his definition within a very specific context: discussions
of some, but not all, embodiments of the invention. This suggests that the broader interpretation of the claim might be appropriate.

When competing interpretations of a claim exist there is often a best case for one construction over another. That is true here. Those of ordinary skill in the art reading the patent were, and are, entitled to rely on the definition set forth by the inventor, who—as all parties agree—acted as his own lexicographer. In using the words "polymerization techniques . . . are excluded from the definition of 'homogenization'" and "'homogenization' for the purposes of the invention requires intimate mixing of at least two components" the inventor provided an explicit signal as to the scope of his definition of homogenization. Plaintiff argues that to import these embodiment-specific limitations into the general definition of homogenization violates the general rule against limiting claims to particular embodiments: yet that argument rings hollow in light of the inventor's choice of words. Plaintiff also argues that the proposed limitations do not make sense out of context. This argument carries more weight, but is resolved by taking account of that context within the definition. For this reason, I construe homogenization as "the formation of an alloy between substances, and in the case of the homogenization of metals and ceramics requiring the intimate mixing of at least two components to form an alloy between the components, but excluding polymerization techniques when the substances to be homogenized consist of polymers."

"hook"

Claims 4, 12, 18, and 31 of the '767 Patent contain the term "hook." SHURflo contends that "hook" means "a curved or bent device meant to catch or fasten something (e.g., a pump)," while Defendants contends that "hook" means "a piece of rigid material formed into a curve or an angle for holding something (e.g., a pump)." The parties' dispute centers around whether a "hook" must be rigid.

Other than a hook's function of holding something, there is nothing inherent about the term "hook" that would imply a necessary level of rigidity. Hooks may be flexible or otherwise non-rigid as long as their structural integrity allows them to serve their function (e.g., a hook made of plastic or rubber may be noticeably non-rigid). Furthermore, other than implication of the function of a hook, nothing in the intrinsic or extrinsic evidence suggests that "hook" should be confined to "a piece of rigid material." Thus, rigidity is not a requirement, and Defendants' proposed construction is improper. However, a hook must be of structural ability to function as a hook in some meaningful context. The claims do not use the term "hook" to simply refer to a piece of curved or bent material. The claims use the term "hook" to refer to the common device that every juror will understand.

Defendants argue that the words "meant" and "catch" in SHURflo's proposed construction are ambiguous, vague, and subjective, and that SHURflo's definition can easily be confused with the several other mechanisms disclosed in the patent. The Court agrees that SHURflo's proposed construction will be unhelpful to the jury. The claim language is clear and understandable to the fact finder and does not require construction. See Orion IP, LLC v. Staples, Inc., 406 F. Supp. 2d 717, 738 (E.D. Tex. 2005) (Davis, J.) (stating that "although every word used in a claim has meaning, not every word requires construction" in declining to construe claim terms). However, the Court has resolved the parties' disputes in accordance with O2 Micro, 521 F.3d 1351, and to the extent that this claim term arises at trial, the Court instructs the parties to tailor their trial arguments to conform with this Order.

"each of said ends further including a downwardly extended end portion for hooking onto a primary spectacle" (claim 24)

Plaintiffs contend that the phrase "downwardly extending end portion" in claim 24 means "that the ends of the arms further include a portion that extends downwardly relative to the remainder of the arm." JS, Exb. B at 54. Plaintiffs further contend that the phrase "hooking onto" means that the downwardly extending end portions of the arms are bent in a manner so as to connect or catch with portions of the primary spectacle frame as if with a hook." Id. at 57.
Conversely, Defendant argues that the instant phrase means "the ends of the arms each include an end portion extending downward i.e. the magnet, to hook over a primary frame." JS, Exh. D at 6.

The Court disagrees with Defendant's construction of the phrase in question to the extent such construction limits the "downwardly extending end portion" to be the magnetic member itself. Although Figure 7 shows such configuration, it is only a preferred embodiment. See Laitram Corp. 863 F.2d at 865.

Based on the above, the court construes the phrase "each of said ends further including a downwardly extended end portion for hooking onto a primary spectacle" in claim 24 to mean each of said ends further including a portion that extends downward relative to the remainder of the arm and where that downward extending portion is bent in a manner to connect or catch with the primary spectacle frame as if with a hook. See Webster's, Nicodema Decl., Exh. 5 at 126, defining "hooked" and "hooking" as "to connect or catch with or as if with a hook" and "hook" as a "curved or a sharply bent, usu. metal device used to catch, drag, suspend, attach, or close something."

1990

1. Horizontal Axis

The construction of the term "horizontal axis" is in dispute. The term appears in the following context: "a wash chamber rotatable about a horizontal axis" and "rotating said wash chamber about its horizontal axis… such that said fabric will tumble in said wash chamber." ('370 patent, claims 1, 8, 15; '718 patent, claims 1, 6.)

Whirlpool argues that this terminology should be construed as follows: "These claim elements mean that the washer has a wash chamber that is rotated about an axis that is oriented primarily or predominantly parallel to the horizon such that the fabric will tumble when the wash chamber is rotated at a speed effecting less than one gravity of centrifugal force on the fabric. This limitation encompasses a wash chamber whose axis may be angled slightly (e.g., at 10 degrees), provided that the fabric will tumble when the wash chamber is rotated at a speed effecting less than one gravity of centrifugal force on the fabric."

LG argues for the following construction of this terminology: "A wash chamber rotatable about a horizontal (i.e., not angled or tilted) axis of the wash chamber…to cause fabric to tumble in the wash chamber."

The dispute here is over whether the term horizontal axis in the claims means that the washer's axis of rotation be predominantly or substantially horizontal, as Whirlpool contends, or strictly and absolutely horizontal, as LG would require. The Federal Circuit has held that the ordinary and accustomed meaning of a disputed claim term is presumed to be the correct one unless a different meaning is clearly set forth in the intrinsic materials, that is, the patent specification or prosecution history. K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1362-63 (Fed. Cir. 1999). Dictionary definitions provide evidence of a claim term's ordinary meaning. Abbott Labs. v. Syntron Bioresearch, Inc., 334 F.3d 1343, 1350 (Fed. Cir. 2003).

Whirlpool submits a dictionary definition that it says makes clear that the term horizontal axis requires only a direction that is predominantly horizontal and includes an axis that is angled or tilted slightly, such as at a 10 degree angle. See WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY (horizontal can mean "of, relating to, or situated near the horizon," or "placed or operating chiefly along a plane parallel to the horizon"). The Court also notes a definition of horizontal in the OXFORD ENGLISH DICTIONARY: "applied to various mechanical contrivances, or artificial structures, of which the whole or the main part lies in a horizontal direction."

LG offers various dictionary definitions supporting its strict construction of the term horizontal axis as not encompassing a wash chamber rotating about any axis that is not at a right angle to the vertical line, such as one rotating on a tilted axis. See THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (horizontal means "in the plane of the horizon" or "at right angles to a vertical line"); id. (axis means a "straight line about which a body or geometric object rotates or may be conceived to rotate"); WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY (horizontal means "parallel to the horizon: being on a level" or "measured or contained in a plane of the horizon"). Referring to one of
Whirlpool's preferred definitions, LG argues that even an object operating "chiefly" along a plane parallel to the horizon must be on that plane a majority of the time, whereas a tilted axis is never operating along a plane parallel to the horizon.

The Court concludes that the dictionary definitions do not conclusively favor either side's view of the plain and ordinary meaning of the term horizontal. Some definitions favor LG's strict interpretation, while others tend to comport with Whirlpool's looser construction. In accordance with the Federal Circuit's direction, this Court concludes that the ordinary meaning of horizontal based on dictionary definitions encompasses both alternatives. See Inverness Med. Switzerland GmbH v. Warner Lambert Co., 309 F.3d 1373, 1378-79 (Fed. Cir. 2002) ("Here there are two possibly pertinent definitions….In such situations, a word that has an ordinary meaning encompassing two relevant alternatives may be construed to encompass both alternatives."); Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002) ("If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings.").

In the face of multiple dictionary definitions, intrinsic evidence "is the most reliable guide to help the court determine which of the possible meanings of the terms in question was intended by the inventor to particularly point out and distinctly claim the invention." Texas Digital, 308 F.3d at 1203. The intrinsic evidence in this case confirms that the term horizontal axis should be construed as Whirlpool suggests. Prior art cited in the patent specification or the prosecution history constitutes intrinsic evidence. Kumar, 351 F.3d at 1368. During prosecution of the patents in suit, the applicants cited and described U.S. Patent Nos. 4,489,455, (Whirlpool Br. Ex. 4), and 4,489,574, (Whirlpool Br. Ex. 5), (collectively, "the Spendel patents"), as prior art disclosing horizontal axis washing machines. (370 patent, col. 1, lines 29-34.) The Spendel patents describe two types of washing machines, top loading and front loading: "The conventional method of washing textiles in an automatic home-type washing machine in the United States is carried out in either a top loading or front loading machine. The difference between the two machines is that in a top loader the wash basket is rotatable around a substantially vertical axis and in a front loader the wash basket is rotatable around a substantially horizontal axis." (Whirlpool Br. Ex. 4., col. 1., lines 27-34; Ex. 5, col. 1, lines 26-33.) (emphasis added) The applicants also cited Australian Patent No. 209,436 to Johnston ("the Johnston patent"), (Whirlpool Br. Ex. 7), as prior art disclosing a "horizontal axis washing machine." The Johnston patent discloses a "tumbler type washer" in which a basket rotates "about a generally horizontal axis" or, in other words, "an axis inclined substantially from the vertical." (Whirlpool Ex. 7, at 12.) These examples of prior art discussed in the prosecution history show that the term horizontal axis, when used to describe front loading washing machines, includes wash baskets with a generally or substantially horizontal orientation. LG argues that Whirlpool could have used qualifiers such as "generally" or "substantially" in its claims, but the Court finds that these terms were unnecessary when they were already subsumed within the ordinary meaning of the word horizontal.

LG points out that during the prosecution, Whirlpool stated that "many attempts, as demonstrated in the patent art, have been made to obtain the advantages of both horizontal and vertical axis machines through the use of a tilted axis." (Response to Second Office Action at 8889, LG Br. Ex. 7.) But Whirlpool also stated that "these references are directed to two different types of processes, a horizontal wash process and a vertical wash process, which one of ordinary skill in the art would not find obvious to combine." (Id. at 8888.) More importantly, Whirlpool never distinguished the prior art tilted-axis machine on the basis of an exactly horizontal axis, nor did Whirlpool limit the term horizontal axis to mean absolutely perpendicular to vertical. See Schwing GmbH v. Putzmeister Aktiengesellschaft, 305 F.3d 1318, 1324 (Fed. Cir. 2002) ("Although prosecution history can be a useful tool for interpreting claim terms, it cannot be used to limit the scope of a claim unless the applicant took a position before the PTO that would lead a competitor to believe that the applicant had disavowed coverage of the relevant subject matter."); ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1091 (Fed. Cir. 2003) (explaining that claim terms should not be limited unless the "patentee intended to deviate from a term's ordinary and customary meaning or…the patentee disclaimed or disavowed subject matter, narrowing the scope of the claim's terms," which requires that the patentee either "has clearly set forth a definition of the term different from its ordinary and customary meaning," or has used "words or expressions of manifest exclusion or restriction."). The Court finds nothing in the intrinsic evidence that would put the public on notice that Whirlpool sought to limit the meaning of horizontal from its broader ordinary and customary meaning.

Perhaps most importantly, ascertaining the meaning of horizontal axis requires reading the claim terms in context: "rotating said wash chamber about its horizontal axis with fabric therein at a spin speed to effect less than a one gravity centrifugal force on said fabric such that said fabric will tumble in said wash chamber." (emphasis added) This sentence as a whole, along with the prosecution history’s discussion of the differences between horizontal and vertical machines, reveals that the distinguishing characteristic of a horizontal machine is that the fabric tumbles when it rotates at less than one gravity.

- 2438 -
Tumbling will occur regardless of whether the axis of rotation is perfectly horizontal or somewhat inclined, in contrast to a vertical or generally vertical machine, where the clothes stay on the bottom.

Accordingly, the Court adopts Whirlpool's proposed construction of the term horizontal axis.

1991

A. Claim Construction

Hearth's motion seeks an interpretation of the following limitations in Claim 1:

(1) "…and one of said remaining walls having a horizontal exhaust pipe connected thereto for insertion through said outside wall of the space to be heated."

(2) "the wall having said horizontal exhaust pipe connected thereto comprising an inner plenum, a middle plenum and an outer plenum."

(3) "Said horizontal exhaust pipe being connected to said inner plenum of said wall having said horizontal exhaust pipe connected thereto…"

The primary disagreement between the parties involves the proper meaning of the phrase "horizontal exhaust pipe." Although both parties concur that the pipe must be horizontal at the point at which it traverses the exterior wall, only FMI asserts that it must also be horizontal at the point at which it is connected to the fireplace.

As stated previously, the Court may look to the claim language, specification, and prosecution history in an effort to divine the proper meaning of a claim. Several observations about the claim language itself suggest that FMI is correct in its interpretation of Claim 1. The phrase "horizontal exhaust pipe" must be given its ordinary meaning. Nothing in the claims, specification, or prosecution history suggests otherwise. In short, "horizontal" means "horizontal;" it does not mean "horizontal and vertical," "angled," or even "substantially horizontal."

In addition, Hearth contends that "connected to" does not mean "directly connected to." Hearth makes this assertion in an effort to circumvent the Court's construction of "horizontal." In other words, if a horizontal pipe may be "connected" to the fireplace through a secondary piece of vertical pipe, then the Court's construction of "horizontal" is irrelevant from Hearth's perspective. Hearth's construction of "connected to" is untenable. A wall with a pipe "connected thereto" implies that there is no intermediate link between the wall and the pipe. This construction of "connected to" applies equally to the phrase "said horizontal exhaust pipe being connected to said inner plenum of said wall…."

The contentious language of Claim 1 is therefore construed as follows: 5 "horizontal exhaust pipe" means the exhaust pipe which is horizontal both at the point at which it exits the building and the point at which it is connected to the fireplace; "connected to" means directly connected to without the presence of an intermediate link. This construction of Claim 1 largely comports with the specification. The descriptions and diagrams emphasize a horizontal exhaust pipe connected to an inner plenum. 6

--- Footnotes ---

5 FMI also urges the Court to interpret the limitation in Claim 1 as a requirement that the wall connected to the horizontal exhaust pipe be vertical or substantially vertical. In support of its contention, FMI relies on a theory involving the antecedent basis for "said remaining walls." FMI contends that "one of said remaining walls" can only refer back to the "said … vertical walls" phrase which immediately preceded it. Although the Court finds FMI's antecedent basis theory marginally persuasive, the patent examiner did not consider the imperfect antecedent basis to be problematic. Consequently, this Court will not adopt FMI's restrictive construction of "said remaining walls."

6 All descriptions and diagrams with the exception of Figure 5 depict a horizontal exhaust pipe connected to the inner plenum of a vertical wall. Although Hearth urges the Court to determine whether Figure 5 is within the purview of the '322
The claim term "horizontal groove" appears in claim 1 of the ‘862 Patent within the phrase "wherein said seal has at least one horizontal groove to facilitate the movement of the seal." ‘862 Patent, col. 1:49-51. Both parties acknowledge that neither "horizontal" nor "horizontal groove" appear anywhere in the Common Specification. (D.I. 116, at 26; D.I. 118, at 29.) ICU contends that the word "horizontal" merely "explains the overall orientation of the groove in facilitating the function," which is to facilitate movement of the seal. (D.I. 118, at 28.) Further, ICU contends that "horizontal" need not be given a precise geometric meaning because it should be construed as broadly as its functional requirements allow (id. at 29), and because other directional terms in the Common Specification are not limited to precise geometric meanings. (D.I. 172, at 16.) RyMed contends that ICU's construction improperly reads out the word "horizontal," substituting it with "non-vertical." (D.I. 116, at 27.) Additionally, RyMed contends that ICU has selectively chosen the dictionary definition most helpful to them, ignoring other definitions defining "horizontal" as "at right angles to the vertical." (D.I. 165, at 24-25.)

As ICU points out, the surrounding context of the claim language demonstrates that the function of the "horizontal groove" is to facilitate the movement of the seal. (D.I. 118, at 28.) Although ICU has supplied the Declaration of Mr. Claude Vidal (D.I. 173) to support its contention that a person of ordinary skill in the art would understand "horizontal" as meaning "from one side of the seal to another" in this context, nothing in the intrinsic record counsels such a broad understanding. "In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314. The plain meaning of "horizontal" is perpendicular to, or at right angles from, a vertical axis, and there is no support for broadening that term to include anything "non-vertical." See Nystrom v. TREX Co., Inc., 424 F.3d 1136, 1145 (Fed. Cir. 2005) ("in the absence of something in the written description . . . to provide explicit or implicit notice to . . . the public- i.e., those of ordinary skill in the art- that the inventor intended a disputed term to cover more that the ordinary and customary meaning revealed by the context of the intrinsic record, it is improper to read the term to encompass a broader definition simply because it may be found in a dictionary, treatise, or other extrinsic source"). Thus, the Court concludes that "horizontal groove" means "at least one groove which is perpendicular to an axis defined by the proximal and distal ends."

The meaning of "horizontal stopping surface" is not greatly disputed based on the parties' submissions. Phoenix says that it means "a surface with a horizontal portion for preventing movement." Silgan says that it means:

a horizontal surface on one member (the bottle) against which horizontal stopping surface or another member (the cap) abuts or engages to preclude further movement of the another [sic] member (the cap) in one direction (downwardly on the
bottle); a horizontal surface on the other member (the cap) which engages with a horizontal surface on the (one member bottle). A surface is an area having length and width.

To the extent Phoenix argues that a horizontal stopping surface is a surface that is only partly horizontal, the Court rejects its definition. Common sense, as well as the patent specification, dictates that a horizontal surface is entirely, not partly, horizontal. The remainder of the parties' definitions are substantially the same. Both agree that the word "stopping" means "to preclude or prevent movement," and Phoenix does not contest that a surface requires "length and width." Thus the Court adopts the following construction of the term: a horizontal area having length and width, which purpose is to preclude movement.

1994

a) Meaning of the Terms "Hot Air Flow Channels" and "Modified 'S' Configuration"

The "modified 'S" configuration of the "hot air flow channels" within the "heating means" described in claims 1 and 4 is a crucial aspect of the Satisfryer. The patent specification explains: "The angulated configuration [i.e. the modified 'S' configuration] of the double hot air flow channels would achieve a greater time within the hot oil that the heat is radiated outwardly into the oil and therefore less heat would escape and be lost to the back through the exiting point of the flow channels." (R. 36. Exhibit 1, column 2, ll. 2-6). Thus the particular "hot air flow channels" described in claims 1 and 4 of the '317 patent increase the efficiency of the Satisfryer. Far West and AFC argue that the "hot air flow channels" limitation, as used within claims 1 and 4, means the actual structures, or tubing, within which the hot air flows thereby heating the cooking oil within the frying chamber. CP counters that the term "structure" never appears in the patent itself and that the limitation "hot air flow channels" must be construed more broadly to include both the physical tubing within which the air flows and the passageway created by the physical tubing.

CP is correct that each flow channel described by claims 1 and 4 of the '317 patent includes a physical tubing within which a passageway is contained. However, the language of the claims, especially when read in conjunction with the entire claim specification, reveals that the term "hot air flow channels," as used within the '317 patent, refers to two very specific physical structures. 5 The "Detailed Description" section of the claim specification describes the structure of the hot air flow channels as follows: "the heating means 40 … would include a pair of parallel flow channels 60 and 62 which would be in parallel spaced apart relation and directed within chamber 15 in a modified 'S' fashion … so that there are a plurality, namely eight alternating left and right angle turns that the heating chambers would go through in order to reach an exit point 64 at the front end 12 of the chamber 15." (R. 36. Exhibit 1, column 4, ll. 9-19) (emphasis added). The flow channels are further defined as being comprised of "a pair of vertical side walls 61 and 63; a floor portion 65; and a pair of top walls 67 and 69 meeting at a central point 71. The walls … would define a continuous heated air passageway 73." (Id. at ll. 57-61) (emphasis added). Thus the "hot air flow channels" described in claims 1 and 4 are clearly defined in structural terms. Specifically, the '317 patent includes two distinct and separate "hot air flow channels," comprised of five-walled tubing, that extend through the frying chamber of the apparatus in a series of alternating left and right angled turns to create a modified "S" pattern. 6 CP is correct that a "passageway" lies within each five-walled channel, but the passageways's existence are completely dependent upon the flow channels's physical structure, and this structure is specifically defined by the claim specification. For the purposes of claim construction, this Court finds the term "hot air flow channel" embodies a specific structural element, as herein described, and the '317 patent is limited by that structural element.

Footnotes:

5 While claims within a patent are not necessarily limited by the claim specification, the written description of the claim is relevant to the claim construction process. Laitram Corp. v. Morehouse Industries, Inc., 143 F.3d 1456, 1463 (Fed Cir. 1998) (relying upon the "Summary of the Invention" portion of the claim specification to interpret the meaning of terms within a claims); see also American Permahedge, Inc. v. Barcana, Inc., 105 F.3d 1441, 1445 (Fed Cir. 1997) (relying upon the figures and written descriptions within the claim specification to interpret a claim).

6 Other language of the specification confirms that the "hot air flow channels" described in claims 1 and 4 of '317 patent have a specific structural element. Throughout the claim specification, the term "flow channels" is interchange with several other terms with structural connotation. The terms "chambers," "tubes," and "elements" are substituted for the term...
"channel" at various junctures within the description of the patented apparatus. (R. 36, Exhibit 1, column 4, ll. 16, 44; column 5, ll. 5, 12). In addition, the flow channels are described as having an "interior" to which the hot air passing through the channels is confined. (Id. at l. 51).

7 CP relies on the opinions of two experts in forwarding this definition of the term "channels." Plaintiff's patent expert, William D. Keisel, esq., opines: "The term 'channels' ... was used to identify both what I would call the passage way as well as the tubes themselves ... really the term 'flow channels' I think in the context of this invention the way they describe it, it could cover both." (R. 38, Exhibit 17, p. 216). Dr. Dupree Maples, plaintiff's technical expert, echoes Kiesel's conclusion. (R. 38, Exhibit 4). A court may rely upon expert testimony in interpreting language within a claim. Markman, 52 F.3d at 979. However, the Federal Circuit has held that a court should not rely upon "extrinsic evidence," such as expert testimony, to interpret patent claims where, as "in most situations, intrinsic evidence alone will resolve any ambiguity in a disputed claim." Vitronics, 90 F.3d at 1583. In this case, the Court is able to resolve all disputed terms within claims 1 and 4 by relying upon the intrinsic evidence in the record--claims 1 and 4 themselves, the patent specification, and the prosecution history. As such, it would be "improper" for this Court to rely upon the expert opinions of Mr. Kiesel and Dr. Maples to assist in claim construction. Id.

The "hot air flow channels" limitation within claims 1 and 4 is further defined by the requirement that each channel structure extend "from the first wall of the chamber to the second wall of the chamber." (R. 36, Exhibit 1, column 6, ll. 14-15, ll. 38-39). This language is illustrated by Figure 2 of the claim specification. It demonstrates how each flow channel begins at the first wall of the cooking chamber (16), extends through the chamber in a series of left and right angle turns, and terminates at the second wall of the chamber (12), which is opposite the first wall (16). (R. 16, Exhibit 1, Figure 2). This limitation further defines the structure of the two "hot air flow channels" described within the '317 patent. As a result, each "hot air flow channel" structure must extend continuously from one end of the cooking chamber to the opposite end in the "modified 'S'" configuration defined above. See supra p. 10.

1995

A. "housing"

All of the independent claims have a housing limitation, such as "a housing of palm-held size." ('783 Patent, Claim 1). Although Minerva and the Palm defendants believe "housing" simply means "a case or enclosure," the Alltel defendants argue that Minerva disclaimed hinges and slides during reexamination. As such, the Alltel defendants recommend that "housing" be construed as "a single rigid casing without hinges or slides."

During reexamination, Minerva distinguished its invention from Mack reference, which described a portable telephone that could be unfolded to form a headset that fits over a user's head. Minerva's alleged disclaimer is based on the following statement to the USPTO: "Mack's device has at least more than three housings connected to each other through hinges, while the claims of the Present Patent require that the camera and the cellphone be provided in the same housing." According to the Alltel defendants, by distinguishing the Mack reference, which had hinges, Minerva has disclaimed multi-segment housings connected through hinges or sliders.

"The purpose of consulting the prosecution history in construing a claim is to exclude any interpretation that was disclaimed during prosecution." Chimie v. PPG Indus., Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005). The alleged disclaimer "must be 'clear and unmistakable,'" however, "and unclear prosecution history cannot be used to limit claims." Cordis Corp. v. Boston Scientific Corp., 561 F.3d 1319, 1329 (Fed. Cir. 2009).

The first portion of Minerva's statement, "Mack's device has at least more than three housings connected to each other through hinges," clarifies the meaning of housing and also acts as a limited disclaimer. The patentee indicates that segments connected via hinges are separate housings; thus, a single housing may not contain a hinge. Through this definition of a "hingeless" housing, the patentee disclaims prior art devices comprised of four or more housings. Minerva does not disclaim hinges altogether, but instead distinguishes devices having at least three hinges. In contrast to hinges, the prosecution history does not show that Minerva has disclaimed sliders or housings having slides. The Mack device contains two segments.
connected by slides. Yet in its statement to the USPTO, Minerva called these two segments "the housing of the cellphone." As such, a housing may contain multiple segments connected by slides.

The second portion of Minerva's statement, "while the claims of the Present Patent require that the camera and the cellphone be provided in the same housing," also acts as a limited disclaimer. Some of the dependent claims add a limitation that the device must have a camera. (E.g., '783 Patent, Claim 5 ("The device of claim 1 or 2, further including a camera provided in said housing . . . ").) Minerva's statement to the USPTO effectively disclaims devices having a camera in one housing and the cellphone in a different housing.

Based upon the prosecution history discussed above, the court construes the term "housing" as "a single case or enclosure, or several cases or enclosures connected through slides."

1996

1. Housing

The term "housing" appears in the claims of the '130 application and in all three of the patents-in-suit. See '130 application claim 1 at 35 ("a housing defining a central passageway having fluid inlet and fluid outlet openings"); '609 patent claim 5 at 20:8-15 ("a housing defining an internal passageway having a gas inlet opening near an upstream end of said housing, and a gas outlet opening spaced from said gas inlet opening, said housing having a first attachment portion configured for connection of an upstream end of said filter assembly to a pressurized source of breathable gas and a second attachment portion configured for connection of a downstream end of said filter assembly to said regulator device") (emphasis added); '958 patent claim 8 at 18:49-54 ("a housing defining a duct with gas inlet and gas outlet openings defined at opposite ends of said duct, said housing having a valve sealing face disposed near said gas inlet opening and adapted for engagement with said high-pressure gas source") (emphasis added); '674 patent claim 1 at 26:45 ("a housing including a bore"); see also '130 application claim 13 at 37, claim 21 at 40, claim 29 at 43, claim 38 at 45, claim 51 at 49; '609 patent claim 1 at 17:55-59; '958 patent claim 1 at 17:62-67; '674 patent claim 13 at 27:24-35.

Aqua-Lung proposes that "housing" be construed as "a structure with internal space that defines the internal passageway" while Two Forty counters with "the body or skeletal portion of the device." Based on a reading of the claim language above, Aqua-Lung's proposed construction is too narrow as not every claim includes an "internal passageway." That portion of its proposed definition, therefore, should not be included in the final construction.

That said, Two Forty's proposed construction is too broad as it fails to take into account the internal space associated with the "housing" claims above. A review of the specifications in the '609 and '958 patents further clarifies that a "housing" surrounds an internal space. The specifications in the '609 and '958 patents contain identical references to the term: (1) "the housing 34 includes a gas inlet opening 38 which is surrounded by a raised collar or flange 40"; (2) "a housing 62 having a top or inlet end 64, a central shaft 65 and a bottom or outlet end 66"; (3) "[t]he housing 62 of this embodiment includes the upper or inlet end portion 64, an bottom or outlet end portion 66, a central bore 78, an annular inner lip 82 forming a narrowed end opening 80, and an exit opening 116"; and (4) "[t]he housing 230 includes an inlet end portion 232 and an outlet end portion 234." '609 patent at 7:37-39, 8:49-50, 10:51:54, 14:44-45; '958 patent at 7:45-47, 8:57-58, 10:59-62, 14:52-53.

Any remaining doubt that a definition of "housing" should refer to an internal space is debunked by the abstract and the summary of the '130 application which provides that "a fluid flow control valve is disclosed. This valve includes a housing which defines a central passageway having fluid inlet and fluid outlet openings." '130 application at 7, 53 (emphasis added); see also '609 patent summary at 4:2-4; '958 patent summary at 4:9-12. These additional examples make clear that the "housing" as used in the claims noted above, defines an internal space. Based on the foregoing, the Court construes "housing" as "a structure surrounding an internal space."
"Housing" terms

Housing

The Court adopts Plaintiffs' construction and construes "housing" to mean "a cover or enclosure." Defendants propose that "housing" be construed to mean "the protective outer cover of the motion detector camera, which excludes any inserts or partitions contained within such protective outer cover." Defendants' construction contains unnecessary limitations. Defendants partially rely on Figure 7 to support their construction. Defendants seem to argue that because Figure 7 shows an outer housing and inside the housing a motion detector and a camera, the enclosures containing the motion detector and camera are not part of the housing and, therefore, "housing" must exclude any partitions or inserts contained within such "housing." Figure 7 is only one embodiment of the invention, and there is no explicit support in the specification for applying Defendants' limitation to the claim term. Defendants also cite prior art in which, according to Defendants, the housing is not considered to include anything within itself. However, Defendants fail to cite anything within the specification or prosecution history that would indicate the examiner or applicant defined or used "housing" in that manner.

The specification broadly describes the housing as "an enclosure for holding the various components of the camera." Col. 2:54-55. Accordingly, the Court construes "housing" as "a cover or enclosure."

1998

Housing

In its briefing, Lantronix argued that "housing" is used according to its plain meaning and therefore does not require construction. Alternatively, if the Court does construe the term, Lantronix argued it should be construed according to its plain meaning: "a case or enclosure."

Digi argued "housing" should be construed as "cover that provides structural and protective support for the enclosed components." Digi contended the housing serves as both a cover and a structure for the enclosed components such as the electrical pins and socket connections. If this were not the case, Digi argued, "the claim language requirement that the connector contain at least two physical interface connection elements and electronic circuitry would contradict the 320 patent, which claimed the insertion of components inside the connector itself."

Further, Digi argued, the components must be attached to the connector's structural supporting unit (the housing) in order for them to be electrically connected and functional. Digi also relied on the 320 patent's prosecution history, which acknowledged that "a housing is required to provide a structure for the connector." See 320 patent prosecution history, Amendment and Response to Official Action, 4/30/1985, p. 5. Finally, Digi contended that Figure 1 and the 470 patent's prosecution history "show that the connector has its own separate housing to distinguish it from prior art where the functional circuitry was part of, and contained within, the computer housing."

During the hearing, the parties agreed to a compromise construction: "case or enclosure to cover and protect the connector's internal components." The Court agrees with the parties' agreed construction. As before, the Court rejects Digi's argument that the 320 patent was incorporated in any way into the 470 patent.

1999

H. Term 10: Housing (as used in claims 1 and 23).

Lutron contends that Term 10 means a "Structure that covers or protects components." Control4 contends it means "A structure, attached to the back of the support yoke, which houses components." Lutron opposes Control4's proposed construction because it requires the housing to be behind the support yoke. According to Lutron, this imposes a limitation that is not present in the patent.
The patent does not define what constitutes a "housing." Claims 1 and 23 state the control device must contain an antenna, transmitter-receiver, and a housing, among other things. The transceiver must be contained in the housing, but the patent does not require the antenna to be in the housing. Control4 contends that the control device, and consequently, the housing are coextensive with the wallbox.

The '103 Patent indicates the control device is located in the wallbox. Yet, in other language, the patent states the control device is only "substantially within an electrical wall box." The patent further states that the antenna is located in the wallbox. This fact is significant because Lutron's antenna is located in front of the yoke, and consequently is not literally within the wallbox. Thus, references to a component being located in the wallbox do not necessarily require that the component be literally and completely within the wallbox.

Control4 further cites to a paragraph in the "Summary of the Invention" to support its contention. The paragraph states:

> It is a further object of the present invention to provide an antenna as part of a lighting control device wherein the antenna is sufficiently small to fit within the area defined by the faceplate of the wallbox outside the opening of the wallbox with the remainder of the control device disposed in the wallbox. In this way, the antenna, although outside the wallbox, is concealed behind the faceplate.

Because the paragraph states the antenna is outside the wallbox "with the remainder of the control device disposed in the wallbox," Control4 argues this supports the requirement that the housing must be completely contained in the wallbox and necessarily be behind the yoke. The Court disagrees.

Control4 argues, however, this does not defeat its interpretation because "remainder" refers to the controlling elements of the control device, not such things as the outer bezel and faceplate. This argument is not supported by the quoted language. Additionally, Claim 23 includes an actuator. The actuator is "coupled to said control circuit to provide a signal thereto to control the status of the controlled electrical device." One could argue, therefore, that the actuator is a "controlling element." Yet, it also must be outside of the wallbox due to its function. The Court therefore concludes the quoted language...
The preambles to claims 1 and 23 state the control device is "adapted to be mounted at least partly within an electrical wall box." Both parties have agreed that the preamble is limiting. Consequently, the claim itself shows that the control device is not co-extensive with the wallbox. Moreover, nothing in the relevant claims states the housing must be fully within the wallbox. This means the housing may be partly outside of the electrical wallbox. The Court therefore concludes the term means "A structure that protects or holds components."

3. Housing; Display Case/Case

a. The Parties' Constructions

LPL argues that "housing" should be given its ordinary and customary meaning. Defendants assert that "housing" should be limited to a case and body of a portable computer. Defendants argue that the inventors became their own lexicographers, when in response to an objection by the examiner, they stated a definition of housing as a display case or case and body. See '641 and '718 patents, 4:54-56 and 6:12-15.

b. The Special Master's Constructions

Unless a patentee becomes his own lexicographer by using terms in a manner other than their ordinary meaning by clearly stating the special definition in the specification or prosecution history, words in a claim are given their ordinary meaning. Vitronics, 90 F.3d at 1582. The Special Master is of the view that no such clear statement of a special definition exists. In fact, the intrinsic evidence contains no explicit definition connecting "housing" to a portable computer.

Addressing the Defendants' argument that housing was defined in response to the examiner's objection, the Special Master is mindful that a patent examiner's objection is distinct from a rejection. In this regard, an objection does not relate to the patentability of the claims. According to M.P.E.P. § 706.01: "[t]he refusal to grant claims because the subject matter as claimed is considered unpatentable is called a 'rejection.' The term 'rejection' must be applied to such claims in the examiner's action. If the form of the claim (as distinguished from its substance) is improper, an 'objection' is made." The amendments made by the inventors addressed a formality raised by the examiner's rejection, i.e., antecedent basis, and were therefore non-substantive and, to coin a phrase, "merely cosmetic." Cf. AK Steel Corp. v. Sollac & Ugine, 344 F.3d 1234, 1242 (Fed. Cir. 2003) ("There was no indication that the amendment was made to relinquish claim scope; rather it was made in response to the examiner's request to replace language that he found vague with language that he felt 'more specifically defined' the same material. Under those circumstances, the amendment clarified the claims without changing their scope."). Moreover, "an inventor may choose to be his own lexicographer if he defines the specific terms used to describe the invention 'with reasonable clarity, deliberateness, and precision.'" Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002) (quoting In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994)) (emphasis supplied). Further, the Special Master finds it noteworthy that the amendment resulted in housing being expressed two different ways, one somewhat more
specific than the other, but in no event in the Special Master's view, in a way clearly stated. 17 Because "housing" was not defined with reasonable clarity, deliberateness, and precision, the Special Master concludes that "housing" should be accorded its ordinary meaning.

--- Footnotes ---

17 "Together, the case and body may be referred to as a housing ..." '641 patent, 4:48-49. "... the body (first portion) and the display case (second portion) (collectively referred to as a housing) ..." '641 patent, 6:6-8.

--- End Footnotes ---

The term "display case" is recited only in claim 40 of the '718 patent. Based on the plain language of the claim, i.e., "arranging the LCD device on ... a display case" and "attaching the LCD device to the display case," the flat-panel display device is both arranged on and attached to the display case. Also, the common specification associates the term "display case" with "housing." There is no special definition attributed to the term.

Accordingly, the Special Master's constructions are as follows:

<table>
<thead>
<tr>
<th>CLAIM TERM</th>
<th>SPECIAL MASTER CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Housing</td>
<td>An outer casing or enclosure</td>
</tr>
<tr>
<td>display case/case</td>
<td>The portion of the housing onto which the flat-panel display device is arranged and attached</td>
</tr>
</tbody>
</table>

---

2001

1. Housing

The first element of Claim 1 is a "housing." The ordinary meaning of "housing" is a case or enclosure that covers or protects another structure. The language of the element itself, "the top wall, bottom wall, and side wall enclosing an interior therebetween," and the specification figures are consistent with this meaning, and the prosecution history does not reveal a definition contrary to it. Accordingly, the Court construes "housing" to mean a case or enclosure that covers or protects another structure.

---

2002

1. Housing

The patentee uses the term "housing" throughout the reexamined 097 patent including specifically in asserted Claims 11, 21, 24, 25, 27, 32, 34, 35, 36, 39, 40, 41, and 42. The parties agree that the proper construction of this term begins with the dictionary definition. Webster's New Universal Unabridged Dictionary defines "housing," in relevant part as "anything that covers or protects" and "a fully enclosed case and support for a mechanism." Webster's New Universal Unabridged Dictionary (1996) ("Webster's Universal"), Stant Ex. 103, p. 928. Stant argues that nothing in the specification or prosecution history adds anything to this definition and thus, the court should give the term this simple definition. Stant's Opening Brief on Claim Construction ("Stant Br.",) p. 11. Gerdes argues, on the other hand, that the claims and specification dictate that external protrusions, including flanges, threads, and vent strips, are not part of the housing and that the definition of housing should reflect this exclusion. Brief in Support of Gerdes GMHB's Claim Construction ("Gerdes Br."), P. 6.

The ordinary definition of the term "housing" does not itself exclude any other structures from being a part of the structure that 'covers or protects.' Thus, the court must look to the manner in which the patentee used the term in claims and specification of the reexamined 097 patent. The parties each point to independent claim 11 for support of their positions. In that claim, the patentee refers to the "housing having a radially outwardly extending first flange on an axially upper portion of said housing." Reexamined 097 patent, Stant Ex. 2, col. 1, 11. 49-51. This usage, however, even with its use of the word
"having," does not clearly indicate a specialized meaning for "housing" that either includes or excludes the flange as a part of the housing. In other claims, for example, the patentee refers to the "first flange attached to the housing." Id. at col. 3, 11. 19, 39. Thus, in the claims the patentee uses the term in a variety of manners, none expressing the clear intent of the patentee to deviate from the ordinary meaning of the term by either excluding any structures from being a part of the "housing" or by requiring any particular structures to make up the "housing."

Further, in the specification the patentee also uses "housing" as a general term to describe the outer covering of the fuel cap. See 097 patent, Stant Ex. 1, col. 1, 11. 34-47. In order to overcome the presumption that the intention of the patentee was to use "housing" in its ordinary and customary manner or in order for the patentee to disavow or disclaim scope of coverage, he or she must use "words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Int'l Rectifier Corp. v. IXYS Corp., 361 F.3d 1363, 1370 (Fed. Cir. 2004). The court finds that in the claims and specification of the 097 patent and the reexamined 097 patent, the patentee has not expressly indicated that the term "housing" has a specialized meaning. For this reason, there is nothing that suggests to a person of ordinary skill in the art that he or she is to read "housing" to mean anything other than its ordinary definition. Thus, the term "housing," as used in the reexamined 097 patent, means a case covering, protecting, or enclosing other parts of the fuel cap.

2003

a. "Housing", "Within Said Housing"

Plaintiffs argue that the LEDs in the AMP Device are not "secured within the connector housing" defined by top, bottom, front, and rear walls. Plaintiffs argue that the LEDs sit exposed and unprotected on the projection above the housing formed by the walls. Defendant maintains that the LEDs are within the housing, on the front wall, as the claim does not limit the invention to a box-like structure with light emitting devices placed within the internal volume of the four specified walls.

i. The claim language

The claim requires that the LED lie "within" the "housing" as opposed to outside of the housing.

The claim reads that the housing is

formed by front, rear, top and bottom walls and having a plug receiving opening formed within the front wall thereof.

'317 patent at 4:58-60. The light emitting devices must-be "within said housing":

at least one light emitting diode integrally secured within said housing adjacent the plug receiving opening formed within the front wall thereof.

'317 patent at 4:61-63.

The housing, as described in the claims, is formed by four walls: front, rear, top and bottom walls. (The Claim does not require that the device have side walls.) The Code of Federal Regulations sets a standard for internal RJ plugs, but sets no standards or limitations describing the external configurations of RJ modular jacks. The issue disputed by the parties is whether a wall of the housing as defined in the claim can include a protrusion or flange, such as that found in the AMP Device. The claim language itself does not specify that the four walls of the housing must be "box-like" in structure or that the edges of the four walls must meet at the four corners at right angles. The claim does not require that the walls be of any particular shape or dimension, or that they be uniform in size.

With respect to devices (as opposed to residences), housing is generally defined as "something that covers or protects," "a casing (as an enclosed bearing) in which a shaft revolves," "a frame or other support for mechanical parts." See Webster's New Collegiate Dictionary 403 (7th ed. 1967).

ii. Specification
The specification states that the configuration of the RJ connector "is not a limitation to the present invention." The specification reads as follows:

It will be appreciated that an RJ connector is available in a variety of sizes, and internal configurations and may be molded in a number of ways commonly known in the art and is not a limitation to the present invention. The only requirement being that the RJ connector has a visible surface accessible for the placement of at least one LED indicator.

'317 patent at 4:23-29 (emphasis added). From this language it appears that the inventor intentionally left the definition of "housing" vague in order to capture within the claims the whole variety of RJ connector configurations known in the art.

iii. Prosecution history

The prosecution history does not provide assistance in defining "housing."

iv. Extrinsic evidence

Mr. Lazar presented credible testimony that housing is understood to be that which supports and insulates various other parts of the connector. He also testified that usually housing is a single molded unit.

v. Construction

Given the general and vague description of "housing" in the claim language, and the explicit statement in the specification that the specific molding of the RJ connector is not a limitation to the invention, the Court finds that the "housing" could include a front wall with a protrusion or extension above the point where the wall meets the top or bottom walls. The broadly written claim does not require that the LED lie wholly within the volume created by four walls of housing. The housing must be a supporting structure made of a single molded unit, with a front, top, bottom, and rear wall.

2004

E. "Housing"

Itron contends that the term "housing" as used in each of the asserted claims means "an enclosure that protects the circuitry for recording time of energy use or the circuitry for recording energy use, mountable beneath the rotatable disc in the meter." In CellNet's proposed claim construction order, which was presented to the Court for the first time during the July 24, 1998 hearing, it takes the position that the term means simply a support.

In the patent specification, the patenpees disclose that the housing depicted in the various drawings have both a front face and a rear face. '623 patent, 5:13-15. Thus, it is at least partially enclosed on two sides. Then, during patent prosecution, CellNet's patent counsel argued to the examiner that the disclosed device is distinguishable from the Keller patent, which disclosed a two-sided flexible circuit board with no housing or enclosure, because "the circuit elements [of Keller] are not contained within a housing that fits beneath the meter disk [sic]." Response to Office Action, p. 6. Based on the above intrinsic evidence, the Court construes "housing" to mean a case or enclosure.

2005

(a) The Housing Requirement

(i) A housing configured to receive the anterior surface of the hand

The '165 Patent itself does not define "housing." The summary of the invention contained in the '165 Patent, indicates that the housing must contain something, but the vague description is not definitive:
Although the critical features of the invention reside in the shape of the housing, being a hand controller apparatus which is usable in conjunction with a computer or computer controlled game, the hand controller of the present invention also provides an underlying, generally planar support member for enclosing the housing and the electrical contents thereof and at least one relative movement sensor of the type previously described and which is well known in the art.

'165 Patent, col. 3, ll. 37-45. Thus, the Court must look to extrinsic evidence to construe the meaning of the word "housing."

In support of its Reply, Defendant offers excerpts from American Heritage Dictionary 625 (2d college ed. 1982) and Webster's II New College Dictionary 536 (1999) for the proposition that the term "housing" means "something that covers, protects or supports." 2 Defendant notes that in Claims 1, 4, and 5 of the '165 Patent, Plaintiff referred to a "hollow housing," but in Claim 7 Plaintiff merely referred to a "housing." Defendant argues, the word "hollow" cannot be read into Claim 7 -- as this would make the inclusion of the word "hollow" in the other claims meaningless. Therefore, Defendant contends the Housing Requirement should be construed to mean a solid structure that supports the palm-side of a user's hand.

2 Defendant's Memorandum in Support of Its Motion for Summary Judgment of Invalidity contains no discussion of the "housing" requirement whatsoever.

Plaintiff offers Webster's New World Dictionary 655 (3rd ed. 1988) for the proposition that in the context of mechanical devices the term "housing" means "a frame, box, etc. for containing some part, mechanism, etc." Plaintiff argues that, by definition, a "housing" must "house" something.

The Court finds that the summary of the invention in the '165 patent and Plaintiff's dictionary definition of "housing," comport with the plain meaning of the word "housing." Therefore, the Court construe the phrase "a housing configured to receive the anterior surface of the hand" to mean a hand controller (which may be hollow or solid) that contains a part or mechanism while receiving the palm-side of the user's hand.

n8 The corresponding phrase is "housing which can be comfortably held in a user's palm."

The defendants contend that the phrase is indefinite because it has no discernible meaning in light of the prosecution history. The court disagrees and finds that the phrase, as written and in the context of the whole patent, can be understood by one of ordinary skill in the art. See In re Marosi, 710 F.2d 799 (Fed. Cir. 1983); Bancorp Services, L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367 (Fed. Cir. 2004). The phrase requires no construction and the court rejects the defendants' indefiniteness argument.

"a housing part for housing a self-expanding stent, said housing part provided at said distal end of said guide tube"
Perouse's proposed construction of "a housing part for housing a self-expanding stent" is "a piece that covers a self-expanding stent." (Perouse Opening Br. 20.) Gore's proposed construction is "a case or enclosure that is capable of temporarily holding a self-expanding stent in a compressed state until placement in the desired location, regardless of whether the housing part actually covers the entirety of the stent or is even capable of doing so." (Gore Proposed Order 2.)

With respect to the ordinary meaning of "housing," the Court does not detect any meaningful difference between the parties' proposed language. "A piece that covers" and "a case or enclosure" are both acceptable constructions that accurately reflect the meaning of "housing" as understood by a person of skill in the art in light of the intrinsic evidence. As explained in the specification, the "housing part" provides housing for the self-expanding stent during endoluminal delivery to the treatment site, until the housing part is "opened" and the stent expands. (See '787 patent col.3 11.1-4, 11.33-43, col.3 1.57-col.4 1.4). The specification makes clear that the "housing part" fits around and covers the outside of the stent. For example, a stent is described as being "inserted" into the housing part of one embodiment. (’787 patent col.3 11.1-4.)

Gore has not objected to Perouse's proposed language, "a piece that covers." In fact, Gore has indicated that it believes the parties are in agreement with respect to this aspect of the construction. (Gore Reply Br. 6.) Perouse's objection to Gore's definition is apparently that "case or enclosure" is too narrow. (Perouse Reply Br. 11.) "Enclosure" is arguably narrower in scope than "a piece that covers." For example, the dictionary definition of "housing" provided by Perouse's expert is "something that covers or protects, as a case or enclosure." (Gold Opening Decl. Ex. 5 at 585.)

There is no indication in the intrinsic evidence that "housing part" requires or excludes any particular type of housing or covering. Therefore, though the parties' constructions may not be substantively different, the Court will incorporate both parties' proposed language into its construction in order to ensure that it captures the full scope of the ordinary meaning of "housing." The Court construes "a housing part" to mean "an enclosure or covering." 9

9 As discussed infra, the Court has used the word "covering" instead of "piece that covers" to avoid any implication that the piece only infringes when it is "actually" covering a self-expanding stent. See infra note 10.

The parties also dispute Gore's proposed limitation that the "housing part" must be "capable of temporarily holding a self-expanding stent until placement in the desired location" (emphasis added). Gore's proposed construction is rejected because the ordinary meaning of "housing" does not include the requirement that the "housing" must constrain the housed object from expansion. While the specification of the '787 patent describes a delivery device that constrains a self-expanding stent, this description does not demonstrate the patentee's intent to implicitly or explicitly redefine "housing," and therefore the ordinary meaning applies.

Finally, Gore has raised an issue regarding whether the "housing part" is required to "cover the entire stent or even [be] capable of doing so." (Gore Reply Br. 9.) Gore apparently interprets Perouse's proposed construction as requiring a housing part that "completely cover[s] the self-expanding stent." (Gore Reply Br. 7.) It is not at all clear, however, that Perouse even advances this "complete coverage" limitation, which is not apparent from Perouse's proposed claim language, "a piece that covers a self-expanding stent." Perouse did not argue for this limitation in its briefs, and addressed the issue only perfunctorily at the Markman hearing. (See Oct. 23, 2007 Tr. 70:12-18.)

Assuming this issue requires resolution, the Court finds that the "housing part" element does not require complete coverage of the self-expanding stent nor does it require that the "housing part" be capable of complete coverage. While the drawings of the '787 patent depict a housing part that completely covers a self-expanding stent, there is no indication that this is a significant or necessary detail. The Court finds that a person of ordinary skill in the art would not interpret the "housing part" element as necessarily capable of completely covering a self-expanding stent. Nothing in the intrinsic evidence indicates that partial coverage is excluded from the scope of this element or that the degree of coverage provided by the "housing part" is an important aspect of the invention.

ii. "for housing a self-expanding stent"
The "housing part" of claim 1 is not a housing part for any object, but a housing part "for housing a self-expanding stent." In the context of the '787 patent, this means a "housing part" that fits a self-expanding stent. A person of ordinary skill would understand that a "housing" is designed to house a particular object or structure. In the context of the '787 patent, the "housing part" element houses a self-expanding stent. That is, the housing part provides a covering, case, or enclosure for a self-expanding stent. Therefore the housing part must be of a size and shape that fit a self-expanding stent.

--- Footnotes ---

10 Gore interprets Perouse's construction, "a piece that covers" as requiring a structure that "actually covers a self-expanding stent." (Gore Reply Br. 7 (emphasis added)) and asserts that this construction is improper because it "implicitly requires a stent to be part of the claimed tool" (Gore Reply Br. 9). Gore seems to be suggesting that Perouse's proposed construction would only cover "housing parts" while they are being used to cover stents. If this is Perouse's contention, this would be an improper functional limitation on a claim addressed to structure, because the scope of an apparatus claim does not depend upon whether it is actually used for its intended purpose or not. See e.g., Catalina Mktg. Int'l, Inc. v. Coolavings.com, Inc., 289 F.3d 801, 809 (Fed. Cir. 2002) ("[T]he patentability of apparatus or composition claims depends on the claimed structure, not on the use or purpose of that structure."); In re Gardiner, 171 F.2d 313, 315-16, 36 C.C.P.A. 748, 1949 Dec. Comm'r Pat. 34 (C.C.P.A. 1948) ("It is trite to state that the patentability of apparatus claims must be shown in the structure claimed and not merely upon a use, function, or result thereof."). However, it is not clear that Perouse makes this argument. To clear up any potential confusion, the Court emphasizes that its construction of "housing part" means that the housing part must "fit" a stent if and when the stent is inserted, not that the tool only infringes when the stent is actually fit inside the tool.

--- End Footnotes ---

Accordingly, the Court construes "a housing part for housing a self-expanding stent" to mean "an enclosure or covering that fits a self-expanding stent."

iii. "said housing part provided at said distal end of said guide tube"

The final dispute between the parties regarding the "housing part" element concerns the location of the housing part along the guide tube. The "housing part" of claim 1 is "provided at said distal end of said guide tube." ('787 patent col.4 11.9-10.) Gore construes this phrase to mean "provided at or in contact with the tip end of a guide tube," while Perouse contends that it means "located at the extremity of a guide tube away from the operator." (Gore Proposed Order 2; Perouse Opening Br. 22.) The primary point of dispute between the parties is whether, as Gore asserts, the housing part must be in contact with the distal tip of the guide tube, 11 or whether, as Perouse asserts, the housing part must simply be located in the area near the distal extremity of the guide tube. (See Gore Opening Br. 26-27; Gore Reply Br. 9-11; Perouse Opening Br. 22-23 & n.16; Perouse Reply Br. 12-13.)

--- Footnotes ---

11 While the language of Gore's construction is ambiguous, Gore's reply brief makes clear the Gore contends that the "housing part" must be "in contact with" the distal tip of the guide tube. (Gore Reply Br. 9, 11 (characterizing propose construction as requiring that "the housing part of the tool is provided at, i.e., in contact with, the tip end of the guide tube") (emphasis added).)

--- End Footnotes ---

Gore construes "distal end" to mean "distal tip." Gore's construction is not consistent with the ordinary meaning of "distal end" as informed by the intrinsic evidence. "End" is used ambiguously in the '787 specification. For example, "end" and "end parts" are used interchangeably in the specification (alternately describing the "flared" portions of the endoprostheses as "ends" and "end parts"), indicating that "end" is not used as a synonym for "tip." ('787 patent col. 1 11.40-42, col.3 11.44-45.) However, "end" is arguably used to mean "tip" when describing the open "distal end" of the housing part or the "cord . . . connected, at its proximal end, to the actuation handle." ('787 patent col.3 11.5-7, col.3 1.67-col.4 1.2.) However, other intrinsic evidence indicates that "distal end" is not used as a synonym for "tip end." Specifically, patents cited during
prosecution of the '787 patent use "end" or "distal end" to refer to the area near the extremity of a device. (See Golds Reply Decl. Ex. 16, col.8 11.26-27; Ex. 17, col.4 11.24-30.); see also V-Formation, Inc. v. Benetton Group SpA, 401 F.3d 1307, 1311 (Fed. Cir. 2005) (stating that prior art references cited in patent or prosecution history are considered intrinsic evidence).

Finally, extrinsic evidence also refutes Gore's proposed construction of "distal end" to mean "distal tip." U.S. Patent No. 4,950,228, a patent issued in 1990 that was not cited during prosecution but nevertheless sheds light on the meaning of the disputed language to a person of ordinary skill in the art at the relevant time, clearly distinguishes between the "distal end" and "distal tip" of a ureteral stent. (Golds Reply Decl. Ex. 18, col.3 1.41-col.4 1.15.) Because both the intrinsic and extrinsic evidence indicate that "distal end" was used by persons of skill in the relevant art to mean either the distal tip or the area near the distal tip, the Court adopts Perouse's construction of this claim term. 12

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

12 Gore's construction of "distal end" as it appears in this claim element is also inconsistent with Gore's construction of the same claim language in the previous element, "a guide tube having a distal end." "[S]aid distal end," in the "housing part" element of claim I, refers to the same "distal end" that is recited in the "guide tube element." See, e.g., Intamin, Ltd. v. Magnatar Techs., Corp., 483 F.3d 1328, 1333 (Fed. Cir. 2007) ("The use of the word 'said' in a claim refers to an earlier use of the term in the claim."). Yet Gore did not construe "distal end" in the "guide tube" element to mean "distal tip," but instead proposed "the extremity of the guide tube away from the operator of the tool." See supra Discussion B.1.b.2. A claim term in a patent should be construed consistently wherever it appears. See, e.g., Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Accordingly, the Court construes the phrase "a housing part for housing a self-expanding stent, said housing part provided at said distal end of said guide lube," to mean "an enclosure or covering that fits a self-expanding stent, regardless of whether the housing part actually covers the entirety of the stent or is even capable of doing so, said housing part located at the extremity of a guide tube away from the operator."
It is possible to rebut the presumption triggered by the absence of the word "means" by showing that the claim element recite[s] a function without reciting sufficient structure for performing that function." Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000). However, "sufficient structure" does not mean "specific structure." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1359 (Fed. Cir. 2004) "Instead . . . it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their functions." Id. at 1359-60. As a result, "the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Id. at 1358. The Federal Circuit has "seldom held" that claim language not drafted using the word "means" is to be construed under § 112 P 6, as a means-plus-function claim. Id. at 1363 (identifying only one opinion in which § 112 P 6 was invoked without the word "means"); but see Mass. Inst. of Tech. v. Abacus Software, 462 F.3d 1344, 1353-55 (construing "colorant selection mechanism" as "means-plus-function" element).

Gore contends that the "housing part opener" element is drafted as a "means-plus-function" limitation and should be limited to the specific embodiments disclosed in the specification. (Gore Opening Br. 27-3 1; Gore Reply Br. 12-13.) Perouse contends that because this element does not include the word "means" and because "housing part opener" is "inherently structural" language, it is not a "means-plus-function" element and should be construed according to its ordinary meaning, "a device that opens the housing part." (Perouse Reply Br. 14-15.) Gore's expert concedes that "opener" does not have a specialized meaning in the relevant art and that the dictionary definition of "opener" is "one that opens." (Matsumura Decl. P 41-43).

Applying the analysis outlined above, the Court first notes that this element was not drafted using the word "means." As a result, there is a presumption that the element is not drafted in "means-plus-function" format. See, e.g., Depuy Spine Inc. v. Medtronic Sofamor Danek, Inc., 469 F.3d 1005, 1023 (Fed. Cir. 2006). To determine whether this presumption is rebutted, the Court must determine whether the "housing part opener" element merely "recites a function without reciting sufficient structure for performing that function." Watts, 232 F.3d at 880.

Neither "housing part opener" nor "opener" appears in the '787 specification. Therefore, the specification does not help to determine whether "opener" constitutes structural language. 13

Footnotes

13 Gore argues that the use of "means" in the specification indicates that "housing part opener" should be construed as a "means-plus-function" element. (Gore Opening Br. 28.) However, "means" must be used in the claim to trigger the presumption that § 112 P 6 applies. See, e.g., 911EP v. Whelen Eng'g Co., 512 F. Supp. 2d 713, 726-27 (E.D. Tex. 2007) (not applying presumption though specification used the word "means").
on a dictionary definition of "connector" that used similarly functional terms.

Expert testimony may be relevant to the determination of whether a claim element is drafted in "means-plus-function" format as long as the testimony is consistent with the intrinsic evidence. Lighting World, 382 F.3d at 1359. Perouse's expert states that the term "opener" indicates structure both in common parlance and to a person of skill in the art. (Golds Reply Decl. PP 6-7.) In support of this claim, she notes phrases like "can opener" and "bottle opener," and cites several pre-1992 patents in which "opener" was used "to indicate structures which opened something." (Golds Reply Decl. PP 6-7.) While these "openers" identified by Perouse's expert obviously are not suitable "housing part openers" for purposes of the '787 patent, these examples confirm that "opener" denotes structure and that the drafter of the patent intended "housing part opener" to refer by analogy to structures that open a housing part. Though "housing part opener," like "connector assembly," may not "bring to mind a particular structure," it is not a generic structural term like "mechanism," "means," "element," or "device." See Lighting World, 382 F.3d at 1360; Mass. Inst. of Tech., 462 F.3d at 1354 ("The generic terms 'mechanism,' 'means,' 'element,' and 'device' typically do not conote sufficiently definite structure."). Instead, "housing part opener" would be understood by a person of skill in the art to be a structural term defined by its function, like "connector." "Housing part opener" is therefore structural for the purposes of the § 112 P 6 analysis. See, e.g., Lighting World, 382 F.3d at 1361 (finding "connector" to be a name for structure "defined in terms of the function it performs"); see also Personalized Media, 161 F.3d at 705 ("[T]he fact that a 'detector' is defined in terms of its function . . . does not detract[] from the definiteness of structure. Even though the term 'detector' does not specifically evoke a particular structure, it does convey to one knowledgeable in the art a variety of structures known as 'detectors'.").

Evidence from the prosecution history of the applicant's intent in drafting the "housing part opener" element also supports the Court's finding that this element should not be construed according to § 112 P 6. See, e.g., Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996) (finding § 112 P 6 not applicable in part because "nothing cited to us from the prosecution history or elsewhere suggests that the patentee intended to claim in that fashion"); Markman, 52 F.3d at 985 ("[T]he subjective intent of the inventor when he used a particular term is of little or no probative weight in determining the scope of a claim (except as documented in the prosecution history)"). (emphasis added). The goal of the analysis used to determine whether § 112 P 6 applies appears to be ascertaining whether or not the drafter intended to take advantage of this provision. For example, the use of the word "means" is a significant factor in the analysis because it is considered a reliable indicator that a drafter intended to draft a "means-plus-function" limitation. See, e.g., Masco Corp. v. U.S., 303 F.3d 1316, 1326 (Fed. Cir. 2002) ("The use of the word 'means' to describe a claim limitation gives rise to a presumption that the patentee intended the term advisedly to invoke the statutory mandates for means-plus-function clauses."); Unidynamics Corp. v. Automatic Prods. Int'l. Ltd., 157 F.3d 1311 (Fed. Cir. 1998) ("The use of the term 'means' generally (but not always) shows that the patent applicant has chosen the option of means-plus-function format. . . .") (emphasis added); DESA IP, LLC v. EML Techs., LLC, 211 Fed. Appx. 932, 936 (Fed. Cir. 2007) ("[T]he claims use both means-plus-function language . . . and structural language . . . , which suggests that the patentee intentionally used 'means' language to invoke § 112, P 6.") (emphasis added).

The '657 application was filed with three claims, numbered 6 through 8. (Gallagher Decl. Ex. B at 5-11, 19, 139.) Claim 6 was the only independent claim. (Gallagher Decl. Ex. B at 10-11.) During prosecution of the '657 application, the examiner rejected claim 6 as "clearly anticipated" by U.S. Patent No. 4,447,222, issued to Santinoranont ("Santinoranont"). 14 In response to the rejection, the applicants canceled claims 6-8 and substituted claims 9-20, which are identical to claims 1-12 of the '787 patent. (Gallagher Decl. Ex. B at 150-53; '787 patent col. 4 11.5--col.6 1.3.) Claim 9, the only independent claim among the new claims, was similar to claim 6. 15 (Gallagher Decl. Ex. B at 150-53.) While the last element of claim 6 recited "means [] for opening the tulip-shaped part longitudinally," this language was replaced in claim 9 by "a housing part opener for opening said housing part independent of the self-expanding stent." (Gallagher Decl. Ex. B at 10, 150.)

14 Santinoranont is a patent for a "tampon inserter" device. The Santinoranont device includes an outer tube with a closed forward end and a tampon that is releasably attached to the forward end of an inner insertion tube. (See Gallagher Decl. Ex. B at 106-11.) The forward end of the insertion tube (with the tampon attached) is inserted into the outer tube and the tampon is pushed into through the closed forward end of the outer tube, rupturing it and permitting the tampon to be inserted into the vagina. (See Gallagher Decl. Ex. Bat 106-11.)

15 Claim 6 of the '657 application claimed:
[A] tool for fitting an auto-expansible endoprosthesis, characterized in that it comprises:

- a guide tube [ ] provided at its distal end with a tulip-shaped part [ ] for housing the endoprosthesis [ ] in the contracted state; and

- means [ ] for opening the tulip-shaped part longitudinally.

(Gallagher Decl. Ex. B at 10.) Claim 9 of the '657 application claimed:

A tool for fitting a self-expanding stent comprising:

a guide tube having a distal end;

a housing part for housing a self-expanding stent, said housing part provided at said distal end of said guide tube; and

a housing part opener for opening said housing part independent of the self-expanding stent.

(Gallagher Decl. Ex. B at 150.)

16 To distinguish claim 9 from Santinorant and overcome the examiner's rejection, the applicants argued:

The objects to be fitted by the present invention (e.g., a self expanding stent) have very little, if any, strength in the longitudinal direction. Therefore, these objects can not be pushed or otherwise used in order to open the housing part because, even if successful (which is doubtful), the objects would probably be damaged. Consequently, the tool of the present invention provides a housing part opener for opening the housing part independent of the objects housed therein.

The Santinorant reference discloses a tampon inserter including an outer tube housing a tampon. The forward end of the outer tube ruptures when the tampon contained therein is pushed against the forward end. This reference does not disclose a housing part with a housing part opener for opening the housing part independent of the object to be fitted (i.e., a tampon).

As discussed above, a tool with a housing part opener for opening the housing part independent of the object to be fitted is critical in order to prevent damage to the object.

(Gallagher Decl. Ex. Bat 153-54.)

The applicants' response to the rejection of claim 6 clearly indicates that the "housing part opener" element in claim 9 of the '657 application (which issued as claim 1 of the '787 patent) was not intended as a "means-plus-function" claim. The corresponding element in claim 6 ("means . . . for opening the tulip-shaped part longitudinally") is clearly drafted as in "means-plus-function" format--it includes the word "means" without any additional structure capable of performing the "opening" function. Biomedino, LLC v. Waters Techs. Corp., 490 F.3d 946, 950 (Fed. Cir. 2007) (noting that presumption arising from use of the word "means" can be rebutted if "the claim, in addition to the functional language, recites structure sufficient to perform the claimed function in its entirety" (quoting Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1375 (Fed. Cir. 2003))). In drafting claim 9, the applicants did not simply add "independent of the self-expanding stent" to the existing language of claim 6. Instead, they replaced "means" in claim 6 with "housing part opener" in claim 9. (Gallagher Decl. Ex. B at 10, 150.) The "means for opening" language of claim 6 demonstrates that the applicants knew how to draft a "means-plus-function" element and could have done so if they had intended. But the applicants reworded the claim without "means" language, signaling their intent to avoid construction of the "housing part opener" element under § 112 P 6.

The Court concludes based on the intrinsic and extrinsic evidence that "housing part opener" was not drafted as a means-plus-function element, and construes this language according to its ordinary meaning, "a device that opens."
ii. "for opening said housing part independent of the self-expanding stent"

Gore addresses the "independent of the self-expanding stent" limitation by asserting that, during prosecution of their patent, the applicants disclaimed all "tools that move the housing part by the action of the stent." (Gore Reply Br. 14.) Gore's argument is based on the fact that, after the examiner rejected claim 6 of the '657 application as anticipated by Santinoranont, the applicants amended their claims to add the limitation "for opening said housing part independent of the self-expanding stent" to the "housing part opener" element of new independent claim 9. (Gore Opening Br. 14-16; Gallagher Decl. Ex. B 139-55.) The applicants argued that this limitation rendered the amended claims patentable over the prior art, including Santinoranont:

As discussed above, a tool with a housing part opener for opening the housing part independent of the object to be fitted is critical in order to prevent damage to the object. The Santinoranont reference does not disclose a tool with such a feature. Therefore, it is respectfully submitted that the rejection raised by the Examiner is not applicable to new independent claim 9, and the claims that depend therefrom, with the additional limitation discussed above.

(Gallagher Decl. Ex. B at 153.); see also supra note 14-16.

Gore is correct that the scope of a claim "may be limited by a disclaimer in the specification or prosecution history." Atofina v. Great Lakes Chem. Corp., 441 F.3d 991, 997 (Fed. Cir. 2006) (citing Phillips, 415 F.3d at 1316-17); see also Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."); Omega Eng'g, Inc., v. Raytek Corp., 334 F.3d 1314, 1326 (Fed. Cir. 2003) (stating that disclaimer requires a "clear and unmistakable" disavowal during prosecution). However, the applicants did not disclaim housing parts that "spread out" or "unfold" by operation of the self-expanding stent, as Gore contends. (Gore Opening Br. 31-32; Gore Reply Br. 13-17.) As the amended claim language indicates, the applicants at most disclaimed all tools in which the housing part opener is not "independent of the object to be fitted."

Gore's argument is based on an incorrect construction of "open" to mean "spread out" or "unfold." Indeed, Gore clarified during the Markman hearing that its construction required that the self-expanding stent may not "push" the housing part apart when it expands. Instead, the housing part must expand "all by itself, automatically. . . . In other words, if the stent were constrained in some way . . . the housing part would still open up." (Oct 23, 2007 Tr. at 88:22-96:25.) Under Gore's interpretation, the housing part is "opened" when it expands radially outward, as it must in order to release the self-expanding stent.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

17 Though neither party construed "open" or "opener" in its claim construction briefs, it is apparent From the parties' arguments in support of their proposed constructions of the "housing part opener" element that Gore interprets "open" to mean "spread out" or "unfold" (Gore Reply Br. 13-I 7), while Perouse interprets this term to mean "create[] a separation" (Perouse Reply Br. 18-19).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

While "spreading out" is undoubtedly one of many permissible definitions of "opening" in common parlance, a person of ordinary skill would understand that a different meaning is used in the context of the '787 patent. The ordinary meaning of a claim term for purposes of claim construction is the meaning that is used by the applicant in the patent and prosecution history. See Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1319 (Fed. Cir. 2005) ("We cannot look at the ordinary meaning of the term . . . in a vacuum. Rather, we must look at the ordinary meaning in the context of the written description and the prosecution history."); Unitherm Food Sys., Inc. v. Swift-Eckrich, Inc., 375 F.3d 1341, 1351 (Fed. Cir. 2004), rev'd on other grounds, 546 U.S. 394, 126 S. Ct. 980, 163 L. Ed. 2d 974 (2006) (proper definition is the "definition that one of ordinary skill in the art could ascertain from the intrinsic evidence in the record").

The specification makes clear that "opening" of the housing part does not refer to the outward expansion of the housing part. For example, the abstract of the '787 patent describes "[c]utting threads [that] cause the housing to open longitudinally." ('787 patent Abstract.) The phrase "to open longitudinally" makes no sense if, as Gore maintains, "open" means "spread out"
or "unfold," because these actions require motion that is directed radially outward, not longitudinally.

Furthermore, the '787 patent describes two embodiments, which differ only in the "means for opening" employed by each. In one embodiment, the housing part is "opened" using "wires for separating, such as by cutting, the . . . housing part, into several petal-like parts, or sections." ('787 patent col.11.54-57.) In another embodiment, "longitudinal opening" of the housing part occurs when a cord is withdrawn from the series of gussets through which it passes. ('787 patent col.11.58-63, col.31.57-col.41.4.) In neither embodiment does "opening" refer to the expansion, "spreading out," or "unfolding" of the housing part. Instead, a person of ordinary skill in the art would understand that, in the context of the '787 patent, "opening" refers to the creation of an opening or separation in the housing part, a step which necessarily precedes and is distinct from the expansion of the housing part and stent.

Furthermore, the construction of "opening" relied upon by Gore to support its disclaimer argument is entirely inconsistent with its argument that the "cutting wires" and "interpenetrating gussets and longitudinal cord" are the structures that correspond to the "housing part opener" element that Gore contends is drafted as a means-plus-function element. In support of this argument, Gore argued that "cutting" and "longitudinal opening" (as performed by the cord and gussets) satisfy the "opening" function. Both "cutting" and "longitudinal opening" create an opening or separation in the housing part, but do not spread it out or unfold it.

Gore's proposed construction is also undermined by the fact that the '787 patent describes no mechanism by which the housing part might undergo radial expansion without the assistance of the self-expanding stent. For the tool of the '787 patent to operate according to Gore's proposed construction, something other than the self-expanding stent must provide the force that expands the housing part. Yet Gore does not dispute the fact that the '787 patent discloses no such mechanism, nor does Gore provide any explanation of its own. A person of ordinary skill in the art would be unlikely to interpret the patent so as to leave such an important aspect of the invention's operation mysterious and unexplained. This is especially true in this case, where an alternative explanation, that the self-expanding stent is the element that expands the housing part, is disclosed in the patent and is entirely consistent with the intrinsic evidence.

The prosecution history also confirms that "opening" does not mean "spreading out." The applicants argued that claim 9 in the '657 application was patentable over Santinoranont because the opener of claim 9 was independent of the object to be fitted, while the opener of Santinoranont was the object to be fitted, i.e., a tampon, which "opened" the device when it was pushed through the end of an outer tube, creating a separation or opening in the device. (See Gallagher Decl. Ex. B at 154.; see also supra notes 14, 16. The applicants noted that self-expanding stents had very little longitudinal strength and therefore could be damaged if "pushed or otherwise used in order to open the housing part." (Gallagher Decl. Ex. B at 106-111, 154.) It is clear that "opening," as used by the applicants in the prosecution history, does not refer to the radial expansion or "spreading out" of the stent and/or housing part because these actions do not implicate the longitudinal strength of the stent. Instead, the use of "opening" in the prosecution history is entirely consistent with the use of this term in the specification of the '787 patent. In the prosecution history, as in the specification, an "opener" is something that creates a separation or opening. As described in the prosecution history, the "opening" of the outer tube in Santinoranont does not involve "spreading out." In fact, the outer tube of the Santinoranont invention does not expand or "spread out" at all—it is "opened" when its forward end is ruptured, permitting the release of the object to be fitted.

Therefore, even if Gore is correct that the applicants expressly disclaimed any tool in which the self-expanding stent is used to open the housing part, Gore's proposed limitation is not consistent with this disclaimer. 18 If the applicants disclaimed any claim scope during prosecution, such disclaimer was incorporated explicitly into the amended claim language, which requires an opener that is "independent of the self-expanding stent." (See Gallagher Decl. Ex. B at 154 ("[T]he tool of the present invention provides a housing part opener for opening the housing part independent of the objects housed therein.").) That is, the effect of any disclaimer on the resulting claim scope is coextensive with the effect of the "independent of the self-expanding stent" limitation that is now part of claim 1 of the '787 patent. Indeed, the applicants indicated that this limitation was added to claim 9 of the '657 application for the purpose of distinguishing the amended claims from Santinoranont. The applicants distinguished their claims by pointing out that the object to be fitted in the applicants' invention "can not be pushed or otherwise used in order to open the housing part," in contrast to the tampon of the Santinoranont device, which "opens" the device when it is pushed through the outer tube, rupturing it. (See Gallagher Decl. Ex. B at 154.) Therefore, when the correct construction of "open" is applied, the language of the amended claim limits the scope of the element to "housing part openers" that do not use the self-expanding stent to create an opening or separation in the housing part.
18 Perouse correctly points out that "independent." as used in the claims and the prosecution history, is an adjective modifying the noun "opener" (Perouse Opening Br. 26; Perouse Reply Br. 14 n.6), not an adverb modifying the verb "opening" ("independently" is the adverb form), as Gore maintains (Gore Reply Br. 13-14 & n.11). However, neither interpretation supports Gore's position. Even if the limitation requires that the "opening" of the housing part must be performed independently, without using the self-expanding stent, the stent may still be involved in the housing part's expansion, because this is distinct from the "opening" of the housing part.

During the Markman hearing, Gore argued that Figures 6 and 8 of the '787 patent disclose a housing part that expands without the assistance of the self-expanding stent. These figures depict the stent and housing part of the tool in mid-expansion, after partial cutting of the housing part (in the case of the first embodiment) or partial withdrawal of the cord from the gussets (in the case of the second embodiment). Gore's argument is based on the fact that these figures show a gap between the stent and the housing part, indicating that the stent is not in contact with the housing part during expansion. (Oct. 23, 2007 Tr. 90:17-95:9.) The Court rejects Gore's argument. It would be obvious to a person of ordinary skill in the art that these figures were merely schematic in nature and were not intended to faithfully reflect every detail of the expansion process. Indeed, the patent explicitly states that Figure 8 is a "diagrammatic[]" representation of the second embodiment. ('787 patent col.3 11.57-58.) Furthermore, as discussed above, Gore's interpretation of these figures is inconsistent with the interpretation that emerges from the remainder of the specification and prosecution history. In light of the intrinsic evidence, it is far more likely that the separation between the stent and the housing part shown in these figures is not significant--it simply contributes to a cleaner diagram in which the reader can easily distinguish the elements.

However, even if Figures 6 and 8 were interpreted as literal representations of the operation of the invention, they would not support Gore's argument, which is based on an incorrect and unsupported construction of "opener." The drawings do not purport to represent "opening." In fact, the patent refers to Figure 6 as illustrating "release" or "expansion." ('787 patent col.3 11.39-40.) Even if the drawings did show release or expansion of the housing part occurring independently of the self-expanding stent (and they do not), this would be irrelevant to this discussion. No such limitation was made part of claim 1 and limitations found only in patent drawings do not alter the scope of otherwise unambiguous claim language.

Regardless what the drawings show, the claim term "housing part opener" is used consistently throughout the intrinsic evidence to refer to something that creates a separation or opening in the housing part, not something that spreads out, unfolds, or expands the housing part. The Court therefore rejects Gore's argument that the applicants' characterization of their invention as "a tool with a housing part opener for opening the housing part independent of the object to be fitted" disclaimed all tools in which the stent is used to spread out, unfold, or expand the housing part.

The Court therefore construes "independent of the self-expanding stent" to exclude from the scope of the "housing part opener" element any housing part opener that uses the self-expanding stent to create an opening or separation in the housing part.

Accordingly, the Court construes the phrase, "a housing part opener for opening said housing part independent of the self-expanding stent," to mean "a device that creates an opening or separation in the housing part, the device not using the self-expanding stent to create an opening or separation in the housing part."

"Hull":

The bottom portion of a sit-on-top kayak, with a bow and stern, generally V-shaped to create a deeper draft than a surfboard to obtain better tracking.
2010

A.

The trial court correctly discerned that the preamble "sit-on-top kayak" should be understood to limit all of the claims to a category of watercrafts and "in general, a preamble limits the invention if it recites essential structure or steps, or if it is 'necessary to give life, meaning, and vitality' to the claim." Catalina Marketing Int'l, Inc. v. CoolSavings.com, Inc., 289 F.3d 801, 808, 62 USPQ2d 1781, 1784 (Fed. Cir. 2002) (quoting Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 USPQ2d 1161, 1165 (Fed. Cir. 1999)). However, the trial court's explanation of what this limitation is, namely that a sit-on-top kayak has "a generally V-shaped hull portion and a deeper draft than a surfboard to allow better tracking," is not consistent with the plain meaning of the term as used in the patents. Old Town, 2001 U.S. Dist. LEXIS 19680, slip op. at 9. To ascribe a hull shape to "sit-on-top kayak" would be redundant in view of the first element of the independent claims that refers specifically to the sit-on-top kayak as comprising "a hull defining a hull outer surface." If "sit-on-top kayak" meant a craft with a particular hull, then it would be unnecessary to also claim a hull.

Similarly, the meaning of "hull" in the claims was improperly limited by the trial court. The written description is used to define but not limit terms in the claims. See LocTite Corp. v. Ultrasel Ltd., 781 F.2d 861, 867, 228 USPQ 90, 93 (Fed. Cir. 1985) ("That the specific examples set forth in the patents occur at room temperature does not mean that the claims are imbued with a room temperature limitation. Generally, particular limitations or embodiments appearing in the specification will not be read into the claims."). The trial court relied on the written description's statement: "the sit-on-top kayak is somewhat similar to a surfboard in overall shape, but normally has a generally V-shaped hull portion and a deeper draft to allow better tracking." Old Town, 2001 U.S. Dist. LEXIS 19680, slip op. at 8 (quoting the '177 patent, col. 1, ll. 25-28). There are two flaws in the trial court's reliance on this statement. First, the plain meaning of "hull" does not include a particular shape (V) because otherwise the phrase "V-shaped hull portion" would be redundant. Second, the contextual meaning of "hull" also cannot include a limitation on its shape because the qualifier "normally" precludes the term from always requiring a V-shape. In the claims, "hull" appears to be a generally descriptive term and as such the appellant is correct that it should be given its full meaning and no modifiers should be added. See York Prods., Inc. v. Central Tractor Farm & Family Cent., 99 F.3d 1568, 1572, 40 USPQ2d 1619, 1622 (Fed. Cir. 1996) ("Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning.").

Moreover, the interpretation of "sit-on-top kayak" in the preamble as having a particular hull shape and of "hull" in the claims to be "generally V-shaped to create a deeper draft than a surfboard to obtain better tracking" is directly contradicted by statements in the written description of the '912 patent describing particular embodiments. One such example is for the description of the fourth embodiment:

The bottom portion 418 of the kayak hull 412 may be any size, shape, and/or configuration as appropriate to provide a stable and efficient platform for movement of the kayak 410 through the water.

'912 patent, at col. 9, ll. 17-20 (emphasis added). As the appellant asserts, this is incompatible with the idea that the terms "sit-on-top kayak" and "hull" in the '912 patent require a particular shape. Our broader interpretation of "sit-on-top kayak" and "hull" is not solely for the '912 patent. The terms should be construed similarly in the '177 patent and the '063 patent because they use the same claim terms and, in fact, the preamble and the first line of the claims (referring to a "hull") are identical in all three patents. Also, all three arise from the same original patent application. The terms must be construed in the same way in all three patents. See Jonsson v. Stanley Works, 903 F.2d 812, 818, 14 USPQ2d 1863, 1869 (Fed. Cir. 1990) (holding that when two patents use the same claim terms the prosecution histories of both are relevant).

We, therefore, adopt the district court's construction of "sit-on-top kayak" and its function as a limitation of the claims with the exception of the clause "with a generally V-shaped hull portion and a deeper draft than a surfboard to allow better tracking." That we reject. Old Town, 2001 U.S. Dist. LEXIS 19680, slip op. at 9. The proper definition includes crafts with both displacement and planing hulls.

We agree with the plaintiff that "hull" refers to a structure that forms "the bottom of the kayak" because it is consistent with the usage of the term in the patent itself. We also note that none of the extrinsic evidence refutes this definition.

GO BACK
The devices at issue in this case -- pillows to place between the thighs to relieve musculoskeletal stress and pain while a person is sleeping -- are technologically unsophisticated. There are, however, two principal problems with the wording of the claims. These relate to: 1) the patent's description of the longitudinal axis of the patented pillow as being "a length no less than that of a human thigh," and 2) referring in claim 6 of the patent to "a cushioned device as defined in claim 7," when there is no claim 7 in the patent.

In my original order, I concluded that, notwithstanding potentially inconsistent claim constructions, a person skilled in the art can comprehend precisely what has been patented. On consideration of the patent in its entirety, including the written description, preferred embodiment, and diagrams, along with the claims, I concluded it is apparent that the longitudinal axis of the patented pillow is defined by reference to the thickness, rather than the length, of the human thigh. In light of this understanding, which I deemed to derive readily from the patent as a whole, I concluded that the patent was valid.

The defendant's motion for relief from judgment asks me to consider handwritten notations on a preliminary draft of the patent as evidence of the meaning that the draftsman intended to give to the longitudinal axis. Those notations make clear, the defendant asserts, that the lawyer overseeing the drafting of the patent instructed his associate to define the longitudinal axis of the device by reference to the thickness, rather than the length, of the human thigh. The associate failed to follow that instruction, and his error (using thigh length, rather than thickness as the benchmark) was caught by neither the lawyer submitting the patent, the inventor, nor the patent examiner.

To the extent that the defendant desires that I accept this evidence as proof of the patentee's intent, it is not admissible. The Federal Circuit expressly prohibits reference to extrinsic evidence of this sort in construing the meaning of a patent's terms. Markman v. Westview Instruments, Inc., 52 F.3d 967 (Fed. Cir. 1995) (en banc). The court noted that such extrinsic evidence would be admissible to clarify an ambiguity in a contract, will, or deed, and thereby to ascertain the intent of the parties to such instruments. But it also made clear that a "patent, however, is not a contract. . . and patent infringement actions have never been viewed as breach of contract actions." Id. at 985.

I do not, accordingly, consider this extrinsic evidence in construing the meaning of claims or determining the validity of the patent. At most, such evidence explains why the patent contains the language that it does; that evidence cannot, however, be used to construe the patent, or to support a finding of either validity or invalidity.

The Federal Circuit has made clear that it does not "permit courts to rewrite claims." Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999). Accord, Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1584 (Fed. Cir. 1995) ("Although we construe claims, if possible, so as to sustain their validity,. . .it is well settled that no matter how great the temptations of fairness or policy making, courts do not redraft claims."); Becton Dickinson & Co. v. C.R. Bard Inc., 922 F.2d 792, 799 n. 6 (Fed. Cir.1990) ("Nothing in any precedent permits judicial redrafting of claims. At most there are admonitions to construe words in claims narrowly, if possible, so as to sustain their validity.").

Despite the rigor of this stricture, I remain convinced that the equally fundamental obligation to "construe claims, if possible, so as to sustain their validity," Quantum, supra, justifies my original decision upholding validity in this case. No reader of the claims--much less, a reader skilled in the art--could read them, despite their poor draftsmanship, without understanding precisely what was patented.

The Supreme Court has instructed that courts "should proceed in a liberal spirit, so as to sustain the patent and the construction claimed by the patentee himself, if this can be done consistently with the language which he has employed." Klein v. Russell, 86 U.S. 433, 466, 22 L. Ed. 116 (1873). I confirm my earlier decision that the language employed in the patent here, even if poorly drafted, can be read to sustain the validity of the patent.

When the questionable language describing the longitudinal axis of the pillow is placed in context, it is apparent that the length of the pillow is described in relation to the thickness of a human thigh. The description of the pillow provides that the pillow is to be sandwiched between the legs of the user, and further describes two "leg engagement areas" wherein the thighs would be. If the legs are to be "engaged" in the pillow, then clearly the pillow would be as long as the thigh is wide. If the pillow were several inches longer, the legs would not be engaged by it. While a more careful description of the length
of the pillow should have been provided, it is apparent from the patent precisely what is being described: the pillow fits between the user's legs, and the concave "leg engagement areas" cradle and conform to the user's thighs.

As detailed in my earlier decision, the numerous diagrams included with the patent demonstrate that the longitudinal axis of the pillow corresponds to the thickness of the thigh rather than the length of the femur. Additionally, the suggested measurement for a "proper fit for most individuals" includes a longitudinal axis of ten inches. As discussed in my earlier decision, this measurement would relate to the length of the femur of two percent of adults. Thus, especially when construed in light of the pillow's orientation between the legs of the user, and the description that the pillow "engages" the leg, the length of the longitudinal axis must relate to the thickness of a typical human thigh.

Once the pillow has been placed between the legs in the manner described by the text and shown in the diagrams, the longitudinal axis runs parallel to a line from the user's navel to his back, not along his leg from his hip to his knee. Specifically, the length of the pillow corresponds to the thickness of the thigh, not the length of the femur. The text of the patent, the diagrams illustrating the product, and the specific measurements given as the proper fit for most individuals are all consistent with this interpretation.

The patent can reasonably be read as stating that the length of the pillow is not less than the length of the thickness of a typical human thigh. Such reading does not require me to create new terms in the text of the patent, but rather is the result of reading the terms of the patent in their proper context. 1

1 Even if a reading of the disputed language would ordinarily indicate that reference was made to the length of a typical femur, the patent as a whole makes clear the drafter's intended meaning. "The words of a claim will be given their ordinary meaning unless it appears that the inventor used them differently." ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988) (internal citation omitted).

The main issue presented by OrthoSupport on appeal is one of claim construction, specifically, whether the district court properly construed the claim limitation, "said longitudinal axis defines a length of no less than that of a human thigh." In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to use to "particularly point [] out and distinctly claim [] the subject matter which the patentee regards as his invention." 35 U.S.C. § 112, paragraph 2. See generally Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1331, 59 U.S.P.Q.2D (BNA) 1401, 1406-07 (Fed. Cir. 2000).

"It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996) (citation omitted). All intrinsic evidence is not equal however. See id. at 1582, 39 U.S.P.Q.2D (BNA) at 1576-77 (delineating a hierarchy among the intrinsic evidence).

First, we look to the claim language. See id.; Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 U.S.P.Q.2D (BNA) 1161, 1165 (Fed. Cir. 1999) ("The starting point for any claim construction must be the claims themselves."); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995) (noting first the mandate to consult the claims). Then we look to the rest of the intrinsic evidence, beginning with the specification and concluding with the prosecution history, if in evidence. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576-77 (delineating this order); Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321, 1329 (Fed. Cir. 1995) ("Claims must be read in view of the specification, of which they are a part."); aff'd, 517 U.S. 370, 370-71, 116 S. Ct. 1384 (1996); Bell Communications, 55 F.3d at 620, 34 U.S.P.Q.2D (BNA) at 1819 (noting first the mandate to consult the claims, followed by inspection of the rest of the specification).
If the claim language is clear on its face, then our consideration of the rest of the intrinsic evidence is restricted to
determining if a deviation from the clear language of the claims is specified. A deviation may be necessary if "a patentee
[has chosen] to be his own lexicographer and use terms in a manner other than their ordinary meaning." Vitronics, 90 F.3d at
1582, 39 U.S.P.Q.2D (BNA) at 1576. A deviation may also be necessary if a patentee has "relinquished [a] potential claim
construction in an amendment to the claim or in an argument to overcome or distinguish a reference." Elkay Mfg. Co. v.
Ebco Mfg. Co., 192 F.3d 973, 979, 52 U.S.P.Q.2D (BNA) 1109, 1113 (Fed. Cir. 1999). If, however, the claim language is
not clear on its face, then our consideration of the rest of the intrinsic evidence is directed to resolving, if possible, the lack
of clarity.

II.
The district court held that the length of the longitudinal axis of the patented pillow corresponds to the length of a human
thigh as measured from the front of a human (belly button side) to the back. The district court called this dimension the
"thickness" of the thigh. We conclude that this definition is consistent with the intrinsic record.

Looking first at the claim language, OrthoSupport contends that the plain meaning of the "length" of a human thigh refers to
the distance from one's hip to knee. However, a "length" does not necessarily refer to an object's longest dimension. The
Oxford English Dictionary provides the following three definitions for "length:"

1. The linear magnitude of any thing as measured from end to end; 2. the greatest of the three dimensions of a body or
figure; 3. longitudinal extent.

Oxford English Dictionary 893 (2d ed. 1989). Thus, the length as used in the claim can be the "distance from end to end" of
a person's thigh as measured along the longitudinal axis of the pillow when the pillow is placed between the person's thighs.
Alternatively, the length can be the greatest dimension of the thigh. Looking at the claim in isolation, the term is somewhat
ambiguous.

We next look to the specification, which provides only one reference to the disputed claim language.

Pillow 10 has a major longitudinal axis 100 extending through the medial section 12 and the end sections 14, 16 that
defines a length no less than a typical human thigh in the preferred embodiment.

771 patent, col. 3, ll. 53-56. Figures 1 and 5 show that the longitudinal axis 100 is oriented in the fore to aft direction of the
body when the pillow is placed between a person's thighs. When reading the claim in light of the specification, it is clear
that the claim term "length" refers to the "magnitude of [the thigh] as measured from end to end" along the longitudinal axis
of the pillow when in use. The dimension of the thigh along that axis is the dimension of a front to back diameter of the
thigh not the dimension from hip to knee, which is a dimension normal to the "longitudinal axis." While the definition of
"length" in the claim may be ambiguous on its face, our review of the specification, drawings, and prosecution history
indicates that the term "length" is only susceptible to the meaning recognized by the district court. Thus, the district court
correctly construed the claim consistent with the intrinsic record.

OrthoSupport cites Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357-59, 52 U.S.P.Q.2D (BNA) 1029,
1034-35 (Fed. Cir. 1999), for the proposition that if a claim term is susceptible to only one reasonable interpretation, and
that interpretation makes the claim "non-sensical," then the claim is invalid. While that statement of the law is accurate, it is
inapplicable to the facts of this case. In Process Control, this court rejected a patentee's argument that the exact phrase that
appeared in two different claim limitations had two different meanings within the same method claim. Id. at 1356-57, 52
U.S.P.Q.2D (BNA) at 1033-34. The court held that the phrase used in the same way in the same claim had to be interpreted
in the same way, and under that construction the claim "makes no sense." Id. at 1358, 52 U.S.P.Q.2D (BNA) at 1034. Thus,
the court held the claim invalid under 35 U.S.C. § 101 for lack of utility and under 35 U.S.C. § 112, paragraph 1, for lack of
enablement. Id. at 1359, 52 U.S.P.Q.2D (BNA) at 1035.

Here, the claim term "length" is only susceptible to one reasonable interpretation. Moreover, unlike Process Control, the one
interpretation does not make the claim "non-sensical." In fact, the district court's claim construction is the only construction
that makes sense. This is not a case where the same claim term requires two different meanings within the same claim to
make sense. The district court defined the claim term consistent with the intrinsic record and in a way that preserves the claim's validity.

OrthoSupport also contends that the district court should have considered handwritten notes in the prosecuting attorney's file regarding the disputed claim terms. We disagree. Because the claim language here is susceptible to a reasonable interpretation consistent with the intrinsic record, the district court properly did not consider the extrinsic evidence. See Key Pharms. v. Hercon Labs. Corp., 161 F.3d 709, 716, 48 U.S.P.Q.2D (BNA) 1911, 1917 (Fed. Cir. 1998). Furthermore, notes of a patent attorney which do not appear in the prosecution history are of little or no probative value. Cf. Markman, 52 F.3d at 985, 34 U.S.P.Q.2D (BNA) at 1334 (Fed. Cir. 1995) ("The subjective intent of the inventor when he used a particular term is of little or no probative weight in determining the scope of a claim (except as documented in the prosecution history.").

2. A hydraulic power unit

I conclude that the term "a hydraulic power unit" as used in claim 1 of the '935 patent means a group of hydraulic components, including a hydraulic fluid reservoir, a pump and lift hydraulic cylinder. The parties dispute whether the claim term should be construed to be a "unitary" hydraulic power system. I agree with plaintiff that adding the word "unitary" to describe the hydraulic components adds nothing but confusion to the construction of the term and would be an improper reading of a limitation from the specification into the claim.

Defendant contends that referring to the hydraulic components as "a unitary hydraulic power system formed on a base" merely defines "unit" as the term is used in claim 1. (It maintains that its plows lack a "unitary hydraulic power unit." Def.'s Br., dkt. # 72, at 20.) However, defendant's reference to a "unitary hydraulic power unit" makes it clear that "unitary" is intended to express something in addition to "unit." The additional something expressed by the use of the word "unitary" is the concept of locating the hydraulic components on the same base or confining them to a single structure.

Defendant cites the Summary of the Invention in the specification to support its contention. Therein lies the problem. "[L]imitations from the specification are not to be read into the claims." Golight, 355 F.3d at 1331. The specification provides a preferred embodiment, but the scope of the claim term depends on the claim and not a preferred embodiment. Kara Technology Inc. v. Stamps.com Inc., 582 F.3d 1341, 1347 (Fed. Cir. 2009) ("The claims, not specification embodiments, define the scope of patent protection."). Nothing in the patent suggests that the patentee was acting as his own lexicographer or disavowing claim scope when he used the term "unit." Patentees are not required to provide an example of every embodiment of a claimed structure in a patent's specification. By itself, the disclosure of only one embodiment does not justify limiting a claim's scope to that single disclosed embodiment. Abbott Laboratories v. Sandoz, Inc., 566 F.3d 1282, 1290 (Fed. Cir. 2009). Thus, although the hydraulic power unit as claimed in the patent requires certain hydraulic components, the claim does not require locating those components on the same base. In other words, nothing in the patent limits the hydraulic power unit to a unitary system as defendant has proposed.

In addition to its unitary argument, defendant contends that a proper construction of a hydraulic power unit should state that it does not include the manifold. Such an addition is unnecessary. Claim 1 recites "said manifold connected to and mounted on said hydraulic power unit." 935 pat., col. 6, Ins. 62-63. This portion of the claim makes it clear that although the manifold is separate from the hydraulic power unit, it must be connected to and mounted on it. Therefore, it would be superfluous to say that the manifold is not included in the construction of "a hydraulic power unit."

2014

d. "hydraulically full"

The term "hydraulically full" appears in Claims 1, 55, 57 and 58 of the '532 patent. CFMT asserts that the term means that the process vessel becomes completely filled with one or more process fluids. YieldUP, on the other hand, asserts that the term "hydraulically full" requires that the vessel lack voids, dead ends, blind spots, or other surface irregularities within the
vessel.

The specification of the '532 patent states that "hydraulically full" means that the wafer vessel becomes completely filled with process fluids. The specification goes on to say that "the vessel should not have blind spots, dead-ends, interior surface irregularities or the like where a process fluid or ambient atmosphere could be trapped." In the prosecution of the '123 patent, which also contains the term "hydraulically full," McConnell and Walter clarified the ambiguity.

As pointed out in the specification . . . it is important that the design of the wafer vessel permits it to become hydraulically full of fluid during the processes of the present invention. Thus the vessel should not have blind spots, dead ends, interior surface irregularities or the like, where a process fluid or ambient atmosphere could be trapped.

The inventors relied on this definition of hydraulically full to distinguish their invention from the prior art. Therefore, the court finds, as advocated by YieldUP, that "hydraulically full" means completely filled with process fluid such that there are no blind spots, dead-ends, interior surface irregularities or the like, where a process fluid or ambient atmosphere could be trapped.

2015

1. "Hydrophilic lens body"

The plaintiff proposes "a lens body, which is the interior core portion of a contact lens, that is capable of attracting and absorbing water." The plaintiff claims that "hydrophilic" in this context means "capable of attracting and absorbing water." The defendants propose "the hydrophilic core lens which, in a hydrated state, prior to surface treatment has an already highly hydrophilic surface as measured by the advancing contact angle measurement." The defendants claim that "hydrophilic" means "having a surface having an affinity for water as measured by the advancing contact angle measurement." The main disputes are 1) whether "lens body" includes the surface and 2) whether the hydrophilic nature of the lens body needs to be determined by the contact angle measurement.

The defendants argue that the "lens body" includes the surface because the invention is directed to contact lenses already having hydrophilic surfaces. See '327 patent, 2:59-65. The defendants also contend that the '327 patent only describes contact angle as a means for determining the hydrophilicity of the contact lens surface. '327 patent, 3:11-13. The defendants point to extrinsic evidence to show that contact lens practitioners measure wettability through the contact angle.

Although the invention is directed to contact lenses with hydrophilic surfaces, the claim refers to a contact lens having two structures, a "hydrophilic lens body" and a "tear-wettable surface layer." '327 patent, 8:8-9. In addition, the intrinsic evidence does not support placing a contact angle limitation for measuring wettability. The patent specifically states that an example of acceptable wettability is determined based on contact angle. '327 patent, 3:11-13.

The Court construes "hydrophilic lens body" to mean "a lens body, which is the interior core portion of a contact lens, having an affinity for and capable of absorbing water."

2016

5. "Hydrophobe Precursor"

Claim 16 of the '693 patent also refers to a "hydrophobe precursor." That claim states in part, "said pellicle having been formed by application of an aqueous mixture of a hydrophobe precursor to the surface of a sheet of absorbent material." (Emphasis added.) Fort James suggests that this term has plain meaning to a POSITA and requires no interpretation. 54 Coating Excellence suggests that the term should be construed to mean "any organic material combining a site reactive toward starch or cellulose with a long hydrophobic tail and having a surface energy of less than 35 dynes/cm when applied to fibers on the surface of the inner absorbent layer." 55
The specification for the '693 patent, in a number of locations, describes the use of a hydrophobe precursor to form the foraminous hydrophobic water-vapor-permeable pellicle. (E.g., '693 patent, col. 2, lines 7-9; col. 4, lines 60-65.) The specification describes "the most convenient method of forming" the pellicle. (Id., col. 7, lines 28-47.) The specification explains that "typically" there will be a surface energy of less than 35 dynes/cm. (Id., col. 7, lines 47-50.) The specification then goes on to describe broadly what a hydrophobe precursor "may be": "Broadly speaking, a hydrophobe precursor may be any organic material combining a site reactive toward starch or cellulose with a long hydrophobic tail such as, for example, a C14-C18 carbon chain length." ('693 patent, col. 8, lines 1-4.) The inventors further identify specific types of chemicals that should be considered "a hydrophobe precursor" and set forth a typical structure for a "hydrophobe precursor." ('693 patent, col. 8, lines 4-52.)

The relationship between the hydrophobe precursor and the resulting pellicle is plain from the language of claim 16. It is, therefore, a close call whether any construction is necessary. However, to avoid any confusion by a juror regarding what a precursor is, the undersigned recommends the following construction: "A precursor is a material from which another material can be formed. A hydrophobe precursor may be, but is not limited to, any organic material combining a site reactive toward starch or cellulose with a long hydrophobic tail, as well as the specific hydrophobic precursors identified in the specification of the '693 patent and materials having the structure of the hydrophobe precursors disclosed in the specification of the '693 patent."

In short, while certain aspects of Coating Excellence's construction are mentioned as embodiments of the invention, the undersigned finds that the specification does not limit the term "hydrophobe precursor" to such embodiments.

The meaning of the term "hypotenuse" is not disputed. Accordingly, the court concludes that "hypotenuse" means "the edge of a triangular cutting surface tooth opposite the interior angle of the triangle that is closest to ninety degrees."
10. Identical

The parties do not agree on the proper interpretation of "identical" in claims 1, 15 through 17, 15 through 20, 23, 29, 31, 37 through 38, 41 through 42, 50, 59, and 65 of the '486 patent and claims 1 through 3, 10 through 12, 23, 27 through 28, and 30.

Unilin takes the position that "identical" means "essentially the same or having the same origin." (Unilin Open. Br. 22-24.) Alloc states that "identical" means "the same." (Alloc Initial Mem. 16-17.) (citing Merriam Webster's On Line Dictionary and Lampi v. Am. Power Prods., No. 93-C-1255, 1997 U.S. Dist. LEXIS 9942, 1997 WL 392239 *7-*8 (N.D. Ill. July 8, 1997).) Unilin maintains that Alloc's proposed construction of "identical" for the claims in which "identical" modifies "one of said panels" is insufficient. At the Markman hearing, Alloc stipulated that "identical" did not rule out minor machining variations.

The term "identical" appears in claim 1 of the '486 patent as follows:

said coupling parts configured to cooperate by coupling with cooperative coupling parts of an identical one of said panel;
said coupling parts comprising a tongue and a groove configured to lock together coupled identical ones of said panel in a direction perpendicular to the plane of the coupled panels when cooperative coupling parts of the panels are engaged, . . . said locking elements including cooperative contact surfaces arranged to be engaged when adjacent identical ones of said panel are coupled together with their coupling parts cooperatively engaged to prevent substantial separation of two coupled identical ones of said floor panels at said upper side edges in a direction perpendicular to the edges of the panel sides and parallel to the undersides of the coupled floor panels; . . . said cooperative contact surfaces defined respectively by said protrusion and said recess, and configured, when engaged in a cooperative relationship upon coupling in a common plane of two identical ones of said panel,

('486 patent, 13:58-64; 14:3-21)(emphasis added.)

It is well established that if more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all consistent meanings. See Brookhill-Wilk 1, LLC. v. Intuitive Surgical, Inc., 334 F.3d 1294, 1300 (Fed. Cir. 2003). In support of its contention that more than one meaning of "identical" is consistent with the specification, Unilin cites four excerpts of language found in the "Brief Summary of the Invention" portion of the '486 patent specification, (1:66-2:22; 2:38-40; 3:19-22; 4:9-10.) Unilin also cites claim 61 of the '486 patent -- a "method" claim. Unilin has not articulated why it believes the cited portions of the specification and claim 61 support its contention. Unilin has not persuaded the Court that more than one meaning of "identical" is supported by the specification.

Both proposed definitions of "identical" are consistent with dictionary definitions of identical. However, the definition of "identical" as meaning "the same" comports best with the use of "identical" in the patent claims and specification. Unilin's definition would add ambiguity. Therefore, the Court construes "identical" as meaning "the same," noting that such definition does not rule out minor machining variations.

II. Identical

As previously noted, Claims 1 and 11 of the '875 patent describe "two separable, identical half shells" while Claim 10 of the '227 patent provides for "two separable half-shells, both half-shells being identically shaped." (App. To Def.'s Markman Br. Ex. A at Col. 4, L. 26 and Col. 5, L.L. 24-25; Ex. B at Col. 5, L.L. 6-7)(emphasis added). There is no dispute that "identical" modifies "half-shells." The only question is the extent of that limitation.

Lampi asserts that "identical" should be interpreted to allow for small differences between the half-shells. Thus, Lampi contends, we should define "identical" as similar or having such close resemblance as to be essentially the same. APP responds that the customary and ordinary meaning of "identical" is the same or exactly alike so that the half-shells are interchangeable.
Once again, we begin with the ordinary and customary meaning of "identical." We believe that meaning is the same or exactly alike. To depart from this meaning, there must be some indication in the claims or specification that the patentee intended a different one. Based on our review of the patents, that is not the case here. Claims 3 and 14 of the '875 patent and Claim 5 of the '227 patent describe half-shells that "are injection molded parts made of plastic." (App. To Def.'s Markman Br. Ex. A at Col. 4, L.L. 32-33 and Col. 6, L.L. 2-3; Ex. B at Col. 4, L. 53). The specifications explicitly provide that the product can be cost-effectively produced using injection molded half-shells and that "both half shells are identically shaped so that they are interchangeable." (App. To Def.'s Markman Br. Ex. A at Col. 2, L.L. 16-21; Ex. B at Col. 2, L.L. 19-24).

Reading the claims in light of the specifications of which they are a part, as we must, it is clear that "identical" means half-shells which are exactly alike or the same so as to be interchangeable.

Moreover, Lampi's interpretation that the half-shells should only be similar and allow for small differences renders the term "identical" meaningless or mere surplusage. Indeed, the term "half" already implies some degree of similarity between the two shells--though not exact similarity as two halves are not necessarily exact in every detail. Thus, if the patentee intended to claim similar half-shells having small differences, he could easily have omitted the term "identical" from the '875 patent and inserted "similar" or "essentially the same." Even more telling is the patentee's use of "identical" in the '227 patent--the continuation of the '875 patent. The patentee explicitly claimed "two separable half-shells, both half-shells being identically shaped." (App. To Def.'s Markman Br. Ex. B at Col. 5, L.L. 6-7)(emphasis added). We will not simply read that term out of the claims by interpreting it as merely similar or allowing for small differences. Rather, we find that the patentee claimed half-shells which are the same or exactly alike both functionally and structurally.

Accordingly, we conclude that the term "identical," when used in the context of "identical half shells" or "half-shells identically shaped," means the same or exactly alike.

2020

The primary claims terms at issue are "positional coordinates," "identification of a position" and "relative to" in independent claims 1, 17 and 26. The patent's specification (together with the plain language of the claims and the prosecution history) mandates the court's construction of "positional coordinates" as "a set of coordinates defining a single reference point within a corresponding geographic vicinity which operates to determine the corresponding geographic vicinity." CIVIX slip op. at 35. CIVIX argues that the term should be construed to refer to any "collection of values sufficient to identify a vicinity . . .". This argument reads out the word "coordinates" in the claim, and is contrary to the repeated language and examples in the specification and the claims stating that the positional coordinates represent a single location, within a vicinity. (See '525 patent, col. 5, II. 16,17 ("The positional coordinates locate one location within the geographic vicinity . . ."); col. 8, II. 36-38 (stating that figure 4A "illustratively shows the positional coordinates . . . for each vicinity . . ." and depicting geographic vicinities each centered around positional coordinates). Figures 3A and 3B are limited to the user display and do not correspond to the "positional coordinates" limitation of the claims. The Semple letter in the file history, which the inventor with counsel chose to include in the '525 patent's public record, further confirms this construction.

Similarly, the district court also properly construed the term "relative to" ("identification of a position . . . relative to the positional coordinates and other items of interest . . .") to denote that the "information transmitted to a user of the system displays the items of interest only relative to the positional coordinates" in an internal grid system, as opposed to absolutely, such as by reference to that item of interest's latitude and longitude. CIVIX slip op. at 40. The prosecution history, together with the claims language, require this construction. CIVIX amended independent claims 1, 17 and 26 by adding the limitation "relative to" in order to overcome an examiner's rejection for indefiniteness, which stated that "the position of an . . . item . . . can be absolute or relative. If the position is meant to be relative it is necessary to distinctly point out the relativity."

CIVIX argues this construction renders the GPS embodiment unworkable, because the system would have to store nearly an infinite number of positional coordinates for each item of interest to allow for continuous redefinition, and because, by referring to a GPS system, the specification implicitly references the use of a system such as latitude and longitude to define a position. However, as the district court's opinion thoroughly discussed, the prosecution history, the overall structure of the specification and the appended source code (which only provides for the user to select a pre-defined area of interest, and not define the positional coordinates himself), as well as the extrinsic evidence, all lead to the conclusion that the claims identify the position of the item of interest in relation to an arbitrary reference point, not by its "absolute" location in a
generally accepted coordinate system. There is no indication in the record that the GPS embodiment stores or transmits location using latitude and longitude. Even if there were, the GPS embodiment was described prior to the claim amendment, and remained in the specification without modification. If the GPS embodiment uses absolute positioning, it falls outside the amended claims and is dedicated to the public. Moreover, as further discussed below, even if CIVIX' claims encompassed the use of latitude and longitude as positional coordinates, defendants' systems still would not infringe because they do not locate each item of interest through "positional coordinates" of a reference point other than that of the item of interest searched by the user, and they do not locate their geographic vicinities by reference to such positional coordinates.

Finally, the considerations requiring the construction of the above two terms together mandate the construction of the term "identification of a position" as "coordinates defining a location using the positional coordinates of the vicinity as a reference." CIVIX slip op. at 41.

2. "IDENTIFICATION STRUCTURE"

The term "identification structure" appears in independent claims 1,9,14, and 18 of the 537 patent and independent claims 1 and 10 of the 728 patent. Claim 1 of the 537 patent states that:

the special lock [would have an] identification structure associated therewith that matches an identification structure previously provided to the luggage screening entity, which special lock the luggage screening entity has agreed to process in accordance with a special procedure…the identification structure signaling to a luggage screener of the luggage screening entity who is screening luggage that the luggage screening entity has agreed to subject the special lock associated with the identification structure to the special procedure…the luggage screening entity acting pursuant to a prior agreement to look for the identification structure while screening luggage and, upon finding said identification structure on an individual piece of luggage, to use the master key previously provided [to open the luggage].

537 patent, col. 6, 11. 14-19, 23-29 & 31-37. Claims 4 and 6, dependent to claim 1, contemplate the identification structure being located directly or formed integrally with the special lock. Claim 9 is nearly identical to claim 1 but the special lock would have a first lock as opposed to a combination lock (covered by claim 1). Claim 14 and dependent claim 15 contemplate a special lock with a combination lock portion and a master key lock portion, where the identification structure is integrally formed with the special lock, while claim 18 covers the same scope as claim 14 but contemplates a special lock with a first lock portion and a master lock portion. Claim 1 of the 728 patent, with respect to the term "identification structure" in sum and substance resembles claim 1 of the 537 patent, but replaces references to "airline baggage," "airline luggage inspection," "luggage screener," and "luggage screening entity" with "carrier baggage inspection," "baggage screening entity," and "baggage screener". Similarly, as with the 537 patent, claims 4 and 5, dependent to claim 1, contemplate the identification structure described in claim 1 as being integrally formed with the special lock where the signaling from the identification structure is visual. Claim 10 of the 728 patent resembles claim 1 in sum and substance but contemplates a first lock portion as opposed to a combination lock portion.

Tropp's proposed construction for identification structure is "indicia associated with a lock that signals to a luggage or baggage screener that the lock is subject to a special screening procedure." Travel Sentry's proposed claim construction for "identification structure" is "an indicia such as a marking, stamping, etching, casting, molding, labeling, inscribing of an alphanumeric symbol, logo, or other distinctive marking." Tropp contends that Travel Sentry's proposed construction only provides examples of indicia but does nothing to further construction of the term "identification structure". (Def.'s Br. 9). Travel Sentry acknowledges that the term "indicia" is a broad term and argues that the specifications use the term "indicia" in referring to the identification structure but does not otherwise distinguish its definition from Tropp's beyond asserting that Tropp's proposed construction is "imprecise, circular, and inappropriately vague." (Pl.'s Br. 8).

The claim language in both the 728 and 537 patents contemplate that "identification structure" is broader than the examples offered by Travel Sentry. The patents-in-suit provide for embodiments where the identification structure may be "located directly" on the special lock, or "integrally formed" with it. The claims do not support limiting identification structure to "an indicia such as a marking, stamping, etching, casting, molding, labeling, inscribing of an alphanumeric symbol, logo, or other distinctive marking." The specification to the 728 patent states that "indicia" is a "broad term and can also include the
special lock itself... a distinctive physical characteristic such as shape, texture, weight and/or other characteristic such as color, that makes it instantly recognizable by individuals... [a]lternatively, a distinctive chemical or electronic characteristic can be used - in short, any distinctive characteristic that can be instantly recognized by persons looking for it." 728 patent, col.4, 11. 44-55. The 537 patent also supports a broad reading of the identification structure. 537 patent, col. 4, 11. 1-16, col. 5, 24-31.

The specifications, therefore, do not support reading Travel Sentry's proposed limitations into the claim terms. See Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988). Read in light of the specifications, the claims clearly contemplate that the identification structure may be associated with a lock (e.g., on a tag near the lock), on the lock, or the identification structure can even be the lock itself. The examples enumerated by Travel Sentry in its definition do not appear in the claims nor are they even acknowledged in the patents' specifications. Accordingly, the Court finds that grafting these examples onto the definition serves no purpose and would, in any event, be misleading. To that end, the Court adopts Tropp's construction and construes "identification structure" as indicia associated with a lock that signals to a luggage or baggage screener that the lock is subject to a special screening procedure.

I. Claim 1: "an identifying feature"

Claim 1 of the '423 Patent provides:

A saw chain comprising:

. . . . at least one link in the sequence of links provided with an identifying feature that causes that link to visually stand out from other links performing a similar function in the saw chain, said feature provided such as to enable that link to be identified by a user regardless of wear to the saw chain . . . .

(disputed term emphasized).

Defendants contend the disputed term means "[p]ermanent coloration or shape of the identifying link causes the link to visibly stand out regardless of dirt or wear on the chain." Defendants note the '423 Patent's specification describes a link for a saw chain that can be readily discerned by a feature that does not wear off after use. '423 Patent col.1 ll.31-39 (filed Aug. 26, 1997). "In a preferred embodiment, the link is a tie strap that is coated with zinc finish that is noticeably different in appearance than the other links of the chain." '423 Patent col.1 ll.51-53. These portions of the specification, however, do not support Defendants' construction. The disputed term merely requires an identifying feature that causes the link to visually stand out from other links that will enable that link to be identified by a user regardless of wear to the saw chain. This Claim 1 term does not make any reference to permanent shape or coloration. Moreover, the specification demonstrates neither permanent shape nor color is required by this portion of Claim 1. In addition to a preferred embodiment zinc-coated link, the specification provides "[o]ther finishes or even a modified link configuration will enable the user to identify the link." '423 Patent col.1 ll.54-58.

 Plaintiffs contend the disputed term is clear on its face and, therefore, can be understood by its ordinary meaning. The Court agrees.

The Federal Circuit has held the task of construing claims is not always difficult:

In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words.

Acumed, 483 F.3d at 805 (quoting Phillips, 415 F.3d at 1312). Here the ordinary meaning of the disputed term is apparent from reading Claim 1. Contrary to Defendants' assertions, there is not any reason to conclude that the required "identifying feature" referred to in Claim 1 must necessarily be either a permanent color or a permanent shape.
Moreover, the dependent Claim 2 sets out that "one link is provided with a wear resistant coating that provides that link with a different appearance." '423 Patent col.4 ll.21-23. Even if the meaning of Claim 1 were not readily apparent, Claim 2 clarifies a particular, permanent coloration of coating is not required. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1369 (Fed. Cir. 2007)(under the doctrine of claim differentiation, different words or phrases in different claims presume different meanings or scope).

Claim 1 is clear on its face and relatively straightforward. It merely requires

an identifying feature that causes that link to visually stand out from other links performing a similar function in the saw chain, said feature provided such as to enable that link to be identified by a user regardless of wear to the saw chain

Accordingly, Court finds this term is understood by its ordinary meaning alone.

2023

11. If Said Operation of Said Vacuum Pump is Interrupted

Claim 14 of the '553 patent provides: "a reserve vacuum assembly coupled to said positioning ring to sustain the vacuum within said cavity if operation of said vacuum pump is interrupted as the head moves across the aperture." 28 Defendants request that this court construe the term to mean: "the trigger for using the reserve vacuum assembly is interruption of the operation of the vacuum pump." (Defs.' Br. at 59.) Plaintiff objects to the use of the word "trigger," and contends that: "To the contrary, in the preferred embodiment, the reserve vacuum assembly is a vacuum tank that "maintains" the vacuum upon pump failure-it need not be "triggered" by interruption of the operation of the vacuum pump." (Pl.'s Reply Br. at 48) (emphasis added). This argument, however, supports the insertion of the word trigger. In other words, even according to plaintiff's own contention, the tank of the preferred embodiment only maintains the vacuum in the event that the pump fails and thus the operation of the vacuum pump is interrupted as recited in the claim language. The inverse of that conclusion is that unless and until the pump fails, the vacuum is not maintained by the reserve tank. Thus the trigger for the maintenance of the vacuum by the reserve tank is in fact the failure of the pump to operate. The specification of the '553 patent does not indicate otherwise: "In the event that the operation of the vacuum pump is interrupted, such as due to a power loss, the reserve tank 215 is preferably structured to maintain a sufficient vacuum to continue the positioning ring's hold on the eye until the movement of the cutting head assembly 50 over the eye is completed." Col. 19, Ins. 10-15. Therefore, I therefore conclude that defendants have proposed an accurate construction of the term: the trigger for using the reserve vacuum assembly is interruption of the operation of the vacuum pump.

28 This Court above construed the term "reserve vacuum assembly" to mean: "the structure, including but not limited to a tank, to one of ordinary skill in the art that is a reserve source of vacuum."

</table>
tested and using equipment such as a lens to provide an image of the pupil to an image plane such as the image plane of a camera, for use in later steps of Claim 9

creating an illumination or brightness inside the pupil which forms an image of the pupil and determining whether the person's pupil is centered and located at the correct distance from a testing instrument such that the illuminated image of the person's pupil formed on an image plane has sufficient intensity and distribution of light falling on a video camera to perform the impairment test

aa. "Illuminating a subject's pupil"

Although Defendant proposed two alternative constructions in its pre-hearing brief, counsel chose to focus exclusively on the second at the hearing. 3 Plaintiff's proposed construction relies primarily on ordinary meaning, supplemented with dictionary definitions. Defendant contends that the literal meaning of this phrase is inoperable because the pupil of the eye is in fact a hole, which is not a structure that can, by itself, reflect light back to the image plane. (Paper 76, at 11). Defendant's expert Mr. Kielar stated that "simply casting light specifically at the pupil of the eye will not yield any image on the image plane and would serve no purpose to the instrument." (Id.).

bb. Preferred Construction

**Plaintiff's construction is the better choice.** Defendant's position appears to be that the claims must be limited to the preferred embodiment in part because a broader claim would not work. First of all, the preferred embodiment never limits or confines the claims unless the claim language so states:

In particular, the Federal Circuit has "repeatedly warned against confining the claims" to the specific embodiments, or examples, of the invention that the inventor has provided in the specification. Phillips, 415 F.3d at 1323; see Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1308 (Fed. Cir. 2003) ("The general rule, of course, is that claims of a patent are not limited to a preferred embodiment, unless by their own language."). As the court pointed out in Acumed, the "preferred embodiment cannot be the only product covered by the claims; if it were, the claims themselves would be unnecessary." 483 F.3d at 809. Importantly, this principle generally holds true even where the specification discloses only a single preferred embodiment: the Federal Circuit "ha[s] expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." Phillips, 415 F.3d at 1323 (citing Gemstar-TV Guide Intern., Inc. v. Int'l Trade Com'n, 383 F.3d 1352, 1366 (Fed. Cir. 2002)).

3 The first was: "illuminating with a light the pupil of the person being tested and determining whether the person's pupil is centered and located at the correct distance from a testing instrument such that an image of the person's pupil formed on an image plane has sufficient intensity and distribution of light falling on a video camera to perform the impairment test."
Second, Defendant's assertion that the only way to implement the method is that in the preferred embodiment does not necessarily make it so. While "an assertion by the patentee that [the embodiment] is the only way to maintain the needed traction force would evidence an intention to narrow the scope of independent claims, see The Saunders Group, Inc. v. Comfortrac, Inc., 492 F.3d 1326, 1332 (Fed. Cir. 2007), there is no such assertion in this patent.

Mr. Kielar states:

The pupil of the eye, however, is a hole, it is not a structure which can possibly, by itself, reflect light back to the image plane. Simply casting light specifically at the pupil of the eye will not yield any image on the image plane and would serve no purpose to the instrument. It is only through the generation of the backscattered light exiting the pupil, that the pupil can be said to be "illuminated" or lit up for the purposes of imaging. Therefore, the step of "illuminating a subject's pupil" must embody the backscattering technique described in the '690 patent or some equivalent.

(Paper 76, Ex. A., Kielar Expert Report, at 3). Defendant and Mr. Kielar simply rely too much on the technique included in the preferred embodiment, and are distracted by their position as to why the PassPoint.net scanner differs from Plaintiff's. The claim terms are much simpler than Defendant would wish: illuminating means causing light to shine on something, here the pupil of the eye. 4

4 Plaintiff points out that other patents use similar language of "illuminating a pupil." It is unclear that the claims in those patents are describing similar methods, but at a minimum they demonstrate that there may well be more than one way to "illuminate a pupil."

cc. "Focusing an image of the subject's pupil on an image plane"

Defendant contends that in order for the illumination or brightness inside the pupil to be "focused," a two part determination must be made: (1) whether the person's pupil is centered from a testing instrument and (2) whether the person's pupil is located at the correct distance from the testing instruments. (Paper 76, at 14). If both of these conditions are met, Defendant argues that the illumination or brightness inside the pupil has sufficient intensity and distribution of light to be "focused" and captured on a video camera to perform the impairment test. (Id.). If these conditions are not met, Defendant asserts that the pupil image will become defocused. (Id. at 15).

Plaintiff disputes Defendant's construction and argues that the specification of the '690 Patent uses the term focus in its ordinary sense. (Paper 80, at 9). Thus, Plaintiff argues that the court should adopt the plain meaning of the term. (Id.). Plaintiff points out that in Webster's Dictionary, the term focusing means "to bring into focus" or "to adjust the focal distance of (the eye, a lens, etc.)" in order to produce a clear image." (Paper 68, at 13). In addition, Plaintiff asserts that Defendant's proposed construction requires the use of an eye imaging apparatus that is present in the preferred embodiment of the specification but that is not called for by the language of Claim 9. (Paper 80, at 8). Plaintiff argues that even if Defendant were correct to characterize eye imaging acquisition as part of focusing, Defendant's construction is still incorrect because it imports a limitation, the use of described eye image acquisition apparatus, from the preferred embodiment into the claim. (Id. at 9). See Glaxo Wellcome Inc. v. Andrx Pharms., Inc., 344 F.3d 1226, 1233 (Fed. Cir. 2003) ("as a general rule claims of a patent are not limited to the preferred embodiment . . . or to the examples listed within the patent specification.")(internal citation omitted).

The parties agree on the meaning of an image plane.

dd. Preferred Construction
Plaintiff's proposed construction is adopted because it is concise, closely resembles the original language of the claim, and comports with the ordinary meaning of the claim language. See Phillips, 415 F.3d at 1313.

2. "illumination optical system" 18

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

18 Claim 3 notes:

A method according to claim 2, wherein: said at least first and second light beams are inclined at a substantially same angle determined in accordance with fineness of said pattern with respect to an optical axis of an illumination optical system through which said at least first and second light beams pass.

Id. at 18:32-37. Claim 4 reads:

A method according to claim 3, wherein: said angle is determined so that non-0-order diffracted beams produced from said pattern by the irradiation of said first light beam pass apart from the optical axis of said projection optical system on said Fourier transform plane.

Id. at 18:38-43. Claim 7 continues:

According to claim 5, wherein: said at least first and second light beams are generated from portions apart from an optical axis of said illumination optical system on the Fourier transform plane in said illumination optical system with respect to said pattern.

Id. at 18:54-59. Claim 8, in turn, reads:

A method according to claim 7, wherein: said portions include 2n portions of which distance from the optical axis of said illumination optical system is substantially same (where n is a natural number).

Id. at 18:60-63.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

ASML and Nikon agree that the definition of the term "illumination optical system" should denote, in some way, a system constituting a component, or group of components, that directs or otherwise acts on an illumination beam. The parties' disagree, however, about the generality with which this definition should be posited. ASML favors a broad construction of the term; Nikon advocates a narrow one.

Specification language refers to--and details--collections of tangible optical components, many of which work on light from an illumination source such that they produce a region of illumination light having a particular distribution at the mask-pattern surface. See Patent '041 at 10:51-11:12; see id. at 1:26-3:37. To the extent Nikon says as much in its description of the operation of an "illumination optical system," the court agrees. But to the extent Nikon seeks to fold this language into a construction of the relevant term, the court cannot agree; that the system should function properly is inherent to the invention itself--whether in the form of an "illumination optical system" or any other--and the court need not include as much in its construction of the "illumination optical system" term. All the court need determine is what an "illumination optical system" is.

The "best mode" description for the '041 patent makes clear that an "illumination optical system" includes a host of component parts--e.g., an ellipsoidal mirror, a relay lens, and a condenser lens--all organized such that light is directed toward a mask. See id. at 10:64-11:12. When construing the "illumination optical system" phrase, the court need not venture
beyond what the claim says and what the specification language teaches. As the claim language says and the specifications teach, an "illumination optical system" is "an optical component, or combination of optical components, that directs light from a light source onto and through a mask pattern." The court construes "illumination optical system" to mean precisely that.

**2026**

B. "Illuminator"

Insight defines "illuminator," as used in claims 2, 4, 16, 31, 34, and 35, in the way it is defined in the specification: "a device generally used to cast light upon a target area or a portion thereof." 6:9-10. SureFire and Glock contend that no construction is necessary, meaning that the term "illuminator" as used in the claims would have its ordinary meaning as understood by those who are skilled in field of the invention. The court adopts the definition provided in the specification.

**2027**

F. "image obtained from a design"

The parties agree that the two components of this phrase in need of construction are "image" and "design." Furthermore, the parties seem to agree generally on the proper construction of "image." The Plaintiff proposes that "image" means "the printed area that recreates the look of" the design. Similarly, the Defendant contends that the term means "a representation of" a design. Neither party argues that the specification nor prosecution history limits the meaning of the term. Thus, the Court construes "image" to mean "a printed representation of" a design.

However, the parties disagree as to the proper construction of "design." The Defendant contends that "design" means "continuous tone photographs, paintings, drawings, or graphic artwork." The Plaintiff argues that this construction improperly imports specific types of designs and a continuous tone limitation that are not required by the claim language. Instead, the Plaintiff proposes that the term be construed broadly to include any type of original graphic. Generally, as the Plaintiff argues, a court may not add a narrowing modifier to an otherwise general term that is unmodified in the claim. Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249-50 (Fed. Cir. 1998); see also Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001) "[U]nless compelled to do otherwise, a court will give a claim term the full range of its ordinary meaning."). However, the Court must read claims in view of the specification. Phillips, 415 F.3d at 1315. For example, if the specification makes clear that a particular feature is not intended to be included in the invention, that feature will be excluded from the scope of the invention, even if the claim language in the abstract might be considered broad enough to include the feature. SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001).

Although preferred embodiments cannot be used to import a limitation, statements that describe the invention as a whole may be used to support a limiting definition of a claim term. C.R. Bard, Inc., 388 F.3d at 864; Alloc, Inc. v. ITC, 342 F.3d 1361, 1370 (Fed. Cir. 2003). Here, the specification states that "[i]n accordance with the present invention the overprint layer is comprised of the combination of colors so as to produce a complex image (e.g., a reproduction of a painting such as the "Mona Lisa") that is extremely difficult to reproduce. . . ." (647 patent, col. 3, 11. 3-7; 504 patent, col. 3, 11. 27-31) (emphasis added). Accordingly, the specification makes clear that the designs reproduced as the overprint layer are complex and difficult to reproduce.

Furthermore, the specification distinguishes prior art on the basis of printing processes and the resulting simple images and points out the advantages of using the more sophisticated printing process of the present invention to create complex images. See SciMed Life Sys., Inc., 242 F.3d at 1343 (specification distinguished prior art as inferior and cited advantages of coaxial lumen used in catheters that were subject of patent). The specification identifies prior art overprinting techniques, typically printing processes that consist of the "application of up to four flat colors in various graphic line designs and/or text," that printed simple designs over the scratch-off area. (647 patent, col. 1, 11. 59-60, 63-65; 504 patent, col. 1, 11. 65-66 -- col. 2, 11. 2-4.) Flat color printing is "a form of color printing in which color dots are not printed on top of each other." GATF Encyclopedia at 313. The specification characterizes these prior art overprinting techniques as inferior because the
processes "create only basic color patterns which are easily duplicated." ('647 patent, col. 1, 11. 66-67-col. 2, 11. 1-7; 504 patent, col. 2, 11. 8-16.) In contrast, the Summary of the Invention describes a process in which individual colors are separated into half tone images which are then printed one over the other. 6 ('647 patent, col. 2, 11. 37-41; 504 patent, col. 2, 11.46-50.) Accordingly, the specification excludes flat color printing and implicitly limits the invention to a printing technique known as process color printing in which "[half tone] dots of one color are overprinted on dots of one or more other colors to produce blends." Id.; see also id. at 167 ("Process color printing involves overprinting halftone dots. . . "). The specification expressly states that when the overprint layer is printed using this process color system, "a full-color design, a photograph, a painting or other complex image is reproduced and applied to the lottery ticket." ('647 patent, col. 4, 11. 55-58; 504 patent, col. 5, 11. 28-31.) Therefore, read as a whole, the specification suggests that the very character of the invention requires that the design reproduced as the overprinting layer be a full-color design, a photograph, a painting, or other complex image. See Alloc, Inc., 342 F.3d at 1370 ("[W]here the specification makes clear at various points that the claimed invention is narrower than the claim language might imply, it is entirely permissible and proper to limit the claims."). The "continuous tone" limitation, however, does not appear in the specification, and the limitation will not be read into the claim. Accordingly, the Court construes "image obtained from a design" to mean "a printed representation of a full-color design or other complex graphic."

6 "Statements that describe the invention as a whole are more likely to be found in certain sections of the specification, such as the Summary of the Invention." C.R. Bard, Inc., 388 F.3d at 864 (citing Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1348 (Fed. Cir. 2004)).

GO BACK

3. "Image Sensing Module"

Plustek asks the Court to construe this term as "a module that is controlled by electronic components located outside of the scanner, and that includes a one-dimensional image sensor, an optical system, and a first illumination source."

Syscan argues it should be "a module including a one-dimensional image sensor, an optical system, and a first illumination source."

The specifications provide, inter alia, that "[T]he scanner itself comprises only an image sensing module and a motion mechanism." See Dang Decl., P 2, Ex. A ('124 Patent), 2:42-44, emphasis added.

"It should be pointed out that, fundamentally different from the scanners in the market, there is no microcontroller and other electronic components in main module 402 to control the operation of the image sensor and the illumination source. Dang Decl., P 2, Ex. A '124 Patent), 7:3-7, emphasis added.

It is clear from the specification that the patentee intended only to claim scanners which contain only the components necessary to operate (an image sensing module and a motion mechanism) to distinguish the patented scanner from the prior art. The Federal Circuit has consistently held that "where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." SciMed Life Systems, Inc., 242 F.3d at 1341; see also CCS Fitness, 288 F.3d at 1366-67 ("a claim term will not receive its ordinary meaning if the intrinsic evidence shows that the patentee distinguished the term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention.").

The Court construes this claim as "a module that is controlled by electronic components located outside of the scanner, and that includes a one-dimensional image sensor, an optical system, and a first illumination source."
E. Claims 19 and 20

Claim 19 of the 885 patent provides:

A method of immediately and positively precluding needlestick injury from a contaminated needle comprising the steps of:

providing an elongated needle having a pointed end, providing a body slidably receiving the needle and having a forward surface through which the needle extends from the body for use and is retracted toward and into the body after use, providing a spring having an imperforate blocking flange, and, affixing said spring to the body so as to preclude axial movement of said spring with respect to the body and to dispose the flange in adjacent relation to the body forward surface and in spring-urged relation to bear against the needle extending from the body when the needle is in use, whereby when the needle is retracted after use to bring its pointed end into immediate proximity to the body forward surface, the imperforate blocking flange is spring urged over the body forward surface past the needle pointed end thereby to block any reemergence of the needle from the body and past the flange to present a needlestick hazard.

885 patent, col.12, ll. 34-57 (emphasis added). The claim terms in dispute have been emphasized in the passage quoted above.

"Unless the patent otherwise provides, a claim term cannot be given a different meaning in the various claims of the same patent." Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 1999); see CAE Screenplates, Inc. v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308 at 1317 (citing Phonometrics, Inc. v. Northern Telecom, Inc., 133 F.3d 1459, 1465 (Fed. Cir. 1998), where the court explained that "[a] word or phrase used consistently throughout a patent claim should be interpreted consistently"). Therefore, having interpreted the disputed terms "immediately," "slidably receiving," and "adjacent" as they are found in claim 13, I need not discuss these same terms again when they appear in other claims. The meaning of the term is the same in all of the claims in issue.

(A) the pointed end of the needle being in the "immediate proximity" to the body forward surface

Citing several dictionaries, MBO contends that the term "immediate proximity" (and the term "proximity" found in claim 27) should be construed to mean "near." MBO points out that the phrase "flush with," used in the original claim 13, has not been made part of claims 19 and 27. To support its position, MBO relies on Tandon Corp. v. U.S. Intl Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987) (explaining that "there is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims").

Becton proposes that the disputed terms be construed to mean that the pointed end of the needle is "flush with" the forward surface of the body. According to Becton, during the prosecution of the 347 patent, MBO sought to distinguish its invention from the prior art by amending its claims (1) to require immediate blocking of the needle tip by movement of the "flange over the front surface of the body," and (2) to emphasize that the safety flange slipped over the needle tip when the needle tip was "flush with [the] front surface" of the body. Becton Exh. 10 p. 9; Exh. 12, p. 4. Citing SciMed Life Sys., Inc., 242 F.3d at 1342, and Ekchian, 104 F.3d at 1304, Becton maintains that the court's construction of the disputed terms cannot include the subject matter that MBO had previously disclaimed.

The language of the claim strongly supports Becton's proposed interpretation of the disputed claim term. It provides that, as soon as the pointed end of the needle comes "into immediate proximity to the body forward surface," the flange is "spring urged over the body forward surface past the needle pointed end." The flange simply cannot go "over the body forward surface" and "past the needle pointed end" unless the needle tip is at least flush with the forward surface of the body.

The specification also supports Becton's proposed construction. In particular, the specification explains that, "with the blocking flange face 98 immediately adjacent the forward surface of the body at 84, as soon as the needle passes behind the flange 98, the spring snaps the flange forward surface over the 84 of the body into needle-blocking position and positively precludes reemergence of the contaminated needle point from the body 82 and thus needlestick injury is absolutely avoided.
While the needle may be withdrawn further into the body 82, such extra movement is unnecessary as the safety spring acts on and over the end face 84 of the body at the immediate point of potential emergence of the contaminated needle" (emphases added). 885 patent, col. 7, ll. 2-12. Several points supporting Becton's construction arise from the quoted language. First, if the blocking flange face is immediately adjacent to the forward surface of the body, the needle tip must be at least flush (or level) with the forward surface of the body before the flange can snap over the body and block the needle from reemerging. Second, the phrase explaining that the flange covers the needle tip "at the immediate point of potential reemergence," also supports Becton's proposed construction of the disputed term. Third, the specification contrasts the invention with the prior art that required that "the needle . . . be withdrawn at least a minimum predetermined distance beyond the exit from the tubular body." 885 patent, col. 7, ll. 16-18. Fourth, the abstract of the invention explains that "a used needle is captured immediately within its carrier upon retraction of the needle flush with the carrier" (emphasis added).

Finally, I note that during the prosecution of the related 347 patent, MBO sought to distinguish its invention from Smith by arguing, inter alia, that the safety means in its invention "immediately blocks reemergence of needle 40 as soon as the needle is flush with front surface 84." Becton Exh. 10, p. 9. See Omega Eng'g, Inc. v. Raytek Corp, 334 F.3d 1314, 1333 (Fed. Cir. 2003) (explaining that "as long as the same claim limitation is at issue, prosecution disclaimer made on the same limitation in an ancestor application will attach"); emphasizing that this rule applies to continuation applications, and continuation-in-part applications); Advanced Cardiovascular Sys., Inc. v. Medtronic, Inc., 265 F.3d 1294, 1305 (Fed. Cir. 2001) (noting that "the prosecution history of a related patent can be relevant if . . . it addresses a limitation in common with the patent in suit"); Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999) (clarifying that "when multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation"); see also Loral Fairchild Corp. v. Sony Corp., 181 F.3d 1313, 1327 (Fed. Cir. 1999).

In light of the foregoing considerations, I conclude that the term "immediate proximity" requires that the needle tip be flush with the forward surface of the body. The same limitation applies with regard to the term "proximity" found in reissue claims 27 and 28.
only to state a purpose or intended use for the invention." Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304, 1310 (Fed. Cir. 2002) (emphasizing that, "if the body of the claim sets out the complete invention, and the preamble is not necessary to give life, meaning and vitality' to the claim, then the preamble is of no significance to claim construction because it cannot be said to constitute or explain a claim limitation" [citation omitted]).

MBO also insists that the specification uses the term "immediately" to refer solely to the action of the spring when the needle passes it and does not describe the amount of time between the withdrawal of the needle from the patient and the blocking flange's sealing of the needle tip. 885 patent, col. 6, ll. 56-58. Tr. 1:30:10 -- 1:30:15. MBO contends that the claims of the 885 patent make clear that the body and the spring are "closely adjacent" to the patient's flesh at the injection site, but are not touching it. MBO reasons that, because there is space between the patient and the body, there necessarily would be some delay between the withdrawal of the needle tip from the patient and its recapture by the body.

Becton's position is that, in the context of the asserted claims, the term "immediately" should be interpreted to mean "simultaneously with" the needle's withdrawal from the donor. Becton explains that the use in the specification of the following phrases establishes that the needle tip is never exposed after it is inserted into the patient: (1) "upon withdrawal of the needle from the blood donor, the needle is immediately retracted within the guard and a shield positively blocks the contaminated needle point and access thereto"; (2) the needle "is shielded simultaneously with its withdrawal from the donor whereby no inadvertent puncture can occur"; and (3) "the healthcare worker at no time has to manipulate an unshielded blood-contaminated needle." 885 patent, col. 3, ll. 3-5; col. 5, ll. 3-4; col. 8, ll. 16-17. Becton points out that, in the "Summary of the Invention" section of the specification of the 885 patent, MBO characterizes its invention as a "new and improved system which [...] shields the blood-contaminated needle simultaneously with its withdrawal from the donor." 885 patent, col. 2, ll. 57-58. Tr. 1:55:6-1:55:8. Citing 37 C.F.R. § 1.73 (requiring that the summary of the invention be "commensurate with the invention as claimed"), Becton argues that MBO's attempt to make its invention more comprehensive than the summary of the invention is improper as a matter of law. Becton also insists that MBO's assertions throughout the prosecution history limit all the claims, including the reissue apparatus claims 32 and 33 (in which the word "immediately" does not appear) to a method whereby the body traps the needle tip simultaneously with the needle's removal from the donor. 10

10 The term "simultaneous" is defined as "existing or occurring at the same time." MERRIAM WEBSTER'S COLLEGIATE DICTIONARY 1094 (10 ed. 1993).

In this instance, the preamble aids in the construction of the disputed claim term. As noted above, the preamble to claim 13 describes "[a] method of immediately and positively precluding needlestick injury from a contaminated needle. . . ." 885 patent, col. 10, ll. 24-26 (emphasis added). This language appears unambiguously to indicate that the term "immediately" should be interpreted to mean that the needle is shielded as it is withdrawn from the donor. It limits MBO's claims because, in this case, it is "necessary to give life, meaning, and vitality" to these claims. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999).

I further note that the 885 patent is replete with MBO's assertions that its system substantially reduces or eliminates the risk presented by the "open manipulation of the contaminated needle between withdrawal and sample securement" by "shielding the blood-contaminated needle simultaneously with its withdrawal from the donor." 11 See Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999) (looking to the specification in interpreting the claims of the invention). In addition, under the established principles of claim construction, the words of the 885 patent must be interpreted in light of MBO's assertions throughout the prosecution history of the original 699 patent and related patents. Alloc, Inc. v. ITC, 342 F.3d 1361, 1368 (Fed. Cir. 2003) (taking into account the patentee's assertions throughout the prosecution of several related patents). During the prosecution of the 699 patent, MBO sought to distinguish its invention from the prior art by emphasizing that its needle safety system provided immediate protection to healthcare workers by retracting the needle into the body at the same time as the needle is withdrawn from the donor. For example, to distinguish its invention (set forth in the 699 patent) from DuPont, MBO contended that, in contrast to DuPont, its invention provided "automatic and immediate safety means." Becton Exh. 7, p.7.
11 MBO contends that in at least one embodiment, the needle is described as withdrawn from the patient and then retracted into the body. The text MBO relies on reads as follows: "Thereby, upon withdrawal of the needle from the blood donor, the needle is immediately retracted within the guard and a shield positively blocks the contaminated needle point and access thereto." 885 patent, col. 3, ll. 3-6. This language does not change my conclusion with respect to the proper construction of the term "immediately."

I conclude that, in light of the above, MBO has acted as its own lexicographer, defining the term "immediately" 12 to mean "simultaneously" with the needle's withdrawal from the donor. Phillips, 415 F.3d 1303, 2005 WL 1620331, at * 8 (explaining that, where the patentee has defined a claim term in a way that differs from the term's usual meaning, the patentee's lexicography controls); see Bell Atlantic Network Servs., Inc., 262 F.3d at 1268 (noting that the patentee need not have explicitly defined the term). 13 I further conclude that the term "immediately," as I have construed it, limits reissue claims 32 and 33. My construction of this term applies with equal force to the time between the retraction of the needle within the guard and the action of the blocking flange.

12 The term "immediately" is defined as "without interval of time" or "as soon as." MERRIAM WEBSTER'S COLLEGIATE DICTIONARY 579 (10 ed. 1993). THE OXFORD ENGLISH DICTIONARY defines the term "immediately" as follows: "without any delay or lapse of time; instantly, directly, straightway; at once."

13 Although I have construed the term "immediately" to mean "simultaneously," it is worth noting that I do not perceive a significant difference between the dictionary definition of "immediately" as meaning "without interval of time" and the dictionary definition of "simultaneous" as meaning "existing or occurring at the same time."

A. Claim language to be construed from Claims 3 and 6 -- "an elongated hollow electrically conductive tube, said tube having an immersion end and a connector end;" -- col. 4, ll. 24-26; col. 6, ll. 29-31

HEN contends that the terms "immersion end" and "connector end" refer to regions of the electrically conductive tube and are used for orientation purposes. Thus, HEN proposes that these terms be construed to mean "the region of the tube which is first immersed in molten metal," and "the region of the tube which is opposite the immersion end of the tube." (HEN CC Br. at 10.) Minco, on the other hand, contends that a person of ordinary skill in the art would understand "connector end" to
mean "the actual final physical endpoint of the conductive tube." 3 (Minco CC Br. at 10.)

HEN points to the language of the claim that describes the sheathing surrounding the electrically conductive tube. The sheathing is claimed as having a minimum thickness adjacent to the immersion end and a shoulder that is adjacent to the connector end. (HEN Ex. A. col. 4, ll. 54-56, 58-60.) HEN argues that the shoulder identified in the claim extends approximately 15-22% up the length of the tube from the connector, (see HEN Ex. A. at Figure 1), and that, therefore, if the shoulder is adjacent to the connector end, then the connector end cannot only refer to the final physical endpoint of the tube. Additionally, HEN argues that the connector, for which the connector end is named, has a connector sleeve that extends up into the connector end of the probe reaching approximately 10% into the tube. Therefore, according to HEN the connector end must refer to the end region and not the physical endpoint, and HEN contends that adopting Minco's proposed construction would effectively exclude the preferred embodiment. HEN also argues that the other language in the specification supports its proposed construction. HEN points to the following "Summary of the Invention":

The present invention is directed to an immersion probe which comprises a unit including a support tube which defines the outer periphery of the unit. One end of the tube is an immersion end. At least one measuring element is supported on a measuring head which closes said tube adjacent its immersion end. A connector closes the other end of said tube. Electrical conductors in said tube extend from said connector to said measuring element. Heat insulating material is provided in said tube for protecting said conductors.

(HEN Ex. A., col. 1, line 61 -- col. 2, line 2.) According to HEN, this language demonstrates that the patent applicants refer to the immersion end and other end (i.e., connector end) for orientation purposes, or to provide a frame of reference to the tube. Additionally, HEN contends that in figure 1 of the patent specification the applicants used an arrow to refer to the immersion end of the probe, as opposed to a lead line. (HEN Ex. A. at Figure 1 and col. 2, ll. 31-32.) HEN contends that if the applicants meant to limit the "immersion end" to mean only the very tip of the immersion tube, the applicants would have used a lead line and not an arrow because arrows may be used at the end of lines, provided their meaning is clear, to indicate an entire section towards which it points. See 37 C.F.R. § 1.84(r).

Minco, however, points to the patent specification and contends that the only drawing presented in the specification shows that the electrical connector is in direct contact with the final physical endpoint of the conductive tube, and that this makes clear that the electrical connector is located at the final physical endpoint of the conductive tube. Minco concludes, therefore, that the "connector end" must be the actual final physical endpoint of the conductive tube. Relatedly, Minco argues that other language in the claim supports its proposed construction. Minco points to the portion of the claim that states that there are "electrical conductors extending from said enclosure to said connector end of said tube." (Minco Ex. A. col. 4, ll. 40-41.) Minco contends that the only representation in the specification shows that the electrical conductors extend from the gas impermeable enclosure all the way down to the actual final physical endpoint of the tube. Therefore, according to Minco, the claim language and the only figure contained in the specification show that the connector end is at the final physical endpoint of the tube, because that is the point to which the electrical conductors travel and end.

Minco also relies on the prosecution history and argues that HEN's proposed construction contradicts limiting arguments it made to the patent examiner to overcome prior art. According to Minco, the prosecution history shows that the patent examiner at one point rejected claims 3 and 6 based on the prior art disclosed in Jackson (U.S. Patent No. 3,784,459) ("Jackson"), in part because Jackson disclosed a molten metal sensing probe comprising "an electrical connector (46/58/60/62/70) closing the connector end of the tube and providing electrical connections for the cell and the tube. . . ." (Minco App. 5E at HEN000313.) According to Minco, in order to overcome this rejection, HEN distinguished Jackson by arguing that the electrical connector in Jackson was not at the final physical endpoint of the tube, but rather removed at a distance away from the end of the tube, and therefore, Jackson did not disclose an electrical connector closing the end of the tube as required by the claims of the '736 patent. According to Minco, through this prosecution history HEN assigned a particular meaning to the claim words "connector end," namely, that the "connector end" means the physical endpoint of the
Inverness agrees that the term "immobilized" means "fixed or incapable of moving." However, it argues that claims 7 and 2482
19 require merely the presence of second binders that are immobilized at the test site in sufficient quantity to "produce a color visible to the unaided eye indicative of the presence of the ligand in the liquid," not that all of the molecules at the test site capable of binding with the conjugate be immobilized.

Turning first to the question of claim interpretation, the Court agrees that "immobilized" as used in the claim means "fixed or incapable of moving" with the passing liquid. With this definition, claim 5 only requires a second binder for capturing the ligand, which is immobilized at the test site, not that all of the binding agent at the test site be immobilized. The presence of other molecules that may bind with the ligand but be washed away does not defeat infringement, as long as there are second binders that are immobilized at the test site, and the "accumulation of colored particles at the test site produces a color visible to the unaided eye indicative of the presence of the ligand in the liquid."

B. Impact Head

One element of claim 6 of the '003 Patent is "a terminal including an impact head." Claims 3 and 14 of the '820 Patent also include an "impact head." The parties agree that this court should give the term "impact head" the same construction in the '003 and '820 Patents. KEI proposes the following construction of the term "impact head":

An "impact head" is a device designed to spread the load of an impact over an impacting vehicle to prevent penetration of the vehicle's body and to provide a mechanical interlock between the energy-absorption safety device and the impacting vehicle to prevent the impacting vehicle from sliding up, down, or sideways along the impact head.

(Pl's Markman Hearing Slide 18). 6 Trinity proposes the following construction of "impact head":

An "impact head is a unitary component that has a wide end facing the flow of traffic that is large enough to receive an impact from a vehicle without penetrating the vehicle's body, and that has a narrower end facing away from the flow of traffic.

(Docket Entry No. 76, p. 8). KEI contends that Trinity's proposed construction is overly narrow because the invention does not require the impact head to be a "unitary component" and does not require the end facing away from traffic to be narrower than the end facing traffic.

-D- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 KEI's proposed construction of the term "impact head" presented at the Markman hearing was a condensed version of the construction KEI proposed in its Markman brief. That construction stated:

An "impact head" is a device designed to take an impact from a randomly oriented surface and control loading application between the impacting surface and the energy absorber. An impact head spreads the load over a portion of the impacting vehicle and provides a mechanical interlock between the energy-absorption safety device and the impacting vehicle. The impact head is designed to prevent the safety hardware from punching through the impacting vehicle and prevent the impacting vehicle from sliding up, down, or sideways along the impact head.

(Docket Entry No. 75, p. 13).

-D- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Trinity contends that the ordinary meaning of the word "head" supports its proposed limitation that the wide end of the impact head face traffic and the narrow end of the impact head face away from traffic. To support its argument, Trinity points to the dictionary definition of the word "head" as "the uppermost extremity or projecting part of an object." (WEBSTER'S THIRD NEW INT'L DICTIONARY, 3d ed. (1993)). Trinity also emphasizes the statement in the specification that "the impact head 30 is a strong wide-mouthed section having its wide portion facing outwardly from the guardrail 16 to receive a vehicle such as 12 and its narrower end connected to one end of the cutting section 36."
Patent, col. 4, ln.22-27). KEI responds that the claim language does not require the end of the impact head facing away from traffic be narrower than the end facing traffic and that nothing in the claims or specification require the impact head to be a "unitary component."

--- Footnotes ---

7 The numbers refer to Figure 1 of the '003 Patent.

Claims must be read in view of the specification, but limitations from the specification may not be read into the claims. Teleflex, 299 F.3d at 1326. Although the specification describes an embodiment in which the end of the impact head facing traffic is wider than the end facing away from traffic, the claims do not require such a construction. The specification teaches that the impact head is sized "(1) to engage a sufficient area of the vehicle that hits the impact head to avoid penetrating the vehicle body; and (2) to avoid any dimension that would permit the impact head to project sufficiently to block the roadway." ('003 Patent, col. 5, ln.47-55). The specification does not provide any design requirements for the end of the impact head facing away from traffic. The end of the impact head facing away from traffic could be as wide as the end facing traffic, or possibly wider, depending, for example, on the type of hazard to which the device is attached. This court cannot construe the term "impact head" as requiring the end of the impact head facing away from the traffic to be narrower than the end facing traffic; to do so would impermissibly read limitations from a preferred embodiment into the claim.

The dictionary definition of the term "head" does not support Trinity's proposed requirement that the end of the impact head facing away from traffic must be narrower than the end facing traffic. The "projecting" part of the definition does not suggest that the head must necessarily be the wider end of the impact head, or that the impact head must have a narrow and wide end. The dictionary definition Trinity provided includes a "ram" as having a head. A ram does not necessarily have a wide and narrow end; a blunt metal cylinder could serve as a ram. The "head" of the ram that impacts, for example, a door, can be a blunt end with the same width or diameter as the other end.

The initial portion of the definition Trinity provided, defining "head" as "the uppermost extremity," is more appropriately applied to the position of the impact head in the overall invention, meaning positioned on the end of the terminal that receives vehicle impacts. ('003 Patent, Figs. 1-2). "Head" does not imply structural features of the impact head itself.

Trinity states that the term "unitary component" means that the impact head is a separately identifiable component in the invention, not that the impact head is made of one solid piece of metal or other material. Construing the impact head as a "unitary component" is unnecessary and potentially confusing. It is clear from the claims that an "impact head" is an separate component of the overall invention. Claim 6 states that the terminal includes the impact head. There is no requirement in the specification that the impact head consist of a single piece; it could, for example, consist of two or more joined pieces. "Unitary component" is a vague term that could be interpreted to mean that the impact head is made of a single, solid piece.

KEI's proposed construction of "impact head" states that an impact head "provides a mechanical interlock between the energy-absorption safety device and the impacting vehicle to prevent the vehicle from sliding up, down, or sideways along the impact head." Nothing in the specification teaches this limitation. Nor does the specification describe an embodiment of "impact head" that contains mechanical interlocking properties. The specification only states that the head should be made of heavy steel or other materials capable of moving the entire terminal during an impact, and that the head should be designed so that it does not penetrate the vehicle body on impact and so that it is not so wide as to block the roadway. ('003 Patent, col. 5, ln.47-55). This court declines to include a "mechanical interlock" in the construction of the term "impact head." 8

--- Footnotes ---

8 KEI cites a different patent that describes an impact head that forms a mechanical interlock with a colliding vehicle. (Pl.'s Markman Ex. 138, United States Patent 5,775,675 (the "675 Patent"), col. 5, ln.38-41. The '675 Patent application was not a parent or child of the '003 Patent application. The '675 Patent is extrinsic evidence upon which it is improper to rely if an
analysis of the intrinsic evidence alone resolves ambiguity in construing a claim term. Vitronics, 90 F.3d at 1583. None of the preferred embodiments of the '003 Patent are excluded by a claim construction that does not include a mechanical interlock in the "impact head." Cf. Dow. Chem., 257 F.3d at 1377 (rejecting district court's claim construction in part because many preferred embodiment experiments were excluded by district court's claim construction).

The claims and written specification support the following construction of the term "impact head":

A component of the terminal designed to receive the impact of an errant vehicle and spread the load of the impact over an impacting vehicle such that the safety device does not penetrate the vehicle.

a. Preamble.

The parties agree that Claim 1 includes a preamble and three elements. The parties further agree that the preamble should be included in the claim because it contains four terms essential to the Patent. The preamble states:

Building modules adapted to fit together for construction of fire, sound and impact resistant security barriers and rooms for use in securing records and prisons, comprising in combination.

(Exhibit 1, Column 6, Lines 22-25.)

The parties disagree, however, as to whether the foregoing terms "fire resistant", "impact resistant" and "sound resistant" are terms of art. The Plaintiff contends that as terms of art, these terms should be defined in accordance with the Model Building Code adopted by the organization of Building Officials and Code Administrators International, Inc., referred to as BOCA. (Plaintiff's Exhibit 4). According to BOCA definitions, "fire resistant" describes the ability to resist the spread of fire, particularly the ability to pass appropriate fire testing procedures. For most security applications, this requires passage of a two-hour loaded fire test. (BOCA definitions, sections 401.0 and 1403.1.1.) Sound resistance is defined as "ability to pass code test for the transmission of airborne and structural noise." (BOCA definitions 715.2 and 715.3.) Impact resistance is defined as "ability to resist any reasonably anticipated forces or kinetic loads in a jail or a prison environment." (Plaintiff's Exhibit 4.)

The Defendant argues that nothing in the Patent suggests that these be regarded as terms of art. Instead, the Defendant contends that they are unique terms that should be defined consistent with their use in the Specification.

With regard to terms "fire resistant" and "sound resistant", the opposing arguments create a distinction without a difference. Although the BOCA Code definitions are extrinsic evidence and the Specification is intrinsic evidence, the meanings and contextual reference of these terms in both sources is essentially the same.

The same cannot be said, however, for the term "impact resistant". With regard to impact resistance, the Defendant's argument is more persuasive. Although the general rule prohibits resort to the Specification in order to ascertain the meaning of a claim, an exception to the rule is applicable here. The term "impact resistant" is not defined in the claim. Therefore reference to some other source is required. The preferred reference is to intrinsic evidence such as the Specification, before resort to extrinsic evidence such as the BOCA definitions. Vitronics, 90 F.3d at 1582. In addition, the BOCA definition of the term "impact resistant" is imprecise because it is contextually dependent. BOCA's definition of impact resistant as the "ability to resist any reasonably anticipated forces or kinetic loads in a jail or prison environment" is meaningless without further explanation or identification of the anticipated kinetic or impact forces to be resisted.

It is the Specification which describes the anticipated forces or kinetic loads reasonably anticipated. It identifies these forces as coming from bullets or bomb fragments.

In secured facilities, and protected barriers, it is feasible that projectiles may be encountered, such as bullets from high
powered guns or bomb fragments. There have not been effective ways of dealing with these powerful impact weapons with inexpensive housing in the prior art.

(Exhibit 1, Column 3, Lines 27-32.)

Thus the modular building construction afforded by this invention provides significant advantage wherever security provision need be provided. Typical wall characteristics include bullet and explosion resistance, fire and heat resistance, acoustic insulation, ease of manual assembly on site, and high structural strength.

Uniquely the advantages of the steel shell modules are combined with thermal and acoustical isolation of two spaced walls in protection against bullet penetration of the walls. Accordingly, those novel features believed descriptive of the nature and spirit of the invention are defined with particularity in the claims.

(Exhibit 1, Column 6, Lines 14-20.)

Although the inventor and expert witnesses testified that the bullet penetration may not be the impact ordinarily associated with prisons, their testimony is disregarded in deference to the clear statement in the Specification that the invention's impact resistance feature pertains to bullets and exploding projectiles. Thus, the Court agrees with the Defendant that term "impact resistant" is defined by the Specification as resisting the impact of bullets, exploding projectiles or bomb fragments.

Have substantially the same impact strength, the body with a substantially uniform impact strength

Claim 1 of the '662 patent contains an example of the terms at issue:

A PCD element comprising a body of bonded diamonds integrally formed with a metallic substrate, the body having a working surface and at least an 85% by volume diamond density, wherein a first volume of the body adjacent to the working surface contains a catalyzing material, a second volume of the body adjacent to the working surface is substantially free of the catalyzing material, and wherein the first volume and the second volume have substantially the same impact strength.

The impact strength limitation is one of the subjects of Defendants' motion for summary judgment discussed in detail above. Baker Hughes contends the entire phrase is indefinite and offers no construction. The Court holds the phrase is not indefinite. ReedHycalog contends "impact strength" should be construed to mean "resistance to impact," but the entire phrase needs no construction. The Court agrees and construes "impact strength" to mean "resistance to impact." The remainder of the phrase needs no construction.

1. Claims 20 and 24

Toro argues that the district court erred in holding that claim 20 was not infringed as a matter of law based on its determination that the accused device does not contain an "impeller means . . . wherein the throwing means comprises a paddle portion which extends over at least approximately one-half of the impeller means' total length." Toro contends that the court misinterpreted the written description in calculating the length of the "throwing means" of the accused impeller, and that the court impermissibly decided disputed issues of fact on summary judgment. Toro argues in essence that the transition sections must be counted as part of the throwing means. Toro also asserts that the court performed an inadequate analysis under the doctrine of equivalents.

Ariens responds that the district court properly granted its motion for summary judgment of noninfringement as to claim 20
because the accused impeller does not meet the disputed limitation in that claim. Ariens points out that the "throwing means" of the accused impeller is only three to four inches long, much less than "approximately one-half of the impeller means' total length" of eighteen inches. Ariens continues that the district court properly interpreted the written description in its infringement analysis and correctly concluded that the transition sections of the accused impeller are not counted as part of the "throwing means." As such, Ariens argues that the district court correctly held that it does not infringe as a matter of law, either literally or under the doctrine of equivalents. For these reasons Ariens also contends that the district court correctly held that claim 24 is not infringed, as that claim contains a limitation similar to the disputed one in claim 20. Toro does not reply to Ariens' contention with respect to claim 24, or challenge the district court's ruling of noninfringement based on that limitation.

As an initial matter, we agree with Ariens that the district court properly interpreted the written description and correctly concluded that there is no genuine issue of material fact that Ariens' device does not infringe claim 20. The disputed portion of claim 20 reads as follows, with the key limitation underscored:

(b) rotatable impeller means carried on the housing for throwing snow upwardly relative to the housing, wherein the impeller means includes means for throwing a snow stream which tapers inwardly as it rises away therefrom, wherein the throwing means comprises a paddle portion which extends generally radially relative to the impeller means and extends over at least approximately one-half of the impeller means' total length. . . .

'726 patent, col. 16, ll. 10-18 (emphasis added). The district court observed, and Toro did not dispute, that the flat, central section of the accused impeller is approximately three to four inches long, and that the total length of the impeller is approximately 18 inches. See Toro I, slip op. at 17. As for the remainder of the impeller, the court agreed with Toro's own expert, John Berner, that the curved portions between the central section and the end sections of the impeller were "transition sections." See id. at 16-17 & n.3; Berner Dep. at 160-161. The court then turned to the following portion of the written description for guidance as to whether it should attribute the "transition sections" to the central snowthrowing section or the end sections:

While each end section 36 has been described as being relatively distinct from central section 34, the axially inwardmost portion of each end section 36 might be considered a transition section in which the shape of the end section is blended to match the shape of the central section 34 at the side thereof. However, if such a transition section does in fact exist, it will be considered as part of the end section for the purposes of definition herein.

Id. at col. 5, l. 67 to col. 6, l. 7; see also Toro I, slip op. at 14-15. The court correctly interpreted the plain language of this passage to mean that any transition portions are considered a transition section in which the shape of the end section is blended to match the shape of the central section 34 at the side thereof. However, if such a transition section does in fact exist, it will be considered as part of the end section for the purposes of definition herein.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

8 Neither party disputes that the structure corresponding to the "throwing means" limitation is the "central snowthrowing section" disclosed in the specification. We also note that while the term "means" is used in the "impeller means" limitation, adequate structure is revealed by the term "impeller," such that section 112, paragraph 6 is not invoked. See Personalized Media Communications, LLC v. ITC, 161 F.3d 696, 703-04 & n.10, 48 U.S.P.Q.2D (BNA) 1880, 1886-87 & n.10.

9 Berner's characterization of what constituted "transition sections" was drawn directly onto the figure of the accused impeller, as shown above, and initialed with "J.B."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -
Sunon argues that the use of the word "means" creates a presumption that section 112, P6 applies, and that the function of the "impeller means" is "the impelling of air through the fan." (R. 96-1, Defs.' Claim Constr. Br. at 13.) The function of "impelling . . . air through the fan," however, does not appear in Claim 29, and the term "impeller means" recites structure, i.e., the "impeller" (the fan blades). Cole, 102 F.3d at 531; Pirelli Cable, 988 F. Supp. at 434. As the Court has already noted, where a claim uses the word "means" but specifies no corresponding function for the "means," it does not implicate section 112, P6. Rodime, 174 F.3d at 1302; Sage Prods., 126 F.3d at 1427; York Prods., 99 F.3d at 1574. Accordingly, section 112, P6 does not apply to the "impeller means" term.

2039

2. "Steam and/or Gas Impermeable"

Plaintiff seeks to construe this term as "not permeable to steam and/or gas," while defendants propose the construction, "having a low enough permeability or transmission rate to steam and/or gas so as to be considered a high barrier to steam and/or gas, respectively, that prevents a measurable loss of weight, flavor, and/or taste during customary production, cooking, and storage." Neither of these proposals is wholly satisfactory.

As the parties acknowledge, the real dispute is whether "impermeable" should be construed in an absolute sense, or, instead, in a functional sense, with reference to the invention's purpose. Plaintiff's proposed construction, which merely replaces the inherent negative in the word "impermeable" with a two-word negative phrase, does nothing to clarify the definition or scope of the disputed term. On the other hand, defendants' proposal is replete with relative terms, some of which ("so as to be considered a high barrier") appear to add nothing to the definition and are presumably geared toward invalidity arguments.

Plaintiff's argument for an absolute construction of "impermeable" finds some support in the intrinsic evidence. First, plaintiff rightly notes that the claim language uses the term "impermeable" without a modifier such as "substantially," or "virtually," which would have made clear that a casing with some minimal degree of permeability falls within the scope of the claim. Also, the specification underscores that "there is no loss in weight at all during the manufacturing process, storage and transport." '613 patent at 2:65-66. (Emphasis added) This language echoes the superlative used in the abandoned parent application of the '613 patent, which disclosed that "[n]o losses whatsoever occur in the weight, taste, and flavoring" of the enclosed food. (Emphasis added) The emphatic use of the phrases "at all" and "whatsoever" is indeed suggestive of an absolute quality.

On the other hand, these terms must be understood in context. The discussion of the prior art in the '613 patent's specification first describes the use of cellulose fiber casings, and explains that "due to the steam and gas permeability of the casing, the production of food in a cellulose fiber casing is always associated with a loss in weight, taste and flavor." '613 patent at 1:27-29. The specification goes on to discuss pure plastic casings that were developed in the prior art "[t]o avoid the disadvantage of steam and gas permeability," and it describes such casings as having "a steam and gas impermeability." Id. at 1:39-42. The patent then explains that "[w]hen using plastic casting (sic) of this type, there is no loss in weight, flavor and taste during the production process nor during storage and shipping." Id. at 1:44-45.

Indeed, the patent repeatedly identifies permeability (or impermeability) as the feature that determines whether losses in weight, taste and flavor occur, and the concepts are linked throughout the patent. For example, in the detailed description of the invention, the specification states, "[s]ince the outer layers of the casing are impermeable, the substances cannot be rinsed out during the boiling process. No losses in weight, taste and flavor result during the production and boiling process or during transport and storage." '613 patent at 4:30-34. No other definition of "impermeable" is offered, nor is the term linked with any object other than that of preventing losses in weight, taste, and flavor. Therefore, it is reasonable to conclude that the patentee defined "impermeable" with reference to that object.

Moreover, plaintiff does not appear to dispute that the pure plastic casings in the prior art, which the '613 patent characterizes as "impermeable," are not, in fact, impermeable in the strict sense, since some transmission of air, gas, or both would be observed if such casings were submitted to certain types of testing. 2 The '613 patent nevertheless described the plastic casings as "impermeable" by contrast to the cellulose casings known in the art (the permeability of which "always" resulted in losses in weight, taste and flavor) because the plastic casings effectively prevented such losses. Because "claim
terms are normally used consistently throughout the patent," Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005), it is reasonable to presume that the word "impermeable" as used in the claims has the same meaning as "impermeable" as applied to the less-than-absolutely impermeable pure plastic casings discussed in the specification.

2 At oral argument, defendants argued that "over time everything [polymeric] is permeable to steam and/or oxygen." Plaintiff does not dispute this proposition.

Plaintiff cites Chef America, Inc. v. Lamb-Weston, Inc., 358 F.3d 1371 (Fed. Cir. 2004), in support of the argument that because claim terms "should be taken as they appear," an absolute construction of impermeable is appropriate. In Chef America, the court considered a patent relating to a process for baking dough so as to achieve a "light, flaky, crispy texture." As written, the claims required "heating the…dough to a temperature in the range of about 400 [degrees] F to 850 [degrees] F." The patentee sought a construction in which this temperature range referred to the temperature of the oven, not to the temperature of the dough itself, on the ground that if applied to the dough, the process would result in a burnt crisp, rather than achieve the stated object of a "light, flaky" product. But the court concluded that the claim language unambiguously required heating the dough, not the oven, to the specified temperature range, and held that courts may not redraft claim terms simply to avoid a "nonsensical result."

Plaintiff argues that under Chef America, I should construe "impermeable" in its absolute sense, regardless of whether such a construction would be, in defendants' words, "impractical" because no food casing in the world achieves 100% impermeability. But whether an absolutely impermeable food casing exists or could exist is beside the point. The point is that the manner in which "impermeable" and related words are used throughout the patent reveal that the patentee defined those words by reference to the quality of preventing losses in weight, taste and flavor. Because this consideration--not merely the desire to avoid a "nonsensical result"--supports a non-absolute construction, Chef-America is not dispositive here.

Plaintiff's citation to Aqua-Aerobic Sys., Inc. v. Aerators, Inc., 211 F.3d 1241 (Fed. Cir. 2000), has superficial appeal because the terms construed in that case are similar to those at issue here. In Aqua-Aerobic, the Federal Circuit affirmed the district court's construction of the phrase "preventing passage of atmospheric air" as requiring that all air be excluded from the system, even though the experts in the case agreed that the system was not absolutely air-tight. The court explained that "the undisputed testimony that experts would understand that the described sealing system would not produce an air-tight device" did not warrant broadening the claims in a manner "directly contrary to the limitations in the claims and the description in the specification." As explained above, however, a less-than-absolute construction of "impermeable" is consistent with, rather than "directly contrary to," the manner in which that word is used in the patent in this case.

Finally, plaintiff objects that the phrase "no measurable losses" begs questions such as, "measurable in what units?", "measurable under what conditions?", and "measurable by whose taste?" and that these open questions render defendants' proposed construction indefinite. It is true that the patent does not establish numeric values for ascertaining losses in weight, nor does it define the conditions under which such losses are measured. But "a patentee need not define his invention with mathematical precision in order to comply with the definiteness requirement." Oakley, Inc., v. Sunglass Hut Intern., 316 F.3d 1331, 1342 (Fed. Cir. 2003) (citing In re Marosi, 710 F.2d 799, 802-03 (Fed. Cir. 1983). At oral argument, plaintiff insisted that the indefiniteness of defendants' proposed construction is illustrated by the fact that while the inventor said losses in weight should be measured in tenths of grams, defendants' experts proposed measuring in grams, as well as by defendants' expert's testimony that "customary" production conditions can vary widely. It is in light of these variations that the patent's absolute language takes on meaning, however: no measurable losses means no losses as measured in any units commonly used as a practical matter in the industry, under any of the range of conditions commonly observed there. As for the elements of "taste" and "flavor," while these undoubtedly have subjective components in the abstract, identifying "losses" in these elements when comparing products before and after processing does not seem to me to be so impossibly subjective that it could not be established by any objective criteria.

In sum, although it is true that the patent could have been more precise on this point, I am satisfied, at this stage, 3 that one skilled in the art would be able to draw the line between a loss and no loss in weight, taste and flavor.
3 As the court noted in Oakley, in which claim definiteness was raised, as it is here, at the preliminary injunction stage, declining to hold the term indefinite at this stage simply recognizes "the presumption of validity" and does not mean that plaintiff cannot ultimately succeed on the merits of an indefiniteness argument later in the litigation. 316 F.3d at 1342.

For the foregoing reasons, I conclude that "steam and/or gas impermeable" means "having a low enough permeability or transmission rate to steam and/or gas to prevent a measurable loss of weight, flavor, and taste during customary production, cooking, and storage."

b. The Court's Construction

The focus of the parties dispute is the term "a support" because both parties propose identical constructions regarding the "impermeable surface." (D.I. 173 at 1.) I find little or no basis for OGT's proposed construction that the support is "a side of a single, mostly flat solid." While a "surface" may be considered "a side" of an object, the clear and plain meaning of "surface" is "the exterior or outside of an object or body." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY OF THE ENGLISH LANGUAGE 2300 (1986). Even OGT uses the term "surface" in the latter part of its proposed construction, indicating that it does not believe "surface" requires further construction. (D.I. 174 at 15-16; D.I. 173 at 1.) Therefore, I construe "to an impermeable surface of a support" to mean "to a solid having a non-porous surface that does not permit diffusion through its substance."
It is undisputed that Dr. Jerre M. Freeman invented the "Punctum Plug and Method for Treating Keratoconjunctivitis" (the '750 patent'), 25 years ago, and that when properly positioned; Dr. Freeman's prior art plug occludes the punctal opening and "protrudes into the vertical portion of the canaliculus." It is undisputed that this patent was in existence when Herrick applied for the '270 patent and the '959 patent, and that Freeman's plug, as well as plugs in general, were discussed in connection with Herrick's patent application. Moreover, there can be no dispute that Claims 1-27 of the '270 patent were rejected initially in the application process on the grounds of indefiniteness and obviousness and that Herrick amended Claim 1 to "sharply and clearly define that the dimension is critical." (Barsky Decl., Tab 5, at 12.) The intrinsic evidence presented to the court establishes an intention to disclaim prior art plugs to obtain the '270 patent. Furthermore, it is undisputed that the Examiner of the '959 patent specifically amended Claim 31, which issued as Claim 4, to further clarify that the implant of Herrick's patent was to be inserted "into the canaliculus of an eye."

1. Herrick Distinguished Its Implant From Prior Art Plugs

In its amended submission of the '270 patent, Herrick went to great pains to distinguish the "canalicular implant" from the prior art "punctum plug:

Neither the Freeman reference nor [the Freeman patent] suggest, disclose, or teach an implant which is disclosed and claimed in the present Application. Specifically, the punctum plug of Freeman is not intended to be passed into the canaliculus and the smooth head portion thereof is designed to be dome shaped and functions to prevent the punctum plug from passing into the horizontal portion of the canaliculus.

(Id., at 15; emphasis in original amended application.) This language alone clearly indicates that Herrick was seeking a patent on a device that passed entirely into the canaliculus in distinction to prior devices whose design prevented them from passing wholly into the canaliculus. Herrick clearly conveyed to the patent examiner that the former is an "implant" while the latter is a "plug."

This is further supported in Herrick's discussion in both the '270 and '959 patents of the prior art where the following discussion of the Freeman device occurs:

"It is also known in the art to utilize other plugs and or techniques for occluding the punctum. One plug device which is known in the art is referred to as a punctum plug . . . .

The punctum plug of Freeman is a rod-like plug formed with an oversized tip or barb portion that dilates and blockingly projects into the vertical canaliculus. The punctum plug has a smaller neck or waist portion around which the punctum sphincter ring tightens. The punctum plug has relatively large, smooth head portion which rests on top of the punctal opening and prevents the punctum plug from passing down onto the canaliculus. . . The head portion functions to prevent the punctum plug from passing into the horizontal portion of the canaliculus. The punctum plug of Freeman is subject to being inadvertently removed from the eye by the patient. "

(Barsky Decl., Tab B, at 144, Col.2:27-58.) (Emphasis added.)

This identical language in both Herrick's patent demonstrates a clear understanding that plugs are inserted into the canaliculus, which undercuts those portions of the argument suggesting that this fact is material to proving infringement. 2 For example, Herrick offers the declaration of a patent attorney to the effect that the Freeman plug, unlike the Herrick device, occludes at the punctum and not at the canaliculus. (Manbeck Decl., P 19, at 8:7-9.) But the Freeman patent itself describes, "A removable rod-like plug for blocking lacrimal fluid flow through the punctum and associated canaliculus of the human eye comprising a projecting tip . . . which is sufficient to occlude the canaliculus when inserted therein . . . ." (Barsky, Tab D, Col.6:12-15.) (Emphasis added.) And Herrick's own declaration states that the "punctum opening is just that, an opening" of virtually no depth. (Herrick Decl., P 14.) Moreover, Herrick acknowledges that "anything of any visible length that penetrates the punctum also penetrates the canaliculus." (Id.) Thus, despite the argument presented in opposition to the present motion, the fact that a device projects into the canaliculus cannot be dispositive since prior art devices projected into the canaliculus. There must be more to it than that or the canalicular implant would have infringed on the prior art punctum plugs.
2 One aspect of this argument is set forth in the Manbeck Declaration, which is, in large part, a legal brief without citations. Manbeck, a patent attorney, argues that the court should construe the patent in a manner favorable to Herrick. The court agrees entirely with Odyssey's observations, set forth in its Reply Memorandum, that the Manbeck Declaration adds nothing to the arguments set forth in the brief. (Reply Memo., at 11.)

2. Herrick Distinguished Its Implant From The Prior Art Implants

Under the heading "Summary of the Present Invention," Herrick separately discusses the "known prior art implants." ('270 patent, at 145, Col. 4.) (959 patent, at 120, Col. 4)(Emphasis added.) In that discussion, Herrick addresses devices (dissolvable and non-dissolvable) that are inserted in their entirety into the canaliculus and discusses their advantages and disadvantages. With respect to "permanent implants" that have "a central body and a tapered end," Herrick states that "such a permanent implant can still migrate within the horizontal portion of the canaliculus. Any migration of a permanent implant is undesirable." (270 Patent., Col.4:28-35.) (959 patent, Col. 4:55-63.) In comparison to these prior art implants, Herrick claims that its design has the advantage of preventing migration of the implant because, among other things, when, positioned in the canaliculus, it "will be held in place by a clamping force which is developed between the interior walls of the canaliculi against the collapsible flared section of the implant." (270 patent, Col. 4:45-50.) (959 patent, Col. 5:12-17.) This discussion has absolutely no application to any device (such as a plug) that does not reside in its entirety in the canaliculus because, as the Freeman patent made clear, the plug, device had

"a head portion of larger cross-section than said neck portion and adapted to rest on the surface of the punctal aperature and prevent said plug from passing down into the canaliculus."

(Barsky Decl., Exh. D, Col.6:24-27.) Migration within the canaliculus is not a relevant concern with plugs, as opposed to implants, because the plug is not meant to pass fully "into" the canaliculus in the first place. Here again, the record establishes that Herrick understood that there is a clear distinction between "plugs" and "implants."

3. Herrick's Drawings Reflect A Device Fully Inserted into the Canaliculus

The words are consistent also with the drawings in the patent. (See Barsky Decl., Tab B, at 140-43.) The drawings of the '270 patent and the '959 patent are identical. Nowhere does the patent contain any depiction of the invention other than as a device that it inserted in its entirety into the canaliculus. The drawings depict exactly what the words describe -- not a plug with an external cap, but a device inserted wholly into and lodged within the canaliculus. (Id., at 143.) Indeed, as Odyssey points out, the patent is even more specific at many points where it speaks in terms of a device that is placed in the horizontal canaliculus. For example, the '959 patent states, "In practicing the present invention, the canalicular implant is placed in the horizontal portion of the canaliculus." ('270 patent, Col. 9:38-40.) (959 patent, Col. 10:4-6.) It is this use of the device that is specifically disclosed in the drawings included in the patent. Thus, it is difficult to imagine that anyone reading the patent would conclude that the word "implant" refers to anything other than a device that resides entirely within the canaliculus.

4. Herrick's Use of the Word "Implant" Excludes Plug-Type Devices

Nevertheless, Herrick argues that the word "implant" is not defined in the '270 or the '959 patents, that no distinction is drawn between a plug and an implant (the foregoing language notwithstanding) and that Odyssey itself uses the word implant in its patent. 3 (270 Oppos. Mem., at 10.) (959 Oppos. Mem., at 14.)

3 In arguing the '270 patent, Herrick claimed that Odyssey never used the term "plug" in its own patent. The court pointed out in its September 27, 1999 order that this was incorrect. Now, in the '959 patent, Herrick has retreated from his earlier position, but still points out that Odyssey uses the term "implant" in its patent.
The definitional argument misses the point. While it may be literally true that the patent does not contain an express definition of "implant," the way that the words are used in the patent and the discussion contained in the prosecution history establishes an understanding that effectively defines the term. The entirety of the intrinsic evidence reveals a consistent usage of the terms "implant" and "plug" and treats them as separate and distinct devices. Whatever meaning the terms may have in common usage, within the '270 and '959 patents, an "implant" is a device that can pass through the punctum and into the canaliculus, and can be moved about within the canaliculus; a "plug" is a device a portion of which is inserted through the punctum and into the canaliculus, but which cannot pass through the canaliculus. 4 It is quite clear to the court, from the evidence presented regarding Herrick's prosecution of it '959 patent that it was tailored to exclude punctum plugs.

4 Odyssey devotes some discussion to the argument that its device does not infringe because it is not formed of a dimension to pass through a canaliculus of the eye. (Odyssey Memo. Of Points and Authorities, at 17, et seq.) In the court's view, this is subsumed in the discussion of whether the device is an "implant" or a "plug."

Given all of this, Herrick cannot now assert that Claim 4 of the '959 patent, which uses the "comprising of" rather than "consisting of" language, can be interpreted to cover plug devices. ('959 Oppos. Mem., at 3:18-22.)

2042

B. Claims Construction in the '415 Patent

On September 19, 2003, the Court held a hearing in accordance with Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996), to construe the disputed terms and phrases of the asserted claims. The Court's October 7, 2003 Order Following Claims Construction Hearing construed the following disputed terms in the '415 patent which are relevant to the present findings on validity and invalidity:

"implant delivery assembly"  "an apparatus for delivery of occlusive devices, such as embolic coils that comprises three distinct components: a pusher, a coupling, and an implant"

"pusher"  "any device or structure intended to push another device or structure"

"selectively operable coupling"  "a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"coupling"  "a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"said coupling operable by fluid pressure so that when a sufficient amount of fluid pressure is applied to the coupling, the fluid pressure a user causes the occlusive implant to separate from the pusher"  "the coupling is a connecting device that can be operated by selectively applying fluid pressure to the coupling to separate the implant from the pusher, and the application of the fluid pressure by the user to the coupling causes the detachment of the implant at the
"delivering fluid pressure through the pusher such that the implant detaches from the pusher by the fluid pressure"

Plain and ordinary meaning applies, no specific construction by the Court

(The Markman Order at 22-29, Docket Item No. 177.)

2. "stent impregnated [with rapamycin]"

This disputed term is found in claims 1 and 2 of the '781 patent, claim 1 of the '146 patent and claim 2 of the '728 patent. The parties have agreed that the term "stent" should mean "a device for placement in a vessel, such as a coronary artery, to provide support." Transcript of July 15, 2010 hearing at 88. This leaves the term "impregnated" for the Court to construe.

Plaintiff argue that the term "impregnated" should mean "filled, imbued, mixed, furnished, saturated, diffused, or permeated with another substance." Defendants proposed construction is very similar: "diffused, saturated, or permeated with another substance." Defendants, however, take issue in particular with Plaintiff's use of the term "furnished," which they argue is far too broad given the context of the term as it is used in the claim. The Court agrees. As Abbott points out, "furnished" can connote any conceivable pairing of two items, which is not contemplated by the plain language of the claim. Considering the various dictionary definitions provided by the parties and the plain language of the claim, the Court finds that a person of ordinary skill in the art would understand the term "impregnated" as it is used in claims 1 and 2 of the '781 patent, claim 1 of the '146 patent and claim 2 of the '728 patent to mean "filled, imbued, saturated, diffused or permeated with another substance," and the Court shall construe it as such.

E. Claims 2 & 10: "an impressed textured surface to trap air so as to facilitate unwinding of said roll of stretched film"

Dependent Claims 2 and 10 explain that the roll of stretched film has an "impressed, textured surface" that traps air between the layers of film and facilitates unwinding of the roll. Pliant asks me to construe these claims as "the plastic film has an embossed pattern that helps trap air and ease unwinding." Defendants argue that while this definition reflects the ordinary meaning of the claim terms, it fails to reflect explicit disclaimers made during the patent prosecution as well as limiting language found in the specification. To that end, Defendants propose that I construe the dependent claim as:

the plastic film has an embossed pattern--i.e., pockets or raised portions--that helps trap air and ease unwinding. The embossed pattern is created by the deliberate application of force to create pockets or raised portions utilizing an embossing roller, and thus would not include incidental impressions, scratches, or markings caused by passing the film over grooved rollers or by stretching of the film.

I begin with the ordinary meaning of the claim language. The parties agree that "impressed, textured surface" is not a term of art. Pliant argues that the term "impress" must be given its ordinary meaning, as defined by a dictionary, which is to produce a mark by pressure, or to imprint. The most recent Federal Circuit opinion to address the role of dictionaries in construing the ordinary meaning of terms, relative to intrinsic evidence, explains: "properly viewed, the 'ordinary meaning' of a claim term is its meaning to the ordinary artisan after reading the entire patent." Phillips, 415 F.3d at 1321. "Heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification." Id. While Defendants do not disagree per se with Pliant's dictionary-based construction of the ordinary meaning of impress, they would add several additional limitations to the definition based on the specification. Defendants' primary argument is that the specification requires that the impressed textured surface originates through "the deliberate application of force," so as to exclude any markings that result from incidental impressions or scratches, for example, those produced by grooved
Magistrate Judge Smith proposed the following construction for "an impression preform": "a thermoplastic resin which serves as an impression material." 6 (R&R 19.) Neither Party objects to the first part of the construction, and the Court finds no clear error in Magistrate Judge Smith's construction insofar as it defines "an impression preform" as "a thermoplastic resin which serves as an impression material." 7 However, Medtech objects to the second part of the proposed definition, arguing that the Court should omit the phrase "consistent with the remainder of the requirements in Claim 17." (Medtech Obj. 22.) As Medtech observes, this construction would appear "to incorporate all other definitions of all other terms (and their limitations) of Claim 17 into 'an impression preform,'" which would be redundant and contrary to "the well-established principle that terms within a claim must have certain meanings." (Id.) Accordingly, the Court construes "an impression preform" as follows: "a thermoplastic resin which serves as an impression material."
Medtech that such a limitation would be improper. (Id. at 19-20.) Dentek asserts that Medtech's acceptance of the limiting word "thermoplastic" as part of this construction is "inconsistent with its attempt to include 'thermosetting' as part of the definition of resin." (Dentek Resp. 5 n.2.) To the contrary, this construction is consistent with Medtech's and the Court's broad construction of "a resin," which reflects that thermosetting materials may be used for the appliance's base resin but that only thermoplastic materials are appropriate for the appliance's preform resin.

3. Court's Construction of Nisus' Patent Claims

The parties requested that the Court construe the claims at issue pursuant to Markman v. Westview Instruments, Inc. ("Markman II"), 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The Honorable Curtis L. Collier, the United States District Judge originally assigned to this case, held a Markman hearing on October 2, 2001 and issued a memorandum opinion construing the claims on January 14, 2002. The Court construed the term "improved depth of penetration," the only remaining claim at issue, to mean "improved cross-grain penetration in comparison to the Japanese prior art" [see Doc. 215 at p. 12].

2047

2. Improved Eschar

The next disputed claim term "improved eschar" is found in Claims 1 and 10 as set forth above.

ConMed's Proposed Definition: A shallower, more uniform and pliable surface layer of treated tissue that stops bleeding by more effectively sealing the affected tissue.

Canady's Proposed Definition: Indefinite.

(Docket No. 58, Ex. B, p. 5). After a review of the claim term itself, I find the term to be unclear. As a result, I turn to the specification for aid. After a review of the same, I disagree with Canady, however, that the claim term is indefinite.

An improved eschar, as indicated by the specification, is described as follows:

The fulguration eschar created by the present invention is characterized by an outer generally uniform depth reticulum of arc-created holes penetrating the tissue from a surface of the eschar; arc holes which are smaller in size, greater in number, more comparable or uniform in a cross-sectional size, and substantially more uniformly spacially distributed over the surface of the eschar; and a greater wall thickness of tissue between adjacent arc hold which provides pliability without cracking. Below the arc hole reticulum there exists a generally uniform-depth thermally desiccated layer which separates the arc hole reticulum from the unaffected tissue. The thermal desiccation layer of the fulguration eschar available from the present invention is also shallower in depth compared to the thermal desiccation layer of an eschar created by prior fulguration techniques....[It] is further characterized by a substantial absence of charring and carbonization in arc hole reticulum.

Docket No. 58, Ex. A, col. 5, ll. 18-40; see also, id. at col. 34, ll. 48-65. Based on the same, I construe the term "improved eschar" to mean an eschar (as defined above) that, when compared to electrosurgical fulguration made prior to this invention, is characterized by a shallower arc hole reticulum layer that has more uniform and smaller diameter holes evenly distributed over the surface of the tissue that is substantially free of charring and carbonization with thicker walls of tissue between adjacent arc holes and is shallower, and with a thermal desiccation layer that is relatively thin and more uniform in depth.

GO BACK
2. Construction of the disputed terms in claim 1.

a. "An improvement in a vehicle."

Claim 1 of the 948 patent is what is known as a Jepson claim, which includes (1) a preamble that sets forth all of the conventional elements of an invention and (2) a subsequent phrase describing the new or improved portion of the claimed invention. See Jepson v. Coleman, 314 F.2d 533, 50 C.C.P.A. 1051, 1963 Dec. Comm'r Pat. 304 (C.C.P.A. 1963); see also 37 C.F.R. § 1.75(e):

Where the nature of the case admits, as in the case of an improvement, any independent claim should contain in the following order: (1) a preamble comprising a general description of all the elements or steps of the claimed combination which are conventional or known, (2) a phrase such as "wherein the improvement comprises," and (3) those elements, steps and/or relationships which constitute that portion of the claimed combination which the applicant considers as the new or improved portion.

The United States Court of Appeals for the Federal Circuit has held that "Jepson claiming generally indicates intent to use the preamble to define the claimed invention, thereby limiting claim scope." Catalina Marketing Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). The phrase "an improvement in a vehicle" is the preamble to the 948 claim.

Plaintiff argues that the phrase should be read to mean "a module combined with a vehicle to create an improvement to the vehicle." Defendants contend that "an improvement in a vehicle" means "a device that is incorporated in, and becomes a part of, a vehicle." The crux of the parties' dispute concerns whether or not the invention is intended to become a permanent fixture inside of the vehicle. Mr. Lundell has answered this question in the affirmative, recommending that the Court adopt the following construction: "a module that becomes part of a vehicle and is intended to remain part of the vehicle during use."

As Mr. Lundell notes, during the prosecution of a previous patent, which described an earlier version of the invention at issue here, Plaintiff distinguished that device from the prior art by noting that the prior art was "not an improvement in a vehicle, but a stationary piece of shop equipment." See Amendment After Final dated December 30, 1991, at 7 (Bates No. JBA 008689) (cited in Superchips' Claim Constr. Br. at 10). That statement had -- and has -- the effect of narrowing the range of claimed devices. Cf. Covad, 262 F.3d at 1273-74. The Court finds, therefore, that although the patented invention may, like any other automobile part, be removed after installation, the patent and prosecution history, when read together, contemplate that the invention will remain part of the vehicle once attached. Accordingly, the Court adopts Mr. Lundell's recommended construction and holds that "an improvement in a vehicle" means "a module that becomes part of a vehicle and is intended to remain part of the vehicle during use."

Next, the district court construed the claim language "in," "within," and "between." Each of these claim construction issues is similar to the interpretation of "between" discussed above in relation to claims 5 and 33-36. The district court construed these words more narrowly than required by the claim language and context. The word "in" does not require that something be completely and continuously inside of something else. The word "within" does not require that something be completely and continuously within something else. Further, as discussed above in more detail, the word "between" does not require that something be completely and continuously between two things.

Nothing in the specification or the prosecution history supports such narrow readings, and no testimony was offered to suggest that these narrow interpretations are the correct meaning to one skilled in the art. Consulting the claim language again, the "between" requirement may be satisfied even if a component extends beyond the specified boundaries. In the same way, the "in" requirement may be met by a component which is located, at least in relevant part, in the defined space, as the "within" requirement may be met by a component which located, at least in relevant part, within the defined area. Accordingly, this court vacates the district court's grant of summary judgment of non-infringement, both literal and under
the doctrine of equivalents, as to claim 11 and remand for a trial on the merits.

2050

Evergreen alleges that Biomed's sputum collector infringes claim 1 of Evergreen's '346 patent. The disputed portion of claim 1 reads:

A specimen collecting device comprising: . . . graspable means releasably coupled to said supporting means, releasably holding said cap means in said supporting means when said supporting means is secured thereto, said graspable means being adapted to be grasped while holding said cap means as said closing means is coupled to and/or released from said container, whereby said graspable means aids in the coupling and/or releasing of said cap means.

'346 patent, col. 6, lines 36, 47-55 (emphasis added to disputed language).

Biomed argues that its device does not literally infringe claim 1 for two reasons which are dealt with seriatim.

1. Biomed contends that its device does not have "graspable means releasably coupled to said supporting means," i.e., a base stand cover. Evergreen responds that this limitation is met by the funnel lid which is "releasably coupled to the base unit via the collection tube." The Court concludes that the word "coupled" does not support Evergreen's interpretation. See ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988) (patents must be interpreted in accordance with the plain meaning of the claims). "Coupled" signifies direct contact between two objects. The specification uses the word "coupled" a multiple of times when referring to the direct contact of two objects. '346 patent, col. 3, lines 52-56; col. 4, lines 3-5, 7-10, 23-24. The other claims use the word "coupled" in the same way. See, e.g., '346 patent, col. 6, lines 66-69; col. 7, lines 22-29, 40-44. The part of Biomed's device which holds the vial cap is not, therefore, "coupled" to the base.

2. Biomed argues that its device does not store "said cap means in said supporting means . . . " Evergreen responds that the vial cap is held in the base unit because it is on the funnel which is on a vial located in the base unit. The word "in," however, is not synonymous with the word "on." The two words denote different spacial relationships. The vial cap of Biomed's device is not at any time encompassed by the base unit. Biomed's device does not, therefore, embody every element of Evergreen's patent claim. Given proper construction of the patent, the Court concludes that a finding of literal infringement is impossible.

GO BACK

2051

I. "In a chain saw"

Claim 1 begins with the term "[i]n a chain saw." Plaintiffs contend this preamble is not a claim limitation or an element of Claim 1, but merely describes a possible use for the invention. Defendants, however, maintain this term is a Jepson-type limitation and, therefore, is itself an element of Claim 1.

A. Jepson-type Preambles Generally.

"Generally, the preamble does not limit the claims." Allen Eng'g Corp. v. Bartell Indus., Inc., 299 F.3d 1336, 1346 (Fed. Cir. 2002). In a Jepson-type claim, however, the preamble to the claim is a limitation on the scope of the claim. See Pentec, Inc. v. Graphic Controls Corp., 776 F.2d 309, 315 (Fed. Cir. 1985). Jepson form allows an inventor to recite in a preamble "elements or steps of the claimed invention which are conventional or known." Kegel Co. v. AMF Bowling, Inc., 127 F.3d 1420, 1426 (Fed. Cir. 1997). When this form is used, a "claim preamble defines not only the context of the claimed invention, but also its scope." Rowe v. Dror, 112 F.3d 473, 479 (Fed. Cir. 1997).

There is no definitive "litmus test" to determine when a claim preamble is written in Jepson-type format. See Catalina Mktg. Int'l, Inc. v. Cool savings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). A preamble, however, "does not limit the scope of the claim when it merely states a purpose or intended use of the invention." In re Paulsen, 30 F.3d 1475, 1479 (Fed. Cir. 1994). See also Rowe, 112 F.3d at 478 (when a "patentee defines a structurally complete invention in the claim body and
uses the preamble only to state a purpose or intended use for the invention, the preamble is not a claim limitation.

Conversely, a preamble is limiting if it "breathes life and meaning into the claim". Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1118 (Fed. Cir. 2004).

In General Electric Co. v. Nintendo Co. Ltd., the claim preamble referred to: "A system for displaying a pattern on a raster scanned display device by mapping bits from a display location in a memory associated with a computer onto the raster." 179 F.3d 1350, 1361 (Fed. Cir. 1999). The Federal Circuit held this preamble was a limitation that gave "life and meaning" to the claim because the preamble made clear that the inventors were attempting to solve a narrow problem pertaining to a particular raster scan display rather than attempting to improve all display systems generally. Id. at 1361-62.

By contrast, the Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc. preamble described "A filter assembly for use with a bottle . . . to simultaneously cap the neck or open end and filter liquid poured out of the bottle. . . ." 381 F.3d at 1118 (emphasis in original). The Federal Circuit found this preamble was not a claim limitation because it merely "recites a purpose or intended use of the claimed filter assembly." Id.

Defendants assert the preamble to Claim 1 is a Jepson-type limitation because the specification of the '783 Patent provides the "invention relates generally to power equipment, and particularly to chain saws used for cutting material." '783 Patent col. 1 ll.6-8 (filed May 23, 1991). See also 35 U.S.C. § 112 (the specification in general is a written description of the invention and the manner or process of making and using it). Although Defendants maintain the specification clarifies that the '783 Patent requires a chain saw as an element of Claim 1, the text cited from the specification does not support Defendants' construction of the preamble.

If, as the specification states, the '783 Patent's invention relates specifically to a chain saw but also generally to power equipment, it is more likely that the preamble merely describes a purpose or intended use rather than laying out a claim limitation. See In re Paulsen, 30 F.3d at 1479. Thus, the specific case of a chain saw is only a subset of the general case of power equipment, and, therefore, the preamble is not a limitation.

As in Innova/Pure Water, and in contrast to General Electric Co., the preamble term "[i]n a chainsaw" does not indicate the '783 patentee was working on a narrow, specific problem. Moreover, the term does not appear to give "life and meaning" to the terms of Claim 1. Instead the preamble informs the reader of an intended use for the invention, and the language from the specification that Defendants highlight bolsters this interpretation.

The prosecution history of the '783 Patent also is instructive. At least two prior versions of the Claim 1 preamble were drafted and submitted to the Patent and Trademark Office. One version provided: "In a chain saw, a sprocket and saw chain combination comprising." Pitchford Decl., Ex. 1 at 40. Another version of the Claim 1 preamble provided: "In a chain saw including an elongated guide bar having a nose sprocket, a nose sprocket and saw chain combination comprising". Pitchford Decl., Ex. 1 at 55 (emphasis in original). Both of these prior versions of the Claim 1 preamble contain limiting and/or descriptive text that does not appear in the operative Claim 1 preamble, "[i]n a chain saw." Thus, the prosecution history demonstrates the '783 patentee ultimately chose a simplified preamble that merely describes a use for the patented invention. In other words, the patentee demonstrated the ability to write a limiting preamble that might have included elements of the claim, but ultimately the patentee chose not to do so.

Accordingly, in the context of the intrinsic evidence, the Court concludes the preamble to Claim 1 is not a Jepson-type limitation, but only describes an intended use for the invention.

On its face, claim 1 requires "a flexible dielectric substrate having a [susceptor] thereon residing in a close proximal relation to a substantial surface portion of said food item." To construe the terms "close proximal relation" and "substantial surface portion," we look to the intrinsic evidence.

The specification discloses food items, i.e., a fish stick, potatoes, and onion rings, wrapped in a manner such that the susceptor, which coats dielectric wrapping material, remains adjacent to the surface of the food item throughout the cooking process. Consequently, "residing in a close proximal relation to . . . said food item," as utilized in claim 1, refers to a
 positional relationship between the susceptor and food item in which the susceptor remains closely adjacent to the food item throughout the cooking process.

2053

B. "In a plane including the axis" as used in Claims 416:1, 5, 6, and 7 and Claim 730:6

Alden offers the following construction of this language: "The phrase 'in a plane including the axis' must be construed liberally rather than with geometric precision to allow for design integrity and manufacturing tolerances which in the real world offset the surfaces or edges slightly from a plane intersecting the bit axis." Alden Br. at 8. Eazypower argues that the plain language of the claims is sufficient.

1. Claim Language

a. Claim 416:1

The full text of this claim is set forth above in the section construing the term "point." The relevant language is: "the scraping edges of the recesses each being in a plane including the axis." DX B, col 3, lns 57-58. The construction offered by Alden contradicts the plain language of the claim. Further, the Court notes that Alden failed to use words of approximation, such as "in a plane approximately including the axis," despite using such terms elsewhere in the patent. See, e.g., DX B, col 4, lns 66-67 ("at a scraping edge acute angle to the axis less than about 70 [degrees]") (emphasis added).

b. Claim 416:5

The full text of this claim is set forth above in the section construing the term "point." The relevant language is: "longitudinal surface facing in a counter-clockwise direction and being in a plane including the axis" and "each rearward edge also lying in a plane including the axis." DX B, col 4, lns 18-20, 26-27. Claim 416:5 will be construed in the same way as claim 416:1.

c. Claim 416:6

The full text of this claim is set forth above in the section construing the term "point." The relevant language is: "the scraping edges of the recesses each lying in a plane including the axis of the bit." DX B, col 3, lns 44-45. Again, use of the phrase in this claim will be construed in the same way as in claim 416:1.

d. Claim 416:7

This claim states:

The combination as claimed in claim 6 including a support portion behind each scraping edge, the support portions each defined by a relief surface curving away from the scraping edge down to a rearward edge bordering one of the longitudinal recesses, the rearward edges both lying in a plane including the axis and being disposed at a third angle to the axis, the third angle being sharper than the second angle.

DX B, col 4, lns 50-57. Nothing about this language compels a treatment different from the other claims just discussed.

e. Claim 730:6

This claim reads exactly the same as claim 416:6, except that claim 730:6 refers to "a pair of longitudinal recesses," as opposed to "a plurality of longitudinal recesses." DX A, col 4, lns 37-54. The relevant language is: "the scraping edges lying in a first plane including the axis of the bit." DX A, col 4, lns 49-51. Once again, use of the phrase in claim 416:5 will be construed in the same way as in claim 416:1.

2. Specification

Both the "Summary of the Invention" and "Detailed Description of Embodiments" sections of the '416 patent essentially
repeat the language used in the claims. DX B, col 1, lns 40-41; col 2, lns 38-39; col 3, lns 10-13. There is no mention of design integrity or manufacturing tolerances in the specifications of either patent. 3. Prosecution History

Alden again refers to the Richards patent in the prosecution history, arguing here that Richards shows a "chisel point" design, in which the edges are slightly offset. For the reasons stated above under the Court's construction of the term "point," the Richards patent is given no weight.

4. Extrinsic Evidence

Alden again relies on the Desaulniers affidavit, here to establish that a person of ordinary skill in the art would understand that phrase is subject to manufacturing tolerances and design integrity limitations. Because the Desaulniers affidavit does not establish that Desaulniers is a person of ordinary skill in the art, the Court rejects the affidavit.

5. Construction

The additional language sought by Alden conflicts with the plain meaning of the phrase "in a plane including the axis." The Richards patent and Desaulniers affidavit are unconvincing. Further, the Federal Circuit has held that reading manufacturing tolerances into a claim is improper. Senmed, Inc. v. Richard-Allan Medical Industries, Inc., 888 F.2d 815, 820 n.10 (Fed. Cir. 1989). Therefore, the Court accepts Eazypower's proposed construction of "in a plane including the axis," and construes the phrase to mean simply what it says: "in a plane including the axis."

--- Footnotes ---

7 Alden cites Danacorp v. American Axle & Mfg., Inc., 110 Fed. Appx. 871 (Fed. Cir. 2004) as support for its proposition that a claim should be construed to account for manufacturing tolerances. The case was unreported and states: "Pursuant to Fed.Cir.R. 47.6, this order is not citable as precedent." Id. at 871. Therefore, the Court ignores Danacorp. Alden also cites Middletown, Inc. v. Minnesota Mining & Manufacturing Co., 217 F.3d 860 (Table), 1999 WL 1072246 (Fed. Cir. Nov. 16, 1999) (Middletown II). In Middletown II, the Federal Circuit noted in dicta that the district court's construction allowed for "normal manufacturing tolerances." Id. at *6. On a second appeal following remand, the Federal Circuit noted (cont'd) that it had not actually construed the term in Middletown II, and then construed the relevant term without allowing for manufacturing tolerances. Middletown, Inc. v. Minnesota Mining & Manufacturing Co., 311 F.3d 1384, 1389 (Fed. Cir. 2002) (Middletown IV). Middletown IV did not discuss whether manufacturing tolerances could ever be read into a claim; rather, the Court found that the evidence allegedly supporting a construction that included manufacturing tolerances was insufficient. Id. In any event, Middletown IV destroyed any basis for reading Middletown II as approving the practice of reading manufacturing tolerances into claim terms, and further, Middletown II was an unreported opinion. Therefore, the Court rejects Alden's reliance on Middletown II and follows Senmed, noting for the record that the Middletown decisions make no mention of Senmed.

--- End Footnotes ---

Judge Simpson construed two phrases of the '322 patent claims in Pillowtex. The first is the phrase "elastic material attached to inelastic material in a plurality of spaced apart parallel lines of attachment," which appears in Claims 1, 11, and 28. Judge Simpson construed this phrase to require that the fitted mattress cover must have embodied in its skirt a configuration of spaced-apart, parallel lines of attached elastic material; that is, that the elastic material itself must be configured in spaced-apart, parallel lines of attachment. The second phrase Judge Simpson construed appears in Claim 34, in the language "rows of elongated elastic cords extending in a longitudinal direction of the skirt...." Judge Simpson construed this phrase to mean that the fitted mattress cover must have embodied in it a plurality of elastic cords incorporated into the skirt material in rows. He rejected Louisville Bedding's contentions that the rows could extend in "more or less a straight line" (finding instead that "extending in a longitudinal direction of the skirt" limited the rows to straight lines), and that "rows" could mean "rows of stitches" (finding that the claim specifically described the configuration of the elongated elastic cords which are incorporated into a material).
Perfect Fit draws a number of conclusions from these rulings to which Louisville Bedding objects: specifically, that the "elastic material" must (1) take the form of strips, cords, yarns, threads, strings and like-shaped materials (i.e., must be elongated); (2) be the attaching mechanism itself, that is, must be stitched into (not onto) the inelastic fabric; and (3) be spaced apart substantially over the width of the sidewall. Perfect Fit correctly infers the first two of these conclusions from Judge Simpson's construction of the phrase "elastic material attached to inelastic material in a plurality of spaced apart parallel lines of attachment," as describing the configuration of the elastic material itself, rather than the points at which the elastic material is attached. Judge Simpson's use of the doctrine of claim differentiation to note that the "elastic material" contained in claims 1, 11 and 28 is not limited to the form of "elongated elastic cords" specified in Claim 34 is not inconsistent with Perfect Fit's assertion; the elastic material may take forms other than cords. But Judge Simpson's central construction, that the elastic material must take the described configuration -- to be attached in spaced-apart, parallel lines of attachment -- forecloses Louisville Bedding's assertion that the patent encompasses a continuous sheet of elastic material, at least to the extent that continuous sheet is not comprised of elastic strips, yarns, etc. which attach themselves in spaced-apart, parallel lines of attachment. 4 This preclusion is further supported by Judge Simpson's infringement analysis, in which he applied his construction to the product at issue in Pillowtex. He reasoned that "the Lycra(R) yarns which represent the only possible material to constitute 'elastic cords' in the # 4059 skirt material are woven into the fibrous base material in an interconnecting pattern of loops which travel in all directions throughout the material. There are simply no rows of elastic cords in Pillowtex's product." Further, Perfect Fit correctly notes that the use of the term "in" rather than "by" or "with" in the phrase "elastic material attached to inelastic material in a plurality of spaced apart parallel lines of attachment" requires an elastic sewn into, not onto, an inelastic material; thus, it is clear that the elastic material must itself be the attaching mechanism.

4 Though Judge Simpson did not explicitly reject the idea of a continuous sheet of elastic material, his construction of Claim 34 over the plaintiff's objections is telling: he states that this claim, which "contains the phrase 'rows of elongated elastic cords' . . . . specifically describes the configuration of the elongated elastic cords which are incorporated into a material. To suggest that the claim states otherwise solely on the basis that it arguably contemplates a woven fabric is unconvincing."

2055

4. "in accordance with" (claim 1)

Flow contends that this phrase does not require construction, but that if it did, the construction should be "in conformity with." Omax seems to agree that this phrase is properly construed as "in conformity with," but proposes also to add language to indicate that this phrase is more general than, and includes, the phrase "as a function of," which appears in claims 14-17. Omax does not argue that there is any dispute about these definitions, nor that there might be any confusion. Therefore, there is no reason to include the additional information proposed by Omax. The Court adopts Flow's construction: "in conformity with."

GO BACK

2056

1. "[I]n alignment" of Claim 5

wherein said transitional area curves upward longitudinally to said sidewall, an annular sidewall continuously extending around said bottom in alignment with said sidewall, said annular wall having a bottom edge forming a lower support surface projecting beyond the bottom surface of said bucket

a. Magistrate Judge's Ruling
The magistrate judge interpreted the phrase "in alignment" in Claim 5 to mean "in a straight line with" after considering both the defendants' and plaintiffs' dictionary interpretations of the phrase. R&R at 14. The magistrate judge relied on Phillips to emphasize that the use of dictionaries to assist in determining the ordinary and customary meaning of claim terms has its limitations. Id. at 12. Further, the magistrate judge noted that 'ordinary meaning' is the meaning to the ordinary artisan after reading the entire patent. Id. at 13. However, the magistrate judge was not persuaded that a person of ordinary skill in the art of molding plastic buckets would interpret "in alignment" to include "parallel." Id. at 13-14. The magistrate judge noted that neither the claims nor the specification provide any description of the placement of any parallel foot extending from the bucket side wall. Instead, Figure 5 of the '493 patent shows the annular sidewall (134) extending underneath the sidewall of the bucket (112) in a straight line. Id. at 13.

b. The Defendants' Objections

The defendants argue that the magistrate judge ignored the ordinary meaning of the term "in alignment" when she rejected citation to dictionary definitions and instead imposed a limitation on the meaning of the term from the preferred embodiment in Figure 5.Defs. Objections at 10. They also contend that the magistrate judge incorrectly relied on Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005), in rejecting dictionary definitions proposed by the parties because the '493 patent does not define or explain the term "in alignment." Id. at 10. Specifically, the defendants submit that the appropriate consideration of dictionary definitions combined with the context of the specification requires a finding that "in alignment" means "generally or substantially in a straight line or parallel lines." Id. at 9-11. In support, the defendants argue that the embodiment in Figure 5 illustrates something other than a straight line because the internal surface of the sidewall may be cored out to support another bucket, and the wall thickness of the lower end of the bucket may be increased up to 20%. Id. at 11.

c. This Court's Construction

In Phillips, the Federal Circuit stated:

Properly viewed, the 'ordinary meaning' of a claim term is its meaning to the ordinary artisan after reading the entire patent. Yet heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context.

Phillips, 415 F.3d at 1321.

Here, nothing in the intrinsic evidence indicates that one skilled in the art would view the ordinary meaning of "in alignment" to mean "parallel." When referring to the annular bottom portion and the sidewall, the specification does not mention the word "parallel," nor does it indicate that these two elements should be parallel. Instead, Figure 5 of the '493 patent shows that the annular sidewall (134) extends directly beneath the sidewall (112) in a straight line. '493 patent at Fig. 5. Further, the specification notes that "[t]he bottom of the bucket merges with sloped sidewall through an interface." Since the sidewall merges with the bottom through the interface, to have the annular sidewall parallel with the sidewall requires an offset configuration, which does not support the patent's intent to prevent corner stress points. See '493 Patent at Cols. 4:65 -- 5:1 (where specification states that "[t]he plastic is allowed to flow freely around the corner in the molding process of bucket and also into the annular bottom portion or foot in order to prevent corner stress at areas upon which the bucket rests").

In addition, even though the '493 patent indicates that the internal surface of the sidewall may be cored out to support another bucket ('493 patent at Col. 5:9-12, Fig. 5) and the wall thickness of the bucket at its lower end may be thickened up to 20% ('493 patent at Col. 5:6-9), one skilled in the art would not interpret these modifications to suggest the annular bottom portion is parallel to the sidewall when it must be positioned straight under the sidewall to prevent corner stress. Finally, the defendant's assertion that the term "in alignment" should be construed to mean parallel would improperly impose a restriction narrower that the term's ordinary meaning. See, e.g., Phillips, 415 F.3d at 1323 (noting that "in Acumed, the Federal Circuit refused to impose a restriction from the specification narrower than the term's ordinary meaning" and declined to interpret "transverse" as meaning "perpendicular" where the intrinsic evidence suggested that the patentees knew how to restrict their claim coverage, but chose a different claim term that implied a broader scope) (citing Acumed LLC v. Stryker Corp., 483 F.3d 800, 809 (Fed. Cir. 2007)).
Based on the language of the specification, the claims, and the figures of the '493 patent, the court concludes that one skilled in the art would not construe "in alignment" to mean "parallel." As a result, the defendants' reliance on the extrinsic dictionary definition does not override the intrinsic evidence supporting this court's construction. Thus, the court construes "in alignment" to mean "in a straight line with."

The parties propose the following constructions for these disputed terms:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Dyson Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>'181/1 an airstream outlet opening in an upper central portion of the dirt separation housing and in communication with the inlet opening;</td>
<td>An opening in the dirt separation housing that is located in or near the top of the dirt separation housing and lies on the longitudinal axis of the dirt separation housing. (Jt. State.)</td>
</tr>
<tr>
<td>'181/1 a support element mounted in an upper portion of said dirt separator housing;</td>
<td>Attached to the dirt separator housing at or near the top of that housing. (Jt. State.)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Bissell Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>'181/1 an airstream outlet opening in an upper central portion of the dirt separation housing and in communication with the inlet opening;</td>
<td>The airstream outlet opening is centrally located in the top half of the dirt separation housing. (Jt. State.)</td>
</tr>
<tr>
<td>'181/1 a support element mounted in an upper portion of said dirt separator housing;</td>
<td>Attached in the upper half of the dirt separator housing. (Jt. State.)</td>
</tr>
</tbody>
</table>

The parties' proposed constructions diverge primarily regarding the meaning of "upper" and "central." The court addresses each word in turn. Bissell proposes construing "upper" to mean "top half." Dyson construes "upper" more narrowly, limiting it to "at or near the top." The word "upper" itself is consistent with "top half." Nothing in the patent language suggests or compels a more limited construction. It is true that the figures in the patent generally disclose an opening at or near the top of the separation housing, as Dyson notes. However, it would be legally improper to limit the claim based on features of illustrative figures alone, particularly where additional intrinsic evidence supports a different conclusion. See MBO Labs., Inc. v. Becton, Dickinson & Co., 474 F.3d 1323, 1333-34 (Fed. Cir. 2007); Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 907 (Fed. Cir. 2005). In this case, the additional intrinsic evidence includes the prosecution history, which reveals that the Patent Office allowed Claim 1 to issue only after considering a prior patent, the "Wright et al. Patent," that disclosed an airstream outlet "in a lower portion of the housing." (Bissell Ex. C-1, Prosecution History of the '181 Patent, at 82.) In its decision to allow Claim 1, the Patent Office emphasized that Claim 1 of the '181 Patent differed from the Wright et al. Patent in placing the airstream outlet in an upper, rather than a lower, portion of the housing. (Id.) The Patent Office required no more limited description of the height at which the airflow outlet was placed. The Patent Office's decision framed the notion of "upper," against its opposite, "lower," not in terms of the top or bottom edge of the structure. This is more consistent with an understanding of "upper" as "the top half."

Neither party has proposed a convincing construction for the term "central." Bissell's proposed construction simply
transforms the adjective "central" into the adverb "centrally" and leaves the term undefined. At oral argument, Bissell further suggested that "central" be construed as "away from the periphery." Dyson's proposed construction weaves something entirely new (a "longitudinal axis") that lacks any textual basis in the patent, the prosecution history or even the extrinsic evidence. The Court rejects the parties' proposed constructions of this word and chooses its own.

The problem with Bissell's original proposed construction is that it does nothing to define or otherwise give limiting content to the disputed claim term. The problem with Bissell's second proposed construction is that it focuses on the wrong point: the claim term "central" suggests an area defined by its relationship to the center of something, in this case the housing; Bissell focuses, instead, on the edge or the periphery of the housing, which has the effect of claiming too broad a region. The central area of a city, by analogy, is not the area "away from the suburbs;" rather, it is the area near the center of town.

This discussion also highlights the problem with Dyson's proposal: Dyson tries to limit "central" to a single set of points on a line in space (the "longitudinal axis"), but the claim term "central" suggests a region, not a point or set of points on a line. Using the same city analogy, the "central city" is not simply the geometric center point of town, but rather an area near the center. Based on these considerations, the Court construes "central" to mean "closer to the center than to the edge of the housing."

Accordingly, the Court construes "an airstream outlet opening in an upper portion" as "the airstream outlet opening is located in the top half of the dirt separation housing and closer to the center than to the edge of the housing;" and the Court construes "mounted in an upper portion" as "attached in the upper half of the dirt separator housing."

D. In Combination

Webster's defines combination to mean: "(1) a result or product of combining; … (2) an ordered sequence … (5) (a) the act or process of combining … (b) the quality or state of being combined." WEBSTER'S at 262. Blank proposes that "in combination" should be construed to mean "two separate items joined together." (Def.'s Markman Brief at 12. Fiala would interpret "in combination" to mean "the aggregate of the first card and the package." (Pl.'s Markman Brief at 23.)

Blank presents a unique argument. "In combination" is a standard introductory phrase in patent claims. The court, however, could find no Federal Circuit opinion which interprets that phrase. Given the ubiquitousness of the phrase in patent claims, the claim language, the specification, and the prosecution history offer no help in interpreting its meaning. All seem to assume that the reader already knows the meaning. Given this situation, the court has surveyed the relevant case law. There is no indication that the presence of the phrase "in combination" indicates that two separate items will be "joined together" as Blank uses that phrase. Cf. Berg Tech., Inc. v. Foxconn Int'l, Inc., 1999 U.S. App. LEXIS 2796, 1999 WL 96414, at *3 (Fed. Cir. Feb. 23, 1999) (stating that terms commonly used in patent claims which have a generally understood meaning should not be given a meaning inconsistent with the generally understood meaning absent some indication in the claims, specification, or prosecution history that such a departure was intended). "In combination" simply indicates that all of the combined elements must be present. See, e.g., General Mills, Inc. v. Hunt-Wesson, Inc., 103 F.3d 978, 979 (Fed. Cir. 1997) (discussing in combination a food item and a wrapping material).

The court, therefore, interprets the phrase "in combination" to mean: "the aggregate of." The evidence before the court indicates that a person of ordinary skill in the art, as well as the patent bar, would have so defined "in combination" at the time the patent was prosecuted.
"the aggregate of [the first card and package]." (Pl. Brief at 23.) SVS contends that the phrase "in combination" speaks for itself, but goes on to argue that the plain meaning of the term "in combination" in the context of claim 12 requires that two formerly separate items (the card and package) be joined together. (Def. Slide 75.)

"In combination" is a standard introductory phrase in patent claims. Given the ubiquity of the phrase in patent claims, the claim language, specification, and prosecution history offer little help in interpreting its meaning. All patent applicants seem to assume that the reader already knows what "in combination" means. Nevertheless, the defendant points out that all the embodiments and drawings show a separate card and package joined together, rather than a unitary package/card combination, and cites several cases for the proposition that the claim language incorporates this assumption. See Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999); Wang Lab., Inc. v. America Online, Inc., 197 F.3d 1377, 1382 (Fed. Cir. 1999); Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001). These cases, however, establish no rule that if "only one embodiment is disclosed in the specification, claim terms are limited to the embodiment disclosed." Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1326 (Fed. Cir. 2002). Resort to the specification to give a patent term other than its ordinary meaning was allowed most recently only after "the applicant admitted that certain claim terms lacked any agreed upon meaning in the art … and unequivocally directed the patent examiner, as well as the public, to the specification as the complete source of meaning for the disputed terms…" Irdeto Access, Inc. v. Echostar Satellite Corporation, 383 F.3d 1295, 1302-03 (Fed. Cir. 2004).

Given the frequent use of the term "in combination" in patent claims, the defendant cannot argue that the term has no agreed upon meaning. There is no indication from the text of claim 12 that the two items claimed "in combination" with one another must have existed separately at any previous time. "In combination" simply means that the two combined elements are present. See, e.g., General Mills, Inc. v. Hunt-Wesson, Inc., 103 F.3d 978, 979 (Fed. Cir. 1997) (discussing "in combination" a food item and a wrapping material). Resolving a dispute similar to this one, this court recently interpreted the phrase "in combination" to mean "the aggregate of." See Barry Fiala, Inc. v. Arthur Blank & Co., No. 02-2282 Ma, 2004 U.S. Dist. LEXIS 28624 (August 24, 2004). The court sees no reason to abandon that construction in the instant case. The court, therefore, interprets the phrase "in combination" to mean: "the aggregate of."

2060

B. Term 2: "in communication with"

The Court construes the term "in communication with" in claims 1 and 2 of the '281 patent as follows:

A portion of a first member is "in communication with" a portion of a second member if those two portions are cavities or tubes whose interior spaces are connected to each other by means of an opening or passageway.

Claim 1 of the '281 patent covers a device with two "members" and requires that "at least a substantial portion of the central portion[s]" of the two members be "in communication with" each other. Claim 2 of the '281 patent depends from claim 1 and covers a device with "disks in communication with one another [that] are attached to one another to define a conjoint disk."

The University contends that "in communication with" means "interconnected with." Am. JCCS Sched. B at 5; Univ. Opening Br. at 22-23. But at oral argument, the University conceded that, as far as this case is concerned, "interconnected" is no different from "connected." Hr'g Tr. at 57. Thus, the University contends that "in communication" as used in the '281 patent is synonymous with the terms "joined," "affixed," and "connected" discussed above. Id.

AGA likewise treats "in communication with" as basically synonymous with "joined," "affixed," and "connected." As it does with respect to the latter three terms, AGA asks the Court to substitute a complete sentence for a word or phrase that functions as an adjective. According to AGA, "in communication with" means: "The first and second members must be physically discrete and separate components; these physically discrete and separate components must be attached to and in contact with each other over a substantial portion of the respective central portion of each member." Am. JCCS Sched. B. at 5; AGA Opening Br. at 19.

AGA's proposed construction wrongly transforms a simple prepositional phrase into a series of statements larded with
factual assertions that relate tangentially (at best) to the claim language to be construed. The University's proposed construction is also unhelpful, although it is at least more sensible than AGA's in form. The University's construction also prompts the question: If "in communication with" just means "connected to," why doesn't the patent just say "connected to"?

The likely answer is that the lawyer who drafted this claim thought (or hoped) that "in communication with" was broader than "connected to." The '281 patent is the last patent to descend from patent application number 07/822,951 filed in 1992. Earlier patents in the same family generally cover "disks" whose central portions are "affixed" to each other. See, e.g., '291 patent claim 1; U.S. Pat. No. 5,334,217 claim 1. But in claim 1 of the '281 patent, the drafter substituted the vague term "member" for the clearer term "disk," in an obvious attempt to claim the patented invention more broadly than earlier patents did. 9

But the word "communication," when used to denote a physical relationship, has a very particular meaning. The relevant definition of "communicate" in AHD Third is "[t]o be connected: apartments that communicate." AHD Third 383. The relevant definition of "communicate" in Webster's Third is "to be connected: open into each other: afford unbroken passage: join <<the two rooms [communicate]> <<the pantry [communicates] with the hall>." Webster's Third 460. These definitions, and the examples they provide, establish two things about the physical relationship of "communication." First, things that communicate physically must have an interior space, as do cavities (such as rooms) or tubes (such as hallways). Second, physical communication involves connecting those interior spaces to one another.

The University relies on the definition of "communicate" in Webster's Third to support its contention that "in communication with" means "interconnected with." Am. JCCS Sched. B. at 7; Univ. Opening Br. at 23. But the University has not explained why the Court should look only at the first portion of the definition ("to be connected") and ignore the remainder ("open into each other: afford unbroken passage").

A patentee can, of course, be his own lexicographer. Phillips, 415 F.3d at 1316 ("[T]he specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs."). But the '281 patent contains nothing to suggest that the word "communication" in claim 1 means something out of the ordinary. To the contrary, the specification of the '281 patent uses a form of the word "communication" twice, and both times the word seems to carry its ordinary meaning.

First, in describing the purpose of the claimed invention, the '281 patent says that "the instant closure device can be used to treat ventricular septal defects, patent ductus arteriosus[,] or any other congenital or acquired orificial or tubular communications between vascular chambers or vessels." '281 patent col. 18:1-4 (emphasis added). An "orificial . . . communication[]" between chambers or vessels is obviously a hole; a "tubular communication[]" is obviously a tube or passageway. Thus, "communications" has its ordinary meaning here. In particular, the "communications" described in the quoted portion of the '281 patent are connections between cavities ("vascular chambers") or tubes ("vessels"), and those cavities or tubes are in communication with each other because an opening or passageway connects their interiors.

Second, in describing a delivery system for the claimed closure device, the '281 patent says that a "chamber 216 must extend through the distal end 211 of the housing to define a distal port 219 therein . . . to permit communication of the control means 230 with the catheter C." '281 patent col. 13:63-66 (emphasis added). From Figures 13 and 14 of the '281 patent, it is apparent that a catheter -- a hollow tube -- is connected by means of an intermediate tubular part to a hollow chamber that contains the "control means" referred to in this sentence. Thus, the catheter and the chamber that houses the control means "communicate" with one another in a conventional sense. The control means itself does not, strictly speaking, "communicate" with the catheter; rather, the control means is connected to a part (a "tubular urging member," '281 patent

9 Notably, in claim 2 of the '281 patent, the drafter forgot to carry out his project of broadening the claim language. Claim 2 covers "[t]he device of claim 1, wherein the portions of the disks in communication with one another are attached to one another to define a conjoint disk." '281 patent claim 2 (emphasis added). But claim 1 does not (as it did in earlier patents in this family) refer to "disks"; it refers to "members."
col. 15:16) that rides within the catheter. But because the control means is connected to a part within the catheter's interior, the control means does, in a loose sense, "communicate" with the catheter.

In light of this intrinsic evidence about how the words "communication" and "communications" are used in the '281 patent, the Court construes the term "in communication with" in claims 1 and 2 according to its ordinary meaning. Whether this construction covers the disclosed embodiments is beside the point, because no other construction is reasonable in light of the evidence. See Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999) ("[A] nonsensical result does not require the court to redraft the claims of the . . . patent. Rather, where . . . claims are susceptible to only one reasonable interpretation and that interpretation results in a nonsensical construction of the claim as a whole, the claim must be invalidated . . .").

2. "A Hollow Valve Liner . . . Defining a First Bore In Communication with a Source of Relatively Hotter Liquid"

At the preliminary injunction hearing, Bradley argued the "in communication" language of claim 6 requires that the first bore and the source of relatively hotter liquid be adjacent. Defs.' Prelim. Inj. Opp'n Br. at 42-43; Prelim. Inj. Hr'g Tr. at 565, Ballanco-Cross. In addition, the language requiring that the liner define a "first bore" and define a "shuttle bore" means that the first bore and the shuttle bore must be two separate bores rather than different sections of the same bore, or just a single annular interior cavity that functions as both a first bore and a shuttle bore. Defs.' Prelim. Inj. Opp'n Br. at 42; Prelim. Inj. Hr'g Tr. at 430, 433, Kline-Direct; id. at 447-48, Kline-Cross.

Lawler disagreed with Bradley's interpretation of "in communication" and with the specific requirements of a liner that defines a first bore and a shuttle bore. At the preliminary injunction hearing, Lawler argued that the phrase in communication meant the same thing as the phrase in fluid communication. Pl.'s Prelim. Inj. Reply Br. at 20-21; Prelim. Inj. Hr'g Tr. at 194, Ovens-Direct. Thus, claim 6 does not require that the first bore be adjacent to the hotter liquid source, only that the part be open to fluid flowing from the hotter liquid source. See Prelim. Inj. Hr'g Tr. at 194, Ovens-Direct. In addition, Lawler argued that the '531 Patent contains no restriction on the overlap of the first bore and the shuttle bore. Prelim. Inj. Prelim. Inj. Hr'g Tr. at 193, Ovens-Direct. Without such a restriction in the '531 Patent, Lawler argued, the first bore and the shuttle bore can overlap until they are both the same physical part, so long as that part has the relationships required by the remainder of the claim.

The Court finds that Bradley's definition of in communication that limits the connection of the parts such that they must be adjacent to or directly connected to one another is not supported by the plain meaning of the claim language or the specification. In common usage, communication can occur directly or indirectly, for example, by face-to-face conversation or by tape-recorded-voice-to-person. In the context of the '531 Patent, the purpose of which is to allow fluid of different temperatures to mix and be controlled to a set degree, there is no reason to limit the communication between various parts of the assembly to direct communication or connection. The important theme is allowing the fluid to flow from one area to another.

Further, the dictionary defines communication as the act of transmitting, connected to or open to. See, e.g., WEBSTER'S THIRD NEW INT'L DICTIONARY 460 (Merriam-Webster Inc. 1981). There is nothing in claim 6 or the other claims that limits this definition of communication to a more narrow one requiring that the parts be "directly open to" or "directly connected to" any other part.

The patent specification further supports this finding. The '531 Patent states: "The hot liquid bore opens into the hot liquid chamber so that liquid can be communicated through the bore and up through the shuttle bore of the valve liner." '531 Patent, col. 7, ll. 63-67. In the specific embodiment pictured, it appears that the inventor intended that the first bore be directly open into the hot liquid chamber. However, the description of the hot liquid bore suggests that the bore need only be open to the hot liquid chamber such that liquid can move, or be communicated, from the hot liquid chamber into the first bore and from there to the shuttle bore and the mixing chamber. There is no language that limits the shape of the opening from the hot liquid chamber to the area called the first bore, only that the first bore be open to the receipt of hot liquid from the hot liquid chamber.
The Court finds that in communication within the context of the '531 Patent means open to or connected to without limitation on proximity or limitation on the mode of connection.

Furthermore, the Court finds that claim 6 is not limited to valve assemblies that have two distinct bores, a first bore and a shuttle bore; claim 6 is broad enough to encompass a liner that defines a single bore that both communicates with the hot liquid source and is the bore in which the shuttle valve moves. The language of claim 6 that describes the liner also describes the first bore, the shuttle bore and the relationship of those bores to each other and to other parts of the liner. Specifically, claim 6 states: "a hollow valve liner defining a number of apertures . . . and defining a first bore . . . said liner further defining a shuttle bore . . . ." '531 Patent, col. 14, ll. 7-13. Whether claim 6 calls for the first bore and the shuttle bore to be two distinct bores appears to turn on the meaning of the word "further" in the context of the patent. Neither party discussed the meaning of this term. However, the common meaning is in addition or also. "In addition" could connote multiple parts, such as "one after the other." But, claim 6 does not distinctly require multiple parts. The claim only requires a liner that defines a number of apertures and two bores that have specific relationships to each other. The specification does not provide otherwise.

However, there is a difficulty in saying definitively that further means in addition or also and not "one after the other" because the language earlier in the claim used the connector "and" rather than "further." Arguably, the difference is relevant because there was no need to use "further" when "and" would have conveyed "also" as it did earlier in the same claim. Faced with this uncertainty, the Court will look to the extrinsic evidence to help clarify this aspect of claim 6.

The extrinsic evidence supports an interpretation of claim 6 that allows for the first bore and the shuttle bore to overlap. Lawler's expert, Dr. William Ovens ("Dr. Ovens"), specifically stated that the two sections of the liner could overlap because there was no restriction or limitation in the patent that would prohibit such an arrangement. Prelim. Inj. Hr'g Tr. at 193, Ovens-Direct. In addition, Bradley's expert apparently agreed that the patent did not preclude a liner in which a single bore defined both the first bore and the shuttle bore. Id. at 574-76, Ballanco-Cross. In fact, Ballanco testified that faced with the ambiguity in the claim, he issued his opinion on infringement based on either interpretation of claim 6: one that allowed for a single bore and one that required two distinct bores. Id. at 576.

In the context of the '531 Patent and in light of the testimony by both experts, the Court finds that there is no limitation that the first bore and the shuttle bore be distinct bores; the bores may overlap or be a single bore so long as the bores have the relationships required by the remainder of claim 6.

The phrase is construed to mean, "Cooling said core while at the same time applying a third pressure."

As above, Defendant urges that the phrase "in conjunction with" fairly implies that the cooling "starts and ends at the same time a third pressure is applied." (Def. Br. at 44.) For the reasons recited above, I reject the Defendant's argument that these words suggest absolute synchronicity (though I question why the patentee could not have used the same terminology in both claims).

Airflow to and from said intercooler in counterflow with coolant

The parties do not dispute that "counterflow" means flowing in an opposite direction. The essence of the dispute is whether the frame of reference for determining the counterflow is outside the intercooler (Rice) or within the intercooler where there
is heat transfer between the air flow and the coolant (i.e., thermal contact) (Rolls-Royce). Rice relies upon the recitation in the claim of air flow "to and from" the intercooler as indicating that it is the overall direction of the air flow between the compressors as established by the outlet and return ducts that is in counterflow with the coolant. That is, Rice focuses on the entry and exit points of each fluid. Rice Br. 22.

Rolls-Royce correctly points out that the plain meaning of the "to and from" recitation merely specifies that the intercooler positioning is such that air flow is to the intercooler from the low pressure compressor and from the intercooler to the high pressure compressor. Further, there is no dispute that one skilled in the art would consider heat exchange with a coolant to only take place inside an intercooler where there is thermal contact. To one skilled in the art, reference to "in counterflow with coolant" would only have meaning in regard to the flow of air through the intercooler and not air flow that is to and from it.

The specification supports a construction that the counterflow with coolant exists for air flow that is through the intercooler. In Fig. 1, the '499 patent provides a schematic diagram of the intercoolers 38, 40 as well as the outlet duct 36 from the low pressure compressor 24 and the return duct 42 to the high pressure compressor 44. As shown, the flow to the intercooler through duct 36 is in the same direction as the flow of the coolant out of the intercooler through line 70. Similarly, the flow out of the intercooler through duct 42 is in the same direction as the flow of the coolant into the intercooler through line 68. Only the flow within the intercooler is consistent throughout the schematic diagram with the plain meaning of "counterflow" as being in an opposite direction.

The prosecution history provides further guidance as to the manner in which the term "counterflow" is to be construed. In the response Rice filed on July 7, 1989, a further amendment to claim 69 was inclusion of the recitation "in counterflow with coolant." See Resp. 2. Rice then remarked that in the Hull patent disclosure "the heat exchanger 16 does not and cannot readily apply counterflow of the compressed air to the coolant." Rice further remarked that, "Therefore, a close approach temperature to the coolant at its entrance temperature is not possible because the partially compressed air and heated coolant flows in the same direction as the compressed air being cooled." Resp. 8.

In the disclosure of the Hull patent, air is divided into an outer stream and an inner stream. The outer stream of cooler air is applied to the input of a heat exchanger 16 as the coolant. The inner stream is compressed, which causes a temperature increase, and is input to the heat exchanger in parallel with the cooler outer stream. The airflow of both streams through the heat exchanger is shown to be in the same direction, as stated by Rice. The disclosure in Hull and Rice's remarks support a construction that counterflow with coolant means air flow through the intercooler is in an opposite direction to the flow of coolant through the intercooler.

Rice contends that the prosecution history is consistent with its proposed definition in that it was the flows to and from the heat exchanger 16 in Hull, which are in the same direction, that were being distinguished. However, Rice's remarks when read closely identify reference is being made to the direction of "the compressed air being cooled." The compressed air is being cooled only inside the heat exchanger. Rice's comment, therefore, only has meaning in regard to flow inside the heat exchanger 16. Rice also contends that Rice's remarks should be taken in the context of other disclosures in Hull concerning alternative flow arrangements. However, the examiner's rejection specified heat exchanger 16 and Rice's remarks specified heat exchanger 16. Moreover, there is no specific description given in Hull of an alternative flow arrangement beyond a generalized statement that the streams could be passed through the heat exchanger twice wherein the bypass fluid flows in one set of passages and the compressed fluid flows through the other set of passages "in radial counterflow passes." This by no means clearly identifies the structure of such a heat exchanger. Moreover, the description is that "each" stream is directed through the heat exchanger twice in radial counterflow passes. This does not suggest that the compressed fluid is moving in the opposite direction to the bypass fluid.

Accordingly, the Court adopts the construction proposed by Rolls-Royce.

2064

In dependence on an expected trajectory of said tooth through formation material

The Court finds that it can give Claim 1's term "in dependence on an expected trajectory of said tooth through formation
material" its "ordinary and accustomed meaning as understood by one of ordinary skill in the art" by virtue of the claim language itself. No one disputes that a person of ordinary skill in bit engineering would interpret "expected trajectory" as an "expected path." Moreover, the claim clearly refers to the path that the drill tooth being adjusted ("said tooth") takes through the well bottom ("through formation material"). Thus, there is a heavy presumption that claim one means "based on the expected path the drill tooth being adjusted takes through the formation." Bell Atlantic Network Services, Inc., 262 F.3d at 1268. Because the claim term is capable of a clear construction and is unambiguous, the Court will only depart from this construction if the patentee has chosen to be its own lexicographer. See id.

9 See Alloc, Inc. v. International Trade Commission, 342 F.3d 1361, 1368 (Fed. Cir. 2003); Bell Atlantic Network Services, Inc., 262 F.3d at 1267.

Smith contends that the patentee has defined the simple term "expected trajectory of said tooth" as "a calculated directed straight line segment extending from a calculated point of engagement of the tooth with the formation to a calculated point of disengagement of the tooth with the formation, wherein the points of engagement and disengagement are calculated from the centerline of the tooth." Thus, Smith argues that the intrinsic evidence "clearly set[s] forth or clearly redefine[s] [the] claim term so as to put one reasonably skilled in the art on notice that the patentee intended to so redefine the claim term." Id. (internal quotations omitted). Smith argues that a paragraph in column 9, at lines 50-67, and figures 3A-3D of the 262 Patent require its construction.

The paragraph in column 9 discusses a calculation that may be performed using the expected tooth trajectory. The first sentence of the paragraph recognizes that "tooth trajectories" are the positions at which the teeth will actually encounter the formation by stating: "the tooth trajectories described above are projected on the hole bottom which is fixed in space." The paragraph then declares that the bit designer must determine the tooth orientation angle from the trajectory in order to properly align the teeth. The specification uses the actual projected points where individual teeth intersect the formation to determine the point at which a tooth will enter and subsequently leave the formation. 10 From these entry and exit points, the patent "approximates" the tooth trajectory as a straight line.

10 The entry point \( P[1] \) is calculated by the formula: \( P[1] = [x[1], y[1], z[1]][c] \). The exit point \( P[2] \) is calculated by the formula: \( P[2] = [x[2], y[2], z[2]][c] \).

The column 9 paragraph does not redefine "expected tooth trajectory." The paragraph describes optimizing tooth orientation by using the actual expected tooth trajectories to calculate an "approximate" tooth trajectory. It is only by first calculating the actual tooth trajectory that the specification allows for calculating an approximate tooth trajectory. Nonetheless, Smith would read the "approximate tooth trajectory" to redefine "tooth trajectory." The patentee chose to use "expected tooth trajectory" in Claim 1, not "approximate tooth trajectory." The paragraph in column 9, far from clearly redefining "expected tooth trajectory," distinguishes between the actual and approximate tooth trajectories. Although the "approximate tooth trajectory" may be necessary to optimize tooth orientation, it is not a part of the claim and the Court will not read it into Claim 1.

Likewise, figures 3A-3D (illustrated infra) do not indicate that the patentee clearly redefined or limited the term "expected tooth trajectory" to a straight line. The figures illustrate a curved anticipated tooth trajectory. Indeed, Smith concedes the point by its statement: "the actual trajectory of each tooth is curved, as shown by the staggered squares." Nonetheless, Smith argues that the straight line on Figures 3A-3D illustrate the "calculated trajectory" Smith gleaned from the column 9 paragraph (discussed supra). Even if the straight line does illustrate the approximate trajectory discussed in column 9, nothing in the illustration indicates any intention to redefine or limit Claim 1's "expected trajectory" to this "calculated trajectory." Without a clear expression of intent, the Court will not read such limitation into Claim 1. Id.
II. "at least two electrodes in direct contact with the cell"

Lifescan contends that the Court need not construe this term, 1 while Roche proposes "the electrodes contact the cavity directly, without any interposed layers or barriers (such as a semi-permeable membrane layer)." The Court construes this term as "at least two electrodes in direct physical contact with the cell." During the hearing, both parties agreed that "in direct contact" means direct physical contact.

--- Footnotes ---

1 Lifescan initially proposed that the Court construe this phrase as "at least two electrodes in direct contact with the sample receiving cell." Lifescan's reply acknowledges that this construction does not define the language at issue, and argues that there is no need to define this term.

--- End Footnotes ---

Roche argues that the Reexamination supports its proposed construction because Lifescan added the "in direct contact" limitation in order to overcome the Examiner's rejections based upon the Lilja reference, which included a semi-permeable membrane. However, the Court finds Roche's construction confusing because it does not define "layers," "barriers," and "semi-permeable membrane." Further, the Court finds it unnecessary to provide certain examples of indirect contact because "direct physical contact" provides sufficient guidance.

GO BACK

2) "In fixed relation adjacent a surface of said vehicle window"

This phrase means that relative to one another, the sunshade and the window do not move when the sunshade is placed in use. The sunshade is placed "adjacent" the window, meaning that it is placed in close proximity, or next to the window. It does not mean that the sunshade necessarily touches the window, but that it comes close to doing so. The sunshade may touch or be next to only a portion of the window and still be "adjacent."

GO BACK

3. "In Fluid Communication"

After the preliminary injunction hearing, the Court undertook a claim construction analysis of the phrase in fluid communication. Prelim. Inj. Order at 48-49. In addition, the Court clarified its definition for the phrase in its Memorandum Opinion and Order on Motion to Reconsider ("Reconsideration Order"). Mem. Op. & Order on Mot. to Recons. at 5 ("Recons. Order"). The Court found that the phrase in fluid communication means "that the parts so delineated communicate through fluid flow; the fluid flowing past one part also flows past the other." Id. at 5.

Lawler asserted in its brief supporting the instant motion that the Court interpreted correctly the phrase in fluid communication. Id. at 5. However, at the Markman hearing Lawler reasserted the view that it asserted at the preliminary injunction hearing: in fluid communication means that there is free movement of fluid from one place to another or an open pathway for fluid. In other words, Lawler argues that in fluid communication means an open unimpeded pathway through which fluid may flow, absent external influences. Pls.' Br. in Supp. of Mot. for Claim Constr. at 5-6. In addition, in arguing the claim construction motion, Lawler called the Court's attention to the Federal Circuit's holding in A.B. Dick Co. v. Burroughs Corp.: It is fundamental that one cannot avoid infringement merely by adding elements if each element recited in the claims is
found in the accused device. For example, a pencil structurally infringing a patent claim would not become noninfringing when incorporated into a complex machine that limits or controls what the pencil can write. Neither would infringement be negated simply because the patentee failed to contemplate use of the pencil in that environment.

713 F.2d 700, 703 (Fed. Cir. 1983), cert. denied, 464 U.S. 1042 (1984) (citations omitted). Furthermore, during the Markman hearing Lawler admonished that when it construes the claims the Court must keep its focus on the structure of the device as described by claim 6 rather than on the manner in which it works in the environment. See Pls.’ Br. in Supp. of Mot. on Claim Constr. at 8. Apparently Lawler was under the impression that the Court had construed the phrase in fluid communication with reference to the way the valve works with the addition of a check valve.

In contrast, at the Markman hearing, Bradley asserted that it agreed with the Court's interpretation of the phrase in fluid communication from the preliminary injunction proceedings and objected to Lawler's renewed argument as an attempt to seek reconsideration of the Court's preliminary injunction ruling on infringement. The Court agrees with Bradley and finds Lawler's argument directed mainly toward an infringement analysis, which is not the purpose of the present motion. However, given that Lawler has presented additional evidence that the definition of in fluid communication is an open unimpeded pathway through which fluid may flow, absent external influences, the Court will briefly reexamine the intrinsic evidence of the meaning of that phrase.

The Court has already determined that the phrase in communication means open to or connected to without limitation on proximity or limitation on mode of connection. The phrase in fluid communication is used once in the claim language itself and approximately five times, with some modifications, in the remainder of the patent. Specifically, the claim language states: "said liner further defining a shuttle bore in fluid communication between said liquid chamber and said number of apertures and said first bore . . . ." '531 Patent, col. 14, ll. 10-13. Because the word fluid modifies communication in the claim, it is logical to conclude that in fluid communication and in communication mean different things. In other words, the word fluid is a limitation on the proximity of the named parts or the mode of connection between the named parts.

In the context of the '531 Patent invention, which is a device that will control the flow and temperature output from hot and cold fluid sources such that it can be used for emergency shower and eyewash systems, in fluid communication apparently means that fluid makes a connection between the named parts or areas of the valve assembly. In other words, fluid is the mode of connection between areas of the valve. This definition is in concert with the use of the phrase in fluid communication in the specification as well.

The specification states that "the thermostatic vanes [sic] each include a valve liner component that is in fluid communication with the cold liquid chamber of the valve body." '531 Patent, col. 2, ll. 51-53. Thus, fluid makes a connection between the valve liner component and the cold liquid chamber of the valve body. It is important to the invention that this be the case because the object of the invention is for the valve assembly to control the temperature and flow of the liquid at the outlet by initially mixing cold and hot liquids within the hollow valve liner. The patent specifically states that the hot and cold liquids are at least initially mixed within the part of the hollow valve liner designated as the shuttle bore. Id. col. 2, ll. 59-61.

In addition, the specification states that "the cold liquid inlet 33 communicates with a cold liquid chamber 46 that extends between and in fluid communication with the two valve bores 42, 43." Id. col. 6, ll. 7-10. In the specific embodiment described by this sentence, there are two separate thermostatic valves enclosed in a single valve housing. The patent teaches that it is important "that the hot liquid chamber 45 and cold liquid chamber 46 [of the valve assembly] surround all of the thermostatic valves 50 disposed within corresponding valve bores, such as bores 42, 43, so that the hot and cold liquid, such as water, can be provided evenly and equally to all of the thermostatic valves." Id. col. 6, ll. 15-20. Thus, the cold fluid must make a connection with the valve bores so that the invention can provide tempered water at the outlets, or in the case of failure of the thermostat or the hot water source, provide cold water at the specified flow rate. Likewise, the specification states that an important safety feature of the invention "is embodied in the multiple thermostatic valves housed within a common valve body in mutual fluid communication with the hot and cold liquid inlets and the mixed liquid outlets." Id. col. 3, ll. 43-48. It is clear that fluid provides the connection between the thermostatic valves, the hot and cold inlets, and the mixed liquid outlets in the valve assembly and is the basis upon which the invention ensures continuous delivery of tempered water. See id. col. 3, ll. 48-50.

Based on this analysis, the Court finds that it must modify slightly its prior definition of in fluid communication. In the
context of the '531 Patent, in fluid communication means that fluid makes the connection between the parts and areas specified, or that the parts so delineated are connected by fluid.

2068

V. "wherein the notch is in fluid communication with the cell"

Lifescan proposes "the notch is connected to the sample receiving cell in a way that the liquid sample flows through the notch and into the cell," while Roche proposes "a notch through which fluid can flow to or from the sample-receiving cell" or as a compromise, "the notch is connected to the sample receiving cell in a way that the fluid flows through the notch and to or from the cell." The disputes here are whether "fluid" is limited to liquid or also includes gases, and whether the term "communication" is broad enough to embrace bidirectional flow (i.e., flow to or from the cell).

The Court agrees with Roche's compromise construction, "the notch is connected to the sample receiving cell in a way that the fluid flows through the notch and to or from the cell."

The Court finds it unnecessary to further define "fluid," and notes that Lifescan's proposal defining "fluid" as "liquid sample" is inconsistent with the claim language, which uses both "fluid" and "liquid sample." The Court also finds that "communication" allows for bidirectional flow because "communication" suggests an exchange between the notch and the cell. Lifescan argues that the "communication" must be unidirectional because claim 1 requires that the notch "allows entry of the liquid sample into the cell," and refers to the cell as the "sample receiving cell." However, this claim language regarding entry of the liquid sample into the cell does not preclude bidirectional "communication" through the notch.

2069

Limitation 6(f) requires "a weathertight gasket mounted on said flange and engaging said lid in its closed position." Plaintiff argues that limitation 6(f) must be construed as though the lid is closed and will remain closed, contending that (1) the lid in claim 6 is only in the closed position or (2) the phrase "in its closed position" modifies both the phrase "mounted on said flange" and the phrase "engaging said lid." The court disagrees. First, claim 6 clearly contemplates (1) a compartment accessible through an opening and (2) a lid that can cover the opening. (See claim 6(a), (c), and (d)). If the court interpreted limitation 6(f) to require that the lid remain closed, never opening, it would be rewriting the claim. Second, the structure of the sentence suggests that the gasket is mounted on the flange before the lid is closed and that the gasket engages the lid when the lid is closed. While not an absolute, courts often rely on the grammatical "rule of the last antecedent," under which a limiting clause or phrase "should ordinarily be read as modifying only the noun or phrase that it immediately follows." Barnhart v. Thomas, 540 U.S. 20, 26, 124 S. Ct. 376, 157 L. Ed. 2d 333 (2003). Under this rule, "in its closed position" modifies the phrase "engaging said lid." This interpretation is consistent with the plain meaning of claim 6. Accordingly, the court finds that limitation 6(f) does not require that it be construed as though the lid is closed and will remain closed.

2070

b. "Performs several functions in one pass"

Both parties agree that the phrase "in one pass" should be afforded its ordinary meaning but disagree as to what is its ordinary meaning. Michaels interprets the phrase to refer to the fact that several cleaning functions are performed in one pass, but are not limited to only a single pass. See Col 3, lines 64-67; Col 6, lines 47-57. In support of this proposed construction, Michaels turns to the specification which states:

in gun barrels which are exceptionally dirty or which have a large accumulation of metal due to heavy use without cleaning, the user may need to perform a "see-saw" action with the gun cleaner. This is accomplished by pulling the cleaning device back and forth in short aggressive strokes while moving the device in an overall direction through the barrel. In effect, the use is performing a multitude of mid-bore directional changes while moving the device in a general direction through the barrel.

- 2514 -
Col 10, lines 12-19.

Clean Gun interprets the phrase "in one pass" to require completion of all of the steps in one pass as the device is pulled once through the gun barrel from one end to another. For support, Clean Gun relies on the specification which criticizes prior art in devices that only include one type of cleaning implement (for example, a brush or a cloth), explaining that these prior devices require "time-consuming and complex" changes of attachments and multiple passes through the barrel with each implement. Col 1, lines 59-62; Col 3, lines 55-63. To remedy this perceived problem, the patent explains that "it is an object of the invention to provide a gun barrel cleaning device which performs several cleaning functions with one pass through the barrel of a gun, thus saving the user a great deal of time and trouble." Col 3, lines 64-67. The patent continues by stating that these different cleaning functions are "accomplished" with one pass through the gun barrel. Col 3, line 67 to Col 4, line 8; see also Col 4, lines 30-33; Col 6, lines 48-63; Col 9, line 52 to Col 10, line 11.

This court disagrees with Clean Gun. The specification clearly requires that the cleaning of the inside surface of a gun barrel be completed in one pull through the gun barrel at a time. However, it also states that, if necessary, any "see-saw" action is acceptable because an "object of the invention is to provide a gun barrel cleaning device which eliminates the possibility of broken cleaning rod tips, broken cleaning rods, jammed cleaning utensils, or stuck patches, cloths or brushes by providing for foolproof mid-bore direction changes." Col 4, lines 12-16; see also Col 2, lines 30-32, 34-39; Col 3, lines 64-67; Col 5, lines 20-22, 53-58. An object of the invention is in the nature of a disclaimer and should be given greater weight than criticism of prior art upon which Clean Gun relies. The fact that the device may need to be pulled through more than once or used in a "see-saw" action to clean a particularly dirty gun barrel does not detract from its usefulness as one continuous pull-through device that both scrubs with a brush and cleans with a cleaning section. Accordingly, the phrase "in one pass" means performing several cleaning functions completed in one pull through the gun barrel with mid-bore directional changes permitted. Nothing in the specification requires the use of only a single pass.

Go Back

2071

BACKGROUND

Princeton is the owner of U.S. Patent No. 5,045,172 ("the '172 patent") entitled Capillary Electrophoresis Apparatus. The '172 patent is directed to an apparatus for use in the process of capillary electrophoresis whereby molecules and proteins are separated from fluid samples as a result of application of an electrical charge. Capillary electrophoresis technology itself is not at issue on appeal. Rather, part of the apparatus used in that process is, namely, the "holder" limitation of claim 32 (emphasized below in element [6]):

32. Capillary electrophoresis apparatus comprising

[1] a capillary tube of the type which can be electrically charged,

[2] said capillary tube having first and second ends,

[3] first means at said first end of said capillary tube providing a source of buffer solution and a source of a sample substance to be analyzed,

[4] second means coupled to said apparatus for applying electrical potential across said capillary tube whereby a sample flows through said capillary tube and past said detector,

[5] said first means includes a rotatable table carrying a plurality of sample cups and

[6] a holder for holding an end of said capillary tube in operative relation with one of the said cups, said cups containing either buffer solution or a sample to be analyzed,

[7] said capillary tube is in the form of a coil of glass tubing...
[8] wherein said coil of glass tubing is secured to a support member. (paragraphing added for clarity). In the claimed apparatus, fluid samples to be tested (or buffer solutions) are contained in sample cups, which in turn are placed on a rotating table to facilitate ease of multiple sample testing. Each individual sample flows through a coiled, glass capillary tube secured to a support member, the capillary tube being held by the holder of element [6] "in operative relation" with the sample cup. As the sample flows through the capillary tube, an electrical potential is applied across the tube and a signal is sent to a detector to facilitate separation of the various components of the fluid sample.

The prosecution history resulting in the issuance of claim 32 will be discussed in the context of claim construction below. Nevertheless, to briefly summarize, claim 32, the only claim at issue on appeal, issued after continuation-in-part (CIP) application 1 claims 1, 39, and 40 were combined. Elements [1] through [6] of claim 32 stemmed from CIP application claim 1, element [7] stemmed from CIP application claim 39, and element [8] stemmed from CIP application claim 40.

1 That a CIP application and not a straight continuation application was filed is not relevant to the disposition of this case, as the new material added to the specification when the CIP was filed was not directed to the holder limitation at issue.

Princeton sued Beckman for patent infringement, asserting that Beckman's P/ACE electrophoresis devices infringed claim 32 of the '172 patent. The P/ACE devices consist of an apparatus in which a vertically moving table and sample cup is "in operative relation" with a stationary capillary. The parties disputed whether the claim covers only the embodiment where the holder and the capillary tube move vertically toward a stationary sample cup and table, or also the alternative embodiment in which the sample cup and table move vertically toward a stationary holder and capillary tube as in the accused devices.

On cross-motions for summary judgment, the district court held a Markman hearing and construed the claim. The district court interpreted the holder limitation of element [6] as "requiring an apparatus equipped with a holder that lowers the capillary into [the] sample cup before testing and raises the capillary out of the cup after testing." Slip op. at 11. In other words, the district court construed the language "in operative relation" in element [6] to require "vertical movement of the arm which holds the capillary" toward stationary sample cups, Slip op. at 14, rather than vertical movement of the sample cups or the tray holding the sample cups toward a stationary arm holding the capillary.

The district court based its claim construction on the specification which it found "consistently describes the arm as a vertically moveable component which would lower the capillary so as to permit it to come into contact with the sample cups." Slip op. at 13-14. The district court also relied on the prosecution history. In particular, the district court cited the following as support for its claim construction: (1) the June 2, 1988 office action rejection over Stevenson, U.S. Patent No. 3,918,913, which "contains all of the critical elements recited in the plaintiff's claims: a rotating turntable, a vertically moving sample probe, etc."); (2) the addition of two new claims (29 and 30) in response to that rejection that were limited to a vertically moveable arm and accompanying comments in the remarks section; (3) a response to the advisory action of January 31, 1989 stating "the application has claims which are very detailed as to the apparatus for raising and lowering a capillary into the sample cups"; and (4) the cancellation of application claims 22 to 24 that claimed the alternate embodiment of a stationary capillary and a vertically moving table and sample cups.

Based on this claim construction, the district court granted Beckman's motion for summary judgment of noninfringement. The district court determined that the accused P/ACE devices did not contain the "exact same holder limitation" and in fact "did not contain any such element." Slip op. at 17. The district court further stated that "the capillary in the alleged infringing device is stationary; it does not move vertically. Moreover, the alleged infringing device has no holder for the capillary at all." Slip op. at 18. As a result of these determinations, the district court granted summary judgment of noninfringement. 2 Princeton appeals.

2 The district court also granted summary judgment of noninfringement under the Doctrine of Equivalents, noting that the
accused devices did not contain an equivalent element to the holder described in element [6] of claim 32, in particular an
element that would move the capillaries in and out of the sample cups. Slip op. at 20-21. Princeton has not appealed the
district court's grant of summary judgment of no equivalent infringement, and this issue may not be raised on remand. See

DISCUSSION

Summary judgment is proper when "the pleadings, depositions, answers to interrogatories, and admissions on file, together
with the affidavits, if any, show that there is no genuine issue as to any material fact and that the moving party is entitled to
a judgment as a matter of law." Fed. R. Civ. P. 56(c); see also Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed.
2d 202, 106 S. Ct. 2505 (1986) (summary judgment is proper when no "reasonable jury could return a verdict for the non-
moving party"). In deciding whether a genuine issue of material fact exists, the evidence must be viewed in the light most

Princeton argues that the district court erred in construing element [6], i.e., the "holder limitation," of claim 32. In particular,
Princeton asserts that the district court erred by requiring a "vertically moving" holder as no such limitation is present in the
asserted claim. Nor, argues Princeton, were any arguments made during the prosecution of the application that resulted in
the '172 patent and directed at claim 32 that would support reading a vertical movement limitation into that claim. We agree.

Claim construction is a matter of law, see Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA)
de novo, see Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en
banc).

On its face, element [6] of claim 32 would encompass embodiments in which both the holder/capillary and the sample
cups/table are vertically movable. In order to narrow the claim as the district court did to require only that the
holder/capillary be vertically movable, the phrase "in operative relation" must be viewed as sufficiently in need of
clarification to resort to the written description as urged by Beckman. See Renishaw PLC v. Marposs Societa' Per Azioni,
158 F.3d 1243, 1248, 48 U.S.P.Q.2D (BNA) 1117, 1121 (Fed. Cir. 1998) ("[A] party wishing to use statements in the written
description to confine or otherwise affect a patent's scope must, at the very least, point to a term or terms in the claim with
which to draw in those statements. Without any claim term that is susceptible of clarification by the written description,
there is no legitimate way to narrow the property right."). To clarify what "in operative relation" means, we conclude that
resort to the written description is permissible in this case.

Beckman urges us to adopt the requirement that the district court did, namely, that the holder is limited to vertical movement
in relation to stationary sample cups on a stationary table. The portions of the written description relied on by Beckman do
indeed indicate such vertical movement. 3 However, Beckman fails to appreciate the import of the clear disclosure in the
written description of the alternate embodiment in which the sample cup and table move vertically in relation to a stationary
capillary and holder:

As a modification of the invention, the apparatus 10 can be adapted to include means by which rather than raising and
lowering the posts 250 and 250' and their associated apparatus, it raises and lowers either just specific sample cups or the
entire tables 170 and 170'. In this embodiment of the invention, the motors 210 and 210' would be constructed to both rotate
the posts 200 and 200' and to raise them and lower them vertically as required to raise and lower the tables 170 and 170'.

'172 Patent, col. 9, ll. 50-58 (emphasis added). Beckman's attempt to minimize the existence of this disclosure as a "lone
sentence" in the written description is meritless.
Patent, col. 4, ll. 42-43; "The capillary can be inserted into a sample cup in table 170." '172 Patent, col. 6, ll. 41-42; "Motor 260 is energized to lower the arm 240 and the apparatus including tube 248 into the cup containing sample material." '172 Patent, col. 8, ll. 61-63; "Motor 260 is energized to lower the post 240 until the motor is stopped by its sensor 263 at just the point where the tip of the tube 248 is at about the bottom of the cup 190." '172 Patent, col. 9, ll. 15-18.

Moreover, in the originally-filed application which eventually resulted in the '172 patent as originally filed, this alternate embodiment was claimed in original application claims 22 to 24:

22. Capillary electrophoresis apparatus comprising

... first means at said first end of said capillary tube providing a source of a sample substance to be analyzed,

... said first means including a rotatable table carrying a plurality of sample cups and a holder for holding an end of said capillary tube in operative relation with one of said cups, and

means for moving said table and said holder with respect to each other so that said end of said capillary tube can be moved into and out of operative relation with a sample cup

23. The apparatus defined in claim 22 wherein said table is movable vertically up and down with respect to said holder and is rotatable with respect to said holder.

24. The apparatus defined in claim 22 and including a vertical post secured to said table and extending downwardly therefrom, and motor means coupled to said vertical post for rotating said table and for driving said table vertically up and down.

(Emphasis added.) The originally-filed claims are deemed part of the original specification. Thus, to the extent that originally-filed claims 22 to 24 and the written description at column 9, lines 50-58 describe an embodiment with a stationary holder and a vertically moving table and sample cups, Beckman errs in relying solely on those portions of the written description describing the vertically moving holder while ignoring those portions describing a vertically moving table. Absent language in the claim specifically limiting the phrase "in operative relation" to vertical holder movement, Beckman cannot find support for the district court's claim interpretation from the specification alone.

4 That claims 22 to 24 were eventually canceled during prosecution does not affect our analysis, and the district court erred in attaching significance to that action in support of its claim construction.

Beckman, reiterating the arguments used by the district court in coming to its claim construction, next asserts the prosecution history to support the district court's claim interpretation. Beckman argues that the patentee limited the scope of the claims to vertically moving holders and stationary tables by amending the claims in response to prior art disclosing vertically moving tables and stationary holders, and by arguing in remarks accompanying those amendments that the invention was limited to that embodiment. Princeton responds that the amendments made in response to prior art were directed to claims that did not result in the issuance of claim 32, and that the prior art cited and interpreted by Beckman would not only preclude claiming vertically moving sample cups and tables but also vertically moving holders and capillaries.

A careful review of the prosecution history reveals that Princeton is correct. Claim 32 resulted from the combination of
claims 1, 39 and 40 as filed in a CIP application. The original patent application contained 28 claims, to which new claims 29 and 30 were added during prosecution. Claim 1 contained the holder limitation found in issued claim 32. Claim 1 was amended in response to prior art to include the vertical movement limitation urged by Beckman, although the holder limitation itself was never amended.

Eventually, a CIP application was filed in which claim 1 was returned to its original, unamended form. Thereafter, claim 1 was rejected as obvious over prior art. However, claim 1 was not subsequently amended to include any requirement of vertical movement and in fact was not amended to distinguish over the cited prior art. 5

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

5 Claim 1 was amended to include the limitations of CIP application claim 49 directed to a T-shaped section of capillary tube inserted into the capillary tube to supply a source of cleaning fluid to clean the capillary tube.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

New claims 31 through 49 were also added when the CIP application was filed. Of relevance to issued claim 32, claim 39, which depended on claim 1, was directed to a glass coiled capillary, and claim 40, which depended on claim 39, was directed to that capillary attached to a support member. Claim 39 was rejected as obvious over the prior art (the Stevenson patent and an article written by Rose and Jorgenson). Claim 40 was objected to -- but not rejected -- and was deemed allowable if the limitations of claims 1 and 39 were incorporated. The applicant adopted the examiner's suggestion sequentially, first combining claims 1 and 39 and then later, after final rejection, including the limitations of claim 40. The examiner thus allowed the combined claim to issue as claim 32 without any amendment being made or any argument being espoused that would limit the holder limitation to the embodiment where the holder/capillary is vertically moving in relation to a stationary sample cup/table.

We hold that the prosecution history does not limit the holder limitation of claim 32 to only vertically movable holders. Although the applicant amended claim 1 to include a vertical movement requirement of the holder in the original application, the subsequent filing of the CIP application and the return of claim 1 to its original, unamended form, counsels against applying the usual rule that the entire prosecution history, including parent and grandparent applications, be analyzed in interpreting a claim. See Mark I Marketing Corp. v. Donnelley & Sons Co., 66 F.3d 285, 291, 36 U.S.P.Q.2D (BNA) 1095, 1100 (Fed. Cir. 1995).

We also hold that the applicant did not limit claim 32 to a vertically moving holder during prosecution as the amendments and arguments cited by the district court were directed to claims other than those that were combined as issued claim 32. See Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 992, 50 U.S.P.Q.2D (BNA) 1607, 1612 (Fed. Cir. 1999) ("carefully-crafted arguments" clearly directed to certain claims and not others will "avoid creating ambiguous or adverse prosecution history"). Beckman's reliance on certain amendments and remarks made by the applicant during prosecution concerning holder limitations specifically limited to a vertically movable holder is misplaced. Those amendments and remarks were directed primarily at application claim 8, a picture claim containing numerous other limitations and directed to the specific embodiment of a vertically moving holder, and not to the broader holder limitation in claim 1 that eventually resulted in issued claim 32.

Beckman's reliance on the prior art, in particular the article by Rose and Jorgenson and the Stevenson patent, also does not lead to the conclusion that the claims must be limited to a vertically moving holder. That prior art discloses embodiments in which capillary tubes, individual sample cups, and rotatable sample tables are raised and lowered. If those combined teachings preclude claiming vertically moveable sample cups and tables as Beckman urges, then those teachings should also preclude claiming a vertically movable holder. Thus, Beckman's interpretation of the prior art would preclude claiming any apparatus having any vertical movement whatsoever.

In summary, neither the written description nor the prosecution history provides any support for Beckman's assertion that the phrase "in operative relation" in the holder limitation must be limited to vertical movement of the holder. Thus, the district court erred in its claim construction. The proper interpretation of the holder limitation is that "in operative relation" encompasses both vertical movement of the holder as well as vertical movement of the sample cups and the table.

GO BACK
"in parts (volume)"

The parties dispute the "in parts (volume)" limitation of Claim 1. Marley contends that the limitation should be construed to mean the measured proportions of the parts of the formulation for a specified container. Mikron contends that the limitations should be construed to mean the proportional volumetric quantity of one material component to all other components within a given formulation.

"Part" is defined as "one of equal or unequal portions into which something is or is regarded as divided; something less than whole". Webster's Third New International Dictionary 1645 (3rd ed. 1986). "Volume" is defined as "space occupied or enclosed by cubic units (as inches, feet, quarts, pecks, bushels, gallons)", Webster's Third New International Dictionary 2563 (3rd ed. 1986), "the amount of space, measured in cubic units, that an object or substance occupies; the measured amount that a container or other object can hold", Random House Webster's College Dictionary 1461 (2nd ed. 1999).

Marley interprets "volume" to mean a specified container or, as stated by Marley in their opening Markman brief, "the 'parts' of the specified volume are percentages of a whole where the reference amount of the whole is 100 parts." This construction fails to give meaning to the term as used in the claim. For example, under Marley's interpretation, a batch could be made in a 1-liter container; such batch could include wood flour in a percentage (part) of 15 - 140. Using the lowest "part" of wood flour, the batch would be made with 15 percent (parts) of wood flour -- 15 percent of the 1-liter container would consist of wood flour (i.e., 150 milliliters). If the largest "part" of wood flour was used to make the batch, the batch would be made with 140 percent (parts) of wood flour -- 140 percent of the 1-liter container would consist of wood (i.e., 1.4 liters or 1400 milliliters). However, the 1 -- liter container can only hold 100 percent -- 1 liter or 1000 milliliters. Accordingly, Marley's construction is not correct.

On the other hand, Mikron's proposed construction does provide meaning to the term "volume". For example, if a 1-liter container was used to make a batch and milliliters was used as the unit volume, the batch could be made with 40 to 140 milliliters of wood flour. This construction gives meaning to the term "volume", enclosed in parenthesis, as used in the claim, i.e., to designate the unit of measurement of the ratio -- volumetric or spatial -- as opposed to other types of ratios which the patent does not include, e.g., weight.

Based on the above, the term in part (volume) is construed to mean the proportional volumetric quantity of one material component to all other components.

b. Claim 30 of the '990 patent

Claim 30 is the only claim of the '990 patent that Dow alleges the Defendants have infringed. The parties dispute two limitations from Claim 30: (1) "nebulizing water in said compressor inlet," and (2) "adding water to modify said nebulized water in a plurality of nebulized water mass flow increments such that operationally-induced thermal stresses within said gas turbine due to the ingestion and evaporation in whole or in part of said nebulized water are sufficiently minimized to preserve structural integrity in said gas turbine."

As to the first limitation in dispute, "nebulizing water in said compressor inlet," the Defendants argue that this limitation means that the spray racks and nozzles that nebulize the water are located in the compressor inlet. Dow, on the other hand, argues that the patent specifications disclose that the spray racks may be located anywhere between the inlet air filter and the compressor inlet, but preferably in the inlet air duct constricted portion, citing Column 11, line 67 to Column 12, line 5.

The patent specifications do not define "compressor inlet," but show a drawing of the compressor inlet in Figure 2A. As further described, the patent specifications indicate that "after entering the compressor inlet 102, the air is compressed in the axial compressor section 103 . . . ." (P1, col. 9, ll. 4-5). Based on these references, the "compressor inlet" is understood as
the entrance or opening to the compressor. This understanding is consistent with the ordinary meaning of inlet as "a way of entering; esp: an opening for intake." Merriam Webster's Collegiate Dictionary (10th ed. 1996).

Dow's arguments concerning where the process of nebulizing occurs is supported by the patent specifications. The inventors described the object of their invention as providing a wet compression apparatus and method where the device for adding water would be located a sufficient distance from the inlet of the compressor section so that broken parts would not enter the compressor. In the inventors' summary of the invention that addresses the language of Claim 30 most directly, the specifications provide:

In another aspect, a method is provided for nebulizing water near the inlet of the compressor as suggested in the known literature but adding the nebulized water to the inlet air in a plurality of water mass flow increments with respect to either position and/or time, so that operationally-induced thermal stresses within the gas turbine due to the use of the nebulized water are sufficiently minimized to preserve the structural integrity of the gas turbine.

(P1, col. 6, ll. 8-14) (emphasis added). Further, the specifications provide that:

The modification of the mass flow of nebulized water to the compressor inlet 102 via a plurality of nebulized water mass flow increments is then done in operation so that operationally-induced thermal stresses within the gas turbine engine 101, due to the use of the modified mass flow of nebulized water, are sufficiently minimized to preserve the overall structural integrity of the gas turbine engine 101.

(Id. at col. 17, ll. 26-33) (emphasis added).

The Court recognizes that there is support for the Defendants' argument that Claim 30 indicates that the spray racks and nozzles must be located within the compressor inlet. 25 However, when the Court defines a term, the Court looks first to the language of the claim itself. Mycogen Plant Science, Inc. v. Monsanto Co., 243 F.3d 1316, 1327 (Fed. Cir. 2001) (citing Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)). "In" is understood to "indicate inclusion, location, or position within limits," as well as "into." Merriam Webster's Collegiate Dictionary (10th ed. 1996). The patent specifications describe the method of nebulizing water, where the nozzles are located on spray rack group assemblies positioned anywhere between the inlet air duct and the compressor inlet, and preferably in the constricted portion of the inlet air duct. In only one instance do the patent specifications indicate that the nozzles are located in the compressor inlet, but this refers to "individual tuning" nozzles included in "some embodiments of the present invention" which are installed either in the spray rack assembly or "at some other location in the inlet air duct 133 or compressor inlet 102 to provide additional degrees of freedom in achieving stable and responsive control of the wet compression process." (P1, col. 18, ll. 16-22). It seems unlikely that the inventors would "define the invention in a way that excluded the preferred embodiment." See Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1581 (Fed. Cir. 1996) (citation omitted). The more reasonable interpretation is that "in" includes into as well as located within.

25 Had the inventors meant to indicate that the claimed method should be performed near the compressor inlet, they could have used this language in the claim limitation. The language in Claim 30 can be contrasted with other claims of the '990 patent: (1) Claims 1, 39, 54, 72, 74, 76, and 78 (an apparatus comprising "means for nebulizing water positioned essentially in said compressor inlet") (emphasis added); (2) Claim 74 (viewport to monitor icing should be "positioned near said compressor inlet") (emphasis added); (3) Claims 87 and 88 (independent method claims "providing an amount of nebulized water to said compressor inlet") (emphasis added); (4) Claim 55 (means for nebulizing water is "positioned in said inlet air duct") (emphasis added); (5) Claim 16 ("essentially in said inlet air duct constricted portion"). Claim 30 alone specifies "in said compressor inlet" with regard to nebulizing water.
Having examined and considered the claim language, the specification, and the context of the '960 invention, the Court is satisfied that Lawler has demonstrated more than a reasonable likelihood of success on the merits. Of the sixteen claims contained in the '960 Patent, the parties have focused on the language in claim 1 that describes a multiple response thermostat element. Pl.'s Ex. 1, '960 Patent. The relevant language in claim 1 reads:

1. A thermostatic control valve assembly for mixing a hot fluid and a cold fluid for discharge at a controlled temperature, the valve assembly comprising:

   * * *

   a multiple response thermostat disposed within said mixing chamber between said outlet and said flow control valve means, said multiple response thermostat including a first thermostat portion having a first response rate and a second thermostat portion having a second faster response rate, said first thermostat portion being connected in series with said second thermostat portion and said second thermostat portion being operably connected to said flow control means.

Pl.'s Ex. 1, '960 Patent, Col. 9, ll.22-44.

--- Footnotes ---

7 The other elements included in claim 1 are not in dispute.

--- End Footnotes ---

Bradley argues that its valves have a single, non-segmented thermostat without segmented coils, therefore, its thermostats are not multiply responsive and do not meet the definition for multiple response thermostat as it is described in the patent. Def.'s Br. in Opp'n at 31; Hrg. Tr. at 32, Defs.' Opening Statement. Moreover, Bradley asserts that if claim 1 is interpreted to include its thermostat, the patent is invalid because several prior art references disclose such a thermostat. Id. None of the prior art references asserted by Bradley were disclosed to the patent office with Lawler's patent application.

In contrast, Lawler argues that the plain language of claim 1 requires only that a multiple response thermostat have a first portion and a second portion, in series, having a first and a second response rate respectively; it is not limited to having thermal coils. Pl.'s Br. at 47; Hrg. Tr. at 650-51 (citing Pl.'s Ex. 1, '960 Patent, col. 6, l. 63). Lawler also argues that the portions must run the length of the thermostat. Hrg. Tr. at 240, Ovens-Redirect. In addition, claim 2 adds thermal coils to the multiple response thermostat described in claim 1, therefore, Bradley's more narrow interpretation of claim 1 must fail for claim 2 to add anything to the invention. Hrg. Tr. at 651, Pl.'s Closing Arg. Lawler asserts that the thermostats used in Bradley's high/low HL200 (3200), HL130 (3130), and HL80 (3080) valves and its EFX60 (2200) emergency valves have a first portion and a second portion, each having a different response rate, and those portions are in series. Pl.'s Br. at 46-47. Therefore, the Bradley valves using such a thermostat in combination with the other elements of claim 1 infringe Lawler's '960 Patent.

Generally, the Court agrees with Lawler. The Court starts with the plain language of claim 1. K-2 Corp., 191 F.3d at 1362. The claim itself does not mention or describe a thermostat that uses thermal coils. Instead, the claim describes a multiple response thermostat that has "a first thermostat portion having a first response rate and a second thermostat portion having a second faster response rate." Pl.'s Ex. 1, col. 9, ll. 38-40. In addition, claim 1 requires that the two portions be connected in series, the "second thermostat portion being operably connected to [the] flow control valve means." Id. col. 9, ll. 43-44. The first mention of a multiple response thermostat in the specification describes it as "segmented to provide multiple response rates tailored to the desired operational characteristics of the thermostatic control valve." Id. col. 6, ll. 41-44. The specification goes on to describe the thermostat depicted in Figure 6, which shows a thermostat "variation of the thermal coil variety . . . . Also contemplated, however, are other segmented thermostats." Id. col. 6, ll. 56-63. Therefore, a multiple response thermostat as described in claim 1 must have 1) two segments or portions, 2) with different response rates, 3) connected in series, and 4) the portion with the faster response rate operably connected to the flow control valve means. There is no requirement that the thermostat have thermal coils and the specification clearly indicates that multiple response thermostats other than those described in the patent itself are contemplated. Dr. Ovens confirmed that one skilled in the art would similarly read claim 1. Hrg. Tr. at 167-68, Ovens-Direct; id. at 220, Ovens-Cross.
Reading claim 1 in light of claim 2 confirms this conclusion. Under the doctrine of claim differentiation, different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope. See Comark Comm. Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). Generally then, limitations in dependent claims are not read into the independent claims upon which they depend, even to avoid invalidity or infringement. See Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999). Here, claim 2 depends on claim 1: "2. The thermostatic control valve assembly of claim 1, wherein said multiple response thermostat includes a thermal coil containing first and second volumes of temperature sensitive fluid corresponding to said first and second response rates, respectively." Pl.'s Ex. 1, col. 9, ll. 45-49. Claim 2 clearly adds thermal coils containing temperature sensitive fluid that correspond to the portioned thermostat described in claim 1. Claim 2 adds nothing else to the invention described in the patent. Although the doctrine of claim differentiation is not a hard and fast rule, see Comark Comm., 156 F.3d at 1187, in this case it supports a construction of claim 1 that allows for a multiple response thermostat without coils.

The parties also presented testimony by its experts about the meaning of "in series." Bradley's expert, Julius Ballanco ("Ballanco"), testified that two thermostat portions would be in series if they were connected with the end of one to the beginning of the other, regardless of their orientation relative to the length of the thermostat or the length of the mixing chamber. Hrg. Tr. at 603-04, Ballanco-Cross. Thus, if a cylindrical thermostat portion was connected to the end of a thermal coil thermostat portion, with the coils wrapped around the cylindrical portion, those portions would be in series. On the other hand, Lawler asserts that "in series" means segmented along its length. Hrg. Tr. at 240, Owens-Redirect.

Starting with the plain language of the '960 Patent, the Court finds Lawler's definition closer to the mark. The '960 Patent's specification provides that the thermostat pictured in Figure 6 "is designed to expand or contract along the axis defined by the push rod in response to a change in the temperature surrounding the thermostat." Pl.'s Ex. 1, '960 Patent, col.6, ll. 57-58. In addition, the thermostat portions must have an orientation that allows the incoming fluid to reach one thermostat portion more quickly than the other to accomplish the stated purpose of the invention: Quick temperature control over a wide range of flow rates, particularly low flow conditions. See id. col.1, ll. 51-60; col. 2, ll. 45-46; col. 6, ll. 47-55. The specification reads:

Generally, [the] thermostat [pictured in Figure 6] includes a first thermostat portion connected in series with a second thermostat portion. [The second thermostat portion has a faster response but smaller travel than the first portion to provide immediate, accurate control nearest the discharge of [the] flow control valve, where at low flows the hot and cold fluids may not be fully mixed. Conversely, [the first thermostat portion has a slower response but greater travel than the second portion to provide subsequent control way [sic] from the discharge of [the] flow control valve, where the hot and cold fluids are more fully mixed.

Id. col. 6, ll. 45-55 (number references omitted). This description of thermostat portions in series corresponds to a definition of "in series" that requires an orientation of thermostat portions such that one comes in contact with mixed fluid at a different time than the other.

Moreover, the specification also specifically distinguishes a thermostat that is comprised of a cylinder portion with a thermal coil portion wrapped around the cylinder and has fluid chambers open to each other. Id. col. 6, ll. 40-44 ("Unlike the linear thermostat of valve assembly 10 [pictured in Figure 1], thermostat 140 is segmented to provide multiple response rates tailored to the desired operational characteristics of the thermostatic control valve."). The thermostat pictured in Figure 1 of the '960 Patent is a thermostat with thermal coils wrapped around a cylinder. The invention in the '960 Patent is different because the thermostat portions are stacked one on top of the other rather than one surrounding the other, regardless of whether there are coils or not. Thus, a definition of "in series" that simply requires one end connected to another, without reference to placement linearly or sequentially along a length does not completely describe the invention in claim 1 of the '960 Patent.

The extrinsic evidence confirms this conclusion. First, the American Heritage Dictionary defines "series" as "[a] number of objects or events arranged or coming one after the other in succession," or "[a] group of objects related by linearly varying successive differences in form or configuration." AMERICAN HERITAGE DICTIONARY (3d Ed. SoftKey Int'l Inc. 1994). Either definition implies an arrangement that has different objects strung along a length rather than different objects overlapping one another.
Second, Kline testified that the '960 Patent distinguished a simple thermostat of the design suggested by Ballanco by extending one of the ends far enough so that one portion would operate after the other rather than simultaneously. Hrg. Tr. at 458-59, Kline-Cross. In addition, Kline testified that this could also be phrased that a multiple response thermostat as described by the '960 Patent is "segmented along its length as it comes down and pushes on the push rod." Id. at 459. Ovens similarly described this requirement stating that "in series"

means the two [thermostat portions] are lined up one after the other, that the head end of one is connected to the tail end of the next, and whatever comes out of the first portion directly acts as part of the input to the second portion, or passes directly through the second portion to wherever the second portion's output is. This is like putting links in a chain one right after another.

Hrg. Tr. at 164, Ovens-Direct. Although this testimony does not specifically address the question of how one skilled in the art at the time the '960 Patent issued would perceive "in series," Kline's testimony as inventor talking about the differences between the thermostat used in the Lawler 66 valve, which existed at the time Kline patented the valve combination described in the '960 Patent, is revealing. This is particularly true in light of its direct contradiction of Ballanco's definition and Bradley's argument stemming therefrom. Thus, the Court is persuaded that "in series" requires an orientation of thermostat portions that are connected in a chain such that one portion comes in contact with fluid in the mixing chamber at a different time than the other.

2075

WMA contends that its Glide-Trak systems do not infringe on the '201 patent because three elements found in Claims 1 through 8 of the '201 patent are not found in the Glide-Trak systems. Because Claims 2 through 8 reincorporate Claim 1's description of a "shelf divider system," we will focus our analysis on the language of Claim 1, which is reprinted as follows:

A shelf divider system comprising:

- An elongated channel mounting member operationally securable to a front portion of a shelf;
- A shelf divider member slidably receivable in said mounting member so that the divider member extend rearwardly over the shelf; track means on said divider comprising a pair of elongated rails, spring-urged pusher means comprising a pusher member having a front pusher face and a pair of flanges engaging said rails whereby said pusher member is operationally slidable on the rails and the pusher means is rearwardly retractable to accommodate a display of merchandise and will bear against the merchandise to automatically urge the same forwardly on the shelf.

WMA first argues that the Glide-Trak systems do not infringe on Claim I of the '201 patent because they do not contain a "divider member slidably receivable in said mounting member." (Emphasis added). This clause of Claim 1 describes how the spring-containing dividers on the '201 system (aligned perpendicular to the shelf's edge) are attached to the system's mounting unit, which is affixed to and runs along the front edge of the store shelf. The front of the '201 divider contains a "depending tongue" which extends downward in the direction of the shelf's surface. This depending tongue is then inserted into and constrained in a channel (shaped like a "U" or a rectangle missing its top side) in the mounting member in which the tongue is tightly held (in the words of the '201 patent, the tongue is "frictionally received and retained in the channel . . . of the mounting member"). Once the tongue is placed into the mounting member's channel, the snug fit keeps the divider attached to the mounting member.

On the other hand, instead of having downward extending tongues at the front of their spring-containing dividers, WMA's Glide-Trak systems' dividers (both Models 1 and 2) have downward facing C-shaped hooks ("C-hooks") attached to their front ends. These hooks fit tightly around tubes (in the shape of a narrow cylinder running parallel to the front of the shelf) that sit atop the Glide-Trak's mounting members. These tubes are physically part of the mounting member, but a raised bar connects the bottom of the tube to the surface of the mounting member. When the C-hook of the divider is locked around the tube of the mounting member, the divider becomes attached to the mounting member.

WMA contends that because the Glide-Trak dividers attach to their mounting members by securing the C-hooks around the mounting member's raised tubes, the Glide-Trak dividers are never "in" the systems' mounting members. Both parties are
satisfied with the definition of the word "in" as stated in the Random House College Dictionary Revised Edition (1988): "(used to indicate inclusion within space, a place, or limits): walking in the park." We therefore will rely on this definition in determining whether the Glide-Trak divider members are slidably receivable "in" their mounting members. WMA's central argument is that the Glide-Traks' divider members attach to the mounting members via C-hooks that connect on or around a raised tube resting atop the mounting member rather than "in" the mounting member. However, preliminarily focusing on the differences between the features of the Glide-Traks and the features of the '201 patent (as written in the patent's description) before determining the plain meaning of the disputed claim term would violate the two-step construction process outlined in Texas Digital. See Intellectual Property Development, Inc. v. UA-Columbia Cablevision of Westchester, Inc., 336 F.3d 1308, 1315 (Fed. Cir. 2003).

Because the parties agree the Random House definition of "in" is appropriate, we can next look to whether the '201's description rebuts or is inconsistent with the meaning of "in" in the 201's Claim 1, "for example whether [RTC] has specifically defined the term or otherwise limited the scope of the claim." Resonate Inc. v. Alteon Websystems, Inc., 338 F.3d 1360, 1364 (Fed. Cir. 2003). The '201's specifications speak of a depending tongue that is to be "frictionally received and retained in the channel of the mounting member." (emphasis added). This description certainly is encompassed by the Random House definition, as it indicates the '201's divider member's tongue being within the space or limits of the mounting member. Under the Texas Digital framework, we see no reason to depart from the plain meaning of "in" that both parties agree is appropriately defined by Random House.

Because of the breadth and expansiveness of the definition of "in," we may not import the more specific limitations of the 201's written descriptions concerning a tongue being frictionally received and retained in the mounting member. Resonate Inc., 338 F.3d at 1365. Contrary to WMA's assertions, the question is not whether the Glide-Traks are different from the '201 patent because the Glide-Traks' divider members attach to their mounts via hooks clamped around tubes rather than tongues inserted into channels. Instead, we must decide whether the Glide-Traks' divider members are slidably receivable within the space or limits of their mounting members. In other words, do the Glide-Trak's dividing members enter the space of their mounting members via a sliding motion? Since the physical characteristics of the Glide-Trak Models 1 and 2 differ slightly, we will analyze each model separately.

--- Footnotes ---

1. The ordinary meaning of "slidably receivable" does not appear to be in dispute. Random House (1988) defines "slide" as: "to move along in continuous contact with a smooth or slippery surface." Webster's Third New International Dictionary (1981) defines "receivable" as: "capable of being received." "Receive" is defined as "to take in or act -- act as a receptacle or container for."

--- End Footnotes ---

2076

1. "A Multiple Response Thermostat" and "In Series"

During the preliminary injunction proceedings Bradley argued that a multiple response thermostat must have more than one segmented coil. Defs.' Prelim. Inj. Opp'n Br. at 31; Prelim. Inj. Hr'g Tr. at 32, Defs.' Opening Statement. Further, thermostat portions would be connected in series if they were connected with the end of one to the beginning of the other, regardless of their orientation relative to the length of the thermostat or the length of the mixing chamber. Prelim. Inj. Hr'g Tr. at 603-04, Ballanco-Cross. In contrast, Lawler argued that a multiple response thermostat is not limited to one with segmented coils; it must have a first portion and a second portion, having a first and second response rate respectively, such that the portions run the length of the thermostat. Pl.'s Prelim Inj. Br. at 47; Prelim. Inj. Tr. at 240, Oven-Redirect; id. at 650-51, Pl.'s Closing Statement. Neither party offered evidence that the inventor limited the definition for the terms during prosecution of the patent, and the Court found none in its review of the prosecution history pursuant to the instant motion.

After reviewing the patent claims, the specification and the prosecution history, the Court finds no reason to deviate from the definitions for these terms that it determined at the preliminary injunction phase of these proceedings. First, the plain language of claim 1 does not specifically describe a thermostat that uses thermal coils. It merely describes two portions,
with two response rates, arranged in series. '960 Patent, col. 9, ll. 37-42. The specification describes the multiple response thermostat as one that would have a tailored response rate. Id. col. 6, ll. 41-44. Moreover, the specification states that the pictured thermostat is a "variation of the thermal coil variety . . . . Also contemplated, however, are other segmented thermostats." Id. col. 6, ll. 56-63. The Court cannot find any reason in the purpose of the multiple response thermostat to limit the portions to thermostats of the thermal coil variety. As discussed in the specification, the thermostat described should be tailored to meet the desired operational characteristics of the thermostatic control valve. Therefore, it appears that the valve designer may choose any type of thermostats, arranged as described in claim 1, to create the result he or she desires.

Finally, pursuant to the doctrine of claim differentiation, dependant claim 2 seems to suggest that claim 1 does not require that the multiple response thermostat have thermal coils. Claim 2 states: "The thermostatic control valve assembly of claim 1, wherein said multiple response thermostat includes a thermal coil containing first and second volumes of temperature sensitive fluid corresponding to said first and second response rates, respectively." Id. col. 9, ll. 45-49. Under the doctrine of claim differentiation, different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope. See Comark Comm. Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). Therefore, limitations in dependant claims generally are not read into the independent claims upon which they depend. See KarlTech Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999). In the '960 Patent, claim 2 clearly adds thermal coils to the thermostat of the invention described in claim 1. This finding, taken together with the plain meaning of the claim language itself and the context given by the specification, leads to a conclusion that a multiple response thermostat need not have thermal coils.

The Court finds that a multiple response thermostat as described in claim 1 must have two segments or portions, with different response rates. The two portions must be connected in series and the portion with the faster response rate must be operably connected to the flow control valve means. The thermostat portions need not have thermal coils.

Turning now to the meaning of the phrase "in series," the Court is convinced that the '960 Patent requires that the thermostat portions be oriented in a chain such that one portion comes in contact with the fluid in the mixing chamber at a different time than the other. The plain meaning of "in series" is a chain of objects, one after the other. Accord AMERICAN HERITAGE DICTIONARY (3d Ed. SoftKey Int'l Inc. 1994). Such a definition is consistent with the context of the '960 Patent. The '960 Patent invention is designed to provide quick temperature control over a wide range of flow rates. Id. col. 1, ll. 51-60; id. col 2, ll. 45-46. In large part, it is the thermostat design that allows the valve to achieve that objective. The specification reads:

Generally, thermostat 140 includes a first thermostat portion 142 connected in series with a second thermostat portion 143. Thermostat portion 143 has a faster response but smaller travel than portion 142 to provide immediate, accurate control nearest the discharge of flow control valve 114, where at low flows the hot and cold fluids may not be fully mixed. Conversely, thermostat portion 142 has a slower response but greater travel than portion 143 to provide subsequent control way [sic] from the discharge of flow control valve 114, where the hot and cold fluids are more fully mixed.

Id. col. 6, ll. 45-55. The design described here requires that the mixed fluid contact the different portions of the multiple response thermostat at different times to achieve the purpose of the invention. In addition, the specification provides that the thermostat depicted in the preferred embodiment "is designed to expand or contract along the axis defined by the push rod in response to a change in the temperature surrounding the thermostat." Id. col. 6, ll. 57-60. Again, this description highlights that the important orientation for the thermostat portions is along the axis defined by the push rod, or along the length of the thermostat itself.

The Court finds that the phrase "in series" requires that the thermostat portions be arranged in a chain or sequentially such that one portion comes in contact with fluid in the mixing chamber at a different time than the other.

b. "Channels Extending Radially in the Base"

In describing the components of a centrifugal unit, Claim 16 uses the phrase "channels extending radially in the base". The
parties agree that it refers to a particular part of the centrifugal vessel which contains 1) a bottom in the shape of a disk and 2) channels that extend radially out from the base's center. The parties disagree, however, with respect to whether "in the base" means that the channels are physically located in the base or simply come into contact with or rest on the base.

The defendants contend that the proper construction of "channels extending radially in the base" is that the channels must be physically located within the base structure. Considering the specific language of the claim, the defendants maintain that "extending radially in" requires a construction in which the channels are physically located in the base. That interpretation depends on what the meaning of the word "in" is. The Shorter Oxford Dictionary defines "in" as "within the limits or bounds, within". The defendants thus argue that "extending radially in the base" requires more than contact between the bottom of the vessel and the channels.

Haemonetics asserts that the phrase has a broader definition than the defendants' proposed construction. It submits that the proper construction is that the channels are in the base of the entire centrifugal unit not that they are specifically in the base of the disk at the bottom of the vessel. In support, Haemonetics directs the Court's attention to the drawings and specifications which allegedly demonstrate that the channels are formed between the bottom and top portions of the centrifugal vessel. The Court agrees.

Having reviewed the claims, specifications and drawings, the Court construes the patent as teaching that the channels are to rest on the base, and not necessarily exist within the base itself. The defendants' reference to extrinsic dictionary sources to interpret the meaning of the contested phrase does not overcome the plaintiff's argument based on the terms and diagrams of the patent itself.

Accordingly, the disputed phrase, "channels extending radially in the base" will be construed as "channels extending radially in or on the base".

2078

B. "In The Body"

This claim term appears in Claim 1: "a deformable diaphragm disposed in the body" and "valve means mounted in the body." The parties dispute the meaning of the word "body" and the terms "disposed in the body" and "mounted in the body."

1. "Body"

Cannon argues that the term "body" should be construed as "the main, central, or principal part of the breast pump. It may consist of a single component or multiple assembled components."

TFY contends that the "body" is limited to a single, unitary structure. (R. 61-1 at 6.) TFY points out that throughout the patent, the term "body" is used to refer to a single piece of molded plastic. TFY attempts to improperly import a limitation from the specification into the claim by narrowing the claim to a particular embodiment. There is no indication in the specification or the prosecution history that Cannon narrowed the ordinary meaning of "body" to require a single piece of plastic.

There is no reason to depart from the ordinary meaning of "body." The ordinary meaning of "body" is "the main or central mass of a thing, such as the hull of a ship, the fuselage of a plane, or the nave of a church." Random House Webster's College Dict. at 147. Accordingly, the Court construes the word "body" to mean "the main, central, or principal part of the breast pump."

2. "In The Body"

This claim term limits the location of the diaphragm ("disposed in the body") and the valve means ("mounted in the body").

TFY argues that it requires that both the diaphragm and valve means be disposed or mounted entirely within the body of the pump. TFY argues that the language of the specification compels this construction. In the first embodiment, the diaphragm...
is located within the cup-shaped upper portion of the body. The specification describes this design as "the diaphragm 20 is mounted directly in the body." '850 patent, col. 4, Ins. 51-52. In the second embodiment, the diaphragm is not actually within the body, but instead merely covers an opening of the body at one end, and sits on the annular surface. The specification describes the diaphragm in this embodiment as "mounted thereon" the body, and teaches to assemble the pump of the second embodiment by lowering the diaphragm "onto the body." 9 '850 patent, col. 6, ln. 15; col. 7, ln. 67 - col. 8, ln. 1.

9 The specification describes "a moulded plastic body 50 with a diaphragm 51 mounted thereon at its upper end." '850 patent, col. 6, Ins. 14-16. When this design is assembled, "the diaphragm 51 with the connector 54 fitted thereto is lowered onto the body 50 until the lip 62 of the diaphragm 61 engages with the annular shoulder 61 of body 50." Id., col. 7, ln. 67 - col. 8, ln. 3.

Cannon argues that the Court should construe the term "in the body" to mean "at least partially contained within" the body. Cannon contends that the word "in" has a range of meaning, and nothing in the specification or prosecution history disclaims the broad meaning of "in." 10

10 "In" is defined as: "on the interior or inner side: within; so as to confine or surround; that is located inside or within." Webster's Third New Int'l Dict. at 1139. It is also defined as "on the inside, within." Random House Webster's College Dict. at 657.

The Court agrees with TFY. The specification selectively uses the phrase "in the body" to describe the location of a diaphragm that is completely contained within the body, but uses different language to describe a diaphragm that is merely mounted on top of it, even though part of that diaphragm extends into the main body of the pump. Accordingly, the diaphragm and valve means must be actually located within the main, central, or principal part of the breast pump, rather than being on top of it or attached to it through some external structural element. The Court construes the term "in the body" to mean "disposed or mounted entirely within the body of the pump."
a. Scope of the '468 Patent Claims

The parties dispute whether the '468 patent claims only the testing strips, and thus is a "product" patent, or whether it is a "method" patent or "combination" patent of the strip and meter. This is an issue of law to be determined by interpreting the claims of the patent.

The claims of the '486 patent are quoted below, as they appear in the patent itself.

What is claimed is:

1. A reagent test strip for use in an apparatus for determining the blood glucose concentration of a sample of whole blood, said apparatus comprising optical means for detecting intensity of light at wavelengths of about 635 nm and about 700 nm reflected from at least a portion of said strip by reading the reflectance of at least a portion of said strip;

   said strip having a porous portion disposed near a distal end of said strip such that the porous portion generally registers with the optical means of the apparatus when the strip is retained by the apparatus during determination of said blood glucose concentration, said porous portion having a sample receiving surface for receiving a sample of whole blood and a testing surface, said porous portion further comprising reagent means for indicating the concentration of blood glucose in said whole blood sample in the presence of optically visible hemoglobin by creating a change in reflectance at said testing surface indicative of the concentration of glucose present in said sample, said reagent means comprising chemical reagents selected to produce said change dependent upon the glucose concentration wherein said chemical reagents comprise a dye precursor forming a chromophore indicative of the concentration of glucose present in said sample, said chromophore absorbing light at about 635 nm but not to any significant extent at about 700 nm.

2. The strip of claim 1 wherein said dye precursor comprises 3-methyl-2-benzothiazoline hydrazone hydrochloride and 3-dimethylaminobenzoic acid.

3. The strip of claim 2 wherein the chemical reagents are at a pH of 3.8 to 5.

Claims 1-3, '468 Patent.

Most persuasive to the court on the issue of claim interpretation is the language of the three claims themselves. Claim 1 begins with the words "[a] reagent test strip" while Claims 2 and 3 refer to "the strip of claim 1." It is clear that each claim constitutes a description of the claimed strip, not a claimed method. Each claim provides a detailed description of the makeup and qualities of the claimed strip, not of the method employed in testing blood glucose levels. Claim 1 repeatedly refers to the strip and its characteristics. Mention of the meter in which the strip is used serves to describe certain strip features, not to describe a combination of strip and meter. The mention of the meter apparatus in the first sentence of claim 1 serves to identify the environment in which the strip will be used, not to create a claim to the method of determining glucose levels in blood or to the combination of strip and meter. See e.g., Smith Corona Corp. v. Pelikan, Inc., 784 F. Supp. 452, 463 (M.D. Tenn. 1992), aff'd, 1 F.3d 1252 (Fed. Cir. 1993); see also In re Stencel, 828 F.2d 751, 754-55 (Fed. Cir. 1987).

In addition to the language of the claims, i.e. the repeated references to the strips described in claims 1 through 3, the court finds that the prosecution history favors a finding that the '468 patent is directed solely to the strips themselves. The '468 patent arose out of a continuation application which was amended to contain new claims directed to a "reagent strip." In June, 1993, these amended claims were amended again, but still directed to a "reagent test strip." Although this amendment, given the number Claim 55, described the apparatus in which it was to be used, the dependent claims added along with Claim 55 each begins with the phrase "the reagent test strip of claim 55 . . ." After considering the amendments of claims 55 through 59, the patent examiner stated that it was "the examiner's position that the claims are directed to a test strip." Additionally, the examiner referred twice more in that communication to "the claimed test strip." Thereafter, LifeScan submitted an amendment canceling prior claims and adding Claim 60 incorporating the limitations of Claim 55. During and after the submission of Claim 60, LifeScan did not dispute the examiner's interpretation of Claim 55 as referring to the strip itself. In addition, Claim 60 added a feature relating to the nature of the chemicals in the strip.
After an initial rejection by the patent examiner, LifeScan conducted an interview with the examiner, during which drafts of new claims 61 and 62 were discussed. The first of the new claims, which later became claim 1 of the '468 patent, was directed to "a reagent test strip for use in an apparatus for determining the blood glucose concentration in a sample of whole blood." The second new claim, which became claim 2 of the '468 patent, was directed to "the strip of" the first claim. Following the interview, LifeScan also submitted a new claim 63, later claim 3 of the '468 patent, which also was directed to "the strip" of the preceding claim. Claim 61, which was later allowed, contains fewer references to the nature of the apparatus in which the strip is to be used. The references to the apparatus, i.e. the meter, which do exist are merely descriptive of the environment of the intended use of the strip. See e.g. In re Stencel, 828 F.2d at 754-55; see also Smith Corona, 784 F. Supp. at 463-65. Based on the court's review of the language of the claims and the patent history, the court has determined that, as a matter of law, the '468 patent claims the testing strip and therefore a product, not a method or combination of method and product.

In addition, this court is not persuaded by Polymer's argument that the '468 patent claims are limited to the reagent strip when in place in the meter with a whole blood sample present thereon. This interpretation is simply not supported by the claim language or the claim prosecution.

The court also finds unpersuasive Polymer's arguments concerning the interpretation of claim 3 of the '468 patent, which reads as follows: "The strip of claim 2 wherein the chemical reagents are at a pH of 3.8 to 5." Based on the claim language and the prosecution history, the court finds that the claim language refers to the pH of the chemical reactants in the dry strip, rather than the "pH of all of the chemicals in the strip when it is placed in the meter and a sample of whole blood is applied thereto" as is argued by Polymer.

Finally, based upon the language of the claims and the claim prosecution, the court finds that the language in claim 1 requiring that the porous portion of the strip

comprise reagent means for indicating the concentration of blood glucose in said whole blood sample in the presence of optically visible hemoglobin by creating a change in reflectance at said testing surface indicative of the concentration of glucose present in said sample, . . .

does not limit the claim to a strip in which the only hemoglobin that can be optically sensed by the apparatus is that which is "in the red blood cells filtered out and held at the surface of the test strip."

Polymer argues that its strip does not meet the elements of claim 1 because hemoglobin not "in the red blood cells filtered out and held at the surface of the test strip" is optically visible. However, the court disagrees with Polymer's interpretation of the claim language. First, the court finds that there is no indication that the '468 patent claim 1 is limited to a strip in which the only optically visible hemoglobin is that which is in the red blood cells. On this point, the court notes that the patent expressly refers to "blood being analyzed [flowing] through the pores of the matrix" and to "blood . . . wetting the polyamide matrix without having an excess liquid penetrate the porous matrix to interfere with the reflectance reading on the opposite side of the matrix." This language indicates that the claim is not limited to hemoglobin inside red blood cells, but rather also encompasses "free" hemoglobin released into the remainder of the sample. Second, even if the claim were limited in the manner alleged by Polymer, Polymer has not asserted that the hemoglobin presence in red blood cells applied to First Choice strips is not "optically visible" to at least some extent by the LifeScan home-use blood glucose meter.

Therefore, after reviewing the claim language, the patent specification, the prosecution history, the expert deposition testimony submitted, and the prior art, the court has determined that the proper meaning or interpretation of the '468 patent is that it is directed to the test strips per se, rather than to a method or combination of strip and meter. Additionally, the '468 patent claims refer to the strips themselves and are not limited to the strips when in the apparatus, with whole blood upon them. Finally, the phrase "in the present of optically visible hemoglobin" does not limit claim 1 to a strip in which the only hemoglobin optically visible is that which is in red blood cells filtered out and held at the surface of the test strip.

GO BACK

2081
d. "In the web"
As noted by BOC, the references to a "web-like" support structure do not appear in the prosecution history of claim 1 until claim 41 was submitted in the Preliminary Amendment dated July 7, 1987. (PX 8 at ND 009958-009959) Although the specification is the primary source for interpretation of words appearing in the claims, a review of the '014 specification indicates that the phrases "web-like support structure" and "in the web" do not appear. Nevertheless, it is to the specification that the court turns in its § 112 P 2 inquiry.

The structure of the invention is described generally in the "summary" of the '014 patent as such: "When the sensor is adhesively fastened, the effect of the light source and photo-sensor being integrated into the adhesive fastener is that they become, in effect, a part of the skin." (PX 7, col. 4, lines 59-62) (emphasis added). The "summary" also describes

a process for making the apparatus. In the assembly of this invention, the light source and the photosensor are mounted to substrates and are constructed of such small dimensions that both independently conform with a low aspect ratio to the flexible adhesive strip. This process also uses sequential layers of surgical tape, opaque vinyl, and light filters. Thereafter, apertured, opaque vinyl and finally a transparent adhesive layer are placed over the entire photo-sensor. The result is a simple flexible adhesive strip apparatus which is in conformance to the blood perfused flesh, i.e., digit, being interrogated for blood flow.

(PX 7, col. 6, lines 9-21) (emphasis added)

The "summary of the invention" similarly describes a nasal sensor, the "photoelectrical components [of which] are embedded into a flexible adhesive substrate ...." (PX 7, col. 5, lines 9-11) (emphasis added). A method for manufacturing a nasal sensor is described as follows:

In the assembly of this invention, the light source and the photo-sensor are embedded in a flexible plastic substrate all of which are constructed of such small dimension that the sensor conforms cutaneously to the patient's external cutaneous layer. The assembly process entails sequestial layers of mounting. There results an apparatus easily affixed on the patient's nose.

(PX 7, col. 7, lines 12-20) (emphasis added).

In the "detailed description of the preferred embodiment," the sequential construction of the preferred embodiment of this invention is described as follows:

Referring to FIG. 2C, it can be seen that the photo-active elements of the sensor substrate 14, 24 are fastened with the inactive side down to an opaque vinyl strip 30 having an adhesive surface 32. Likewise, a porous, flexible adhesive tape overlies the opaque vinyl strip 30 and a porous flexible tape layer 34 having an adhesive side 35.

Once the photo-active elements 14, 24 are attached, a second opaque vinyl tape is placed over the photo-active elements at 37. This tape has a downwardly exposed adhesive layer 38 and effects capture of the light source substrate and the photosensor substrate between strip 30 and strip 37.

Strip 37 is apertured at respective apertures 40, 41. These apertures allow light to pass. At the same time, they conform the thickness of the photo-active substrates to the overall thickness of the flexible adhesive strip to which attachment occurs. The photoactive substrates as thus captured are ideally indistinguishable in the tactile sense from the flexible adhesive strip itself.

Finally, a layer of clear polyester 45 having double adhesive coatings 46, 47 is placed over the central narrow length of the flexible adhesive strip. This enables the passage of light and yet ensures intimate bonding of the photo-sensor to the skin and the flexible adhesive strip.

A protective layer of release tape 50 protects the entire article during manufacture and before use.

(PX 7, col. 9, lines 19-53) (emphasis added).
Claim 1 discloses a probe comprising:

- a flexible, initially substantially planar, web-like support structure having substantially parallel, spaced, oppositely facing upper and lower surfaces;
- a light source mounted in the web of said support structure …;
- a photo-sensor mounted in the web of said support structure …;
- an adhesive layer on said lower surface for removably securing said lower surface to said convex portion of said skin so that said lower surface is held in conformance with said skin, said support structure being flexible also to conform to said skin without stressing ….

(PX 7, col. 11, lines 16-20, 24-25) (emphasis added).

The only structure described in the specification which correlates to the "web-like support structure" disclosed in claim 1 is a "flexible adhesive strip apparatus" made up of "sequential layers of surgical tape, opaque vinyl, and light filters" and "a transparent adhesive layer." (PX 7, col. 6, lines 15-17, 19) The specification does not refer to this "flexible adhesive strip apparatus" in terms of "support" but, rather, in terms of "conformance to the blood perfused flesh." (PX 7, col. 6, lines 19-20) Likewise, the other limitations of the claim discussed above focus on the conformance characteristic of the invention. Given the language of the specification and the problem primarily addressed by the invention (conformance to the convex nature of a patient's skin, not placement of optical components), the court construes claim 1 to disclose a "flexible adhesive strip apparatus" which properly positions or holds in place the optical components on the blood perfused tissue for transillumination.

The court finds that the phrase "in the web" is capable of definition and, therefore, that it does not render invalid claim 1 of the '014 patent.

4. The term "incidental heat loss" in claim 1 is construed as: "atmospheric or other ambient heat loss." Plaintiff argues that this term did not require construction or, in the alternative, that it be construed as "[a]ny heat which is surrendered to the atmosphere air in the processing facility or which is otherwise removed from the product during ambient temperature processing." Dkt. # 49, at 5. Defendant argues that this term should be construed as "heat incidentally lost to the atmosphere as the product is conveyed directly between step (a) and step (b), and directly between step (b) and step (c)." Dkt. # 51, at 19. From the language of the claim and the specifications in the patent, it is clear that the term is intended to describe heat incidentally radiated to the product's surroundings after it is heated in step (a) or step (c). The prosecution history shows that plaintiff intended this term to describe the product's natural loss of heat, rather than a procedure by which the product is cooled. See Dkt. # 51, at 20-21. For example, if a product were permitted to sit idle after passing through a heating oven, the heat it would lose would be incidental heat loss. Defendant's requested insertion of the word "directly" would introduce an unintended limitation into claim 1, as the claim does not require that the product travel directly between steps of the process, only that there be no intervening cooling procedure between steps.

2083

 Claims 3, 4, 13, and 21 of the '951 patent refer to "an inclination mechanism secured to said frame structure effective to permit selective inclination of said deck member by the user." Precor urges the Court to adopt a means-plus-function construction of "inclination mechanism," while Life Fitness argues that the disputed element should be given its ordinary meaning.
The Court concludes that this claim element is written in means-plus-function format. The Court recognizes that this disputed claim element does not include the word "means," which is most often used to trigger a means-plus-function construction. However, words other than "means" can invoke the limitations of 35 U.S.C. § 112, ¶ 6. See Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996). In light of the fact that the disputed claim element sets forth no definite structure, the Court concludes that in this context the word "mechanism" is the linguistic equivalent of the word "means."

The specification refers to several embodiments of the "inclination mechanism." These embodiments can be found at figures 2A, 3A, 3D, and 4, as well as column 13, line 46-column 15, line 7. The Court adopts these varying embodiments in order to define the scope of the disputed claim element.

The '900 Patent concludes with the following claims:

The embodiment of the invention in which an exclusive property are claimed are as follows:

1. A bin for containing material to be spread by a spreader vehicle having a floor-mounted conveyor positioned within the bin to extract such material, wherein the bin walls are curved inwardly towards the conveyor, commencing from a first height that is above the level of the conveyor, and terminating at the edge of the conveyor, the bin walls having an inclination that is sufficient to cause material which is to be spread when positioned thereon to slide spontaneously to the conveyor, under the agitation arising from vehicular motion.

2. A bin as in claim 1, wherein the bin walls each have an upper bin wall portion which is virtually vertical. '900 Patent, col.4, ll.35-48 (emphasis added). The following figures are instructive:

GET DRAWING SHEET 3 OF 3

'900 Patent, figs.3-5 (handwritten circle and number 18 in original patent).
