Similar to the analysis undertaken to arrive at the conclusion that the chemically embossed "portion" referred to those areas of the surface covering in which a "regulator," "inhibitor," "retarder," or similar chemical compound was applied to create the desired texture, this court construes the entire phrase "a mechanically embossed portion" to refer to the raised areas of the surface covering (the areas that are not chemically embossed) that are mechanically imprinted with a surface texture to produce the desired effect. This construction is clearly supported by the written description:

In any event, the portion of the foam layer which has been overlaid with the design layer having the retarder composition is not mechanically embossed.

'903 at 6:6-9; '008 at 6:17-20.

In the preferred embodiment of the invention, the chemical embossing of the joint or grout lines is deeper than that of the portions of the surface covering which have only been mechanically embossed. In this way, the surface texture created by the mechanical embossing is limited to the raised areas.

'903 at 2:45-50; '008 at 2:53-58.

Thus the surface covering of the invention, which does not include mechanically embossed surface texture in the joint or grout lines, has the appearance of mechanical embossing in register ….
In the preferred embodiment of the present invention, the chemical embossing of the joint or grout lines is deeper than that of the portions of the surface covering which have only been mechanically embossed. This process, which does not create the mechanically embossed surface texture in the joint or grout lines, imparts to the surface covering the appearance of mechanical embossing in register.

'903 at 6:45-49; '008 at 6:46-53.

... There is no mechanically embossed surface texture in the chemically embossed areas because the minimum chemical embossing depth of about 0.010 inches is deeper than the maximum depth of the mechanically embossed surface texture of about 0.008 inches.

'903 at 10:3-8; '008 at 10:13-18.

In contrast to the court's construction that chemically embossed portions were not limited to joint or grout lines as provided in the preferred embodiment, it is the opinion of this court that the inventors predicated the patentability of their invention on the mechanical embossing of the raised areas only, therefore, the '903 and '008 patent claims cannot support an invention containing mechanical embossing in the chemically embossed areas. This construction is also consistent with the prosecution history of the patents. 9

Footnotes

9 In response to an Office Action on November 20, 1998 rejecting original claims 9 and 10 of the '903 parent application, the inventors responded by stating that "the realism of applicant' surface covering comes from the fact that the claimed procedure prevents the joint or grout lines … from being textured by the mechanical embossing step." D.I. 328 at 89-93.

2513

3. "money dispensing mechanism"

Tidel proposes this term means "a device to dispense coins and/or paper currency from inside of the safe." FKI proposes the term means "a four-to-eight bin set of hoppers wherein a bin is assigned to loose dollar coins, quarters, nickels, pennies and optionally dimes the mechanism also dispenses rolled bills and single or multiple bills from a stack." FKI argues that the specification describes alternative embodiments of coin dispensing mechanisms having four bins, five bins, or six bins. Further, FKI argues, the specification teaches that the "money dispensing mechanism" has up to eight bins. FKI is attempting to limit the claim to the preferred embodiment described in the specification. Additionally, FKI is attempting to limit "money dispensing mechanism" to the "dispensing means" construed above. Here, however, the "dispensing means" is only one subcomponent of the "money dispensing mechanism." 1

Footnotes

1 "money dispensing mechanism . . . containing a supply of coins of a plurality of denominations, a receptacle for coins dispensed from said supply located on the exterior of said secure locking cabinet, and dispensing means for dispensing coins from said supply through a penetration in said secure locking cabinet to said receptacle for coins." [claim 1, 11:63-12:5]

At the court's request, the parties filed supplemental briefs on whether the term should be construed under 35 U.S.C. § 112 P 6. The Federal Circuit has found that "mechanism" at times lacks sufficient structure to avoid § 112 P 6. Because the word "means" is not found in the claim, there is a presumption that § 112 P 6 does not apply. Lighting World v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) The presumption, however, is rebuttable. The "generic terms 'mechanism,' 'means,' 'element,' and 'device,' typically do not connote sufficiently definite structure" to avoid § 112 P 6.

- 3010 -
Massachusetts Institute of Technology and Electronics for Imaging, Inc. v. Abacus Software, 462 F.3d 1344, 1354 (Fed. Cir. 2006). Sometimes § 112 P 6 can be avoided if the generic term is further defined in the claim language. See id. For example, the Federal Circuit found that "detent mechanism" provided sufficient structure to avoid § 112 P 6. Greenberg v. Ethicon Endo-Surgery, Inc. 91 F.3d 1580, 1583 (Fed.Cir. 1996). The definition of "detent" was well understood in the art, and that definition "connoted sufficient structure to avoid § 112 P 6." Id. In MIT, however, the Federal Circuit held that "colorant section" as a modifier to "mechanism" did not provide sufficient structure to a claim because "colorant section . . . has no dictionary definition, and there is no suggestion that it has a generally understood meaning in the art." MIT, 462 F.3d at 1354.

In MIT, the claim language that defined "colorant mechanism" was only in terms of the function that "colorant section" provided. Id. Additionally, the defendant has cited to two recent cases where the Federal Circuit has found that "mechanism" did not connote sufficient structure to avoid § 112 P 6. See Aspex Eyewear, Inc. v. Altair Eyewear, Inc., 288 Fed.Appx. 697, 704 (Fed.Cir. 2008); See also Welker Bearing Co. v. PHD, Inc. 550 F.3d 1090, 2008 U.S. App. LEXIS 25069, 2008 WL 5205639 (Fed.Cir. 2008).

In Welker, the court found that "mechanism for moving said finger" did not provide sufficient structure to avoid § 112 P 6. Welker, 2008 U.S. App. LEXIS 25069, [WL] at *4. The claim "provide[d] no structural context for determining the characteristics of the "mechanism" other than to describe its function." Id. In Aspex, the Court found that "retaining mechanism" was too broad to connote structure, and unlike "detent" in Greenburg, "retaining" had no well understood meaning in the art. Aspex, 288 Fed.Appx. at 704.

While "money dispensing" may not have a well understood meaning in the art, the claim language as a whole connotes sufficient structure to avoid § 112 P 6. The generic term is defined in the claim language. See MIT, 462 F.3d at 1354. Unlike the cases cited by the defendant, the term at issue is not defined simply by the function it performs. Indeed, it is defined by structural elements: "supply of coins" and "receptacle for coins." [11:63-65]. Additionally, the inventor did not use "mechanism" synonymously with "means"; the "money dispensing mechanism" includes a "dispensing means" as one of its defined components. [11:63-12:5] Accordingly, the defendant has failed to rebut the presumption that "mechanism" should not be construed under § 112 P 6.

Because the term is defined by structural components in the claim, the court construes the term using the plain and ordinary meaning of the language used in the claim. The term incorporates both "stored coins" and "dispensing means," which the court has construed above. Those constructions, therefore, are incorporated in the construction of "money dispensing mechanism." The court construes "money dispensing mechanism" as "a device for dispensing money that includes stored coins of more than one denomination, a receptacle for coins dispensed from storage, and a dispensing mechanism 32 consisting of hoppers or bins 33, 34, 35, and 36 and their equivalents."

Although the parties fault each other for their failure to reach an agreement as to precisely which aspects of claim 1 remain in dispute, it is evident from their submissions that Plaintiff and Defendant disagree only as to one element of this claim. Specifically, the parties dispute the meaning to be given to the claim language referencing a "mechanism" for moving the pin clamp's fingers into and out of the locating assembly. Through the present motion, Defendant contends that the term "mechanism" as used in claim 1 should be viewed as a means-plus-function limitation, such that this term must be construed as encompassing only the corresponding structure described in the patent specification for performing the function of this "mechanism." The Court agrees.

The disputed term is found near the end of claim 1, which reads in its entirety:

1. A locating and clamping assembly comprising:

   a body defining an internal cavity and an opening from said cavity to the exterior of said body;
a locating pin disposed in said cavity and extending along an axis A out of said opening to a distal end;

an actuator for moving said locating pin rectilinearly along said axis A into and out of said opening;

at least one finger supported by said locating pin adjacent said distal end;

said assembly characterized by a mechanism for moving said finger along a straight line into and out of said locating pin perpendicular to said axis A in response to said rectilinear movement of said locating pin.

(Defendant's App'x, Ex. D, '254 patent at 8:12-24 (emphasis added).) Apart from their dispute over the term "mechanism," the parties evidently agree as to the ordinary and customary meaning that should be assigned to the remaining elements of this claim.

As to this sole disputed element, the parties' disagreement turns upon whether the term "mechanism" dictates that this element be construed as a means-plus-function limitation governed by 35 U.S.C. § 112 P 6. Under this statutory provision, a claim element "may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof," in which case the claim "shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P 6. As the Federal Circuit has explained, § 112 P 6 "permits the use of purely functional language in claims," but "limits the breadth of such claim language by restricting its scope to the structure disclosed in the specification and equivalents thereof." Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1582 (Fed. Cir. 1996).

"In determining whether a claim limitation is a means-plus-function limitation, the use of the word 'means' creates a presumption that § 112, P 6 applies." Wenger Manufacturing, Inc. v. Coating Machinery Systems, Inc., 239 F.3d 1225, 1232 (Fed. Cir. 2001) (internal quotation marks and citation omitted). By the same token, if the word "means" does not appear, the limitation in question "is presumptively not subject to [§] 112 P 6." Greenberg, supra, 91 F.3d at 1583-84 (emphasis added). Nonetheless, "a limitation lacking the term 'means' may overcome the presumption against means-plus-function treatment if it is shown that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Greenberg, supra, 91 F.3d at 1583 (internal quotation marks and citations omitted). In this case, Defendant argues that the presumption against means-plus-function treatment is overcome by the use of the term "mechanism" in a purely functional way, unaccompanied by any sort of language suggestive of a structure that performs the function of this "mechanism."

As Defendant points out, MIT itself was a case in which the Federal Circuit held that a claim's reference to "mechanism" was synonymous with "means," and hence was properly construed as disclosing a means-plus-function limitation. The patent in that case "disclose[d] a color processing system for producing copies of color originals," and one of the elements of claim 1 of this patent was a "colorant selection mechanism" that received "appearance signals" derived from a scanned original image and selected "corresponding reproduction signals" that would result in a "colorimetrically-matched reproduction." MIT, 462 F.3d at 1353 (emphasis added). Nonetheless, "a limitation lacking the term 'means' may overcome the presumption against means-plus-function treatment if it is shown that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." MIT, 462 F.3d at 1353 (emphasis added). In this case, Defendant argues that the presumption against means-plus-function treatment is overcome by the use of the term "mechanism" in a purely functional way, unaccompanied by any sort of language suggestive of a structure that performs the function of this "mechanism."

We agree with the district court's conclusion that the presumption here [against means-plus-function treatment] is overcome and that the phrase "colorant selection mechanism should be construed as a means-plus-function limitation. The generic terms "mechanism," "means," "element," and "device," typically do not connote sufficiently definite structure . . . .

Here, the patentee used "mechanism" and "means" as synonyms. At least one dictionary definition equates mechanism with means. See The Random House Webster's Unabridged Dictionary 1193 def. 2 (2d ed. 1998) (defining "mechanism" as "the agency or means by which an effect is produced or a purpose is accomplished"); see also The Random House Dictionary of the English Language -- The Unabridged Edition 889 (1973) (same). The term "mechanism" standing alone connotes no more structure than the term "means."

462 F.3d at 1354 (citations omitted).

In so ruling, the court distinguished an earlier decision, Greenberg, supra, 91 F.3d at 1583-84, in which another Federal
Circuit panel had held that the phrase "detent mechanism" did not trigger means-plus-function treatment under § 112 P 6. In Greenberg, the district court had concluded that "detent mechanism" was subject to § 112 P 6, in part "because the term did not describe a particular structure but described any structure that performed a detent function." Greenberg, 91 F.3d at 1583. The Federal Circuit found this reasoning insufficient to justify means-plus-function treatment:

. . . [T]he fact that a particular mechanism -- here "detent mechanism" -- is defined in functional terms is not sufficient to convert a claim element containing that term into a "means for performing a specified function" within the meaning of section 112(6). Many devices take their names from the functions they perform. The examples are innumerable, such as "filter," "brake," "clamp," "screwdriver," or "lock." Indeed, several of the devices at issue in this case have names that describe their functions, such as "graspers," "cutters," and "suture applicators."

"Detent" (or its equivalent, "detent mechanism") is just such a term. Dictionary definitions make clear that the noun "detent" denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms. It is true that the term "detent" does not call to mind a single well-defined structure, but the same could be said of other commonplace structure terms such as "clamp" or "container." What is important is not simply that a "detent" or "detent" mechanism is defined in terms of what it does, but that the term, as the name for structure, has a reasonably well understood meaning in the art.

91 F.3d at 1583 (citations omitted).

Despite some similarity in the language at issue -- "colorant selection mechanism" in MIT versus "detent mechanism" in Greenberg -- the court in MIT nonetheless found that Greenberg was distinguishable:

Claim language that further defines a generic term like "mechanism" can sometimes add sufficient structure to avoid [§] 112 P 6. For example, in Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996), which involved a mechanical device, we held that [§] 112 P 6 did not apply to the term "detent mechanism" because "the noun 'detent' denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms." Id. at 1583. The court recited several dictionary definitions for "detent," including "a mechanism that temporarily keeps one part in a certain position relative to that of another, and can be released by applying force to one of the parts." Id. (internal quotation marks and citations omitted). These definitions connoted sufficient structure to avoid [§] 112 P 6 . . . .

In contrast, the term "colorant selection," which modifies "mechanism" here, is not defined in the specification and has no dictionary definition, and there is no suggestion that it has a generally understood meaning in the art. We therefore agree with the district court that "colorant selection mechanism" does not connote sufficient structure to a person of ordinary skill in the art to avoid [§] 112 P 6 treatment.

MIT, 462 F.3d at 1354 (footnotes omitted).

Returning to the present case, this Court readily concludes that the claim language at issue here is far more analogous to the "colorant selection mechanism" of MIT than to the "detent mechanism" of Greenberg. As explained in MIT, "[t]he term 'mechanism' standing alone connotes no more structure than the term 'means.'" MIT, 462 F.3d at 1354. It follows that a "mechanism" should ordinarily be construed as a means-plus-function limitation absent accompanying claim language that is suggestive of structure, at least to a person of ordinary skill in the relevant art. This, then, was the crucial distinction between the claim language addressed in Greenberg and in MIT -- the additional "detent" qualifier in the former case was found to be a "name for structure" that had a "reasonably well understood meaning in the art," Greenberg, 91 F.3d at 1583, while the "colorant selection" modifier in the latter case lacked any comparable structural connotation that was "generally understood in the art," MIT, 462 F.3d at 1354.

The term "mechanism" as used in claim 1 of the '254 patent is still further along the means-plus-function spectrum than the "colorant selection mechanism" under consideration in MIT, because the reference to a "mechanism" in this case is utterly unaccompanied by any language that is suggestive of structure, whether specific or generic. As stated earlier, the pertinent portion of claim 1 discloses a locating and clamping assembly that is "characterized by a mechanism for moving said finger along a straight line into and out of said locating pin perpendicular to said axis A in response to said rectilinear movement of said locating pin." All that can be said about this "mechanism" is that it moves the device's clamping fingers into and out of
the locating pin in a direction perpendicular to the axis along which the locating pin travels, and that it does so in response to the "rectilinear movement" of the locating pin into and out of an opening in the clamping assembly.

While this claim language discloses the function to be performed by the referenced "mechanism" -- namely, to move the clamping fingers in a specified direction in response to the movement of the locating pin -- it says nothing at all about any sort of structure for performing this function. Nor is the generic term "mechanism" modified or further defined by any accompanying claim language that might connote structure, whether under an ordinary dictionary definition or to a person of ordinary skill in the relevant art. Rather, the term "mechanism" stands alone, and therefore "connotes no more structure than the term 'means.'" MIT, 462 F.3d at 1354. It follows that the presumption against means-plus-function treatment has been overcome, and that the "mechanism" referred to in claim 1 of the '254 patent must be construed in accordance with § 112 P 6 -- i.e., it must be restricted in scope "to the structure disclosed in the specification and equivalents thereof." Greenberg, 91 F.3d at 1582.

Although Plaintiff suggests a number of grounds for avoiding this result, the Court finds none of them persuasive. First and foremost, Plaintiff contends that the need for any construction of claim 1 of the '254 patent has been obviated by Defendant's purported concession in discovery that all of the claim's terms should be given their "ordinary meaning." As evidence of Defendant's purported "admission" on this point, Plaintiff cites (i) the deposition testimony of Defendant's vice president, William Davenport, who was designated as the firm's deponent under Fed. R. Civ. P. 30(b)(6), and (ii) Defendant's objection to Plaintiff's interrogatory requesting that Defendant identify any claim terms that should be given a "special meaning" rather than their "common and ordinary meaning."

Contrary to Plaintiff's assertion, the Court sees nothing in Defendant's conduct during discovery that might constitute any sort of "waiver" of Defendant's opportunity to advocate a particular claim construction in the course of dispositive motion practice. First, in the deposition testimony cited by Plaintiff, Mr. Davenport was not asked to offer any sort of construction of the term "mechanism" as used in claim 1. Rather, he was asked only (i) whether Defendant's allegedly infringing product "has a mechanism for moving [a clamping] finger along a straight line into and out of the locating pin," (ii) whether the straight line along which the clamping finger moves in Defendant's product is "perpendicular to the axis that has the rectilinear movement of the locating pin," and (iii) whether the mechanism in Defendant's product moves the clamping fingers "in response to rectilinear movement of the locating pin." (Plaintiff's Response, Ex. A, Davenport Dep. at 156-57.) By acknowledging that Defendant's product has such a "mechanism," Mr. Davenport was in no way confirming, or even postulating, that claim 1 of the '254 patent should be construed as encompassing any and all pin clamps that have any sort of "mechanism," as that term is commonly understood, for performing the function described in this claim. 1 Indeed, nothing in the cited passage of his deposition testimony can be viewed as an expression of any opinion whatsoever as to how any element of claim 1 should be construed, much less whether any of this claim's terms might trigger means-plus-function treatment under § 112 P 6. 2 Instead, Mr. Davenport merely was asked to confirm that Defendant's product had certain features and performed certain functions as identified by Plaintiff's counsel. The Court is at a loss to see how this testimony can be viewed as reflecting, much less limiting, the claim construction positions that Defendant would or could advocate in its dispositive motion practice.

--- Footnotes ---

1 Moreover, and for what it is worth, Mr. Davenport further opined at his deposition that the mechanisms used in Plaintiff's and Defendant's competing products were "[w]holly different," with Plaintiff's pin clamp using a "pivoting motion" to move the clamping fingers out of the locating pin and Defendant's product using purely "linear motion" to achieve this result. (Id. at 81.)

2 Of course, even if Mr. Davenport had offered an opinion on this latter subject, Plaintiff has failed to suggest a reason why any weight should be given to the testimony of a lay witness on a legal issue reserved to the Court. See Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) ("The task of determining whether the limitation in question should be regarded as a means-plus-function limitation, like all claim construction issues, is a question of law for the court."). At most, Mr. Davenport's testimony might reflect how a person of ordinary skill in the relevant art might read and understand the language of the claim. On this point, however, his testimony seemingly suggests precisely the opposite of what Plaintiff would read into it, where he opined that the parties had settled upon two wholly different structures for accomplishing the function assigned to the "mechanism" in claim 1.
Neither can the Court discern how Defendant's objection to an interrogatory might be construed as either (i) an acknowledgment that Plaintiff's view of the "ordinary meaning" of claim 1 was correct, or (ii) a waiver of any opportunity to propound a means-plus-function reading of the term "mechanism" as used in this claim. In the interrogatory in question, Defendant was asked to identify any terms in the patents-in-suit that it believed should be given a "special meaning different from the[ir] common and ordinary meaning." (Plaintiff's Response, Ex. B, Interrogatory No. 10.) Defendant responded by objecting to the interrogatory as "premature," where "[d]iscovery ha[d] just begun," no deadlines had been set "relative to claim construction issues," and Plaintiff purportedly had yet to "[i]dentif[y] what claims of the patents-in-suit it contends to have been infringed and [which of Defendant's] products it believes to embody one or more of the claims of the patents-in-suit." (Id.) Because Defendant evidently did not supplement this response at any point during discovery, Plaintiff surmises that Defendant should be bound by the "ordinary meaning" of the terms of claim 1.

This argument is riddled with flaws, both factual and logical. First, the Court notes that Defendant's above-quoted discovery objection was merely an early salvo in a protracted squabble, spanning essentially the entire discovery period, over the timing, sequencing, and sufficiency of the parties' discovery responses regarding matters of claim construction. Plaintiff promptly responded to Defendant's objection by moving to compel full and complete responses to its first set of interrogatories. Yet, in a stipulated order dated December 27, 2006, the scheduled hearing on Plaintiff's motion was cancelled in light of Defendant's agreement to supplement certain of its interrogatory responses. Notably, the interrogatory now identified by Plaintiff was not mentioned in this stipulated order -- instead, this order recited Defendant's broader agreement to "provide its claim construction pursuant to a scheduled exchange as agreed to by counsel." (12/27/2006 Order at 2.) Since the parties did not exhibit any particular reluctance to seek the Court's intervention in their discovery disputes, the Court can only assume that Defendant satisfactorily discharged this obligation. 3

In any event, Plaintiff fails to explain why the means-plus-function construction advanced in Defendant's motion should qualify as a "special meaning" that Defendant was obligated to identify in response to Plaintiff's interrogatory, as opposed to merely an "ordinary" meaning that happens to differ from the "ordinary" meaning that Plaintiff would assign to the term "mechanism" as used in claim 1. To the extent that Plaintiff means to suggest that judicial claim construction is unnecessary so long as the parties agree that a claim's terms should be given their "ordinary meaning," this unduly discounts the capacity of patent litigants to argue over what this "ordinary meaning" should be. As one court recently observed, "parties in patent cases rarely agree on the 'ordinary meaning of [the patent's] claims' or what claims of the patents-in-suit it contends to have been infringed and [which of Defendant's] products it believes to embody one or more of the claims of the patents-in-suit." (Maytag Corp. v. Electrolux Home Products, Inc., 411 F. Supp.2d 1008, 1037 (N.D. Iowa 2006) (alteration in original).) Likewise, it begs the question in this case to appeal, without further discussion or explanation, to the "ordinary meaning" of the term "mechanism," because the "ordinary meaning" of this term, along with the words that accompany or modify it, determines whether means-plus-function treatment is warranted. Accordingly, the Court rejects Plaintiff's unstated premise that Defendant has advanced some sort of novel claim construction position by urging a means-plus-function interpretation of claim 1.

More fundamentally, even if Plaintiff could establish some element of sandbagging or "unfair surprise" in Defendant's motion -- and the record falls well short of such a showing -- there is no indication of any resulting prejudice or need for remedial measures. If, for example, Defendant had provided misleading or incomplete discovery responses that caused Plaintiff to forgo a particular line of inquiry, the proper remedy at this juncture would be a request for additional discovery

- 3015 -
pursuant to Fed. R. Civ. P. 56(f). Indeed, Plaintiff has made just such a request in response to one of the grounds advanced in Defendant's other pending motion, arguing that Defendant seeks to rely on a prior art reference that was not timely identified during discovery. In its response to Defendant's motion for claim construction, in contrast, Plaintiff fails to suggest any impediment to its ability to advocate an interpretation of claim 1 that differs from the one sought by Defendant. Consequently, the Court sees no reason to abstain from construing the disputed terms of claim 1, at least to the extent that such claim interpretation is a necessary predicate to the resolution of the parties' cross-motions for summary judgment.

Having addressed Plaintiff's threshold procedural challenges to Defendant's request for a judicial construction of claim 1 of the '254 patent, the Court turns to Plaintiff's substantive challenges, such as they are, to the particular claim construction advocated by Defendant. Beyond terse expressions of surprise, with little or no accompanying explanation, that Defendant has failed to discuss certain decisions that Plaintiff views as most relevant to the claim construction inquiry, 4 Plaintiff first contends that Defendant has failed to produce the "substantial amount of proof" that purportedly is necessary to overcome the presumption against means-plus-function treatment of claim elements that lack the word "means." Yet, the decision in MIT belies any such claim of an onerous evidentiary burden, where the court in that case relied solely on (i) language within the four corners of the patent-in-suit, (ii) a dictionary definition that "equates mechanism with means," and (iii) the absence of evidence that the modifying "colorant selection" language had "a generally understood meaning in the art." MIT, 462 F.3d at 1354.

4 Plaintiff chides Defendant, for example, for its "incredibl[e]" failure to discuss the Federal Circuit's Greenberg decision. Apart from the fact that Greenberg is, in fact, addressed in Defendant's motion, albeit only in a footnote, any arguable omission in this regard is overcome by Defendant's extensive reliance on the MIT decision, which in turn discusses Greenberg at length and finds it distinguishable.

There is even less of a need here for Defendant to supply a "substantial amount of proof" in order to overcome the presumption against means-plus-function treatment. As explained earlier, and in contrast to the claim language at issue in MIT, the term "mechanism" in claim 1 of the '254 patent is utterly unaccompanied by any language that modifies this "generic term" or that might connote "sufficient structure to avoid [§] 112 P 6." MIT, 462 F.3d at 1354. Rather, the accompanying language merely discloses the function that this "mechanism" performs, without in any way suggesting a structure that might perform this function. Under these circumstances, it is enough for Defendant to point to (i) the Federal Circuit's express recognition that "[t]he term 'mechanism' standing alone connotes no more structure than the term 'means,'" MIT, 462 F.3d at 1354, and (ii) the absence of any accompanying claim language that might be understood by a person of ordinary skill in the art as connoting a structure that performs the stated function. Certainly, with the one possible exception discussed below, Plaintiff has not identified any such language in claim 1 that supplies the structure that is otherwise lacking in the unadorned reference to "mechanism" alone. In a relatively easy case like the present one, where the term "mechanism" is "simply a nonce word or a verbal construct that is not recognized as the name of structure and is simply a substitute for the term 'means for,'" Lighting World, supra, 382 F.3d at 1360, the Court is confident that Defendant need not shoulder a particularly heavy burden in overcoming the presumption against means-plus-function treatment.

Plaintiff next contends that Defendant's proposed construction of claim 1 runs afoul of the doctrine of claim differentiation, under which each claim in a patent is presumed to have a different scope. See Comark Commns. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). 5 If claim 1 were construed as including a means-plus-function limitation, thereby restricting its scope by reference to the corresponding structure described in the patent specification, Plaintiff submits that the result would be to eliminate a significant distinction between independent claim 1 and dependent claims 4, 5, and 6. In particular, claims 4 through 6 add structure to the "mechanism" of claim 1, disclosing that this "mechanism" includes a rotating central post. Yet, this same "rotating central post" limitation would be incorporated into claim 1, by way of the patent specification, if this claim's reference to the term "mechanism" were construed as a means-plus-function limitation.

5 Once again, Plaintiff prefaces its argument on this issue with a pointless and utterly gratuitous declaration that Defendant has failed to address the "leading case" on this subject.
As recognized in Comark Communications, however, "the doctrine of claim differentiation is not a hard and fast rule of construction," but rather establishes only a "presumption that each claim in a patent has a different scope." Comark Commun., 156 F.3d at 1187. Indeed, the Federal Circuit has expressly emphasized, in decisions both before and after Comark Communications, that "the judicially developed guide to claim interpretation known as 'claim differentiation' cannot override . . . the express mandate of section 112(6)." Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991); see also Wenger Manufacturing, supra, 239 F.3d at 1233. Moreover, the court has cautioned that "[a] means-plus-function limitation is not made open-ended by the presence of another claim specifically claiming the disclosed structure which underlies the means clause or an equivalent of that structure," as such a rule of construction "would provide a convenient way of avoiding the express mandate of section 112(6)." Laitram Corp., 939 F.2d at 1538.

This same reasoning defeats Plaintiff's appeal in this case to the doctrine of claim differentiation. Regardless of whether a means-plus-function limitation might diminish, or even eliminate, the distinction between claim 1 and claims 4 through 6 of the '254 patent, the Court has already explained why, in its view, there is simply no tenable reading of the term "mechanism" and the surrounding language of claim 1 that would connote sufficient structure to avoid the application of § 112 P 6. The situation was different in Wenger Manufacturing, 239 F.3d at 1233-34, for example, where the court applied the doctrine of claim differentiation to ensure that a means-plus-function limitation was confined strictly to those "structural limitations from the written description that are necessary to perform the claimed function." Thus, while the Court is mindful, as discussed below, of a similar need here to avoid the sweeping importation into claim 1 of structural elements that are not necessary to fulfill the function of the "mechanism" disclosed in that claim, the Court cannot allow a rule of construction to override the statutory command of § 112 P 6 where, as here, a claim element is stated in purely functional terms.

Plaintiff next suggests that Defendant's proposed construction of claim 1 is somehow undermined by the Federal Circuit's recent decision in Applied Medical Resources Corp. v. United States Surgical Corp., 448 F.3d 1324 (Fed. Cir. 2006). Yet, the parties in that case agreed almost entirely as to the proper construction of the claim at issue, and the court found that the one possible point of dispute was not preserved for appeal. See Applied Medical Resources, 448 F.3d at 1332-33 (electing to "apply the undisputed claim construction adopted by the district court"). The significance of that decision, then, lies not in its discussion of claim construction principles, but rather -- as Plaintiff itself characterizes it -- in its "enunciat[ion] [of] a precise process for determining infringement of a 'means plus function' claim." (Plaintiff's Response Br. at 7 (emphasis added).) Plaintiff does not explain what bearing, if any, Applied Medical Resources should have on the proper disposition of Defendant's motion for claim construction, and its relevance likewise is not evident to the Court.

Next, and rather remarkably, Plaintiff requests that the Court permit "full briefing" on the issue of claim construction, so that the parties and the Court alike may "not only decide the claims that need to be evaluated, but also clarify the decisions to be made, and the standards against which those decisions need to be framed." (Id. at 8.) Yet, Plaintiff fails to suggest any reason why the parties' existing round of briefing on Defendant's present motion for claim construction would not qualify as the desired "full briefing" on this subject. Neither has Plaintiff identified any impediment to its opportunity to fully address all of the issues of relevance to the Court's claim construction effort within the four corners of its response to Defendant's motion. To the contrary, Plaintiff appears to have accurately identified the points -- or, more accurately, the single point -- upon which the parties disagree in light of the arguments raised and interpretations propounded in Defendant's motion, and has taken the opportunity in its response to advance various reasons why its proposed construction should prevail over Defendant's as to this single point of contention. Under these circumstances, the Court finds no basis for permitting supplemental briefing on issues that have been thoroughly addressed and debated in the parties' initial round of briefs, as well as at oral argument.

Indeed, at the November 29 hearing, Plaintiff and its counsel suggested for the first time that claim 1 does, in fact, disclose structure corresponding to its "mechanism" element. In particular, Plaintiff contends that the term "mechanism" should be construed as part and parcel of the "actuator" referenced earlier in claim 1. Plaintiff further asserts that an "actuator," like the "detent" qualifier in Greenberg, supra, 91 F.3d at 1583, is a "name for structure" that has a "reasonably well understood meaning in the art." In Plaintiff's view, then, the close relationship between the "actuator" and "mechanism" elements of claim 1 obviates the need to consult the patent specification to determine the structure corresponding to the latter element.

This proposed construction, however, cannot be squared with either the language of claim 1 itself or the overall patent of
which it is a part. First and foremost, claim 1 discloses an "actuator" and a "mechanism" as two distinct elements that perform different functions. Under the express language of the claim, the "actuator" performs the function of "moving said locating pin rectilinearly along said axis A into and out of said opening" in the device's locating and clamping assembly. The "mechanism," in contrast, performs the function of "moving said finger along a straight line into and out of said locating pin perpendicular to said axis A in response to said rectilinear movement of said locating pin." To be sure, these functions are related, with the "mechanism" moving the device's clamping fingers "in response to" the actuator's movement of the locating pin. Yet, the two functions are nonetheless distinct, as the claim itself makes clear by disclosing them in two separate elements. There is simply no basis in the language of claim 1 for treating the "mechanism" as somehow ancillary to, and structurally defined by reference to, the "actuator" that serves a wholly distinct purpose in the overall device.

The specification confirms this distinction. It summarizes the invention as including an "actuator" that "moves the locating pin rectilinearly along the axis into and out of the opening" in the locating assembly, as well as a "mechanism" that "rotates in response to the rectilinear movement of the locating pin for moving the finger radially." (254 patent at 2:21-27.) It then devotes entire paragraphs to separately defining and describing (i) an "actuator 52" that is mounted to the body of the locating assembly and connected to the locating pin through a pin mount, and that performs the function of "rectilinearly moving the locating pin 12 along the axis A" using a combination of a piston, coupler, and coupler plate, (id. at 4:56-5:18), and (ii) a "mechanism 68" that includes a rotating central post "disposed between the actuator 52 . . . and the fingers" that "rotates in response to the rectilinear movement" of the actuator, as well as a "motion converter" that converts the rotational movement of the central post into radial movement of the fingers, (id. at 6:3-27).

The separate functions and structures of the "actuator" and "mechanism" are emphasized in the description of the latter's central post as "independent from" the actuator's piston in order to "separat[e] the rotational movement of the central post 70 from the rectilinear movement of the locating pin 12." (Id. at 6:14-16.) Similarly, the accompanying figures depict the "actuator" and "mechanism" as wholly distinct parts of the device with separate, albeit adjacent, structural components. Thus, if one were to review only those portions of the specification addressing the "actuator," no hint could be found of any structure corresponding to the distinct function performed by the "mechanism" in the patented device. Likewise, if one were to construct an "actuator" in accordance with the specification, the resulting component would not perform the function assigned to the "mechanism" -- namely, moving the device's clamping fingers in a straight line into and out of the locating pin in a direction perpendicular to the axis along which the locating pin moves.

The Federal Circuit has recognized a presumption that the use of different terms "connotes different meanings." CAE Screenplates Inc. v. Heinrich Fiedler GmbH & Co., 224 F.3d 1308, 1317 (Fed. Cir. 2000); see also Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1119 (Fed. Cir. 2004) (explaining that the use of "different terms in a claim" raises the inference that the applicant "intended his choice of different terms to reflect a differentiation in the meaning of those terms"); Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1579 (Fed. Cir. 1996) (holding that the "plain meaning" of the claim at issue in that case would "not bear a reading" under which two different claim terms were construed as describing a single element). Plaintiff has not identified any basis for overcoming this presumption here, but instead offers only its counsel's bare assertion at the November 29 hearing that the terms "actuator" and "mechanism" are used interchangeably in claim 1. Because such a reading is contrary to both the language of the claim itself and the patent as a whole, the Court adheres to its determination that the term "mechanism" discloses a means-plus-function limitation governed by § 112 P 6.

There remains only the question of precisely how the Court should construe this means-plus-function limitation. As noted earlier, the application of § 112 P 6 dictates that the "mechanism" referenced in this claim must be restricted in scope "to the structure disclosed in the specification and equivalents thereof." Greenberg, 91 F.3d at 1582. Yet, the Court must take care not to "import functional limitations that are not recited in the claim, or structural limitations from the written description that are unnecessary to perform the claimed function." Wenger Manufacturing, 239 F.3d at 1233. In this case, this means that the Court should look to the specification only for those structural limitations that are necessary to perform the function of the "mechanism" referenced in claim 1 -- i.e., the function of "moving said finger along a straight line into and out of said locating pin perpendicular to said axis A in response to said rectilinear movement of said locating pin."

In Defendant's view, this facet of the Court's claim construction inquiry is entirely straightforward, and flows directly from the description of the "mechanism" as disclosed in the specification. In particular, the specification describes this "mechanism" as "rotat[ing] in response to the rectilinear movement of the locating pin . . . to move the fingers . . . radially." (Defendant's App'x, Ex. D, '254 patent at 5:67-6:2.) The specification then discloses the structural elements that achieve this
function:

The mechanism 68 includes a central post 70 disposed between the actuator 52 at a first end 72 and the fingers 60 at a second end 74. The central post 70 rests on a surface 76 of the coupler plate 56, which rectilinearly moves the central post 70 in response to the rectilinear movement of the actuator 52. The central post 70 rotates in response to the rectilinear movement. The surface 76 of the coupler plate 56 in contact with the central post 70 functions as a thrust bearing to facilitate the rotational movement of the central post 70.

A motion converter 84 converts the rotational movement of the central post 70 into radial movement of the fingers 60. As shown in FIG. 7, the converter 84 includes the slots 64 in each of the fingers 60 and dowels 86 extending axially from the second end 74 of the central post 70 and into each of the slots 64, respectively. The dowels 86 are offset from the axis A for radially moving the fingers 60 in response to rotational movement of the central post 70.

The rotational movement of the central post 70 moves the dowels 86 along an arcuate path. As the dowels 86 move through the respective slots 64, which are straight, the dowels 86 force the fingers 60 to move radially to maintain the slots 64 in alignment with the dowels 86.

...[A] pair of cams 90 and corresponding cam followers 92 interconnect the central post 70 and the body 16 for rotating the central post 70 in response to the rectilinear movement of the locating pin 12. The pair of cams 90 and the corresponding cam followers 92 are disposed on opposite sides of the axis A. The pair of cams 90 and corresponding cam followers 92 stabilize the central post 70 to allow the central post 70 to rotate smoothly within the cavity 18.

(2d. at 6:3-55.)

Whether in its response to Defendant's motion or through the arguments of its counsel at the November 29 hearing, Plaintiff has failed to identify any specific respect in which Defendant's proposed construction of claim 1's means-plus-function limitation impermissibly imports either (i) functional limitations that are not recited in the claim itself or (ii) structural limitations that are unnecessary to perform the claimed function. Instead, Plaintiff has focused its arguments almost exclusively upon the threshold question whether the term "mechanism" as used in claim 1 warrants means-plus-function treatment under § 112 P 6. Having resolved this more general question in Defendant's favor, the Court adopts Defendant's construction of the claim's means-plus-function limitation as essentially unopposed.

---- Footnotes ----

6 In any event, and as will become clear below, many of the structural details of the "mechanism" as described in the '254 patent specification are not material to the determination whether Defendant's products infringe this patent. To the extent that the precise contours of this "mechanism" bear upon the question of infringement, the Court will consider below whether, as Plaintiff's counsel generally asserted at the November 29 hearing, Defendant has impermissibly sought to import functional or structural limitations from the specification beyond what is necessary to meet the dictates of § 112 P 6.

---- End Footnotes ----
that do not include the word "means," this presumption is rebutted if the claim does not "recite[] sufficiently definite structure." TIP Sys., 529 F.3d at 1374 (citing CCS Fitness, 288 F.3d at 1369).

The court finds that means-plus-function construction is appropriate for this claim because "mechanism" is the sort of generic term construed by the Federal Circuit to indicate a means-plus-function limitation. See Mass. Inst. of Tech., 462 F.3d at 1354. Nor does the claim provide sufficient structure to preclude means-plus-form construction. See TIP Sys., 529 F.3d at 1374 (citing CCS Fitness, 288 F.3d at 1369). Finally, the language of this phrase largely parallels those above which the court has construed in the means-plus-function format.

The parties disagree as to the construction of the function and the corresponding structure. The parties again disagree regarding the construction of the word "restrict": Plaintiff argues that "restrict" is the ordinary meaning and no further construction of the claim language is required, whereas Defendant argues for the use of "confine." (Pl.'s Reply at 14; Chart at 17.) The court finds that "restricting" is the better construction because it contemplates the flow of fluid from one bladder into another and maintains the possibility of the dynamic nature of process described, albeit limited or inhibited. Use of "confining" would limit the claim by not preserving this connotation and imputing a more static nature to the condition of the fluid.

The parties do not materially disagree regarding the construction of the corresponding structure, and the court will construe it in substantial accord with Claim 10 of the '029 Patent. The court will construe the claim as follows:

Function:

- a mechanism restricting the flow of fluid from one portion of the interior of the bladder to another portion.

Corresponding Structure:

- a bladder within a container;
- open-cell foam arranged within the interior of the bladder.

The term "a media writing device . . . whereby . . . works . . . can be written to a removable medium" appears in claims 43 and 68 of the '345 patent. The plaintiff proposes a construction of "a media interface, for writing digital works to a medium removable from the interface." The defendant's counter-construction is "a media writing device for writing works to a medium removable from the media writing device."

The term "a media write unit . . . for writing items . . . to a removable medium" appears in claim 34 of the '725 patent. The plaintiff proposes that this term be construed the same as the above term. The defendant proposes a construction of "a media write unit for writing works to a medium removable from the write unit."

The crux of the dispute is whether the terms "media writing device" and "media write unit" can be construed to mean an "interface" for communication with a separate device for writing a work. A secondary issue is whether the work must be "digital." With respect to the secondary issue, the specification states "[i]n yet another aspect, the method includes building a list of media elements which can come from a variety of sources. Preferably, the media elements are storable in a digital format." '725 patent at col. 2, 11. 15-18 (emphasis added). Therefore, the storage is not limited to a digital format.

Similarly, there is no warrant for imposing the plaintiff's interface construction. The plain language of the claim refers to a media writing device and a removable medium. Regardless of the language of the claims as originally filed, the grammar of the claim language as allowed suggests that "removable" characterizes the type of medium used in the media writing device. The specification is consistent with this construction, identifying audio and video tapes and CDs as examples of removable
media. '725 patent, col. 2, 11. 2-3. As a result, the court construes the relevant terms to mean "a media writing device for writing works to a medium removable from the media writing device."

ii. "Member" / "first frame member" / "second frame member" / "third frame member"

The chart below describes the parties' competing definitions of the "member" terms. 8

--- Footnotes ---

8 For the purpose of my limiting term constructions to ten to twelve, I consider these "member" terms collectively as a single term construction.

--- End Footnotes ---

<table>
<thead>
<tr>
<th>180s' Construction</th>
<th>Gordini's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;member&quot;</td>
<td>a unitary component having a length that may be coupled to one or more other unitary components; when the unitary components are coupled, they manifest motion relative to one another appropriate</td>
</tr>
<tr>
<td>term &quot;member&quot; never appears in the separate construction of the term &quot;member&quot; is necessary or appropriate</td>
<td></td>
</tr>
</tbody>
</table>

"first frame member" a part of an ear warmer frame a first "member" (construed above)

"second frame member" a part of an ear warmer frame, separate and distinct from the first frame member a second "member" (construed above)

"third frame member" a part of an ear warmer frame, separate and distinct from the first and second frame members a third "member" (construed above)

First, I construe "member" as a "part." In light of the claim language, specification, and illustrative figures in the patent, "member" is synonymous with "part." (See Pls.' Mem., Ex. A at col. 7, ll. 39-52, Figs. 16 & 17.) Gordini's proposed construction of "member" is both too narrow and unnecessarily confusing. Nothing in the claim language necessitates that
"members," when coupled, "manifest motion relative to one another." Although the specification indicates that some members in some embodiments "move relative to each other to adjust the overall length of the frame[,"] (see Pls.' Mem., Ex. A at col. 7, ll. 40-45), the widely accepted understanding of "member" does not, explicitly or implicitly, implicate "movement relative to one another."

Additionally, I construe "[first/second/third] frame member" as follows:

- "First frame member": a part of an ear warmer frame, separate and distinct from the second and third frame members
- "Second frame member": a part of an ear warmer frame, separate and distinct from the first and third frame members
- "Third frame member": a part of an ear warmer frame, separate and distinct from the first and second frame members

This construction closely, but not identically, parallels 180s proposed construction. I added the extra "separate and distinct . . ." language to the "first frame member" and the "second frame member" to make clear that each "member" is separate and distinct from each other "member." Any redundancy this language creates is outweighed by the clarity it establishes.

B. "Member positionable within said first hole and being extendable within said slot" and similar language as used in Claims 20, 43 and 48 of the '588 patent

The parties dispute two elements of this claim language: the meaning of "member" and of "positionable within said hole and being extendable within said slot." The pertinent language of Claim 20 of the '588 patent, with the disputed terms in italics, is representative:

20. A mounting device attachable to a raised portion on a building surface, said mounting device comprising:

(d) a securing assembly comprising a first hole extending from one of said side surfaces through said mounting body to interface with said slot and a first member positionable within said first hole and being extendable within said slot to secure at least said upper part of said raised portion within said slot by engaging said upper part of said raised portion within said slot with said first member.

The first disputed term, "member," is defined broadly by common and technical dictionaries to mean a "structural unit such as a . . . beam or tie, or a combination of these" or a "distinct part of a whole." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1367 (Fed. Cir. 2002) (internal quotations and citations omitted). In CCS Fitness, the Federal Circuit found that these definitions encompass units of a larger whole and thus that the term "member" was not limited to single, unitary structure as asserted by the defendant in that case. See id.

Contek points to the prosecution history of the '248 and '588 patents to argue that "member" has a more limited meaning in these patents, namely a unitary blunt-nosed screw. CFE concurs that the prosecution statements relied upon by Contek show that Mr. Haddock and his counsel limited "member" to a "blunt-nosed fastening device," Pls.' Report in Further Support of Pls.' Markman Positions (Doc. 49) at 9, but dispute that the statements further limited this device to a unitary structure.

I find that the relevant prosecution history establishes that "member" as used in the '588 patent means "blunt-nosed screw." First, Claim 2 of the '248 patent application claimed a means for frictionally engaging that "comprises a member extendable from a wall of said cavity to contact said external surface of said one raised portion." Pls.' Markman Br., Ex. 3 [hereinafter "'248 patent prosecution history"] 27 (emphasis added). After the Examiner rejected this claim as unpatentable over the prior art Opplinger in view of Darnall, Mr. Haddock deleted "member" from the claim and amended it to provide that the means for frictionally engaging was limited to a "blunt nose screw." Contek's Br. re: Interpretation of Pls.' Patents (Doc. 35), Ex. D ('248 patent prosecution history) at 82-83, 110. This amendment provides insight into what Mr. Haddock originally
claimed as his invention, and what he gave up in order to meet the Examiner's objections. Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 978 (Fed. Cir. 1999); see Wang Labs, Inc. v. America Online, Inc., 197 F.3d 1377, 1384 (Fed. Cir. 1999); see also Phillips, 415 F.3d at 1317 (prosecution history can demonstrate "how the inventor understood the invention and whether the inventor limited the invention in the course of the prosecution, making the claim scope narrower than it otherwise would be.") Because the '588 patent derives from the '248 patent and its patent application, this history is relevant to the '588 patent and its use of this term as well. See Wang, 197 F.3d at 1384; Elkay, 192 F.3d at 980.

The conclusion that Mr. Haddock limited the meaning of the term "member" to "blunt nosed screw" is also supported by the prosecution history of the '588 patent. With respect to several application claims, Mr. Haddock equated the term "member" as used in these claims with a "screw" and/or the blunt-nosed screw disclosed in the specification. See, e.g., Contek's Br. re: Interpretation of Pls.' Patents (Doc. 35), Ex. E ('588 patent prosecution history) at 189-91. Given that the inventor himself defined "member" to mean "screw" or "blunt-nosed screw" to obtain issuance, it would be improper to find a broader construction than this.

The conclusion does not mean, however, that the term "member" as stated in Claims 20, 43 and 48 must be unitary in structure. Contek's arguments in this regard are based on its contention that a "screw" or "blunt-nosed screw" can only be a unitary structure. I reject this contention for the reasons stated earlier in this decision. "Member" as used in the referenced claims means “blunt-nosed screw,” which may have either a unitary or multi-part structure.

The referenced claims further require that the "member" or "members" be "positionable within" one or more holes in the "mounting body" and "being extendable within said slot to secure" the upper part of the raised portion "within said slot by engaging" the raised portion within the slot with the member(s). '588 patent, col. 20, ll. 33-37 (Claim 20); see id., col. 22, l. 66 - col. 23, ll. 3 (Claim 43), col. 23, ll. 7-12 (Claim 48). These terms are not defined in the claim language, specification or prosecution history, which leads me to consult dictionary definitions to determine their ordinary and customary meaning.

The root of the term "positionable" is the verb "position," whose ordinary meaning as relevant here is "to put in a or the proper position: PLACE, SITUATE." Webster's Third New Int'l Dictionary at 1769; see Knopik v. Amoco Corp., 96 F. Supp. 2d 892, 905 (D. Minn. 2000), aff'd, 95 Fed. Appx. 332 (Fed. Cir. 2004). The ordinary meaning of "within" as used here is "in the inner or interior part of: INSIDE OF." Webster's Third New Int'l Dictionary at 2627; see Watson Indus., Inc. v. Murata Elec. N. Am., Inc., 301 F. Supp. 2d 933, 942 (W.D. Wis. 2003), aff'd, 115 Fed. Appx. 441 (Fed. Cir. 2004). It is undisputed that the referenced "hole" is an opening in the "mounting body," which is the metal block or clamp, that extends from the outer surface of the clamp through the clamp body to the slot or cavity that surrounds the metal roof's standing seam. n6 Given these ordinary meanings and my construction of the term "member" to mean a "blunt nosed screw," I find the phrase "member positionable within first said hole" means the blunt-nosed screw, whether a unitary or multi-piece structure, is capable of being placed inside the hole that extends through the clamp to the slot surrounding the standing seam. This construction is consistent with the specification of both asserted patents. n7

n6 Claim 20 of the '588 patent, for example, describes the "first hole" as "extending from one of said side surfaces through said mounting body to interface with said slot." '588 patent, col. 20, ll. 32-34.

n7 CFE asserts that this phrase should be interpreted to mean that the member is "wholly or partially positionable within a fastening hole." Jt. Notice & Stip. Concerning Markman Hearing (Doc. 54), Ex. 1 (Plaintiffs' proposed interpretation, emphasis added). The ordinary meaning of a "member positionable within" the fastening hole, however, does not suggest that this requirement is satisfied if only a portion of the member (screw) is capable of placement within the hole. CFE also fails to cite any intrinsic or external evidence supporting this proposed interpretation.

The parties agree that the final portion of this disputed language, the phrase "member . . . being extendable into said slot" means that the "member" must be able to enter the slot or cavity of the clamp and physically contact and deform the roof seam. See Pls.' Report in Further Support of Pls.' Markman Positions (Doc. 49) at 9; Defs.' Br. re: Interpretation of Pls.' Patents (Doc. 35) at 27-28. This construction is supported by the dictionary definition of the relevant terms and is also consistent with the intrinsic evidence. Accordingly, I find this phrase means that the "member," construed for the reasons
stated above to mean "blunt-nosed screw," is able to enter the slot of the clamp and physically contact and deform the roof seam.

5. Luminal Attachment Member

Claim 15 includes the following element:

[a] luminal attachment member coupled to said housing, said luminal attachment member adapted to have a lumen portion attached thereto…

See Claim 15, Col. 8, lines 47-49. The parties disagree over whether this element is written in means-plus-function format under 35 U.S.C. § 112, P6. Ravo and Nicolo argue against such a construction. They insist that the word "member" is commonly used in describing structural elements of mechanical devices. Ethicon counters that the term "member" does not identify a specific structure and that the claim element must necessarily be written in means-plus-function format.

As Ravo and Nicolo point out, the phrase at issue does not include the word "means." Federal Circuit precedent establishes that "a claim term that does not use 'means' will trigger the rebuttable presumption that § 112 P6 does not apply." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002). "The presumption that a limitation lacking the term 'means' is not subject to section 112 P6 can be overcome if it is demonstrated that 'the claim term fails to 'recite sufficiently definite structure for performing that function.'" Lighting World v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004), citing, CCS Fitness, 288 F.3d at 1369. However, "the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, 382 F.3d at 1358 (citations omitted).

Thus, I begin with the presumption that § 112, P6 does not apply and consider whether Ethicon has successfully rebutted this presumption. Ethicon simply argues that the claim element recites a function - attaching the lumen - but recites no structure that would perform this function. See Docket No. 18, p. 20 and Docket No. 23, p. 5-7. I find Ethicon's argument to be unpersuasive for several reasons.

First, while I agree that the term "member" does not bring to my mind a particular structure, I must consider Ravo's and Nicolo's argument that persons of ordinary skill in the art would understand "member" to refer to something structural. Unfortunately, Ravo and Nicolo did not submit any expert testimony on this issue. Such testimony would have been helpful. Nevertheless, Federal Circuit precedent teaches that reference may be made to dictionaries. See Lighting World, 382 F.3d at 1361 (stating "we have looked to the dictionary to determine if a disputed term has achieved recognition as a noun denoting structure…"). Having consulted several dictionaries, I am convinced that the word "member" would be understood by those skilled in the relevant art to denote structure. The McGraw Hill Dictionary of Scientific and Technical Terms defines "member" as: "[a] structural unit such as a wall, column, beam or tie, or a combination of any of these…" McGraw Hill Dictionary of Scientific and Technical Terms (6th ed.), p. 1308. Similarly, Webster's Third New International Dictionary defines "member" as "a part of a building or other structure…[or] an essential part of a framed structure, a machine, or a device." Webster's Third New International Dictionary, p. 1408 (1993). Thus the luminal attachment must be structured in such a manner that a lumen may be attached to it.

In addition to the fact that the word "member" is defined in dictionaries as something structural, a review of the entire '148 Patent makes clear that Ravo and Nicolo used the phrase to mean a structure. For instance, the claim element itself does not describe a function. Additionally, Ravo and Nicolo use the word "means" elsewhere in the '148 Patent to take advantage of the means-plus-function manner of describing a claim. It would be odd, indeed, for the drafters to have used the word "means" in Claims 1, 2, 3, 4, 5, 7, 9, 10, 11, 12 and 13 to describe a means-plus-function element, yet suddenly substitute the word "member" for "means" in Claims 15, 16, 17 and 19. Additionally, the '148 Patent uses the word "member" in conjunction with several other phrases. See Col. 4, line 61 ("wedge-shaped member"); Col. 5, line 17 ("ligation member"); Col. 6, line 52 ("bowel members."). These phrases connote something structural.

Finally, I agree with Ravo and Nicolo that other prior art patents appear to use the word "member" to refer to structural elements. See Patent No. 4,304,236 entitled "Stapling Instrument Having an Anvil-Carrying Part of Particular Geometric
B. Construing the term "Member"

E'Lite argues the use of the term "member" in the '054 and '811 patents limits the patent claims to devices containing a separate magnetic piece that attaches to the bridge of the primary eyeglasses. E'Lite supports its position by noting the claim language does not speak of the magnetic connector member as included in the frame, but rather speaks of it as separate and secured to or in the frame. Consequently, E'Lite contends the C-Clip does not infringe the '054 and '811 patents because its magnetic connector member is not separate but is an integral part of the primary eyeglass frame.

Contour responds that an element of the accused device, namely the magnetizable substances Cobalt and Chromium located in the bridge of the C-Clip, corresponds to a patent limitation, the magnetic connector member secured in the bridge; therefore, E'Lite has no defense to the charge of literal infringement. Alternatively, Contour argues the C-Clip infringes patents '054 and '811 under the doctrine of equivalents. According to Contour, the C-Clip satisfies the doctrine of equivalents because the substance in the C-Clip's bridge performs the same function (attracting the magnet in the secondary frame) by the same means (magnetic attraction) to achieve the same result (magnetic engagement of the primary and secondary frame) as the magnetic connector member discussed in the patent claims.

Because the Federal Circuit has held the common definition of "member" is "distinct part of a whole" the Court concludes the C-Clip's lack of a separate magnetic member on the bridge of its primary frame is a defense to Contour's charge of literal infringement. However, E'Lite has failed to present evidence raising a genuine issue of material fact regarding whether the magnetic substance in the C-Clip performs the same function to achieve the same result by the same means as the magnetic member contained in the patent claim. Consequently, the Court concludes E'Lite's asserted defense to infringement under the doctrine of equivalents fails.

No genuine issue of material fact exists regarding whether either of E'Lite's two defenses against Contour's claim of infringement will prevail. The C-Clip contains a "frame" within the meaning of the term as used in patents '054 and '811. Additionally, although the C-Clip does not contain a magnetic member on the bridge of its primary frame, the magnetic substance in the bridge is equivalent. Because E'Lite has failed to show any lack of correspondence between the elements of the C-Clip and the limitations of patents '054 and '811 the Court will grant summary judgment on the issue of infringement to Contour.

5. A Member

Claim 5 refers to the patented device as a "member." Defendants ask that the term "member" be defined as "a single part, made of cardboard or a suitable plastic material that if scored and folded will fold repeatedly and uniformly without breaking." Def. Claim Construction Chart (DE # 38). Plaintiff suggests that the term be construed to mean the patented device is unitary, composed of one piece. Tr. at 8. Defendant seeks to include the enablement restrictions into the definition.
of "member." Def. Mem. in Support of Proposed Claim Construction (DE # 37) at 18. This Court holds that the term "member," by the terms of the claim, in context, refers to the unit which embodies the patent.

In Smith & Nephew v. Ethicon, No. CV 98-76-MA, (D. Or. June 11, 1999), 2 Magistrate Judge Hubel construed "member" as "the anchor itself." He further held this term requires "that the entire member is resilient." As set out in an earlier opinion, Judge Hubel's construction applies here under principles of claim preclusion. Judge Hubel did not, however, define "resilient," and the parties now dispute the import of this term.

The first dispute concerns the meaning of the claim's requirement that the lockup means "also include an elongated locking member." Col. 7, line 32. Giving the terms their ordinary meaning, the Court agrees with EPC that a "member," defined generally, is a part or a piece, a "locking member" is a part or piece capable of being locked, and an "elongated locking member" is a locking member which is slender in length relative to width. See, e.g., Webster's New World Dictionary, 2d ed. (1970); The American Heritage Dictionary, New College Ed. (1976). A more difficult issue regarding this phrase, however, is whether the patentee's use of the word "member" in the singular form limits the scope of the claim to one elongated locking member consisting of a single piece as arguably reflected in the patent drawings. Donaldson insists that it does consist of only one piece, while EPC argues that the use of the singular form in this instance cannot be so limited and that the claim would encompass a locking member made up of multiple elongated pieces.

Nothing in the specification suggests to this Court that the patentee intended to give a novel meaning to the term, "member." Donaldson cites the patent drawings and numerous references throughout the specification in support of its position that "member" -- under its ordinary meaning and as used by the patentee -- refers to a single piece. There can be no dispute that in the patent drawings the locking member is drawn as a single piece. Further, in the "Description of the Preferred Embodiment" ("Description"), the patentee's description of "an elongated locking member [= # 96] angled as shown at its upper end [= # 106] and having notches [= # 98] formed on its side" (emphasis added), and references to "the member" or "said member," appear to contemplate a single locking member. But, as repeatedly cautioned by the Federal Circuit, while the specification may inform the court as to the definition of a claim term, "particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiment." KCJ Corp., 223 F.3d at 1356 (citations omitted). To that effect, use of the word "member" does not necessarily define a component made of a single piece or exclude a component made up of multiple pieces. A recent opinion by a sister court in this district addressed a similar dispute and reached the same conclusion:

The pertinent definition of member is "a constituent part of a whole," see, e.g., Merriam Webster's Collegiate Dictionary (10th ed., 1995), and the synonym "part" is defined, inter alia, as "a constituent member of a machine or other apparatus." See id. Ordinary experience teaches that a constituent part or member of a machine or apparatus may itself consist of one or several components, depending, for example, on the intricacy of the "part" or "member" and the machine or apparatus to which it belongs.

Kudlacek, 115 F. Supp. 2d at 1023.

This Court agrees that one skilled in the art of air filter indicator manufacturing would read "member" in claim 1's lock-up
means element to encompass a piece or part of something else, regardless of whether that "member" is made of one or more components. Consequently, the Court finds that the lock-up means element of claim 1 encompasses a locking member, comprised of either a single piece or multiple pieces joined together, which is slender in length relative to width.

2524

The final set of disputed claim terms are "shoe mounting member," '047 Patent, col.4, 11.24, 28, 36-37, 52, & 67, col.5, 11.8, 25, & 60, & col.6, 11.8, 25, & 62-63, "shoe attachment means," id. col.5, 1.22, "mounting member," id. col.2, 1.41, and "shoe attaching member," id. col.4, 1.42, col.5, 1.5, & 56-58, col.6, 1.6, 23, & 58, col.7, 1.8, & col.8, 1.8. The parties contest whether the terms are means-plus-function terms, and assuming arguendo that they are, whether the construction should be limited to the figures and functions expressly stated in the patent, or also "equivalents thereof."

1. The Parties' Contentions

Greenkeepers aver that the '047 Patent's claim language details the structural features required to attach the covered cleats to a shoe, that being that the member has an axis AL and projects outwardly, and thus, that the disputed terms are not means-plus-function terms. (Pls. Opening 38-40, Pls.' Resp. 36.) In particular, Greenkeepers contend that the asserted claims do not use the word "means," thereby failing to trigger the statutory means-plus-function presumption, and that "member" has been routinely held to not indicative of a means-plus-function. (Pls.' Opening 38-39.) Greenkeepers contrast their proposed construction from that of Defendants, which purportedly reads limitations from the '047 Patent's preferred embodiments into the claims, a reading that is impermissible under Federal Circuit law, and is belied by the requirement that a term, even if construed to be a means-plus-function, be construed to include "equivalents" to the structure described in the patent specification. (Pls' Resp. 38.) Greenkeepers thereby urge the Court, should it find the disputed terms to have means-plus-functions, to construe them as not limited to the structures illustrated or described in the '047 Patent. (Pls.' Resp. 39.)

In response, Defendants contend that the '047 Patent's specification provides no structural limitations on a shoe attaching or mounting members, and only offer the function that such a member fix the golf cleat to a shoe. (Defs.' Opening 28.) Defendants continue that the disputed terms should be construed as being limited to the three structures identified in the specification: (1) a threaded stud with a plastic fillet, (2) a threaded stud surrounded by a series of latching teeth, and (3), an interlocking triangle. (Defs.' Opening 28.) Defendants fault Greenkeepers for focusing on an imaginary "axis AL" line that does not require the member to be symmetric about it. (Defs.' Reply 16-17.) To the extent that Greenkeepers urge the Court to construe the disputed terms as including functionally equivalent structures, Defendants aver that equivalences are questions of fact determined by the jury. (Defs.' Reply 17.)

ECCO adds that the '047 Patent abandoned the structural limitations defined in United States Patent Number 5,794,367 (filed Feb. 20, 1997), the original patent application filed by the '047 Patent's inventor to cover outwardly angled golf cleats, thereby indicating that the '047 Patent contains only a functional description. (ECCO Opening 9-10.) ECCO also contends that Greenkeepers' proposed means-plus-function construction is overbroad, and that a patentee cannot assert undisclosed techniques or methods that could perform the function, but must focus on the structures found in the specification. (ECCO Resp. 4-8.)

2. Analysis

The Federal Circuit has explained that "Section 112, paragraph 6 [of Title 35 of the United States Code,] allows a patentee to recite a function to be performed as a claim limitation rather than reciting structure or materials for performing that function." Omega Eng'g, 334 F.3d at 1321. "Means-plus-function claiming applies only to purely functional limitations that do not provide the structure that performs the recited function." Phillips, 415 F.3d at 1311. In construing means-plus function terms, courts first "identify the claimed function, staying true to the claim language and the limitations expressly recited by the claims"; then, courts must "ascertain the corresponding structures in the written description that perform those functions." Id. In sum, a means-plus-function term is construed so that it is limited to "the structure . . . necessary to perform the claimed function." Id.

When a term does not contain the word "means," courts presume that section 112, paragraph 6 does not apply. See, e.g., Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). This presumption is a "strong one
that is not readily overcome." Id. In this case, the only term using the word "means" is "shoe attaching means," but Greenkeepers are not asserting claim 6 of the '047 Patent, the only claim containing the terms. Thus, the presumption that the terms are not means-plus-function terms applies; however, "merely because an element does not include the word 'means' does not automatically prevent that element from being construed as a means-plus-function element." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996). The Court must examine whether "the alleged means-plus-function claim element" "recite[s] a definite structure which performs the described function." Id. If this question is answered in the affirmative, the terms are not means-plus-function ones, and need not be limited to the structures "necessary to perform the claimed function." Omega Eng'g, 334 F.3d at 1321.

Turning to shoe attaching or mounting members in the pending case, the Court finds that they are not means-plus-function terms for purposes of section 112, paragraph 6. The Federal Circuit has cautioned against employing "unduly restrictive" readings to determine whether claim terms recite sufficient structure, and has determined "that it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function." Lighting World, 382 F.3d at 1359-60. Here, even though the term shoe attaching or mounting member may not bring to mind a particular structure, there is language in the '047 Patent's specification that describes the required structure necessary for the members described in the patent: the member has "an axis AL which is perpendicular to said inner face and project[s] outwardly from said inner face and adapted to secure said cleat in a receptacle in said golf shoe upon rotation of said shoe mounting member about said axis in said receptacle." '047 Patent, col.4, 11.52-57. Contrary to Defendants' assertions, the '047 Patent's shoe attaching or mounting member does not cover "every conceivable device" (Defs.' Resp. 29); rather, the asserted claim language requires that a member be secured in a golf shoe's "receptacle" "upon rotation of said shoe mounting member," '047 Patent, col.4, 11.55-57, thereby eliminating structures that are recessed in the cleat or that are engaged by sliding into the receptacle.

In addition, courts, including the Federal Circuit, have repeatedly found that

- dictionary definitions, not to mention common sense, point to the word "member" (descriptive modifier notwithstanding) as a structural term. See Webster's New International Dictionary (2d ed. 1956) defining "member" as, inter alia, "... 5. A part of a whole; an independent constituent of a body, structure, or any organized thing, or a unit in a series... 12. Engin. Any essential part of a framed structure."

SDS USA, Inc. v. Ken Specialties, Inc., 107 F. Supp. 2d 574, 591 (D.N.J. 2000); see also, e.g., CCS Fitness, Inc., 288 F.3d 1359, 1367 (Fed. Cir. 2002) ("[M]ember,' as defined by common and technical dictionaries, refers to a structural unit such as a beam or tie, or a combination of these." (internal quotation marks and alteration omitted)). As a result, the Court has determined that there is insufficient evidence to overcome the "strong" presumption, Lighting World, 382 F.3d at 1358, that "shoe attaching member," "shoe mounting member," "shoe attachment means," and "mounting member" are not means-plus-function terms, and will adopt Greenkeepers' construction.

2525

1. "Flexible Sealing Member(s)"

Claims 19 and 35 of the 557 Patent present close variations in regard to the term "flexible sealing member," and neither claim uses the term "means" to recite any limitation of the claimed apparatus. (Id. cls. 19c, 35b) Although Dade acknowledges that the term "flexible sealing member" is presumptively not a means-plus-function limitation, Dade contends that Claims 19 and 35 fail to recite sufficient structure to perform the desired function. (Doc. 70 at 3). As support for this assertion, Dade has provided the affidavit of a potential expert witness, who states that the term does not have a generally understood meaning in the art of food storage. (See id. Ex. 8, P 8). Dade's other support for its assertion is an analogy between language used in the 557 Patent's claims and in the patent claims at issue in Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1213-1215 (Fed. Cir. 1998).

Mas-Hamilton involved a patent for a "High Security Electronic Dial Combination Lock" which included, inter alia, a claim requiring: "a movable link member for holding the lever out of engagement with the cam surface before entry of a combination and for releasing the lever after entry of the combination." Id. at 1209, 1214 (emphasis in original). Although the claim did not contain the term "means," the Mas-Hamilton court opined that the language, as to the two functions the
"movable link member" performs, is precisely what was contemplated by the statute governing means-plus-function limitations. Id. at 1215. Accordingly, the court concluded that "movable link member" was such a limitation. Id.

According to Dade, Mas-Hamilton reveals the term "flexible sealing member" to be a means-plus-function limitation. Yet, unlike the context in Mas-Hamilton, Claims 19 and 35 of the 557 Patent set forth, in relevant part, simple structural limitations starting with "a chamber defined by a floor, ceiling, and sidewalls" which together with certain internal barriers direct fluid flow in relation to stored product. (Doc. 66, Ex. A). Dade concedes that "member" connotes a part of this apparatus, "flexible" indicates that the member is capable of being bent or flexed, and "sealing" indicates that the member prevents air leakage. (Doc. 70 at 3). In regard to the flow directing function in Claims 19 and 35, the term "flexible sealing member" is one in a set of sufficiently definite performing structures. The presumption against the term being a means-plus-function limitation, therefore, prevails, and this term carries the following ordinary meaning in the following claims:

Claim 19c: a flexible constituent part of the apparatus that divides and seals the chamber into a first volume between the stored product and a sidewall and a second volume outside the first volume; and

Claim 35b: a flexible constituent part of the apparatus that divides and seals the chamber into a first volume and a second volume. 4

4 A flexible sealing member cannot divide the chamber into two separate volumes without forming a complete or substantially complete seal with stored product. Moreover, unless the member in interpreted to perform a sealing function, the "sealing" limitation is rendered superfluous.

B. Term One

Datascope argues that the term "fragmentation member" is governed by 35 U.S.C. § 112, P 6, which states:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

"[Section] 112, P 6 operates to restrict claim limitations drafted in such functional language to those structures, materials, or acts disclosed in the specification (and their equivalents) that perform the claimed function." Personalized Media Communications, LLC v. Internat'l Trade Comm'n, 161 F.3d 696, 703 (Fed. Cir. 1998).

"[U]se of the word 'means' creates a presumption that § 112, P 6 applies" and "the failure to use the word 'means' creates a presumption that § 112, P 6 does not apply." Id. at 703-04. Datascope concedes that the word "means" is not used. Datascope Br. at 25. The presumptions, however, "can be rebutted if the evidence intrinsic to the patent and any relevant extrinsic evidence so warrant." Personalized, 161 F.3d at 704. "In deciding whether either presumption has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of § 112, P 6." Id.

Considering these principles, the Court concludes that the term "fragmentation member" is a means-plus-function term because the claim does not create a sufficiently definite structure. Although the presumption is against such a finding, the term "member" is a generic structural term like "element" or "device." See id. at 705. The term member does not evoke a particular structure or even a limited group of structures. Moreover, the "fragmentation member" has a specific function as described in the claims: expanding and causing fragmentation. Accordingly, it will be limited by § 112, P 6.

As the only structure corresponding to the term "fragmentation member" that is disclosed by the specification is the wire
cage or basket the term shall be so limited. E.g., 191 patent, Col. 2 Lns. 62, 65, 67; 191 patent Col. 3 Lns. 4, 10. Similar language is found in the specifications of the other two patents. Accordingly, a "fragmentation member" is a wire cage or basket (or their equivalents) that breaks up clots.

2527

F. "a peripheral flexible member extending from said support structure and including at least two independently flexible sections attached to said membrane" (claims 6 and 10)

PolyVision's proposed construction
No construction required. Alt.: peripheral flexible member: A structure or element (consisting of one or more components) that extends from the support structure at the edge (periphery) of the support structure and is flexible in at least some part.

including at least two independently flexible sections attached to said membrane:
Having a minimum of two flexible portions, where each portion can be separately flexed, and the flexible portions are attached to the membrane.

Smart's proposed construction
peripheral flexible member:
A peripheral flexible wall, a peripheral compressible member of foam, silicone, or rubber, or a compressible tube, which includes at least two flexible sections that are flexible independently of each other.

including at least two independently flexible sections attached to said membrane:
Independent, separate, or distinct sections of the claimed peripheral flexible member; having at least two component parts that are flexible independently with respect to each other and both of which are attached to the membrane.

Footnotes

3 The Court notes that Smart's construction has changed over time, although this proposed construction is taken from Smart's materials presented at the March 7, 2007, hearing. For example, a prior proposed construction required that the peripheral flexible member "be a unitary flexible member extending from the periphery of the support structure," while the present proposed construction does not include such a condition. Smart continued to advance the unitary requirement in its claim construction brief by asserting the Claim 1 does not read on a particular embodiment, but it has apparently abandoned that position.

The claim language itself, as well the written description, shows that the term "peripheral flexible member" refers to the part of the invention that extends from the edge of the support structure and is attached to the membrane and "pretensioned," such as the flexible wall 22 shown in Fig. 1. Smart contends that the prosecution history provides the definition of "peripheral flexible member" as a peripheral flexible wall, a peripheral compressible member of foam, silicone, or rubber, or a compressible tube. (Prosecution History Appendix at PLV 00472.) While the prosecution history does provide some support for this argument, it would be improper to limit the claim term to those embodiments because the inventors did not limit the peripheral flexible member to those embodiments. Rather, they stated that "the peripheral flexible member in any form prevents sagging of the flexible membrane" and that "[t]he flexible member could be," but did not have to be, one of those embodiments. Thus, the prosecution history does not constitute a clear disavowal, as is required to limit the scope of the claim to the disclosed embodiments. See NTP, Inc. v. Research In Motion, Ltd., 392 F.3d 1336, 1361-62 (Fed. Cir. 2004).

To the extent that Smart continues to assert that the peripheral flexible member must be a "unitary" or one-piece component,
such as that shown in Fig. 1, the Court rejects the assertion. The prosecution history, upon which Smart relies, states that the flexible member may be a compressible tube. Fig. 10, which illustrates that embodiment, shows that the compressible tube member would not be unitary. This conclusion is also supported by the specification, which states that "[t]he base and the flexible sections may be integral." (Col. 2, l. 40), and shows an embodiment in Fig. 7 where the peripheral wall consists of separate parts and "is not integral with [the] base." (Col. 4, l. 42.)

The Court concludes that PolyVision's construction is more accurate, although as Smart notes, there is no support in the patent for the phrase "flexible in at least some part." All of the intrinsic evidence shows that the peripheral member must be "flexible." Accordingly, the Court will adopt the following construction for "peripheral flexible member": A flexible structure or element (consisting of one or more components) that extends from the edge of the support structure which includes at least two independently flexible sections.

With regard to the phrase "independently flexible sections," the specification shows that it merely means separate sections or parts of the peripheral flexible member that may be pushed, moved, or flexed independently of each other. (Col. 2, ll. 20-21; Col. 3, ll. 31-34; Figs. 1, 2, 5.)

J. "flexible member" (claim 20)
PolyVision's proposed construction
No construction required. Alt.: A flexible wall, a compressible flexible part (consisting of one or more components) of an apparatus.

Smart's proposed construction
A flexible member of foam, silicone or rubber, or a compressible tube.

This term is similar to "peripheral flexible member," which the Court construed above. For the reasons stated above, the Court rejects Smart's proposed construction. Consistent with the above construction, the Court construes the term as: A flexible structure or element (consisting of one or more components) that is attached to the support structure.

F. Term 7: "membrane"

The Court construes the term "membrane" in claim 1 of the '291 patent to mean "a thin sheet or layer of material."

The word "membrane" is an ordinary word, and it is used in the '291 patent in its ordinary sense. For instance, in describing one embodiment, the patent says:

[T]he membrane is preferably formed of a thin, flexible material, such as a fabric which may be folded and pulled taut without being damaged. Elastic polymeric materials such as nylon, polyester, polypropylene, polytetrafluoroethylene (Teflon), and expanded polytetrafluoroethylene (GoreTex), as well as natural fabrics such as silk, have been found to work quite well, with elastic nylon appearing to be the best material for the present purposes. Alternatively, the membrane may be formed of a thin piece of a superelastic material, such as a thin sheet of [nickel-titanium] alloy or a superelastic polymeric composite.

'291 patent col. 4:60 to col. 5:4. In describing a second embodiment, the patent says:
The membrane . . . of the present invention is not a single layer of fabric, but rather is a flexible, collapsible balloon-type member which can be inflated to define an internal cavity . . . . The membranes . . . may be formed of any suitable material, such as a thin, flexible latex or the like.

The University asks the Court to construe "membrane" to mean "a relatively thin material." Am. JCCS Sched. B at 21. The Court believes that the University's proposed construction does not differ meaningfully from the construction adopted by the Court. The Court declines to describe the membrane as "relatively thin" because "relatively" confuses, rather than clarifies, the disputed term's meaning (relative to what?). And the Court describes the membrane as a "sheet or layer" of material, rather than simply "material," because the Court agrees with AGA that a wire could be called a "thin material" even though a wire is plainly not a "membrane." 17

But the Court rejects AGA's contention that the "membrane" referred to in claim 1 of the '291 patent must be "sufficiently impermeable to stop the flow of blood through a defect within an acceptably short period of time." Am. JCCS Sched. B at 21. The function of the claimed invention is, of course, to stop blood flow across a heart defect. But not every limitation in a patent claim incorporates the claimed invention's purpose. Put another way, there is no more reason to construe "membrane" in claim 1 to mean "membrane that stops the flow of blood" than there is to construe "disk" in claim 1 to mean "disk that stops the flow of blood."

To the extent that a term in claim 1 of the '291 patent could be construed to reflect the function of the claimed device, that term is "occluding," not "membrane." As described above, AGA asked the Court to construe "occluding" to mean "sufficiently impermeable to stop the flow of blood through the defect within an acceptably short period of time." Am. JCCS Sched. B at 19. Although the Court rejected AGA's proposed construction of "occluding" for the reasons already given, AGA's attempt to narrow the claim language to reflect the invention's purpose was at least reasonable in connection with "occluding."

AGA's attempt to narrow "membrane," however, is not reasonable. After all, the patent expressly says that the membrane in the preferred embodiment is "formed of a relatively porous material." '291 patent col. 10:5-6. In such an embodiment, blood flow is blocked not by the membrane alone, but rather because "blood will tend to coagulate in the conjoint disk after it has been in place for some time . . . ." Id. col. 10:8-10. In short, nothing in the '291 patent dictates giving the ordinary word "membrane" the extraordinary meaning proposed by AGA.
The '547 patent claims a method, system, and apparatus for performing PD. To that end, a medical fluid pump for a dialysis system is provided. See '547 patent, 1:4-8.

Claim 12 of the '547 patent recites:

A pump connected to at least one vacuum source for use in a system for providing dialysis treatment, the pump comprising:

- a first chamber wall;
- a second chamber wall, the second chamber wall defining an aperture;
- first and second fluid receiving membranes disposed between the first and second chamber walls, the [sic] at least one vacuum source operable to apply a vacuum between the membrane and the walls;
- a piston, at least a portion of which moves through the aperture, the piston including a piston head having an external shape substantially similar to a mating internal shape of the first chamber wall, the piston in operation contacting one of the membranes; and
- a dialysis fluid opening enabling dialysis fluid to be pulled in between the first and second membranes upon movement of the piston.

Fresenius contends that claim 12 of the '547 patent requires that the two "membranes" form a dialysate receptacle, and that in operation, the membranes be pulled apart from one another by application of the vacuum and movement of the piston, which allows the receptacle to fill with dialysate. Thus, Fresenius asserts, the "membranes" recited in claim 12 must be flexible, and must permit deformation in response to the pressures applied by the piston and the pneumatic vacuum.

The court finds, however, that none of the claims of the '547 patent - including claim 12 - suggests that the ordinary and customary meaning of the term "membrane" as a "barrier" should be given a construction other than the agreed-upon construction for the '369 and '626 patents. In particular, there is no indication in the language of the claims of the '547 patent that the generic word "membrane" should be given any special meaning, or that it should be construed as being "flexible."

In claim 12, both a rigid and a flexible membrane can be "fluid receiving," and both can "contact" the piston.

"[T]he person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Phillips, 415 F.3d at 1313. The '547 patent specification refers both to generic membranes and to specific types of membranes. The specification uses the term "membrane" to refer not only to the disposable layers between which fluid flows during pump operation, but also to a patient's peritoneum, see '547 patent, 1:44-46 ("dialysate contacts the patient's peritoneal membrane in the peritoneal cavity"); to a flexible housing, see id., 6:12-17 (the disposable unit in one embodiment of the invention "includes a first flexible membrane and a second flexible membrane that house the pump receptacle, the fluid heating path and the rigid valve manifold" and a "rigid frame that attaches to at least one of the first and second flexible membranes"); and to hydrophobic tips that form a liquid barrier between the patient line and the atmosphere, see id., 22:32-40 (Fig. 12 illustrates cross section of tip protector 280, and a "hydrophobic membrane" is placed on outer edge of tip protector).

Fresenius argues, however, that the only "membranes" recited in claim 12 of the '547 patent are the "first and second fluid receiving membranes" that form the fluid receptacle within the pump chamber. Fresenius contends that the claimed "fluid receiving membranes" are different from the "hydrophobic membranes," which are located completely outside of the pumping chamber and are not claimed in the '547 patent, but are only mentioned in the specification.

Fresenius suggests, therefore, that only those portions of the specification that discuss the operation of the fluid-receiving membranes in the disposable unit are the portions that are relevant to the meaning of "membrane" in claim 12. Fresenius points to the "Summary of the Invention," which describes the invention as a dialysis system with a "disposable unit" that "has at least two flexible membranes that bond together at selected locations and to a rigid plastic piece or manifold . . . The membranes seal to one another so as to define a pump receptacle and a fluid heating pathway." Id., 3:32-37.
Fresenius also notes that the "Summary of the Invention" explains that "[t]he heater heats the fluid heating pathway defined by the flexible membranes of the disposable unit," id., 5:18-19; and that "[t]he disposable unit in another embodiment includes a first flexible membrane and a second flexible membrane that house the pump receptacle, the fluid heating path and the rigid valve manifold. The disposable unit also includes a rigid frame that attaches to at least one of the first and second flexible membranes," id., 6:12-17.

Based on the above-cited portions of the specification, Fresenius asserts that the specification explicitly distinguishes between the "flexible membranes" and the rigid plastic to which they are attached. Fresenius contends, moreover, that every embodiment disclosed in the '547 patent specification describes disposable unit 160 as including "a pair of flexible membranes, including an upper flexible membrane 162 and a lower flexible membrane 164," see, e.g., id., 15:38-47, 33:8-11; and that no broader category of "membrane" as part of a fluid receptacle is mentioned anywhere in the patent.

Fresenius contends in addition that the specification explicitly requires that the "membranes" of the fluid receptacle be capable of deformation by application of vacuum and mechanical pressure. The patent describes Fig. 13 as "a sectional view of one embodiment of a single layer film structure for the disposable unit membranes of the present invention," and describes Fig. 14 as "a sectional view of one embodiment of a multiple layer film structure for the disposable unit membranes of the present invention." Id., 8:25-30. The "Detailed Description of the Invention" refers to Figs. 13 and 14 in a section entitled "Membrane Material for the Disposable Unit," explaining that

upper and lower membranes 162 and 164 can be fabricated from a monolayer film structure 312 (Fig. 13) or a multiple layer film structure (Fig. 14). The film 312 is constructed from a non-PVC containing polymeric material and must satisfy numerous physical property requirements. The film 312 must have a low modulus of elasticity so that it can be deformed under low pressure to function as a pumping element. What is meant by low modulus is the film 312 has a modulus of elasticity when measured in accordance with ASTM D882, of less than 10,000 psi, more preferably less than about 8,000 psi and even more preferably less than about 5,000 psi and finally, less than 3,000 psi, or any range or combination of ranges defined by these numbers.

In addition, Fresenius notes, the membrane must be sufficiently flexible so that "it can be deformed under a pressure of 5 psi." Id., 29:14-15. "The film maintains its low modulus and deformability properties even after sterilization to continue to meet the pumping requirement." Id., 29:15-17. Fresenius contends that this is an express definition, and that it controls the meaning of the term "membrane" as used in the '547 patent.

"In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314. The word "membrane" is a widely understood term that means "barrier." Where a disputed claim term is accompanied by a clarifying adjective, that clarifying adjective may assist the court in construing the disputed term. See id.

Here, however, Fresenius is attempting to confine the construction to one embodiment in the specification. The specification for the '547 patent does not require that the "membrane" in claim 12 be flexible. In every reference cited by Fresenius, the specification clearly indicates that the description applies to one or more embodiments - not that it applies to every possible embodiment of the invention.

For example, while it is true, as Fresenius asserts, that the specification states with reference to Figs. 13 and 14 that the "film" from which the membranes may be fabricated "must have a low modulus of elasticity so that it can be deformed under low pressure to function as a pumping element," id., 23:67-24:2, the patentees earlier clarify that they are describing only one of many kinds of membranes that may be used in the invention:

Referring now to Figs. 3A, 4A, 4B, 5, and 6, various embodiments of the disposable unit 160 are illustrated. In each of the embodiments, the disposable unit 160 includes a pair of flexible membranes, including an upper flexible membrane 162 and a lower flexible membrane 164. . . . The flexible membranes 162 and 164 can be made of any suitable sterile and inert material, such as a sterile and inert plastic or rubber. . . . One preferred material for the flexible membrane is described
below in connection with Figs. 13 and 14.

Id., 15:39-56.

Fresenius has established that at least one embodiment utilizes two (or more) flexible membranes, capable of deformation. However, the specification also discloses embodiments in which only one of two (or more) membranes is flexible, while the other may not be. For example, the "Summary of the Invention" describes an embodiment in which only one of the two membranes has these characteristics:

Thus, in an embodiment, the system maintains a negative pressure on one of the membranes of the fluid receptacle of the disposable unit to pull same away from the other membrane and draw dialysis fluid into the fluid receptacle.

Id., 4:64-67; see also id., 5:1-7 ("The negative pressure on the active membrane is then released, which pushes the membrane toward the other membrane and dispels the dialysis fluid from the pump receptacle. In another embodiment, a mechanical pump piston can be pneumatically attached to one of the membranes, wherein the system mechanically pulls the membrane away from the other membrane.")

In examining the specification for proper context, the court should avoid importing limitations from the specification into the claims. See Varco, L.P. v. Pason Sys. USA Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006). Even if every disclosed embodiment uses flexible membranes, Phillips squarely rejects limiting the claim on that basis, unless the specification makes clear that "the patentee . . . intends for the claims and the embodiments in the specification to be strictly coextensive." Phillips, 415 F.3d at 1323, quoted in JVW Enters., Inc. v. Interact Accessories, Inc., 424 F.3d 1324, 1335 (Fed. Cir. 2005).

"Membrane" means "barrier."

The defendant argues that the term "membrane" in the '550 Patent should be construed as not including a plug. The defendant notes the plaintiff's admission that "the Graves plug is not a membrane." (Mattes Decl. P 5 & Ex. 213.) The defendant also cites evidence that, to those skilled in the art of injection molded plastics, the ordinary meaning of the term "membrane" is a relatively thin covering and does not include a plug. (Belcher Decl. P 9.) The Court also notes that this construction is consistent with the ordinary lay meaning of the term.

These proposed constructions are reasonable and supported by relevant evidence, and are not opposed by the plaintiff. Accordingly, the Court adopts the proposed constructions as a matter of law.

"Memory Selection Second Switch Means" - Claim 5

Claim 5 recites a "memory selection second switch means being adapted to select a first position . . . and . . . a second position." Because this claim element utilizes the term "means" and the claim does not specify any structure or material for performing the recited function, the district court properly held "memory selection second switch means" is a means-plus-function element under 35 U.S.C. § 112, P 6 (1994). See Al-Site Corp. v. VSI Int'l, Inc., 174 F.3d 1308, 1318, 50 U.S.P.Q.2D (BNA) 1161, 1166 (Fed. Cir. 1999) ("if the word 'means' appears in a claim element in combination with a function, it is presumed to be a means-plus-function element"). Thus, "memory selection second switch means" covers the "corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112, P 6 (1994).
The district court's determination of corresponding structure is a matter of claim construction, see Chiuminatta, 145 F.3d at 1306, which this court reviews de novo. See Cybor, 138 F.3d at 1456. Determining whether Figure 3 is a "corresponding structure" for the "switch means" of claim 5 requires the court to consult again the language of the claim and the other factors that inform claim meaning. Of course, the central focus remains on the claim language. The written description, the prosecution history, and admissible extrinsic evidence may supply context to understand the claim language. See Vitronics Corp. v. Conectronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996); Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1309, 51 U.S.P.Q.2D (BNA) 1161, 1169 (Fed. Cir. 1999).

In construing claim 5, the district court determined the term "memory selection second switch means" encompasses the same scope as the "memory selection switch" of claim 1. Specifically, the district court determined that "memory selection second switch means" covers only the mechanical switch of Figure 2, not the software embodiment of Figure 3. The written description of the '364 patent and the prosecution history, however, reveal a broader meaning of "memory selection switch means."

As previously explained in this court's analysis of claim 1, Figure 3 illustrates a flow diagram "describing both the operate and program modes of the invention." '364 patent, col. 4, ll. 23-24. The two lower-right corner dialog boxes of Figure 3 describe steps to "store code at location pointed to by the code location pointer" and "increment code location pointer[;] if pointer increments over five then load code location pointer with one." See id. at Fig. 3 (emphasis added). Dr. Rhyne's expert testimony shows that one of ordinary skill in the computer science art would understand the underlined terms to describe software operations.

Although software operations do not fall within the literal scope of the "memory selection switch" in claim 1, the reissue prosecution history also discloses a broader reading for the "switch means" of claim 5. First, the patentees' representation to the Patent and Trademark Office in its November 29, 1989 sworn declaration indicated their intent to include the algorithm of Figure 3 as a "corresponding structure" for the switch means. The patentees stated:

We believe the aforesaid Letters Patent to be wholly or partly inoperative or invalid by reason of our claiming less than we had a right to claim in the patent. More specifically, we believe the sole independent original claim [i.e., claim 1 of the '118 and now claim 1 of the '364 patent] is too narrow in three respects:

(c) The claim requires a "switch moveable" and a "memory selection switch" but should have required a --first switch means-- and a--memory selection switch means--, respectively, because switch means includes electronic switches as well as mechanical switches.

J.A. at 5388 (emphasis added). While this statement weighs against construing claim 1 to include software operations, it gives a broader reading to claim 5. This statement evinces the patentees' use of the term "switch means" to include microprocessor operations driven by software, i.e., "electronic" switches, as opposed to a mechanical switch of Figure 2. The patentees' use in claim 5 of the term "switch means" rather than "switch" and "being adapted to select" rather than "setable" and "set," to describe software operations, further support a broader construction.

Later in the reissue proceedings, the patentees argued in response to an anticipation rejection:

Applicants' method and apparatus is intended to simplify the remote control of equipment by code transmitters. . . . Such simplifications are provided by including multiple storage locations in the receiver and including a programming routine which receives and stores codes transmitted from the code transmitters of the system.

J.A. at 5822 (emphasis added). This statement further supports reading "switch means" to include structure corresponding to Figure 3.

The differences in claim language, bolstered by the patentees' statements during the reissue proceedings, cause this court to reach a broader construction for claim 5 than for claim 1. See Vitronics, 90 F.3d at 1582. The district court erred in ruling that only the mechanical switch in Figure 2 is "corresponding structure" for the claimed "switch means."

"Switch means," when properly construed, also covers the software-based embodiment described in Figure 3.
Chamberlain asserts that, should this court construe claim 5 to cover the software embodiment of Figure 3, then it is entitled to summary judgment of literal infringement. An accused device satisfies a means-plus-function element literally if it performs the identical function required by the limitation, and incorporates the structure disclosed in the specification or an equivalent thereof. See Cybor, 138 F.3d at 1456. The language of claim 5 and the written description establish that the function of "switch means" is to select different memory locations, thereby enabling the microprocessor to store transmitter identifiers in the memory locations. The parties do not dispute that the Intellicode's memory selection software program performs this function.

The Intellicode, however, constitutes a different "structure" than the software disclosed in the '364 patent because it uses a different algorithm to perform the recited function. Figure 3 and the corresponding description indicate that the code location pointer increments through a series of memory locations, automatically erasing the previous contents of a memory location when it stores a new transmitter code in that location. When the pointer can no longer increment, i.e., when it is pointing to the last memory location in the series, the microprocessor "loads code location pointer with one," causing the pointer to loop back and select the first memory location in the series. The Intellicode, on the other hand, randomly chooses an unused memory location. Thus, the Intellicode's memory selection scheme is not identical to the structure disclosed in Figure 3 of the '364 patent.

Moreover, Overhead Door presented evidence that its memory selection scheme is not structurally equivalent to that of Figure 3. A structure in an accused device is equivalent to the disclosed structure corresponding to a means-plus-function element if it is insubstantially different from the disclosed structure. See Chiuminatta, 145 F.3d at 1309. Overhead Door urged that the Intellicode software is substantially different from the claim element because its software uses memory more efficiently and minimizes the chances of overwriting previously-stored codes. Viewing the evidence in a light most favorable to the non-movant Overhead Door, this court finds that Overhead Door has raised a genuine issue of material fact precluding summary judgment of literal infringement of claim 5. Accordingly, this court remands for the fact-finder to determine whether the Intellicode uses a structure equivalent to the mechanical switch in Figure 2 or to the software-implemented algorithm in Figure 3, for selecting different memory locations.

"Memory Selection Switch" - Claim 1

The district court construed the "memory selection switch" element of claim 1 to mean "a switch separate from the microprocessor which is user operated to select different positions of the switch." The claim uses the term "switch," a word connoting a mechanical device with different settings, such as "on" or "off." Claim 1 further defines the memory selection switch as "connected to" the microprocessor, "setable in" a first position, and "set in" a second position. This claim language is more consistent with a mechanical switch attached to the microprocessor, rather than software programmed into the microprocessor.

In the '364 patent's "Brief Description of the Drawings," the patentee states that "Fig. 2 illustrates in block form the invention." Col. 2, l. 43 (emphasis added). Figure 2 complements the definition supplied by the claim language:

[SEE FIGURE 2 IN ORIGINAL] Figure 2 shows the program/operate switch 22 as a mechanical switch, which alternates between "program" and "operate." Moreover, the drawing depicts the memory selection switch 23 as a mechanical switch with five separate numbered positions. The associated written description identifies the memory selection switch with 23, see '364 patent, col. 3, ll. 9-11, and describes it as a five-position, moveable switch separate from and "connected to" the microprocessor 44. See id. at col. 3, ll. 9-19 (emphasis added); see also Fig. 2. Again this part of the patent suggests a mechanical switch.

Finally, Chamberlain does not contest the special master's interpretation of the program mode "switch" as a mechanical toggle switch. To interpret the term "switch" consistently in the claim and to harmonize the drawing depiction with the claim language, this court confirms the district court's reading of the term "switch." Thus, the term "memory selection switch" means a mechanical device separate from the microprocessor. This interpretation is also most in harmony with the prosecution history of the reissue application, as explained later.
In reaching this claim interpretation, this court considered but rejected the contention that Figure 3 discloses as part of the claim a software embodiment for the switch of claim 1. Figure 3 of the '364 patent, shown below, illustrates how the invention receives and validates codes:

[SEE FIGURE 3 IN ORIGINAL] In Figure 3, the two dialog boxes in the lower-right corner refer to storing the code at the location "pointed to" by the "code location pointer," "incrementing" the code location pointer, and "loading" the code location pointer with a value of one. The '364 patent, however, does not indicate whether the "code location pointer" is a particular embodiment of the "switch" of claim 1, or some other (unclaimed) component. "Code location pointer" appears nowhere in the claims. Moreover, the only reference to a code location pointer in the written description is a single sentence that does not illuminate Figure 3: "If the switch 22 is in the 'program' mode as shown in FIG. 3 when the incoming signal from a transmitter is received, the flow diagram is followed so as to store the new incoming program in the code location pointed to by the code location pointer 23." Col. 4, ll. 57-61. The vague terms in Figure 3 do not override the claim language and written description that closely identify the "memory selection switch" as a mechanical device. This court interprets "memory selection switch" to mean a mechanical switch with different positions, each position corresponding to a different location in memory, thus enabling the garage door operator to store codes in different memory locations. Thus, this court affirms on review the district court's interpretation of "memory selection switch."

Applying this claim construction to the accused device, this court affirms the district court's summary judgment of no literal infringement of claim 1. "Literal infringement of a claim requires that every limitation recited in the claim appear in the accused device, i.e., that the properly construed claim reads on the accused device exactly." Amhil Enters., Ltd. v. Wawa, Inc., 81 F.3d 1554, 1562, 38 U.S.P.Q.2D (BNA) 1471, 1476 (Fed. Cir. 1996). Claim 1 covers a mechanical "memory selection switch." The accused Intelicode system, in contrast, selects memory locations with a software program, not with a mechanical switch. Thus, the "memory selection switch," as correctly construed, is literally absent from the Intelicode. Therefore, the Intelicode does not literally infringe claim 1.

The district court erred, however, in also deciding on summary judgment that the Intelicode did not infringe under the doctrine of equivalents. The doctrine of equivalents requires that the accused product contain each limitation of the claim or its equivalent. See Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 520 U.S. 17, 40, 41 U.S.P.Q.2D (BNA) 1865, 1875, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). An element in the accused product is equivalent to a claim element if the differences between the two are "insubstantial" to one of ordinary skill in the art. Warner-Jenkinson, 520 U.S. at 39-40; Hilton Davis Chem. Co. v. Warner-Jenkinson Co., 62 F.3d 1512, 1517, 35 U.S.P.Q.2D (BNA) 1,641 (Fed. Cir. 1995) (en banc), rev'd on other grounds, 520 U.S. 17, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). The district court found as a matter of law that the Intelicode had no equivalent of the memory selection switch claim element.

"Although equivalence is a factual matter normally reserved for a fact-finder, the trial court should grant summary judgment in any case where no reasonable fact-finder could find equivalence." Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1423, 44 U.S.P.Q.2D (BNA) 1103, 1106 (Fed. Cir. 1997). This case does not satisfy this lofty standard. The record contains considerable evidence, including several reports and declarations by Chamberlain's expert, Dr. Rhyme, that one of ordinary skill in the art would find the Intelicode's software-driven memory selection system insubstantially different from the hardware switch of claim 1. Dr. Rhyme averred in his June 2, 1997 report: "[i]t is a fundamental and well understood tenet of the computing art [that] . . . 'any software process can be transformed into an equivalent hardware process, and any hardware process can be transformed into an equivalent software process.'" See ED KLINGLER, MICROPROCESSOR SYSTEMS DESIGN 5 (1977). Dr. Rhyme stated that this "dualistic transformation," known as the "hardware/software" trade-off, effectively means that the selection of a software pointer for a microprocessor versus a hardware switch to control a microprocessor-based system is simply a matter of design choice. This record evidence shows that one of skill in the art would recognize these alternative systems as interchangeable substitutes. Drawing all reasonable inferences in favor of Chamberlain, as this court must in reviewing the summary judgment of non-infringement, this court concludes that Dr. Rhyme's statements and supporting citations to computer science literature show a genuine issue of material fact precluding summary judgment.

In discerning this genuine factual issue, this court also considered the district court's interpretation that a mechanical switch would necessarily require a human operator. In operation of a mechanical switch, a human operator would indeed set the memory selection switch to one of five positions. This "user operated" characteristic of a mechanical switch, however, would not necessarily preclude a finding that software performs equivalently without human operation. Indeed in other
contexts, this court has noted the interchangeability of hardware and software. See, e.g., Pennwalt Corp. v. Durand-Wayland, Inc., 833 F.2d 931, 935, 4 U.S.P.Q.2D (BNA) 1737, 1740 (Fed. Cir. 1987) (en banc) ("If . . . the accused devices differ only in substituting a computer for hard-wired circuitry, [the patentee] might have a stronger position for arguing that the accused devices infringe the claims."). Moreover the Supreme Court has acknowledged that interchangeability can be one of the hallmarks of an equivalent. See Warner-Jenkinson, 520 U.S. at 37 ("known interchangeability . . . for an element of a patent is one of the express objective factors . . . bearing upon whether the accused device is substantially the same as the patented invention"); Graver Tank & Mfg. Co., Inc. v. Linde Air Prods. Co., 339 U.S. 605, 609, 85 U.S.P.Q. (BNA) 328, 331, 94 L. Ed. 1097, 70 S. Ct. 854 (1950) ("An important factor [in determining equivalency] is whether persons reasonably skilled in the art would have known of the interchangeability . . .").

This court has explained that the "function-way-result" test may help detect an equivalent, particularly for mechanical elements. See Dawn Equip. Co. v. Kentucky Farms Inc., 140 F.3d 1009, 1016, 46 U.S.P.Q.2D (BNA) 1109, 1113 (Fed. Cir. 1998). The function-way-result test dictates that an element in the accused device is equivalent to the claim element if it "performs substantially the same function in substantially the same way to obtain the same result." Graver Tank, 339 U.S. at 608. Applying the function-way-result test to claim 1, the district court found that "the function of the memory selection switch [is] . . . to permit selection of a particular memory location at the receiver for subsequent storage of a transmitted code, by use of a switch connected to the microprocessor." Overhead Door Corp, No. 95-CV-1648-D, at 24 (N.D. Tex. Jan. 13, 1999) (emphasis added). The district court then found that this function was "totally missing" from the accused device because "the user is unable to predetermine selection of specific, desired memory locations." This application of the function-way-result test erroneously incorporates the claim element's "way" into the definition of the function, effectively limiting the claim element to its literal terms.

The claim language and the specification explain that the "memory selection switch" functions to select memory locations. This claim element accomplishes its function by way of a mechanical switch. This particular switch constitutes the claim element's "way" of accomplishing the memory selection function, not the function itself. The result of this element is storage of codes in different memory locations. The record at this stage, preliminary to a trial, creates a genuine issue of material fact whether the Intellicode accomplished substantially the same function, in substantially the same way, to achieve substantially the same result.

Moreover, contrary to the district court's determination, this court's ruling in Sage Products does not limit the range of equivalents to the memory selection switch in this case. In Sage Products, this court noted that the claim limitations "top of the container" and "over said slot" constituted "a precise arrangement of structural elements" and a "clear structural limitation" in a "relatively simple structural device." Sage Prods., 126 F.3d at 1425. Finding that Sage's theory of equivalence - i.e., a container having two constrictions below its top was equivalent to the claimed container having a constriction above and a constriction below -- would "remove entirely the 'top of the container' and 'over said slot' limitations from the claim," this court affirmed the district court's grant of summary judgment of non-infringement. Id. at 1423-24. Thus, the proposed application of the doctrine in Sage Products would have utterly written out of the claim not one, but at least two (maybe more) express limitations of the claim. Indeed under Sage Products' equivalents theory, a finding of equivalents for one limitation ("at the top") would necessarily require writing out of the claim another limitation ("over said slot"). No matter how the patentee purported to apply the claim to the accused device under the doctrine, the device was always missing at least one limitation. Thus, the claim language specifically negated the patentee's equivalence theory. Moreover, this court in Sage Products noted that "any subsequent change in the state of the art, such as later developed technology" would have been eligible for coverage under the doctrine of equivalents, thus clearly defining at least one type of expanded claim coverage under the doctrine. Id. at 1425.

In contrast to the facts in Sage Products, claim 1 of the '364 patent does not contain any clear structural limitations that preclude a reasonable jury from finding a software system equivalent to the claimed system. By definition, an equivalent does not fall literally within the claim language. Although the literal meaning of the "memory selection switch" does not cover the software-implemented Intellicode, this case does not preclude application of the doctrine under Sage Products because any application of the doctrine would not leave some aspect of the claim missing from the accused device. Applying the doctrine of equivalents to cover Intellicode's software does not vitiate the "memory selection switch" element. See id., at 1423-24.

As properly construed, the "memory selection switch" means a mechanical switch for selecting memory locations. The question remains whether the Intellicode's software-driven memory selection scheme is equivalent to a mechanical switch.
The parties ask the Court to construe the phrase "whereby the meniscus provides a constant flow of said chemical onto said substrate surface" in Claim 5 of the Allen Patent. Joint Statement at 1. The parties agree that meniscus refers to the "curved surface of the solvent." Oki's Response to AMD's Opening Markman Brief at 1; AMD's Markman Reply Brief at 9. The parties also agree that a meniscus forms as a result of surface tension. AMD's Markman Reply Brief at 9; see Oki's Response to AMD's Opening Markman Brief at 4.

Beyond that, the parties are at odds. Oki argues that the meniscus must extend "continuously from the nozzle tip to the substrate." Oki's Response to AMD's Opening Markman Brief at 1. AMD's definition only require the meniscus to form at the substrate. AMD's Markman Reply Brief at 9. Oki argues that prosecution history estoppel places limits on the definition. Oki's Response to AMD's Opening Markman Brief at 1-3. The dispute again boils down to two issues. (1) Does Oki's proposed requirement that the meniscus extend from the nozzle tip to the substrate have any support in the intrinsic evidence? (2) Does AMD's decision to amend the claims to overcome a rejection place any limits on the scope of the claims? The answers to those questions are no and yes, respectively.

1. The Claims of the Allen Patent

Nothing in the claims supports the requirement that the meniscus be continuous and unbroken. The Allen patent describes a method for removing coating from the edges of a silicon wafer. 678 Patent, at [57]. Claim 5 describes a process that involves "contacting one surface adjacent to the periphery of a [rotating wafer of] substrate with a chemical capable of dissolving the coating material." Id. at col.6 ls.48-50. This is accomplished "by forming a meniscus between [the] surface [of the substrate] and a nozzle positioned adjacent to the periphery of [that] surface." Id. at ls.50-52. The claim then introduces the limitation in dispute: "whereby the meniscus provides a constant flow of said chemical onto said substrate surface." Id. at ls.52-54. Thus, the claims impose three limitations on the meniscus. First, the formation of the meniscus must lead to the contact between the edge of the spinning wafer and the solvent. Second, the meniscus must form between the spinning wafer and the nozzle. Finally, the meniscus must provide a constant flow of the solvent onto the spinning wafer.

None of these requirements support Oki's contention that the meniscus must extend continuously and unbroken from the nozzle tip to the substrate. In fact, the claims hint that such a requirement is unlikely. Oki's requirement that the meniscus extend continuously and unbroken springs from a dictionary definition. That definition defines meniscus as "[t]he curved upper surface of a nonturbulent liquid in a container that is concave if the liquid wets the container walls and convex if it does not." Oki's Response to AMD's Opening Markman Brief at 3 (quoting the American Heritage Dictionary (4th ed. 2000)) (internal quotations omitted). Oki then derives the continuous and unbroken requirement from the word nonturbulent. Id. at 3. However, in the Allen Patent, the meniscus does not exist in a stationary container. Instead, it exists between a nozzle out of which the solvent flows and a rotating wafer of substrate that is covered with a coating material. 678 Patent col.6 ls.44-45, 56, 64-66. Given that the substrate is rotating, one would not expect the meniscus in the patent to replicate the behavior of a "nonturbulent liquid in a container." The Court rejects Oki's attempt to force the invention to behave in accordance with a dictionary definition that describes the behavior of a liquid in a context contrary to the plain language of the claims.

The claims also do not impose Oki's requirement that the meniscus extend from the nozzle to the substrate. Oki's logic proceeds as follows: (i) the definition refers to a single convex or concave surface between two stationary walls of a container; (ii) in the Allen patent, the liquid exists between the nozzle and the substrate; (iii) therefore, the meniscus here must be one concave or convex surface between the nozzle and the substrate. Again, this logic suffers from the same fallacy: the claims indicate that the solvent does not lie stationary in a container but flows from a nozzle to the substrate. Furthermore, the word "between" in the claims only requires that the meniscus exist between the nozzle and the substrate, not extend like a bridge from one to the other. The Court finds no support in the claims for Oki's requirement that the meniscus extend continuously and unbroken from the nozzle to the substrate.
2. The Specification of the Allen Patent

The specification also casts doubt on Oki's attempt to impose its dictionary-based limitation on the claims. The specification refers to the meniscus twice. Referring to an illustration of the preferred embodiment, the specification describes how the meniscus forms. First, a valve is opened and the solvent flows under pressure from a reservoir through a series of tubes into the nozzle. Id. at col.3 ls.46-50. "As the chemical exits [the] nozzle . . . at [the] nozzle tip . . ., a meniscus is formed by the exiting liquid between [the] nozzle tip . . . and the underside of [the] substrate. . . . Forming of this meniscus is expedited by closely spacing [the] nozzle tip . . . to [the] substrate. . . ." Id. at col.3 ls.50-54. The specification reveals two important features of the meniscus. First, it may be formed by a liquid that is flowing under pressure. Second, moving the nozzle tip closer to the substrate expedites formation of the meniscus. The first limitation runs counter to Oki's argument that the meniscus behave like a stationary liquid in a glass vessel. The second limitation is one that the parties conceded at oral argument when they both agreed that in order for the meniscus to form, the nozzle tip must be very close to the wafer.

3. The Prosecution History of the Allen Patent

The prosecution history sheds light on what the patent claims mean when they require that "the meniscus provide [] a constant flow of [the] chemical onto [the] substrate surface." Id. at col.6 ls.52-54. During prosecution, the Examiner rejected all the claims of the Allen Patent as obvious or anticipated in light of the Sato patent. Oki's Response to AMD's Opening Markman Brief, Ex. 2 ("Allen Rejection") at 1, 3. The Sato Patent teaches a process similar to that of the Allen Patent. The Sato Patent describes a device that ejects liquid from a nozzle towards the edge of a spinning substrate to remove coating at the edge of the substrate. U.S. Patent No. 4,113,492 col.3 ls.28-47. However, nowhere does the Sato Patent mention a meniscus. Thus, AMD responded to the rejection by adding a new claim which eventually issued as Claim 5 of the Allen Patent. Oki's Response to AMD's Opening Markman Brief, Ex. 3 ("Response to Allen Rejection") at 5, 7. AMD distinguished the Allen Patent from the Sato Patent by pointing to the meniscus language at issue here. AMD stated that ",while the applicant . . . does use a nozzle as does Sato, applicant's removal process comprises positioning the nozzle sufficiently close to the spinning coated wafer to establish a meniscus formed between the nozzle and the spinning wafer." Id. at 9. According to AMD, formation of this meniscus allows the invention to "control . . . the amount of surface contacted by the solvent solely by control of the rotational speed of the coated substrate." Id. at 12. AMD claimed that the Sato Patent neither anticipated nor made obvious this feature. See id. at 11-12. This exchange during the prosecution of the Allen Patent explains what the disputed claim terms mean. Because the meniscus provides a constant flow of the solvent onto the spinning wafer, the invention can control how much of surface area of the wafer the solvent contacts solely by varying the speed of rotation of the wafer. Thus, the claim limitation requiring the meniscus to provide a constant flow of the solvent onto the substrate distinguishes Claim 5 of the Allen patent over the Sato reference.

4. Construction of Disputed Terms in the Allen Patent

The intrinsic evidence directs the Court to construe the phrase "whereby the meniscus provides a constant flow of said chemical onto said substrate surface" of Claim 5 of the Allen Patent as follows. The meniscus, i.e., the curved surface of the chemical created by the surface tension of the chemical when the chemical contacts a solid, supplies a constant flow of the chemical onto the substrate. The meniscus exists between the nozzle and the substrate. The meniscus cannot form unless the nozzle is positioned sufficiently close to the spinning coated wafer.

2536

Titled "Stackable Recycling Crate," the '202 patent is directed to "a box-like structure with four walls and a bottom." '202 patent at Col. 2, lines 67-68. Like an ordinary, uncovered box, the '202 crate contains a bottom side, two side walls, a front wall, and a back wall. Two features alter the typical configuration of a box to enable simultaneously the placement of large articles in the crate when stacked with other crates of its kind, while retaining the articles within the confines of the crate once the articles have been so placed. First, the upper and lower portions of the front wall are cut out such that when stacked, the upper cut-out portion of each lower crate and the lower cut-out portion of each upper crate together form a large, overall opening into which articles may be easily placed. Second, the front portion of the bottom side tapers to an
incline that joins the central portion of the front wall, forming an internal storage compartment that is further enclosed laterally by the side portions, or "legs," of the front wall remaining after the upper and lower portions of the front wall have been excised.

The '202 patent originally recited 16 claims. The broadest original claim, claim 1, reads as follows:

1. A stackable crate comprising:

(a) a pair of opposing sidewalls;

(b) a back wall coupled to the sidewalls;

(c) a front wall coupled to the sidewalls and having a first substantially rectangularly shaped opening at the top portion of the front wall and a second substantially rectangularly shaped opening at the bottom portion of the front wall, thereby defining in the front wall a central portion with the bottom edge of the central portion extending to form at each end a lower leg segment and the top edge of the central portion extending to form at each end an upper leg segment; and

(d) a bottom side being planar as the bottom side extends away from the back wall and tapering upwardly to merge with the central portion, wherein the bottom side as joined to the sidewalls and to the back wall to define a storage compartment in the interior of the crate.

On January 3, 1994, Spectrum apprised Sterilite of its view that Sterilite's "Storage Cart" product may infringe the '202 patent. On that same day, Spectrum also mailed a request for reexamination to the U.S. Patent and Trademark Office ("PTO"). A protracted 30-month reexamination proceeding ensued, culminating in a decision by the Board of Patent Appeals and Interferences, mailed July 26, 1996, affirming the examiner's final rejection of 11 out of the original 16 claims, including claim 1. Only claims 2, 11, and 14-16 survived reexamination. Claims 14-16 are not pertinent to this appeal and will not be further discussed.

Claims 2 and 11 each contain the requirement that the bottom side of the crate merge with at least a substantial portion of the bottom edge of the central portion of the crate's front wall. See '202 patent at Col. 5, lines 24-26; Col. 6, lines 4-7. During reexamination, the examiner lodged a rejection of claims 2 and 11 over a prior art crate, shown in Figure 1, disclosed in DePutter, U.S. Patent No. 3,682,351 ("DePutter").

To rebut the rejection, Spectrum argued that in the prior art crate, the bottom side merges with the top edge of the central portion of the front wall, but not the bottom edge. The PTO sustained the patentability of claims 2 and 11 solely on the basis of this argument.

Armed with its Board decision, Spectrum filed suit in the Southern District of New York on October 24, 1996, charging Sterilite with infringement of claims 2 and 11 by the "Storage Cart" illustrated in Figure 2:

[SEE FIGURE 1 IN ORIGINAL]

[SEE FIGURE 2 IN ORIGINAL]
After discovery, a hearing was held on cross-motions for summary judgment, and on January 28, 1998, the district court issued an order and judgment granting Sterilite's motion for summary judgment of noninfringement and denying Spectrum's cross-motion for summary judgment of infringement. The court reasoned that because Spectrum did not, in the court's view, provide any special definition for the claim term "wall," the term's ordinary meaning, as discerned by the court, controlled. Given its construction of the claims, the court found that Sterilite's accused product does not have a front wall as required by claims 2 and 11, and as such does not infringe these claims either literally or under the doctrine of equivalents. Spectrum now appeals. We have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1) (1994).

II

Spectrum predicates its argument for reversal of the district court's decision as to both claims 2 and 11 on a deconstruction of Sterilite's accused product. This deconstruction, presented by Spectrum in its opening brief, is shown in Figure 3:

[SEE FIGURE 3 IN ORIGINAL]

Referring to this diagram, Spectrum asserts that Sterilite's accused product contains a back wall (b), a pair of opposing sidewalls (a) coupled to a front wall (c) having rectangular openings at the top (c[t]) and bottom (c[b]) that define a central portion (cp) with a top edge (cp[t]) and bottom edge (cp[b]), wherein the central portion extends to form an upper leg segment (l[t]) and a lower leg segment (l[b]), and further wherein a bottom side (d) that is planar as it extends away from the back wall tapers upwardly to merge with at least a substantial portion of the bottom edge of the front wall, along the line marked "X". As such, argues Spectrum, Sterilite's accused product meets each limitation common to claims 2 and 11.

Of particular note is Spectrum's reliance on line "X" as representing the set of points along which Sterilite's accused crate meets the limitation in claims 2 and 11 requiring that the upwardly tapering bottom side merge with at least a substantial portion of the bottom edge of the central portion of the front wall.

Spectrum recognizes that it must rely on line "X" because unless the merger of the bottom side and the front wall occurs along line "X", Sterilite's accused product cannot infringe either claim 2 or 11, whether literally or by equivalents. As the relevant portion of Sterilite's reply-brief diagram of its accused crate's side view, shown in Figure 4, makes clear, if the upwardly tapering (D2) bottom side (D1) of the accused crate is considered to merge with the front wall at the interface of D3 and D4, rather than at the interface of D2 and D3 as asserted by Spectrum, the merger of the accused crate's bottom side and its front wall occurs at the top, not the bottom, of the central portion, contravening the explicit requirement in claims 2 and 11 to the contrary. Accordingly, literal infringement is precluded. See, e.g., Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1211, 48 U.S.P.Q.2D (BNA) 1010, 1015 (Fed. Cir. 1998) ("To prove literal infringement, the patentee must show that the accused device contains every limitation in the asserted claims. If even one limitation is missing or not met as claimed, there is no literal infringement.") (internal citations omitted). Moreover, because merger of the bottom side and central portion of the front wall at the interface of D3 and D4 constitutes the very embodiment that Spectrum explicitly relinquished during prosecution, doctrine of equivalents infringement is precluded as well under the opposing doctrine of prosecution history estoppel. See, e.g., Wang Lab., Inc. v. Mitsubishi Elecs. Am., Inc., 103 F.3d 1571, 1577, 41 U.S.P.Q.2D (BNA) 1263, 1269 (Fed. Cir. 1997) ("Prosecution history estoppel acts as one check on application of the doctrine of equivalents, by precluding a patentee from regaining, through litigation, coverage of subject matter relinquished during prosecution of the application for the patent.") (internal citations omitted).

[SEE FIGURE 4 IN ORIGINAL]

Spectrum attempts to evade the consequences of a straightforward determination of noninfringement on this basis by presenting, in essence, two arguments. First, citing Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271, 229 U.S.P.Q. (BNA) 805, 812 (Fed. Cir. 1986), for the proposition that a claim employing the transitional term "comprising" does not exclude additional, unrecited elements, Spectrum contends that the open "comprising" language of claims 2 and 11 permits Spectrum to deconstruct Sterilite's cart and call line "X" the merging interface of the bottom side and front wall in Sterilite's accused crate, because Sterilite has done nothing more than add an irrelevant, unrecited element to the "front" of an otherwise infringing device. Second, Spectrum argues that nothing of record either limits the front wall recited in claims 2 and 11 to any particular height or precludes claim 2 and 11 (again relying on the open claim language "comprising") from encompassing crates in which the bottom side merges with both the bottom and top of the front wall's central portion. As
such, the mere fact that the central portion of the "front wall" in Sterilite's accused crate--D3 in Figure 4, according to Spectrum--is a single, thin layer of plastic having a top and bottom that both merge with the upwardly tapering bottom side of the accused crate does not preclude, and indeed warrants, a finding of infringement.

The district court focused on, and found fault with, the first prong of Spectrum's second argument, i.e., Spectrum's contention that D3 in Figure 4 is a front "wall" for purposes of claims 2 and 11. Opening during oral hearing that such a construction of the term "wall" flies in the face of any reasonable interpretation of the term, the district court found that Sterilite's accused crate does not possess a "front wall" as required by claims 2 and 11, and therefore does not infringe these claims as a matter of law, either literally or under the doctrine of equivalents.

Spectrum asserts legal error in the district court's construction of claims 2 and 11 on the ground that as its own lexicographer, Spectrum had made clear in the claims and written description of the '202 patent that the "front wall" of claims 2 and 11 places no limitation on the size of the openings above and below the central portion, and hence on the height of the central portion itself. Spectrum also argues in the alternative that the "legs" in the accused crate supply any requisite height requirement imposed by the claim term "wall" and that the central portion, defined by the upper and lower openings, is unbounded by any requirement for a particular vertical dimension. In either event, Spectrum contends that the district court improperly interpreted claims 2 and 11, and as a result, erred in finding no infringement either literally or under the doctrine of equivalents. Sterilite points to a dictionary definition of "wall" in support of the district court's diagram, what Spectrum calls "legs" are clearly part of the side wall, not the front wall. As such, Sterilite urges this court to find no merit in either of Spectrum's theories for reversal.

III

Summary judgment is proper when no genuine issue of material fact exists and the moving party is entitled to judgment as a matter of law. See Fed. R. Civ. P. 56(c). Even disputed material facts will not defeat summary judgment when, taking all factual inferences in favor of the nonmovant, the moving party is nonetheless entitled to judgment as a matter of law. See Young Dental Mfg. Co. v. Q3 Special Prods., Inc., 112 F.3d 1137, 1141, 42 U.S.P.Q.2D (BNA) 1589, 1592 (Fed. Cir. 1997). We review a grant of summary judgment de novo. See id. Our review, as with any infringement inquiry, must first engage the legal step of construing the asserted claims and then dispose of the factual infringement issue by comparing the accused device with the asserted claims in accordance with their proper construction. See, e.g., Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1302, 41 U.S.P.Q.2D (BNA) 1364, 1366 (Fed. Cir. 1997).

In determining the proper meaning of the claims, "we first consider the so-called intrinsic evidence, i.e., the claims, the written description, and, if in evidence, the prosecution history." Digital Biometrics, Inc. v. Identiq, Inc., 149 F.3d 1335, 1347, 47 U.S.P.Q.2D (BNA) 1418, 1424 (Fed. Cir. 1998). Moreover, "if upon examination of this intrinsic evidence the meaning of the claim language is sufficiently clear, resort to extrinsic evidence, such as treatises and technical references, as well as expert testimony when appropriate, should not be necessary." Id.

Unambiguous intrinsic evidence in turn provides sufficient input to the rules of claim construction, in particular in this case, the rule that explicit statements made by a patent applicant during prosecution to distinguish a claimed invention over prior art may serve to narrow the scope of a claim. See Southwall Techs. Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."); Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448, 452, 227 U.S.P.Q. (BNA) 293, 296 (Fed. Cir. 1985) (stating that the prosecution history, which includes "all express representations made by or on behalf of the applicant to the examiner to induce a patent grant," limits the interpretation of the claims "so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance").

2 Our recourse to language emphasizing the relinquishing of subject matter during prosecution should not be construed to undermine the "clear distinction between following the statements in the prosecution history in defining a claim term, and the doctrine of prosecution history estoppel, which limits expansion of the protection under the doctrine of equivalents when a claim has been distinguished over relevant prior art." Southwall, 54 F.3d at 1578, 34 U.S.P.Q.2D (BNA) at 1679 (citing
That explicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations makes sense, because "the public has a right to rely on such definitive statements made during prosecution." Digital Biometrics, 149 F.3d at 1347, 47 U.S.P.Q.2D (BNA) at 1427 (pointing to "notice [as] an important function of the patent prosecution process, as reflected by the [patent] statute itself"). Indeed, "by distinguishing the claimed invention over the prior art, an applicant is indicating what the claims do not cover." Ekchian, 104 F.3d at 1304, 41 U.S.P.Q.2D (BNA) at 1368. Therefore, a patentee, after relinquishing subject matter to distinguish a prior art reference asserted by the PTO during prosecution, "cannot during subsequent litigation escape reliance [by the defendant] upon this unambiguous surrender of subject matter." Southwall, 54 F.3d at 1581, 34 U.S.P.Q.2D (BNA) at 1681; Ekchian, 104 F.3d at 1304, 41 U.S.P.Q.2D (BNA) at 1368 (citing Southwall). Accordingly, "claims may not be construed one way in order to obtain their allowance and in a different way against accused infringers." Southwall, 54 F.3d at 1576 (citing Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1562, 19 U.S.P.Q.2D (BNA) 1500, 1504 (Fed. Cir. 1991)); see also Alpex Computer Corp. v. Nintendo Co. Ltd., 102 F.3d 1214, 1221, 40 U.S.P.Q.2D (BNA) 1667, 1672 (Fed. Cir. 1996) ("Therefore, because Alpex admitted during prosecution that its claims do not cover a video display system based on shift registers as in Okuda . . . . Alpex's claims cannot now be construed to cover the [accused device], which possesses the same structural and functional traits as Okuda."). This principle applies with equal force to arguments made by a patentee to sustain the patentability of claims during reexamination. See, e.g., Cole v. Kimberly-Clark Corp., 102 F.3d 524, 532, 41 U.S.P.Q.2D (BNA) 1001, 1007 (Fed. Cir. 1996) ("We also believe the district court correctly interpreted the prosecution history to require that the 'perforation means' limitation cannot be construed to include ultrasonic bonded seams. Cole surrendered ultrasonic bonded seams in her requests for reexamination.").

IV

As discussed, Spectrum argued to the PTO during reexamination that the limitation in claims 2 and 11 requiring that the bottom side of Spectrum's claimed crate merge with the bottom edge of the central portion of the front wall distinguishes over DePutter because in DePutter's crate the bottom side merges with the top edge, and not the bottom edge, of the central portion of the front wall. Spectrum now argues that this claim limitation does not exclude infringement by a crate in which the bottom side merges with both the bottom edge and the top edge of the central portion of the front wall, because the open claim term "comprising" permits the addition of any elements to those listed in the claims. In effect, Spectrum argues for a broad construction of the phrase "wherein the bottom side merges with at least a substantial portion of the bottom edge of the central portion of the front wall" that does not exclude the possibility that the bottom side merges with both the bottom edge and the top edge of the central portion of the front wall.

Spectrum's argument must fail. If "comprising" permits the addition of any elements, then it not only permits the addition of merger of the bottom side with the top edge of the central portion of the front wall, but also allows the addition of a downward-projecting appendage to the central portion along the line at which the bottom side merges with both the bottom and top edges of the central portion, thus transforming merger of the bottom side with the bottom and top edges of the central portion into merger of the bottom side with the top edge alone. But this embodiment is in the prior art. Therefore, to have sustained the patentability of claims 2 and 11 over the prior art asserted during reexamination, Spectrum must have relinquished from the language of these claims the possibility that merger of the bottom side also occurs with the top edge of the central portion of the front wall. Were the result otherwise, Spectrum could cut off the downward-projecting central portion of DePutter's front wall, be left with a crate in which the bottom side merges with both the bottom and top edges of the central portion of the remaining front wall, add back the downward projection with "comprising,", and thus hold DePutter liable for infringement. This Spectrum clearly cannot do.

Spectrum's reliance on Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271, 229 U.S.P.Q. (BNA) 805, 812 (Fed. Cir. 1986), as support for its attempt to encompass the additional, unrejected elements in Sterilite's accused crate within the confines of claims 2 and 11 through recourse to the recitation in these claims of the term "comprising" is thus misplaced. To be sure, Moleculon acknowledges that "a transitional term such as 'comprising' . . . . does not exclude additional unrejected elements, or steps (in the case of a method claim)," 793 F.2d at 1271, 229 U.S.P.Q. (BNA) at 812, but in the very same sentence the court limited this broad view of "comprising" to avoid altering the scope of the particular claim step at issue. See id. Neither may the term "comprising" alter the scope of the merger element in the claim at issue here. "Comprising" is
not a weasel word with which to abrogate claim limitations. See id.

To summarize, we conclude that the limitation in claims 2 and 11 requiring that the bottom side merge with the bottom edge of the central portion of the front wall excludes the possibility that the bottom side also merges with the top edge. The claim term "comprising" cannot restore this excluded subject matter.

5. "[W]herein, along a [180 degree] meridian, the distance between the inner zone and the peripheral edge is less than 1.3mm." Used in '903 patent, claims 29 and 34.

"[A] superior distance A being defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, and an inferior distance B being defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, and wherein .33A</=B</=A." Used in '903 patent, claim 38.

The dispute is about how to measure the distances described in the two limitations above. CooperVision believes the distance between two points on a contact lens should be measured by the straight line distance between the two points. CIBA believes that the distance between the two points should be measured over the lens curvature (the "arc length").

CooperVision proposes "the distance, measured as a straight line, between the ballast periphery and the peripheral edge of the contact lens body is less than about     mm along the     [degree] meridian. The     meridian is found by starting with zero degrees at the 3:00 position and moving counterclockwise around the circle of the lens." CIBA proposes "the distance, measured along the curve of the anterior face of the lens, between the outermost edge of the inner zone and the peripheral edge of the contact lens body is less than approximately     mm along the     meridian, which is found by starting with zero degrees at the 3:00 position and moving counterclockwise around the circle of the lens."

The Toric Patents do not explain how claim distances are to be calculated. However, the specification explains that "thickness is measured radially with respect to the curvature of the anterior face" of the lens. '903 patent, col. 9, ll. 24-26 (Italics added). There is no indication that the peripheral zone width and A:B ratio measurements should be made in any other way. Given that the patent discloses a methodology of measuring thickness using the curvature of the anterior face, the court finds that method of measurement is appropriate for these claims. 4

4 CIBA further directs the court's attention to the specification referring to a "flattened" lens. See '903 patent, col. 5, ll. 22-40 ("For simplicity, the elevational views shown herein are flattened, with the base sphere removed . . . so that the particular surfaces and thickness of the present invention can be more clearly illustrated."(Italics Added.)) This may lend credence to CIBA's argument that a linear measurement may be made after a contact lens is flattened, which is tantamount to measuring the arc length.

The court defines these terms, respectively, as:

"[W]herein, along a [180 degree] meridian, the distance between the inner zone and the peripheral edge is less than 1.3mm” means: the distance between the outermost edge of the inner zone and the peripheral edge of the contact lens body, measured along the curve of the anterior face of the lens, is less than approximately 1.3 mm along the [degree] meridian, which is found by starting with zero degrees at the 3:00 position and moving counterclockwise around the circle of the lens.

"[A] superior distance A being defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, and an inferior distance B being defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, and wherein .33A</=B</=A” means: Where A is defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, measured along the curve of the anterior face of the lens, and B is defined along the vertical meridian and within the inner zone from the optic zone to the peripheral zone, measured
along the curve of the anterior face of the lens, then .33A</=B</=A.

A. The ‘231 Patent

On appeal, Backyard challenges the district court's claim construction, arguing that "mesh" should be construed to mean "non-woven, non-welded sheet material with a pattern of holes." It argues that the intrinsic evidence supports its construction and that the doctrine of claim differentiation lends further support. Backyard also relies on the examiner's allowance of a non-statutory disclaimer. Finally, Woodlink cross appeals, arguing that the district court improperly denied its motion for summary judgment as to invalidity of the ‘231 patent in light of the Finn patent.

Based on the intrinsic evidence, we hold that the district court properly found the claim term "mesh" means "expanded mesh." As the district court noted, the term "mesh" alone is ambiguous. Indeed neither party argues for a broad construction without limitation. Thus, because the meaning of "mesh" is ambiguous, we look to the specification and the prosecution history.

In light of the specification, the term "mesh" should be construed as "expanded mesh." As Woodlink properly points out, "expanded" modifies "mesh" eighteen times in the specification. Moreover, in a number of those instances that do not use "expanded" as a modifier for "mesh," the independent use of "mesh" simply refers back to the immediately prior reference, which was modified by "expanded." Beyond the sheer volume of references to "expanded mesh," the specification also suggests that the novelty of the invention resides in the use of expanded mesh. The specification particularly points out that expanded mesh does not require welding, weaving, or galvanizing. ‘231 patent, col. 1, ll. 37-38. It also notes that using expanded mesh allows one to regulate the size of the openings during manufacture, facilitating customization to attract particular bird species. ‘231 patent, col. 1, ll. 41-45.

As with the specification, the prosecution history suggests limiting the construction of "mesh" to "expanded mesh." In particular, the prosecution history repeatedly distinguishes between expanded and non-expanded mesh. These distinctions, discussed below in the context of determining whether Backyard should be estopped from arguing infringement under the doctrine of equivalents, all suggest construing "mesh" as "expanded mesh."

Further, we do not find support for Backyard's arguments regarding the doctrine of claim differentiation. Dependent claim 10 claims: "A bird feeder according to claim 1, wherein the mesh is expanded." As such, Backyard argues, the court should not read the "expanded" limitation into independent claim 1. As the district court correctly pointed out, however, the doctrine of claim differentiation only creates a presumption that claims cover different inventions. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991) (citing Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391 (Ct. Cl. 1967)). Here, the evidence favors limiting the construction of "mesh" to "expanded mesh," thereby overcoming the presumption.

Finally, based on the facts of this particular case, we do not rely on the patent examiner's allowance of a non-statutory, rather than a statutory, disclaimer to overcome a double-patenting rejection. We are not bound by what the examiner perceived to be the scope of the claim. Here, the parent application specifically claimed coverage of "expanded mesh" in the sole independent claim. See U.S. Pat. No. 5,826,539, col. 4, ll. 8-15. The only change between the parent and continuation application was the removal of the term "expanded" modifying "mesh" in the independent claim. Otherwise, the Abstract, Specification, and Drawings are identical, focusing, as discussed above, on the use of "expanded mesh." Thus, based on the totality of the intrinsic evidence, we find that the term "mesh" must be construed as "expanded mesh."

Reviewing the grant of summary judgment of non-infringement de novo, we find no remaining issues of material fact based on the claim construction. Specifically, Woodlink does not literally infringe because it uses perforated mesh, not expanded mesh, in manufacturing its birdfeeders. As to infringement under the doctrine of equivalents, the district court properly applied the doctrine of prosecution history estoppel. The prosecution history contains a number of arguments that limit the range of equivalents. 1 First, in an affidavit submitted to the Patent and Trademark Office, the patentee favorably compared his own "expanded mesh" feeders to those employing "non-expanded mesh." Second, the prosecuting attorney repeatedly distinguished the invention over prior-art, non-expanded-mesh feeders. Third, the patentee submitted tests illustrating the
advantages of using expanded mesh over non-expanded mesh.

1 Notably, the prosecution history referred to here (and used by the district court) relates to the parent application, App. No. 08/679,049, July 12, 1996, issued as U.S. Patent No. 5,826,539 on October 27, 1998. We use this earlier prosecution history because "the prosecution history of a parent application may be considered in construing claim terms." Masco Corp. v. United States, 303 F.3d 1316, 1324 (Fed. Cir. 2002).

Mars' first argument is that the Preamble in Claim 1 ("A metal detector . . .") sets forth part of the invention that the inventor desired to define and protect, and that therefore its language may constitute a claim limitation. Coinco responds that even if the Preamble is a claim limitation, a "metal detector" would include a metal coin detector, and Mars' accused products would infringe that limitation because the accused Mars' products detect the presence of metal coins. In response to Coinco's argument that "a metal detector," as used in the '857 patent should be interpreted as anything which detects metal, Mars asserts that it is the "identifying" and "distinguishing" aspects of metal detection, rather than mere detection, which are relevant and useful in the context of the '857 patent. Therefore, Mars argues, all claims should be interpreted to require metal detection that also identifies and distinguishes coins and other objects. Mars points to the specification and the prosecution history for support. At column 2, lines 7-13 and lines 30-34, and column 6, lines 34-38, the specification emphasizes the importance of being able to distinguish and identify slugs and similar foreign and domestic coins. Another example is the reference to a "principal object" of the invention as "distinguishing between and identifying objects such as coins..." '857 patent, col. 3, lines 31-36. As to the prosecution history, in response to a rejection of Claim 1 and other claims, applicants argued that they had devised "a novel detecting device for accurately distinguishing between metal objects, such as between coins" and producing an output with characteristics "representative" of an object such as a coin. DX 640, Prosecution History, p. 61, line 1 of Remarks - p. 62, line 7. This is a clear expression of the applicants' understanding of the "distinguishing" aspect of their invention.

Nonetheless, the Court is unable to accept Mars' claim construction argument that "metal detector" should be interpreted to mean a metal detector that is also capable of recognizing individual coins and other objects and distinguishing one from another. While the specification and the prosecution history certainly provide some support for this interpretation, the claim language itself supports Coinco's interpretation because the language of claim 1 does not limit the claim in the way Mars suggests. See Merrill v. Yeomans, 94 U.S. 568, 570, 24 L. Ed. 235, 1877 Dec. Comm'r Pat. 279 (1876) (explaining that the claims are "of primary importance, in the effort to ascertain precisely what it is that is patented"); Markman, 52 F.3d at 980 ("The written description part of the specification itself does not delimit the right to exclude. That is the function and purpose of the claims."). Claim 1 refers to "an object to be detected" (col. 14, line 53) and the reference to "characteristics ... representative of the object" (col. 14, lines 60-61) is insufficient to support a claim limitation of identifying and distinguishing among coins as well as detecting them. The specification also to some extent supports Coinco's interpretation. At column 3, lines 46-48, it states:

Another object of the invention is to make use of the damped wave characteristics of a pulsed oscillator circuit in a metal detecting device.

This part of the specification makes no mention of the identifying and distinguishing functions that are at the heart of Mars' claim construction argument. The Court does not believe that the Preamble to Claim 1 should be expanded beyond the plain meaning of "metal detector," even where some other intrinsic evidence supports a qualification of that plain meaning, i.e., a metal detector which also can identify, and distinguish among, objects detected. Where, as here, the meaning of the relevant claim term is clear, the specification and prosecution history should not be used to modify that meaning. See, e.g., Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) ("In some cases, the ordinary meaning of claim language as understood by a person of ordinary skill in the art may be readily apparent even to lay judges, and claim construction in such cases
involves little more than the application of the widely accepted meaning of commonly understood words.

The Court's construction is also supported by the doctrine of claim differentiation. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1368 (Fed. Cir. 2007) (explaining that the doctrine of claim differentiation is based on "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope" (citation and internal quotations omitted)). Claim 25, not at issue herein, refers to a circuit for detecting and discriminating between objects, but is otherwise similar in this context to other claims, including Claim 1 (emphasis added). If Mars' claim interpretation argument were accepted, Claim 25 would have little independent meaning.

2540

b. "metal interconnect layer"

The scope of an independent claim incorporates the embodiments recited in dependent claims. See Transmatic, Inc. v. Gulton Industries, Inc., 53 F.3d 1270, 1277 (Fed. Cir. 1995). Claim 1 of the '785 patent claims the method of "forming a metal interconnect layer above the substrate surface." Claim 3 recites the method of claim 1 "wherein said metal interconnect layer comprises an aluminum alloy." The court agrees with EMI that the term "metal interconnect layer" includes interconnects made of metal alloys. The specification lends further support for this construction, as it states that the most common metal interconnects are made "of aluminum or aluminum alloys." The term "metal interconnect layer" thus refers either to pure elemental metals or to alloys.

C. A Metal Wood-Type Golf Club Head (Claim 13)

The Court concludes that the subject term should be construed to refer to a type of golf club that had traditionally been made of wood. Drivers and fairway woods are such clubs. There may be others. Spalding seeks to have the term include all metal clubs which have a hollow head structure. 12 This would encompass, it appears, certain clubs that were not traditionally made of wood, but which were made of metal in the first place. On this theory, the claim language would include products which Spalding refers to as "trouble woods, hybrid irons (wood, utility woods, etc.) composed of hollow, metal bodies or shells." Defendants' Response at 31.

12 Traditionally, woods were made of solid wood, but metal "wood" clubs are hollow or filled with foam. Metal clubs are not solid metal. In fact, a solid metal wood-type club may well be too heavy for practical use.

The Court concludes that metal clubs with hollow heads other than drivers and fairway woods may well be analogous to wood-type golf clubs. But, they are not wood-type golf clubs in the context of the patent unless they are types of clubs that were traditionally made of wood.

In connection with the dispute over the construction of "wood-type club", the parties debate whether the following language adds a limitation to the claim: "thereby providing added strength and stability to the club head and minimizing pinging of the club head when ball contact is made."

This time, 13 Spalding seeks to have the Court treat the quoted language as a non-limiting description of the effect of the previously described structure. Plaintiff, this time, 14 seeks to have the Court give operative meaning to the claim language. The Court finds that, to the extent this subsidiary argument is relevant, it finds Plaintiff's position more sound. That is, the quoted claim language should not be ignored altogether. However, this subsidiary issue does not appear to be significant in regard to the "wood-type club" issue.
13 Compare Spalding's attempts to have the Court include as limitations language not even found in claims.

14 Compare Plaintiff's attempts to ignore other claim limitation language.

The term "meter" appears in independent Claims 1, 38, 40, and 49 of the '529 Patent. Plaintiffs propose that "meter" should be construed as "a device that transports, feeds, or dispenses something at a controllable, determinable, or regular rate." Defendants, on the other hand, contend that "meter" should be construed as "a structure that measures the amount of something as it flows."

The ordinary meaning of the term "meter" is "an instrument for measuring and recording the amount of something (as water, gas, electricity) as it flows" or "a device (as a valve in a carburetor) that regulates the flow of a fluid" or, in its verb form, "to supply (fuel, oil, or other fluid) in a measured or regulated amount." Webster's Third New International Dictionary 1422 (1993). The intrinsic evidence of the '529 Patent supports a construction that is more consistent with the latter two definitions of the term. The specification states that the device includes "a meter connected to the bin for controllably releasing a desired amount of the particulate matter from the bin into the conduit while disallowing entry of the liquid carrier to the bin." ('529, c. 1, ll: 46-51.) In the '529 Patent, the meter does not serve to measure precisely the amount of material that flows through the meter. Rather, measuring occurs during the initial calibration step of the device. Once calibration occurs, the meter dispenses or supplies the particulate matter at a controlled release rate, but does not measure or record the amount of material that passes through. Thus, the Court construes the term "meter" to mean a device that transports, feeds, or dispenses particulate matter at a controllable, determinable, or regular rate.

The district court correctly construed "metered manner" to require that the claimed invention must perform the feeding function using a predetermined amount of dough. Although the claim itself does not explicitly define "metered manner," the patentee successfully argued before the PTO that the "novel feeding arrangement" "assured a uniform feeding of the mixed ingredients by feeding small predetermined amounts of the entire mixture towards the extruder," in order to overcome the examiner's rejection over the prior art. The patentee's use of the language "predetermined amounts" in describing the "novel" feeding arrangement which the patentee argued expressly distinguished the '575 patent from the prior art, precludes the patentee from now broadening the meaning of "metered manner" to cover all uniform feeding of dough. The declaration of its expert that the claim itself does not require "uniform packing" or "metered" amounts of dough cannot now change what it defined the term to mean. Therefore, in light of the patentee's explicit definition of the term during the prosecution as meaning both measured and uniform amounts, and the fact that the ordinary meaning of "metered" is either measured or uniform and that nothing in the claims or specification precludes this definition of "metered," the correct meaning of "metered manner" is both measured and uniform. Because Popeil's device undisputably drops random amounts of dough into the extrusion chamber, there is no genuine issue of fact, and, as the district court correctly concluded, Popeil is entitled to summary judgment of non-infringement.
The parties propose different constructions for the term "method." Essentially, the difference in the parties' proposed constructions lies in the order of the steps described in claim one of the '400 patent. Caponey proposes: "the method imposes no specific order to the sequence in which all the steps are to be performed." (Pl.'s Claim Construction Br. 9.) ADA Enterprises proposes: "the claimed method must be performed in the order provided." (Def.'s Claim Construction Br. 5.)

"Unless the steps of a method actually recite an order, the steps are not ordinarily construed to require one. However, such a result can ensue when the method steps implicitly require that they be performed in the order written." Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1342 (Fed. Cir. 2001) (internal quotation marks and citations omitted).

The court construes the word "method" in the '400 patent to mean the steps described in claim one must be performed in the order listed in the claim, but that additional steps may be added. This result is dictated by logic and the language of the claim. Further, the parties agreed to this construction at the Markman hearing. (Markman H'g Tr. 57-58).

A. "A method for amusing pet animals"

The analysis of this preamble mirrors that of Claims 1 and 11, in that Plaintiff relied upon the amusement element to avoid prior art references during prosecution, and shall be limited by this. Accordingly, the preamble phrase "a method for amusing pet animals" shall be construed as: "A method for the amusement of an animal kept for pleasure or companionship, rather than solely for utility."

As a preliminary matter, I briefly address the preamble of Claim 14: "A method for monitoring the percentage of blood alcohol content of a human subject, said method comprising the steps of . . . ." '919 Patent col.13 ll.66-68. Although I expound on the import of this language below, this clause deserves quick mention at the outset. The phrase "comprising the steps of" signifies in patent parlance that the claim is an "open claim," meaning that the steps listed are not exclusive and an allegedly infringing device is not saved by the presence of additional elements outside the scope of the patent. See Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1371-72 (Fed. Cir. 2005).

Step (c) of Claim 14 describes a "method for monitoring the percentage of blood alcohol content of a human subject, said method comprising the [step] of . . . measuring a percentage of alcohol expelled through the subject's skin into said measurement device and storing a measurement result." '919 Patent col.13 l.66 to col.14 l.8. The parties disagree sharply about the extent of activity that a person of ordinary skill in the art would interpret this language to cover. Plaintiff essentially argues that Step (c) covers any measurement of the amount of alcohol expelled through a subject's skin.

Defendants, on the other hand, assert that Step (c), viewed more broadly as part of Claim 14 as a whole, only covers devices which measure the amount of alcohol expelled through a subject's skin and then convert that measurement to a percentage of blood alcohol content.

The parties have agreed for the purposes of this motion that a person of ordinary skill in the art is someone having at least a Bachelor of Science Degree in Biology, Mechanical Engineering, or Forensic Science and at least two years of experience in blood, breath, and/or transdermal alcohol testing. Pl.'s Br. in Opp'n to Defs.' Mot. for Sum. J. of Non-Infringement and Invalidity [Docket No. 139] at 45; Reply Br. in Supp. of Defs.' Mot. for Sum. J. of Non-Infringement and Invalidity [Docket No. 151] at 26.

Plaintiff argues that "the customary and ordinary meaning of 'measuring a percentage of alcohol expelled through the skin' could not possibly mean measuring blood alcohol content." Pl.'s Br. in Opp'n to Defs.' Mot. for Sum. J. of Non-Infringement and Invalidity [Docket No. 139] ("Pl.'s Opp'n Br.") at 23. Instead, plaintiff argues that "[u]sing the ordinary and customary
meaning of these terms, step (c) of claim 14 means ascertaining the proportion of the alcohol expelled through the skin into the device." Id. It is true that Step (c) by itself only describes "measuring a percentage of alcohol expelled through the subject's skin," and not the measuring of blood alcohol content. In plain language, "measure" means to ascertain a figure, extent, or amount. See Merriam-Webster's Collegiate Dictionary 769 (11th ed. 2007). "Percentage" means a part of a whole -- in other words, a proportion -- expressed in hundredths. 3 See Merriam-Webster's Collegiate Dictionary 918 (11th ed. 2007). By definition then, percentage is a relative term requiring more than mere detection of an amount in relation to a set unit of measure; it typically requires a calculation whereby one takes the amount measured, divides it by some larger whole, then multiplies it by 100.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 Although Phillips cautions courts against undue reliance on dictionary definitions, the case also recognized dictionaries' utility in claim construction where a dictionary definition is supported by intrinsic evidence. See Phillips, 415 F.3d at 1322. The '919 Patent's specification supports a conclusion that a person having ordinary skill in the relevant art would interpret the words "measure" and "percentage" as used in the patent in accordance with the common dictionary definition. For example, the '919 Patent's summary of the invention states that

[t]he system provides for the continuous monitoring of a subject's blood alcohol level by measuring the level of ethanol that has been expelled through the subject's skin. The system determines the subject's blood alcohol level by measuring the amount of ethanol at a predetermined distance away from the subject's skin, which provides an indication of the relative amount of ethanol in the subject's blood.

'919 Patent col.3 ll.23-31.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

J. Robert Zettl, whom the parties have accepted as a person of ordinary skill in the relevant art, on being questioned by defendants' counsel at a deposition in this case, testified as follows:

Q. But the SCRAM, is it fair to say in your opinion, is designed to yield a measurement that is analogous to a measurement from a breathalyzer?

A. Yes.

....

Q. So in letter (c), just so I'm clear, when it says "measuring a percentage of alcohol," to you, that means measuring so that you get a measurement that's in grams per 100 milliliters?

[Objection omitted]

A. Yes, since it says "percentage of alcohol."

Q. (By Mr. Tucker) By "percentage of alcohol," you mean blood alcohol concentration?

A. Yes.

Therefore, Step (c) contemplates more than the mere ascertaining of the amount of alcohol emitted from a person's skin. Some calculation or series of calculations must take place which lead to the identified percentage. It is true that Step (c) does not indicate literally that the calculation undergone at this stage arrives at a measure of blood alcohol content. However, Step (c) is only one part of the overall patented process of Claim 14. Claim 14 as a whole does indicate that such a calculation is to occur; its preambulatory language explains that the invention consists of a "method for monitoring the percentage of blood alcohol content of a human subject." '919 Patent col.13 ll.66-67. It is axiomatic that a device could not
"monitor" one's percentage of blood alcohol content without first determining what that percentage is.

The most logical step in Claim 14 which accommodates the calculation of a percentage of blood alcohol content is Step (c). Therefore, because a person of ordinary skill in the art would understand Claim 14 to require a calculation of blood alcohol content, I construe Step (c) as including that calculation. See Bell Commc'ns Research, Inc. v. Vitalink Commc'ns Corp., 55 F.3d 615, 620 (Fed. Cir. 1995) ("[W]hen the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects."). Reading this requirement into Step (c) is consistent with Federal Circuit law instructing district courts to read patent terms in their context. See Phillips, 415 F.3d at 1314 (noting that "the context in which a term is used in the asserted claim can be highly instructive"). Therefore, Step (c) in particular and Claim 14 as a whole are infringed only where the raw measurement of the amount of alcohol emitted from a subject is in some way converted to a percentage of blood alcohol content.

The conclusion that Step (c) as part of Claim 14 requires both measurement of the amount of alcohol emitted and a calculation of blood alcohol content is well supported in the '919 Patent's specification. For example, the specification notes that "[t]he sensor measures the amount of alcohol being emitted through the subject's skin thereby providing an indication of the subject's blood alcohol content." '919 Patent, col.6 ll.64-66 (emphasis added). To get from an "indication" to an actual blood alcohol content, some calculation must be made. One possible series of calculations is described in the '919 Patent:

If alcohol is present, block 1002 transfers to block 1004 which calculates the amount of alcohol present. The amount of alcohol present is calculated by comparing a reading from the sensor 218 to the known readings in the characterization data to produce a base line blood alcohol result. This base line reading is then multiplied by the calibration factor which compensates for sensor drift from the time the characterization was performed. This result is further multiplied by a temperature coefficient to provide the final amount of blood alcohol present.

'919 Patent col.11 ll.28-39. Additional support for the Court's interpretation is found elsewhere in the specification:

. "There is need in the art then for an apparatus and method to passively test the blood alcohol content of a human subject. . . . The present invention satisfies these and other needs." '919 Patent col.2 ll.45-61.

. "It is an aspect of the present invention to perform testing which indicates the blood alcohol content of a human subject." '919 Patent col.2 ll.64-66.

. "The system provides for the continuous monitoring of a subject's blood alcohol level by measuring the level of ethanol that has been expelled through the subject's skin." '919 Patent col.3 ll.23-26.

. "Typically, the device can be attached to a subject's arm or leg to provide periodic monitoring of the subject's blood alcohol content." '919 Patent col.3 ll.42-44.

. "The portable blood alcohol monitor 102 analyzes the readings taken to determine whether the subject's blood alcohol content has exceeded a predetermined level." '919 Patent col.4 ll.47-50.

. "The characterization data is data that was created by characterizing the fuel cell 302 (FIG. 3) and is used to adjust the readings obtained from the fuel cell to obtain a more accurate percentage of alcohol content." '919 Patent col.8 ll.49-53.

Footnotes - End Footnotes

4 For the purposes of infringement analysis there is a "distinction between a claim to a product, device, or apparatus, all of which are tangible items, and a claim to a process, which consists of a series of acts or steps. A process consists of doing something, and therefore has to be carried out or performed." NTP, Inc. v. Research In Motion, Ltd., 418 F.3d 1282, 1317 (Fed. Cir. 2005) (quoting In re Kollar, 286 F.3d 1326, 1332 (Fed. Cir. 2002) (internal quotation marks, omission marks, and alteration marks omitted). The '919 Patent specification does not distinguish between descriptions of its method claims, of which Claim 14 is one, and its product claims. That distinction seems inconsequential to the claim construction at hand.
While the Federal Circuit admonishes courts against importing limitations from a patent's specification, it also notes that the specification is particularly useful in construing patent claims as a person skilled in the relevant art would interpret them. See Phillips, 415 F.3d at 1323 ("[T]he line between construing terms and importing limitations can be discerned with reasonable certainty and predictability if the court's focus remains on understanding how a person of ordinary skill in the art would understand the claim terms.")

Here, construing Claim 14 to include both measurement of the amount of alcohol emitted from a subject's skin and conversion of that figure to a percentage of blood alcohol content is not imported from the '919 Patent's specification. Rather, the specification is consulted to give context to Step (c) and Claim 14 as a whole, assisting the Court in understanding how a person of ordinary skill in the art would view the claim. The portions of the specification excerpted above do not contradict what is the plain reading of Claim 14 in light of its introductory clause; rather, they support it.

In summary, infringement of Claim 14 can occur only where a device not only measures the amount of alcohol being emitted from an individual's skin, but uses that measurement to calculate a percentage of blood alcohol content. Claim 14 does not preclude others from merely testing for the presence or amount of alcohol emitted through a person's skin. Rather, Claim 14 of the '919 Patent entitles the owner of that patent to exclude others from making, using, selling, offering to sell, or importing a device that otherwise infringes and measures the presence and level of alcohol in an individual and then converts that measurement into a percentage of blood alcohol content. See 35 U.S.C. § 271(a) (2006); NTP, Inc. v. Research in Motion, Ltd., 418 F.3d 1282, 1317 (Fed. Cir. 2005) ("A method or process consists of one or more operative steps, and, accordingly, it is well established that a patent for a method or process is not infringed unless all steps or stages of the claimed process are utilized." (internal quotation marks and alteration marks omitted).

2547

1. "Microscope station" (claims 16, 17, 21)

Cytyc argues that the term "microscope station" should be construed as "equipment, not including a cell analysis instrument, at which a human operator performs microscope analyses." Tripath objects to the exclusion of cell analysis instruments and the requirement of a human operator. It proposes a broader definition: "a place equipped with a microscope." The claims and the specification support the narrower definition.

Claim 16(b) describes three elements that each microscope within a "microscope station" must include: a movable slide stage, a means for computing that stores and shares information about the slide being examined, and a means for automatically recording location information of interest of the slide stage during slide examination. Claim 16 by itself appears to define "microscope station" broadly as any location equipped with a microscope that satisfies the three requirements. However, four dependent claims suggest a narrower meaning.

Claim 17 adds to the microscope station a terminal for a database having information relevant to the appropriate examination of the slide specimen. Claim 22 adds a means for recording time information, such as how long a previous user spent viewing a particular location of interest on the slide. These claims indicate that a "microscope station" is a place where a user can store and retrieve information about slides for use in diagnosis.

Claims 21 and 24 further narrow the definition of "microscope station" by distinguishing a "cell analysis instrument". Claim 21 states that the network "includes at least one cell analysis instrument and that at least one microscope station "comprises a terminal for receipt of analysis from the cell analysis instrument." Claim 24 states that separate microscope stations are "linked to a cell analysis instrument" and "analysis data from the cell analysis instrument and results of the microscope examination are simultaneously available at the separate microscope stations for review thereRouting." These two claims make clear that the cell analysis instrument is a specialized machine for producing analytical data. In contrast, the "microscope station" receives the data from the cell analysis instrument and other sources. Its purpose is to allow users to access the data.

The specification supports this distinction between a "microscope station" and a "cell analysis instrument." The specification repeatedly refers to "microscope stations" as places where end users access data. For example, the Detailed Description of the Invention states:
The network reviewing method comprises the step of causing the computer storage means to be independently accessible by at least two separate microscope stations in a network, each of the stations comprising a microscope and computer means, with each of the microscope stations being separately individually linked to at least one computer means capable of recalling the stored movements and location information from the . . . microscope used in the original examination.

Id. at col. 3, 11. 13-23. Another passage reads:

recalling, at one or more of said microscope stations from said computer storage means, a computer generated image of a slide . . . , onto the viewing means of the respective microscope station for review.

Id. at col. 3, 1.65 -- col. 4, 1. 1.

Beginning at column 8, line 10, the specification describes in detail how a pathologist uses the "microscope station" in practice. Id. at col. 8, 1. 10 -- col 9, 1. 24. The pathologist interacts with the "microscope station" by placing the slide on the stage, finding locations of interest, viewing data on a screen, and printing reports. Id. These examples show that a "microscope station" is a place where different types of information is gathered, stored, and viewed. It follows that the "microscope stations" must have some means for data storage, sharing, and access by a human.

The description of "cell analysis instrument" is quite different. The specification provides examples of four types of instruments: hemotology analyzers, PAP smear analyzers, image analyzers, and laser scanning cytometers. Id. at col. 9, 11. 25-27. n13 These instruments scan slides and process the data from these slides. Id. at col. 9, 11. 27-30. They then isolate, locate, and characterize cells based on the scan data. Id. Importantly for purposes of claim construction, the specification states that "one or more of the instruments can be interfaced with at least one of the microscope stations on the network in accordance with the present invention." Id. at col. 9, 11. 30-33. This last sentence makes clear that a cell analysis instrument is not part of a "microscope station." It can be linked to a "microscope station" so that its data can be accessed there, but it is a separate apparatus.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n13 Claims 25-28 specifically claim each of these four types of instruments.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Figure 1 illustrates these differences between "microscope station" and "cell analysis instrument" in a preferred embodiment. The Cytology Lab Pathfinders and Anatomic Pathology Pathfinders, represented by the number one, consist of a microscope equipped with stage position encoders, a microprocessor, a display screen and a keyboard. Id. at col. 6, 11. 54-58. These are "microscope stations." Id. The Pathfinder DS System, numbers four and eight, has similar components, and is also a "microscope station." The Laser Scanning Cytometer, which is a type of cell analysis instrument, is shown as number five. Id. at col. 9, 11. 36-37. It is depicted as a separate entity, with different components than the "microscope stations." Id. at col. 9, 11. 37-39.

TriPath contends that Figure 1 depicts four types of "microscope stations": Cytology Lab Pathfinders (number one), Anatomic Pathology Pathfinder (number one), Pathfinder DS System (numbers four and eight) and the Laser Scanning Cytometer (number five). It contends that these "stations" meet the requirements of claim 16 because each includes a microscope, some sort of microprocessor or personal computer, and a microscope staged encoder.

However, TriPath fails to recognize that the requirements of claim 16(b) refer only to the microscope component of a "microscope station." Claim 16(b) leaves open the possibility that a "microscope station" has other features." n14 As I explained above, the specification and the other claims define these other features in such a way that a "microscope station" is a place, separate from a cell analysis instrument, where a human conducts cell analysis and review.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n14 The preamble of claim 16 (b) provides: "A network of interconnected microscope stations comprising . . ." From this
language, it is not clear whether "comprising" refers to the "network" or the "microscope stations." However, claims 16(a) and (b) refer to the connections between microscope stations, suggesting that claim 16 read as a whole describes the elements comprising the network, not the microscope stations.

TriPath also argues for a broader construction on the grounds that independent claims must be construed independently of and irrespective of dependent claims which specify a specific structure. It relies on Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991), for this proposition. However, Laitram does not apply to the present situation.

In Laitram, independent claim 21 contained a means-plus-function claim relating to a "means for joining" ends of a conveyer belt. Id. at 1534-35. Dependent claim 24 specifically required a cross-member as a means for joining the ends of the belt. Id. at 1538. Laitram argued that claim 21 could not also require a cross-member because that interpretation would violate the prohibition against reading limitations from a dependent claim into the independent claim and would frustrate the doctrine of claim differentiation. Id. The Federal Circuit rejected both of these arguments. Id. It held that the interpretation of "means for joining" as requiring a cross-member was proper because it derived from the specification, not the dependent claims. Id. It also found that claim differentiation was a judicially developed presumption that did not override § 112, P 6, the statute authorizing means-plus-function claims. Id.

In this case, unlike Laitram, the term "microscope station" itself is not a means-plus-function claim governed by § 112, P 6. Claim 16(b)(ii) and (iii) are means-plus-function claims describing two elements of the microscopes in a "microscope station." I do not read claims 17, 21, 22 and 24 as enumerating the means required to complete the functions in claims 16(b)(ii) and (iii) or as limiting claim 16 to the structures in the dependent claims. Rather, I look at the dependent claims to shed light on the meaning of a term that appears in the independent claim and three of the four dependent claims. See Phillips, 415 F.3d 1314 ("Other claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term.").

Finally, TriPath claims that Cytyc's proposed construction is incorrect because it would invalidate the preferred embodiment. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, (Fed. Cir. 1996) (holding that an interpretation that invalidates the preferred embodiment is "rarely, if ever, correct and would require highly persuasive evidentiary support"). This is simply not the case. Figure 1 represents the preferred embodiment. 969 patent at col. 6, ll. 54-55. As discussed earlier, the Cytology Lab Pathfinders and the Anatomic Pathology Pathfinders are "microscope stations" that contain the movable slide stage, means for computing, and means for automatically recording required by claim 16. Id. at col. 6, ll. 56-58. The Pathfinder DS System, depicted as numbers four and eight, is also a "microscope station" according to claim 16. Id. col. 7, ll. 50-55; col 8, ll. 28-29, 59-61. The Laser Scanning Cytometer is a "cell analysis instrument" that meets the requirements of claims 21, 24 and 28. Therefore, the preferred embodiment falls within the claims and is presumably valid.

In sum, the specification and claims support a narrow reading of "microscope station." Thus, I construe "microscope station" to be equipment, not including a cell analysis instrument, at which a human operator performs analysis.

---

1. "Mid-section." Consistent with the claim language and its ordinary meaning, 1 and the specification, 2 the court construes "mid-section" to mean "a portion of the substrate that is between the substrate ends but does not extend to the substrate ends, and includes the middle point of the substrate."

---

1 D.I. 148, ex. 6 at 722 (defining "mid-section" as "a section midway between the extremes"); D.I. 151, ex. E at 752 (same); Random House Dictionary of the English Language 1218 (2d ed. 1987) (defining "midway" as "in the middle of the way or distance; halfway").

2 '264 patent, col. 2, ll. 5-7; col. 6, ll. 6-9; figs. 1-10.

---

PUBPAT
iv. Middle bridge portion

Plaintiffs argue that "middle bridge portion" means "the middle part of the eyeglasses spanning the nose." The Defendant has not indicated any disagreement with this interpretation.

The court finds that "middle bridge portion" means "the middle part of the eyeglasses spanning the nose."

E. Mildly Agitating

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposed Construction</th>

</tr>
</thead>
<tbody>
<tr>
<td>mildly agitated</td>
<td>being on the low end of an absolute scale which would involve less agitation than agitating the contents of the mixing chamber.</td>
<td>agitated gently, not significantly, on the low end of an absolute scale, and less than the level of agitation that results from inserting foam in the mixing chamber outside the lump ring.</td>
</tr>
</tbody>
</table>

The next term appears in both claims 25 and 36: the foam is inserted into the discharge conduit, "such that the foam is mildly agitated to thereby minimize destruction of the foam while uniformly dispersing the foam in the aqueous gypsum dispersion." As mentioned earlier, Judge Hart has already construed "mildly agitated." He concluded that, "mildly" should be given "its ordinary meaning of being on the low end of an absolute scale." United States Gypsum Co., 508 F. Supp. 2d at 620. In so doing, Judge Hart expressly rejected USG's contention that "mildly agitate" means "less agitation than is applied when mixing the gypsum and water to form the aqueous dispersion." Id. In distinguishing the language of the patent from USG's proffered definition of "mild" as a relative term, Judge Hart said: "Those statements [in the patent], however, are true even if 'mildly agitated' is construed as an absolute term. Viewed as points on an absolute scale, 'mildly agitated' would involve less agitation than 'agitating the contents of the mixing chamber' as stated in claim 25, or 'mixing and agitating calcined gypsum and water' as stated in claim 36." Id.

Notwithstanding Judge Hart's standing construction, Defendants claim "mildly agitated" is indefinite because the patent does not identify "where the dividing line is between mild and not mild agitation." (Defs' Br. at 20). The bright line Defendants would require is not a precondition for definiteness. Use of terms of degree are ubiquitous in patent claims; such usages, when serving reasonably to describe the claimed subject matter to those skilled in the field of invention, and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the courts. Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 821 (Fed. Cir. 1988). The term "mildly agitating" is sufficiently clear to avoid indefiniteness. It clearly admits of a construction, since Judge Hart was able to provide one. Further, even had the court not previously construed the term, the court finds that a person skilled in wallboard construction would have understood "mildly agitating" to mean roughly what Judge Hart understood it to mean: agitating on the low end of an absolute scale. The court sees no reason to reconsider or depart from Judge Hart's construction.

If the court affirms Judge Hart's standing construction, Defendants urge, it should at least modify his language by defining mild as "gentle and not significant." The court finds the proposed modification adds nothing of value to the ordinary meaning of "mild," which does not require further definition. If anything, use of the language "not significant" is misleading. In common usage, mild is defined as "moderate in action or effect," and "not being or involving what is extreme." MERRIAM
WEBSTER COLLEGIATE DICTIONARY at 738 (10th ed. 1997). Insignificant is defined as "lacking meaning" and "not worth considering." Id. at 605. On the absolute scale proposed by Judge Hart, "mild" (being on the low end) seems to mean something greater than "not significant" (being almost nothing).

Both parties' proposed constructions suggest alternative points in the wallboard manufacturing process to serve as a reference point for determining just how much agitation is mild. The parties disagree, however, on which point in the process should serve as the reference. Plaintiff's proposed construction incorporates Judge Hart's language that mild agitation "would involve less agitation than agitating the contents of the mixing chamber," but Plaintiff takes Judge Hart's statement out of context. In effect, Plaintiff seeks to use the level of agitation in the mixer as a ceiling, under which everything is mild agitation. This is the very argument Judge Hart previously rejected. While Judge Hart's opinion indicates that "mild agitation" could be described by referring to other points in the manufacturing process, it makes clear "mild agitation" is to be defined as a point on absolute scale. In short, while the court has held that the parties may call witnesses and introduce evidence that compare levels of agitation at different points in the manufacturing process (i.e. the mixing chamber, lump ring, and discharge conduit, etc.), the definition of "mild agitation" itself is not relative. Mild agitation is assuredly less than the agitation that occurs in the mixer, but not every level of agitation below that of the mixer could accurately be called mild.

The court rejects Defendants' proposed construction for similar reasons. Defendants rely on the second embodiment of the patent, which depicts the foam intake inside the mixer, but outside the "lump ring," the outer periphery of the mixer. (Defs' Br. at 22-23; '635 Patent, Figure 3, element 30.) The patent does not identify the configuration depicted in the second embodiment as giving rise to "mild agitation." As a result, Defendants urge the court to draw the negative inference that the second embodiment acts as a limit on the level of agitation that could constitute "mild." Defendant's logic is tortured. It does not follow that because the patent fails to refer to the second embodiment as mild, it therefore must be understood to describe the second embodiment as "not mild." The disputed claims themselves make no reference to the "lump ring" and the description of the embodiment makes it clear that the claims are not limited to the type of mixing chamber depicted in the second embodiment. ('635 Patent col. 8, ll. 4-9) ("It should be appreciated that this depiction of an agitator is relatively simplistic and meant only to indicate the basic principles of agitators commonly employed . . . . Many different, and often more complex, agitator designs (having vertically extending pins or paddles, different shapes, etc.) can also be employed.") There is simply no reason to conform the term "mildly agitated" by measuring it against a substantially unrelated embodiment of the patent. Further, as Judge Hart observed, it is not necessary to define "mildly agitate" by comparing it to other steps in the manufacturing process. The ordinary meaning of the word "mild" is sufficient.

The court adheres to Judge Hart's existing construction. Accordingly, the court adopts the following construction for "mildly agitating": "agitating on the low-end of an absolute scale."

14. "Milling"
"Milling" is construed to mean, "using a machine to remove."

Claim 1 of the '099 patent recites a step of "milling a region of said core to a controlled depth so as to form a cavity which exposes at least one contact pad of said electronic element." '099 patent, col. 9:3-5. Claims 1 and 22 of the '367 patent recite virtually identical steps.

Claim 1 of the '099 patent recites a step of "milling a region of said core to a controlled depth so as to form a cavity which exposes at least one contact pad of said electronic element." '099 patent, col. 9:3-5. Claims 1 and 22 of the '367 patent recite virtually identical steps.

Plaintiff proposes that the ordinary meaning of the word milling, from the Dictionary of Composite Materials, p. 91, is "[a] machining process for removal of material." (Pl. Br. at 25.) The specifications are consistent with this construction, stating that each card undergoes a controlled-depth milling operation to form a window or cavity. '099 patent, col. 8:1-6. Defendant does not object, so I adopt Plaintiff's definition.
1. Claim interpretation

I begin with construction of the claims, which requires reference to the specification, the patent claims and the Prosecution history. Fonar Corp. v. Johnson & Johnson and Technicare Corp., 821 F.2d 627, 631 (Fed. Cir. 1987), cert. denied, 484 U.S. 1027, 98 L. Ed. 2d 764, 108 S. Ct. 751 (1988). The '049 patent contains three claims. All of these claims require the step of

immediately guiding the web and felt contiguous relative to each other around a vacuum guide roll disposed downstream relative to the dryer, the arrangement being such that the web is supported by the felt during passage of the web along a minimal felt draw between the dryer and the guide roll.

By itself, the claim language offers little to suggest the meaning of "minimal felt draw," making it necessary to turn to other sources to help in interpretation. As I have found, the only discussion of "minimal felt draw" contained in the specification of the '049 patent is set forth at column 2, lines 18-26. It indicates that the joint run of the web and felt between the dryers and the guide rolls be minimal. This language is consistent with Voith's position that "minimal felt draw" means that the vacuum rolls and the dryer rolls are in close proximity.

Voith asserts that the Prosecution history gives additional support to its position. Voith refers specifically to the attempts of Beloit's patent agent to distinguish Beloit's invention over the '762 patent on the ground that the felt draw in the '762 patent was not minimal as required in application claim 11. Although Beloit's efforts to distinguish from the prior art are consistent with the conclusion that minimal felt draw is synonymous with placing rollers in close Proximity to one another, they do not mandate that conclusion. Finally, Voith cites Wedel's testimony from the June 23, 1994 deposition to the effect that "minimal felt draw" means the vacuum roll is in close proximity to the dryer.

In opposition, Beloit cites only to another part of Wedel's deposition in which he defined "close proximity" as being "several feet," which is much longer than the joint runs otherwise described to this court. Assuming for now that it is proper to give weight to the post-issuance statements of an inventor when interpreting a patent, this evidence does not refute the argument that the term minimal felt draw means that the rolls are in close proximity to one another.

The parties cast but dim light on the meaning of minimal felt draw. However, Voith has the better of the argument. I agree that the fair construction of the term "minimal felt draw" is that the felt draw is kept to a minimal length, requiring the adjacent rolls to be "in close proximity." This raises the second question: whether a determination of the meaning of "close proximity" in a prior litigation between the same parties involving a different patent precludes Beloit from asserting infringement of the '049 patent.

2. Issue preclusion

Under the doctrine of issue preclusion, also called collateral estoppel, a judgment on the merits in an earlier suit precludes relitigation in a later suit of issues actually litigated and determined in the first suit. In re Freeman, 30 F.3d 1459, 1465 (Fed. Cir. 1994) (citing Lawlor v. National Screen Serv. Corp., 349 U.S. 322, 326, 99 L. Ed. 1122, 75 S. Ct. 865 (1955)). Issue preclusion does not require that the patent claim in the first and second suits be identical. Id. "Rather, application of issue preclusion centers around whether an issue of law or fact has been previously litigated." Id. (citing International Order of Job's Daughters v. Lindeburg & Co., 727 F.2d 1087, 1091 (Fed. Cir. 1984)). "Issue preclusion is appropriate only if (1) the issue is identical to one decided in the first action; (2) the issue was actually litigated in the first action; (3) resolution of the issue was essential to a final judgment in the first action; and (4) the party to be precluded had a full and fair opportunity to litigate the issue in the first: action." Id. (citing A.B. Dick Co. v. Burroughs Corp., 713 F.2d 700, 702 (Fed. Cir. 1983).

The parties agree that as a matter of law, the question whether the vacuum guide roll of Consolidated's Rapids 16 machine was "in close Proximity to the dryer" was an issue essential to the judgment in the prior litigation and was actually decided by the finder of fact. The parties agree also that Beloit had a full and fair opportunity to litigate this issue and did not appeal the jury's finding on that issue. The remaining question is whether the issue of the meaning of "close proximity" in the present litigation is identical to the issue of the meaning of "close proximity" in the prior litigation. Because I conclude that it is not, I will deny Voith's motion for partial summary judgment on this issue.

Delineating the issue on which litigation is foreclosed is one of the most difficult problems in applying the doctrine of issue preclusion. Restatement (Second) of Judgments § 27 comment c (1980); Freeman, 30 F.3d at 1465. The problem entails a
balancing of important interests: a desire not to deprive a litigant of an adequate day in court and a desire to avoid repetitious litigation of what is essentially the same dispute. Id.

Voith urges construction of the meaning of "close proximity" in the context of the '049 patent as identical to "close proximity" in the context of the prior litigation. But, as Justice Holmes stated in Towne v. Eisner, 245 U.S. 418, 425, 62 L. Ed. 372, 38 S. Ct. 158 (1918): "A word is not a crystal, transparent and unchanged; it is the skin of a living thought and may vary greatly in color and content according to the circumstances and the time in which it issued."

The words "close proximity" carry different meanings in different contexts. To say that two blades of grass are in close proximity to one another may connote a scale of inches, whereas a statement that two buildings are in close proximity might indicate a scale of several yards. The facts in this case present two situations of a much closer nature. In both instances, "close proximity" is used to describe the distance between rollers in a paper making machine. It is an inescapable fact, however, that the term is being examined in the context of one patent and a jury question posed at a trial involving a separate and distinct patent.

Because the doctrine of issue preclusion rests upon principles of fairness, courts have some discretion to decide whether the doctrine is appropriate in particular instances. Freeman, 30 F.3d at 1467 (citing A.B. Dick, 713 F.2d at 702). I am not convinced that it would be fair to preclude Beloit from arguing that the Combined Locks No. 7 machine contains vacuum and dryer rolls in close proximity (thus employing minimal felt draw) on the basis of the facts presented in the trial of this specific Patent. "A device not previously before the court, and shown to differ from those structures previously litigated, requires determination on its own facts." Del Mar Avionics, Inc. v. Quinton Instrument Co., 836 F.2d 1320, 1324 (Fed. Cir. 1987).

2553

7. "Minimal . . . Ram Pressure"

The word "minimal" in the phrase "minimal first ram pressure" means, "The smallest or least amount [of ram pressure] necessary to accomplish the designated step."

At the outset, I note that I am focusing here solely on the words "minimal…ram pressure" rather than on the entire phrase "minimal first ram pressure." This is because the parties greatly dispute what "first" means as used in this phrase, and this is not the place to discuss that issue. This phrase appears in claim 16 of the '207 patent, and claim 15 of the '155 patent:

positioning said core in a laminator apparatus, and subjecting said core to a heat and pressure cycle . . . comprising the steps of: (i) heating said core in said laminator, in the presence of a minimal first ram pressure.

'207, col. 8:19-23; '155 patent, col. 8:15-19.

The specifications for the '207 patent indicate that "minimal" means "little or no." Col. 4:41-44.

Defendant proposes that this phrase means "applying little or no pressure to the 'core,' but in no event a ram pressure more than about 10 pounds per square inch."

According to Defendant, "minimal" is not a technical term, and it is defined in Webster's to mean "relating to or being a minimum: constituting the least possible size, number or degree." (Def. Br. at 36.) "Minimum" is defined in Webster's to mean, "the least quantity assignable, admissible, or possible." (Id.) To this extent, Defendant is precisely correct.

But Oberthur goes on to argue Leighton has capped the minimal first ram pressure at 10 pounds per square inch for all applications. (Def. Br. at 37.) It derives this number from language in the specifications for the '099 and '367 patents (whose claims, interestingly, do not use the phrase "minimal….ram pressure"). The '099 patent (col. 5:56-61) says this about the amount of pressure required for a particular step:

One book is positioned in laminator . . . the first lamination cycle is initiated by closing laminator platens preferably
applying little or no ram pressure to book. This is preferably done using hydraulic pressure, and a pressure not to exceed about 10 pounds per square inch is believed sufficient for most applications.

'099 patent, col. 5:56-61 (numerical references omitted.)

I reject Defendant's proposed definition. The word "minimal" does not connote any sort of numeric cap. And to the extent the references in the '099 and '367 specifications to 10 p.s.i. are relevant at all, I am constrained to note that the patentee expressly states that he "believes" this amount of pressure will be "sufficient for most applications" -- indicating that it is entirely possible that slightly more pressure (how much is not specified) may be needed for some applications.

But nothing in Webster's or the patent specifications remotely suggests that 10 p.s.i. of ram pressure will qualify as "the least possible size" in every possible case. Therefore, I reject Defendant's argument.

6. Minimally Sufficient Pressure

This phrase is found in Claim 23 of the '575 patent.

Phrase: Minimally sufficient pressure

Construction: A summation of the pressure necessary to prevent airway collapse in the absence of respiratory efforts (collapse due to airway structure, muscle tone, and body position) and the pressure necessary to overcome the collapsing and splinting effects of respiratory efforts.

Reasoning: The real dispute between the parties as to the appropriate construction of this phrase stems from a disagreement as to how many of the claim elements, and how much of the patent specification, must be read into this phrase. Defendant contends that illustrative equations from the patent specification must be used to define this phrase and that claim language relating to proportionality, fluid characteristic, and first gain, must be read into the phrase. Plaintiffs argue that this phrase has been used consistently throughout the family of patents, and has a clearly established meaning. We agree with plaintiffs.

While the formulas urged by defendant may help illustrate the phrase, the phrase is not limited to them. Any additional limitations from the remainder of this Claim regarding proportionality, fluid characteristic, or gains can be addressed in the infringement analysis. However, in terms of construing the disputed phrase "minimally sufficient pressure", we find that the phrase is given a clear and consistent definition throughout the family of patents.

F. Minimize Destruction of the Foam

Claim Term  | Plaintiff's Proposed Construction | Defendants' Proposed Construction
---|---|---
[to thereby] minimize destruction of the foam | to reduce foam loss by inserting foam in such a way that it is "mildly agitated." | the least possible destruction of the foam

The next term follows the "mildly agitated" language in both claims 25 and 36. Defendants first contend that this term is indefinite because the term "offers no guidance or standard for measuring how much foam can be destroyed and still be minimized." (Defs' Br. at 24.) Again, Defendants urge a level of specificity that is not required for definiteness under the Patent Act. Claims must be read in view of the specification, of which they are a part. Markman, 52 F.3d at 978. Reading the claim in context, a person skilled in wallboard manufacture would understand the scope of the subject matter. As the background portion of the patent explains, a fundamental problem in wallboard manufacture is how best to "disperse the
foam relatively uniformly in the slurry while not destroying any more of the foam or producing any larger variations in bubble size than is unavoidable." (‘635 Patent, col. 2, ll. 49-52.) In that context, the disputed terms of claims 25 and 36--"to thereby minimize destruction of foam while uniformly dispersing the foam in the aqueous gypsum dispersion"--clearly indicate the scope of the subject matter. When read together, the terms indicate the invention achieves low levels of foam destruction while maintaining an even distribution of foam. This indication is sufficiently definite. The patent need not give an accounting of foam destruction with mathematical precision in order to be valid. Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir. 1996).

Again, each party's proposed construction of this term is unsatisfying. Plaintiff urges the court to consider the term in context and to construe "minimize" as to "reduce foam loss by inserting foam in such a way that it is mildly agitated." The court notes, first, that use of the term "mildly agitated" here is redundant. Although the court must consider terms in context, each term may be construed without repetition. The court further rejects Plaintiff's proposed construction of the term "to minimize" as meaning "to reduce." In its ordinary meaning, "to minimize," meaning "to keep to a minimum," has a more specific connotation than merely "to reduce." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY at 741 (10th ed. 1997). In this usage, to minimize denotes an effort to reduce to the "least quantity assignable, admissible, or possible." Id. Defendants' proposed construction, "the least possible destruction of foam," comes closer to this connotation. Defendant's proposed construction is imperfect, however. It implies that "least possible" is a finite quantity; but the context of the claim suggests "minimize" is used here as a relative term. Efforts to minimize must be balanced against effort to achieve uniformity and other circumstances of manufacture.

Accordingly the court adopts the following construction for "minimize destruction of the foam": "to reduce destruction of the foam as much as possible given the circumstances."

"A minimum distance outward from the outer spatial volume expandable surface"

Cytoc's proposed construction
Xoft's proposed construction
(no construction required) (indefinite)

Claims 2, 24, 32, and 36 all include the phrase "the target tissue being defined between the outer spatial volume expandable surface and a minimum distance outward from the outer spatial volume expandable surface." 14 Xoft asserts that "minimum distance" is indefinite in this context because the patent does not explain how the minimum distance is determined.

Here, "minimum" does not appear to add anything to the patent. The "target tissue" is the tissue outside of the outer chamber for a fixed distance in all directions, but this fixed distance or how one determines it are not explained. It seems that one skilled in the art would know how to determine the distance. See Tr. at 85-89. But the patent may as well read "a short distance outward" or "a determined distance outward" or merely "a distance outward."

Cytoc claims that specification provides some guidance and that the minimum distance may in some instances be between half and one centimeter. The specification does state that

device A can readily be configured to provide a dose in a therapeutic range, say between 40 to 60 Gray, at a distance between 0.5 and 1.0 cm from the outer spatial volume for an outer spatial volume having a diameter of 4.0 cm and being in contact with the resection cavity wall.
'204 patent, col. 6, ll. 31-35. However, Cytyc neglects to mention that "device A" is "an interstitial brachytherapy apparatus . . . such as those employed in U.S. Pat. No. 5,429,582, having a single spatial volume 50 filled with a radioactive material in solution." '204 patent, col. 6, ll. 3-7. In any case, this discussion does not use the phrases "target tissue" or "a minimum distance outward." Nevertheless, Xoft has presented no evidence that one skilled in the art would not understand the phrase "the target tissue being defined between the outer spatial volume expandable surface and a minimum distance outward from the outer spatial volume expandable surface." Xoft has not met its burden of proving by clear and convincing evidence that this language is indefinite, and the court finds that no construction is necessary.

**Claim Language**

- A minimum distance outward from the outer spatial volume expandable surface

**Court's Construction**

- (no construction necessary)

The parties have requested construction of the phrase "minimum prescribed dose" and point out that the term appears in claims 2, 18, 24, 32, and 36 of the '204 patent. The parties do not argue that the term should be construed differently for different claims. However, claims 2, 24, 32, and 36 contain the phrase "minimum prescribed absorbed dose," and claim 18 contains the phrase "prescribed absorbed dose." These inconsistencies seem irrelevant, however, because the parties' dispute is whether any such doses should be limited to treatment of cancer cells or allowed to cover any potential therapeutic effects. The court's construction of "brachytherapy" limits the claims to treatments "at or near a tumor or other proliferative tissue disease site." Xoft's proposed construction is too narrow, and Cytyc's is too broad. However, in light of the construction of "brachytherapy," no construction of "minimum prescribed dose" or similar phrases is necessary.

**Claim Language**

- minimum prescribed dose

A. "Minimum Prescribed Absorbed Dose" Limitation in Claim 2 of the '204 Patent

In its motion for summary judgment of non-infringement, SenoRx contended that the multi-dwell position plans do not meet the "minimum prescribed absorbed dose" limitation to claim 2 of the '204 Patent. SenoRx's argument is that "minimum prescribed absorbed dose" means the total delivered dose to the target tissue. As a result, for any particular dwell position and source in a multi-dwell plan, the dose of radiation delivered to the tissue will be less than the minimum prescribed dose because the dose delivered by sources at other dwell positions contribute to the total dose. Thus, the multi-dwell position plans do not meet this limitation, and the court should grant summary judgment of non-infringement for these plans.

Hologic did not respond to this argument until its reply in support of its own motion for summary judgment and claimed that SenoRx had failed to previously disclose this non-infringement position. Hologic requested further briefing on this issue. The court granted leave for the parties to file supplemental briefing on this issue and withheld ruling on SenoRx's motion for summary judgment on claim 2 because the meaning of the "minimum prescribed absorbed dose" limitation was potentially dispositive.

Having reviewed the parties' supplemental briefs, the court finds that "minimum prescribed absorbed dose" means the total delivered dose to the target tissue. Three reasons support this construction. First, failing to interpret this language to mean
the total dose would read "prescribed" out of the claim. The plain meaning of a "prescribed" dose is the dose prescribed by a physician to be delivered to a patient during a course of radiation treatment. Hologic has provided no evidence that physicians ever prescribe less than the total dose to be delivered to the target tissue. Because a "claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so," Merck & Co., Inc. v. Teva Pharmaceuticals USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005), the court finds that "minimum prescribed absorbed dose" refers to the total delivered dose.

Second, this construction is supported by the specification. Claims are read in view of the specification, which is the "single best guide to the meaning of the disputed term." Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005). In the "Summary of the Invention" section of the specification, the patent states: "[t]he predetermined dose range is defined as being between a minimum prescribed absorbed dose for delivering therapeutic effects to tissue that may include cancer cells, and a maximum prescribed absorbed dose above which healthy tissue necrosis may result." '204 Patent 2:52-55 (emphasis added). Since the purpose of the invention is to deliver radiation to target tissue with a desired intensity without overexposing un-targeted tissue and causing healthy tissue necrosis (id. at 2:27-32), "maximum prescribed absorbed dose" must refer to the maximum total delivered dose to target tissue. After all, the objective is to keep the total delivered dose low enough such that it does not cause healthy tissue necrosis. Given that "maximum prescribed absorbed dose" refers to the maximum total delivered dose, one of ordinary skill in the art would logically conclude that "minimum prescribed absorbed dose" refers to the minimum total delivered dose.

In addition, the specification also states: "After a prescribed absorbed dose has been delivered to tissue surrounding the apparatus, the apparatus is removed." Id. at 3:9-11. As pointed out by SenoRx, no balloon brachytherapy device is removed prior to the complete delivery of treatment. Therefore, this language in the specification also demonstrates that a "prescribed absorbed dose" must refer to the total delivered dose.

Third, this construction is supported by the language in dependent claim 5: "wherein the minimum prescribed absorbed dose is 40 Gray." '204 Patent 8:47-48. The parties agree that the total, cumulative dose delivered to tissue during treatment is 34 Gray, and Hologic concedes that in claim 5, the minimum prescribed absorbed dose of 40 Gray would likely be the total, cumulative dose delivered to tissue during a course of treatment. Plaintiffs' Supplemental Brief p. 3. The Federal Circuit has made it clear that claim language in other claims is useful in construing a disputed claim term:

Phillips, 415 F.3d at 1314. Therefore, the fact that "minimum prescribed absorbed dose" is understood to mean the total delivered dose in claim 5 is strong evidence that "minimum prescribed absorbed dose" also means total delivered dose when used in claim 2.

For the foregoing reasons, the court construes "minimum prescribed absorbed dose" to mean the total delivered dose to the target tissue. As a result, the court also grants summary judgment of non-infringement of claim 4 of the '204 Patent with respect to multi-dwell dose plans using the Contura.

3. Mirror Image

Memory chips that are mounted on a circuit board in such a manner that the memory chips on the second side are located directly behind the chips on the first side and the pins or leads of the corresponding memory chips are matched. In other words, the memory chips are mirror images in both location on the board and lead location.
97. Step 3. Micro-Waste Micro-Waste seeks to limit "mixing" in step 3 to that which "is accomplished by a conveying screw." This proposed limitation relies on the specifications in the '000 patent, which explain:

To improve a uniform temperature distribution … the conveying device may be constructed as a microwave field distributor in the form of a shaftless metal conveying screw. This conveying screw consequently produces not only a thorough mixing of the refuse to be heated, but also produces multiple reflections, with the result that the occasional differences in heating are smoothed out by direct and indirect heating. Improved mixing can furthermore be achieved by an inclined installation of the microwave chamber and the falling back of the granulated material produced thereby.

98. Industries contends that "mixing" refers generally to "any degree of combining or blending." This interpretation derives from the dictionary definition of "mix" as "to combine or blend into one mass," "to combine with another," or "to bring into close association." See WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY 761 (9th ed. 1987). None of these definitions specifies the extent to which the substances must be combined or blended.

99. There is "a heavy presumption that a claim term carries its ordinary and customary meaning." Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1327 (Fed. Cir. 2003). "Mixing," in its ordinary sense, does not contemplate the use of a specific device.

100. "[I]nterpreting what is meant by a word in a claim is not to be confused with adding an extraneous limitation, … which is improper." Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989) (quoting E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988)) (emphasis in the original); see also Rambus Inc. v. Infineon Techs. AG, 318 F.3d 1081, 1088 (Fed. Cir. 2003) ("While claims often receive their interpretative context from the specification and the prosecution history, courts may not read limitations into the claims.").

101. "[P]articular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." See Rhine v. Casio, Inc., 183 F.3d 1342, 1346 (Fed. Cir. 1999)) (quoting Electro Med. Sys. S.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054, 32 U.S.P.Q.2d 1017, 1021 (Fed. Cir. 1994)).

102. The specification cited by Micro-Waste does not mandate the use of a conveying screw. Cf. Rhine, 13 F.3d at 1346 (rejecting a proposed claim limitation, though it was included in the preferred embodiment, because the specification did not require it).

103. The Court construes "mixing" in Step 3 according to its common meaning, as any degree of combining or blending.

B. Mixing Chamber

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>mixing chamber</td>
<td>a device equipped with a powered moving agitator having one or more inlets through which at least calcined gypsum and water are inserted</td>
<td>an enclosed space where mixing occurs</td>
</tr>
</tbody>
</table>

The term "mixing chamber" is mentioned three times in Claim 25: first the calcined gypsum and water is inserted into the mixing chamber "through one or more inlets," then the chamber's contents are agitated to "form an aqueous dispersion of the calcined gypsum" and, finally, its contents are discharged "through a discharge outlet into a discharge conduit." (635 Patent Claim 25.) Defendants propose reading "mixing chamber" as "an enclosed space where mixing occurs." (Def's Opening Br. at 16.) In contrast, Plaintiff would limit the term based on its reading of the patent specification and prior art to include a chamber with a powered agitator. (Pl's Br. at 10.) Plaintiff also proposes requiring that any mixing chamber have "one or more inlets through which at least calcined gypsum and water are inserted." The court rejects that addition as
redundant: the claim already specifies that the mixing chamber has calcined gypsum and water inserted into it through one or more inlets. Cross Medical Products, Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293, 1307 (Fed. Cir. 2005).

According to Plaintiff, calcined gypsum and water cannot be agitated without a powered agitator, so when the claim refers to a mixing chamber in which those elements are agitated, it must be referring to a chamber "equipped with a powered moving agitator." (Pl's Br. at 10.) Limiting a patent to a preferred embodiment is improper, however. E.g., Howmedica Osteonics Corp. v. Wright Medical Technology, Inc., 540 F.3d 1337, 1345 (Fed. Cir. 2008). Plaintiff's contention appears to confuse the claim terms based on its contention of what the physically possible embodiments are. The court rejects this argument because Plaintiff provides no support for its assertion about how calcined gypsum and water must be agitated. The Patent specification specifically notes that an implementation of the device could use one of many different agitator designs. (‘635 Patent, col. 8, ll. 3-9.)

Where Plaintiff's proposed construction is too specific, Defendants' proposed construction is too general. (Def's Opening Br. at 16-18.) Any time two substances are placed in a chamber, some mixing occurs, but that does not require the conclusion that the enclosed space is a "mixing chamber." To distinguish between a chamber where mixing occurs incidentally and a chamber in which the mixing is intentional, the court relies on language from the Patent's background section that describes a mixing chamber as "containing a means for agitating the contents." (‘635 Patent, col. 1, ll. 48-52.) The court also finds that the word "chamber" needs no construction because the ordinary meaning is sufficient. O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1361 (Fed. Cir. 2008). Accordingly, the court adopts the following construction for "mixing chamber:" "a chamber containing a means for agitating its contents."

A. "Mixing"

Claim 1 of the '989 patent recites the following limitation, "mixing said delivered blood with said shunt blood flow." On its face, the meaning of this limitation is clear. Plaintiff suggests that mixing is, "the combining or putting together of two or more substances or things so that the constituents of each are diffused among those of the other(s)." 2 Defendant propose the following construction: "to bring together with a loss of separateness or identity." In support of this construction, defendants state that "Transonic represented to the PTO that 'complete mixing' is required by the claims." However, this assertion overstates plaintiff's representations to the PTO.

2 This definition is consistent with at least one dictionary definition which defines the verb to mix as, "(1)(a)(1) to combine or blend into one mass; (2) to combine with another; (b) to bring into close association; . . . [mix] may or may not imply loss of each element's identity." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY (1991).

During the prosecution of patent '989, the PTO notified plaintiffs that a prior art referred to as "Hester" rendered plaintiff's patent claim obvious. In response to this allegation, plaintiffs met with the PTO examiner. Pursuant to this interview, the examiner noted on September 16, 1994, "applicants will submit claims defining the method steps including mixing, measuring shunt flow, measuring flow in venous line . . . . Method presented by applicants overcomes the prior art record." No mention of "complete mixing" was made by the examiner. Plaintiff did explain to the PTO in written remarks submitted following the aforementioned interview that "complete mixing" was a primary feature of the invention. However, when read in context, plaintiff's isolated reference to "complete mixing" appears to be a careless misstatement. Nothing in the prosecution history suggests plaintiff, by virtue of this isolated misstatement, intended to impart a limited meaning to the generic term "mixing" for the purposes of the patent.

Therefore, because the term is unambiguous, the Court adopts plaintiff's proposed construction of the "mixing" limitation as follows: "the combining or putting together of two or more substances or things so that the constituents of each are diffused among those of the other(s)."
NMT’s appeal of the district court’s grant of Transonic’s motion for a preliminary injunction is based on the court’s claim construction. Claim construction is a question of law that we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2d (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). NMT argues that the court misconstrued the “mixing,” “changing,” and “calculating” and “determining” limitations of the asserted claims.

With regard to the “mixing” limitations, NMT raises the same arguments that it raised before the district court, asserting that the statement in the prosecution history regarding “complete mixing” limits the scope of the claims. NMT also cites external evidence, including correspondence between the inventors and their patent attorney and articles authored by the inventors, as demonstrating that “complete mixing” is a required aspect of the invention. Finally, NMT argues that the district court’s construction of “mixing” renders the term meaningless because mixing will always occur as a result of the “delivering” steps.

NMT argues that the “changing” limitations are drafted in step-plus-function form and, therefore, must be construed in accordance with 35 U.S.C. § 112, P6. When so construed, NMT argues, “changing” requires the addition of an indicator because that is the only corresponding act disclosed in the specification. NMT argues that even if the “changing” limitations are not construed under § 112, P6, statements in the prosecution history made by the applicant and by the examiner limit the “changing” step to the addition of an indicator. NMT also argues that the district court erred when it determined that the “blood parameter” that is changed to produce a “distinguishable blood characteristic” includes chemical and biological characteristics of the blood, in addition to the physical characteristics disclosed in the specification.

After careful consideration, we reject NMT’s arguments. We discern no error in the district court’s construction of the “mixing” and “changing” limitations or in its findings that those limitations are met by NMT’s Delta H method. However, as far as the “calculating” and “determining” limitations are concerned, we believe that the district court’s construction was too broad.

a. "Mobile, Road-Hauled"

Both the plaintiff and the defendants request the Court to construe the term "mobile, road-hauled." This term appears in the first sentence of claim 1, in which the patentee claims "[a] mobile, road-hauled aggregate material processing plant . . . ." The defendants request that the Court construe "mobile, road-hauled" to mean, “with a chassis mounted on wheels so that the plant can be towed or pulled along a road on its own wheels." The plaintiff opposes this definition and requests that the Court construe the term to mean, "mobile and capable of being hauled on a road, with or without any other devices." Neither party contends that "mobile, road-hauled" is a term that has special meaning within the art. Additionally, the parties agree that "road-hauled" limits the claim to an invention that can be transported on a road.

As a preliminary matter, the Court views "mobile, road-hauled" as a term with a straightforward definition for a lay person. The term "mobile" speaks for itself, and the Court may well encroach upon the province of the jury by acting as a mere thesaurus to interpret this term. Similarly, "road-hauled", in common parlance, means "capable of being hauled on a road." The term implies no additional restriction on how something is hauled on a road.

Nonetheless, the defendants contend that the patent specification limits the scope of "mobile, road-hauled." In particular, the defendants rely on the following passage from the patent specification:

[A screening plant's] processing capacity is heavily influenced by the ability to quickly and effectively deliver the processed material away from the plant. . . . (and while the manner in which such lateral conveyors are connected to the plant is relatively simple, where the processing plant is mobile, major problems arise in ensuring that the overall width and height of the mobile plant is within certain dimensions when carrying such conveyors during transport.)
The defendants argue that this passage demonstrates that the processing plant is described as "mobile" only in the sense that it could be transported over long distances.

The defendants also point out that the patent specification describes--both in writing and in drawings--a processing plant that is pulled on its own wheels when transported over long distances. Thus, the defendants maintain that, when the patentee described the invention as "road-hauled", he meant to limit the patent to a device that was capable of being pulled or towed on a road on its own wheels.

The Court agrees that, in the context of the entire patent, the term "mobile" refers to the plant's capacity to be moved over large distances. It is sufficiently clear to the Court that the essence of the invention was to create a screening plant that be moved among sites that are miles apart, and that the term "mobile" refers to this quality. However, the Court does not find that "road-hauled" was intended to limit the invention to a device that was towed or pulled on its own wheels. Being "towed or pulled" on its "own wheels" are qualities of the preferred embodiment of the invention, but they are not qualities that are implied by the term "road-hauled" itself, nor are they qualities that the Court views as essential to the invention. See Agfa Corp., 451 F.3d at 1376 (holding that is generally improper to incorporate limitations from a patent's preferred embodiment into the patent's claims).

The Court therefore construes "mobile, road-hauled" as meaning "capable of being hauled over long distances on a road, with or without other devices."

2565

7. "Mobile Scanner"

Plustek asks the Court to construe this term narrowly, as "a dual-mode portable scanner."

Syscan asks for a broader interpretation, as "a portable scanner, so lightweight that it can be used in any conditions."

The patentee distinguished prior art based on the patented scanner's ability to perform both opaque and transparent scanning:

According to one aspect of the present invention, the disclosed scanner comprises two demountable cases. The main case houses the image sensing module and the motion mechanism and the base case houses a second illumination source. The first illumination source in the image sensing module provides front illumination to an opaque scanning object while the second illumination source provides back illumination to a transparent scanning object, as such the disclosed scanner is capable of scanning both opaque and transparent materials, a dual scanning feature that has been long sought in the scanning market…21

Base module 404 is one of the distinctive features of the present invention. With base module 404 mounted to main module 402, mobile scanner 400 is capable of scanning both transparent and opaque documents.

Where the specification clearly shows a particular feature that is distinctive over the prior art, then the claims should be construed to include that feature. SciMed, 242 F.3d at 1342-44; see also CCS Fitness, Inc., 288 F.3d at 1366-67.

The Summary of the Invention of the '124 Patent states, "According to another aspect of the present invention, the disclosed scanner comprises two demountable cases" (2:59-60). The Specification further states that a "dual scanning feature" has been long sought in the scanning market (3:1-2) and further specified that (i) this embodiment of the mobile scanner has two demountable portions, a main case and a base case (5:24-27), emphasis added, (ii) in this embodiment the operator user uses a main module to scan paper-sheet materials (6:3-6), and (iii) the user can mount the base module onto the main module when the user decides to scan transparent materials (6:6-9), emphasis added.

The Specification makes clear that this embodiment of the mobile scanner can perform (i) a single-mode scanning feature solely for the opaque materials by using main case (2:60-66, 6:3-6), and (ii) another single-mode scanning feature for the transparent materials by mounting the base case to the main case (2:62-66, 5:43-46, 6:6-9).

The asserted claims can be assigned a narrower scope only if there is some indication in the patent or the prosecution history.
that the term was meant to have a more restrictive meaning as used in the patent, or a broader meaning was disclaimed during prosecution. Phillips v. AWH Corp., 415 F.3d 1303, 1316 (Fed. Cir. 2005) (en banc).

The Court construes this claim as "a portable scanner, so lightweight that it can be used in any conditions."

II. Claim Construction

The sole issue of claim construction here is the proper interpretation of the phrase "mobility of said labelled reagent within said test strip is facilitated by . . . a material comprising a sugar, in an amount effective to reduce interaction between said test strip and said labelled reagent." The parties argue for two different definitions of the term "mobility." The appellee (alleged infringer) asserts that mobility must be facilitated at the time of release of the reagent. The appellant (owner of the patent) asserts that mobility need only be facilitated either at the time of release or during the subsequent transit of the reagent, i.e., at some time during the operation. The claim construction adopted by the district court and now supported by appellee requires the sugar to "help or improve the release of the labelled reagent from the test strip." Opinion at 8 (emphasis added).

We begin claim construction analysis with the ordinary meaning of the disputed claim term. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567, (2002); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996). It is well settled that dictionaries provide evidence of a claim term's "ordinary meaning." Tex. Digital Sys., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567; CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 USPQ2d 1658 (Fed. Cir. 2002) (citing Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1344, 60 USPQ2d 1851, 1855 (Fed. Cir. 2001)). Such dictionaries include dictionaries of the English language, which in most cases will provide the proper definitions and usages, and technical dictionaries, encyclopedias and treatises, which may be used for established specialized meanings in particular fields of art. The parties here do not argue that the term "mobility" has an established specialized meaning in technical dictionaries, encyclopedias, or treatises of the relevant field of art, and we agree that "mobility" has no such specialized meaning. Accordingly, standard dictionaries of the English language are the proper source of ordinary meaning of the phrase.

We may look, therefore, to the dictionary definition of the claim term "mobility" as of the date the patents issued. 1 As with most words, the standard dictionaries offered multiple definitions. 2 "Where there are several common meanings for a claim term, the patent disclosure serves to point away from the improper meanings and toward the proper meaning." Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250, 48 USPQ2d 1117, 1122 (Fed. Cir. 1998); see also Tex. Digital Sys., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567, Here, our examination of the available definitions and the specification suggest that there is only one relevant definition, namely "the quality or state of being mobile: the capacity or facility of movement: MOVABILITY." Webster's at 1450. The pertinent definitions of the word "mobile" 3 are fully consistent with the second portion of the definition provided for "mobility," namely "the capacity or facility of movement." The claim term "facilitate" means "to make easier or less difficult." Id. at 812. Accordingly, the ordinary meaning of the phrase "mobility . . . is facilitated" is properly interpreted as: the capacity to make movement easier. 4

--- Footnotes ---

1 Our decisions have not always been consistent as to whether the pertinent date is the filing date of the application or the issue date of the patent. Compare Tex. Digital Sys., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567, No. 02-1032, with Schering Corp. v. Amgen, Inc., 222 F.3d 1347, 1353, 55 USPQ2d 1650, 1654 (Fed. Cir. 2000). No party here has suggested that the pertinent sources changed between the application and issuance dates.

2 Webster's defines mobility as "1: the quality or state of being mobile: the capacity or facility of movement: MOVABILITY . . . 2: the measure of the rate at which a solid is deformed under stress after the yield point has been exceeded 3a: the average speed at which either gaseous or electrolytic ions move under the influence of a unit potential gradient b: the average speed with which molecules in solution diffuse under the influence of a unit of osmotic pressure gradient." Webster's 3rd New International Dictionary 1450 (1968) (Webster's). The Oxford English Dictionary defines mobility as "the quality or condition of being mobile." 1 The Shorter Oxford English Dictionary 1267 (3d ed. 1947) (OED).
3 Webster's defines "mobile" as "capable of moving or being moved from one place to another . . . capable of moving or being moved about readily." Webster's at 1450. The Oxford English Dictionary defines "mobile" as "capable of movement; movable . . . characterized by facility of movement." 1 OED at 1266-67.

4 Appellee relies on part of the dictionary definition of the term "mobilize," which provides in part: "to put into movement or circulation: make mobile . . . to release (something stored in the body) for body use." Webster's at 1450. The dictionary, however, does not define the recited claim term "mobility," in terms of the word "mobilize." The definition of that term, therefore, is irrelevant.

Contrary to appellee's contention, there is nothing in the remainder of the claim language that introduces an ambiguity. In its analysis of the claim language, the district court found other language, which, it said, required that the term "mobility" be limited to mobility at the point of release. The district court concluded that "according to the claim language, 'release of the labelled reagent into mobile form' is caused by a liquid biological sample. The labelled reagent, therefore, becomes mobile when released from the test strip by urine or some other biological sample." Opinion at 5 (emphasis in original). The portion of the claim language cited by the district court, however, is not concerned with the expressly recited facilitation of mobility in the presence of sugar. The cited recitation merely states the obvious -- that mobility is commenced by the application of a liquid biological sample. The claim language relied upon by the district court does not restrict the meaning of "mobility" to the point of release. Indeed the language appears also to contemplate mobility after release. The recitation "release of the labelled reagent into mobile form," therefore, does not render the phrase "mobility . . . is facilitated" ambiguous. Similarly, contrary to the district court's view, the use of the claim term "upstream" to describe the position of the sugar prior to use does not limit mobility to the point of release, but rather simply limits the position of the sugar prior to use.

Appellee argues that the disputed language, when read in context, refers to "release," pointing out that "migration" of the reagent is separately recited, and that, therefore, "mobility" cannot include migration, i.e., movement after the point of release. That "mobility" and "migration" are used in the same claim, however, does not suggest that mobility excludes migration. The term "migration," in context, does not refer to the effect of the sugar. The claim language is equally consistent with the notion that "migration" is subsumed within "mobility."

Further weakening appellee's argument is the language of claims 17 and 18, which depend from claim 1, and provide "wherein mobility of said labelled reagent within said test strip is further facilitated by blocking excess binding sites within said test strip" respectively with "polyvinyl alcohol" or "protein." Claims 17-18 of the '871 patent (emphasis added). 5 A claim term used in multiple claims should be construed consistently ( CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1159, 42 USPQ2d 1577, 1586 (Fed. Cir. 1997), cert. denied, 522 U.S. 1109, 140 L. Ed. 2d 105, 118 S. Ct. 1039 (1998)), and it makes no difference that claims 17 and 18 refer to "mobility" facilitated respectively by polyvinyl alcohol and protein, rather than sugar. Construing the term "mobility" as used in claims 17 and 18 in the manner suggested by the district court and appellee would require the recited polyvinyl alcohol or protein to block excess binding sites at the point of release. The express language of the claims, however, requires the facilitation of mobility within the test strip. Further, the specification teaches that the polyvinyl alcohol or protein should be used throughout the test strip. '871 patent, col. 6, ll. 45-51. In short, considering the language of the claim as a whole and the use of the term in other claims, the term "mobility" is not ambiguous, but rather encompasses both release and migration.

5 Those claims provide:

17. The test device according to claim 1, wherein mobility of said labelled reagent within said test strip is further facilitated by blocking excess binding sites within said test strip with polyvinyl alcohol.

18. The test device according to claim 1, wherein mobility of said labelled reagent within said test strip is further facilitated by blocking excess binding sites within said test strip with a protein.
However, the general rule that the ordinary meaning of an unambiguous claim term controls is subject to two limitations. First, "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification . . . ". Vitronics Corp., 90 F.3d at 1582, 39 USPQ2d at 1576 (citing Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578, 38 USPQ2d 1126, 1129 (Fed. Cir. 1996), cert. denied, 519 U.S. 911, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996)); see also Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325, 63 USPQ2d 1374, 1381 (Fed. Cir. 2002) ("The patentee may demonstrate an intent to deviate from the ordinary and accustomed meaning of a claim term by including in the specification expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope."). Second, "even where the ordinary meaning of the claim is clear, it is well-established that the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Pall Corp. v. PTI Techs. Inc., 259 F.3d 1383, 1392, 59 USPQ2d 1763, 1769 (Fed. Cir. 2001) (citing Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 USPQ2d 1673, 1676 (Fed. Cir. 1995) cert. denied, 516 U.S. 987, 133 L. Ed. 2d 424, 116 S. Ct. 515 (1998)), vacated on other grounds, 153 L. Ed. 2d 152, 122 S. Ct. 2324 (2002); see also Robotic Vision Sys., Inc. v. View Eng'g, Inc., 189 F.3d 1370, 1375, 51 USPQ2d 1948, 1952 (Fed. Cir. 1999). A broader definition may be disclaimed, for example, where the examiner adopts a narrow definition and the applicant does not object. See Elkay Mfg. Co. v. Ebe Co. Mfg. Co., 192 F.3d 973, 979, 52 USPQ2d 1109, 1113-14 (Fed. Cir. 1999), cert. denied, 529 U.S. 1066, 146 L. Ed. 2d 482, 120 S. Ct. 1672 (2000) (holding that failure to respond to an examiner's reason for allowance functioned as a disavowal of a different interpretation of the claim).

Appellee does not cite to a definition provided in the specification for the disputed claim term. Appellee does, however, cite to the following statement by the patentee in the prosecution history as providing a disclaimer of claim scope:

The use of sugar in the invention to facilitate mobility of the labelled reagent is advantageous over conventional methodology within the art in part because the sugar allows rapid and effective release of the water-insoluble particulate direct label from the porous carrier when liquid is applied.

Amendment After Final Rejection of Dec. 19, 1995, at 2 (emphasis added). The cited passage, however, states only that the improvement is "in part . . . rapid and effective release." This is not a clear and unambiguous disclaimer of a claim scope that would cover mobility after release as required to deviate from the ordinary meaning of the claim recitation. See, e.g., N. Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1294, 55 USPQ2d 1065, 1075 (Fed. Cir. 2000) (requiring prosecution history statements cited as narrowing claim scope to have "reasonable clarity and deliberateness."); IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1439, 54 USPQ2d 1129, 1141 (Fed. Cir. 2000), cert. dismissed, 530 U.S. 1299, 147 L. Ed. 2d 1047, 121 S. Ct. 24 (2000) ("In light of the ambiguity of the patentee's statements and the subject matter actually disclosed in the references, we cannot say that the patentee clearly disavowed coverage of [claim scope].")

The appellee also cites a statement by the examiner assigned to the '675 application provided in a "Reasons for Allowance" that "the prior art currently of record neither teaches nor suggests use of a material comprising a sugar . . . to facilitate the release of the water-insoluble particulate from the direct label from the porous carrier when liquid is applied.

Amendment After Final Rejection of Dec. 19, 1995, at 2 (emphasis added). The cited passage, however, states only that the improvement is "in part . . . rapid and effective release." This is not a clear and unambiguous disclaimer of a claim scope that would cover mobility after release as required to deviate from the ordinary meaning of the claim recitation. See, e.g., N. Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1294, 55 USPQ2d 1065, 1075 (Fed. Cir. 2000) (requiring prosecution history statements cited as narrowing claim scope to have "reasonable clarity and deliberateness."); IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1439, 54 USPQ2d 1129, 1141 (Fed. Cir. 2000), cert. dismissed, 530 U.S. 1299, 147 L. Ed. 2d 1047, 121 S. Ct. 24 (2000) ("In light of the ambiguity of the patentee's statements and the subject matter actually disclosed in the references, we cannot say that the patentee clearly disavowed coverage of [claim scope].")

The appellee also cites a statement by the examiner assigned to the '675 application provided in a "Reasons for Allowance" that "the prior art currently of record neither teaches nor suggests use of a material comprising a sugar . . . to facilitate the release and mobility of the labelled reagent as claimed." (Appellee's Br. at 30 (emphasis added)). Based on this statement, the appellee argues that "the Patent Office explicitly stated that the Unipath Patents were granted because Unipath's claims, in contrast to the prior art, taught the use of sugar to facilitate the release of the labeled antibodies." Id. at 29-30. The examiner's statement, however, contradicts the appellee's position, as that statement does not interpret mobility as meaning the same thing as release. Instead, the examiner refers to mobility and release as two distinct concepts.

Because the plain meaning of the unambiguous recitation "mobility . . . is facilitated" is not contradicted by either the specification or prosecution history, that meaning must control. Accordingly the disputed phrase means "the capacity to make movement easier." The district court having applied an incorrect construction of the claims when granting summary judgment, that judgment is vacated. 6 The case is remanded to the district court for consideration of any remaining issues including issues of claim construction not addressed in this opinion and issues of validity and infringement of the claims as correctly construed.

6 Contrary to the district court's ruling of December 18, 2000, the issue of infringement is not whether the accused device "works without sugar." Motion Hearing at 54. The question of infringement to be addressed on remand is whether the capacity for movement of the labelled reagent is made easier by the use of sugar in the accused product.
An audio recording and tape measuring system for enabling the measurement of distance using a measuring tape and enabling the measurements to be orally enunciated and recorded for later use, said system comprising

A. a housing

B. a measuring tape securely mounted in the housing for being removed therefrom, whenever desired, to any desired length to enable measurements of distances to be made; and

C. an audio signal recording circuit mounted in the housing and construction for receiving and recording audible information and replaying the recorded information upon demand, said circuit comprising

a. circuit controlling and processing means,

b. an information storage address

1. controllably interconnected to the controlling and processing means for receiving signals corresponding to orally enunciated information,

2. storing said signals therein, and

3. transmitting, upon demand, stored signals to the circuit controlling and processing means,

c. a microphone connected to the circuit controlling and processing means and constructed for

1. receiving an orally enunciated signal corresponding to the desired information to be recorded, and

2. transmitting the signal to the controlling and processing means for transmission to and retention in the storage address,

d. output means connected to the circuit controlling and processing means for receiving signals retrieved from the storage address and presenting the stored information as an audible signal corresponding to the stored information, and

e. a mode selector switch connected to the circuit controlling and processing means and movable between a RECORD and a PLAY mode, enabling the circuit controlling and processing means to establish the desired operation of the recording circuit.

The Activation Switch

I find that the plain language of Claim 3(C)(e) does not require an activation switch that initiates the operation of the recording circuit in the selected mode and is distinct from the mode selector switch. Zircon argues that Claim 3’s mode selector switch’s primary purpose is to define the operation performed by an activation button. In its preferred embodiment,
this dual mode selector and activation switch combination allows one button to perform either record or play function from multiple address locations; a distinct mode selector/activation switch combination requires only one activation button per location. Zircon argues that this differs from the Repeater's design. The Repeater requires both a record and a play button. From a distinct activation switch and mode selector switch requirement, Zircon maintains, it is a short step to find that the Repeater does not infringe on Claim 3(C)(e) because it does not have modes as Claim 3 requires. Unfortunately for Zircon, I find that while the preferred embodiment does have dual mode selector switch/activation switches, the patent is not necessarily so limited. Transmatic, Inc. v. Gulton Industries Inc., 53 F.3d 1270, 1277 (Fed. Cir. 1995). For Zircon's argument to be persuasive, I must read distinct activation and mode selector switch requirements into Claim 3.

After careful reading I hold that Claim 3 does not require separate activation and mode selector switches; Claim 5 does. Where some claims are broad and others narrow, the narrow claim limitations cannot be read into the broader claim. Transmatic, 53 F.3d at 1277 (Fed. Cir. 1995); D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir. 1985). Given this legal rule and Claim 3's language, I hold that the Claim 3(C)(e) does not require an activation switch distinct from its mode selector.

--- Footnotes ---

2 Claim 5 reads as follows:

The audio recording and tape measuring system defined in claim 3, wherein said system is further defined as comprising

D. at least one activation switch mounted to the housing for ease of access by the user and constructed for transmitting an activation signal to the circuit controlling and processing means for initiating the operation of the audio signal recording circuit in the selected mode.

--- End Footnotes ---

The following sets forth the claims which are disputed by the parties.

Claim Term | Plaintiff's Proposed Construction | Defendants' Proposed Construction
---|---|---
"modernized"/"modernizing" | "exchanging at least one old component for at least one newer component" | "a more or less complete exchange of components in an elevator installation. This would include replacement of all the elevator components, including the elevator car, the elevator drive, the conveying cable, and the elevator control"

('861 Patent, claims 1, 2, 3, and 11); ('465 Patent, claims 1, 2, 3, and 10)

Inconstruing this term, both Plaintiff and Defendants rely upon the specification of the '465 Patent, 3 which states:

If after such a length of time a general overhaul of the elevator installation is needed, the components of the elevator installation are often old in terms of technology, which obliges a more or less complete exchange of components. Such an exchange of components of an elevator installation is termed a "modernization" in the following. The modernization is often carried out in staggered time, wherein control units and elevator cars are modernized in a first stage, drives are modernized in the machine room in a further stage, and floor call transmitters are modernized at the individual floors in a final stage.

('465 Patent, col. 1:12-22.) Defendants seize on the language "a more or less complete exchange of components," and also cite to another portion of the specification which states that "at least one elevator 10, 10' is substantially completely modernized in each method step." (Id. col. 10:54-59.) Defendants argue that this language taken together indicates that Plaintiff meant to define "modernization" as a complete exchange of components that is performed through various steps,

- 3073 -
rather than merely a partial process in which only certain components are replaced.

--- Footnotes ---

3 Defendants actually cite to the specification for the '861 Patent; however, the relevant language in these patents is identical and has no bearing on construction of this claim.

--- End Footnotes ---

Plaintiff counters that the specification further describes "modernization" to include "in one method step, the drive is modernized, the conveying cable of the elevator is modernized, the elevator control of this elevator is modernized . . . " (Id. col. 3:49-54.) Plaintiff argues that this language indicates "modernization" occurs in stages such that it can include both: (1) the exchange of some components of an elevator installation; or (2) the exchange of individual components of an elevator installation. Plaintiff further cites language describing the modernization process as a "more or less complete exchange of components" (id. col. 1:11-14); and that an "elevator is substantially completely modernized" (id. col. 10:58-59); to indicate that a total replacement of components is not required.

The Court concludes that Defendants' interpretation is more consistent with the principles of claim construction since the specification implies a type of complete modernization process. A patent's specification is recognized by the Federal Circuit as strong evidence of a claim's meaning even where this meaning arises by implication. See Phillips, 415 F.3d at 1321 (stating that the "specification 'acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication.") (quoting Vitronics, 90 F.3d at 1582); Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004) ("Even when guidance is not provided in explicit definitional format, the specification may define claim terms by implication such that the meaning may be found in or ascertained by a reading of the patent documents.") (internal citation omitted).

The specification clearly states that "[i]f after such a length of time a general overhaul of the elevator installation is needed, the components of the elevator installation are often old in terms of technology, which obliges a more or less complete exchange of components. Such an exchange of components of an elevator installation is termed a 'modernization' in the following." ('465 Patent, col. 1:12-18) (emphasis added). The specification essentially defines the term "modernization" by characterizing it as a "general overhaul" of an elevator system which requires "a more or less complete modernization," both of which are more consistent with Defendants' proposed construction. Furthermore, the use of the adjective "complete" to describe the modernization process belies Plaintiff's proposed interpretation that only one old component needs to be replaced in order to modernize the elevator system.

Defendants' proposed construction, however, goes too far in adding the language that "modernization" would necessarily "include replacement of all the elevator components." The qualifying language "more or less" in describing the exchange of components forecloses the argument that each and every component needs to be replaced in order to complete the modernization process. Thus, Defendants' proposed construction oversteps the definitional limitations in the specification.

Therefore, the Court will adopt Defendants' proposed construction in part, and define the term "modernized" and/or "modernizing" as "a more or less complete exchange of components in an elevator installation." The Court concludes that this definition is most consistent with the specification as it incorporates the exact language used in the specification itself. See Phillips, 415 F.3d at 1321 (explaining that the specification is the "single best guide to the meaning of a disputed term", and it "acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication") (internal quotation marks and citation omitted).

---

d. "Modifying the Diameter"

The World Wide Plaintiffs also seek construction of the phrase "modifying the diameter" in Claim 18c, which uses the phrase in terms of "modifying the diameter of the plug to enhance its frictional engagement with the wall of the cannula." ('760 Patent col. 6, ll. 58-59.) Each of the three dependent claims that follow Claim 18 recites one of these three methods of
modifying the diameter. Id. at col. 6, ll. 60-65. The World Wide Plaintiffs propose a construction of "to change the form or qualities of the plug." AnazaoHealth suggests a more specific definition, "mechanical distortion so as to alter the diameter of the plug or expanding the diameter of the plug by heating the material until it swells or exposing the plug to solvents."

The specification states that holding the plug in place "may be accomplished" by modifying the diameter by mechanical distortion, or by expanding the diameter through heat, or by exposing the plug to solvents. Id. at col. 2, ll. 53-57, and depicts in Figure 5 a plug that "may be held in place" by a solvent coating to adhesively fix the plug in place, or by heat, or by minute distortions of the cannula. Id. at col. 4, ll. 65-67. The World Wide Plaintiffs argue that use of the term "may" indicates that the recited methods are merely illustrative examples. AnazaoHealth argues that the Court should construe the phrase in terms of the express disclaimers in the intrinsic record as to how modification of the plug is to be accomplished.

Where the specification makes clear that the invention does not cover a particular feature or embodiment, that feature or embodiment is deemed outside the reach of the patent even though the language of the claims without reference to the specification might be considered broad enough to encompass that feature in question. Harmon at § 6.3(a)(ii) at 345; Honeywell Inc. v. Victor Co. of Japan, Ltd., 298 F.3d 1317, 1325 (Fed. Cir. 2002). That disclaimer, however, must be clear. Likewise, a disavowal of the scope of a claim in the prosecution history must be clear and unequivocal. See Harmon at § 6.3(c); Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324-25 (Fed. Cir. 2003). Here, the Court finds no such clear and express disavowal. Thus, the Court declines to limit "modifying the diameter" to the three methods disclosed in the three dependent claims. At the same time, the Court finds that Plaintiffs' proposed construction is overbroad and ignores the specific language of the Claim which speaks of modifying the diameter. The Court construes this phrase as "changing the diameter of the plug by means such as by heat, by treating the plug with a solvent, or by mechanical distortion."

Claims 20 and 24

As noted above, independent claim 20, from which claim 24 depends, recites, inter alia, a "modular motor body housing" and "a modular control unit in the form of an encasement, removably connected to said motor body in mating relationship therewith." '541 patent, col. 9, ll. 30-31. The disputed claim term is "modular." The district court construed modular units as "standardized units that may be conveniently removed and replaced without significant impact to other components." Animatics Corp. v. Quicksilver Controls, Inc., No. C99-05133 WHA, slip op. at 10 (N.D. Cal. Mar. 11, 2002) ("First Claim Construction Order").

During trial, Quicksilver presented an in-court demonstration in which a technician disassembled and reassembled the accused product. After viewing the demonstration, the district court stated that, "having seen that demonstration about how hard it is to take these things apart, no way does that satisfy the court's definition of 'modularity.'" Accordingly, the district court granted Quicksilver's JMOL motion for non-infringement with respect to claims 20 and 24.

On appeal, Animatics argues that the district court erred in construing claim 20 by adding the adverb "conveniently." According to Animatics, the court incorrectly added a reference to the level of ease with which the motor and controller modules may be taken apart and reassembled. Animatics argues that the district court's claim construction improperly imports a restriction from the specification into the claims. Quicksilver, on the other hand, argues that "it is clear from the specification and the prosecution history that the use of the term 'modular' was specifically meant to emphasize the ease with which the motor and the controller could be separated and individually replaced."

There is "a heavy presumption in favor of the ordinary meaning of the claim language." Johnson Worldwide Assocs. v. Zebeco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999). The district court began its construction of "modular" by referring to a dictionary for the word's ordinary and accustomed meaning. See Texas Digital Sys., Inc., v. Telegenix, Inc., 308 F.3d 1193 (Fed. Cir. 2002). "Modular," according to Webster's Seventh New Collegiate Dictionary, means "constructed with standardized units or dimensions for flexibility and variety of use." Webster's Seventh New Collegiate Dictionary 244 (1976). The district court did not find that the specification compelled a different meaning. However, the court ultimately construed modular to mean "standardized units that may be conveniently removed and replaced without significant impact to other components."

First Claim Construction Order at 10 (emphasis added).
We think that the district court improperly imported a limitation from the specification into its construction of "modular." It is axiomatic that limitations from the specification should not be read into the claims. Comark Communications v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998). The specification describes a benefit of the claimed modularity as "providing for ease of interchange or replacement..." '541 patent, col. 2, ll. 13-15. However, there is no clear indication that the patentee intended to depart from the ordinary meaning of modular, which does not explicitly mandate a limitation on the ease with which the "modular" units may be removed or replaced. See Johnson Worldwide, 175 F.3d at 989 (stating that the ordinary meaning is to be used unless a special definition is shown "with reasonable clarity, definiteness, and precision"). Nonetheless, we believe this error was harmless. After reviewing the testimony surrounding the in-court demonstration of the disassembly of Quicksilver's accused product, we do not believe any jury could reasonably find that the accused product meets the ordinary definition of "modular." Furthermore, claim 20 requires that the modular control unit be "removably connected to said motor body in mating relationship therewith." '541 patent, col. 9, ll. 30-31. The in-court demonstration illustrated that this relationship is absent from the accused product. Accordingly, we affirm the district court's JMOL of non-infringement of claims 20 and 24.

1. "Modular Jack"

The term "modular jack" is used in the claims of the '641 patent as follows:

1. A modular jack to be mounted on a circuit board, said modular jack comprising:

   a printed board containing an electronic element for suppressing noise;

   a contactor for contacting with a plug, said contactor being electrically connected with the electronic element by a wire on the printed board;

   a terminal for contacting with the circuit board, said terminal being electrically connected with the electronic element by a wire on the printed board; and

   an insulating housing for encasing the printed board.

2. A modular jack as claimed in claim 1, wherein the noise suppressing electronic element is an array of common mode choke coils.

4. A modular jack as claimed in claim 1, wherein the noise suppressing electronic element is a chip capacitor.

6. A modular jack as claimed in claim 1, wherein the interior of the housing is divided into a first chamber in which the printed board is set and a second chamber to which the contactor is extended, and the terminal is protruded outside the housing from the first chamber.

The parties agree that "modular" refers to "the geometric configuration of jacks and their corresponding plugs, such as the RJ-11 series, RJ-45 series and the like, which are now commonly seen on telephony apparatus, computer modems, switches, and routers, and similar equipment." Murata's Opening Brief, at 12; Bel Fuse's Responsive Brief, at 25. Murata argues that "jack" should be construed as "a socket to which wires of a circuit are connected at one end and into which a plug is inserted at the other end." Murata's Opening Brief, at 12. Bel Fuse argues that a "jack" should be construed as "a female connector to which wires of a circuit are connected at one end and into which a plug is inserted at the other end." n4 Bel Fuse's Responsive Brief, at 25. Thus, the parties dispute whether a "jack" is more properly characterized as a "socket" or a "female connector." The parties have not explained to the court why construing some thing as a "socket" as opposed to a "female connector" is a distinction with a difference; indeed, their briefs indicate that both parties understand the meaning of "jack" as it is used in the '641 Patent. Nevertheless, the court will consider which is the more appropriate term.
Murata argues that "female connector" is too general a term because the '641 Patent does not claim female connectors generally; it claims a modular jack. Instead, Murata argues that "socket" is a more specific term that is consistent with the intrinsic record n5 of the '641 Patent. Dr. David Hughes ("Dr. Hughes"), Murata's expert, opined that the word "jack" means "a socket to which wires of a circuit are connected at one end and into which a plug is inserted at the other end." Hughes' Expert Report at 4, Ex. 2 to Murata's Opening Brief. He based his construction on a definition from Rudolf F. Graf, The Modern Dictionary of Electronics 529 (6th ed. 1984) ("The Modern Dictionary of Electronics") ("1. A socket to which the wires of a circuit are connected at one end, and into which a plug is inserted at the other end."). Id. Dr. Hughes also opined that the "plug" is usually thought of as the "male portion of the assembly," and the "jack" is usually thought of as the "female portion." Id.

n5 In evaluating the intrinsic evidence, the court notes that while the parties have provided the prosecution history of the '641 Patent, that history provides no assistance in the task of claim construction. See Ex. 11 to Bel Fuse's Responsive Brief. The patent application was filed on January 30, 1991. On May 30, 1991, the examiner held an interview with the applicant by telephone. According to the examiner's summary, in that interview, the examiner and applicant reached an agreement to amend claim 5. Subsequently, the examiner issued a notice of allowability along with an examiner's amendment. That amendment changed "the pitch among the terminals" in claim 5 to "the pitch among a plurality of terminals" and also deleted "the" from "among the contactors on the printed board."

Thus, the patentee made no representations during the prosecution of the '641 Patent about the constructions of the terms at issue here. Indeed, the claims at issue in this case (1, 2, 4, and 6) were issued without amendment.

In support of its position that "female connector" is too broad a term, Murata cites the deposition testimony of Albert Willette ("Willette"), who is apparently Bel Fuse's expert. Willette testified that there are other kinds of female connectors that are not jacks. Willette Dep., 81:5-15, Ex. 19 to Murata's Opening Brief. Willette also testified that a jack and plug together form a connector. Id. at 78:7-12. Murata also cites the specification of the '641 Patent which states: "The present invention relates to a modular jack in a modular connector. . . ." '641 Patent, col. 1, ll. 6-7. According to Murata, adopting Bel Fuse's construction would cause this sentence to be nonsensical, reading "a modular connector in a modular connector." The court notes that Murata is incorrect; Bel Fuse's construction would cause the specification to read, "a female modular connector in a modular connector." Given the fact that Willette testified that the jack and plug together form a connector, testimony that Murata cites, the court finds that this substitution makes sense.

Additionally, it appears that Bel Fuse's proposed construction would not cause the claims of the '641 Patent to read on all types of modular connectors. Instead, it would describe only the female portion of a connector into which a plug is inserted. This appears to be an appropriately narrow construction of a "jack." Other references in the same art area show that jacks are often described as "connectors." See U.S. Patent No. 4,772,224 (titled "Modular Electrical Connector" and describing a "modular jack"), Ex. 8 to Bel Fuse's Responsive Brief; U.S. Patent No. 4,799,901 (referring to jacks as "connector subassemblies" and stating "U.S. Patent No. 4,726,638 discloses a transient suppression assembly for retrofitting existing electrical connectors, such as telephone jacks") (emphasis added), Ex. 10 to Bel Fuse's Responsive Brief; U.S. Patent No. 4,878,848, col. 2, ll. 40-42 ("The adapter system comprises a modular connection means, such as a modular jack, and a housing structure connected to the modular jack."), Ex. 12 to Bel Fuse's Responsive Brief.

Thus, the court finds that a jack and plug together form a modular connector. Indeed, Murata cites Willette's deposition testimony in which he testified that a jack and plug together form a modular connector. Willette Dep., 78:9-10. Murata bases
its proposed construction of a "jack" as a "socket" on only a single dictionary definition in the Modern Dictionary of Electronics n6 and Dr. Hughes' expert report which refers only to that same definition without further explanation. The Federal Circuit has stated that "conclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court." Phillips, 415 F.3d at 1318. While Dr. Hughes' assertion is not wholly unsupported (it refers to a dictionary definition), it is only marginally useful to the court because it provides no explanation as to why the particular definition was chosen or why it is consistent with the view of a person of ordinary skill in the art.

After reviewing all of the evidence, both intrinsic and extrinsic, the court finds that adopting a construction which characterizes a "modular jack" as "the female portion of a modular connector" is consistent with the intrinsic evidence, and reflects the view of a person of ordinary skill in the art. Adding the restriction "in which wires of a circuit are connected at one end and into which a plug is inserted at the other end" appropriately narrows the definition such that it is clear that a "jack" does not encompass all female connectors. Additionally, the parties have agreed that the additional modifier "modular" restricts the construction of the claim "modular jack" to certain configurations. Thus, the court construes the term "modular jack" as "the female portion of a modular connector in which wires of a circuit are connected at one end and into which a plug is inserted at the other end."

2572

B. "An Inner Moisture Transfer Material"

The composite liners described in Claims 1-7 incorporate a first layer termed "inner liner." In contrast, the first layer of the Claim 8 composite liner is named "inner moisture transfer material." The parties agree that the "inner liner" described in Claims 1-7 is synonymous with "inner liner 10," the name given to the first layer of a composite liner described in the specification and depicted in the patent diagrams. They disagree, however, whether the narrow definition that the examiner gave the term "inner liner 10" during patent prosecution also applies to the term "inner moisture transfer material."

Generally speaking, the doctrine of "claim differentiation" teaches that when different words or phrases are used in separate claims, there is presumed to be a difference in the meaning or scope of the claims. See Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). Yet, this is not a hard and fast rule. The Tandon court also cautioned that "two claims which read differently can cover the same subject matter." Id. In the instant case, the specification does not clearly indicate whether "inner liner" and "inner moisture transfer material" have the same definition. Thus, the Court must dig deeper into the intrinsic evidence.

The prosecution history is instructive. Plaintiffs originally submitted fourteen claims for patent approval. Eight of them (Application Claims 1-8) described a composite liner with an "inner liner" attached to a "first layer of foam." The remaining six claims (Application Claims 9-14) described a composite liner with a first layer of "inner moisture transfer material" followed by a "first layer of foam." Finding no clear definition in the claim language, the patent examiner limited the definition of "inner liner" to a list of moisture transferring fabrics described in the specification at column 3, lines 7-61. He did not separately define "inner moisture transfer material."

The examiner then proceeded to approve the eight claims naming a first "inner liner" layer, and Application Claim 14, which named the first "inner moisture transfer material" layer. 2 He rejected the rest of the claims that named a first layer of "inner moisture transfer material," however, as anticipated by the prior art. It is the significance of the examiner's failure to define "inner moisture transfer material," and his subsequent rejection of most of the claims employing that term as a first layer, about which the parties now disagree.
2 Application Claim 14 recited the elements that are now Claim 8. It differed from the claims the examiner rejected by incorporating "reversible enhanced thermal properties" as a claim element.

Plaintiffs argue that throughout the specification and patent diagrams, the only liner found next to a "first foam layer" is "inner liner 10." By implication, they contend, "inner moisture transfer material" must be synonymous with "inner liner 10," since "an inner moisture transfer material" precedes a "first foam layer" as an element of Claim 8. Defendants counter that if "inner moisture transfer material" were synonymous with "inner liner," then there would have been no reason for Plaintiffs to use the term "inner moisture transfer material" in the first place. Rather, they contend, "inner moisture transfer materials" are any material that transfers moisture, not simply those fabrics enumerated in column 3, lines 7-61.

The prior art the examiner relied upon consists of three patents for layered composite materials that are permeable to water vapor and include a first, moisture vapor-permeable layer of film or "poromeric" (synthetic leather) material. Neither films nor poromeric materials are included in the list of fabrics described in column 3, lines 7-61. Nonetheless, the examiner found that these prior art liners anticipated composite liners with a first "inner moisture transfer material" layer. By implication, the examiner read "inner moisture transfer material" to include, at a minimum, moisture-transferring films and poromeric materials. 3 Plaintiffs did not object to this interpretation in their subsequent prosecution of the '810 patent. 4

3 It is irrelevant to this conclusion whether the examiner defined "moisture transfer" in the active sense in which the Court defines it in this Claim Construction. Even supposing that the first layers of the prior art did not actively conduct moisture, their failure to do so would be relevant only to the validity of the claims the examiner rejected. It would not undercut the conclusion that the examiner considered "inner moisture transfer material" to be a broader category than fabrics.

4 Plaintiffs argue that they did not disclaim a broader reading of the term because they have continued to prosecute Application Claims 9 through 13. That evidence does not form a part of the prosecution history in this case, however, and the Court will not speculate as to Plaintiffs' motivations for dropping those claims in earlier proceedings.

Because the Plaintiffs appeared to concede the examiner's construction, and because Plaintiffs need not have used the general term "inner moisture transfer material" when "inner liner" would have served the purpose, the Court finds that the terms are different. It construes "an inner moisture transfer material" as any material that actively conducts moisture as described in this claim construction, including, but not limited to, those materials listed in column 3, lines 7-61 of the '810 patent specification.

1. "[M]olded bucket" of Claim 5

Claim 5 includes the term "molded bucket." The defendants argue that the magistrate judge erred in failing to construe the term "molded bucket," and ask this court to do so. Specifically, the defendants ask this court to reject the plaintiffs' contention that the term "molded bucket" includes the mold used to make the bucket.

Before the magistrate judge, the plaintiffs initially contended that the patent covered buckets as well as molds. Pls.' Claim Chart at 2, Dkt # 413. However, the plaintiffs subsequently agreed that the issue of whether the patent covers molds to make buckets, as well as buckets, was not an issue of claim construction but rather an issue of applying the claims to a product. Tr. at 59-60, Def. Appx. Exh. 7. At the hearing, the magistrate judge did not construe the term "molded bucket" apart from its ordinary meaning, stating, "I'm going to find as a matter of claim construction that both parties agree that the term 'molded bucket' means a molded bucket." Tr. at 71:19-21, Def. Appx. Exh. 7.
"It is well settled that claims may not be construed by reference to the accused device." Neomagic Corp. v. Trident Microsystems, Inc., 287 F.3d 1062, 1074 (Fed. Cir. 2002). See also Info. Tech. Innovation, LLC v. Motorola, Inc., 391 F. Supp. 2d 719, 730-31 (Fed. Cir. 2005). Moreover, a court does not fail to discharge its duty under Markman when a term does not require construction or does not depart from its ordinary meaning. Biotec Biologische Naturverpackungen GmbH & Co. KG v. Biocorp, Inc., 249 F.3d 1341, 1349 (Fed. Cir. 2001)(discussing that the district court did not fail to discharge its duty when it declined to construe "melting" because the term did not require construction nor did it depart from its ordinary meaning, and the issue in dispute was the application of the melting step in the accused process, a factual question of infringement).

In this case, there is no dispute as to the ordinary meaning of the term "molded bucket." The plaintiffs conceded that a "molded bucket" means a molded bucket. Tr. at 70-71, Def. Appx. Exh. 7. To impose exclusions on the term "molded bucket," such as excluding molds, would be construing the terms in reference to the accused device. See Neomagic Corp., 287 F.3d at 1073-76 (determining that the district court erred by examining the accused device before it construed the term "power supply" to mean that it must supply a constant voltage, which would exclude the accused device).

It is an issue for claim infringement whether or not the term "molded bucket" in Claim 5 can apply to bucket molds that could make potentially infringing buckets. See Info. Tech., 391 F. Supp. 2d at 730-31 (where parties agreed on the ordinary meaning of the term "dynamic model" but the defendants wished to insert an exclusion to show that there was a distinction between the model itself and the data files that go into the model, determining that the defendants' exclusion was unnecessary and an issue for infringement, not claim construction). Therefore, the court concludes the meaning of the term "molded bucket" does not depart from its ordinary meaning and does not require further construction.

The phrase "said second end cap comprising molded polymeric material" appears in claim 7 of the '712 Patent. Donaldson asserts that the phrase has a meaning readily understood by one of skill in the art and construction of the language is not necessary. Baldwin asserts that the phrase should be construed as "the second end cap is made of a uniform molded polymeric material." Baldwin argues that its construction is appropriate because the claims are properly limited to a single type of material. In support, Baldwin argues that the claim language and references in the specification refer to the polymeric material of the end cap in singular form.

The Court determines that addition of the term "uniform" to the claim language is not warranted. As a threshold matter, the Court notes that Baldwin's proposed use of the word "uniform" to indicate a singular type of material is problematic because the word "uniform" has several meanings. For example, "uniform" can mean "having always the same form, manner, or degree: not varying or variable," "of the same form with others," or "presenting an undiversified appearance of surface, pattern, or color," Merriam-Webster's Collegiate Dictionary 1287 (10th ed. 2001). Thus, to the extent that Baldwin seeks to limit the claim to a single material, its proposed use of the word "uniform" is not appropriate. Looking to the claim language--"comprising molded polymeric material"--the Court further notes that there is no limitation requiring the polymeric material to be of a singular type; nor is there any requirement that it be "uniform." Baldwin is correct that there are references to "a" soft polymeric material in the patent specification. See '712 Patent, col. 3, ll. 11-12 ("In preferred embodiments, a soft polymeric material is utilized for the first and second end caps."); id., col. 6, ll. 65 ("[e]nd cap 24 is of an appropriate material"). However, the claim itself does not recite a single or uniform material. Therefore, the Court declines to read into the claims any such limitations from the specification. See Phillips, 415 F.3d at 1323.
support for Baldwin's proposed construction, the Court declines to construe the claim language.

8 The present case differs from the cases relied on by Baldwin wherein both the claim language and the specification indicated that certain patent claims were singular. See, e.g., Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1024 (Fed. Cir. 1997) (construing "a metallic gas-confining chamber," noting that the article "a" suggests a single chamber); Insituform Techs., Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1106 (Fed. Cir. 1996) (construing claim reciting "a cup" followed by reference to "the cup"); Baldwin Graphic Sys., Inc. v. Siebert, Inc., 03-CV-7713, 2005 U.S. Dist. LEXIS 15527, 2005 WL 1838451, *4 (N.D. Ill. July 28, 2005) (construing "a pre-soaked fabric roll"). Here, the text of the claim does not refer to "a" polymeric material.

GO BACK

2575

CooperVision contends that this term means "a prism ballast portion made with front surface and back surface molds without subsequent machining or polishing." CIBA proposes "a prism ballast portion that is manufactured primarily in a mold."

CooperVision's construction would impermissibly read into claim 38 a limitation that the prism ballast portion be "fully molded" i.e. molded without any post-processing steps. Claim 38 of the '903 patent does not disclose a "fully molded" contact lens as do claims 29 and 34. A more generic description of "molded" accords with the text of claim 38, and it does not impermissibly read into claim 38 the limitation of a mold without need for subsequent machining or polishing.

The court defines this term as follows:

"[M]olded prism ballast portion" means: a prism ballast portion that is manufactured primarily in a mold.

2576

B. The '141 Patent and the '483 Patent

Cleanox owns two patents for inventions developed by R. Vigneri for the remediation of certain groundwater contamination. See Amended Complaint at 3, P 12. The '141 Patent was filed 12 February 1993 and was issued 15 February 1994. See '141 Patent. The '483 Patent was filed 10 February 1994 and was issued 28 May 1996. See '483 Patent.

Both patents describe their processes as "a method for remediating a hydrocarbon-contaminated region of a subterranean body of groundwater to destroy or reduce the initial levels of hydrocarbon contaminants." '141 Patent at col. 8, lines 23-26; '483 Patent at col. 9, lines 33-35. The two patents rely upon the interaction of hydrogen peroxide and the hydrocarbon contaminants to alleviate the harm caused by groundwater contaminants.

Claim One of the '141 Patent provides as follows:

1. A method for remediating a hydrocarbon-contaminated region of a subterranean body of groundwater to destroy or reduce the initial concentration levels of hydrocarbon contaminants, comprising the steps of:

(a) providing a plurality of mutually spaced wells intersecting said groundwater region ("Step A of the '141 Patent");

(b) determining the existence of acceptable continuity and well interflow paths for the said region by generating a test
flow of a solution of hydrogen peroxide from one of said wells and monitoring pH changes at each other of said wells as a function of time to detect a pH drop of at least 0.2 ("Step B of the '141 Patent"); and

(c) subsequent to detecting said pH drop, providing a treating flow of said hydrogen peroxide solution from one or more of said wells ("Step C of the '141 Patent").

Claim One of the '141 Patent (emphasis added).

Claim One of the '483 Patent provides as follows:

1. A method for remediating a hydrocarbon-contaminated region of a subterranean body of groundwater to destroy or reduce the initial concentration levels of hydrocarbon contaminants, comprising the steps of:

   (a) providing a plurality of mutually spaced wells intersecting said groundwater region ("Step A of the '483 Patent");

   (b) providing a treating flow of acetic acid from one or more of said wells into said groundwater region, to establish acidic conditions therein ("Step B of the '483 Patent");

   (c) introducing a turbulent flow of an aqueous solution of ferrous ion into said groundwater region, for mixing with said acidified groundwater, thereby providing a catalyst for disassociation of hydrogen peroxide ("Step C of the '483 Patent"); and

   (d) providing a treating flow of hydrogen peroxide solution from one or more of said wells into said groundwater region, said hydrogen peroxide undergoing a Fenton-like reaction in the presence of said acidic conditions and said ferrous ion to generate hydroxyl free radicals for oxidizing said contaminants ("Step D of the '483 Patent").

Claim One of the '483 Patent (emphasis added).

LEGAL STANDARD

A. Patent Infringement Generally

In a patent infringement action, a two-step analysis must be conducted. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454, (Fed.Cir. 1998) (in banc); CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1152 (Fed.Cir. 1997), cert. denied, U.S., 140 L. Ed. 2d 105, 118 S. Ct. 1039 (1998); Cole v. Kimberly-Clark Corp., 102 F.3d 524, 528 (Fed.Cir. 1996)), cert. denied, U.S., 139 L. Ed. 2d 20, 118 S. Ct. 56 (1997); Markman, 52 F.3d at 976 (citing Read Corp. v. Portec, Inc., 970 F.2d 816, 821 (Fed.Cir. 1992)); Phillips Elec. North Am. Corp. v. Universal Elec. Corp., 930 F. Supp. 986, 997 (D.Del. 1996). First, the meaning and scope of the patent claims asserted to be infringed must be determined. See Markman v. Westview Instruments, 517 U.S. 370, 384, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996); Cybor Corp., 138 F.3d at 1454; CVI/Beta Ventures, 112 F.3d at 1152; Cole, 102 F.3d at 528; Markman, 52 F.3d at 976. This step is commonly referred to as "claim construction" or "claim interpretation." 8 Markman, 52 F.3d at 976. Second, the properly construed claims must be compared to the device or method that is accused of infringing. See Cybor Corp., 138 F.3d at 1454; Markman, 52 F.3d at 976.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

8 For purposes of consistency, the term "claim construction" will be used throughout this opinion when referring to the first step in an infringement analysis.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

As mentioned, the only issue sub judice is the question of the construction of Claim One of the '141 Patent and Claim One of the '483 Patent. Accordingly, only step one of the infringement analysis, i.e., claim construction, is discussed in this, the Supplemented Opinion.

B. Claim Construction

- 3082 -
A patent is a fully integrated document; it must set out a written description of the invention "in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains" to practice the invention. 35 U.S.C. § 112. "It has long been understood that a patent must describe the exact scope of an invention and its manufacture to 'secure to [the patentee] all to which he [or she] is entitled, [and] to apprise the public of what is still open to them." Markman, 517 U.S. at 373.

The interpretation and construction of a patent claim are "exclusively within the province of the court." Markman, 517 U.S. at 391; see Cybor Corp., 138 F.3d at 1454; CVI/Beta Ventures, 112 F.3d at 1152. A court therefore has "the power and obligation to construe as a matter of law the meaning of language used in the patent claim." Markman, 52 F.3d at 979; see Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1556 (Fed.Cir. 1995), cert. denied, 518 U.S. 1020, 135 L. Ed. 2d 1073, 116 S. Ct. 2554 (1996); CVI/Beta Ventures, 112 F.3d at 1152. When performing such an analysis, various sources may be consulted, including those that are intrinsic and extrinsic to the patent claims. See Cybor Corp., 138 F.3d at 1454; Lubrizol, 64 F.3d at 1556; Vironetics Corp. v. Conceptronics, Inc., 90 F.3d 1576, 1582-83 (Fed.Cir. 1996); CVI/Beta Ventures, 112 F.3d at 1152; Markman, 52 F.3d at 979-80.

There is a hierarchy of evidence which must be considered with the emphasis given first to the words of the claims, then to the specification of the patent, then to the prosecution history of the patent and finally to extrinsic evidence. Vitronics, 90 F.3d at 1582; see also Cybor Corp., 138 F.3d at 1454 (majority opinion) and Cybor Corp., 138 F.3d at 1462 (Plager, J. concurring); Lubrizol, 64 F.3d at 1556. Despite this hierarchy, a court nevertheless may properly decide to hear all proffered evidence prior to construing the claims, provided it does not accord any weight to extrinsic evidence that is inconsistent with the intrinsic evidence. Vitronics, 90 F.3d at 1584; see also Cybor Corp., 138 F.3d at 1454 (majority opinion) and Cybor Corp., 138 F.3d at 1475 (Rader, J. dissenting).

1. Intrinsic Evidence

The intrinsic evidence of the public record must first be examined when construing the meaning of a patent claim. See Vitronics, 90 F.3d at 1582. Such evidence is "the most significant source of the legally operative meaning of disputed claim language." Id. Reliance on intrinsic evidence enables individuals to review the public record, apply the established rules of claim construction, ascertain the scope of the claimed invention and, then, design around the claimed invention.

Intrinsic evidence includes (1) the claims, (2) the specifications of the patent and (3) the prosecution history of the patent. See Cybor Corp., 138 F.3d at 1466-67 (Mayer, C.J. concurring); Vitronics, 90 F.3d at 1582; see also Quantum Corp. v. Rodime, PLC, 65 F.3d 1577, 1580 (Fed.Cir. 1995), cert. denied, 517 U.S. 1167, 134 L. Ed. 2d 666, 116 S. Ct. 1567 (1996); Markman, 53 F.3d at 979. In most instances, an analysis of the intrinsic evidence alone will resolve any asserted ambiguity in a disputed claim term. Markman, 517 U.S. at 389; Vitronics, 90 F.3d at 1583.

a. The Claims

Section 112 of Title 35 of the United States Code requires a patent specification "conclude with one or more claims 9 particularly pointing out and distinctly claiming the subject matter which the applicant regards as his [or her] invention." 35 U.S.C. § 112. The claims of the patent define "the precise scope of the patent." Lucas Aerospace, Ltd. v. Unison Indus., L.P., 890 F. Supp. 329, 332 (D.Del. 1995) (citing Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 395 (Fed.Cir. 1967)).

9 A patent claim typically has three parts: the preamble, the transition, and the body. See Donald S. Chisum, Patents § 806(1)(b) (1997). The preamble is an introductory phrase summarizing the invention, its relation to the prior art, or its intended use or properties. The transition is a phrase connecting the preamble to the body of the claim. The body consists of a recitation of the elements and limitations that "define the product or process to be encompassed within the patent." Id.
Vitronics, 90 F.3d at 1582 (citing Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed.Cir. 1995)). The words are interpreted in accordance with their ordinary meaning, as understood by a person reasonably skilled in the art. See Quantum, 65 F.3d at 1580; Vitronics, 90 F.3d at 1582; Intelllicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387 (Fed.Cir. 1992); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed.Cir. 1984); Phillips Elec. North Am. Corp. v. Universal Elec. Corp., 930 F. Supp. 986, 997 (D.Del. 1996) (citing Loctite Corp. v. Ultraseal, Ltd., 781 F.2d 861, 867 (Fed.Cir. 1989)).

Technical terms should be construed from the perspective of a person experienced in the field of the invention. See CVI/Beta Ventures, 112 F.3d at 1153 (quoting Hoechst Celanese Corp. v. BP Chems., Ltd., 78 F.3d 1575, 1578 (Fed.Cir. 1996)). A claim should not be construed in a manner that renders the claim language "meaningless or superfluous." Lucas Aerospace, 890 F. Supp. at 332 (citing Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 988 F.2d 1165, 1171 (Fed.Cir. 1993)).

If the inventor has used a term in a manner other than its ordinary meaning, that meaning should be given effect because the inventor is free to be his or her own lexicographer. See Vitronics, 90 F.3d at 1582 (citing Hoechst Celanese Corp. v. BP Chems., Ltd., 78 F.3d 1575, 1578 (Fed.Cir. 1996)); see also Markman, 52 F.3d at 980; accord Hormone Research Found., Inc. v. Genentech, Inc., 904 F.2d 1558, 1563 (1990); ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1580 (Fed.Cir. 1988). Any term given a special meaning, however, must be so defined in the specification or its definition must be clear by implication. See Markman, 52 F.3d at 980; accord Vitronics, 90 F.3d at 1582.

b. The Specification

The patent claims "must be read in view of the specification, of which they are a part." Markman, 52 F.3d at 979 (citing Autogiro, 384 F.2d at 397)); see also SRI Intern. v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1121 (Fed.Cir. 1985). Section 112 of Title 35 of the United States Code provides:

The specification shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same, and shall set forth the best mode contemplated by the inventor of carrying out his invention.

35 U.S.C. § 112. The specification is "highly relevant to the claim construction analysis" because it contains a written description of the invention that must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Vitronics, 90 F.3d at 1582.

The specification must be reviewed "to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning." Vitronics, 90 F.3d at 1582; CBI/Beta Ventures, 112 F.3d at 1153. In this regard, the specification "may act as a sort of dictionary, which explains the invention and may define terms used in the claims." Markman, 52 F.3d at 979. It acts as a dictionary when it "expressly defines terms used in the claims or when it defines terms by implication." Vitronics, 90 F.3d at 1582.

The specification "does not delimit the right to exclude. That is the function and purpose of the claims." Markman, 52 F.3d at 980. In addition, "references in the specification to a preferred embodiment, or an illustrative example, do not limit the scope of the patent claim." Lucas Aerospace, 890 F. Supp. at 332.

c. The Prosecution History
When construing the language of a claim, the prosecution history of the patent also should be considered, provided that it is in evidence. Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed.Cir.), cert. denied, 516 U.S. 987, 133 L. Ed. 2d 424, 116 S. Ct. 515 (1995); Markman, 52 F.3d at 980; Vitronics, 90 F.3d at 1582 (citing Graham v. John Deere, 383 U.S. 1, 15 L. Ed. 2d 545, 86 S. Ct. 684 (1966)); CBI/Beta Ventures, 112 F.3d at 1155. The prosecution history "contains the complete record of all the proceedings before the Patent and Trademark Office, including any express representations made by the applicant regarding the scope of the claims." Vitronics, 90 F.3d at 1582. It is "often of critical significance in determining the meaning of the claims." Id.

The prosecution history "limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall, 54 F.3d at 1576; see CBI/Beta Ventures, 112 F.3d at 1155. However, the prosecution histories "cannot 'enlarge, diminish, or 'vary the limitations in the claims." Markman, 52 F.3d at 980 (quoting Goodyear Dental Vulcanite Co. v. Davis, 102 U.S. 222, 227, 26 L. Ed. 149 (1880)).

In the instant action, the parties agree there is no relevant prosecution history that would be instructive in interpreting the disputed claims because the United States Patent and Trademark Office accepted all the claims without objection or amendment. See Brief - Cleanox at 3, 5; Markman Hearing Transcript at 62:10-12.

2. Extrinsic Evidence

Extrinsic evidence is "all evidence external to the patent, including expert and inventor testimony, dictionaries, and learned treatises." Markman, 52 F.3d at 979, 980; see Hormone Research Found., 904 F.2d at 1562. This type of evidence may be consulted during construction of a claim to assist with the understanding of "scientific principles, the meaning of technical terms, and terms of art that appear in the patent and prosecution history." Markman, 52 F.3d at 980; see Vitronics, 90 F.3d at 1584. In addition, extrinsic evidence may be received to aid in "coming to a correct conclusion' as to the true meaning of the language employed' in the patent." Markman, 52 F.3d at 979 (citations omitted). Moreover, if, after consideration of all available intrinsic evidence, there still is some genuine ambiguity in the claims, extrinsic evidence may be consulted to interpret the meaning of the language used in the claim. See Vitronics, 90 F.3d at 1584. Extrinsic evidence cannot be used, however, for the purpose of varying or contradicting the terms of the claims. See id.

ANALYSIS

A. Claim Construction of Claim One of the '141 Patent and Claim One of the '483 Patent

The preambles of Claim One of the '141 Patent and Claim One of the '483 Patents are identical. See '141 Patent at col. 8, lines 23-26; '483 Patent at col. 9, lines 33-36. In addition, sub-part (a) of Claim One of the '141 Patent and sub-part (a) of Claim One of the '483 Patent are identical. See '141 Patent at col. 8, lines 28-29; '483 Patent at col. 9, lines 37-38. The parties appear to agree on the interpretation of the preambles, which reads from the beginning of the claim up to the colon. See Brief - Cleanox at 3; Brief - Defendants at 6. The parties also appear to agree that the words in sub-part (a) of Claim One of each patent, "providing a plurality of mutually spaced wells intersecting said groundwater," must be construed to mean physically providing at least two wells. See Brief - Defendants at 6; Markman Hearing Transcript at 65:3-9.

As mentioned, however, the following issues are disputed by the parties: (1) the meaning of the term "well" in Claim One of the '141 Patent and Claim One of the '483 Patent, (2) whether Step B of Claim One of the '141 Patent requires that pH be monitored for a particular purpose, (3) whether the term "treating flow" in Step C of Claim One of the '141 patent requires a "pressure limitation" and permits "bioremediation," and (4) whether Claim One of the '483 Patent requires that each of its steps be performed separately and sequentiality in order to practice the invention. See Brief - Cleanox at 3 n.1; Brief - Defendants at 6 n.1 and Exhibits C and D thereto; 18 December 1997 Letter.

After briefs were requested and received, reply briefs were sought from the parties. In their briefs and at the Markman Hearing, the parties advised that extrinsic evidence need not be considered to properly construe the meaning of Claim One of the '141 Patent and Claim One of the '483 Patent. See Brief - Cleanox at 3; Brief - Defendants at 8-10. Nevertheless, the parties cited extrinsic evidence in their briefs. When offered a hearing on the construction issues, the parties stated that they did not believe one was necessary but welcomed the opportunity to address these issues. See supra, note 3. Accordingly, each party was permitted to present testimony and arguments at the Markman Hearing.
2. Construction of Step B of '141 Patent

The parties dispute whether Step B of the '141 Patent requires that pH be monitored for a particular purpose.

a. The Cleanox Argument

Cleanox argues that Step B of '141 Patent "does not require that the practitioner have any specific purpose or intent in monitoring pH." Reply Brief - Cleanox at 4 (emphasis in original). The practitioner's intent during monitoring, Cleanox argues, is irrelevant to an infringement analysis if the practitioner practices what Step B of '141 Patent teaches. See id. (citing Hilton Davis Chem. Co. v. Warner-Jenkinson Co., 62 F.3d 1512, 1519 (Fed.Cir. 1995), rev'd on other grounds, 520 U.S. 17, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997)). Cleanox contends, therefore, that any monitoring of pH by a practitioner infringes Step B of the '141 Patent. See id.

b. The Defense Argument

Defendants argue Step B of '141 Patent expressly requires "the pH be monitored for the particular purpose of determining the existence of acceptable continuity and well interflow paths." Reply Brief - Defendants at 3. They argue the reliance by Cleanox on the testimony of Dr. Piotrowski to interpret the meaning of Step B of the '141 Patent is misplaced because, among other things, it is extrinsic evidence. See id. at 4. Finally, in an effort to avoid jury confusion, Defendants seek a ruling that Step B of the '141 Patent requires all of the following:

1) generating a test flow of a solution of hydrogen peroxide from one of the wells provided in the step of subpart(a);

2) monitoring the other wells provided in the step of subpart(a) to detect a pH drop of at least 0.2; and

3) using the detected pH drop of at least 0.2 for the express purpose of determining that continuity and well overflow paths are acceptable to receive the treating flow.

See id. at 4 n. 1; see also Brief - Defendants at 11.

c. Judicial Construction

The express language of Step B of the '141 Patent requires that the pH be monitored to "determine the existence of acceptable continuity and well interflow paths." Step B of the '141 Patent. The reliance by Cleanox on extrinsic evidence, such as the testimony of Dr. Piotrowski, to construe the meaning of Step B of the '141 Patent is unnecessary for the reasons previously discussed in this Supplemented Opinion. Although Cleanox correctly states that the intent of a practitioner while practicing the invention is not a proper element of patent infringement, here the intent of the practitioner is not analyzed. Rather, the patent claim itself is construed to determine whether it discloses a purpose for the pH monitoring. As mentioned, the language of Step B of the '141 Patent expressly teaches the purpose of such monitoring is to "determine the existence of acceptable continuity and well interflow paths." Step B of the '141 Patent. Finally, Step B of the '141 Patent should be read to require all of the following:

1) generating a test flow of a solution of hydrogen peroxide from one of the wells provided in the step of subpart(a);

2) monitoring the other wells provided in the step of subpart(a) to detect a pH drop of at least 0.2; and

3) using the detected pH drop of at least 0.2 for the express purpose of determining that continuity and well overflow paths are acceptable to receive the treating flow.

Conclusion

- 3086 -
For the reasons stated, the claim construction of the disputed terms is as follows: (1) the term "well" in Claim One of the '141 Patent and Claim One of the '483 Patent means "a structure used for both monitoring and injecting the groundwater," (2) Step B of the '141 Patent is read to require that pH be monitored for the particular purpose of determining the existence of acceptable continuity and well interflow paths, (3) the term "treating flow" in Step C of the '141 Patent is read to have no pressure limitation associated with it and to be limited to "chemical remediation", and (4) Claim One of the '483 Patent is read to require the performance of Steps A-D both separately and sequentially to practice the invention.

A.

Initially we resolve a problem resulting from the fact that the district court never construed any of the '063 patent's claims. The district court opinion focuses primarily on weighing the credibility of the factual evidence presented to the court by various witnesses. While such credibility determinations are an important part of the district court's fact-finding role, an equally important role is the interpretation of the claims.

The parties dispute the meaning of the claims. Claim construction is a matter of law which we perform without deference to the district court. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). Although the district court never construed the claim language, on this appeal we may resolve the parties' legal dispute regarding the proper interpretation of "monitoring." The parties contest the meaning of the word "monitoring" as used in the preamble and in a claim limitation of claim 30. In particular, step (b) of claim 30 requires "monitoring the torque conditions during said step of sensing the torque to detect if a satisfactory threaded connection is obtained." '063 patent, col. 15, ll. 51-53. PMR's principal contention is that the method performed by the December 1980 device did not satisfy claim 30 because "monitoring" as used in step (b) of the claim requires the determination and instantaneous calculation of the torque and its rate of change so that the shoulder is identified ("picked" in the art) within a satisfactory range and the proper amount of supplemental torque is applied within the maximum allowable torque, all in real time so that the '063 system controls the makeup of the connection in real time without the necessity of human intervention.

Appellants Opening Brief at 38-39 (emphasis added). Thus, PMR contends that the monitoring step in the claim requires control over the make-up and performance of the step by the apparatus described in the '063 patent without the need for any human intervention. Appellees counter that "monitoring," as used in the patent claims, should not be interpreted as having the special meaning PMR proposes, and that the ordinary meaning of monitoring allows that "monitoring can be done by an operator" and "[is] not limited to instantaneous, computer-driven calculations and shut-off features excluding an operator as proposed by [appellant]." Brief for Connection Technology Ltd., et al. at 7. In particular, appellees urge that "monitoring' can be accomplished simply by an operator viewing a dynamic display unit (computer screen) that displays the torque applied during threading." Brief for Tubular Makeup Technology, Inc. at 42. The crucial distinctions between the claim constructions urged by the parties is (1) whether the "monitoring" requires that the make-up of the connection be controlled; and (2) whether "monitoring" must be performed by the apparatus described in the '063 patent or whether it may also be performed by a human operator using the apparatus.

In construing patent claims, we first look to the intrinsic evidence of record -- the claims, the specification, and, if in evidence, the prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996). If ambiguity remains after consideration of the intrinsic evidence, "extrinsic evidence may also be considered, if needed to assist in determining the meaning or scope of technical terms in the claims." Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1216, 36 U.S.P.Q.2D (BNA) 1225, 1228 (Fed. Cir. 1995) (citations omitted), cert. denied, 520 U.S. 1115, 137 L. Ed. 2d 326, 117 S. Ct. 1243 (1997). It is also well-settled that, as a general rule, "words in a claim will be given their ordinary and accustomed meaning, unless it appears that the inventor used them differently." Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 U.S.P.Q. (BNA) 473, 477 (Fed. Cir. 1984) (internal quotations omitted).

Here, the language of claim 30 (quoted in full above at page 6) generally claims in the preamble "[a] method of monitoring torque conditions during the make-up of a threaded tubular connection, wherein shoulder contact is formed in the threaded
connection" and in step (b) "monitoring the torque conditions during said step of sensing the torque to detect if a satisfactory threaded connection is obtained." '063 patent, col. 15, ll. 15-47, 51-53. On its face the language requires only the "monitoring" of torque. However, contrary to PMR's contention, the common meaning of "monitor" 8 does not require the application of torque. The clear language itself is also not limited to a machine- or computer-implemented method of monitoring, and does not explicitly exclude human intervention.

8 Dictionary definitions of "monitor" include: "15. to observe, record, or detect (an operation or condition) with instruments that have no effect upon the operation or condition. 16. to oversee, supervise, or regulate: to monitor the administration of a test. 17. to watch closely for purposes of control, surveillance, etc.; keep track of; check continually: to monitor one's eating habits." Random House Webster's Unabridged Dictionary 1242 (2d ed. 1998); "2: to test . . . for intensity of radiation . . . to determine whether the intensity comes within specified limits. . . . 3: to watch, observe, or check, esp. for a special purpose . . . 4: to keep track of, regulate, or control . . . ." Webster's Ninth New Collegiate Dictionary 1460 (9th ed. 1983).

We turn then to the specification to determine if the patentees defined "monitoring" to include the application of torque or to exclude human intervention. The "Operation of Apparatus" section of the written description and the flow charts shown in Figures 2A, 2B, 2C, and 2D do not suggest that "monitoring" requires the application of torque. Nor do they preclude human intervention. They may be understood to mean that the monitoring is generally done automatically by the apparatus. However, the specification also suggests an interpretation of "monitoring" under which a human operator detects the torque conditions. The specification states that "monitoring torque conditions . . . permits an operator of apparatus [sic] according to the present invention to initially detect whether or not the shoulder condition is achieved in making up a premium threaded connection," id. at col. 5, ll. 28-33, and that "the dynamic display unit permits an operator to monitor progress of each connection or joint as it is being made up . . . ." Id. at col. 5, ll. 8-10. Thus, while the apparatus described in the '063 patent may be necessary for performing the steps of "(a) sensing the torque imposed on the connection during makeup" and "(d) displaying the torque sensed during make-up," neither the plain language of the claim nor the specification excludes a human operator from performing the step of "(b) monitoring the torque conditions during said step of sensing the torque to detect if a satisfactory threaded connection is obtained." '063 patent, col. 15, ll. 49-57. Therefore, a human operator may use the apparatus described in the '063 patent to perform the method claimed in claim 30.

We conclude that "monitoring" as used in the '063 patent claims does not require the application of torque or exclude human participation during make-up of a connection.

The parties' dispute involves only two claim terms: "monolithically formed head" and "head members." Both parties appear to agree that the term "monolithic" means "cast as a single piece," as defined in Merriam Webster's Collegiate Dictionary. Dft.'s Reply to Plt.'s Resp. to Dft.'s PFOF, dkt. # 42, P 109. The language in claim 1 requires the "monolithically formed head" to be common to both cylinder housings and to include the "head members" and tube "so that the tube is joined to each head member with a fluid tight and fixed rigid connection." I understand the parties to use the term "head member" interchangeably with the term "cylinder head," and that the head member in combination with the tube forms the "monolithically formed head" in the '521 patent. It is undisputed that in the type of compressor technology at issue, a "cylinder head" with inlet and exhaust chambers is mounted on each cylinder and provides inlet and outlet chambers to the cylinders. It is undisputed also that to be operational, the portion of the compressor above the cylinder must: 1) communicate with the cylinder while enclosing the cylinder on its top; 2) provide inlet and exhaust chambers; and 3) close the chambers on top. Therefore, in order for the compressor to work correctly, the chambers inside the "cylinder head" must be closed, presumably with a "cover" or "cap." However, because of the need to open up the upper portion of the compressor for maintenance, the entire portion above the cylinder cannot be monolithically formed. There must be at least one separate piece in the upper portion of the compressor; it may be the "cover" that sits on top of the chamber portion of the compressor or it may be the bottom portion upon which the chamber portion rests. The crucial question is whether the term "head member" as used in the '521 patent includes a "cover" over the top of the inlet and exhaust chambers as part of the monolithic formation, as shown in the preferred embodiment of the '521 patent, or whether the '521 patent encompasses
something more than the preferred embodiment. According to plaintiff, the head member of the monolithically formed head does not include a cover or cap over the inlet and exhaust chambers. Plaintiff would define "monolithically formed head" as "A portion of a pump including head members and a tube, wherein the head members and the tube are formed into a single piece of continuous material."

Defendant asserts and plaintiff does not deny that defendant's proposed definition of "monolithically formed head" encompasses the concept of a cover over the head members. Defendant would define "monolithically formed head" as "a single piece of continuous material comprising the uppermost part of a compressor that includes head members completing the inlet and exhaust chambers."

The question is whether the '521 patent requires the "head" to have a cover over the inlet and exhaust chambers as part of its monolithic formation, as defendant argues, or whether the chambers in the "head member" could be covered by a separate piece on top. In plaintiff's view, the preferred embodiment in the '521 patent shows a mere design choice, that is, a cover formed monolithically with the inlet and exhaust chamber portions of the head members. It contends that the "monolithic" term of the '521 patent refers to the improvement over the prior art that makes the tubes and chamber portions of the head member one piece, instead of separately manufactured and fastened tubes and chamber portions of the compressor. The crux of plaintiff's argument is that the '521 patent did not explain whether the inlet and exhaust chambers were to be enclosed by a separate cover or cap or by a cover monolithically formed with the chamber portions because the different ways of doing so were well known in the art at the time the '521 patent was issued. Plaintiff limits the term "head member" to a portion of a compressor "in fluid communication with a cylinder that provides cavities or chambers which when enclosed facilitate or permit the flow of gases (air or liquid) into the cylinder and out from the cylinder to another head member or other desired location." Plt.'s Br., dkt. # 27, at 8 (emphasis added).

Resolving this question requires review of the '521 patent's preamble to claim 1, written description and prosecution history.

1. Preamble

Both parties agree that claim 1 of the '521 patent is written in Jepson format, which means that the claim contains a preamble describing the prior art and a subsequent portion that describes a claimed improvement made on the prior art. When a patentee employs a Jepson format, "the claim preamble defines not only the context of the claimed invention, but also its scope." Rowe v. Dror, 112 F.3d 473, 479 (Fed. Cir. 1997). Moreover, the application that resulted in the '521 patent was a continuation-in-part of the 1996 application and the patent examiner cited the Thomas 2619 compressor as a basis for rejecting the 1996 application. Furthermore, the background section of the '521 patent cites plaintiff's 2600 series of compressors as examples of two-cylinder, in-line compressors and the '521 patent relates to an improved version of those compressors. '521 pat., col. 1 Ins. 9-10, 34-36. Therefore, defendant argues, one should read the term "head member" in the preamble consistently with its use in the Thomas 2619 compressor.

It is undisputed that the head of the Thomas 2619 compressor appears as follows:

[SEE FIGURE IN ORIGINAL]

Plt.'s PFOF, dkt. # 25, exh. 14, at 12. It is undisputed also that parts 2 are "heads." The picture shows that the heads include covers over the chamber portions, making the covers monolithically-formed as part of the heads. In addition, the illustration of plaintiff's 2650 model compressor shows a cover formed monolithically with the head, as shown below:

[SEE FIGURE IN ORIGINAL]

Plt.'s Resp. to Dft.'s PFOF, dkt. # 37, exh. 47. Taking into consideration the facts that the preamble defines the scope of claim 1 and the patent examiner and '521 patent specified as prior art plaintiff's 2600 series of compressors, which had covers formed monolithically with the head, one could conclude that the applicant assumed in the preamble that the improved version claimed in the '521 patent would also have a cover formed monolithically with the head. Defendant's proposed definition for "monolithically formed head" includes the function of a cover by describing the head as a component that completes the inlet and exhaust chambers. However, unlike plaintiff's proposed definition, defendant's definition does not specify the tube that joins the head members as part of the monolithic formation. Claim 1 of the '521 patent requires the monolithically formed head to include both the head members and tube. Therefore, any definition of the
monolithically formed head would have to specify both the head members and tube.

2. Written description

Although the written description in the patent does not mention the term "monolithically formed head," the parties seem to agree that it refers to synonymous terms like "one-piece cylinder head" or "one-piece head." Plt.'s Br., dkt. # 35, at 22; Dft.'s Br., dkt. # 20, at 16. Defendant argues that the language in the written description supports its definition of "monolithically formed head" because 1) the abstract of the '521 patent states that the "one-piece cylinder head serves as the final retention member, clamping the housings axially while maintaining radial orientation" (emphasis added); 2) the figures in the '521 patent show the head attached as the final and uppermost part in the compressor; and 3) the '521 patent specification states that the "assembly [of the compressor] is complete by joining the two housings 14a and 14b with the one-piece head." '521 pat., col. 5, Ins. 58-59 (emphasis added). Plaintiff notes that having the head as the final retention member does not rule out the possibility that the patent encompasses products with a separate cover for the head. In fact, according to plaintiff, the language in the abstract supports the idea that a separate cover would not act as the final retention member because a cover could not clamp the housings and maintain them in a fixed orientation. Plt.'s Br., dkt. # 35, at 22.

Plaintiff is correct when it argues that the phrase "final retention member" would not necessarily rule out a head member with a separate cover. However, when this term is read together with other language in the written description, the '521 patent appears to limit the head members as including a cover in their monolithic formation. Plaintiff notes that the intrinsic evidence does not expressly limit the '521 patent to the preferred embodiment and that it is legal error to do so. The patent does not mention the need for a cover. According to plaintiff, this omission means that the '521 patent encompasses different methods of enclosing the chambers. Citing Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002), plaintiff argues that an invention should not be limited to the preferred embodiment unless the specification or prosecution history includes "an expression of manifest exclusion or restriction demonstrating an intent" to impose such a limitation. Plaintiff fails to mention that in Teleflex the court added that "whether an invention is fairly claimed more broadly than the 'preferred embodiment' in the specification is a question specific to the content of the specification, the context in which the embodiment is described, the prosecution history, and if appropriate the prior art . . ." Id. For example, in Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1273 (Fed. Cir. 2001), the court found that because the patentees used the word "mode" consistently throughout the patent specification, they limited the word by implication. In the '521 patent, plaintiff uses the word "head" and "head member" to imply that a cover is already part of the head. Every figure shows a cover formed monolithically with the head. The specification states that the assembly is complete when the two housings are joined with the one-piece head. Indeed, it is undisputed that the compressor will not work unless the chambers are closed by something. Nothing in the written description suggests that the patented invention may require a separate cover for the head. It is logical to assume that if the '521 patent contemplated a head that required a separate cover for operation, the patent would disclose the need for such a cover somewhere. See, e.g., 3 Donald S. Chisum, Chisum on Patents § 7.03 (2000)("Since 1790, the patent laws have required that the inventor set forth in a patent specification sufficient information to enable a person skilled in the relevant art to make and use the invention.") (Emphasis added.)

3. Prosecution history

The prosecution history of the '521 patent provides additional support for the limitation that the cover is formed monolithically with the head. Plaintiff states that neither the prosecution history nor the language in the patent discusses covers or any methods to enclose the inlet and exhaust chambers but focuses instead on the way the tubes connect the chamber portions in one continuous piece of material. However, defendant points out that there was no need to discuss covers for the inlet and exhaust chambers because that function was performed by the monolithically formed head. It is undisputed that the patent examiner cited the Thomas 2619 compressor as a basis for rejecting both the 1996 and 1998 applications and that the 2619 compressor had a cover formed monolithically with the head. It is undisputed that plaintiff called the cover formed monolithically with the head in the 2619 compressor a "head" and that the patent examiner referred to these "separate heads" and tubes in the 2619 compressor as indistinguishable from the proposed invention in the 1996 application. The patent examiner's use of the word "head" in reference to a part that included a cover as part of the monolithic formation helps define the term as it is used in the '521 patent. See, e.g., Chimie, 402 F.3d at 1380-81 (prosecution history can and should be used to understand language used in claims)(citing Markman v. Westview Instruments, Inc., 52 F.3d 967, 980 (Fed. Cir. 1995)).
Because the intrinsic evidence, including the preamble, written description and prosecution history, supports defendant's argument that a "monolithically formed head" includes a cover, I am persuaded to include that part in defining the term. Plaintiff's argument that extrinsic evidence supports adoption of its proposed definition is not persuasive. Plaintiff cites three types of extrinsic evidence to give the claim terms meaning as they would be understood by persons in the field of invention: 1) prior art not cited in the patent or during prosecution; 2) expert testimony; and 3) technical dictionaries, especially as those dictionaries help to define the term "cylinder head." "Intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vanderland Industries Nederland v. International Trade Commission, 366 F.3d 1311, 1322 (Fed. Cir. 2004). Prior art not cited in the patent and expert testimony holds little value when compared to intrinsic evidence.

Even if I considered plaintiff's proposed definition for "cylinder head," a term that the '521 patentees use throughout the specification and plaintiff defines as "The cap that serves to close the end of the piston chamber of a reciprocating engine, pump or compressor," The McGraw-Hill Dictionary of Scientific and Technical Terms, (6th ed. 2003) at 538 (emphasis added), I would still include the concept of a cover in the definition for "monolithically formed head." According to Webster's New World College Dictionary (4th ed. 2001) at 216, a "cap" is a "cover or top." Similarly, The Oxford English Dictionary Online defines "cap" as "a cap-like covering; a cover or case." Both the intrinsic and extrinsic evidence support the inference that the monolithically formed head in the '521 patent includes a cover, which would be the uppermost portion of the compressor and would complete the inlet and exhaust chambers. Therefore, I will adopt the language of defendant's proposed definition for "monolithically formed head" that the head members complete the inlet and exhaust chambers of the compressor; in other words, they act as covers. However, I will add language to the definition that specifies that the tube is also part of the monolithically formed head. The resulting definition of "monolithically formed head" is: "A single piece of continuous material comprising the uppermost part of a compressor that includes head members that complete the inlet and exhaust chambers and a tube."

Defendants argue that the proper construction of the term "monomers" is "small molecules capable of reacting with like or
unlike molecules to form a polymer." 35 Defendants point to two sources of intrinsic evidence to support their proposed construction. First, like Plaintiff, Defendants point to the '450 patent specification which states that "monomers are connected in a chain-like fashion to form a polymer." 36 Second, during the prosecution history of the '450 patent, the USPTO patent examiner stated that Plaintiff-defined monomers were not actually monomers in the sense that that term should be used. 37 Defendants also point to one source of extrinsic evidence, the Standard Terminology Relating to Rubber, to support their claimed construction. 38

35 Docket No. 356, at 10.
36 Id.
37 Id. at 10-11.
38 Id. at 10.

The Court believes that Plaintiff's intrinsic evidence, as well as Defendants' evidence from the prosecution history, support that Plaintiff acted as its own lexicographer with respect to this term. Collectively, the above mentioned limitations and specifications clearly state that Plaintiff referred to monomers as they existed within an already formed polymer, and not as unreacted molecules. This conclusion is supported by the fact that the USPTO, during the prosecution of the patent by Plaintiff, noted that the Plaintiff was using a rather unorthodox definition of the term. Additionally, the Court views Plaintiff's construction as correct because an adoption of Defendants' proposed definition, as it relates to this patent, would obviate Plaintiff's invention. 39

2580

A. The '578 Patent - Claim 17

Claim 17 provides:

A method of using a catheter to form an occlusion comprising:

disposing an electrolyzable core wire near the situs of said occlusion;

disposing a separable elongate tip portion extending from said catheter and coupled to said core wire at said situs of said occlusion, said separable elongate tip portion being more resistant to electrolytic disintegration in fluid than said electrolyzable core wire, and being a long and substantially flexible segment prebiased to form a helix when extended from said catheter; and

detaching said separable elongate tip portion from said core wire by electrolysis.

The parties dispute the proper construction of only one phrase of Claim 17: "elongate tip portion being more resistant to electrolytic disintegration in fluid than said electrolyzable core wire." Specifically, the dispute is over the proper
construction of the phrase, "more resistant to electrolytic disintegration."

Claim 17 is a method claim. The method is performed with an apparatus which is comprised of an "electrolyzable core wire" with a "separable elongate tip portion." The language of Claim 17 provides that the "elongate tip portion" is "more resistant to electrolytic disintegration in fluid" than the "electrolyzable core wire."

The phrase "resistant to" is a commonly used non-technical phrase which means "not susceptible to," a phrase construed by the Court with respect to the '136 Patent. The same phrase appearing in different claims in the same patent should be given the same meaning unless it is clear from the specification and prosecution history that the phrases have different meanings. Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1328 (Fed. Cir. 2006). In addition, a phrase should be interpreted consistently if it appears in different claims of different patents but which are of common ancestry, unless the specification or prosecution history suggest otherwise. Epcon Gas Sys. Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1031 (Fed Cir. 2002).

There is no suggestion in the specification that the Court should define the phrase "resistant to" inconsistently from the construction given to "not susceptible to."

The Court construes "more resistant to" as it is used in the phrase "elongate tip portion being more resistant to electrolytic disintegration in fluid than said electrolyzable core wire," in Claim 17 of the '578 Patent to mean:

An elongate tip portion of the invention which has attributes which make that portion more resistant to electrolytic disintegration than the electrolyzable core wire of the invention.

Omax proposes this construction: "Instructions to a machine tool that cause it to move." Flow argues for the following: "Time delay and incremental instruction consisting of a series of step and direction commands consisting of either a 1 or 0 with a sign of + or - that effect movement." Flow's proposed construction mirrors its proposed construction of the claim terms in claims 1 and 14, which refers to "a series of incremental motor commands for the motor, each increment for the motor being one of: zero, positive increment, or negative increment." 2 The Court agrees with Omax's argument that this approach violates the principle of claim differentiation. Comark Commc'ns. Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) ("There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims."). The patent consistently refers to the incremental motion control commands in claims 1 and 14, and consistently refers only to motion control commands in claims 9 and 23. Moreover, Flow's proposed construction contradicts the intrinsic evidence available in the prosecution history of the '596 patent: "Claim 12 [which later became claim 9] is similar to Claim 1, except that the limitation that the segments are incremental motor commands is eliminated." FLO 002008-13. Accordingly, the Court adopts Omax's proposed construction.

2 The parties' slightly divergent constructions of this claim, addressed in the joint claim chart, are not addressed in their Markman briefs.

4. "Motion Mechanism"

Plustek asks the Court to construe this term as "a mechanism that is controlled by electronic components located outside of
the scanner, and that is responsible for moving the scanning document so as to cause it to pass through the image sensing module at a steady speed."

Syscan argues for "that mechanism responsible for moving the scanning document so as to cause it to pass through the image sensing module at a steady speed."

The specification states that "fundamentally different from the scanners in the market, there is no microcontroller and other electronic components in main module 402 to control the operation of the image sensor and the illumination source." See Dang Decl., P 2, Ex. A ('124 Patent), 7:3-7, emphasis added. The interface engine and the control circuit are electronic components that control the operation of the image sensor and the illumination source as well as the motion mechanism. See e.g., Dang Decl., P 2, Ex. A ('124 Patent), Fig. 3, 6:32-34, 11:9-13 (claim 5), Fig. 5, 7:63-65, 7:66-8:10.

The patent's express exclusion dictates that the image sensor (or image sensing module) and the motion mechanism must be controlled by electronic components located outside of the patented scanner. SciMed Life Systems, Inc., 242 F.3d at 1341 ("where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question"); see also CCS Fitness, 288 F.3d at 1366-67 ("a claim term will not receive its ordinary meaning if the intrinsic evidence shows that the patentee distinguished the term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention.").

The Court construes this claim as "a mechanism that is controlled by electronic components located outside of the scanner, and that is responsible for moving the scanning document so as to cause it to pass through the image sensing module at a steady speed."

</tr>
</thead>
<tbody>
<tr>
<td>&quot;a motor for moving said plunger drive ram&quot;</td>
<td>an electric motor for moving said plunger drive ram</td>
<td>a motor for moving the plunger drive ram</td>
</tr>
</tbody>
</table>

The parties dispute whether the motor of the invention must be an electric motor. Mallinckrodt argues that the motor can be any kind of motor where as E-Z-EM urges the court to construe "motor" to mean "electric motor." E-Z-EM argues that, based upon the specification, the invention is an improvement upon "typical injectors," and "typical injectors" contemporaneous with the filing date used electric motors. E-Z-EM further argues that the only motor disclosed in the patents is an electric motor.

The Court declines to construe "motor" narrowly, as E-Z-EM suggests. To do so would improperly import a limitation from the preferred embodiment. Nothing in the claims or specification supports the conclusion that the motor claimed cannot be a hydraulic motor, or any other type of motor. The Court construes "motor" to be "a device that imparts motion."

2584

"motor"

a machine that imparts motion
E. “Motor” and “Tracks the Location of Said Motor”

24 The Court reviewed L-F’s Supplementation in Reply (Doc. No. 220) relating to this issue, Medrad’s Motion to Strike L-F’s Supplementation (Doc. No. 224), and L-F’s memorandum in opposition (Doc. No. 235). These filings relate to extrinsic evidence not considered by the Court when construing the claim terms.

L-F requests that the Court interpret the terms “motor” and “tracks the location of said motor” as they are used in the 612 and 197 patents. Each of the asserted independent claims of the 612 and 197 patents recites that the injector has a motor which advances and retracts a plunger and that the device includes a control circuit which causes the motor to move and tracks the location of the motor while moving the motor.

L-F asserts that “motor” actually means the “drive mechanism” and “tracks the location of said motor” means “tracks the location of the drive mechanism.” (Doc. No. 164, pp. 26-27). Medrad, relying strictly on dictionary definitions, argues that “motor” means a machine that imparts motion and that “tracks the location of said motor” means that the motor is moving to another location within the injector and that this movement is being tracked. (Doc. No. 172, pp. 33-34). The Court finds both L-F’s and Medrad’s arguments illogical and unpersuasive.

The terms “motor” and “tracks the location of said motor” are not defined by any of the asserted claims in the 612 and 197 patents. Therefore, the claims must be read in light of the specification to define the terms. See Interactive Gift Express, 256 F.3d at 1331.

The Court believes the following excerpt from the specification sufficiently defines the terms in question.

The motor 98 is coupled to a gear box which translates rotary motion of the motor to linear translation of the plunger. . . The rotation of the motor is detected by optical encoder 166 . . . Encoder 166 sends electrical pulses to circuit board 160, which relays them to PowerPC 50, allowing CPU 52 on the PowerPC to monitor movement of the motor.

612 patent, col. 10, lines 50-62
197 patent, col. 10, lines 48-60

(Doc. No. 30, Exhs. 3, 4). In other words, the “motor” is a mechanism that rotates and this rotation causes gears in the gear box to move which ultimately results in the linear movement of the plunger. "Track the location of said motor" refers to the monitoring of the rotation of the motor. 25

25 In Plaintiff Liebel-Flarsheim Company's Opposition to Medrad's Motion for Partial Summary Judgment of Invalidity and Non-Infringement of the Asserted Claims of U.S. patent Nos. 5,662,612 and 5,928,197 (Doc. 174), L-F, in its argument regarding the construction of the terms "motor" and "tracks location of said motor", presented an argument identical to the Court's present analysis of these terms. It is unclear why L-F presented a completely different, and in the Court's opinion incorrect, argument in its summary judgment motion for claim construction.

L-F's proposed interpretation equates "motor" with the "drive mechanism of the plunger". However, the term "motor" is
shown in the specifications and used in the claims as a distinct element. "Motor" is assigned reference number 98 and is depicted in Figure 5 of both patents, where the motor is different and distinct from the "gear box" (Ref. No. 164), the "optical encoder" (Ref. No. 166), the "plunger" (Ref. No. 12), the "linear pot" (Ref. No. 168), the "main circuit board" (No. 160), and other elements. (Doc. No. 30, Exhs. 3, 4). It appears that the "drive mechanism" includes parts in addition to the motor such as the gearbox, the ram, and all of the component parts that work to drive the plunger. Therefore, the motor cannot be the equivalent of the drive mechanism of the plunger.

Medrad's proposed interpretation, that the motor is moving from location to location, ignores the specification which clearly indicates that the motor is stationary. Furthermore, Medrad's proposed interpretation would exclude the preferred embodiment disclosed in the 612 and 197 patents, which describes a motor that is stationary. See Vitronics, 90 F.3d at 1583; Burke, Inc. v. Bruno Independent Living Aids, Inc., 183 F.3d 1334, 1341 (Fed.Cir. 1999).

In light of the clear and unambiguous language of the specification, the Court finds that its construction of the terms "motor" and "tracking the movement of the motor" is the more logical construction. Therefore, the Court construes the term "motor" as a stationary mechanism that rotates causing the movement of the gears in the gearbox and the term "tracking the movement of the motor" as the monitoring of the rotation of the motor.

A. "Motor Powered Means"

The parties dispute the proper construction of "motor powered means" as used in the phrase "said assembly 4 having motor powered means including a dumping assembly and an extendable element carrying an engagement assembly." See 245 Patent, col. 8, lines 3-5 (emphasis added). The parties agree "motor powered means," as used in the above phrase, is not a "means plus function" term.

Plaintiff argues the subject term should be construed as "one or more motor powered structures, including a dumping assembly and an extendable element carrying an engagement assembly." (See Pl's Proposed Order at 2:2-4.) The phrase "including a dumping assembly and an extendable element carrying an engagement assembly," however, is already included in the claim. See 245 Patent, col. 8, lines 3-5. Consequently, plaintiff's proposed construction is, more precisely, "one or more motor powered structures." Defendant argues the term should be construed as "a tool or device that has a power source for use in obtaining a particular end." 5 (See Def.'s Proposed Order at 2:7-8.)

Plaintiff argues the subject term should be construed as "one or more motor powered structures, including a dumping assembly and an extendable element carrying an engagement assembly." (See Pl's Proposed Order at 2:2-4.) The phrase "including a dumping assembly and an extendable element carrying an engagement assembly," however, is already included in the claim. See 245 Patent, col. 8, lines 3-5. Consequently, plaintiff's proposed construction is, more precisely, "one or more motor powered structures." Defendant argues the term should be construed as "a tool or device that has a power source for use in obtaining a particular end." 5 (See Def.'s Proposed Order at 2:7-8.)

Because plaintiff's proposed construction includes the word "motor," and defendant's proposed construction does not purport to construe "motor," 6 the word "motor" does not require construction. See United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997) (holding "claim construction is a matter of resolution of disputed meanings and technical scope, to clarify and when necessary to explain what the patentee covered by the claims" and is "not an obligatory exercise in redundancy"). Similarly, the word "powered" does not require construction because both parties' proposed
construction includes the word "power." See id. Finally, the ordinary definition of "means," the remaining word in the disputed term, is "structure." See Chiuminatta Concrete Concepts, Inc. v. Cardinal Indus., Inc., 145 F.3d 1303, 1308 (Fed. Cir. 1998) (holding "means" is "generic reference for corresponding structure").

6 In its brief, defendant cites a dictionary definition of "motor" as "one that imparts motion: a source of mechanical power." (See Def.'s Response to Pl.'s Opening Claim Constr. Brief at 11:22 -- 12:1.) In its proposed construction, however, defendant does not include such, or similar, language.

Accordingly, "motor powered means" is construed as "one or more motor powered structures."

1. "a body . . . mountable to the underwater cable"

This phrase is used in claim 1 of the '992 Patent. WG argues that it should be construed as "a device attached externally to an underwater cable." Ion argues that the phrase should be construed as "a body attachable . . . to the underwater cable."

In a predictable role reversal, Ion now argues that WG's construction attempts to improperly limit the scope of the claim term to a disclosed embodiment in the specification. Ion points out that, unlike with the specification of the Bittleston and Zajac Patents, that the Ion Patent does not contain any "present invention" language that would suggest that it should be so limited. Ion further argues that the testimony of Peter Canter, WG's expert, describing the difference between in-line and external devices is conclusory and should be ignored. WG points out that Ion's invention is essentially a "clamping device," which should be distinguished from the in-line devices that are embodied in WG's patent and its "Q-Marine" product. (See Peter Canter Expert Report, WG Br. Ex. D, P 55 (noting the distinction between in-line and externally attached devices).) In order to establish this distinction, WG seeks to add the word "externally" to the claim construction.

The patent claim language does not immediately reveal how the term "mountable" should be construed. However, considering the plain and ordinary meaning of the claim term, the Court agrees with WG that the word "mountable" generally connotes an external connection of some kind, rather than on in which the connection allows the attachment to become part of the base structure. Moreover, WG's construction is consistent with the single embodiment of the invention revealed in the specification, which describes an "external device" mounted to an underwater cable. ('992 Patent, Pl. Br. Ex. 6, Doc. No. 161, col. 2 ll. 66-67, col. 3 ll. 16-18.) Figure 32 of the '992 Patent likewise portrays a diagram of the streamer with an attachment that is labeled "external device." ('992 Patent at WG00029644.) Although Ion is correct that the specification does not contain the kind of "present invention" language that courts have held signal a limitation to the patent scope, the Court must acknowledge that this is the single embodiment disclosed in the specification and is consistent with the natural meaning of the claim language, as something that is "mounted" is supported by something else while remaining an entirely separate object. Finally, as WG pointed out during the Markman hearing, an examination of the prosecution history of this patent reveals that the original application for the '992 Patent specifically described an invention "having one or more external devices mounted on the cable." ('992 File History, at ION617.) Nothing in the later amendments to the application appear to have altered this initial characterization of the claimed invention.

Moreover, to construe this claim term such that the body is attached externally does not undermine the possibility of an internal component to the invention. That a body is externally mountable says nothing as to whether there might be non-external component with which the mounted body interacts for inductive coupling, as Ion's invention apparently includes. In so recognizing, the Court will not adopt WG's language which attempts to equate the term "body" with the entire device, as the portion of the invention that remains under the skin of the streamer could certainly be said to be part of the device, though perhaps not part of the body.

In the Court's opinion, the term "mountable" sufficiently conveys the notion that the body of the device is externally connected to the steamer such that it needs no construction. However, both parties appear to seek construction of the phrase.

- 3097 -
Of the two proposed constructions, the Court is of the opinion that WG's more accurately reflects the Court's understanding of the term "mountable" as it is used in this claim term. Ion's use of the word "attachable" appears to broaden the scope of the claim language, because to say that an object can be "mounted" implies something slightly more specific that to say that it can be "attached." Neither the claim language nor the specification reveal any possible embodiment of the claimed invention in which the body in question is attached, but not mounted, to the seismic streamer. The Court therefore adopts WG's construction and construes this term as "a body attached externally to the underwater cable."

2588

The parties dispute whether the In-Bed Trunk(R) weatherstrip is mounted to the channel of the In-Bed Trunk(R). As defined by the court, "mounted" means "securely affixed or fastened to." Here, the In-Bed Trunk(R) weatherstrip is not mounted to the channel. When the lid is closed the weatherstrip is compressed between the channel and the lid, but once the lid is opened, the weatherstrip remains with the lid and no longer touches the channel. In essence, the difference between the '625 patent and the In-Bed Trunk(R) is that the '625 weatherstrip is mounted to the flange and the In-Bed Trunk(R) weatherstrip is mounted to a part of the lid. This difference causes plaintiff's literal infringement claim to fail. See, e.g., Budde v. Harley-Davidson, Inc., 116 Fed. App'x 270, 273-74 (Fed. Cir. 2004) (holding that fuel injectors mounted in the intake manifold did not literally infringe a patent that required fuel injectors to be mounted in the throttle body); Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1424 (Fed. Cir. 1997) (recognizing that an accused product containing a slot in a container could not literally infringe a claim requiring that the slot be at the top of the container).

2589

1. "mounted"

The district court construed "mounted" to mean "securely affixed or fastened to." Literal Infringement Op. 2007 U.S. Dist. LEXIS 78564 at *3. Felix argues that "mounted" has the broader meaning of simply "positioned." Felix offers four arguments in support of this broader construction, each of which we reject.

First, Felix argues that the claims consistently use the term "mounted" or "mounting" "to relate the relative position of one item with another," rather than to denote affixing or fastening. Appellant's Br. at 21. Felix cites various examples from the claim language, including "a proximate end pivotally mounted in said compartment interior," "a pair of hinges each mounted on said vehicle bed," "a catch mounted on said compartment back wall," "a latch mounted on said lid lower surface," and "a knob mounted on said cable proximate end." Id. at 21 (quoting '625 patent col.4 ll.7-9, 11, 16, 18, 23-24). Felix is correct that, "[b]ecause claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims." Phillips, 415 F.3d at 1314. But nothing in the language of any of the claims requires or even suggests that "mounted" means simply "positioned" as Felix asserts. To the contrary, the use of "mounted" in the very claim terms that Felix cites strongly suggests that "mounted" means "securely affixed or fastened to." Specifically, claim 1 recites a catch "mounted" on a back wall of the storage compartment. '625 patent col.4 l.16. If the catch were merely "positioned" on the back wall without being securely affixed or fastened to the wall, it would fall off. Likewise, claim 1 recites a latch "mounted" on the lid's lower surface--i.e., on the underside of the lid. Id. col.4 l.18. If the latch were merely "positioned" on the underside of the lid, it would fall off. It is difficult to imagine how--consistent with the law of gravity--any structure could be "mounted" on the underside of any other structure if "mounted" merely meant "positioned." Additionally, claim 1 recites a prop rod "pivotally mounted" in the interior of the compartment. Id. col.4 ll.7-9. The adverb "pivotally" modifies "mounted" to make clear that the rod can pivot on the compartment interior. But if "mounted" meant simply "positioned," then "pivotally" would be surplusage, because the rod would not be affixed to the compartment interior and could move freely, without needing to "pivot" relative to the interior. We therefore conclude that the claims use "mounted" consistently to mean "securely affixed or fastened to."

Second, Felix argues that the specification does not provide "a specific method of mounting one item on or to another," but merely provides one non-limiting example--"welding." Appellant's Br. at 21-22. To the contrary, like the claims, the specification repeatedly uses "mounted" to describe structures that must be securely affixed or fastened together, else they would fall apart by operation of gravity. See, e.g., '625 patent col.3 ll.28-29 ("catch . . . mounted on the compartment back

- 3098 -
Third, Felix relies on a dictionary to argue that "mount" means simply "position." Preliminarily, we note that "it is improper to read [a claim] term to encompass a broader definition simply because it may be found in a dictionary, treatise, or other extrinsic source." Nystrom v. TREX Co., 424 F.3d 1136, 1145 (Fed. Cir. 2005). But more importantly, Felix's argument concerning the dictionary definition of "mount" is at best highly misleading and borders on a misrepresentation to the court. Citing a page from Merriam-Webster's Collegiate Dictionary (10th ed. 1997), Felix asserts that "[t]he dictionary definition of 'mount' includes 'to put or have in position' . . . ." Appellant's Br. at 22 (citing J.A. 612). But this is a misquotation. The actual definition in the cited dictionary is: "to put or have (as artillery) in position." J.A. 612 (emphasis added). A definition concerning artillery is of little relevance to a patent concerning a truck bed. By omitting the "as artillery" qualification, Felix has distorted the meaning of the cited definition. Without ellipses or some other indication that the "as artillery" language has been removed, Felix's quotation is highly misleading. Each of Felix's other proposed dictionary definitions--though quoted accurately--concerns a specialized meaning of "mount" inapplicable in the context of the '625 patent, and is inconsistent with the patent's use of the word "mounted." See J.A. 612 (defining "mount" to include "to set on something that elevates" and "to seat oneself (as on a horse) for riding" (emphasis added)). Moreover, the very dictionary that Felix cites also includes the more general definition "to attach to a support," id.--which is fully consistent with the use of the term "mounted" in the '625 patent. We therefore reject Felix's dictionary definition argument.

Finally, Felix argues that the preposition "on" in the phrase "weathertight gasket mounted on said flange," '625 patent col.6 l.1 (emphasis added), suggests that "mounted" is meant to refer only to location of the gasket relative to the flange, rather than the relationship between the gasket and the flange. According to Felix, if the limitation had been intended to indicate a connection between the gasket and the flange, it would have recited "mounted to" rather than "mounted on." We reject this argument. The preposition "on" can be used to indicate attachment. See, e.g., Oxford English Dictionary (2008) (including definition of "on" as "[a]ttached to (a chain, lead, etc.), esp. by way of restraint"). Moreover, the specification of the '625 patent consistently uses the phrase "mounted on"--not "mounted to"--in each instance discussed above, in which the specification describes structures that must be securely affixed or fastened together, else they would fall apart. See '625 patent col.3 l.128 ("mounted on"); id. col.3 l.131 (same); id. col.3 l.134 (same); id. col.3 l.140 (same); id. col.3 l.144 (same); see also id. col.3 ll.15-16 ("A compartment . . . is mounted (e.g., welded) on the truck bed floor . . . ." (emphasis added)); id. col.3 ll.32-35 ("[A]n actuator cable [is] mounted on the lid lower surface . . . by mounting clips . . . ." (emphasis added)). Thus, we are not persuaded that the preposition "on" transforms "mounted" into "positioned."

We therefore conclude that the district court's construction of "mounted" was correct. As used in claim 6 of the '625 patent, "mounted" means "securely affixed or fastened to."

GO BACK

6. "mounted"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendants' Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set or arranged on something for to use</td>
<td>Fixedly attached to use</td>
</tr>
</tbody>
</table>

a. Innoveration's Proposed Construction

Innoveration insists that the Court must look to the claims only in defining the term "mounted" because the specification provides that the embodiments are provided only by way of example. In any event, Innoveration insists, the defendants cannot deny that the Laser Gun and Target Tower game pieces of the accused game are "mounted" to their game board.
b. The Defendants' Proposed Construction

The defendants insist that their proposed construction of "mounted" is supported by the claim language, which is given life by the specification and preferred embodiments. The defendants also contend that the Examiner noted that mounting the light source on the game board was a feature that distinguished the '242 patent from prior art.

c. The Court's Construction

Claims 15 and 25 teach that there are two beam emitting devices "mounted to the game board." The Court finds that the claim language and the specification favor the defendants' posited construction. Moreover, the Court finds that the term should be given its ordinary meaning, in light of the context of the claims and specification; accordingly, the Court adopts the defendants' proposed construction defines "mounted" as "fixedly attached to."

2591

5) "Mounted in an open configuration to said vehicle window frame"

When twisted and folded for storage, the sunshade is in a "closed configuration." Consequently, the above bolded phrase means that when untwisted and unfolded, the sunshade is in its "open configuration." When held against the window, whether by the use of visors or otherwise, the sunshade is "mounted." Contrary to Defendant's contention, "mounting" does not require "fastening." Just as one can "mount" a horse without being "fastened" to the horse, so there is no requirement that the sunshade be "fastened" to the window. There must merely be some means of holding the sunshade against at least a portion of the vehicle window.

2592

Although we disagree with the court's conclusion that, as a matter of law, the Ridian Server constituted the second microcomputer means in the IridNet system, that was not the only ground on which the district court based its summary judgment on claim 1. The court also held that claim 1 could not be infringed because, "even if there was a corresponding local second microcomputer means, it is not mounted." In particular, the court construed the '421 patent to require that the structures corresponding to the second microcomputer means be "mounted on the workstation, with the result that each workstation is independent." In the accused system, the court concluded that the alleged second microcomputer means is not mounted on each workstation, and each workstation does not contain a unique mounted microcomputer.

In support of the district court's claim construction, Jenoptik argues that the phrase "mounted thereon" should be given its ordinary meaning of "fastened into position" or "fixed securely to a support." Jenoptik contends that the cell controllers in the IridNet system, which are electrically connected to one or more workstations by a serial cable but are not otherwise attached to the workstations, cannot be regarded as "mounted on the respective workstation" within the ordinary meaning of that phrase. In contrast, Asyst argues that the phrase "mounted on the respective workstation" includes direct electrical connection with the workstation, such as by a serial cable. Asyst further contends that the fact that a single cell controller in the IridNet system may be connected to and serve more than a single workstation does not avoid infringement, because claim 1 does not require that there be a one-to-one relationship between each second microcomputer means and each workstation.

We agree with Jenoptik that the ordinary meaning of "mounted on," i.e., securely attached, affixed, or fastened to, applies here and that Asyst's much broader definition must be rejected. Asyst failed to point to any intrinsic evidence to show that in the pertinent art or in the context of the '421 patent the phrase "mounted on" means connected via a serial cable.

Asyst's expert, Phillip Faillace, submitted a declaration in which he stated that, in his opinion, a cable connection between the cell controller and the workstation satisfies the "mounted thereon" limitation. That single conclusory statement by Mr. Faillace, however, is insufficient to demonstrate that the term "mounted on" had that meaning to a person of ordinary skill in
the art at the time of the patent application, particularly in light of the fact that Mr. Faillace's definition departs significantly from the ordinary meaning of the phrase.

As Jenoptik points out, both the specification and the prosecution history support the district court's determination that the phrase "mounted on" should be accorded its ordinary meaning. The specification uses the phrase "mounted on" to refer to a number of other components, and the context makes clear that the phrase is used in those instances to mean securely affixed to objects such as the transportable container, a workstation, or some component of those structures. See, e.g., '421 patent, col. 2, ll. 19-41 (describing storage means "mounted on" the transportable container; communicating means "mounted" on the processing station "adjacent the engaging means"); data processing means "mounted on" the transportable container; and means for receiving data "on the transportable container"). The phrase "mounted on" is repeatedly used interchangeably with the term "on," which in context clearly denotes a form of attachment, not simply an electrical connection. See id., col. 3, line 41 to col. 4, line 20. Moreover, on occasion the patent distinguishes between features that are "mounted on" an object and those that are "connected to" or "in electrical communication with" an object, which strongly supports the court's conclusion that the phrases "mounted on" and "in electrical communication with" do not mean the same thing in the '421 patent. See id., col. 3, ll. 48-53 ("means 50 for communication with an electronic card 40" is "mounted on the processing station" but is "connected to a data processor 20 on the processing station"); id., col. 8, ll. 14-16 (local processor 20 "is mounted on the work station 100" but is "in electronic communication with the [communication] means 50").

The prosecution history also suggests that the inventors intended the phrase "mounted on" to have its ordinary meaning and not the broader meaning proposed by Asyst. In claim 10 of the parent to the application that matured into the '421 patent, the inventors referred to a "data processing means mounted on the transportable container," but did not specify any location for the associated "communication means." When the examiner rejected that claim based on a prior art patent to Hainsworth (U.S. Patent No. 4,492,504), the inventors added a limitation that required the communication means to be "disposed adjacent the at least one processing station." The examiner continued to reject the claim on the ground that "adjacent" simply meant "not distant" and thus did not sufficiently distinguish the prior art reference. At that point, the inventors filed the continuation-in-part application that matured into the '421 patent. Claim 21 of that application, which corresponded to claim 10 of the parent application, claimed both a second two-way communication means "mounted on" a workstation and a microcomputer means "mounted on" a transportable container. The inventors commented at that time that the new claim language distinguished the Hainsworth patent because Hainsworth did not teach or suggest "the 'second two-way communication means' mounted on a work station." Although those changes related principally to the communication means rather than to the second microcomputer means, they provide evidence that the inventors meant for the term "mounted on" to be narrowly limited to a structure that is "affixed to" an object and not to include structure that is "adjacent to" that object.

There are two further problems with Asyst's proposed definition of "mounted on." First, as the district court pointed out, in the IridNet system a single cell controller may be connected to multiple workstations, and it is awkward, at the very least, to refer to a single device as being "mounted on" two separate workstations. Second, Asyst's proposed definition is in tension with one of the objectives of the "distributed processing system," as expressed in the specification and the prosecution history, i.e., to enable a system that "does not require centralized control." '421 patent, col. 11, ll. 5-6. As the inventors explained to the examiner, the claimed apparatus "permits the control of the processing of articles . . . to be maintained locally (at the 'work station') without the need for a central computer." Since Asyst's definition of "mounted on" would be consistent with a system in which a single cell controller controlled all the workstations in the system (and thus, according to Asyst's definition, would be deemed "mounted on" all of them), that system would no longer feature localized control, but would be centralized in nature, contrary to the inventors' characterization of their invention in the specification and the prosecution history. These considerations lead us to conclude that the district court was correct in holding that the IridNet system does not literally infringe claim 1 of the '421 patent.

With respect to whether the IridNet system might infringe under the doctrine of equivalents, the district court concluded that the "mounted on" limitation is binary in nature. That is, the second microcomputer means must be either mounted or unmounted. For purposes of equivalents, the court concluded, "an unmounted microcomputer means cannot be equivalent to a mounted one."

We agree with the district court's conclusion with respect to the claim of infringement under the doctrine of equivalents. To hold that "unmounted" is equivalent to "mounted" would effectively read the "mounted on" limitation out of the patent. As the district court noted, the "all elements rule" provides that the doctrine of equivalents does not apply if applying the
doctrine would vitiate an entire claim limitation. See Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 520 U.S. 17, 29, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). This case falls within both that doctrine and its corollary, the "specific exclusion" principle, since the term "mounted" can fairly be said to specifically exclude objects that are "unmounted." See SciMed Life Sys. v. Advanced Cardiovascular Sys., 242 F.3d 1337, 1346 (Fed. Cir. 2001) (noting the close kinship of the "all elements rule" and the "specific exclusion" principle); Moore U.S.A., Inc. v. Standard Register Co., 229 F.3d 1091, 1106 (Fed. Cir. 2000) ("it would defy logic to conclude that a minority--the very antithesis of a majority--could be insubstantially different from a claim limitation requiring a majority, and no reasonable juror could find otherwise"); Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1582 (Fed. Cir. 1996) ("specific exclusion" principle is "a corollary to the 'all limitations' rule"). In this case we hold that the district court was correct in ruling that the doctrine of equivalents cannot be extended to reach an "unmounted" system such as the IridNet system without vitiating the "mounted on" limitation altogether. We therefore uphold the district court's summary judgment of noninfringement with respect to claim 1, both literally and under the doctrine of equivalents.

---

4. "mounted on"

Tidel proposes the term means "attached to." FKI proposes the term means "mounted externally, not internally." Tidel's only argument is that FKI agreed to "attached to" for the construction of "mounted" in claim 3. FKI argues the plain and ordinary meaning; "on" is "on" and does not allow for "in." The specification provides that the bill receiving apparatus in the preferred embodiment can be "mounted on the interior surface or rear face of the safe door." [2:54-55] The applicant clearly intended for multiple ways to mount the apparatus. There is no support for FKI's argument that the mounting must only be on the exterior part of the door. The term mounted by itself does not connote only an attachment to the surface of the door. Mounted is defined as "set up or adjusted for use." Oxford English Dictionary. The court, therefore, construes "mounted on" to mean "attached for use."

---

5. At Least Some of Said Clusters Are Mounted on Said Base for Selective, Relative Positional Adjustment

Microsoft argues that this phrase should be construed to mean that the keys or the keys clusters must be mounted in a way that allows the keys or the clusters "to be moved by the user to different locations relative to each other to fit different hand sizes." Microsoft's Memorandum in Support of Non-Infringement of '477 patent, p. 21. Plaintiff does not contest Microsoft's construction or offer an alternative one. Rather, plaintiff argues that the plain language of the claim does not require that the keys or key clusters be adjusted to accommodate different hand sizes. I disagree.

The claim language discloses key clusters "mounted . . . for selective, positional adjustment"; thus, the plain meaning of the terms require that the keys be attached in a manner that allows them to be adjustable. Further, the specification gives context to this claim language:

"The kind of positional adjustment which has just been described may, in a certain way, be viewed as a gross adjustment -- namely, one wherein entire clusters of keys are shifted as a unit to accommodate different hand sizes. . . . For example, one can imagine a modification in which . . . the mounting structure could actually be a divided structure which permits relative positional adjustment between . . . the two keys closet closest to the tip of the associated finger as a unit with respect to the other two keys in the row."

'477 Patent, Col. 6:53-64.

Whatever this means, it is clear that the keys or key clusters must be adjustable in relation to one another. Microsoft also relies on the patent specification, which describes the purpose of allowing adjustment of the keys or the key clusters to fit different hand sizes:
Recognizing that a one-size-fits-all approach may not be entirely appropriate to deal with users' hands that are significant larger or smaller than, say, hands fitting within the 'median' of hand sizes, the structure of the invention proposed herein permits positional adjustment of arrays and clusters of keys to accommodate a size-differential concern.

'477 Patent, Col 2:46-53; see also Col. 6:42-43, 52-63.

Thus, I find that Microsoft's construction reflects the plain meaning of the language and the description of the claimed element in the specification. Accordingly, I construe this claim element to mean that keys or key clusters must be mounted on a base so as to allow for selective adjustment of the keys or key clusters to accommodate different hand sizes.

2595

(A) "mounted on said body"

MBO insists that the term "mounted on" should be construed to mean "attached to" something or "fixed securely to a support." Becton claims that the words "mounted on" should be construed to mean "attached to the exterior surface of the body." The claim language unambiguously indicates that the disputed term should be interpreted to mean "attached to the exterior surface of the body." In addition, the drawings of the 885 patent uniformly display a blocking flange that is attached to the exterior surface of the body. Furthermore, in describing the spring and the flange, the preferred embodiment explains that the gripping legs of the spring "snap past the body projections 94, and positively hold the spring on the body with no chance or [sic] accidental removal." 885 patent, col. 6, ll. 10-12. I, therefore, construe the term "mounted on" to mean "attached to the exterior surface" of the body.

2596

F. The Term "Mounted on Said Body"

The district court found that where the term "mounted on said body" appears, the mounting must be on the body's exterior. There is no reason to so limit the patent's scope. The patent figures all depict the flange connected mainly to the outside, but patent coverage is not necessarily limited to inventions that look like the ones in the figures. See, e.g., Gart v. Logitech, Inc., 254 F.3d 1334, 1342 (Fed. Cir. 2001) ("These drawings are not meant to represent 'the' invention or to limit the scope of coverage defined by the words used in the claims themselves."). To hold otherwise would be to import limitations onto the claim from the specification, which is fraught with "danger." Phillips, 415 F.3d at 1323; see also Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) ("We recognize that there is sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification."). Limiting claims from the specification is generally not permitted absent a clear disclosure that the patentee intended the claims to be limited as shown. Phillips, 415 F.3d at 1323. The proper construction for "mounted on said body" is "attached to said body."

IX. Mounted to Said Inner Tubular

Claim Term | Davis-Lynch's Proposal | Weatherford's Proposal
---|---|---
"mounted to said inner tubular" | Formed in, fastened, or attached to said inner tubular. | Fastened or attached to the inner tubular.
Claims 34, 35, 37

With regard to this term, the parties dispute whether the drop member receptacle may be "formed in" the inner tubular. To the extent that it appears elsewhere in the claims at issue, the parties have agreed to construe the term "mounted" as "fastened or attached." (Doc. Nos. 135, 136.) This construction is consistent with the plain and ordinary meaning of the term.
"mounted," and with the patent specification. For example, it describes the drop member held in a cage-like catcher/seat as being "mounted." '336 patent at 7:49-51. It describes the inner tubular held in place inside the outer tubular by shear pins as being "mounted." 7:32-35. Finally, it describes the outer tubular as being "mounted" inside the tubular string. Davis-Lynch relies on this latter example to support its construction. It points out that the patent specification states that the outer tubular may be "cemented, molded, or otherwise mounted" within the tubular string. 7:4-6. Davis-Lynch argues that the term "formed in" is synonymous with the term "molded."

Weatherford contends that the specification reference relied upon by Davis-Lynch is irrelevant because it relates to the outer tubular rather than the drop member receptacle. It further contends that even if the reference were relevant, Davis-Lynch's proposal is inconsistent with the claim language. It argues that whereas the term "mounted" relates to the fastening together of two separate objects, the term "formed in" relates to the formation of two sections of a single object. It argues that Davis-Lynch's proposal implies that the drop member receptacle is a part of the inner tubular, rather than a separate component mounted to the inner tubular.

Weatherford correctly points out that the patent specification contains no support for Davis-Lynch's position that the drop member receptacle forms a part of the inner tubular. While Davis-Lynch is technically correct that the terms "formed in" and "molded" may be synonymous, the '336 patent never uses the term "molded" in that manner. The lone reference in the patent specification relied upon by Davis-Lynch reiterates the point that the term "molded" refers to the fastening together of two separate components. To explain how the outer tubular can be "molded, or otherwise mounted" into the tubular string, the patent specification states the outer tubular may be held in place by "cement, plastics, glues, composite materials, elastomers, fibers or combinations of the above . . . and/or other attachment means such as braces, grips, latches, grooves, insets, threads, or the like." '336 patent at 7:13-20. This passage explains that the term "molded" refers to the fastening together of two separate components, e.g., a shoe that molds to the wearer's foot, rather than the formation of one component out of a material, e.g., molding a vase out of clay. Thus, even if the intrinsic evidence discloses that the drop member receptacle may be "molded" to the inner tubular, this provides no support for Davis-Lynch's proposed construction of "formed in." Weatherford's proposed construction is consistent with every other use of the term "mounted" in the patent. Accordingly, the Court adopts Weatherford's proposed construction.

The Court construes this terms of this claim element in accordance with its construction of these terms in claim 50. A "patient support assembly" must include at least one conventional mattress and an underlying patient support frame. As "mounted" means "attached to a support," WEBSTER'S, at 1477, "mounted to the frame" indicates that the patient support assembly is attached to the hospital bed frame.
"Mounting"

When construing the term "stem mounting means for mounting the stem extension to the base mounting means," the Federal Circuit asserted that the claimed function is "mounting" and held that the disclosed structure for performing this function is a Morse taper. The Federal Circuit then cited two examples from the specification. First, the Federal Circuit referenced Figure 2 of the 313 patent, which depicts a Morse taper with the mating pin on the stem extension and the recess on the base portion. Next, it pointed to Figure 8, which shows the recess on the stem extension which mates with a corresponding pin on the base portion. Based on these assertions, Zimmer argues that this claim limitation requires either the pin or recess of a Morse taper or equivalent structures. Zimmer further asserts that in holding that the claimed function is "mounting," the Federal Circuit failed to construe the term "mounting."

Zimmer asserts that "mounting" should be construed according to its ordinary meaning. Zimmer alleges that "to mount" means "to fix on or in a support, backing, setting, etc. . . . mounting means fixing' which means to make fast." 04/06/05 Zimmer Mem. at 14. Zimmer states that this construction is consistent with the way those skilled in the art use the word "mount." As such, Zimmer believes that "mounting" in this claim should be construed as "a Morse taper or equivalents thereof for fastening the stem extension to the base portion, such that the stem extension and base portion are not free to move relative to one another." (emphasis added). 04/26/05 Zimmer Mem. at 13; 05/24/05 Zimmer Mem. at 5. Zimmer argues that, in orthopaedic art, a Morse taper is a tapered post or pin that is configured to connect with a tapered recess to form a secure mating interlock. Crowninshield Decl. P 50; ex. 4, U.S. Patent 609, col. 1 ll. 28-29; Ex. G to Vogler Decl. 835 patent, col. 2 ll. 24-28. Zimmer asserts that the goal of the invention is to substitute for rigid bone. Finally, Zimmer asserts that "mounting" means "fixing," which means "to make fast." 04/06/05 Zimmer Mem. at p. 14 (quoting Webster's New Universal Unabridged Dictionary (1992) at 537 ("to make fast, firm, or stable"); 688 ("to place securely; make stable or firm").

Howmedica opposes the inclusion of an additional function beyond merely "mounting," i.e. "fixing or fastening . . . such that the stem extension and base portion are not free to move relative to one another." Rather, Howmedica proposes that this term should be construed as "a Morse taper or equivalent structures capable of performing the claimed function of mounting the stem extension to the base." Transcript of Oral Proceedings Held on 06/09/05 at 5. In its argument, Howmedica also refers to mounting as mating. Howmedica asserts that claim 1 does not recite this additional "fixing without relative movement" function. Further, Howmedica argues that the Federal Circuit instructed that section 112, paragraph 6 equivalents "must merely perform that claimed function" and that "claim 1 does not include a radial adjustability' or a releasability during surgery requirement." Fed. Cir. Op. at 12.

Howmedica asserts that a broad construction of "mounting" is consistent with the intrinsic record. The specification states that the "stem mounting portion 2 is radially adjustable in cooperation with the base mounting portion 12." 313 patent, col. 3 11. 15-16. Howmedica asserts that Zimmer's narrow construction, requiring "fixing without relative movement," would necessarily exclude this preferred embodiment. 05/06/05 Howmedica Mem. at 11. Howmedica also disputes Zimmer's assertion that the "fixing without relative movement" limitation would serve to meet the goal of the invention by stating, "the specification only discusses certain embodiments that may have a fixed arrangement." Id.

Finally, Howmedica asserts that functions other than the claimed function, such as fixing without relative movement, are irrelevant and goes on to state that Zimmer's definition of "mounting" is not supported by its own dictionaries. Id. at 10. Rather, Howmedica states "while mounting' may also include fixing or fastening, it is not limited to this. The meaning of mounting' is broader." Id. To this end, Howmedica cited definition 10a for mounting in the American Heritage Dictionary, 2 which states "to set in position for use: mount guns." Id. Howmedica reasons that this definition is applicable and useful here and further analogized that a "mounted gun is not necessarily fixed or fastened to prevent movement." Id.
This Court's construction of "mounting" does not contradict the Federal Circuit's construction of the same term. Rather, the Federal Circuit held that the claimed function in "stem mounting means for mounting the stem extension to the base mounting means" is mounting, but did not construe what the term "mounting" actually means. Therefore, this Court undertakes to construe that particular term.

Again, this Court begins its consideration of this term by looking to the claim language itself and to the specification. The specification states that "after selecting the desired position for "axis B" relative to the base portion . . . the stem extension can be releasably fixed to the base portion in the selected orientation. 313 patent, col. 3. ll. 25-29. Further, the specification describes the Morse taper as providing a "secure mating interlock" between its recess and pin and notes that additional features may be used to "further secure" the tapered connection. 313 patent, col. 3 11. 48-50. Each embodiment in the specification discloses the base mounting means being fastened to the stem mounting means, but the specification never asserts that there is no movement between them. There is nothing, then, in the written description or specification to suggest that the base portion and stem extension would not or could not have freedom of movement once mounted. See Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1462 (Fed. Cir. 1998). Rather, the specification merely discusses fixing the pin and recess together by way of a tapered or conical pin and mating recess. 313 patent, col. 3, 11. 48-50.

The specification states that the invention is "particularly suitable for modular tibial prosthesis components having modular stem extensions." 313 patent, col. 1, 11. 9-11. However, the features of this invention "could be adapted as appropriate, to other prosthetic components." 313 patent, col. 1, ll. 11-12; See also 313 patent, col. 2, ll. 5-7 ("it is particularly suitable for use with modular tibial prosthesis components, although it is not limited thereto"). This court may not limit the invention to the specific examples or preferred embodiment found in the specification. Phillips, 415 F.3d at 1323. Therefore, while the components may not actually move relative to each other when mounting tibial components, the same may not be true with other components, such as a wrist. It is not clear from the specification and prosecution history that this mounting must be accomplished without movement; in other words, a variation in the joint type (e.g. one allowing movement) might also be securely fixed in terms of mounting while still allowing for movement between the two. As such, it would be improper to limit this claim term in this manner.

A broad construction of "mounting" is consistent with the intrinsic record in this case. The specification states, "the stem mounting portion is radially adjustable in cooperation with the base mounting portion." 313 patent, col. 3, 11. 15-16. Restricting this claim in the manner requested by Zimmer would not only unnecessarily narrow this claim but also would exclude the preferred embodiment. This the Court will not do. Eolas Technologies, Inc., v. Microsoft Corp., 399 F.3d 1325, 1337 (Fed. Cir. 2005)(citing Telecom Ltd. v. Samsung Elecs., 215 F.3d 1281, 1293 (Fed. Cir. 2000). "It is elementary that a claim construction that excludes the preferred embodiment is rarely, if ever correct and would require highly persuasive evidentiary support." Neomagic Corp. v. Trident Microsystems, Inc., 287 F.3d 1062, 1074 (Fed. Cir. 2002)(quoting Vitronics, 90 F.3d at 1583 (Fed. Cir. 1996). Finally, Howmedica's construction of the term "mounting" is correct because it is consistent with the claim language and the specification. Zimmer's construction, on the other hand, is inconsistent with the claim language. If, after consulting extrinsic evidence, the claim is susceptible to a broader and narrower meaning, the narrower meaning is chosen if it is the only one clearly supported by the intrinsic evidence. Phillips, 415 F.3d at 1317-19 (discussing the proper use of extrinsic evidence). While Zimmer is correct that mounting is defined as "to make fast, firm, or stable" 3 and "to place securely; make stable or firm," 4 it also means "to set in position for use." 5 Thus, Zimmer's more narrow construction is not the only definition clearly supported by the intrinsic evidence. This Court declines to narrow the construction of this claim. Rather, it opts to construe the term in such a manner as to encompass all consistent meanings. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1343 (Fed. Cir. 2001). Therefore, this Court adopts Howmedica's proposed construction of this claim and construes this claim as: "a Morse taper or equivalent structures capable of performing the claimed function of mounting the stem extension to the base."
The proper construction of "mounting … to" is addressed next. Panduit argues that the term "mounting" requires that the exit trough be in contact with and rest upon the top edge, noting that the plain language of the claim is "mounting … to." ADC contends that the term "mounting" does not require the exit trough to be resting upon the top edge, but that it means attached to the top edge. However, ADC's construction implicitly presupposes an overly expansive meaning of "top edge," which is rejected as previously explained. The proper construction is that the term "mounting … to" requires the exit trough to be affixed to and in contact with the top edge of the lateral trough section.

a. "mounting a plurality of sensor systems at different locations on the vehicle"

Plaintiff contends that the court need not construe this phrase; however, Defendant maintains that the court should construe the phrase as "attaching at least two sensor systems to different vehicle components which are at different locations in the vehicle." (Chart at 22-23.) The parties primarily dispute whether "attaching" should be substituted for "mounting," and whether "different components" should be substituted for "different locations."

Plaintiff argues that the specification supports the use of the language in the claim, stating: "As used herein, a 'sensor system' includes any of the sensors listed below in the definition of 'sensor' as well as any type of component or assembly of components which detect, sense or measure something." '080 Patent col. 9 l.64-67. The specification also states: "Another method for controlling a part of the vehicle comprises the steps of mounting a plurality of sensor systems on the vehicle, measuring a state of the sensor system or a state of the respective mounting location of the sensor system." '080 Patent col. 8 l.36-40.

Defendant, however, argues that the prosecution history, specifically the reexamination of the '080 Patent supports its proposed construction. In particular, Defendant argues that the reexaminer rejected Plaintiff's claim because of prior art of Patent No. 5,481,906 to Nagayoshi, et al. ("Nagayoshi Patent"), which showed "a plurality of sensor systems (1) for the throttle position, for the air flow sensor, and for the oxygen sensor. Each of these respective sensor systems provides a measurement related to where it is mounted." (Def.'s Ex. 20 at 3 (internal citations omitted)). "Nagayoshi et al. does not disclose mounting a plurality of sensors systems at different locations on the vehicle. The sensor systems in Nagayoshi et al., e.g., a throttle position sensor, air flow sensor and oxygen sensor, are all mounted at the same locations, i.e., on the engine." (Def.'s Ex. 21 at 11.) Plaintiff argues that during been reexamination it argued that the Nagayoshi Patent did not disclose mounting a plurality of sensors at different locations because all of its components were located on the engine. (Def.'s Ex. 21 at 11.)

Plaintiff's claim construction is more persuasive. What constitutes a "location" or "component" on the vehicle is not defined here, nor does it appear to have been defined, or particularly considered during the reexamination in light of the Nagayoshi Patent. This prosecution history does not provide sufficient justification or explanation as to why it should override the ordinary meaning of the claim language. However, the court will construe the claim to include the term "attaching" in place of "mounting" as synonymous because "attaching" is plainer. See Merriam-Webster, available at http://www.merriam-webster.com/dictionary/mount[2] (last visited Jul. 7, 2009) ("mounting" has the meaning of "to attach to a support").

Accordingly, the court will construe "mounting a plurality of sensor systems at different locations on the vehicle" as
"attaching at least two sensor systems at different locations on the vehicle."

E. Mounting Member

Defendants seek a construction whereby the term "mounting member" would be limited to a horizontal platform. The Court finds no basis to so limit the term. Rather, the term should be construed to include a platform, frame or support on which a video game controller is mounted by the means specified in the claim.

D. Mounting Member

'092 patent claim 81 states that the table comprises two mounting members "connected to the table top" that receive the cross brace members of the retaining assemblies. (R. 58, Keller Decl., Ex. A, '092 Patent, Claim 81.) GSC claims that four of its tables (the Enduro four foot table, the Enduro Rochester table, and the 2003 Enduro six foot and eight foot tables) lack mounting members. The underside of these tables include a channel through which each cross bar passes, which GSC claims is not a mounting member.

By stating that the mounting member is connected to the table top, the claims indicate that the mounting member is a separate and distinct entity from the table top. Lifetime, once again, asserts that the specification indicates that the term "mounting member" should be broadly construed because it states that the mounting member "may be integral with the table top and may be formed by means of a corresponding mold and blow-molding process." (Id. at 11:47-53.) We decline to adopt this broad construction because it is at odds with the claim language that states that the mounting member is connected to the table top. The ordinary meaning of the term "connect" is "to become joined," which envisions that two connected items were at one time unconnected. Therefore, we construe the term "mounting member" as a structure that is separate and distinct from the table top; a mounting member cannot be an integral part of the table top.

Footnotes

6 We also note that the differences between the mounting member in this patent and the mounting member in patent '331, discussed in more detail below, which is "integrally formed in the mounting surface of the, [sic] table top." (R. 58, Keller Decl., Ex. B, '331 Patent, Claim 1.)

B. Mounting Surface

'092 patent claim 76 states that the table comprises "a frame connected to the mounting surface of the table top." (R. 58, Keller Decl., Ex. A, '092 Patent, Claim 76.) GSC contends that, even if the side rails on its tables constitute a frame, the side rails are connected to interior walls, rather than to a mounting surface. GSC asserts that the mounting surface should be construed as the "flat underside of the table top." For the reasons provided below, we adopt GSC's proposed construction.

The patent's claims do not explicitly define the term "mounting surface." Claim 1 simply states that the table comprises "a working surface and a mounting surface." (Id., Claim 1.) This claim does not provide any other details about the mounting surface. The patent's specification supports a broad interpretation of mounting surface because it states that the interior walls are part of the mounting surface. (Id. at 5:51-54.) This broad definition, however, is inconsistent with other claims. For example, claim 17 refers to a "boundary defined by the mounting surface and the downwardly extending lip." (Id., Claim
17.) The downwardly extending lip is, therefore, not part of the mounting surface. And claim 15 states that the support pedestals "are disposed generally parallel and adjacent to the mounting surface of the table top in the collapsed position." (Id., Claim 15.) The mounting surface must be generally flat to permit the support pedestals to be generally parallel to it in the collapsed position. Were the mounting surface to encompass the entire underside of the table top, there would be no boundary between the downwardly extending lip and the mounting surface and it would be impossible for anything to be generally parallel with the mounting surface. The claims, therefore, limit the scope of the mounting surface to the "flat underside of the table top." Notwithstanding the broad meaning of mounting surface used in the specification, we construe the term "mounting surface" as the "flat underside of the table top."

2606

6. "Mouth Feature"

Hoodlums defines "mouth feature" as "[t]he part of the face through which food is taken, including but not limited to the mouth features shown in Figures 5 through 9 of the '972 patent." (Doc. 37, Ex. B at 5-6.) Redtail defines "mouth feature" as "[p]rominent and distinctive characteristics of the opening in the head of an animal through which food is ingested." (Id.)

The term "mouth feature" closely resembles the previously defined terms "skull facial features," "facial features," and "nose feature." In this case, "mouth feature" is only found in claim 1, and the specification and the prosecution history do not provide any particular meaning to the term. The dictionary defines "mouth" as "an opening between lips of men and animals through which food is taken." New Webster's Dictionary and Thesaurus, 251. This definition captures the ordinary and customary meaning of the word "mouth." However, the addition of the word "feature" strongly suggests that the term "mouth feature" includes more than just the definition of "mouth." See Phillips, 415 F.3d at 1314.

Looking to the claims, the specification, Federal Circuit law, and the dictionary, the court defines "mouth feature" as "the part of the face through which food is taken, including, but not limited to, the mouth features shown in Figures 5 through 9 of the '972 patent."

2607

3. mouthpiece

P&M construes the term "mouthpiece", as used in both the '886 and '300 patents, as "that part of the apparatus which is placed in the mouth to introduce air into the housing where it moves over the pen and out the nozzle's outlet orifice." (Pls. Opening Mem. at 15.) P&M cites the Webster's Third New Int'l Dictionary definition of mouthpiece as "a part which goes in the mouth." (Pls. Opening Mem. at 16.) Rose Art construes "mouthpiece" in both patents as the "piece placed at the mouth for entry of air into the airbrush, but not including connectors (e.g. flexible tubes)." (Def. Pre-Markman Hr'g Br. at 21.)

Rose Art supports its argument by citation to extrinsic evidence, namely British Patent 237,278 from 1925 (the "Plasto-Vertrieb patent") which, Rose Art states, claims a mouthpiece which includes only the piece which comes into contact with the mouth and not the flexible tube attached to it. (Def. Pre-Markman Hr'g Br. at 22.) Rose Art contends that a person skilled in the art would understand this prior patent to mean that "mouthpiece" is never used to describe a connector.

The preferred embodiment of the '886 patent which is seen in figs. 1 and 4 has a mouthpiece which may be released or separated from the housing. ('886 patent, col. 4, ll. 22-23.) The fig. 8 preferred embodiment of the '886 patent has a mouthpiece which is the end of a tube connected to the barrel of the housing. ('886 patent, col. 3, ll. 21-22.) The description of fig. 8 in the '886 patent specification states "connected to one side of the barrel 20 is a tube 26 formed at its free end with a mouth piece 27. In this embodiment, therefore, air is blown through the mouth piece 27 and tube 26 into the barrel 20 . . . ." ('886 patent, col. 3, ll. 21-24.) Since the mouthpiece on the fig. 8 embodiment is part of the connector, the term "mouthpiece" cannot be construed to exclude connectors. Vitronics, 90 F.3d at 1583-84. Moreover, since the patent does not distinguish between the materials which could be used for this connector, the term cannot be construed to exclude connectors which are made of flexible plastic tubes. In fact, the specification states that the apparatus may "be produced from a variety of materials, one typical material being plastics." ('886 patent, col. 3, ll. 29-30.) Accordingly, the term

PUBPAT
"mouthpiece" as used in both the '886 and '300 patents is construed as "that part of the apparatus which is placed in the mouth to introduce air into the housing where it moves over the pen and out the nozzle's outlet orifice." Since the entirety of the intrinsic evidence with regard to this term is not ambiguous, the Court did not consider the extrinsic evidence submitted by the parties with respect to this term.

2608

b. "Movable" or "Moved"

The terms "movable" and "moved" are found in Claim 5 of the '477 Patent. See '477 Patent col. 10 ll. 3-4 ("elongate members being movable within said one or more shafts from an open position to a closed position"); id. col. 10 l. 17 ("elongate members are moved to said open position"). Millipore contends that the term "movable" should be given its ordinary meaning, namely "capable of being moved." Millipore further argues that the term "moved" should be construed to refer to the past principle of the verb to move, i.e., "to change position." In making this argument, Millipore relies on dictionary definitions.

As noted above, when the meaning of claim language is readily apparent, "general purpose dictionaries may be helpful." Phillips, 415 F.3d at 1314. Consequently, I adopt Millipore's construction of the terms "movable" and "moved," as being respectively "capable of being moved" and the past principle of the verb to move, i.e., "to change position." See Webster's Third New International Dictionary at 1479-80 (2002).

2609

The Meaning of "Movable"

Phillips teaches that words should generally be given their ordinary and customary meaning, particularly from the vantage point of a person of ordinary skill in the art. 415 F.3d at 1313. (This provides the objective baseline from which claim construction should begin. Id.) The parties predictably offer competing versions of the meaning of "movable."

(1) Innovation's Proposed Construction

Innovation first insists that "movable" must be given its plain meaning; and adds that the defendants did not seek construction of "movable" despite having had an opportunity to do so during the Court's Markman proceeding. Unsurprisingly, Innovation equates plain meaning with a generous construction of "movable"; that "movable" be defined as it is in the dictionary: "able to be moved" (The Oxford American Dictionary (1980)) or "possible to move" (The American Heritage Dictionary of the English Language, 4th ed. (2006)). Innovation submits that the defendants fail to overcome the presumption that a claim term carries its ordinary and customary meaning, and therefore fail to demonstrate a reason to narrow the scope of the claim term from that meaning. Moreover, Innovation insists, the defendants' proposed construction (which begins with repeating the term it seeks to construe, then adding 21 additional words to modify "movable" rather than define the term) is contrary to its plain meaning. 13

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

12 The plaintiff relies on Eli Lilly and Co. v. Aradigm Corp., 376 F.3d 1352, 1360 (Fed. Cir. 2004), in which the court determined that the defendant had waived its right to request construction of relevant claim, and had "thereby implicitly conceded that the meanings of the terms in [the relevant claim] are clear and not in need of construction." (The defendant
had never requested the district court construe the relevant term, and never offered a construction of the claim until all of the evidence was presented to the jury. Id.)

13 Innovention points out that it used additional wording beyond "move" when it intended to mean movement within the rules of the game; for example, each of claims 39 and 40 recite "each turn comprising moving, either a translational or a rotation, a piece" and go on to add "wherein moving a piece consists of a movement one space in a horizontal, vertical, or diagonal direction to an unoccupied adjacent space." Finally, Innovention seeks to overcome the defendants' argument that it is estopped from asserting a broad construction of "movable" by asserting that it did not contrast the stationary deflecting pieces with movable key game pieces; rather, Innovention states that it distinguished the key pieces of its claims from the deflecting pieces of the prior art by pointing out that the deflecting pieces "are two-sided mirrors", and as a result did not meet the "non-mirrored" requirement of the key pieces. In distinguishing Swift, Innovention stated:

[the Swift patent] fails to disclose that some of the game pieces have no mirrored surfaces (non-mirrored), as recited, for example, in independent claims 15, 25, 31, 40 and 41. Accordingly, Swift also fails to disclose non-mirrored game pieces that are movable, as recited in independent claims 31 and 41.

(2) Defendants' Proposed Construction

The defendants seek a contrary construction of "movable." They insist that the patentee intended to mean something more than "not cemented to the Earth"; defendants further suggest that the claims of the '242 Patent use the word "movable" to mean more than something that can be removed from the game board when the game is being disassembled. What Innovention is referring to, say defendants, is "moves that players make according to the rules of the game." 14 Accordingly, defendants submit that "movable" must be construed as: "movable from space to space or by rotation within a single space according to the rules of the game during play."

14 Indeed, during oral argument, counsel for defendants emphasized that, in the board game playing context, the concept of the root "move" is a term of art: telling your opponent "your move!" means none other than suggesting that it is your opponent's turn to move one of the game pieces on the board.

Because the claims of the '242 Patent themselves define "moving" as either "translational or rotation" of a game piece, and also specify that moving a piece "consists of movement one space in a horizontal, vertical, or diagonal direction to an unoccupied adjacent space" or that it consists of "remaining in the same space and rotating the piece", something limiting the plaintiff's advocated construction of the term is explicit in the claim terms. The written description of the '242 Patent confirms that there are two kinds of movement relevant to game pieces, say defendants: (1) translational movement from space to space or (2) rotational movement within a space.

(3) The Court's Construction

As this Court previously noted in its February 19, 2009 Order and Reasons:

[The] key pieces disclosed in the Swift reference are permanently fixed to the game board and, therefore, cannot be moved prior to or during game play. The key pieces of the '242 Patent, by contrast, may be positioned in different spaces at the beginning of each game and can also be moved during game play. There are thus two possible distinctions that may have been intended by the plaintiff with the addition of the term "movable" key pieces to claims 31, 39, 40 and 41. Which of those distinctions was in fact intended by the plaintiff will be a question for the Court to determine during its claim construction analysis.

Now faced with this task, though belatedly so, the Court begins with the words of the claims themselves. Claims 31, 39, 40, and 41 invoke the concept of "movable."
Claim 31, for example, discloses:

A board game for two opposing players or teams of players comprising:

- a game board, movable playing pieces having at least one mirrored surface, movable key playing pieces having no mirrored surfaces, and a laser source,

wherein alternate turns are taken to move playing pieces for the purpose of deflecting laser beams, so as to illuminate the key playing piece of the opponent.

Claim 39 discloses:

A method of playing a game by opposed players; said game comprising two sets of distinguishable playing pieces, each set having movable pieces with no mirrored surfaces, of which one is a key piece, and pieces with at least one mirrored surface, a game board consisting of a first end, a second end, and a plurality of rows and columns, intersecting to form a plurality of spaces, the method comprising the steps of: placing each player's set of playing pieces on the game in a predetermined starting configuration; and alternating turns, each turn comprising moving, either a translation or a rotation, a piece followed by activation of a laser, said alternating moves continuing until one player illuminates the opposing player's key piece; wherein moving a piece consists of a movement one space in a horizontal, vertical, or diagonal direction to an unoccupied adjacent space.

The Court adopts a slightly modified construction of "movable." The Court finds that, based on the claim language and the plain meaning of the term, "movable" means "capable of movement as called for by the rules of the game or game strategy."

--- Footnotes ---

15 The defendants' posited definition contains limitations not inherent in the ordinary meaning of "movable" and would render redundant other claim language, while the plaintiffs' posited construction is too far removed from the claim language and its contextual written description. The Court also notes that prosecution history appears to favor a less cramped construction of "movable", contrary to the defendants' suggestion, as noted by the Court in its February 19, 2009 Order & Reasons, given that the pieces in Swift were permanently fixed to the game board.

--- End Footnotes ---

E. "Movable"

Tessera proposes that the Court adopt the TI construction of "movable": "In the operation of the assembly, the terminals are capable of being displaced relative to the chip by external loads applied to the terminals, to the extent that the displacement appreciably relieves mechanical stresses, such as those caused by differential thermal expansion which would be present in the electrical connections absent such displacement." See TI Order at 19. Samsung proposes "capable of being moved."

The Court finds that Tessera's proposed construction is more appropriate. Movable, in the context of the claims at issue, is a term of degree. The claim term means movable enough to appreciably relieve mechanical stresses. Thus, "movable" means that "in the operation of the assembly, the terminals are capable of being displaced relative to the chip by external loads applied to the terminals, to the extent that the displacement appreciably relieves mechanical stresses, such as those caused by differential thermal expansion which would be present in the electrical connections absent such displacement."

--- Back ---
1. Movable Bridge.

The Court believes that the term "movable bridge" is not clear on its face to one of ordinary skill in the art and that, therefore, construction is warranted. The parties agree that the term refers to contact arms 50 and 70, listed in the specification. See Leviton's Memo at 18; Defendants' Memo at 29; Defendants' Presentation at 33, 36. The patent does not any where else define or reference, however, either "movable bridge" or contact arm, and thus the term "movable bridge" needs constructing.

Leviton points out that the examiner used "movable bridge" in communications with it during prosecution of the '766 patent. See Leviton Memo, Exhibit D, Examiner's Amendment at 2-3. The examiner merely restates the term, however, and does not further elucidate its meaning. See id. The Defendants' note that the '766 patent's re-examiner, reasoning that "all of the unfixed or non-permanent electrical connections in the claim are designed as 'capable of being connected,' whereas the connection between the movable bridge and the first electrical conductor is designed as being 'electrically connected,'" construed "movable bridge" as always connected to the "first electrical conductor." Defendants' Memo, Exhibit F, Inter Partes Reexamination at 2, 3, 6-8. Because "movable bridge" is not clear on its face to one of ordinary skill in the art, and because the patent does not, either in the claims or specification, give meaning to the term, it is appropriate to look to extrinsic evidence such as dictionaries and textbooks. See Markman v. Westview Instruments, Inc., 52 F.3d at 980 (stating that it is appropriate to consult extrinsic sources, such as dictionaries, learned treatises, and expert testimony, if ambiguity persists after reviewing intrinsic sources).

The McGraw-Hill Dictionary of Scientific and Technical Terms defines "bridge" as "[a]n electrical shunt path." Defendants' Memo at 29 (quoting McGraw-Hill Dictionary of Scientific and Technical Terms 268 (5th ed. 1994)). A "shunt path" is "an electrical path in which components are each connected in parallel (i.e. to the ends of the circuit)." Defendants' Memo at 29 (citing McGraw-Hill Dictionary of Scientific and Technical Terms 1443, 1818, 2002 ("shunt . . . [ELEC] 1. A precision low-value resistor placed across the terminals of an ammeter to increase its range by allowing a known fraction of the circuit current to go around the meter. Also known as electric shunt. 2. To place in parallel with another. parallel . . . [ELEC] Connected to the same pair of terminals. Also known as multiple; shunt. terminal . . . [ELEC] 1. A screw, soldering lug, or other point to which electric connections can be made. Also known as an electric terminal. . . . 3. One of the electric input or output points of a circuit or component."). Leviton does not dispute the Defendants' interpretation of the terms defined in the McGraw-Hill dictionary.

Based upon the claims, specification, re-examiner's statements, and the definitions extracted from the McGraw-Hill Dictionary, the Defendants propose that the term "movable bridge" be construed as: "At least one moveable arm that is always electrically connected to the first electrical conductor and that has the ability to create a parallel conductive path between the first, second, and third electrical conductors." Defendants' Presentation at 32. Citing its expert Dr. De La Ere's testimony, Leviton contends that the Defendants' construction is wrong, because the claim language refers only to the creation of a "single electrical connecting point," rather than two distinct electrical connecting points as would be required for a "parallel conductive path" to be created. Leviton's Memo at 18; De La Ere Declaration P 22, at 11. The Defendants counter, however, that the fact that the unbroken circuit paths constitute but a "single point" does not mean that the circuit does not have "separate conductive paths." Memorandum of Points and Authorities Further Supporting Defendants' Claim Construction for U.S. Pat. No. 6,864,766 at 11 ("Defendants' Response"). The Defendants support that assertion by pointing out that Dr. De La Ere conceded that the device claimed in the '766 patent would contain a first, second, and third electrical conductor when each of the conductive paths is electrically connected to the other, and would maintain electrical conductivity from the line terminals to the downstream terminals, even if the contact in the device was damaged such that it would not conduct electricity to the user accessible load terminals. See Defendants' Response at 11; Defendants' Response, Exhibit B, Deposition of Jaime De La Ere at 64:8-18 (taken August 31, 2006)("August 31 De La Ere Deposition"); Id. at 73:7-17.

The Court disagrees with Leviton's position that "movable bridge" is clear on its face to one of ordinary skill in the art. See Leviton Manufacturing Co., Inc.'s Responsive Brief on Claim Construction, Exhibit D, Plaintiff's Proposed Claim Construction of the '766 Patent, filed September 15, 2006 (Doc. 115). The Court also concludes that the construction Leviton proposes for the term, "a movable bridge is a movable structure," serves to make the term more open ended and less...
certain than it already is. Id. Given those conclusions, finding that there is sufficient prosecution history to support the "is always electrically connected to the first electrical conductor" portion of the Defendants' proposed construction, see Phillips v. AWH Corp., 415 F.3d at 1317 (the prosecution history is intrinsic evidence that should be considered in determining the meaning of claims); Defendants' Memo, Exhibit F, Inter Partes Reexamination at 2, 3, 6-8, finding that intrinsic sources leave the term "movable bridge" ambiguous, and concluding that the dictionary derived meaning the Defendants put forth clarifies the term, see Markman v. Westview Instruments, Inc., 52 F.3d at 980 (stating that it is appropriate to consult extrinsic sources, such as dictionaries, learned treatises, and expert testimony, if ambiguity persists after reviewing intrinsic sources); McGraw-Hill Dictionary of Scientific and Technical Terms at 268, 1443, 1818, 2002, the Court will adopt the Defendants' proposed construction of "movable bridge."

2612

D. "Moveable"

Claims 8, 26, and 40 describe the mobile workstation as being supported by "a moveable chassis." (Joint Claim Construction Statement at 6). The Plaintiff defines the term moveable as "adapted for mobility." (Joint Claim Construction Statement at 6). The Defendant counters with a broader definition and describes the term as "capable of being conveyed from one place to another." (Joint Claim Construction Statement at 6).

The Defendant argues that its limited definition of "moveable" is more consistent with the ordinary meaning of the term. The Defendant argues that many things can be moveable, and yet not mobile. In this vein, the Federal Circuit has cautioned against district courts reading limitations into terms from the specifications in the patent. See, e.g., Phillips, 415 F.3d at 1323. However, Phillips also made clear that "the purposes of the specification are to teach and enable those of skill in the art to make and use the invention and to provide the best mode for doing so." Id. Sometimes, it is clear from the patent documents that "the claims and the embodiments in the specification [are] to be strictly coextensive." Id. This is such a case. Here, the name of the invention is a "Mobile Clinical Workstation." (the '178 patent, Col. 1). In the "Summary of the Invention," the invention is described as "meet[ing] the needs [of] a mobile workstation that includes a wheeled chassis. . . . A medical practitioner making the rounds can push the mobile workstation from room to room..." (the '178 patent, Col. 2, lines 61-62). Every drawing of the chassis has wheels attached to it. Claim 1 says that the mobile workstation is comprised of a "wheeled chassis." (the '178 patent, claim 1). Even when the chassis is described as "moveable," it is still preceded as being part of "a mobile workstation." (the '178 patent, claims 8, 26, 40). Any person skilled in the art would recognize that the workstation was meant to be wheeled around by practitioners. It is clear that the moveable chassis is indeed adapted for mobility, and not meant to be capable of being conveyed - by any means - from one place to another.

2613

s. "Movable Element" (Claim 34)

121. This claim limitation uses the term "element" which is the equivalent of "means" for the same reasons stated above. The terminology "movable element" has not been shown to have a generally understood meaning in the art. Cf., Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996) ("detent mechanism" had well-understood meaning in the field). This term is neither mentioned nor defined in the specification of the '656 patent. The term finds its first appearance in Claim 34 where it is defined in purely functional terms.

122. The specific words chosen for this element by the patentee show an intent to define the claim language in the § 112 P6 format. The word "element" is modified by "movable", a functional description. The "element" or means is also described principally in terms of its five functions: (1) being disengaged from the driving surface on the cam before entry of the combination; (2) for projecting a sufficient distance; (3) so that movement of the driving surface on the cam moves the movable element which in turn causes the movable link member to be moved; (4) thereby permitting the lever to engage the cam surface; and (5) so that movement of the cam surface moves the lever. The "element" is thus described in terms of what
it does, i.e. its function, not in terms of what it is -- its mechanical structure -- thus bringing the claim limitation within § 112 P6.

123. In the specification of the '656 patent, the movable element or means is described as a spherical ball which is normally positioned below the upper surface of the solenoid housing and out of contact with the dial cam. When the solenoid is actuated, the spherical ball can project, extend or protrude outwardly of the upper surface of the solenoid housing so as to project into the path of a protrusion or boss on the dial cam. Further rotation of the dial cam causes the protrusion or boss to contact the spherical ball and move the solenoid housing linearly. Movement of the solenoid housing causes the lower end of the cantilever arm to be displaced from the recess on the upper surface of the solenoid housing allowing the lever arm to be released, thereby permitting the nose of the lever to engage the cam surface so that further rotation of the dial moves the lever arm to pull the bolt.

GO BACK

2614

124. This limitation should be construed as a means-plus-function claim element for the same reasons as "movable element"; the term "element" is the equivalent of "means". There is no evidence that a "movable link element" has any commonly understood meaning in the field. Cf., Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996) ("detent mechanism" had well-understood meaning in the field). In the '656 patent, the "movable link element" is defined as a spherical or curved surface detent ball 96 which can project, extend, or protrude outwardly of the solenoid housing to a detented or engagement position upon actuation of the solenoid. Col. 6, lines 12-22. Even though this element may be defined in terms of some minimal structure, "the recitation of some structure in a means-plus-function element does not preclude the applicability of § 112(6)". Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991).

125. In Claim 31, the "movable link element" is defined primarily in terms of its function. The term "movable" modifying "link element" shows an intent to define the term functionally -- that the link element is movable, rather than being defined in a particular structural way. The "movable link element" is also defined by the words which follow, principally in terms of seven functions: (1) being movable from a withdrawn position; (2) being movable to an engagement position; (3) being movable in such a way that at least part of the cam engages the movable link element; (4) being positioned substantially at the withdrawn position; (5) being movable to the engagement position only after entry of the combination; (6) wherein the cam contacts and moves the movable link element; and (7) movement of the link element by the cam causes the lever moving element to move the lever.

126. In the specification of the '656 patent, the movable link element is identified as a spherical or curved surface on detent ball 96. In connection with the portion identified as a "movable link element", actuation of the solenoid causes the spherical detent ball to move in a straight line from a first position within the solenoid housing to the detented position where the ball projects, extends or protrudes above the top of the solenoid housing within the path of a boss on the periphery of the dial cam. Movement of the solenoid housing releases the lower end on the cantilever arm which causes the arm to shift position and move the lever into engagement with the dial cam.

GO BACK

2615

127. This claim limitation defines a movable link member "for holding the lever out of engagement with the cam surface before entry of a combination and for releasing the lever after entry of the combination. Thus, the movable link member is defined in terms of an element for performing the described functions. As previously noted, merely because an element does not include the word "means" does not prevent that element from being considered as a mean-plus-function element under § 112 P6.

128. This term is neither used nor defined in the description of the '656 patent. The terminology appears for the first time in
the claims where the element is defined in purely functional terms. There is no evidence that a "movable link member" has a well-understood meaning in the art. Cf. Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996) ("detent mechanism" had well-understood meaning in the field).

129. The prosecution history demonstrates that the patent applicants used the word "member" and "element" interchangeably, since many of the claims were amended to change from one term to the other. In fact, Claim 43 was expressly amended to change from "movable link element" to "movable link member". PX 45, p. 140, 169, 194. The reason for this change was not for substantive reasons, but simply to "more clearly define the invention". Id, p. 169, 194. Consequently, no substantive change was intended by the patent applicants. Other claims were similarly amended to use the terms "element" and "member" interchangeably. See PX 45, p. 139, 168-9, 193-4 (Claim 57, "element" to "member"); p. 139, 169, 194, 237 (Claim 58, "element" to "member"); p. 168, 193, 237 (claim 56, "member" to "element"). These amendments, as well, were made to eliminate indefiniteness, and to more clearly define the invention, not for substantive purposes. Id, p. 169, 194. This demonstrates the applicants' intention to use the term "member" synonymously with "element". Since "element" has been shown hereinabove to be synonymous with "means", "member" is also synonymous with "means". Thus, while this claim limitation does not use the term "means for", its language is equivalent to means-plus-function format under the principles described above: the use of the term "member for" is synonymous with "means for". Even though this claim limitation may be defined in terms of some minimal structure, the recitation of some structure in a means-plus-function element does not preclude the applicability of § 112 P6. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991).

130. In these claims, the "movable link member" is defined primarily in terms of its functions. The term "movable" modifying "link member" shows an intent to define the term functionally -- that the link member is movable, rather than being defined in a particular structural way. The "movable link member" is also defined by the words which follow, principally in terms of two functions: (1) holding the lever out of engagement; and (2) releasing the lever. This demonstrates a clearly expressed intent to claim in § 112 P6 format. Clearly, the applicants did not attempt to claim the "member" in terms of structure, but rather functionally in terms of its two stated functions. Consequently, this claim limitation should be construed according to § 112 P6.

131. In the specification of the '656 patent, the structure disclosed associated with the movable link member comprises a lever held up out of contact with the dial cam by a cantilever arm which is an integral part of the lever and which includes a movable spring-loaded pin contained within a bore. The lower end of the spring-loaded pin normally rests within a recess in the upper surface of the solenoid housing. The solenoid housing (which is also called a rigid body or element) slides in a channel to release the lever from its disengaged position. Consequently, after the combination has been entered, the movable link member releases the lever.

2. "Movable Sealing Baffle(s)"

The parties' other claim-construction dispute concerns the meaning of the term "movable sealing baffle" in the following two limitations: "one or more parallel, movable sealing baffles operatively connected to the chamber and extending along the height of the product for forming a seal between the product and the sidewall," (Doc. 66, Ex. A, cl. 19d); and "a movable sealing baffle operatively connected to the chamber and extending the height of the product for controlling fluid flow through the chamber," (Id. cl. 35c).

As to these limitations, Thermal and Dade propose competing interpretations, Thermal's toward abstraction, and Dade's toward a preferred embodiment. Thermal suggests that the term "movable sealing baffle" should be read broadly to include a baffle capable of partial movement, flexing, vibration, and compression in response to force. (See Doc. 80 at 37). Dade contends that the term "movable sealing baffle" describes a unitary baffle capable of being moved, in its entirety, into or out of a sealing arrangement between the sidewall and the stored product, so as to change the volume of the chamber to account for different sized loads of stored product. (Doc. 70 at 11). Thermal, in response, points out that Claims 19d and 35c do not say a "baffle that's movable in its entirety.' It just says, 'a movable sealing baffle.' Dade is seeking to add extraneous limitations." (Id. at 15).
To be sure, the Court cannot read extraneous limitations into a claim. See Intervet America, Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989). Nevertheless, "in judicial 'claim construction' the court must achieve the same understanding of the patent, as a document whose meaning and scope have legal consequences, as would a person experienced in the technology of the invention." Toro Co. v. White Consol. Indus. Inc., 199 F.3d 1295, 1299 (Fed. Cir. 1999). This is not achieved by simply relying on a dictionary of general linguistic usage. Id. The meaning of a claim is to be understood in context. See id.; Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1251 (Fed. Cir. 1998).

Although, in certain contexts, the term "moveable" may be understood, in a very general sense, to connote any type of movement, including flexing, the context of the instant claims does not admit such a meaning. Thermal's construction of the term "movable sealing baffle" conflates that term with the term "flexible sealing member." Neither the claim, nor the other intrinsic evidence, would put a person of ordinary skill in the art on notice of such a meaning. Rather, the movement about which the 557 Patent gives notice is a baffle's capacity to be moved, as an entire unit, into and out of a sealing orientation in respect to the chamber and the stored product. 5 The Court thus concludes that the term "movable sealing baffle" carries the following meaning in the following claims:

5 This understanding of the term "movable sealing baffle" extends to both Claims 19 and 35. The Court may undertake a more precise construction of that term once the issues, or contested embodiments, are drawn into sharper focus. Suffice it to say that the Court views the probable function of the movable sealing baffle(s) as being to reduce the volume (size) of the "first" or "second" volume into which the fluid control unit injects fluid. Variations in the amount of stored produce could create a need to reduce the volume into which fluid is injected. It appears, for instance, that a chamber half full of stored product would require a movable sealing baffle and a flexible sealing member to work together, in relation to the stored product, to create a division between -- thus, creating -- the first and second volumes.

Claim 19d: one or more parallel structures, operatively connected to the chamber and extending along the height of the product, that deflect, check, or regulate fluid flow by being positioned, as entire units, to create a seal between the sidewall and the stored product; and

Claim 35c: a structure, operatively connected to the chamber and extending the height of the product, that deflects, checks, or regulates fluid flow by being positioned, as an entire unit, to create a seal between the chamber and the stored product.

6 Claim 19 explicitly limits the sealing orientation to between the sidewall and the product. Claim 35 appears to contain the same limitation as the baffle "extends the height" of the product.

Safety 1st's argument with respect to the "movably connected" limitation of claim 36 is that it would be counter to the ordinary meaning of the chosen claim language if the "suspension assembly" and "support frame" were permitted to have in
common a major structural component, namely, one of the legs. In support, Safety 1st cites to Maxwell v. J. Baker, Inc., 86 F.3d 1098, 1105 (Fed. Cir. 1996), where we refused to construe a claim that separately recited a "shoe upper" and a "tab" that extended along the shoe upper in a manner that would have allowed the "tab" to include a portion of the "shoe upper." In similar fashion, Safety 1st asserts that "if one component is said to be 'movably connected' to another, and if 'movably connected' is given its ordinary meaning, it would seem that the two components would have to be separate.

The problem with this argument, as Fisher-Price notes, is that nothing in the plain meaning of the phrase "'movably connected' [inherently] eliminates the possibility of common portions shared between the members so connected." In fact, Fisher-Price compellingly argues that such a construction would read out a preferred embodiment of the invention. Finally, the district court noted that Fisher-Price put forth expert testimony to support its infringement theory. Fisher-Price, 279 F. Supp. 2d at 541. The expert used demonstrative exhibits and models of the accused products to support his testimony. Id. On the other hand, Safety 1st "adduced no expert opinion to the contrary, but merely argued though counsel that the accused products did not meet the 'movably connected' limitation." Id. As the district court noted, "the jury rejected [Safety 1st's] argument, as it was entitled to do." Id.

Because the district court did not err in its construction of the "movably connected" limitation, and because there is substantial evidence to support the jury's factual finding that the Bouncenette products meet this claim limitation, we will not disturb the jury's infringement determination.

2618

H. "Movably Mounted" and "Movably Suspended"

The next terms to construe are "moveably mounted" found in claim 1 of the '677 patent and "moveably suspended" found in claim 7 of the '677 patent. Hysitron asserts that these terms are common and easily understandable and do not require clarification. Joint Claim Construction Statement at 48, 58. To the extent the terms require a definition, Hysitron offers "the pick-up plate be mounted in a manner that enables it to move relative to the drive plate." Id. MTS asserts the terms mean "directly attached to springs or to some other compliant suspension element allowing movement or relative motion." Id. at 49, 58. The dispute over these terms echoes the dispute discussed in the previous section, and MTS's construction fails for the same reason. The Court construes "moveably mounted" and "moveably suspended" to mean that "the pick-up plate be mounted in a manner that enables it to move relative to the drive plate."
As with the previous two groups of terms, Crane urges the court to adopt the plain meaning for "movement by gravity." The defendants assert that claim differentiation warrants the restriction of the patents' use of "movement by gravity," generally, to "movement only by gravity." The defendants points to three claims in which the term "gravity" is used to move the beverage containers.

15. The method of claim 14, wherein the step of transferring one of the beverage containers from the selected container queue includes releasing said first-in-line container for movement by gravity into said robotic assembly.

57. The vending machine of claim 35, including release means cooperatively connected with said container holding means and activatable by said beverage container capture means for releasing by gravity a selected container from said container holding means to said beverage container capture means.

86. The vending machine of claim 85, wherein said robotic assembly is operable to remove said selected products from said at least one inclined queue by sliding said selected products with the help of gravity into said robotic assembly. '930 Patent, cls. 15, 57 & 86.

Generally, the defendants contend that the claims imply that the force of gravity may influence the movement of the product in varying degrees. In other words, because claims 57 and 86 include the terms "releasing" and "help of," respectively, use of the term "movement" in claim 15 must mean that gravity alone causes the product to move into the robotic assembly.

The court is not persuaded. Nothing in claim 15 requires that gravity alone causes the product to move into the robotic assembly. And, the specification expressly states that "the principles of this invention do not require movement of the products . . . to be accomplished entirely by gravity." This statement challenges the defendants' construction. '930 Patent, col. 10, 1. 46 (emphasis added).

For these reasons, the court rejects the defendants' proposed construction that "movement by gravity" means "movement only by gravity." The claim language needs no additional construction.
history, or in the extrinsic evidence to conclude that "movement" might be confusing to jurors, or that it is used in some technical sense recognized by those skilled in the art. The parties' agreement to the meaning of "initially ceasing to be in motion" as discussed above, supports this analysis.

To simply define "movement of the person" in terms such as "motion of the person" does not add much clarification. One skilled in the art, and the average juror, would likely understand that these are synonyms, and apply their ordinary meaning. Claim construction "is not an obligatory exercise in redundancy." U.S. Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997). The court finds no reason to construe "movement of the person" in these claims.

4. "Movement of the foot of the person." Used in Claims 27(b), 31, 44(b), and 55.

For the reasons discussed above, the court finds that this term has no special or technical sense from the point of view of one skilled in the art. This analysis is supported by the parties' agreement to the meaning of "foot initially ceasing to be in motion." The term is non-technical language, used in its ordinary, everyday sense, and needs no further construction.

12. movement tracking capability

This term appears in claims 25 - 38, 43, and 53 of the '213 patent and in claims 10 - 12 of the '283 patent. The plaintiff proposes a construction of "the processor receives information corresponding to the path of contact as it moves laterally across the face of the work platform." The plaintiff additionally avers that "movement tracking capability' is distinct from the 'occurrence of contact,' which is the act of causing contact to occur at a location on the work platform." The defendant's counter-construction is "the processor detects new locations of a block (object) while it is moved on the working platform." The defendant additionally urges that "laterally' means from side to side." The court concludes this term means "the ability to track the movement of an object."

E. Longitudinal Movement

Finally, the parties dispute the meaning of the phrase "the track incrementally moves longitudinally relative to the substrate" in claim 20 of the '518 Patent. Claim 20, in pertinent part, reads as follows:

An apparatus for printing on substrates having a tendency to deform when exposed to energy from a curing head comprising:

- a substrate support to support a substrate for printing thereon;
- a printhead track extending transversely of the support having a printhead carriage moveable thereon;
- a drive operative to impart longitudinal movement between a substrate on the support and the track;
- a carriage motor operative to move the carriage in a scanning motion transversely on the track;
- at least one ink jet printhead on the carriage;
- a controller operative to control the drive, the [carriage] motor and the printhead, to selectively jet UV curable ink onto a substrate on the support from the printhead with the carriage moving bidirectionally in successive transverse rows as the track incrementally moves longitudinally relative to the substrate.

L&P contends that the use of the word "relative" in the phrase "the track incrementally moves longitudinally relative to the
The plain text representation of this document is:

substrate" means that either the printhead track or the substrate may move relative to the other. Vutek maintains that claim 20 only refers to movement by the printhead track.

This dispute is significant in light of the two possible arrangements of the printhead discussed in the specification. The first, a "fixed bridge" embodiment, requires the printhead to travel transversely, or side-to-side, over a substrate along a "bridge" that remains in a fixed position on the printing machine frame. In this embodiment, a conveyor belt moves the substrate longitudinally under the "fixed bridge." The preferred embodiment teaches the opposite arrangement. In the preferred embodiment, the substrate remains in a fixed position while the "bridge" moves longitudinally along the "longitudinal tracks" labeled numbers 133b and 134b in Figure 1 of the specification.

While the specification clearly allows for either the "bridge" or the substrate to move relative to the other, the specific apparatus described in claim 20 does not encompass both of these arrangements. Claim 20 refers to the "bridge" as "a printhead track extending transversely of the support having a printhead carriage moveable thereon." (Emphasis added). The claim further provides that "the track incrementally moves longitudinally relative to the substrate." (Emphasis added). The subject of the verb "moves" is "track," thus clearly indicating that the "track," not the substrate, is the object that must move.

This interpretation is consistent with the use of the terms "move" and "relative to" in the specification. For example, when describing the "fixed bridge" embodiment, the specification states that the conveyor belt is "used to move the [substrate] relative to a printhead on a fixed bridge." (Emphasis added). It is clear from the description of the "fixed bridge" arrangement that the substrate, not the bridge, is the object that must move in the printing process. Likewise, the plain language of the phrase "the track incrementally moves longitudinally relative to the substrate" requires the "track," or "bridge," to move, not the substrate.

7. "moving a pair of spaced apart heating electrodes against another surface of said terminal to form a current path between said electrodes through a portion of said terminal extending there between"

This phrase appears in Claims 1 and 16. Plaintiff's proposed construction is as follows: "moving two side-by-side heating electrodes into compression contact with a surface of the terminal (other than a surface in contact with the wire) with sufficient pressure to establish and maintain electrical continuity between the electrodes and the terminal to allow a flow of electrical current through the electrodes and the portion of the terminal between the electrodes." Defendants, on the other hand, assert that the disputed phrase means "moving two electrodes against a surface of the terminal other than the surface in contact with the wire to allow a flow of electricity between said electrodes through a portion of said terminal extending therebetween."

Looking first to the beginning of the disputed phrase "pair of spaced apart heating electrodes," Defendants proposed construction would replace this phrase simply with "two electrodes." Such a construction is overly broad, and completely ignores the terms "spaced apart" and "heating." Plaintiff, on the other hand, proposes that "pair of spaced apart heating electrodes" be construed as "two side-by-side heating electrodes," which is more consistent with the claim language itself as well as the specification of the '015 Patent. Indeed, in the drawings and written description of the '015 Patent the heating electrodes are consistently depicted and described in a side-by-side relationship.

The parties disagreement regarding the remainder of the disputed phrase centers on the term "against" or, perhaps more accurately, the phrase "moving . . . against . . . said terminal to form a current path." Plaintiff argues that a person of ordinary skill in the art would understand this phrase to involve movement of the electrodes into "compression contact" with the terminal with sufficient pressure to establish and maintain electrical continuity. In support of its argument, Plaintiff points to the specification, as well as the testimony of the parties and other extrinsic evidence. For example, the specification states that "[t]he primary function of the fusing apparatus is to bring the free end of the fusing and ground electrodes into compression contact with the tang." '015 Patent col. 4:64-66 (emphasis added). The specification later again describes that "the fusing and ground electrodes are brought down via mounting arm or piston under control of the welding control unit into contact with tang," and that current is applied to generate heat only "once electrical continuity has been established between the fusing and ground electrodes." '015 Patent col. 6:5-10; see also col. 7:19-21 ("fusing electrode is brought down into compression contact with the tang").
Plaintiff also cites the testimony of Defendants' engineer, Douglas Walz, as well as the inventor of the '015 Patent, Edward Riordan. The testimony of both teach that pressure to the electrodes must be applied and maintained in order to establish electrical continuity. See Buckingham Decl., Ex. U at 34-35, 52-54; Ex. V at 67-70. Although, as Defendants argue, the particular testimony cited may relate to the fusing process generally as opposed to the '015 Patent specifically, the testimony is highly relevant to understanding how a person skilled in the art would construe the disputed claim terms.

Last, Plaintiff refers to other extrinsic evidence, namely technical journal papers and patents regarding fusing, that is consistent with the understanding that in order to "form a current path" electrodes must be moved against the terminal with sufficient pressure to establish electrical continuity. See Buckingham Decl. at Ex. P at 598 ("Low pressure when power is first applied can result in a poor contact between the electrode and the tang, resulting in arcing and possible destruction of the tang"); Ex. H at col.3:45-53 ("Downward force is applied by fusing electrode . . . until firm and extensive contact has presumably been established . . . It is then safe to begin passing substantial electrical current"); Ex. J at J01488 ("fusing to take place only when a predetermined electrode pressure is reached"); Ex. K at J01505 ("The most foolproof system is a spring override, which activates the fusing transformer when a given pressure is reached"); Ex. O (during initial stage of fusing, the"objective … is to achieve a consistent, reliable contact between the fusing electrode and the commutator tang prior to initiating current flow").

The Court concludes that a person of ordinary skill in the art would understand the phrase "moving . . . against . . . said terminal to form a current path" to mean movement of the electrodes into compression contact with the terminal with sufficient pressure to both establish and maintain electrical continuity. Accordingly, the Court shall construe the phrase

"moving a pair of spaced apart heating electrodes against another surface of said terminal to form a current path between said electrodes through a portion of said terminal extending there between" consistent with Plaintiff's proposed construction as follows: "moving two side-by-side heating electrodes into compression contact with a surface of the terminal (other than a surface in contact with the wire) with sufficient pressure to establish and maintain electrical continuity between the electrodes and the terminal to allow a flow of electrical current through the electrodes and the portion of the terminal between the electrodes."

Vnus argues the term "moving … along" does not require construction. Defendants argue "moving … along" should be construed as "moving the electrode catheter along the inner wall of the vein while maintaining physical contact between the electrode and the inner wall of the vein while the electrode applies energy to the vein."

The Court, for the reasons stated by Vnus, finds "moving … along" does not require construction.

7. "Moving the instrument in response to motor signals." The surgical instrument of the robotic surgical system is moved by the robot in response to signals received by drive mechanisms or motors/actuators in the robotic arm.

The first claim of the '261 patent describes a method for processing samples mounted on microscope slides that are placed on a platform. See '261 Patent 12:14-25. In addition to other characteristics, the method provides for "moving the platform and a liquid dispenser relative to each other." Id. at 21-22. The second claim of the '261 patent depends from claim 1 and describes the same method with the distinction that "each heating element heats only one slide." Id. at 26-28. The parties dispute the meaning of the language, "moving the platform and a liquid dispenser relative to each other," and each party bases its summary judgment argument on its proposed claim construction. According to plaintiff, the disputed language
means that "[t]here is relative movement between the platform and the liquid dispenser. Relative movement may be accomplished by moving the platform, or the liquid dispenser, or both." (Pl.'s Mem. in Support of its Combined Mot. 7). Defendant, on the other hand, urges that ",[t]his claim language requires moving both 'the platform' and 'a liquid dispenser.' It does not permit moving only one of them." (Def.'s Mem. in Opp. to Pl.'s Combined Mot. 6). Giving rise to the dispute are certain of defendant's slide processing products that -- solely for purposes of arguing the instant motion, the parties agree -- involve a mobile liquid dispenser but a stationary platform.

"[P]atent infringement analysis involves two steps: claim construction, and application of the construed claim to the accused product or process." Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1326 (Fed. Cir. 2006). The first step, claim construction, requires that the Court construe "only those terms . . . that are in controversy, and only to the extent necessary to resolve the controversy." Vivid Technologies, Inc. v. American Science & Engineering, Inc., 200 F.3d 795, 803 (Fed. Cir. 1999). "[T]he words of a claim 'are generally given their ordinary and customary meaning,'" in other words, "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention, i.e., as of the effective filing date of the patent application." Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005). A disputed claim term may be interpreted according to ","the words of the claims themselves, the remainder of the specification, the prosecution history, and extrinsic evidence concerning relevant scientific principles, the meaning of technical terms, and the state of the art." Id. at 1314.

Plaintiff relies, first, on the plain language of the disputed claims and argues that the phrase, "relative to each other," requires only that either the platform or the dispenser move, since either event would create relative movement. As defendant argues, however, this interpretation negates the conjunctive term "and," as used in the phrase, "moving the platform and a liquid dispenser relative to each other." Plaintiff's expert, Professor Alexander H. Slocum, explains the term "and" from the perspective of an individual with ordinary skill in the art -- for example, an engineer with basic training in physics -- as creating reciprocal frames of reference. The platform is the frame of reference for whether the dispenser moves, and the dispenser is the frame of reference for whether the platform moves. (See Slocum Aff. P 9). Even if, in fact, the platform is static and only the dispenser moves, a tiny observer standing on the platform who sees the moving dispenser would not know whether to attribute the motion she observes to the platform or the dispenser. Thus, at least in theory, both the dispenser and the platform are moving relative to each other. The perspective is similar to that of a passenger who sits on a stationary northbound train next to a stationary southbound train on adjacent tracks. When one or both of the trains begin moving, the passenger will comprehend motion but will not know whether it is his train alone, the southbound train alone or both trains together that are moving.

The difficulty with this position is that it does not account for a third frame of reference created by the requirement that something or someone be "moving" the platform or dispenser. In describing a method of moving the platform or dispenser, the claim language adopts the perspective of the person or thing responsible for causing this movement, not the theoretical perspective of an observer sitting on either the platform or dispenser. While such a theoretical observer may be unable to discern whether movement comes from the dispenser or the platform, the person or thing responsible for moving the platform and dispenser will have this knowledge.

Defendant's expert, Professor Geoffrey Nunberg underscores this understanding from the view of a linguist interpreting the disputed claim language according to rules of grammar. However, "one of ordinary skill in the art" generally refers to an individual with expertise in the field of the patented invention, not someone skilled in the field of language and drafting. See Phillips, 415 F.3d at 1333 (explaining that ",[t]he words of a claim 'are generally given their ordinary and customary meaning,'" in other words, "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention."). Thus, while interesting, Professor Nunberg's testimony is not representative of a person of ordinary skill in the art, and I do not rely on his opinion in resolving the instant dispute.

Plaintiff next argues that its interpretation of the language in claim 1 is more consistent with the articulation of dependent claims in the '261 patent. Plaintiff focuses on claim 3 that describes a "method of processing samples . . . wherein the platform is a moving platform capable of indexing slides adjacent to a stationary liquid dispensing location." '261 Patent 12:29-32. According to plaintiff, depiction of the platform as "moving" necessarily implies that the platform may otherwise be immobile. Defendant counters that the purpose of claim 3 is not to identify the platform as moving, but to provide that it be "capable of indexing slides adjacent to a stationary liquid dispensing location." Defendant also relies upon claim 7 that references "said moving platform" and, thereby, implies that the "said" platform portrayed in claim 1 is mobile. Plaintiff asserts that this language resulted from a clerical error that should have been, and will eventually be, amended. "An error in the prosecution record must be viewed as are errors in documents in general; that is, would it have been apparent to the
interested reader that an error was made, such that it would be unfair to enforce the error." Biotec Biologische Naturverpackungen GmbH & Co. KG v. Biocorp, Inc., 249 F.3d 1341, 1348 (Fed. Cir. 2001). Because nothing suggests that an interested reader would have understood the inclusion of the term "said" to be in error, claim 7 should be read as originally drafted.

The patent specification further supports defendant's position, as the parties agree that none of the preferred embodiments describe a stationary platform. Plaintiff correctly notes that the embodiments do not foreclose the possibility of a stationary platform, but they certainly do not support an interpretation of the claim language as describing a stationary platform. While the Federal Circuit "ha[s] repeatedly warned against confining the claims to [very specific] embodiments" and "strictly limiting the scope of the claims to the embodiments disclosed in the specification," it has also discouraged "divorcing the claim language from the specification." Phillips, 415 F.3d at 1323-24. Appropriate interpretation will consider the full context of the patent. See id. Turning from the platform, plaintiff focuses on the first preferred embodiment's description of the liquid dispenser. The embodiment describes a stationary hammer that helps push liquid from the dispenser onto a slide. See '261 Patent 5:25-51. In order to define the dispenser as including a stationary element, plaintiff characterizes the hammer as part of the liquid dispenser. However, the patent specification defines the hammer as part of the dispensing station, not the dispenser, and plaintiff offers no rationale for a different characterization. See id. 5:25-26 (providing that "the dispensing station comprises a soft hammer . . .").

The file history of the '261 patent also favors defendant. It reveals amendments to the language in claim 1 that include replacing the term "moving platform" with "moving the platform and a liquid dispenser relative to each other." (Pl.'s Mem. in Support of Summ. J. and Claim Construction 10-11). Plaintiff believes that this change underscores the importance of relative motion and the ability to accomplish such motion between the platform and the liquid dispenser without having a moving platform. (Id.). This understanding is inconsistent, however, with the repeated description of "moveable slides" and the use of a carousel in describing the platform, as cited by defendant. (See Def.'s Mem. in Opp. to Pl.'s Combined Mot. 19-24). Plaintiff argues that independent slide heating, and not movability, constituted the Examiner's focus on the patent, so that use of these terms occurred only in passing, not deliberately. Even assuming arguendo that plaintiff is correct, "a patentee's statements during prosecution, whether relied on by the examiner or not, are relevant to claim interpretation." Microsoft Corp. v. Multi-Tech Systems, Inc., 357 F.3d 1340, 1350 (Fed. Cir. 2004). Plaintiff also posits that the term moveable "was appropriate, given that the movement had already [sic] been defined as relative to the liquid dispenser." (Pl.'s Mem. in Support of Summ. J. and Claim Construction Footnote 4). This reasoning cannot provide additional support for plaintiff's position, because it necessarily presumes that plaintiff's argument for relative motion would prevail and thus is circular.

In light of the applicable legal standard, the parties' written submissions, and the argument of counsel, I construe the disputed claim language as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moving the platform and a liquid dispenser relative to each other</td>
<td>Moving both the moveable platform and a moveable liquid dispenser relative to each other</td>
</tr>
</tbody>
</table>

In this case, the parties dispute the construction of claim 5 of the patent. 2 This claim, with the disputed terms highlighted, states as follows:

A method of forming a plurality of grooves in the surface of a road, the method including the steps of rotating a cutting cylinder about an axis which is substantially horizontal and which axis is at an angle to the longitudinal direction of the road, moving the rotating cutting cylinder along the road, and simultaneously, moving said cylinder alternately up above the road surface and down into said road surface, to thereby form a plurality of generally parallel grooves in the road each groove having a forward side wall and a rearward side wall.

---

2 On April 11, 2006, the PTO issued an "Ex Parte Reexamination Certificate" which confirmed the patentability of claims 1-
The parties first dispute whether the inventor's use of the term "road" in claim 5 was intended to encompass the cutting of grooves on the shoulder of a road. Defendant asserts that it was intended as such and plaintiff asserts that it was not. The patent does not particularly define the term road and the term's general definition is simply "an open way for the passage of vehicles, persons, and animals." Webster's Third New International Dictionary, 1963 (2002). However, considering the language of the entire patent, including the specification, the court concludes the term road should not be read to include a shoulder.

The primary purpose of the patent is to drain water from the road surface onto the shoulder by cutting grooves on or near the "edge" of the road. See "Background of the Invention," P1; "Summary of the Invention," Column 2, lines 2-4. The grooves secondarily serve as rumble strips to alert a driver to the edge of the road. See "Detailed Description of the Invention," P 8, lines 25-28. For purposes of both, the patent refers to the edge and surface of the road distinct from the shoulder. In addition, the figures representing the embodiment of the invention indicate that the grooves are cut into the road surface not the shoulder. See, e.g., Figs. 2 & 4:

Accordingly, the court construes the term "road" in claim 5 of the patent to mean that portion of the roadway designed or ordinarily used for travel which does not include the shoulder. 3

3 Plaintiff has submitted extrinsic evidence on this subject in the form of the deposition testimony of Inventor Whitney. While the court affords little weight to such after-the-fact testimony, it notes the inventor's recent statement of his former intentions is consistent with the court's construction.

With respect to the second disputed phrase, both parties agree that the method of cutting grooves as defined in the patent requires three simultaneous moves -- moving the cutting cylinder along the road while it also moves up and then down to cut a groove. Defendant states that the language of claim 5 describes a continuous movement through the cutting of at least two or more grooves as opposed to stopping and starting the cutting cylinder between cuts. Plaintiff claims this interpretation is too narrow and asserts that the language also covers a method of cutting whereby the machine, essentially, stops between cuts and then is moved forward for the next cut. This method is referred to as "stopping and indexing." Plaintiff claims that while the preferred method may be continuous, that is not the only method embodied by the claim. In construing the meaning of these disputed terms, the court need look no further than the language of claim 5 itself. First, the claim refers to a method of forming "grooves" rather than a groove. Thus illustrating that more than one groove will be cut during the process. Second, the use of the term "plurality," which refers to a number greater than, one, 4 anticipates the cutting of at least two grooves. Finally, a repetitive cut is consistent with the entire language of the patent which advises that the method of cutting grooves is intended to be continuous. See, e.g., Summary of the Invention; Detailed Description of the Invention, P 7. Accordingly, the court construes the disputed language to mean that the cutting cylinder simultaneously rotates, moves along the road and moves up and down through at least two cuts.

Lastly, the parties dispute whether the phrase "generally parallel grooves" includes end-to-end or "co-linear" grooves such as those depicted in Fig. A of plaintiff's Markman brief:

[SEE FIGURE A IN ORIGINAL]

Plaintiff contends that such end-to-end grooves are anticipated by claim 5 because they are capable of being parallel along their width dimension. However, plaintiff's proposed construction contradicts the very purpose of the patent which is primarily rain drainage and secondarily rumble strips. In addition, it ignores clarifying language in the claim itself. The words of the patent refer to the "formation of transverse grooves in a road." Claim 5 states that such grooves have a "forward side wall and rearward side wall." Claim 5, lines 16-17. End-to-end grooves, which would not lie transverse or crosswise to the longitudinal direction of the road, would not have a forward or rearward side wall as required by claim 5 because their sides would run parallel to the longitudinal direction of the road. Further, the patent figures do not depict end-to-end grooves as the preferred embodiment of the invention. See Figs. 2, 3, & 4:

--- Footnotes ---

5 See Background of the Invention.

6 Thus, they would be more accurately described as having "end walls" rather than side walls.

--- End Footnotes ---

Accordingly, the court construes the disputed language to mean grooves which are arranged side by side with their long sides parallel to each other and which are generally oriented transverse to the travel direction of the road.

C. "Mulch flakes" (claim 1)

Plaintiff's proposed construction:

Defined by the claim.

Defendant's proposed construction:

Irregular platelets with a thickness which is less than the dimensions across the platelet.

Claim 1 discloses a mulch product comprising a seed component and "mulch flakes." The parties disagree whether claim 1's reference to "mulch flakes" requires that the mulch product be in "flake form," which the specification describes as "irregular platelets with a thickness which is less than the dimensions across the platelet." 499 pat., col. 2, Ins. 6-8. The plain language of the claim suggests that claim 1 requires flake form; after all, "flake" means flake. Plaintiff has several arguments in opposition to adopting defendant's construction, none of which is persuasive.

First, plaintiff contends that the term "mulch flakes" is a product-by-process claim, which means that it is "defined at least in part in terms of the method or process by which it is made." SmithKline Beecham Corp. v. Apotex Corp., 439 F.3d 1312, 1315 (Fed. Cir. 2006) (quoting Bonito Boats, Inc. v. Thunder Craft Boats, Inc., 489 U.S. 141, 158, 109 S. Ct. 971, 103 L. Ed. 2d 118 (1989)). According to plaintiff, because claim 1 describes how mulch flakes are prepared (by agglomerating and compacting a raw material and then comminuting it), there is no need to include the shape requirement imposed by calling the mulch product a "flake." I disagree. The purpose of product-by-process claims is to allow inventors to define a claim by its process when it "resists definition by other than the process by which it is made." SmithKline Beecham, 439 F.3d at 1315
(citation omitted). Thus, to the extent an inventor can and does describe the claim by means other than a process, such as by describing the shape of a processed product, the plain meaning of that description should not be disregarded. Plaintiff cites no case to the contrary.

Next, plaintiff notes that the specification describes the flake form as a "preference," not a requirement, '499 pat., col. 2, ln. 5, identifies other shapes that may be useful for helping the mulch performing its intended functions, id., col. 2, Ins. 8-11 and appears to use "mulch" and "mulch flakes" interchangeably in the specification, id., col. 1, ln. 59 ("the mulch flakes of the present invention") and ln. 66 ("the mulch flakes of the present invention." If the claims themselves do not distinguish "mulch" and "mulch flakes," plaintiff might have a stronger argument for treating the two interchangeably or for treating "mulch flakes" as a mere preference. However, where claim 1 requires the mulch product to contain "mulch flakes," claim 11 does not, leaving that claim open to the other types of mulch shapes identified in the specification. Later, claims 17-21 build on claim 11 by disclosing a "flaked mulch product." The language within the claims themselves shows that the patentee was well aware of the difference between "mulch" and "mulch flakes" and intended to limit claim 1 to "mulch flakes." Therefore, I will reject plaintiff's construction and adopt defendant's construction of "mulch flakes."

**Court's construction:**

Irregular platelets with a thickness which is less than the dimensions across the platelet.

3. ANALYSIS

3.1 SPECIFICATION

The specification common to all the patents-in-suit uses the term "the present invention" 5 times to describe the 2 embodiments for achieving multifocality. Judge Love in the Vistakon claim construction opinion expressly found that only those 2 ways of implementing multifocality (undulating surface and ion implantation) were disclosed. (Vistakon Claim Construction Decision, 2007 U.S. Dist. LEXIS 5742 at *8-9.) And "each term must be construed to implement the invention described in the specification.” On Demand Mach. Corp. v. Ingram, Inc., 442 F.3d 1331, 1344 (Fed. Cir. 2006).

As originally filed in 1987 (and as issued), Portney's '461 patent announces his invention as follows:

**ABSTRACT**

An improved ophthalmic lens is disclosed which has a plurality of alternating power zones with a continuously varying power within each zone, as well as in transition from one zone to another. In other words, a plurality of concentric zones (at least two) are provided in which the variation from far to near vision correction is continuous, i.e., from near correction focal power to far correction focal power, then back to near, and again back to far, or vice versa. This change is continuous (progressive), without any abrupt correction changes, or "edges". Two versions of the invention are disclosed. In the first version continuous, alternating power variation is accomplished by a continuously changing curvature of the lens posterior surface, thereby altering the angle of impact of light rays on the eye. In the second version continuous, alternating power variation is accomplished by creating non-homogeneous surface characteristics having refractive material indexes which continuously vary in the lens radial direction (out from the optical axis).

(U.S. Patent Application No. 056,050 ("050 App.") at 20; '461 patent (all underscoring in quotations is added unless otherwise noted).) The desired progressive change in power is accomplished in only 2 ways: a constantly undulating surface or ion implantation. The application continues by saying exactly what is "the present invention":

**SUMMARY OF THE INVENTION**

The present invention provides an improved multifocal ophthalmic lens by combining (a) a series of alternating power zones with (b) a continuously varying power within each zone, as well as in transition from one zone to another. In other
words, a plurality of concentric zones (at least two) are provided in which the variation from far to near vision correction is continuous, i.e., from near correction focal power to far correction focal power, then back to near, and again back to far, or vice versa. This change is continuous (progressive), without any abrupt correction changes, or "edges". ('050 App. at 4; '461 patent, col. 2:35-45.) Thus, the "invention" always has two features: (1) a series of alternating power zones, and (2) continuously varying power across the entire surface, both in the "zones" and in the transitions between zones.

Portney has asserted that his invention shows areas of constant/spherical curvature beyond the lens center. (Portney's Opening Brief on Patent Claim Construction at 18.) But the specification says the opposite: "The present invention provides . . . (b) a continuously varying power within each zone, as well as in transition from one zone to another." ('461 patent, col. 2:35-39.) Both "zones" and "transitions" have continuously changing power. And, at his deposition, Portney agreed that an area of constant power could not be considered a progressive area. (Portney Dep. 140:2-8.)

The specification also discusses and distinguishes the prior art with reference to the use of constant/spherical curvature. Figure 1 of the '461 patent describes a "bifocal" contact lens with a central, circular, constant/spherical area for focusing near objects, surrounded by another constant/spherical area for focusing far objects. ('050 App. at 6-7; '461 patent, col. 3:33-40.) Figure 2 describes a multifocal lens that is completely aspheric (with "continuously changing curvature from its center to its periphery") and thus, "a continuous change of focusing power for . . . far objects . . . to . . . near objects. . . . " ('050 App. at 7; '461 patent, col. 3:46-58.) The specification then praises the "advantages" of continuously varying power "over" use of constant power. ('050 App. at 7-8; '461 patent, col. 3:59-68.)

The specification then again states what "the present invention" is:

\[\text{In order to minimize the problems due to the need for centering, due to pupil size variation, and due to fitting requirements (progressive type), the present invention, as shown in FIG. 4, uses several zones, each of which includes a progressive power change from near correction to far correction. In other words, a three zone contact lens, the progressive variation of the FIG. 2 lens would be repeated six times, three times as a variation from lower to higher power, and three times as a variation from higher to lower power.}\]

('050 App. at 8-9; '461 patent, col. 4:14-23.) The specification then gives this one exception:

\[\text{The specification continues:}\]

\[\text{The higher and lower corrective powers in each zone of the four annular concentric zones shown in FIG. 4, occur as the undulating curve progresses from one peak 54 to the adjacent valley 56, and then back to the next peak 54. Except for the small centrally placed zone of a constant curvature which provides power for middle correction, a zone is considered to include a complete cycle, i.e., from the intermediate power through the high power, then back through the intermediate power to the low power, and finally back to the intermediate power.}\]

('050 App. at 11; '461 patent, col. 5:9-19.)

Nowhere does the specification disclose that a Portney lens can have a segment of constant (i.e., spherical) curvature except at the very center of the lens. Portney told the public that the lens surface he invented, except at the very center, is "continuously" varying -- not sometimes varying, and sometimes constant. In the Vistakon litigation, Judge Love expressly held that "vary continuously" means "continuously changing." (Vistakon Claim Construction Decision, 2007 U.S. Dist. LEXIS 5742 at *14-15.) Because Judge Love had to construe a § 112 P 6 means-plus-function limitation, he had to determine what structures were actually disclosed in the specification. He held that the only structure using curvature to effect progressive vision correction was "an undulating lens posterior surface that has a continuously changing curvature."
(Vistakon Claim Construction Decision, 2007 U.S. Dist. LEXIS 5742 at *25.) Despite Portney's previous agreement with Judge Love's holding (Vistakon Claim Construction Decision, 2007 U.S. Dist. LEXIS 5742 at *25), Portney now argues that the PTO nonetheless "determined" in the '461 term extension process that the '461 claims covered the ARRAY lens having constant segments. (Portney's Opening Brief on Patent Claim Construction at 13-14.) But it is undisputed that CIBA Vision's accused lenses do not use ion-implantation to create multifocality. They use surface curvature. It is permissible during claim construction to focus on the aspects of the claims that matter for the determination of whether the claims cover the accused product. Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1327 (Fed. Cir. 2006); Pall Corp. v. Hemasure Inc., 181 F.3d 1305, 1308 (Fed. Cir. 1999). This claim construction applies only for structure using curvature to effect progressive vision correction.

Likewise, nowhere does the specification disclose that a Portney lens can have fewer than 2 cycles of Far-to-Near-to-Far (or Near-to-Far-to-Near). Although the word "series" usually means three, in this case it means "at least two" because that is what the patent specification says. There is no indication that Portney contemplated any alternative way to embody or accomplish the curvature-changing version of the invention.

Also, nowhere does the specification disclose that the Far and Near powers in one cycle can be different from the Far and Near powers in another cycle. Although Portney now argues that different Far and Near powers are disclosed in the coordinates included in column 6 of the '461 patent (Portney's Opening Brief on Patent Claim Construction at 18-21), that argument is contradicted by what the specification says occurs in each zone:

Except for the small centrally placed zone of a constant curvature which provides power for middle correction, a zone is considered to include a complete cycle, i.e., from the intermediate power through the high power, then back through the intermediate power to the low power, and finally back to the intermediate power.

('461 patent, col. 5:13-19.) The specification speaks in the singular: one high power and one low power per lens. As will be discussed, this is confirmed by the prosecution history.

Portney argues that "multifocal ophthalmic lens" should have its "ordinary and plain meaning" because two prior art lenses discussed in the specification are also called "multifocal ophthalmic lenses." (Portney's Opening Brief on Patent Claim Construction at 11-12.) But the "multifocal ophthalmic lens" for the Court to construe is the one Portney says he invented -- the one that follows the words "I claim" and "What is claimed is." Portney cannot claim to have invented the lenses disclosed in NUCHMAN or SCILIPOTI. He claims to have invented only "an improved multifocal ophthalmic lens." ('461 patent, col. 2:35-36.) The nature of that "improvement" is described as "the present invention" and is necessarily different from NUCHMAN or SCILIPOTI.

Using the same term for the prior art and "the present invention," does not rob that conspicuous phrasing of its dispositive legal effect.

3.2 PROSECUTION HISTORY

The descriptions of "the present invention" in the specification of the issued patent are echoed by the broadest claim originally filed by Portney in 1987 which also required "power . . . to vary continuously and progressively from a first vision correction value to a second . . . and then back to the first . . . ; each cycle of such continuous variation . . . being repeated in a plurality of zones . . . ." ('050 App. at 17.) The original application also included independent claim 11 which discussed fabrication of the invention by "preparing a lens . . . shaped as segments of spheres . . . ; reshaping . . . one surface . . . by cutting it . . . to create an undulating cross-sectional curve . . . ; and programming the . . . computer to continuously vary the center of curvature of the cutting tool . . . to form a lens surface which . . . has a progressively varying shape undulating between the adjacent peaks and valleys." ('050 App. at 18-19.) The specification calls this "aspherizing of
the surface by utilizing continuous curvature variation." ('050 App. at 5; '461 patent, col. 2:61-62.) Confirming this, the specification says, "[f]or full progressivity, each point on the undulating curve has a different radial center from the centers of the adjacent points." ('050 App. at 12; '461 patent, col. 5:45-47.)

As already discussed, Portney's argument that different Far and Near powers are disclosed in the coordinates included in column 6 of the '461 patent, (Portney's Opening Brief on Patent Claim Construction at 18-21), is contradicted by the specification, which speaks in the singular: one high power and one low power per lens. The prosecution history confirms that nowhere does the specification disclose that the Far and Near powers in one cycle can be different from the Far and Near powers in another cycle. Portney tried to amend the claims to permit different "Near" and "Far" powers from zone to zone, but the Examiner rejected that amendment as "new matter." ('461 File History, Amendments and Remarks (Jan. 18, 1989); '461 File History, Office Action (Mar. 23, 1989).) Portney acquiesced and removed the amendment. ('461 File History, Amendment (May 23, 1989).) Where an examiner rejects an amendment in this manner, it "implies that the examiner had determined that the [amendment] disclosed new matter." Dealertrack, Slip. Op. at 19. Thus, Portney's argument is not only contradicted by what the specification says occurs in each zone but also is almost twenty years late.

Events during prosecution of the non-U.S. patents also support CIBA Vision's proposed claim construction. The European Patent Office rejected claim 1 of Portney's European patent application because it did not recite "features [that] appear essential in order to realize the invention" including "continuously varying power within each zone, as well as in transition from one zone to another." (European Patent Office Examination Report at P 1(c) (June 11, 1993).) Responding to a rejection by the Canadian Patent Office, Portney stated "One feature of applicant's multifocal ophthalmic lens is the provision of multiple progressive power regions." (CA1326389 File History, Official Action (Jan. 18, 1993) & Remarks (May 18, 1993).)

3.3 PORTNEY'S SUBSEQUENT CONTINUATION-IN-PART PATENT APPLICATION

CIBA Vision's proposed claim construction is supported by other evidence. In 1991, Portney filed a "continuation-in-part" ("CIP") of the '461 patent which ultimately became U.S. Patent No. 5,225,858 (which CIBA Vision is not accused of infringing). In it, Portney characterized the '461 invention and distinguished the '858 invention. "The '858 application incorporated the text of the '461 Patent by reference but contrasted itself by saying that in the '461 lens, 'the progressive vision correction power is varied between far and near through the several zones,' while in the '858 lens, 'improved image quality . . . [is] accomplished by maintaining the near vision correction power of appropriate zones of the lens substantially constant for a major segment . . . .'" (Order Denying Portney's Motion for Partial Summary Judgment at 4, Dkt. No. 295 (Feb. 6, 2009); '858 patent, col. 1:18-29 and col. 1:64-2:17.)

Examiner Sugarman rejected all claims of the '858 CIP application on the basis of "obviousness-type double patenting," saying that the CIP's claims were not patentably distinct from the '461 patent. ('858 File History, Office Action (July 29, 1992).) In seeking to identify a patentable difference, Portney pointed to the following characteristic of the '858 invention: "In addition, each of the regions have 'a major segment in which the near vision correction power is substantially constant.'" ('858 File History, Response to Office Action (Nov. 30, 1992).) Examiner Sugarman apparently agreed this made the '461 and '858 different. He issued a Notice of Allowability. ('858 File History, Notice of Allowability (Feb. 23, 1993).) Portney thus overcame a double patenting rejection of the '858 continuation-in-part application by saying that the '858 claims were patentably distinct from the '461 claims because the '858 invention had "a major segment in which the near vision correction power is substantially constant." That is a clear and unmistakable statement by Portney that the '461 claims do not include major segments of constant power.

3.4 EXTRINSIC EVIDENCE

During the Vistakon litigation, Portney issued an Expert Report admitting as follows:

Thus, the objective of my new multifocal lens was to offer a continuous vision from distant to near similar to one produced by a pin-hole. . . . A continuous power variation can be produced by changing a surface shape, i. e. varying surface curvature over the lens surface.

. . . . In order to accomplish this objective the power variation from distant to near must be repeated over the lens surface. . . .
Thus, my multifocal lens invention is based upon two concepts: (1) continuous vision from distant through intermediate to near and (2) repeatability of regions of the power over the lens surface.

(Feb. 28, 2007 Portney Expert Report at 4.) As already discussed, the court issued a Markman ruling in that case. The court was not asked to rule on the exact scope of "multifocal ophthalmic lens," but several rulings support CIBA Vision's proposed claim construction. For example, Judge Love held that "the claim language . . . requires that the power 'vary continuously', which is the same as 'continuously changing.'" (Vistakon Claim Construction Decision, 2007 U.S. Dist. LEXIS 5742 at *14.) He also explained that "the only embodiment disclosed in the Portney Patents to demonstrate how vision correction power was adjusted . . . depicted a lens surface that gradually transitioned between high and low vision correction powers, through intermediate . . . ." 2007 U.S. Dist. LEXIS 5742 at *28. Indeed, he said: "The parties also substantially agree that the corresponding structures are the only two structures disclosed in the Portney Patents for carrying out the recited functions. Both parties agree . . . the first structure is an undulating lens posterior surface that has a continuously changing curvature . . . ." 2007 U.S. Dist. LEXIS 5742 at *25.

The Patent Office has interpreted Portney's '461 patent consistent with CIBA Vision's proposed claim construction. In 1995, Dr. John De Carle filed a patent for a multifocal contact lens that had Far ("Distance") zones with a spherical surface (i.e., constant curvature) and Near zones with aspheric surfaces (i.e., with a continuously changing curvature). (U.S. Patent No. 5,798,817 at 1:64-2:3.) Examiner Sugarman was assigned to the application, the same Examiner assigned to all of the Portney Patent Family U.S. applications after the '461 patent. Examiner Sugarman issued a § 102 rejection, saying claims were anticipated (not novel and not patentable) by the Portney '461 patent. ('817 File History, Office Action Summary (July 22, 1997).) In response, Dr. De Carle argued:

In the Portney reference, there are no separate near or distance vision zones. . . . there is no distance vision zone in Portney which is spherical, all of the zones in Portney being aspherical.

('817 File History, Amendment and Remarks (Nov. 21, 1997) at 3.) Examiner Sugarman accepted the argument and allowed the De Carle patent. ('817 File History, Notice of Allowability (Feb. 17, 1998).) Thus, persons of skill in the art, Dr. De Carle and Examiner Sugarman, agreed that "all of the zones in Portney ['461 are] aspherical."

The correctness of CIBA Vision's proposed claim construction is confirmed by the expert testimony of Dr. Duncan Moore. Dr. Moore directs his opinions toward the specification itself and says that the terms collectively referred to as "a multifocal ophthalmic lens" should be construed as proposed by CIBA Vision because a person of ordinary skill in the art would understand the "multifocal ophthalmic lens" of the patent to be the particular kind of lens invented by Dr. Portney and not just any multifocal lens in the abstract. (Moore Rebuttal PP 82-108.)

3.5 NON-U.S. PATENTS AND PATENT APPLICATIONS

Finally, Portney argues that the Court should not construe the terms of the asserted non-U.S. claims and that "the foreign patent claims should be given their ordinary meaning by the jury during trial." (Portney's Opening Brief on Patent Claim Construction at 18.) Portney, however, offered no support for his implicit proposition that non-U.S. claims are not construed by a court before infringement is determined. Of course Markman, as such, doesn't apply abroad. It holds that judges, not juries, interpret claims. Non-jury countries would not ask the question Markman answered. But claims still must be construed.

Portney cited no authority that non-U.S. jurisdictions would ever let a jury construe their patent claims, and it is contrary to U.S. authority not to instruct the jury on all material issues. Sulzer Textil AG v. Picanol NV, 358 F.3d 1356, 1366 (Fed. Cir. 2004). Accordingly, the Court will construe the asserted non-U.S. patent claims. Portney gives no reason why the scope of non-U.S. patent claims would be different. All claim priority to the '461 patent.

4. CONCLUSION

The Court therefore construes the term "multifocal ophthalmic lens" in the context of the Portney Patents as having the following scope: "a multifocal ophthalmic lens (1) that has no segment of constant (i.e., spherical) curvature except (optionally) at the center, and (2) that contains at least 2 cycles in which vision correction power moves from Far to Near
and back to Far (or vice versa from Near to Far to Near), and (3) that has the same Near power in each cycle."

2631

(1) "Multiple Embossed Pattern"

As discussed, there is a hierarchy to the evidence to be considered in claim construction: the claim language first, then the patent specification and finally the file history. Vitronics, Inc., 90 F.3d at 1582-85. In this case, the language of the claim, the patent specification and the file history clearly show that the term "multiple embossed pattern" defines a product-by-process patent requiring sequential embossing patterns.

While the language of the claim does not mention the word "sequential," it nevertheless illustrates that the term "multiple embossed pattern" requires sequential embossments. In particular, the claim provides for "[a] web carrier, comprising:

- at least one surface that has a multiple embossed pattern having a first embossed pattern and a second embossed pattern." (Adkisson Decl., Ex. A, Col. 9, Ins. 33-36.)

Moreover, even if the claim's language is ambiguous, which it is not, the patent specification makes absolutely clear that the term "multiple embossed pattern" mean sequential embossments. As the court in Vitronics stated, and as plaintiff cites, the patent specification is "usually dispositive; it is the single best guide to the meaning of a disputed claim." Vitronics, 90 F.3d at 1582; (P's Reply Mem. in Supp. of Mot. for Prelim. Inj. at 2.); see also, United States v. Adams, 383 U.S. 39, 49, 15 L. Ed. 2d 572, 86 S. Ct. 708 (1966)("while the claims limit the invention, and the specifications cannot be utilized to expand the patent monopoly, claims are to be construed in the light of the specifications and both are to be read with a view to ascertaining the invention."); Autogiro Co. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 397-398 (Ct. Cl. 1967)("the specification aids in ascertaining the scope and meaning of the language employed in the claims inasmuch as words must be used in the same way in both the claims and the specification. The use of the specification as a concordance for the claim is accepted by almost every court, and is a basic concept of patent law.").

The specification defines the term "multiple embossed:"

"Multiple embossed" means two or more embossing patterns that are superimposed on the web to create a complex pattern of differing depths of embossing.

(Adkisson Decl., Ex. A, Col. 2, In. 1-3.) Not only does that definition on its face describe a product-by-process patent, the definition specifically requires two or more embossing patterns. Moreover, that term read in the context of the rest of the specification is consistent with the understanding that "multiple embossed pattern" describes a product-by-process requiring sequential steps. In fact, the language of the sentence in the specification immediately following the definition of the term "multiple embossed pattern" provides: "Another aspect of the present invention is a carrier web having at least one surface that is multiple, sequentially embossed, wherein depressions created from the prior embossing pattern(s) are substantially preserved during the subsequent embossing pattern(s)" Id. (emphasis added). Other language in the specification further emphasizes that the term "multiple embossed pattern" in claim 1 means sequential embossing steps:

..."Although the multiple embossing steps could be combined into a single step with the design of a suitable tool or mold, the advantage of multiple steps is that the depressions formed by the prior step(s) can be filled with a material prior to the subsequent embossing step(s). The number of same or different materials can be as many as the number of sequential step(s) or can be any subset of them." (Adkisson Decl., Ex. A., Col. 2, Ins. 11-17 (emphasis added)).

..."An advantage of the present invention is to create a means of sequential manufacturing of articles using different depths of depressions of the same or different materials." (Adkisson Decl., Ex. A, Col. 3, Ins. 16-18 (emphasis added)).
"A sequential manufacturing process for the web 10 or liner 20 determines the order of the embossings. The manufacturing of the double embossed liner 20 actually requires the formation of the smaller embossing pattern 26 first, followed by the formation of the larger embossing pattern 24, second." (Adkisson Decl., Ex. A, Col. 5, Ins. 5-9.(emphasis added)).

"Because the embossing of the pattern 26 occurs before the embossing of pattern 24, the depths identified here are the cumulative effects of both embossings, not necessarily the height of the embossing tool." (Adkisson Decl., Ex. A, Col. 6, Ins. 16-24.(emphasis added)).

"A multiple embossed web of the present invention can be used for the formation of materials that utilize the complex topography of the surface of the web. Because the multiple embossings of the web occur sequentially, material can be placed in the depressions caused by first pattern being formed before the second embossing pattern is applied." (Adkisson Decl., Ex. A, Col. 6, In. 64- Col. 7, In. 2.(emphasis added)).

The prosecution history further illustrates this understanding. Plaintiff argues that because it took the word "sequential" out of claim 1, the court would commit an error of law pursuant to the theory of file wrapper estoppel to read "sequential" back into the claim. Plaintiff's argument is unpersuasive, given the context of the prosecution history. The examiner rejected the original claim 1, finding the claim confusing. (Adkisson Decl., Ex. A, No. 4. at p. 3.) In response, plaintiff filed claim 1 as "a multiple embossed pattern having a first embossed pattern and a second embossed pattern." In contrast to plaintiff's assertion, the file history makes absolutely clear that plaintiff's patent requires a second embossed pattern following a first embossed pattern. The court therefore rejects plaintiff's file wrapper estoppel argument and finds that the term "multiple embossed pattern" means sequential embossing patterns.

4 The court is well aware that the cannon of claim construction providing that the court cannot import a limitation from the specification's general discussion. See, e.g., Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1278 (Fed. Cir. 1995) (finding the district court "erred by importing unnecessary functional limitations into the claim."). The court, however, does not import a limitation from the specification into the claim but instead reads the term "multiple embossed pattern" in light of the specification's language, including the language about sequential embossing patterns, to interpret the term "multiple embossed pattern." See Young Dental Mfg. Co. v. Q3 Special Prods., Inc., 112 F.3d 1137, 1143 (Fed. Cir. 1996)("Although limitations may not be read into the claims from the specification, claims are to be read in view of the specification of which they are a part."); Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 93 F.3d 1572, 1578 ("the district court did not import an additional limitation into the claim; instead, it looked to the specification to aid its interpretation of a term already in the claim, an entirely appropriate practice.").

2632

The district court erred when it defined the term "multiple embossed patterns" to include a limitation that the patterns be created sequentially. The use of the terms "first" and "second" is a common patent-law convention to distinguish between repeated instances of an element or limitation. See, e.g., Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1304 (Fed. Cir. 2003) ("first and second sidewall surfaces"); Springs Window Fashions LP v. Novo Indus., L.P., 323 F.3d 989, 992 (Fed. Cir. 2003) ("first and second opposed ends"). In the context of claim 1, the use of the terms "first . . . pattern" and "second . . . pattern" is equivalent to a reference to "pattern A" and "pattern B," and should not in and of itself impose a serial or temporal limitation onto claim 1.

In the specification, 3M clearly acted as its own lexicographer, and the definition provided requires only that the "two or more embossing patterns" be "superimposed." '930 patent, col. 2, ll. 1-2. Despite Avery's arguments to the contrary, the use of "superimposed" in this definition neither transforms claim 1 into a product-by-process claim nor even limits the scope of the claim to a serial method of manufacture; it describes only the structural relationship between the embossing patterns.

See Webster's Third New International Dictionary 2294 (1993) (defining "superimposed" as "layered"). Furthermore, even words of limitation that can connote with equal force a structural characteristic of the product or a process of manufacture are commonly and by default interpreted in their structural sense, unless the patentee has demonstrated otherwise. See Hanzai v. United States Int'l Trade Comm'n, 126 F.3d 1473, 1479 (Fed. Cir. 1997) (concluding that "chemically engraved" was not a process term); Vanguard Prods. Co. v. Parker Hannifin Corp., 234 F.3d 1370, 1372 (Fed. Cir. 2000) (holding that the claim term "integral" describes a structural relation, not the particular manufacturing process related in the specification); cf. id. ("A novel product that meets the criteria of patentability is not limited to the process by which it was made." (citing 3 Donald S. Chisum, Chisum on Patents § 8.05, at 8-79 (2000))).

Nothing in the intrinsic evidence of the patent requires that a limitation of sequential creation of the "multiple embossed pattern" should be included in claim 1. The limitation of serial embossing clearly present in method claim 6 cannot be read into claim 1; furthermore, method claim 6 creates new terms--"the first embossing step" and "the second embossing step"--to carry the serial-embossing limitation. It is true that language in the specification of the '930 patent recurrently recites serial application of the two patterns. See, e.g., '930 patent, col. 3, ll. 16-17 ("An advantage of the present invention is to create a means of sequential manufacturing of articles using different depths of depressions and same or different materials."); id., col. 6, ll. 66-67 ("Because the multiple embossings of the web occur sequentially . . . ."). Limitations from the specification, however, cannot be imported into the claims, and this rule must be strictly enforced in light of the clear definition of "multiple embossed" provided in the specification--a definition devoid of sequential limitation. Furthermore, the specification also discloses the option, albeit not the preferred option, of creating multiple embossed patterns in a single step. See id., col. 2, ll. 11-15 ("Although the multiple embossing steps could be combined into a single step with the design of a suitable tool or mold, the advantage of multiple steps is that the depressions formed by the prior step(s) can be filled with material prior to the subsequent embossing step(s).")

A broadening claim amendment made during the prosecution history of the '930 patent supports a plain-meaning construction of claim 1 without a sequential-embossment limitation. As filed in the original patent application, claim 1 was expressly limited to a "multiple sequentially embossed" web. 3 In response to the examiner's § 112, P 2 indefiniteness rejection, 3M amended claim 1 to claim a carrier web "that has a multiple embossed pattern having a first embossed pattern and a second embossed pattern," referring to definitions of "multiple embossed" and "embossed" that were in the specification at the time of the original patent application. The fact that 3M broadened its claims in response to an indefiniteness rejection and dropped the sequential limitation is perhaps unusual, but it is entirely permissible, and the plain language of the claim as issued must control. Cf. Smith v. Snow, 294 U.S. 1, 16, 79 L. Ed. 721, 55 S. Ct. 279, 1935 Dec. Comm'r Pat. 757 (1935) ("It is of no moment that in the course of the proceedings in the Patent Office the rejection of narrow claims was followed by the allowance of the broader claim 1."); United States v. Telectronics, Inc., 857 F.2d 778, 782-83 (Fed Cir. 1988) (concluding that adding a limitation to a claim during prosecution and then removing it when the limitation failed to result in allowance of the claim over the prior art does not permit reading of limitation into claim when the claim issued without it).

- - - - - - - - - - - - - Footnotes - - - - - - - - - - - - -

3 As initially filed, claim 1 read: "A carrier web, comprising: at least one surface that is multiple, sequentially embossed with a pattern, wherein depressions created from the prior embossing pattern(s) are substantially preserved during the subsequent embossing pattern(s) even though the subsequent embossing pattern(s) are superimposed on the depressions from the prior embossing pattern(s)."

- - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - -

Avery also argues that claim 1 contains a sequential-embossment limitation because of the arguments that 3M made during prosecution to overcome section 102(b) anticipation and section 103(a) obviousness rejections by the examiner. To traverse an anticipation rejection of both product claim 1 and method claim 8 (which eventually issued as method claim 6) based on references that taught that "two or more adhesives having different properties may be coated into the same recesses" on the web, 3M stated that:

Applicants here are claiming two different embossed patterns where the first embossed pattern survives the embossing of the second pattern. See Fig. 2, for an illustration of this patentable point. In [the prior art reference], there is only one embossed pattern, that can be filled with the same or different adhesives. There are not two embossed patterns as Applicants
The examiner withdrew his objection in response to 3M's argument. 4

4 3M made similar arguments to traverse another anticipation and an obviousness rejection as well.

Avery argues that 3M thus expressly disclaimed any patent scope beyond sequential embossment of patterns when it used language pregnant with temporal implications--the first pattern "survives" the embossing of the second--to traverse the examiner's rejections. 3M's use of the term "survives" in the prosecution history, however, does not constitute the clear and unambiguous disavowal of claim scope that is required to read a limitation into an expressly defined term. See Middleton, 311 F.3d at 1388. To distinguish the prior art in question, 3M needed only to argue, as it did in the last two sentences of the quotation above, that the '930 patent claimed "two embossed patterns" rather than "one embossed pattern." When the patentee has expressly defined a term in the specification and remarks made to distinguish claims from the prior art are broader than necessary to distinguish the prior art, the full breadth of the remark is not "a clear and unambiguous disavowal of claim scope as required to depart from the meaning of the term provided in the written description." Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 833 (Fed. Cir. 2003). Furthermore, Figure 2 of the '930 patent, to which 3M directed the examiner, illustrates only the coexistence of two distinct patterns in the final product, not the sequential embossing of the patterns.

Finally, in explaining a subsequent anticipation rejection under section 102(b) on the basis of other prior art, the examiner stated that claim 1 was "drafted in the product-by-process format." 3M never responded to this statement during the remainder of the prosecution because the objection was overcome without any need to address whether claim 1 was or was not a product-by-process claim. In this context, the examiner's statement does not constitute a clear and unmistakable surrender of claim scope. See Middleton, 311 F.3d at 1388. "Prosecution history . . . cannot be used to limit the scope of a claim unless the applicant took a position before the PTO." Schwing GmbH v. Putzmeister Aktiengesellschaft, 305 F.3d 1318, 1324-25 (Fed. Cir. 2002) (emphasis added). An applicant's silence in response to an examiner's characterization of a claim does not reflect the applicant's clear and unmistakable acquiescence to that characterization if the claim is eventually allowed on grounds unrelated to the examiner's unrebutted characterization.

III. DISCUSSION

The "multiply folded" term appears in certain claims of the '385 and '498 patents. Independent claims 7, 15, 32, and 38 of the '385 patent each refer to either a "relaxed coil capable of being multiply folded upon itself" 2 or a "deformable object capable of being multiply folded upon itself." Dependent claims 3 and 9 of the '498 patent each describe the "detachable elongate tip portion" as a "substantially pliable segment adapted to be multiply folded upon itself." While Defendant has requested construction of the phrase "multiply folded," (see Defendant Cordis's Brief in Support of Claim Construction of Term "Multiply Folded," "Def.'s Br.,” Docket Item No. 891, at 1), Plaintiffs seek construction of the phrases "capable of being multiply folded upon itself" and "adapted to be multiply folded upon itself," (see Plaintiffs' Brief Regarding Claim Construction of the "Multiply Folded" Claim Term, "Pls.' Br.,” Docket Item No. 893, at 1). The Court finds it appropriate to take this latter approach, but for convenience will continue to refer to these phrases collectively as the "multiply folded" term.

2 Although the Court construed the term "relaxed coil" in the '385 patent in its October 7, 2003 Markman Order, the phrase following that term, "capable of being multiply folded upon itself," was not construed by the Court. (See Markman Order at 17-18.)
 Defendant contends the "multiply folded" term should be construed to mean "a coil that is not prebiased, so that there is no restriction on its ability fold on itself multiple times in the body cavity being treated." (Def.'s Br. at 1.) Plaintiffs urge the Court to construe the term to mean having "an overall shape that is capable of being folded upon itself more than one time to conform to the shape of the cavity." (Pls.' Br. at 1.)

 Defendant contends its definition-which excludes prebiased coils- is consistent with the claims, specification, and prosecution history, including the recent statements made by the USPTO examiner in the reexamination proceedings of the '498 patent. With respect to the claim language, Defendant contends Plaintiffs' proposed construction cannot be adopted because "it would mean that a relaxed coil and a coil capable of being multiply folded upon itself are one and the same, even though both phrases are used in the claims." (Def.'s Br. at 3.) With respect to the specification, Defendant contends that while the specification does not specifically define the "multiply folded" term, "the context in which that phrase is used makes clear that the phrase was intended to encompass only a coil without prebias, so that there is no restriction on the ability of the coil to fold." 3 (Def.'s Br. at 4.) With respect to the prosecution history, Defendant makes two arguments. First, Defendant contends the USPTO, in the reexamination proceedings of the '498 patent, construed the "multiply folded" term to exclude prebiased coils. 4 (Def.'s Br. at 6-8.) Second, Defendant contends that during the prosecution of patent application number 07/840,211 ("the '211 application"), which was one of a series of continuation applications from which the '385 and '498 patents issued, the applicants repeatedly distinguished prior art on the ground that it was prebiased. (Def.'s Br. at 10-11.)

 3 The context to which Defendant refers is a sentence in the "Detailed Description" section of specification which states "[t]he tip may be elongate and flexible so that it packs the cavity by being folded upon itself a multiple number of times." (Declaration of Roland H. Schwillinski in Support of Plaintiffs' Brief Regarding Claim Construction of the "Multiply Folded" Claim Term, "Schwillinski Decl.," Ex. B, '498 patent, col. 6, Ins. 57-59.)

 4 Defendant also contends the patent owner (the Regents of the University of California) was obligated to file an objection during the reexamination proceedings and that silence in the face of the examiner's statement precludes Plaintiffs from making contrary arguments now. (Def.'s Br. at 8-10.)

 Plaintiffs disagree with each of Defendant's contentions. Regarding the claim language, Plaintiffs contend the claims of the '385 and '498 patents say nothing about whether the coil has a prebiased shape or not. (Pls.' Br. at 3.) Rather than having anything to do with prebias, Plaintiffs contend the "multiply folded" term "concerns the coil's ability to fold upon itself multiple times to conform to the interior shape of the aneurysm being occluded." (Pls.' Br. at 3.) With respect to the specification, Plaintiffs contend the specification not only emphasizes a coil may either be prebiased or not prebiased but also discloses various prebiased shapes that the coils may have, including a "spiral" or "helix" shape. (Pls.' Br. at 4.) With respect to the prosecution history, Plaintiffs contend the USPTO examiner in the reexamination of the '498 patent did "not state that all coils that multiply fold upon themselves cannot have any prebiased shape." (Pls.' Br. at 5.) Additionally, during the prosecution of the '211 application, Plaintiffs contend the applicants continued to emphasize the coils could be prebiased. (Pls.' Br. at 6.)

 The Court is not convinced there is a basis for construing the "multiply folded" term so as to exclude prebiased coils. The language of the claims does not provide any context from which it can be determined whether such an exclusion results from the "multiply folded" term. The Court also does not read in such a limitation given the disclosure of both prebiased and non-prebiased coils in the specification. See Vitrionics, 90 F.3d at 1583 (implying that excluding one of the disclosed embodiments from the claim scope is rarely, if ever, correct). The first embodiment described in the specification is a coil that is "prebiased to form a cylindrical or conical envelope. . . ." (Schwillinski Decl., Ex. B, '498 patent, col. 7, Ins. 60-61.) The third embodiment is a coil that is "not prebiased, nor does it contain any internal reinforcement, but is a free and open coil. . . ." (Schwillinski Decl., Ex. B, '498 patent, col. 9, Ins. 2-4.) Additionally, the specification states "it must be understood that the shape of the tip or distal platinum coil used in combination with the wire according to the invention may be provided with a variety of shapes and envelopes." (Schwillinski Decl., Ex. B, '498 patent, col. 12, Ins. 27-29.) The Court
does not find the claim language or specification support Defendant's proposed definition of the "multiply folded" term.

Aside from the claim language and specification, Defendant also relies on the USPTO examiner's statement in the NIRC as support for its proposed definition. Contrary to what Defendant contends, however, the examiner did not state that all coils which multiply fold upon themselves cannot be prebiased. Rather, the examiner merely states the '069 patent discloses coils which return to predetermined shapes and that these particular coils are not capable of being multiply folded upon themselves. (See Schwillinski Decl., Ex. F at 3.) Accordingly, the Court finds the examiner's statement does not support a definition of the "multiply folded" term that excludes prebiased coils. 5

5 As the examiner's statements do not bear on the definition of the "multiply folded" term, the Court does not reach the question of whether the patent owner had an obligation to respond to the examiner's statement. See supra note 4.

Finally, the Court considers whether statements made by the applicants during the prosecution of the '211 application support a construction of the "multiply folded" term that excludes prebiased coils. According to Defendant, in an attempt to distinguish the coils disclosed in the '069 patent, the applicants repeatedly relied on the fact the '069 coils were prebiased. (Def.'s Br. at 10.) Defendant cites the following statement made by the applicants in an information disclosure statement submitted to the USPTO:

Essential to the operation of [the '069 coil] is that the wire have a memory which returns it from its stretched to its relaxed condition as the wire is released from the catheter into the vascular cavity. . . .

An occlusion coil with this feature is more difficult to fabricate than a coil which is disposed within the catheter in a relaxed configuration and when disposed out of the catheter does not undergo any process wherein it conforms to some earlier shape or configuration. In addition, a wire having a preferred or memorized shape inherently requires that it have some type of springiness in order to conform to its predisposition configuration. This inherent springiness makes the coil less pliable. . . . [T]he coil will form a shape completely independently of the shape of the vascular cavity and will be modified only to the extent that a balance of force is obtained between the random mass, which the coil attempts to form, and the constraining force of the wall of the vascular cavity.

(Powers Decl., Ex. 5 at 9-10.) Defendant also cites the following statement made by the applicants as part of their explanation for certain claim amendments:

A relaxed coil which is flexible and which can be multiply folded in order to pack or substantially space fill a cavity necessarily can be described as relaxed or having no memory of a predisposed shape. Such a coil can be called not only flexible, but shapeless in that there is no preferred shape, but it assumes the shape into which it is folded within the vascular cavity.

(Powers Decl., Ex. 6 at 5.) This statement, Defendant contends, further shows that the applicants believed prebiased coils could not multiply fold on themselves. (Def.'s Br. at 11.) Defendant contends the public was entitled to rely on these distinctions drawn during the prosecution of the patent.

The Court recognizes the public has a right to rely on statements made by an applicant during the prosecution of a patent application. See Hockerson-Halberstadt, Inc. v. Avia Group Intl, Inc., 222 F.3d 951, 957 (Fed. Cir. 2000) ("The prosecution history constitutes a public record of the patentee's representations concerning the scope and meaning of the claims, and competitors are entitled to rely on those representations when ascertaining the degree of lawful conduct, such as designing around the claimed invention."). Nevertheless, "[t]o balance the importance of public notice and the right of patentees to seek broad patent coverage, [the Federal Circuit has] thus consistently rejected prosecution statements too vague or ambiguous to qualify as a disavowal of claim scope." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325 (Fed. Cir. 2003). In other words, for prosecution history disclaimer to attach, "precedent requires that the alleged disavowing actions or statements made during prosecution be both clear and unmistakable." Id. at 1326.
The Court does not find the applicants' statements cited above clearly distinguished the prior art on the basis that it was prebiased. Rather, in these statements, the applicants appear to have been emphasizing that the '069 coils were different because they had a "preferred or memorized shape" or "predisposition configuration." (See Powers Decl., Ex. 5 at 9.) The applicants certainly could have drawn a distinction based on the prebiased nature of these coils—a prebias that coincidentally enabled the coils to take on a memorized or predisposed configuration—but they did not do this. The emphasis instead was placed on the '069 coils' memory—i.e., their ability to return to a particular shape. As the applicants explicitly stated, "[e]ssential to the operation of [the '069 coils] is that the wire have a memory which returns it from its stretched to its relaxed condition as the wire is released from the catheter into the vascular cavity." (Powers Decl., Ex. 5 at 9.) Accordingly, the Court does not find the statements cited by Defendant distinguish the prior art on the basis of prebias.

IV. CONCLUSION

The Court construes (i) "capable of being multiply folded upon itself" to mean "capable of being folded upon itself more than one time" and (ii) "adapted to be multiply folded upon itself" to mean "adapted to be folded upon itself more than one time." The Court invites the parties to stipulate as to whether there is a difference between the terms "capable of" and "adapted to." If the parties do not file a stipulation within thirty (30) days of this Order, the Court will set a hearing for further construction of these terms.

2634

Claim 28
Preamble: "A multipurpose exercise apparatus adapted for providing an individual with support as a user moves between an upper first position and a lower second position during performance of an exercise"

Unlike the Preamble to Claim 15, the parties were not able to reach an agreement that construction of the Preamble to Claim 28 was unnecessary. Fitness Quest limited its request at the Markman hearing, and now primarily seeks construction of the term "multipurpose exercise apparatus" in the preamble, offering for its proposed construction: "an apparatus that permits a user to perform two exercises: (1) sit ups; and (2) lower abdominal flexion." Transcript 220. Monti contended that construction was unnecessary, as the preamble was not a limitation, and then (if necessary) offered his own broader construction. This Court determines that construction of the preamble in fact is not required.

Claim preambles, like all other claim language, are construed consistent with the basic principles of claim construction, including the principle that the language of the claim defines the scope of the invention protected by the patent. Bell Commun. Research, Inc., v. Vitalink Commun. Corp., 55 F.3d 615, 619-20 (Fed. Cir. 1995).

Whether a preamble to a claim requires construction depends on whether the preamble language limits the language found in the claim itself. "[A] preamble simply stating the intended use or purpose of the invention will usually not limit the scope of the claim, unless the preamble provides antecedents for ensuing claim terms and limits the claim accordingly." Boehringer Ingelheim Vetmedica, Inc., v. Schering-Plough Corp., 320 F.3d 1339, 1345 (Fed. Cir. 2003) (citation omitted). "[P]reamble language will limit the claim if it recites not merely a context in which the invention may be used, but the essence of the invention without which performance of the recited steps is nothing but an academic exercise." Id. (citation omitted). Stated differently,

A claim preamble has the import that the claim as a whole suggests for it. In other words, when the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects.

Bell Commun., 55 F.3d at 620 (citations omitted). Whether the preamble to Claim 15 requires construction therefore depends on whether the language of the preamble is necessary to an understanding of the invention described in the body of the claim.

Fitness Quest asserts that the preamble to Claim 28 must be construed, and then offers its construction. Monti, by contrast, contends that it does not act as a limitation on Claim 28 and therefore need not be construed. Fitness Quest contends that the initial use of the terms "first position" and "second position" in the preamble, each preceded by an indefinite article ("an")
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

and "a", respectively), provides a necessary context to the use of those terms later in the elements of Claim 28. Fitness Quest Response Brief at 9-10. Fitness Quest further argues that Monti "clearly" relied upon the preamble language in the prosecution history of the 749 Patent. Id.

Fitness Quest's arguments are unavailing. The preamble to Claim 28, when reviewed in the context of the entire claim, does not constitute a limitation on the claim, as it is at best a summary description of the device more precisely described in the claim elements, rather than any kind of further-limiting language.

"[P]reambles describing the use of an invention generally do not limit the claims because the patentability of apparatus or composition claims depends on the claimed structure, not on the use or purpose of that structure." Catalina Marketing Ina, Inc., v. Coolsavings.com, Inc., 289 F.3d 801, 809 (Fed. Cir. 2002). Here, the preamble to Claim 28 broadly describes the apparatus formed by the elements of Claim 28 and the purpose of it. As such, it does not limit the claim language and requires no construction.

The preamble contains the language "an upper first position and a lower second position." Fitness Quest contends that the preamble must be construed, so that these terms, used later in Claim 28, may be correctly understood. The basis for Fitness Quest's contention appears to be the adjectives "upper" and "lower," which Fitness Quest contends do not appear elsewhere in the claim. Strictly speaking, this is true. But the claim does contain the following language: "the first position is oriented above the second position." It is not a very daunting leap of faith to understand from this language that the first position is the "upper" of the two, and the second position is the "lower" of the two. The language in the preamble simply is not "necessary to give life, meaning, and vitality' to the claim." Catalina Marketing, 289 F.3d at 808, quoting Pitney Bowes, Inc., v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999).

Fitness Quest's reliance on the Manual of Patent Examining Procedure is equally unavailing. Rather than providing the bright-line rule Fitness Quest suggested in the hearing -- that the use of a definite article in the claim elements required reference back to a corresponding indefinite article in the preamble -- the Manual is not so rigid. See Transcript 52, 67; Fitness Quest Inc.'s Response to Mr. Monti's Opening Claim Construction Brief (Doc. 32) at 9-10. "Obviously, however, the failure to provide explicit antecedent basis for terms does not always render a claim indefinite. If the scope of a claim would be reasonably ascertainable by those skilled in the art, then the claim is not indefinite." MPEP 2173.05(e). As noted above, the scope of the claim, at least at to the issues raised by Fitness Quest, is reasonably ascertainable without resort to the preamble.

Finally, Fitness Quest contends that Monti relied on the preamble language in the prosecution of the patent, and it therefore should be understood as limiting Claim 28. Fitness Quest Response Brief at 10. While the prosecution history can be relevant to an understanding of whether a preamble requires construction, this Court is hard-pressed to read the excerpt referenced by Fitness Quest as demonstrating Monti's reliance on the language of the preamble per se rather than the claim elements in the prosecution of this patent.

The preamble to Claim 28 is not essential to an understanding of the language of the claim, and therefore does not require construction.

2635

a. Narrow beam of light

One World asserts that the phrase to "emit a narrow beam of light" means to give off a thin ray of light. Porter-Cable's proffered definition is a ray of light that appears narrow regardless of the vantage point from which it is viewed and does not cover a fan-shaped projection of light. In submitting this interpretation, Porter-Cable urges the Court to define the term so as to explicitly exclude a fan-shaped projection of light, which is the type of laser beam emitted by the Porter-Cable defendants' inventions.

Thus, the ordinary meaning of narrow beam of light is a ray or shaft of light of slender width.

Porter-Cable does not appear to disagree that this is the ordinary meaning of the claim language. See Porter-Cable Resp. at 11. It urges the Court, however, to additionally specify that a fan-shaped projection of light does not fall within the bounds of this definition of "narrow beam." Porter-Cable refers the Court to the discussion of the Kelly Patent that appears in the background section of the patent and in the prosecution history. Porter-Cable argues that the Kelly Patent makes it clear that one of ordinary skill in the relevant technology would not include a fan-shaped beam within the definition of narrow beam. In essence, Porter-Cable urges the Court to undertake an infringement analysis, as all of Porter-Cable's products use light projectors that project light in a fan shape. It is settled law, however, that claims must not be construed with reference to an accused product. See SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1118 (Fed. Cir. 1985). "It is only after the claims have been construed without reference to the accused device that the claims, as so construed, are applied to the accused device to determine infringement." Id. Thus, Porter-Cable's request that the Court find that "narrow beam" does not encompass a fan-shaped projection of light is premature.

Porter-Cable also submits the testimony of its expert, Paul Hatch, as evidence that one of ordinary skill in the technology would construe a claim limitation containing the term "narrow beam" to mean narrow from any vantage point and that this limitation excludes a fan-shaped beam. Though the Court was willing to entertain Hatch's testimony during the claim construction hearing to educate itself about the underlying technology, we will not rely on his expert testimony in construing the claim. As mentioned above, courts should rely on extrinsic evidence only if the meaning of a claim is ambiguous from the intrinsic evidence. See Hockerson-Halberstadt, Inc., 222 F.3d at 955. The parties have not suggested that the meaning is ambiguous, nor does the Court find the language ambiguous. Nothing in the claim language, specification, or prosecution history suggests that the phrase narrow beam of light means something different from its ordinary and customary meaning. Moreover, the proposed expert testimony specifically relates to whether or not a fan-shaped beam falls within the scope of the claim limitation. The Court reiterates that it is premature to make that determination at the claim construction juncture. In sum, the Court construes "narrow beam of light" to mean a ray or shaft of light of slender width.

2636

3. "Narrowly confined scanning volume"

PSC argues that the term "narrowly confined scanning volume" refers to a scanning volume that is narrowly confined in the sense that the shape of the scanning volume diverges at a relatively small rate as it is projected from the scanner. See Def.'s Br. at 23. PSC argues that "narrowly confined scanning volume" is defined as follows:

The volume in which a bar code symbol can be scanned must be narrow. A scanner with a narrowly confined scanning volume is suitable for presentation scanning and is not designed for sweep scanning. Also the angle of divergence of each group of scan lines must not exceed the 12 [degrees] rate of divergence in the example. Furthermore, the term is not so broad as to cover all scanning volumes that are generally confined.

See Def.'s Markman Presentation, Slide 50. Defendant PSC thus contends that the claim must be construed such that the angle between the emitted parallel lines must diverge no more than 12 degrees. See '852 Patent Fig. 1, Def.'s Markman Presentation, Slides 47, 50.

Plaintiff Metrologic argues that "narrowly confined volume" refers to

An area in which the bar codes can be successfully read that is generally confined within a narrow, yet diverging volume, e.g., a pyramid, cone, frustum, etc., which is centered about a projection axis which is substantially but not precisely perpendicular to the plane of the window. Further, a "narrowly confined volume" must be sufficiently confined so that the operator can obtain a successful read of a bar code in the area in front of and slightly diverging from the front of the scanner (up to 6 inches), but not outside the area, thereby preventing unintended reads.

Pl.'s Markman Br. at 17.

This Court considers the claim language, the specification, and the prosecution history, and it finds that plaintiff's
construction is correct. The claim language referring to the "narrowly confined scanning volume" provides:

(h) control means within said compact housing for controlling the operation of said counter-top projection laser scanner so that, during scanner operation, the laser beam produced from said laser beam producing means passes along a portion of said central reference plane, to the first, second and third rotating light reflective surfaces of said laser beam sweeping means, and as the laser beam sequentially reflects off said first, second and third rotating light reflective surfaces, the laser beam is repeatedly swept across said first, second, third, and fourth and fifth stationary light reflective surfaces thereby producing first, second, third, and fourth and fifth groups of plural scan lines, respectively, which are projected out through said light transmission window and intersect about a projection axis within a narrowly confined scanning volume extending from adjacent said light transmission window to at least about six inches therefrom so as to produce a highly collimated scanning pattern within said narrowly confined scanning volume, . . . .

'852 Patent, col. 12, ll. 26-45. Plaintiff contends that language in Limitation 15 sets forth additional definition. That section states: "the code symbol is scanned omnidirectionally by said highly collimated scanning pattern while preventing unintentional scanning of code symbols on objects located outside of said narrowly confined scanning volume." '852 Patent, col. 12, ll. 53-57. Although plaintiff maintains that the "narrowly confined scanning volume" refers to preventing the "unintentional scanning of code symbols on objects" located outside the volume, the position of terms in the claim language indicates that the scanning volume refers to the area in which items are scanned, while "narrowly confined" refers to the characteristic of that area.

The specification throughout refers to the volume as "relatively narrow, yet diverging." Id. col. 3, ll. 15-20. The specification, in the summary of the invention and the detailed description of the preferred embodiment, indicates that the patent is designed to be projected downward or outward from the face of the scanner, as it gives examples of the following volumes: pyramid, cone, and frustum. See id. & col. 5, ll. 34-40. Specifically, with respect to the volume, the claim specification states:

The scanning pattern is generally confined within a relatively narrow, yet diverging volume, e.g., pyramid, cone, frustum, etc., centered about a projection axis which is substantially but not precisely perpendicular to the plane of the window.

'852 Patent, col. 3, ll. 15-20. From this language, it can be inferred that the scanning volume of this patent, much like the scanning pattern discussed above, is not wide, but rather, narrow.

Defendant states that, while there is little guidance, if any, to be found in the specification and prosecution history, the specification contains a few uses of the term "narrow," which it compiles at Palmer Declaration P44:

A bar code scanner for stationary disposition at a counter to [sic] projecting a scanning pattern comprising first, second, third, fourth and fifth group of parallel scan line within a relatively narrow, yet diverging volume . . .

'852 Patent, at Abstract (emphasis added).

For example, in some check-out counter applications it is desirable to create a scanning pattern which, although aggressive, is confined within a relatively narrow volume, to prevent unintentional scanning of nearby objects.

Id. col. 2, ll. 7-11 (emphasis added).

The scanning pattern is generally confined within a relatively narrow, yet diverging volume, e.g., pyramid, cone, frustum, etc., centered about a projection axis which is substantially but not precisely perpendicular to the plane of the window.

Id. col. 3, ll. 16-20 (emphasis added).

Moreover, by virtue of the fact that the volume or space in which [the] scanning pattern is projected is somewhat narrow or confined, the amount of counter space which must be kept clear of other bar coded items to enable the proper scanning of the selected bar coded items, can be kept to a minimum. This should be contrasted with the use of conventional "slot-type" scanners, if mounted on a counter to project the scanning pattern thereabove. In such an arrangement the slot scanner produces such a wide or divergent pattern that a large amount of counter space must be reserved for scanning, and thus
The scanning pattern 26 is projected into a confined space or volume 38 (see FIG. 1), which as mentioned earlier is a relatively narrow, yet diverging and is centered about a projection axis 38. The diverging volume 36 containing the pattern may be of any shape, e.g., pyramidal, conical, irregular, etc., depending upon the length of the various lines of the pattern (i.e., the "envelope" defined by the end points of each line of the pattern) and may be established by the size of the scanner's mirrors and/or the size and shape of the window.

Id. col. 5, ll. 31-40 (emphasis added). This specification language repeatedly refers to the volume as being "relatively narrow, yet diverging," with narrow being interchangeable with "confined." In addition, the volume may take a "pyramidal, conical, irregular" shape. This reinforces the construction of the term "narrowly confined volume" as narrow, and taking the shape of a cylinder that slightly diverges.

Plaintiff notes, however, that nothing in Limitation 13 or 15 requires that a "highly collimated" pattern be present throughout the entire narrowly confined scan volume, and that as long as a portion of the narrowly confined volume is highly collimated for purposes of omnidirectional scanning, these limitations are satisfied. Operating under its construction that the term "highly collimated" refers to the rich nature of the scan lines, plaintiff argues that the claim language simply does not require that the scan pattern be omnidirectionally read throughout the entire volume. Given the Court's construction of "highly collimated projected scanning pattern" above, there is no need to determine whether the "narrowly confined scanning volume" must contain a scan pattern that can be read omnidirectionally everywhere in the pattern.

Defendant argues in particular that "narrowly confined scanning volume" must be construed to require a volume in which the angle of divergence between the scan lines is 12 [degrees] or less. PSC notes that the mirror mounting angles of the rotating assembly of mirrors (the polygon) are 2 [degrees], 4 [degrees], 6 [degrees], and 8 [degrees]. '852 Patent, col. 8, ll. 14-15. Specifically, the specification provides:

The reflective faces 46 of the polygon are each disposed at a slight angle (e.g., 2, 4, 6, and 8 degrees) to the rotational axis 44 each reflective face of the polygon sweeps the laser beam 48 across a different portion of the folding mirrors 82-90, thereby producing the parallel lines 40 (i.e., the "raster") of the various groups.

'852 Patent, col. 8, ll. 13-19. Defendant submits that these angles determine how quickly the scan lines within each of the five groups in the scan pattern diverge from one another as the distance from the scanner increases, resulting in an angle of divergence no greater than 12 [degrees] for each group of scan lines. Specifically, the 12 [degrees] angle of divergence is arrived at by multiplying by two the difference between the largest (8 [degrees]) and smallest (2 [degrees]) angles, which is 12 [degrees] in this case.

The language in the specification that "the lines making up the scanning pattern are preestablished in configuration and orientation with respect to one another . . . ." supports defendant's contention that the angles of divergence are fixed. The specification, however, refers to these angles of the polygon in terms of approximation, as "e.g., 2, 4, 6 and 8 degrees," '852 Patent, col. 8, ll. 14-15, and "approximately 2, 4, 6, and 8 degrees," id. at col. 7, l. 67-col. 8, ll. 1-2. All degrees referred to are given in approximation, and are referenced in the specification, not the claim language itself. While the specification suggests this angle of divergence, there is nothing in the claim itself that requires it. To define the angle of divergence to be no greater than 12 [degrees] is to unnecessarily limit the claim.

Furthermore, given the estimated angles from the vertical axis, they may define the angle of divergence between the scan lines themselves, yet they do not substantially describe the "narrowly confined scanning volume" which contains the lines. Taking defendant's theory to its logical extreme, the exact dimensions of the resulting volume could be calculated, using the estimated angles and the estimated length of 6 inches from the light source. The claim language, however, does not require such a calculation, and a construction providing for more than is claimed would be in error.

Based on the language of the claim, the specification, and the prosecution history, this Court construes the term "narrowly confined scanning volume" to be a volume that is narrow, yet diverging, from the transmission window of the scanner, which may take a pyramidal, conical, irregular, or similar shape. There is no construction requiring that the scan lines in any
given group diverge at 12 [degrees] or less.

2637

4. A "natural tissue plane" is the interface between one tissue and another tissue, where tissue may include, but is not limited to, nerves, blood vessels, muscles, tendons and bone.

2638

A. Claim 1

Claim 1 reads as follows:

A feline onychectomy surgical method using a laser cutting instrument, the method comprising:

(a) forming a first circumferential incision in the epidermis near the edge of the ungual crest of the claw, thereby severing at least some of the epidermis from the ungual crest;

(b) applying cranial traction to the epidermis severed from the ungual crest to displace the distal edge of the epithelium cranially;

(c) incising the extensor tendon near its insertion on the ungual crest;

(d) incising the synovium of the PII-PIII joint;

(e) applying traction to the claw in the palmar direction for disarticulating the PII-PIII joint;

(f) ablating the medial and lateral collateral ligaments;

(g) incising the digital flexor tendon; and

(h) incising the subcutaneous tissues of the pad of the second phalanx.

Defendant argues that Claim 1 is invalid for indefiniteness because it is indistinguishable from the prior art and thus, cannot apprise one skilled in the relevant field of the scope of the invention. Specifically, Defendant argues that Step (a), which instructs the surgeon to form the "first circumferential incision in the epidermis near the edge of the ungual crest of the claw," contains a word of degree, "near," which the specification leaves unexplained. Defendant asserts that a surgeon attempting to begin a declaw procedure using any dissection method would be unable to avoid infringement because dissection procedures, long before Plaintiff received his patent, began the first incision "near" the ungual crest.

It is well-settled law that words of degree are permissible "when serving reasonably to describe the claimed subject matter to those of skill in the field of the scope of the invention. Specifically, Defendant argues that Step (a), which instructs the surgeon to form the "first circumferential incision in the epidermis near the edge of the ungual crest of the claw," contains a word of degree, "near," which the specification leaves unexplained. Defendant asserts that a surgeon attempting to begin a declaw procedure using any dissection method would be unable to avoid infringement because dissection procedures, long before Plaintiff received his patent, began the first incision "near" the ungual crest.

It is well-settled law that words of degree are permissible "when serving reasonably to describe the claimed subject matter to those of skill in the field of the scope of the invention." (citing Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 822 (Fed. Cir. 1988); see also Hybritech Inc. v. Monoclonal Antibodies, Inc., 802 F.2d 1367, 1385 (Fed. Cir. 1986) ("The claims, read in light of the specification, reasonably apprise those skilled in the art and are as precise as the subject matter permits. As a matter of law, no court can demand more.") (citing Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed. Cir. 1985)). In Amgen, Inc. v. Chugai Pharm. Co., Ltd., 927 F.2d 1200, 1218 (Fed. Cir. 1991), the court found a claim indefinite because the following words of degree failed to inform the public of the patent's bounds:

4. Homogeneous erythropoietin characterized by a molecular weight of about 34,000 daltons on SDS PAGE, movement as a single peak on reverse phase high performance liquid chromatography and a specific activity of at least about 160,000 IU [international units] per absorbance unit at 280 nanometers. 1
Id. at 1203 (emphasis added). The court found the phrase "about 160,000 IU" indefinite because the range of measurement encompassed by the term "about" anticipated a measurement of as low as 120,000 IU, which had already been described in the prior art. The court explained that such wording "served neither to distinguish the invention over close prior art … nor … permitted one to know what specific activity values below 160,000, if any, might constitute infringement." Id. at 1217. Moreover, a physician-inventor behind the patent was unable to define "about" 160,000, stating only that he had not "given a lot of direct considerations to that." Id. The court held: "When the meaning of the claims is in doubt, especially when, as is the case here, there is close prior art, they are properly declared invalid." Id. (citing Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448, 453 (Fed. Cir. 1985)).

--- Footnotes ---

1 Erythropoietin (EPO) is a protein consisting of 165 amino acids that is used to stimulate the production of red blood cells. Medical professionals use it to treat anemias or blood disorders characterized by low red blood cell counts. Amgen, Inc. v. Chugai Pharm. Co., Ltd., 927 F.2d 1200, 1203 (Fed. Cir. 1991). EPO is created "through the concentration and purification of urine from both healthy individuals and those exhibiting high EPO levels." Id.

--- End Footnotes ---

Applying Amgen to Claim 1, Step (a), the Court finds the word "near" indefinite, pursuant to 35 U.S.C. § 112 P 2, for failing to distinguish the claimed subject matter from the prior art. Defendant has convinced this Court, by clear and convincing evidence, that a veterinary surgeon attempting to avoid infringement would be unable to do so because "near" fails to distinguish Plaintiff's patent from prior art. Plaintiff's attempts to distinguish the phrase "forming a first circumferential incision in the epidermis near the edge of the ungual crest of the claw" from the prior art are without merit. He argues that all prior art instructs surgeons to cut straight through the PII-PIII articulation, which means the point at which the two joints meet, rather than making the first incision at a point near the edge of the ungual crest. For example, during his February 15, 2005 deposition, Dr. Young testified that his procedure was distinguishable from that outlined in a well-established textbook. See THERESA WELCH FOSSUM ET AL., SMALL ANIMAL SURGERY 145-47 (1997) (hereinafter the "Fossum Reference"). In response to defense counsel's questions, Dr. Young testified as follows:

Q: And in your opinion, these previous techniques [referencing use of a scalpel, nail clippers, scissors, or electrocautery] did the incision at the PII-PIII joint?

A: Without fail.

***

Q: And in your view, scalpel technique [taught in Fossum] is different than the laser technique?

A: Yes

Q: Why is that?

A: In my laser technique, they're a lot different.

Q: Okay. Tell me.

A: In Fossum's scalpel technique?

Q: Sure.

A: Fossum's scalpel technique is a straight PII-PIII amputation.

Young Dep. II. at 30-32.
2 Dr. Young testified similarly during the September 7-8, 2004 Inequitable Conduct Hearing:

Every incision in Fossum, every incision in Slatter, ever incision in the Luxar reference is done in the plane of the PII-PIII joint. They may attack it from different angles, they may come through this way, they may come through that way, but in essence they only cut through PII-PIII. There is no cut at any time made outside the plane in that joint.

Inequitable Conduct Hearing Transcript at 11-74 (hereinafter "Inequitable Conduct Tr.").

Defendant, however, proved by clear and convincing evidence that the Fossum Reference instructs a surgeon to make the incision at essentially the same point described in the '579 patent. The Fossum Reference, in a chapter written by Dr. Cheryl S. Hedlund, Ph.D., reads: "Circumferentially incise the hairless, cuticle-like skin away from the claw near the articulation between the second and third phalanx." Id. at 146. Dr. Hedlund testified that she has always instructed her students, both in veterinary school and in her textbook chapter, to make the first incision circumferentially "at the most distal aspect of the nonhaired skin." Hedlund Dep. at 20. Specifically, Dr. Hedlund stated: "I insert the Number 11 scalpel blade parallel with the claw where the cuticle like skin attaches to the claw. So it goes around at that point. That's where the circumferential incision is made when I direct the declaw." Id. at 64. 3

Although the Fossum Reference mentions a scalpel as opposed to a laser, the Court finds the difference nominal. Dennis Olsen, DVM, a veterinarian who testified on behalf of Defendant, testified that the declaw process was "essentially identical" whether a surgeon uses a laser or a scalpel. Inequitable Conduct Tr. at I-72. He also explained that the increased use of lasers is a reflection of their decline in price over time. Olsen Supp. Decl. at P 23. ("When the price of lasers dropped in the late 1980's and early 1990's, veterinarians began to use them to perform surgery….").

In light of this strikingly similar prior art, the Court does not see how the first step in Claim 1 of the '579 patent adequately delineates the scope of the invention. Even Dr. Young, on cross-examination, admitted that he was unable to discern what constituted "near the most distal edge of the ungual crest." Markman Hearing Transcript at 86 (hereinafter "Mkmn. Tr.").

Alternatively, Dr. Young asserts that his patent is distinguishable from the prior art if the surgeon intends to, or does, save enough skin to cover the wound. 4 This argument fails, however, because infringement cannot depend on another's intent; rather, a patent's claims must be clear enough so that an objective person skilled in the art would be able to determine the patent's scope. See Hilton Davis Chem. Co. v. Warner-Jenkinson Co., Inc. 62 F.3d 1512, 1519 (Fed. Cir. 1995) (en banc), rev'd on other grounds, 520 U.S. 17, 117 S. Ct. 1040, 137 L. Ed. 2d 146 (1997) ("This question [of infringement] is one irrespective of motive. The defendant may have infringed without intending, or even knowing it; but he is not, on that account, the less an infringer…. The immediate question is the simple one, has he infringed?") (citation omitted). Thus, Claim 1, Step (a) is invalid for indefiniteness because Defendant has proved by clear and convincing evidence that it would be impossible for someone skilled in the art to determine the meaning of "near: so as to avoid infringement. 5

4 Dr. Young testified as follows during his February 15, 2005 deposition:

Q: Your view is that your claims are infringed if a person intends to use the tissue to cover the surgical site for a feline declaw as long as the incision is not made through the joint?

A: And it's sufficient, it is of sufficient nature to cover the declaw site, I think that is pretty clear.

Young Dep. II. at 332.
5 Defendant's papers contain extensive and persuasive arguments that Claim 1's remaining steps are indistinguishable from the prior art and thus, not valid. This argument, however, concerns the obviousness of the patent, not the construction of its claims. Because the patent's obviousness has been neither fully briefed nor argued in this Court, the Court will not now resolve that issue.

Because Claims 2 through 5 are dependent on Claim 1, they are similarly invalid for indefiniteness. Datamize, LLC, 417 F.3d at 1347 ("Since claim 1 is the '137 patent's sole independent claim, the court's grant of summary judgment of indefiniteness as to claim 1 invalidated each claim in the '137 patent."). The Court now turns Claim 6, the only remaining independent claim.

A. Indefiniteness

On appeal, Young argues that the district court incorrectly determined that the term "near" is indefinite. According to Young, the district court never considered the intrinsic evidence to determine the meaning of the term "near," and instead only relied on extrinsic evidence, such as the prior art Fossum Reference and the Hedlund deposition testimony. Young asserts that the term "near" is clearly defined in the specification and can be construed such that it is not indefinite. Moreover, Young asserts that all the witnesses understood the term, including Hedlund, who, in fact, used the term "near" in the Fossum Reference to describe the location of an incision. Finally, Young contends that the court misapplied Amgen, which involved a limitation that was not supported in the specification or the prosecution history.

Lumenis responds that the district court properly determined that the term "near" fails to distinguish the claimed invention from the prior art, and thus fails to apprise potential infringers of the scope of the claims. Lumenis further asserts that if the claims were unambiguous, there would have been no need to resort to extrinsic evidence. Lumenis contends that there is, in fact, no definition of the term "near" in the specification so that it was proper for the court to rely on extrinsic evidence. According to Lumenis, the district court's focus on whether the claims distinguished what was claimed from what was in the prior art was the appropriate inquiry, as stated by this court in Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342 (Fed. Cir. 2005). Lumenis argues that the prior art is very close. Lumenis further asserts that the term "near" is a word of degree and is indefinite because it fails to inform the public of its bounds and is thus akin to the situation in Amgen, as the district court noted.

We agree with Young that the district court erred in determining that the term "near" is indefinite. A patent specification must "conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2. The purpose of the definiteness requirement is to "ensure that the claims delineate the scope of the invention using language that adequately notifies the public of the patentee's right to exclude." Datamize, 417 F.3d at 1347 (internal citation omitted). Claims are considered indefinite when they are "not amenable to construction or are insolubly ambiguous . . . . Thus, the definiteness of claim terms depends on whether those terms can be given any reasonable meaning." Id. Indefiniteness requires a determination whether those skilled in the art would understand what is claimed. To make that determination, we have explained that "in the face of an allegation of indefiniteness, general principles of claim construction apply," Id. at 1348. In that regard, claim construction involves consideration of primarily the intrinsic evidence, viz., the claim language, the specification, and the prosecution history. Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) (en banc).

We first consider the claim language. The term "near" is recited in Claim 1(a) as: "forming a first circumferential incision in the epidermis near the edge of the ungual crest of the claw." That language implies that an incision is made in the epidermis somewhere close to or at the edge of the ungual crest. As used in the claim, the term "near" is not insolubly ambiguous and does not depart from the ordinary and customary meaning of the phrase "near" as meaning "close to or at" the edge of the ungual crest.

Reference to the specification shows that it is consistent with that understanding of the term. The specification makes
reasonably clear that the first incision is made very close to or at the edge of the ungual crest. In the "Brief Summary of the Invention," the specification describes the invented method as including a first incision in the epidermis "at the edge of the ungual crest of the feline's claw." 579 patent col.1 ll.63-67. The specification further describes that the first incision "severs the most distal portion of the epidermis from the underlying fascia of the ungual crest." Id. Additionally, in the "Detailed Description of the Invention," the disclosure states that the first incision "is made near the most distal edge of the epidermis and extends circumferentially around the claw to sever the epidermis from the ungual crest." Id. col.4 ll. 39-42. Thus, based on the several descriptions in the specification, we understand the term "near the edge of the ungual crest" as recited in the claims to mean close to or at the most distal edge of the epidermis. In fact, Figure 2 shows an example of such an incision "near" the edge of the ungual crest, as illustrated by line A-A. That figure illustrates where the first incision is made in relation to the crest and phalanx, and provides a standard for measuring the meaning of the term "near."

Moreover, because the term "near" describes a location on an animal, its use, as opposed to a precise numerical measurement, is not inappropriate because the size of the appendage and the amount of skin required to be incised will vary from animal to animal based on the animal's size. Akin to the term "approximately," a person having ordinary skill in the art would know where to make the cut; thus the use of the word "near" does not deprive one of ordinary skill from being able to ascertain where the cut should be made.

Lumenis argues that the district court properly applied Amgen and determined that the term "near" is indefinite because it fails to distinguish the claims over the prior art. We do not agree that Amgen supports the district court's decision. In Amgen, the invention was directed to homogeneous erythropoietin ("EPO"), a protein consisting of 165 amino acids that stimulates the production of red blood cells. 927 F.2d at 1203. The claim recited homogenous EPO characterized by the limitation "specific activity of at least about 160,000 IU per absorbance unit." Id. The district court determined that "bioassays provide an imprecise form of measurement with a range of error" and that the use of the term "about" 160,000 IU coupled with the range of error already inherent in the specific activity limitation, did not distinguish the invention over close prior art, which described preparations of 120,000 IU, or permitted one of ordinary skill in the art to know what specific activity values below 160,000 IU might constitute infringement. Id. at 1217. The claims as filed included the limitation "at least 120,000." After the examiner rejected the claims because the prior art included EPO having a specific activity of 128,620 IU, the claims were amended to change the "at least 120,000" language to "at least about 160,000" to avoid the cited prior art.

Because the term "about" did not give any indication as to which numerical value between the prior art specific activity value of 128,620 and 160,000 constituted infringement, the court held the term "at least about" to be indefinite. Id. at 1218. The district court further observed that there was nothing in the specification or prosecution history that provided any indication as to what range of specific activity was covered by the term "about," and no expert testified as to a definite meaning for the term. For those reasons, we affirmed the district court's determination of invalidity, stating that when the meaning of the claims is unclear, especially when there is close prior art, the claims properly may be held to be invalid. Id.

Unlike the situation in Amgen, here the intrinsic evidence does provide guidance on the meaning of the term "near." When intrinsic evidence resolves the claim construction, a term is not "insolubly ambiguous," and thus reference to the prior art is not needed. That is the situation here. In addition, there were no office actions issued by the PTO during the original prosecution rejecting the claims over the prior art. There were also no amendments or arguments filed by the patentee. Thus, unlike in Amgen, the claims were not amended to include vague language in order to overcome close prior art.

In sum, Lumenis did not prove by clear and convincing evidence that the claims are invalid for indefiniteness. The claim language and the specification make clear that the term "near" means close to or at the most distal edge of the ungual crest.
with an opening existing in the structure of a meter for securing said housing therein.

The Court construes the term "near" to mean not far distant in place. Webster's Collegiate Dictionary (9th Ed. 1984). CellNet's proposed definition of "near" as spacing sufficient so that the mounting holes will work for their intended purpose, which is to fit various standard watthour meters" is rejected because there is no indication in claim 6, where the term appears, that the term was intended to have a functional correlation. CellNet's definition is also indefinite because the physical dimensions of "standard watthour meters" are not given in claim 6, nor in claim 5 upon which claim 6 depends. Finally, Itron's proposed construction of "near" as "within a .0005 inch range" must be rejected since it clearly does not modify any specific number or dimension in claim 6.

HECO interprets this clause as follows:

The side wall of the bin is continuously curved; it includes an upper portion that is nearly vertical with respect to ground, and a lower portion that is "near horizontal" with respect to ground. The term "continuously" requires no flat, non-curved portions. "Near horizontal" means the lower portion must have some inclination with respect to ground above the horizontal, as outlined in Claim 1 above. In addition, the lower portion must be curved.

JCCC at 20. Cives and Monroe propose the following construction:

The side wall of the bin is continuously curved from an upper, outer portion that is nearly vertical with respect to the ground to a lower, inner portion that is "near horizontal" with respect to the ground. "Near horizontal" means substantially or approximately horizontal.

Id.

The parties do not expend much effort trying to distinguish between the two constructions, and at first glance it is unclear how they differ. It appears, however, that the difference is as follows: whereas HECO believes that the bin must be continuously curved, Cives and Monroe assert that it must only be continuously curved "from an outer, upper, near vertical portion of the sidewall to a lower, inner, near horizontal portion of the sidewall." Moreover, Cives and Monroe claim that "near horizontal" may be construed as "substantially" or "approximately" horizontal, whereas the court assumes that, to be consistent with its interpretation of claim 1, HECO believes that "near horizontal" means an inclination of "at least 7% degrees above horizontal."

Assuming the court has adequately stated the parties' respective positions, the court shall adopt the construction that Cives and Monroe propose. The claim only requires that a certain portion of the side wall of the bin be curved, i.e., "from an outer, upper, near vertical portion of the sidewall to a lower, inner, near horizontal portion of the sidewall." It does not require the entire sidewall to be curved, as HECO's construction suggests. For example, as the court discussed in Part VII.A.1, the sidewall can have an upper vertical portion. The specification makes clear that these optional upper vertical portions are part of the sidewall. See, e.g., Col.3, ll. 10-20 (discussing figure 3 and stating that "[u]pper vertical portions of the sidewalks are optional: the bin sidewalls may commence with inwardly curved portions" (emphasis added). The court also declines to adopt HECO's construction of "near horizontal" as an inclination of "at least 7 degrees above horizontal" for the same reasons outlined in Part VII.A.2. The plain and ordinary meaning of "near horizontal" is "substantially" or "approximately" horizontal. Cf. Aero Prods. Int'l, Inc. v. Intex Recreation Corp., 466 F.3d 1000, 1008 (Fed. Cir. 2006) (noting that the parties had agreed that "substantially hermetic seal" meant "nearly or largely impervious to air").
the reflector body has lugs on a side nearest the light emission window.

The parties are not far apart on the meaning of "lugs". Philips urges that it means "small projecting parts of the reflector body used for positioning the light source." Iwasaki advocates that it means "projections, pads or ridges". Based upon my review of the specification and without reading a non-existent functional limitation into the claim language, I conclude that lugs, in the context of the claim language, means "small projecting parts of the reflector body". 7

7 I note that "lugs" is defined in Webster's Third New Int'l Dictionary, Unabridged (1961) as "a small projecting part of a larger member".

The parties disagree as to the meaning of "on a side nearest" in the phrase "the reflector body has lugs on a side nearest the light emission window". Philips argues that it means the lugs are positioned at the front or top end of the reflector body closest to the light emission window. Iwasaki urges that it means a side at the front end of the reflector body.

The claim language describes the relationship of the lamp to the reflector body: "the electric lamp being fixed in the reflector body with the first end portion inside the neck-shaped portion, while the cavity lies within the reflecting portion and the electric element is on the optical axis wherein the reflector body has lugs on a side nearest the light emission window." There is no dispute that the "light emission window" means a part of the reflector body through which light is emitted outside. At first review, the use of the indefinite article "a" -as in "a side"--and the superlative "nearest" in the phrase "lugs on a side nearest the light emission window" appears ambiguous. The use of both terms assumes the possibility of multiple. Furthermore, the claim language does not differentiate between reflector bodies that, at the end through which light is transmitted, are circular in shape and those that are rectangular in shape. Thus, there can be multiple sides to a given reflector body. In claim 6, the term "front side" is employed and, for the reasons that will later be explained, I construe that term to mean the side that faces in the same direction as the emitted light. I will not construe "a side nearest the light emission window" to be synonymous with "front side". I construe the term "a side nearest the light emission window" to mean any side that is at or near the end of the light emitting end of the reflector body and includes the "front side" as defined below, as well as the outer circumference of the reflector body at points closest to the light emitting end.

7. "needle protector clip"

Braun construes "needle protector clip" to mean "needle guard." (D.I. 99 at 20; Tr. at 115) Terumo instead construes the term to mean "unitary needle guard." (D.I. 71 at 21) Thus, the only dispute is whether the word "unitary" should be part of the construction. (Tr. at 115)

There is not entire agreement as to what "unitary" means. To Terumo, "unitary" means made of a single piece of metal. (D.I. 71 at 23; Tr. at 129) Braun disagrees. (D.I. 99 at 21 n.5; Tr. at 116-17) For purposes of my analysis, I interpret "unitary" to mean "made of a single piece of metal."

Nothing in the language of the asserted claim itself indicates a limitation that the needle protector clip (or needle guard) be unitary. Independent claim 9, in which the disputed term appears, reads in pertinent part:

a needle protector clip positioned in the clip cavity and having a ready to use position, in which the needle protector clip is positioned proximally of the needle tip, and a protective position, in which the needle protector clip blocks the needle tip . . . .

(‘613 patent, col. 16 lines 4-8) (emphasis added)

Terumo, as support for its "unitary" limitation, points out that the other two independent claims -- claims 1 and 20, which
each claim "a tip protector" -- have dependent claims -- claims 7 and 23, respectively -- "wherein the tip protector is an integrally formed unit" (emphasis added). (See D.I. 71 at 22; '613 patent, col. 15 lines 60-61 & col. 17 lines 6-7.) To Terumo, it follows that claim 9, which lacks a similar dependent claim, must somehow also be limited to an "integrally formed unit," a phrase evidently having the same meaning as "unitary." I do not agree. Rather, the structure of these claims indicates that the patentee knew how to limit his claims to "unitary" clips when he wished to do so, rendering it meaningful that he chose not to do so in claim 9.

Turning to the specification, it, like the claims themselves, demonstrates that the patentee knew how to indicate when an embodiment was "unitary." Several embodiments are expressly described as a "unitary needle guard" or a "unitary spring clip." ('613 patent, col. 3 lines 13-14; id. col. 5 line 60) (emphasis added) Other embodiments, however, are not described as "unitary," such as "the spring clip needle guard 96" shown in Figures 7A-7C and "the spring clip 96" shown in Figures 8 and 9. ('613 patent, col. 8 lines 24-28)

Terumo offers several justifications for a "unitary" limitation, but none are persuasive. First, Terumo emphasizes the first sentence of the Abstract, which states: "[a] safety IV catheter includes a unitary, resilient needle guard received in a catheter hub." (D.I. 71 at 22-23) But neither the Abstract nor any part of the specification states that "unitary" is an "essential component" of the invention; there is no basis to import this limitation into the claims. See Saunders Grp. v. Comfortrac, Inc., 492 F.3d 1326, 1332-33 (Fed. Cir. 2007). Next, Terumo observes that the specification discloses that one of the objects of the invention is "to provide a safety IV catheter of the type described which is relatively simple and inexpensive to manufacture." (613 patent, col. 2 lines 46-48) However, even assuming it is easier and cheaper to manufacture a unitary needle guard than one consisting of multiple pieces, there is no teaching in the patent that these features of the manufacturing process are essential to the invention. Nor is there any requirement that every claim of a patent accomplish every objective of the invention. See generally i4i Ltd. P'shp v. Microsoft Corp., 598 F.3d 831, 843 (Fed. Cir. 2010) ("[N]ot every benefit flowing from an invention is a claim limitation."). Finally, Terumo again cites to Wynkoop's deposition, but again the testimony on which it relies does not address the scope of the claims. (D.I. 98 Ex. 1 at p. 140-41 (Wynkoop reiterating 2001 testimony about embodiment depicted in Figure 10A))

Thus, I recommend that the Court construe "needle protector clip" as a "needleguard."

2644

I. Top surface having a negative slope from left to right (Claims 1, 6-10, 18-21)

The plaintiff's proposed definition is "the top surface slants downward from left to right such that the highest point is left of center." The defendant's proposed definition is "the entire top surface slopes downwardly from the left wall to the right wall so that no arch is present when viewed from the rear." The defendant objects to the plaintiff's definition because it would encompasses an arch on the top of the mouse. The defendant points to the prosecution history, in which the patent examiner distinguished the '683 patent from the prior art.

In October 1996, the PTO rejected the plaintiff's application based in part on the prior art -- the Gart mouse, the Bacon mouse, the Kaneko mouse, and the Maynard mouse. See Joint Appendix ("JA") 77-78. In January 1997, the plaintiff filed an amendment addressing the examiner's concerns. See JA 81-89. The plaintiff argued that "the top surface of the Gart mouse does not have a negative slope from left to right" as recited in the plaintiff's claims, but a gentle, clearly distinctive arch. See JA 85. The plaintiff distinguished the Bacon, Kaneko, and Maynard mice on the same grounds. See JA 87 ("The Bacon mouse and the Kaneko mouse both have an arched top surface, not a top surface having a negative slope from left to right.").

In March 1997, the PTO again rejected the plaintiff's application in view of the prior art. See JA 99-104. The examiner found the slope of the Gart mouse from left to right in the range of 20 to 30 degrees to be "negative enough" to preclude the plaintiff's application. See JA 102. In April 1997, the plaintiff submitted another amendment, which was rejected by the PTO. See JA 112.

On May 21, 1997, the plaintiff had a personal interview with the examiner to discuss all pending claims. In the record of the interview, the examiner described the general nature of the meeting: "Applicant and his representative discussed the
difference between the instant invention and the prior art device (including the negative slope from left to right and the curved bottoms) and the criticality of these features for operation of the invention." JA 113.

In its summary of interview and request for reconsideration, the plaintiff emphasized that its invention requires a negative slope from left to right in a range of 20 to 30 degrees in contrast to the Gart patent, which shows a top surface with a negative slope from center to right but a positive slope from left to center. See JA 117. The examiner subsequently issued an amendment which permitted certain of the plaintiff's claims. The examiner noted that although the Gart mouse had a negative slope on the top surface, the slope "is not entirely negative as shown in the present invention." See JA 122 (addressing Figure 2 of the plaintiff's invention) (emphasis added). The examiner explained that "the negative slope claimed in the present invention is critical" to obtaining the positive results intended by the patent.

Based on this history, the defendant argues the examiner only permitted the plaintiff's patent after she was convinced that the plaintiff's invention avoided the prior art by requiring an entirely negative slope from left to right. The plaintiff responds that if the examiner meant to require the slope to be entirely negative, then the examiner would have required the plaintiff to amend the patent language before awarding the patent. The plaintiff argues that the claim language itself does not require an entirely negative slope. The plaintiff further points to the drawings in the specifications, which do not show an entirely negative slope.

After considering the prosecution history, the Court finds that the defendant's definition is correct. The plaintiff avoided the prior art before the examiner by claiming the slope was entirely negative from left to right and should not be permitted to change those representations now. See Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."). If the plaintiff disagreed with the examiner's characterization of the invention as having an entirely negative slope, then the plaintiff had an obligation to correct it. 1 The plaintiff will not be permitted to benefit from the examiner's characterization and then try to disclaim that characterization in the above-styled cause.

- - - - - - - - - Footnotes - - - - - - - - -

1 The record reveals that the plaintiff did file a comment on the examiner's reasons for allowance, but failed to address the examiner's conclusion that the plaintiff's invention had an entirely negative slope. See JA 131-32.

- - - - - - - - - End Footnotes - - - - - - - - -

This same interpretation -- requiring an entirely negative slope -- will be applied to the definition as it applies to a negative slope from front to rear.

2645

The plaintiffs' patent concerns an ergonomically superior computer mouse that minimizes the amount of stress placed on the user's fingers, wrist, and hand. The invention is intended to conform as closely as possible to the user's neutral hand position, which is also referred to as the position of repose. The plaintiff contends that the defendant's products - specifically the Intellimouse Pro and the Intellimouse Explorer-are infringing claims 1, 6-10, and 18-22 of the '683 patent as well as claim 42 of the '553 patent.

On January 14, 2000, the Court entered an order construing the claims of '683 patent. One area of dispute concerned the phrase "having a negative slope" from left to right. The parties disagreed whether the term should be defined to encompass an arch. The defendant proposed defining the phrase to mean "the entire top surface slopes downwardly from the left wall to the right wall so that no arch is present when viewed from the rear." The plaintiffs' proposed definition was "the top surface slants downward from left to right such that the highest point is left of center."

During the prosecution, the patent examiner distinguished the '683 patent from the prior art, specifically the Gart mouse. The examiner noted that although the Gart mouse had a negative slope on the top surface, the slope "is not entirely negative as shown in the present invention." See Joint Appendix ("JA") 122; see also JA 85 (claiming the Gart patent does not have a negative slope from left to right but a gentle sloping arch); JA 87 ("The Bacon mouse and the Kaneki mouse both have an
arched top surface, not a top surface having a negative slope from left to right."). The examiner explained that "the negative slope claimed in the present invention is critical" to obtaining the positive results intended by the patent. Relying in large part on the prosecution history, the Court adopted the defendant's definition. See Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution.").

On December 21, 1999, the PTO issued the '553 patent, which is a continuation-in-part of the '683 patent. Claim 43 of the '553 patent discloses:

A computer mouse for operation, on an operating surface, by a right hand, the computer mouse comprising:

- a bottom wall having an opening to accommodate a controlling device; a housing, joined to the bottom wall, including a top surface, a front surface, a right side surface and a left side surface; the top surface having negative slope from front to rear and from left to right to support the right hand in a state of approximate repose with pronation in the range of approximately 10 degrees to approximately 45 degrees from the horizontal, while the heel of the right hand rests on the operating surface; a longitudinal peak running substantially left of center along the length of the mouse; and at least one button having negative slope downward to the front and right.

(Emphasis added). On January 18, 2000, the Court granted the plaintiff leave to file a third amended complaint that asserted claims based on the '553 patent.

The defendant urges the Court to apply the construction of "negative slope" in the '683 patent to the '553 patent. See, e.g., Wang Lab., Inc. v. America Online, Inc., 197 F.3d 1377, 1384 (Fed. Cir. 1999) (rejecting the patentee's argument that a statement made during the prosecution of the parent application should not apply to the continuation-in-part application); Elkay Mfg. Co. v. EBCO Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999) ("When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation."); Augustine Med. Inc. v. Gaymar Indus. Inc., 181 F.3d 1291, 1302 (Fed. Cir. 1999).

The defendant also argues it is entitled to summary judgment because the accused products do not contain "a flattened surface adjacent to said one or more buttons . . . such that the user's ring finger receives support from the flattened surface" as required by dependent claims 18 and 22 of the '683 patent, which the Court interpreted to require "a surface that is sufficiently flat, wide, and horizontal to support a user's ring finger without the finger touching the mouse button."

Finally, the defendant argues prosecution history estoppel precludes the plaintiff from prevailing under the doctrine of equivalents. See Augustine Med., Inc., 181 F.3d at 1298 (describing the numerous principles that "strictly limit" the application of the doctrine of equivalents). Because the plaintiff relinquished coverage for a mouse with an arched surface in its arguments to the examiner, the defendant argues the plaintiff is precluded from reclaiming this feature under the doctrine of equivalents. See Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1304 (Fed. Cir. 1997) ("By distinguishing the claimed invention over the prior art, an applicant is indicating that the claims do not cover."). The defendant concludes it is entitled to summary judgment of noninfringement as to both the '683 and '553 patents.

The plaintiff criticizes the defendant's noninfringement arguments as being based on a "faulty claim construction." The plaintiff continues to argue that the phrase "top surface having a negative slope from left to right" does not preclude the top surface from having an arch when viewed from the rear. The plaintiff argues the express terms of the '553 patent vitiate the
Court's interpretation of the '683 patent. As mentioned above, claim 43 of the '553 patent requires a "longitudinal peak running substantially left of center along the length of the mouse." Claim 46 of the '553 patent recites:

The computer mouse of claim 43, wherein the longitudinal peak runs along the length of the computer mouse, substantially from a forward juncture of said left side surface and said front surface, toward a rearward juncture of said top surface and said left side surface.

The plaintiff interprets claim 46 to require the longitudinal peak to be located on the extreme left edge of the top surface. Based on the doctrine of claim differentiation, the plaintiff argues that claim 43 permits the longitudinal ridge to be located somewhere between the extreme left edge of the top surface and substantially left of the center of the top surface. See, e.g., Kraft Foods, Inc. v. International Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000) (noting that the doctrine of claim differentiation creates a presumption that each claim in a patent has a different scope). If the longitudinal ridge is placed anywhere to the right of the extreme left edge of the top surface, the mouse will not have an entirely negative slope from left to right and an arch will be present when the mouse is viewed from the rear. The plaintiff asserts that by granting claim 43 of the '553 patent, the examiner must have recognized that the surface of the invention described in both the '683 and the '553 patents did not require an entirely negative slope from left to right. Thus, the plaintiff concludes the Court's interpretation of negative slope is manifestly erroneous.

Alternatively, the plaintiffs argue the accused products infringe under the doctrine of equivalents. According to the plaintiffs, the negative slope from left to right provides pronation relief by placing the hand in a state of approximate repose. The plaintiffs argue the left to right slope of the accused products perform the same function and achieve the same result. Similarly, the plaintiffs argue the negative slope from front to back of the accused devices provides support to the palm and fingers in the same way and achieves the same result as the claimed inventions. The plaintiffs reject the defendant's prosecution history estoppel argument. The plaintiffs allege they distinguished the prior art Gart design on various grounds, including the apparent symmetry in the top surface. The plaintiffs argue it is inappropriate for the defendant to focus on just one of the bases given for distinguishing the Gart mouse instead of focusing on the combination of reasons.

The defendant replies by disagreeing with the plaintiff's proposed interpretation of claim 46. The defendant interprets claim 46 as describing where the longitudinal peak starts and ends rather than telling where it is located with reference to the center of the top surface of the mouse.

The Court finds the defendant is entitled to summary judgment on noninfringement as to both the '683 and the '553 patents based on the prosecution history of the '683 patent. Although the prosecution history of the '683 was detailed in the Court's previous claims construction order, it is helpful to repeat that history here. In October 1996, the PTO rejected the plaintiff's application based in part on the prior art -- the Gart mouse, the Bacon mouse, the Kaneko mouse, and the Maynard mouse. See JA 77-78. In January 1997, the plaintiff filed an amendment addressing the examiner's concerns. See JA 81-89. The plaintiff argued that "the top surface of the Gart mouse does not have a negative slope from left to right" as recited in the plaintiff's claims, but a gentle, clearly distinctive arch. See JA 85. The plaintiff distinguished the Bacon, Kaneko, and Maynard mice on the same grounds. See JA 87 ("The Bacon mouse and the Kaneko mouse both have an arched top surface, not a top surface having a negative slope from left to right.").

In March 1997, the PTO again rejected the plaintiff's application in view of the prior art. See JA 99-104. The examiner found the slope of the Gart mouse from left to right in the range of 20 to 30 degrees to be "negative enough" to preclude the plaintiff's application. See JA 102. In April 1997, the plaintiff submitted another amendment, which was rejected by the PTO. See JA 112.

On May 21, 1997, the plaintiff had a personal interview with the examiner to discuss all pending claims. In the record of the interview, the examiner described the general nature of the meeting: "Applicant and his representative discussed the difference between the instant invention and the prior art device (including the negative slope from left to right and the curved bottoms) and the criticality of these features for operation of the invention." JA 113.

In its summary of interview and request for reconsideration, the plaintiff emphasized that its invention requires a negative slope from left to right in a range of 20 to 30 degrees in contrast to the Gart patent, which shows a top surface with a negative slope from center to right but a positive slope from left to center. See JA 117. The examiner subsequently issued an amendment which permitted certain of the plaintiff's claims. The examiner noted that although the Gart mouse had a
negative slope on the top surface, the slope "is not entirely negative as shown in the present invention." See JA 122 (addressing Figure 2 of the plaintiff's invention) (emphasis added). The examiner explained that "the negative slope claimed in the present invention is critical" to obtaining the positive results intended by the patent.

After considering the prosecution history, the Court confirms its earlier determination that the term "negative slope" requires an entirely negative slope. The plaintiff avoided the prior art before the examiner by claiming the slope was entirely negative from left to right and should not be permitted to change those representations now. If the plaintiff disagreed with the examiner's characterization of the invention as having an entirely negative slope, then the plaintiff had an obligation to correct it. See Elkay Mfg. Co., 192 F.3d at 979 (adopting the examiner's construction when the patentee failed to respond to the examiner's statement of allowance). The plaintiff will not be permitted to benefit from the examiner's characterization and then try to disclaim that characterization in the above-styled cause. The Court is unpersuaded by the plaintiff's argument that if the examiner intended the term "negative slope" to mean an entirely negative slope, the examiner would have required an amendment to the claim language. See id. (rejecting a patentee's argument that certain subject matter was not disclaimed because it did not result in a substantive amendment of the claim language).

--- Footnotes ---

2 The record reveals that the plaintiff did file a comment on the examiner's reasons for allowance, but failed to address the examiner's conclusion that the plaintiff's invention had an entirely negative slope. See JA 131-32.

--- End Footnotes ---

The issuance of the '553 patent does not alter the Court's conclusion. Contrary to the plaintiff's argument, the newly added element of "a longitudinal peak running substantially left of center along the length of the mouse" does not compel the Court to interpret the phrase "negative slope from left to right" to mean that the highest point on the top surface of the mouse is left of center. As the plaintiff has pointed out previously during this litigation, the subject of the '683 and the '553 is a computer mouse with a rounded construction. For this reason, although the claim recites a top surface, a front surface, a left side surface and a right side surface, the precise juncture of these surfaces is difficult pinpoint. The examiner might have permitted the addition of the longitudinal peak element in recognition of the mouse's somewhat amorphous boundaries, such that the placing of the longitudinal peak "substantially" left of center would still result in an entirely negative slope on the top surface of the mouse.

Nevertheless, the reason for the allowance of claim 43 of the '553 patent is not clear from the prosecution history. The examiner of the '553 did not expressly address the "negative slope" element or its relationship to the "longitudinal peak" element. Under these circumstances, the plaintiff remains bound by the Court's interpretation of the prosecution history of the '683 patent. During that prosecution, the plaintiff disclaimed an arched top surface. Although the plaintiff now argues it only disclaimed a symmetrical arched top surface, its written correspondence with the examiner and the PTO does not reflect this distinction. The Court finds the presumption of claim differentiation between claims 43 and 46 of the '553 patent is overcome by the prosecution history of the '683 patent. See Kraft Foods Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000) (finding the written description and prosecution history overcame any presumption arising from the doctrine of claim differentiation); Wang Labs, Inc. v. America Online, Inc., 197 F.3d 1377, 1384 (Fed. Cir. 1999) ("The doctrine of claim differentiation can not broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence."). Because the summary judgment evidence establishes the accused products do not contain an entirely negative top surface, either from left to right or front to back, the defendant is entitled to summary judgment of no literal infringement.

--- Footnotes ---

3 Alternatively, the defendant is entitled to summary judgment of no literal infringement on claims 18-21 of the '683 patent because the accused products do not contain a flattened surface adjacent to the buttons that provides support for the user's ring finger. The summary judgment evidence establishes that the buttons on the accused products extend across the entire width of the top surface. As a practical matter, this precludes a flattened surface adjacent to the buttons. Based on the Court's claim construction, the right side wall of the accused devices, which is substantially vertical, does not meet this element.

--- End Footnotes ---
3. Netting Arrangement

Plaintiffs proposed construction of the term "netting arrangement" is "lateral and longitudinal strands that intersect in locking engagement to form a grid-like pattern." Although quite similar, defendants seek construction of the term as "longitudinal and lateral strands that intersect in locking engagement with one another to form a grid-like pattern and having not as close a knit and larger opening than the stockinette member." Defendants' construction is the flip side of their construction for "stockinette member." In other words, if the construction of "stockinette member" includes "having a closer knit and smaller opening than the netting arrangement," the netting arrangement must have a less close knit and a larger opening that the stockinette. As discussed above, this is an impermissibly narrow construction.

The term "netting arrangement" has a discernable plain and ordinary meaning. Accordingly, the Court construes "netting arrangement" as "longitudinal and lateral strands that intersect in locking engagement to form a grid-like pattern with less stretch capacity than the threads of the stockinette member."

3. nib

This term appears numerous times in claim 1 and claim 12. Chip-Mender argues that "nib" means "nib"--that the term does not require independent construction because the common meaning will suffice. Sherwin-Williams argues for the common meaning of "nib"--a small projecting point--but asserts that the term should be construed as "the fibrous or solid structure of a fluid applicator that contacts and transfers fluid to a surface."

Chip-Mender asserts that nib is used throughout the patent to describe the structure that seals the applicator, regulates paint flow from the applicator, and applies automotive paint composition to the painted surface of the vehicle in need of repair. Chip-Mender contends that the language of the claims makes it clear that the "nib" cannot be porous, citing specifically to "the flow of said paint through said passageway, to said nib," which appears in both claim 1 and claim 12, see col. 5, ll. 37; col. 6, ll. 19-20; and to "applying a slight pressure to force said nib upward allowing it to open and permit said paint to flow by gravity from said reservoir through said passageway to said nib and transferring to the painted surface of the vehicle," which appears in claim 12, see col. 6, ll. 23-27.

In opposition, Sherwin-Williams asserts that Chip-Mender cannot point to any claim language in the '299 patent that excludes fibrous structures from the ordinary and customary meaning of "nib," which Sherwin-Williams notes is defined in the McGraw-Hill Dictionary of Scientific and Technical Terms as "a small projecting point." Sherwin-Williams argues that because "nib" is not defined by its structural composition, it should be construed broadly, without any structural limitation.

Sherwin-Williams submits that the '299 patent describes "nib" as both porous and solid because it references three prior art patents, each of which discloses a pen system or device using a porous nib. In the "Background" section, the '299 patent states that "pen nib systems" are shown in U.S. Patent Nos. 5,468,082 ("the '082 patent"--"Hori") and 4,838,723 ("the '723 patent"--"Suzuki"), and that "pen devices using nibs" are described in U.S. Patent No. 4,923,317 ("the '317 patent"--"Bishop"). Sherwin-Williams notes that the '082 patent discloses a paint maker "with a felt tip as a nib"--i.e., a fibrous nib--and also discloses a solid "nib or ball tip;" that the '723 patent discloses a nib that is both porous and fibrous; and that the '317 patent discloses a "porous plastic wear-resistant tip."

Sherwin-Williams contends that because Russo used the Hori, Suzuki, and Bishop references to describe "nib" in the '299 patent, those prior art references are intrinsic evidence. Relying on Kumar v. Ovonic Battery Co., Inc., 351 F.3d 1364 (Fed. Cir. 2003), Sherwin-Williams argues that such prior art references may be of "particular value" in construing a disputed claim term because it may indicate not only the meaning of the term to persons skilled in the art, but also that the patentee intended to adopt that meaning.
The court finds that "nib" means "nib" or "a small projecting point." The term "nib" is not explicitly defined in the claims, the specification, or the prosecution history. The nib is identified in claims 1 and 12 as an essential element of the applicator unit. '299 patent, col. 5, II. 27-31; col. 6, II. 8-12. The claims also describe the location of the nib--"slidably located in [the] passageway… [and] including a portion extending from said passageway." Id. col. 5, II. 27-30; col. 6, II. 8-11. In addition, the claims and specification state that the nib transfers the paint to the painted surface of the vehicle. Id., col. 5, II. 35-39; col. 6, II. 17-21; col. 2, II. 25-28. Thus, in the context of the '299 patent, the nib is the structure of the applicator that contacts and transfers the paint to the surface. There is no dispute regarding the size or shape of the nib, and no dispute that the purpose of the nib is to transfer or apply paint to the painted surface of the vehicle.

Chip-Mender argues that the common meaning of "nib" applies, and that the term requires no construction. The common meanings of "nib" are "the point of a pen" and "a sharp tip or point." Webster's II New Riverside University Dictionary (1988). Sherwin-Williams asserts that a "nib" is "a small projecting point." The dictionary definition-- "sharp tip or point"-- combined with the language in claims 1 and 12--"including a portion extending from said passageway"--equates with "a small projecting point." The court concludes that both parties agree that the commonly understood meaning applies.

The primary dispute between the parties is whether the nib must be solid or whether it can also be made of a material that is porous or fibrous. The patent does not specify whether the whether the nib is solid or fibrous, and, as noted above, the claims do not define "nib." Sherwin-Williams contends that the nib can be porous or fibrous, based solely on the fact that certain prior art uses the word "nib" to refer to structures that are porous/fibrous.

The court finds, however, that the nib in the '299 patent should not be construed as "porous" or "fibrous," because the specification states that the nib "serves as a regulator of the flow rate of paint composition." '299 patent, col. 2, II. 10-12. Absent a clear definition in the claims, the specification is "the single best guide to the meaning of a disputed term." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). A porous/fibrous nib would not be effective in regulating the flow of paint, because it would have to absorb paint before it could transfer paint to effectuate the repair to the painted surface. Further support for this construction is found below, in the discussion of disputed terms Nos. 7 and 8.

The court disagrees with Sherwin-Williams' argument that under Kumar, the Hori, Suzuki, and Bishop references that disclose "pen nib systems" or "fluid pen devices" with porous and/or fibrous nibs must be taken into account as evidence that Russo intended the '299 patent to include a nib made of a porous/fibrous material. In Kumar, the Federal Circuit found a prior art reference cited during the prosecution history of the patent at issue to be controlling, on the grounds that the applicant and the examiner considered the reference to be highly pertinent, and that the reference was discussed extensively and distinguished during the prosecution of the patent. See 351 F.3d at 1368. In the present case, however, Sherwin-Williams has not demonstrated that Russo discussed the Hori, Suzuki, or Bishop references extensively during the prosecution of the '299 patent or that Russo embraced those references as applying specifically to the claims at issue. The prosecution history reflects only a discussion regarding whether claims 1-4, 6-9, and 11 were obvious in light of Kremer in view of Saad, and whether claims 5 and 10 were obvious in light of Kramer in view of Saad, and further in view of Nakai.

2648

1. "Nipple Cover"

For the term "nipple cover," Plaintiff proposes "an article for covering the nipple on a human breast, that is not supported by attached straps around the body or by a brassiere, that is smaller than a brassiere, and that does not substantially enhance the apparent size of a woman's breast." 2 Defendants offers: "a small, thin, flexible, flesh-colored device that covers the nipple and extends a short distance beyond the nipple and areola and that is not intended to replace or enhance a woman's breast and is not intended to provide support to the breast." 3

Footnotes

2 In both the initial joint claim construction charts provided to the court and the parties' claim construction briefs, Plaintiff initially included "an article for concealing the nipple..." for her proposed construction of nipple cover. Though the parties briefed the issue as if it were a point of contention, the most recent joint construction chart provided to the Court included
for Plaintiff's proposal "an article for covering the nipple..." instead. By using "covering" in the most recent joint construction, Plaintiff and Defendant apparently no longer have a dispute on this issue.

3 Defendants later agreed to drop the "thin, flexible, flesh-colored" language from their proposed construction. See Transcript of Markman Hearing at 5.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

The parties' proposed constructions contain essentially three key disputed elements: (1) the size of the cover, (2) whether the nipple cover is supported by straps or provides support, and (3) the enhancement element. After comparing the parties' proposals and considering all relevant evidence, the Court adopts the following construction for the term "nipple cover": "an article for covering the nipple that extends beyond the nipple and areola; is unsupported by attached straps around the neck, back, shoulders, or arms; and does not replace or substantially enhance the apparent size of a woman's breast."

Turning first to the size aspect of the nipple cover, both parties agree the concept of size is part of the ordinary meaning of "nipple cover." Plaintiff argues that a nipple cover must only be "smaller than a brassiere." Defendants argue that the nipple cover must, at a minimum, "cover the nipple and extend a short distance beyond the nipple and areola." The specification provides useful guidance for defining the nipple cover's minimum size. While the specification states that the illustrations in the figures are not intended to provide a specific size limitation, it also states that "the nipple cover is of sufficient size such that it can cover a user's entire nipple and areola." Compare '606 patent col. 2 ll. 60-64, with '606 patent col. 2 ll. 50-51. Indeed, the patent's purpose centers around the nipple cover's ability to cover the entire nipple shape-any less coverage, and the purpose would be frustrated. See, e.g., '606 patent col. 1 ll. 42-44; '606 patent col. 2 ll. 27-30; '606 patent col. 2 ll. 50-51. Between the overt statement in the specification and the overall purpose of the patent, there is strong evidence that the nipple cover must cover, at a minimum, the user's entire nipple and areola. The parties' proposed constructions seek, however, to either go beyond this basic defining characteristic or take an entirely different approach to specifying the size aspect of the cover.

Instead of defining the coverage area, Plaintiff takes the different approach of defining the nipple cover's size through a maximum size concept by arguing that the cover must only be "smaller than a brassiere." Plaintiff's proposal finds support in the specification, as it specifically states that the nipple cover is smaller than a brassiere. See '606 patent col. 1 ll. 46-47 ("The nipple cover is also an improvement over the use of a brassiere because it is smaller in size and bulk..."). However, solely using the language "smaller than a brassiere" would be confusing since the patent provides no pertinent comparison to define the 'smaller' size. Does 'smaller' mean the nipple cover is smaller than a particular brassiere cup size, or does it mean smaller overall when brassieres straps and belts are also included in addition to the cup portion of the bra? Given these uncertainties, particularly when taken in conjunction with the varying sizes, styles, and structures of brassieres, the phrase "smaller than a brassiere" provides little helpful guidance in defining the term "nipple cover." 4

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Other parts of the Court's final construction incorporate the idea that the nipple cover is generally smaller in bulk and size than an average brassiere without having to specifically include that language in the construction. Both the sizes provided in the claims and the inclusion of language in the construction reflecting the lack of straps incorporate the idea that the nipple cover is conceptually lesser in bulk and size than a brassiere.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Defendants argue that not only does the specification disclose the nipple cover's size is sufficient to cover the entire nipple and areola, but that it should also extend a "short distance" beyond the nipple and areola. In support of their assertion, Defendants first point to the preferred embodiment in the specification. In the preferred embodiment, the specification outlines that "the nipple cover will extend approximately one-eighth to one-fourth of an inch beyond the areola." '606 patent col. 2 ll. 53-55. However, the specification on the whole qualifies the precise distances listed in the preferred embodiment by noting that "the exact size of the nipple cover... will vary." '606 patent col. 2 ll. 55-56. More importantly, the Federal Circuit has repeatedly cautioned against limiting the claims to the preferred embodiment. See Phillips v. AWC Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005) (en banc). Defining the term using the precise distances described in the preferred
embodiment would be importing limitations into the claim, as the claimed invention seemingly allows for nipple covers of greater or lesser coverage than those described in the preferred embodiment. Using the preferred embodiment as the sole guidepost to require that the nipple cover must extend a "short distance" beyond the nipple and areola is therefore inappropriate.

In addition to the preferred embodiment, Defendants also point to other areas of the specification which state the nipple cover should extend a "short distance" beyond the nipple and areola. See '606 patent col. 2 ll. 51-53 ("The cover will also extend a short distance beyond this area to ensure complete coverage"). Between the preferred embodiment and other portions of the specification, it is clear the specification discloses that the cover should extend some distance beyond the nipple and areola. However, using the phrase a "short distance" in the nipple cover's definition presents the same problems as using "smaller than a brassiere," and is ultimately problematic for other reasons as well. Similar to the problem with using "smaller than a brassiere" to define the nipple cover's size, interpreting what qualifies as a "short distance" is ambiguous and difficult to assess. Also, the claims do not limit the invention to extending only a "short distance" beyond the nipple and areola. What is clear from the specification is that the patent's method utilizes a nipple cover to ensure complete coverage of the nipple and areola, and also to blend smoothly with the surface of the breast for aesthetic purposes. By stating that the nipple cover "extends beyond" the nipple and areola, the Court's construction effectively conveys this central purpose, and is also consistent with the claim language without limiting the claims (which require coverage of roughly one half of the breast at a minimum). See '606 patent col. 4 ll. 16-18. For the size aspect, the Court therefore adopts the phrase "extends beyond the nipple and areola" as part of the Court's construction.

Turning next to the question of support, Plaintiff offers as part of her construction the language that the nipple cover "is not supported by attached straps around the body or by a brassiere," while Defendants' construction incorporates the language "is not intended to provide support to the breast." Each party takes a different approach to the support element of the nipple cover. Plaintiff's construction focuses on how the nipple cover itself is not supported, while Defendant's proposal instead focuses on how the nipple cover does not support the breast.

Other than reference to use of an adhesive to attach the nipple cover in dependent Claim 4, the claims do not directly discuss this question of support to the nipple cover and breasts. In the specification, however, it is clear that the inventor was trying to distinguish the nipple cover from a brassiere through a lack of supporting straps: "the nipple cover is also an improvement over the use of a brassiere because . . . it also lacks the use of straps and belts which can cause discomfort." '606 patent col. 1 ll. 46-49. Indeed, a large part of the purpose of the patent was to avoid the discomfort of belts and straps pressing against the body. See '606 patent col. 1 ll. 30-33. Using this intrinsic evidence as a guide, the portion of Plaintiff's proposed construction stating that the nipple cover is "unsupported by attached straps" appears correct. 5 The parties' chief disagreement centers on Plaintiff's inclusion of the "around the body" language, and the Court agrees with Defendant that the language in Plaintiff's proposal that it lacks straps "around the body" is over-inclusive and vague. The key concept is that the nipple cover lacks straps supporting the cover itself, and also lacks straps to avoid visibility or pressure against the body. Straps around the neck, back, shoulders or arms attached to the nipple cover would provide support to both the nipple cover and the breast, and would likely be visible under sheer clothing and press against the body. The Court therefore adopts the phrase that the nipple cover "is unsupported by attached straps around the neck, back, shoulders, or arms" as part of the Court's final construction. 6 There is little support for any construction more specific or inclusive than the Court's construction.

5 The parties' actually agree that the nipple cover lacks straps. See Transcript of Markman Hearing at 9-10. The President of Ce Soir Lingerie, one of the defendants, also noted in her deposition that a nipple cover does not have straps. See Pl.'s Claim Constr. Br. 6, Exh. 8, Ann Deal Deposition, 6/1/2007, 128:25-129:10.

6 At the Markman hearing, there was much discussion about whether two nipple covers could have a strap between them. See Transcript of Markman Hearing at 5-10. Whether or not the claimed invention would allow for a strap between two nipple covers is unclear, since it is questionable whether such a strap would support the cover, cause discomfort, or be visible. What is clear from the specification is that the device is unsupported by straps which would be visible or press against the body.
Instead of discussing straps and belts in their construction, Defendants' cite the specification to argue only that the nipple cover is "not intended to provide support to the breast." See '606 patent col. 2 ll. 29-30. By saying the nipple cover lacks straps around the neck, back, shoulder or arms, the Court's construction largely incorporates Defendants' proposal. 7 If the nipple cover has no straps around the arms, shoulder, or back to support the cover, any incidental supporting effect the nipple cover provides is merely an unintended side effect of the other functions of the cover. Further, inserting an intent element in the construction could result in unnecessary confusion. 8 Again, the key concept in the specification is that the nipple cover lacks visible straps or belts pressing against the body, and the Court's construction accounts for these considerations.

7 At the Markman hearing, Defendants agreed "that the patented device is not intended to include straps or belts." Transcript of Markman Hearing at 9-10.

8 Though the specification states that the cover is not intended to provide support, the nipple cover could arguably contain some minuscule supporting effect through the use of the adhesive to attach the cover. Determining whether the incidental support from the adhesive or other aspects of the cover were intended could result in unnecessary confusion over a relatively minor point.

The final element of the support limitation that bears analysis is Plaintiff's proposed language that the nipple cover is not supported by a brassiere. Starting with the claim language, the only discussion of the interplay between a nipple cover and brassiere comes in Claim 3, which states: "The method of Claim 2, further comprising a step of wearing clothing in contact with an outer surface of the nipple cover without a brassiere." '606 patent col. 4 ll. 33-35. There are a couple noteworthy considerations in Claim 3's language. First, Claim 3 is a dependent claim—it is dependent upon Claim 2, which is in turn dependent upon Claim 1. Claim 3 is ultimately adding a limitation to an independent claim (Claim 1, via Claim 2), the limitation being a step of wearing clothing in contact with the surface of the nipple cover without a brassiere. The Federal Circuit has stated that when a dependent claim adds a limitation to an independent claim, it is presumed that the independent claim does not include the limitation. Phillips, 415 F.3d at 1314-15. The term "nipple cover" appears in both claims. Therefore, independent Claim 1 presumably does not contain the "step of wearing clothing in contact with an outer surface of the nipple cover without a brassiere," or Claim 3 would be unnecessary. Taken independently, Claim 1 therefore would seem to allow for a method of wearing the nipple cover in contact with a brassiere instead of other clothing.

The specification also supports such an assertion. Indeed, the specification directly discusses situations where a nipple cover can be worn with a brassiere. See '606 patent col. 2 ll. 17-20 ("The present invention consists of a flexible, reusable and flesh-colored apparatus that covers the nipple so that a woman can go braless or wear a thin bra or lingerie") (emphasis added). Though neither the claims nor the specification call for a brassiere to support a nipple cover; it nonetheless appears to be within the scope of the invention.

In support of her argument that a nipple cover is not worn with a brassiere, Plaintiff turns to the prosecution history, other portions of the specification, and prior art patents. During prosecution, the patentee distinguished certain prior art by pointing out that the claimed invention "is not for putting underneath a bra." See Pl.'s Reply Br. Claim Constr. 2, Exh. 9, Remarks, P5080. Plaintiff also argues the specification "repeatedly contrasts the invention with devices held on by belts and straps around the body or a brassiere," with lines stating that "[t]he present invention can therefore be used in instances where the use of a brassiere is not practical," and "a woman can go braless." Pl.'s Claim Constr. Br. 5 n.1 (citing '606 patent col. 1 ll. 44-45; '606 patent col. 2 l. 19). Finally, Plaintiff also cites prior art patents discussing nipple covers to support her assertion. See Pl.'s Claim Constr. Br. 6 (citing U.S. Patent No. 4,333,471 col. 1 ll. 19-28). The Court agrees with Plaintiff that generally it appears a nipple cover is designed to allow the cover to be worn without a brassiere. However, the quotes Plaintiff chose from the specification which "repeatedly contrast the invention" with devices held in place by a brassiere both state only that a nipple cover can be used without a brassiere, not that it must be worn without one. The second half of one of the quotes Plaintiff provides (that a "woman can go braless") even specifically states that the nipple cover can be worn under a brassiere. See '606 patent col. 2 l. 19-20. The specification therefore undermines Plaintiff's arguments. Plaintiff's references to the prior art patent's discussion of the nipple cover eliminating the brassiere, when taken in proper

- 3159 -
context, also offer no support. 9 When the patent is thoroughly examined, the only support for Plaintiff's assertion is the
isolated quote during the prosecution history that the invention is not to be worn under a bra.

9 In her claim construction brief, Plaintiff points to prior art patents for interpreting the ordinary meaning of nipple cover,
and argues that U.S. Patent No. 4,333,471 (hereinafter "the '471 patent") states that the nipple cover is not held in place by a
brassiere: "it was 'developed with an aim of eliminating the... brassiere [which] presses upon the breast and body of the user
by its belts and straps with a resultant inherent discomfort and inconvenience.'" Pl.'s Claim Constr. Br. 6 (citing '606 patent
col. 1 ll. 19-28) (emphasis in original). However, Plaintiff's cropped quote takes the statement in the '471 patent out of its
proper context, giving this section of the patent a different meaning than originally stated. Plaintiff's use of the ellipsis in the
quote makes it imply that the '471 patent directly stated or implied that the intent of the nipple cover in the '471 patent was
specifically to eliminate the brassiere. However, rather than specifically stating the nipple cover was designed to eliminate a
brassiere, the '471 specification states the nipple cover was designed to eliminate the disadvantages of a brassiere. See '471
patent col. 1 ll 27-28 ("The present invention was developed with the aim of eliminating the above disadvantages"). Much
as the '606 patent does, the '471 patent discusses the disadvantages of a brassiere as being the visibility of the brassiere
through clothing, discomfort of straps and belts pressing upon the body, and excessive perspiration under a brassiere during
hot weather. See '471 patent col. 1 ll. 16-24. The '471 patent does not, however, specifically discuss eliminating the brassiere
itself--only eliminating the disadvantages. Plaintiff's cropped and out-of-context quote is therefore misleading. The Court
agrees that the nipple cover is an option to women who wish to wear something other than a brassiere to hide their nipples,
however neither the specification of the '471 patent nor the method described in the claims of the present invention
specifically disclaim the possibility of a nipple cover and a brassiere being worn together.

Ultimately, Plaintiff has not presented enough convincing evidence limiting the definition of "nipple cover" to being
unsupported by a brassiere. 10 The claimed invention does not preclude the nipple cover being worn under a brassiere; in
fact, the specification specifically teaches that a nipple cover be utilized under a brassiere, which would ultimately provide
support to the nipple cover. See '606 patent col.2 ll. 19-20. Though Plaintiff did state during prosecution history that the
nipple cover is not for wearing under a bra, the method she claimed suggests the opposite, and the claims govern the
boundaries of the invention.

10 Plaintiff also points out in her reply brief that Defendants do not dispute this aspect of her proposed construction in either
their claim construction brief or at the Markman hearing. While true, Defendants did not include the 'unsupported by a
brassiere' language in their proposal, and the Court has no evidence before it indicating Defendants wished to adopt this
portion of Plaintiff's proposal.

The final disputed aspect of the definition of "nipple cover" included in both parties' proposed construction is the
enhancement limitation. To reflect her view on the invention's relation to enhancement of the breast, Plaintiff proposes that
the nipple cover "does not substantially enhance the apparent size of a woman's breast." Defendants propose that the nipple
cover "is not intended to replace or enhance a woman's breast." Defendants' proposed language that the nipple cover is not
intended to enhance a woman's breast would be incorrect. "Enhance" means either "to make greater," or "to provide with
certain sense, a nipple cover does intend to enhance a woman's breast--it serves to cover erect nipples, thereby enhancing the
breasts' appearance.

The Court agrees with Defendants that the nipple cover is not designed to replace a breast. However, the Court also agrees
with Plaintiff that the cover is not designed to substantially enhance the apparent size of the breast. The inventor stated as
much during the prosecution history. Pl.'s Claim Constr. Br. 11; Exh. 9, Remarks, dated 5/24/06 at 11 (P5080). Since the
nipple cover does enhance the breast in a certain manner, and it will inevitably increase the size of the breast at least a small
amount, the Court finds that Plaintiff's construction largely incorporates these concerns. The Court therefore adopts
Plaintiff's proposal, with the inclusion of Defendants' language that the nipple cover is also not intended to replace the breast, for this portion of the Court's construction.

With all of the above analysis in mind, the Court's final construction of nipple cover reads: "an article for covering the nipple that extends beyond the nipple and areola: is unsupported by attached straps around the neck, back, shoulders, or arms; and does not replace or substantially enhance the apparent size of a woman's breast."

2649

E. "Nominal Radial Interference"

The parties seek construction of the phrase "a nominal radial interference between the first and second lips as the lid and main body are engaged" and offer the following constructions:

   . Plaintiff: The first lip protrudes sufficiently from the inner surface of the groove and the second lip protrudes sufficiently from the outer surface of the rim so that, as the lid and the main body are engaged, the lips contact each other and a portion of at least one of the lips deflects, where each point of contact between the lips occurs in a direction along a radius of the cup.

   . Defendant: The outward extension of the first lip in the radial direction and the inward extension of the second lip in the radial direction overlap each other to cause deflection of the first and second lips during the process of assembling the lid and the cup.

1. The parties' disputes

The parties' primary dispute is whether both lips must deflect as the lid and cup are engaged or whether it is sufficient that one of the lips deflect during the process. Unsurprisingly, defendant is seeking the narrower reading. However, the evidence does not support such a limitation. The one piece of intrinsic evidence that remotely supports requiring both lips to deflect is the fact that the preferred embodiment is "molded by a polypropylene." '784 pat., col. 3, ln. 4. As defendant points out, polypropylene is flexible, suggesting that the lips would bend. Defendant's argument fails for a number of reasons. First, a preferred embodiment is rarely grounds for importing a limitation into a claim; defendant has not explained why the preferred material, polypropylene, should be the required material. Moreover, even polypropylene lips do not necessarily deflect; a lip supported by a sturdier base may not deflect at all as it passes by a lip supported by a much flimsier base. Thus, even the preferred embodiment does not require that both lips deflect.

Defendant's other argument in support of requiring both lips to deflect comes from testimony plaintiff's expert provided at a deposition. In particular, he answered the following question:

   23 Q Okay. So the deflection is essentially, and I'm going 24 to talk very simply, when the lips are moving past 25 each other, they're each squished a little bit to get 1 past each other as they're being engaged?

   .

   4 A Correct.

Dkt. # 23, Exh. 10, at 61-62. This statement is a far cry from admitting that the claim requires both lips to deflect. In short, I am not persuaded that the intrinsic or extrinsic evidence supports requiring both lips to deflect to achieve "nominal radial interference."

The other dispute involves plaintiff's proposed requirement that "each point of contact between the lips occurs in a direction along a radius of the cup." As with plaintiff's proposed constructions for "projecting radially," the reference here to a point occurring "in a direction" along a radius does not make sense. Plaintiff has no response to this. As with the concerns related to the proposed constructions for "projecting radially," it is not clear whether clearing up this confusion is necessary to resolve the parties' disputes. Therefore, I will decline to include that phrase. If the parties continue to disagree about whether
such a limitation is required, they may address the matter at summary judgment.

2. The court's construction

Because I agree with the gist of plaintiff's proposed construction, I will adopt it, with modifications to eliminate the questionable phrase related to "each point of contact." The construction is as follows. "The first lip protrudes sufficiently from the inner surface of the groove and the second lip protrudes sufficiently from the outer surface of the rim so that, as the lid and the main body are engaged, the lips contact each other and a portion of at least one of the lips deflects."

For purposes of the current summary judgment motion, the parties contest the interpretation of several key elements of claims one and nine of the '036 patent.

**Claim One states:**

A grass edging device that is stored without external packaging and adapted for use adjacent borders of walks and plant beds comprising:

- a length of flexible plastic material having a longitudinally extending upper body portion and a vertical barrier of nominal thickness depending therefrom, said vertical barrier having a blade extending perpendicular to a side surface of said barrier along a bottom portion thereof and a receptacle means disposed on an opposite side surface of said barrier for use when said device is placed into a coiled position whereby said grass edging device is stored without external packaging by securing said blade to said receptacle means, said blade and receptacle means are available for anchoring said device to the earth in an uncoiled position.

Claim nine states:

A grass edging device that is stored without external packaging and adapted for use adjacent borders of walks and plant beds comprising:

- a length of flexible extruded thermoplastic having a longitudinally extending body portion defining a circular transverse cross section along an upper portion thereof and a vertical barrier depending therefrom with a first outwardly extending blade disposed on a first side of said barrier and a second and third spaced apart outwardly extending blade disposed on a second side of said barrier, whereby said device is stored in a coiled position by placement of said first outwardly extending blade in between said second and third blades on said second side for use in maintaining said barrier in a common plane while in a coiled position wherein said blades are available for anchoring said barrier to the earth when said device is uncoiled.

The court will address only the contested elements of these claims.

The claims are open-ended because of the term "comprising" in both preambles, which state: "A grass edging device that is stored without external packaging and adapted for use adjacent borders of walks and plant beds comprising . . . ." (emphasis added). The term "comprising" "is a term of art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim." Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997) (citations omitted). Avon, therefore, will not escape a finding of infringement merely by adding elements to the patented claims.

Avon first asserts that the "nominal thickness" of the vertical barrier should be read to mean "thin." Suncast did not dispute this language in its response. Avon's interpretation comports with ordinary usage, so the court will accept that interpretation.
Plaintiff urges the court to reconsider its construction of the claim term "non-conical and non-tapered distal end portion" in Claim 1 of the '155 patent. The court construed the term to mean that "the distal end [portion] of the catheter does not taper anywhere along its length." 2003 U.S. Dist. LEXIS 2329, 2003 WL 21078033, *5-6, and that "the distal end portion does not have a conical shape anywhere along its length." Id. 2003 U.S. Dist. LEXIS 2329, [WL] at *5, n.7. Plaintiff now contends that the court made an error of law by narrowly construing the term "non-tapered," thus limiting the term to what appears to be the preferred embodiment of the patent, contrary to the express statement in col. 3, lines 5-11 of the '155 patent that the invention is not limited to the preferred embodiment. (Plaintiff's Motion at 11.)

The court acknowledges that the patent is not limited to the preferred embodiment, but is not persuaded that its interpretation was in error. Plaintiff introduced the limitation "non-conical and non-tapered" during patent prosecution to distinguish his invention from a prior art catheter with a smooth tapered distal end. 2003 U.S. Dist. LEXIS 2329, 2003 WL 21078033, *6. Nothing in the claims, the specification, or the prosecution history of the '155 patent suggests that the distal end portion of the catheter may be non-conical and non-tapered at some points along its length and conical or tapered at other points. But even if one is to presume that the broad construction proposed by the Plaintiff is supported by the prosecution history (in particular, by presuming that the Plaintiff intended to surrender just enough scope to avoid the prior art but not more), the court's construction is correct under a controlling legal precedent. The Court of Appeals for the Federal Circuit has held in Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996) that when a claim is subject to two possible constructions, the narrower construction should be adopted. In Athletic Alternatives, the specification offered no guidance as to the scope of the term being construed, and the prosecution history supported both a broad and a narrow construction. Id. at 1580. The Athletic Alternatives court held that both proposed constructions were equally plausible and because under 35 U.S.C. § 112, P2 the patentee was required to "particularly point out" and "distinctly claim" the patented invention, the narrower construction should be adopted. Athletic Alternatives, 73 F.3d at 1581. Here, the court's construction is narrower and, hence, more appropriate.

Finally, Plaintiff contends that the court's construction of the term "non-conical and non-tapered distal end portion" is a manifest error of law because the court relied on a legally deficient construction of the term "distal end portion having a cross-sectional area." The court construed "having a cross-sectional area" to mean that the distal end portion has "only one cross-sectional area." 2003 U.S. Dist. LEXIS 2329, 2003 WL 21078033, *5. The Plaintiff relies on Crystal Semiconductor Corp. v. Tritech Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001) for the proposition that "a" or "an," when used in a patent claim, means "one or more" in claims with open-ended transitional phrases. Plaintiff thus argues that the distal end portion may have one or more different cross-sectional areas since the phrase "having" is an open-ended transitional phrase.

As Defendants point out, Plaintiff has omitted crucial language from the Crystal Semiconductor opinion. (Defendants' Response at 12.) The Crystal Semiconductor court held that while "having" can make a claim open, that word "does not create a presumption that the body of the claim is open." Id. at 1348. The court must examine the claim in its full context to determine whether the use of "having" limits the claim to its recited elements.Id. Here, the article "a" is consistently used as a singular modifier in Claims 1 and 7 when preceded by the "having" transitional phrase. (Defendants' Response at 13.) The court concludes that its construction of the terms "a cross-sectional area" and "non-conical and non-tapered distal end portion" do not reflect a manifest error of law.

2652

2. "Non-Electronic Carrier"

A "non-electronic carrier" means, "A device that holds an electronic element to protect it from physical damage during lamination, where the device is not part of a circuit that utilizes a semiconductor device."

Plaintiff states that the phrase "non-electronic carrier" generally appears in the claims at issue in the following context: "positioning said at least one electronic element in the absence of a non-electronic carrier directly between said first and second plastic core sheets." (Pl. Br. at 18, citing Cohen Decl. at Exh. L, p. 2.) Defendant refers to the same language in claim 1 of the '207 patent. Thus, as noted above, the essence of the Patents is the lack of any "non-electronic carrier."
According to Plaintiff, a "carrier" is defined as a "compartmentalized holder used for storing, transporting, hauling, and testing electronic devices to protect them from physical damage." (Pl. Br. at 18, quoting the Electronic Packaging, Microelectronics, and Interconnection Dictionary ("EPMI Dictionary"), p. 26.) Plaintiff refers to its prior definition of "electronic" as "pertaining to circuits utilizing semiconductor devices," and to Webster's Collegiate Dictionary (10th ed. 1999) ("Webster's"), p. 788, for the definition of "non-" as negating the "usual especially positive characteristics" of "electronic." (Pl. Br. at 18.)

Plaintiff also urges that these dictionary meanings should be modified to reflect the prosecution history of the '207 patent, discussed above, during which Leighton clarified that no buffer zone or protection was needed for the embedded electronic element during lamination in any of the Patents. (See discussion supra, p. 12.)

Based on the dictionary definitions and the prosecution history, therefore, Plaintiff argues that a "non-electronic carrier" should be construed to mean "a holder used for electronic devices to protect them from physical damage, which device is not part of a circuit that utilizes a semiconductor device." (Id. at 18-19). Plaintiff omits from the dictionary definitions cited above words that it claims would be inaccurate here (i.e., compartmentalized, storing, transporting, hauling, and testing).

Defendant's proposed definition is very similar, and reads, "A structure without any substantial electronic function, such as a recess, buffer or protective carrier, that at least partially protects during lamination the 'electronic element' from damage caused by lamination pressure." (Def. Br. at 22.) Defendant also relies on the prosecution history of the '207 patent to support the idea that the significant difference between the '207 patent and the '024 patent is the fact that the '207 patent does not require protection of the electronic element during the lamination process. (Id.) Defendant additionally concludes--and I agree--that Leighton relinquished any interpretation of "non-electronic carrier" that includes any protection for the electronic element. Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570 (Fed. Cir. 1995). (See Def. Br. at 22.) Defendant notes that Leighton made the same arguments about the absence of protection of the electronic element during prosecution of the '099 patent. (Def. Br. at 52.)

I agree with the parties that Leighton intended to distinguish the Patents at issue here from the '024 patent on the basis of, among other things, the fact that no protection is needed for the electronic element during lamination in the Patents at issue. Plaintiff's construction of the phrase "non-electronic carrier" addresses this issue without redundancy or ambiguity. I therefore adopt it in haec verba.

2653

D. "the polymeric material . . . is non-flowable and non-adherent at room temperature" ('753 patent) and "the heat bondable material is non-flowable and non-adherent at room temperature" ('290 patent)

34) The claim language "the polymeric material . . . is non-flowable and non-adherent at room temperature" is more than a description of the heat bondable material in its isolated state. It requires the heat bondable material to be bonded by the application of heat.

35) The specification teaches that for the polymeric material to bond, it must be heated so as to flow and become adherent. Without heat, the material does not flow and will not adhere. D.I. 70, Ex. A ('753 patent) at 3:52-57; see id. at 3:59-65; 2:20-23. As Dr. Bonutti explained to the Patent Office - and thus to the public - this is an important limitation that distinguishes his invention from Palmaz's drug-eluting stent, where the polymeric material adheres merely by being "placed upon" the stent. D.I. 70, Ex. M at 5-6.

36) Consistent with the claim language, the specification, and the prosecution history, the Court construes the language "the polymeric material . . . is non-flowable and non-adherent at room temperature" from claim 1 of the '753 patent as meaning "the polymeric material cannot flow at room temperature and cannot adhere to the implant if placed on the implant at room temperature."

37) Consistent with the claim language, the specification, and the prosecution history, the Court construes the phrase "the heat bondable material is non-flowable and non-adherent at room temperature" from claim 1 of the '290 patent as meaning "the heat bondable material cannot flow at room temperature and cannot adhere to the tubular member if placed on the
Identifying two claims for interpretation - Claims 14 and 33 of the '845 patent - Defendant Ion Beam argues Plaintiff adopted a restrictive definition of terms used in the those claims during the prosecution of the '845 patent. The controversy turns on the meaning of the words "intensify," "intensification" and "non-intensify." (Compare Optivus P.&A. at 34-35; and Ion Beam P.&A. at 37.) Plaintiff argues the controversy would be resolved if the court construed the term "non-intensified" in Claims 1 and 25 according to its alleged ordinary and customary meaning. (Optivus P.&A. at 34:24-27.)

Claim 14 of the '845 patent recites, in pertinent part:

An imaging system for a proton beam therapy system . . . comprising: an X-ray source . . .; an X-ray beam receiver . . .; an image capture device which receives said photon image directly from said X-ray beam receiver, and produces a patient orientation image of the region of the patient's body that is positioned in said beam path so that said patient orientation image is substantially undistorted by intensification; and a controller . . . .

(Rosenberg Decl. Ex. 5, the '845 Patent at 14:66-15:47, emphasis added.) Defendant argues the proper construction of the relevant portion of Claim 14 is "an image capture device which receives a non-intensified photon image directly from said X-ray beam receiver, and produces a patient orientation image of the region of the patient's body that is positioned in said beam path so that said patient orientation image is substantially undistorted by intensification." (Ion Beam P.&A. at 38, emphasis added.) In other words, Defendant argues that the term "said photon image" in Claim 14, should be modified to read "a non-intensified photon image." (Id.) Defendant does not produce any evidence to support this construction. (Id. at n. 227.) 32

32 In an attempt to add argument to a 40 page brief that addresses issues the parties were explicitly instructed to avoid, the Defendant directs the court's attention to an exhibit that simply extends the Points and Authorities with pages of extra argumentation. (Id.) If counsel wanted more space, it should have followed instructions and only addressed claim construction in the instant Motion. Instead, counsel ignored the court's order and addressed issues beyond the scope of the instant set of Motions.

The court reminds counsel that it is not the task of the court to scour the record in search of a triable issue of fact. Keenan, supra, 91 F.3d at 1279. The court relies on the parties to identify, with reasonable particularity, the evidence supporting the parties' positions. See id. Counsel for the defense complicated this task by adding Exhibit 29 to the Rosenberg Declaration. Exhibit 29 is not evidence. Exhibit 29 contains additional argument presented in impermissible format in violation of court order and the local rules.

That being said, the court has taken considerable time and effort to review the patent specification and prosecution history to determine whether the claim should be limited in the manner Defendant suggests.

However, that is not an invitation for counsel to employ similar tactics in the future. If counsel for either party attempts to circumvent page limits or any other rule or order of this court by such "creative" devices, the pleading will be stricken.

Claim 33 provides:

A therapeutic imaging system for a treatment beam therapy system . . . comprising: an X-ray beam source mounted on said beam delivery system. . .; a fluorescing screen . . . ;
a digital camera which receives said photon image directly from said fluorescing screen and produces a patient orientation image of the region of the patient's body that is positioned in said beam path so that said patient orientation image is substantially undistorted by intensification.

(Id. at 18:8-31, emphasis added.) As in its construction of Claim 14, Defendant adds the following limitation: where the claim states "receives photon image," Defendant argues the patent should read "receives a non-intensified photon image."

Plaintiff directs the court's attention to the language of Claims 1 and 25. Claim 1 of the '845 patent describes:

An imaging system for a proton beam therapy system . . . comprising:

an imaging beam source mounted on said beam delivery system wherein said imaging beam source is movable . . . ;

an imaging beam receiver attached to said gantry . . . ;

an image capture device proximate to said receiver, wherein said image capture device directly receives a non-intensified signal from said receiver and produces a patient orientation image of the region of the patient's body that is position in said beam path; and

a controller which receives said master prescription image and said patient orientation image . . . .

(Id. at 13:20-68, emphasis added.)

Claim 25 recites:

A method of aligning a patient in a proton beam therapy system so that the center of a beam line from a nozzle is centered at a target isocenter positioned within the body of the patient, said method comprising. . . :

obtaining a master prescription image of the patient . . . ;

positioning the patient on a treatment table so that . . . ;

transmitting an imaging beam along the treatment beam path so that the imaging beam is transmitted into the region of the patient's body positioned in front of the nozzle;

receiving the imaging beam after it has been transmitted into the region of the patient's body and directly capturing a non intensified patient orientation image of the region of the patient's body that is position in said beam path that is provided to said computer system;

designating said one or more monuments, using said computer system, on said master prescription image. . . ;

designating said one or more monuments . . . on said patient orientation image . . . ;

determining the relative position of the center of said treatment beam with respect to one or more monuments designated . . . [.]

(Id. at 16:38-16:67, emphasis added.)

Relying on definitions taken from common dictionaries, Plaintiff contends the proper construction of the term "non-intensified" means "without the use of an image intensifier." (Optivus P.&A. at 35:1-7.) Defendant, on the other hand, argues the relevant claim term is "non-intensified photon image" in Claims 15 and 33. (Ion Beam P.&A. at 38.)

The court begins with the plain meaning of the terms. The American Heritage Dictionary defines "intensification" as "to make more intense"; or "To increase the contrast of (a photographic image)." Similarly, the Oxford English Dictionary defines "intensification" as "[i]he action of intensifying"; or in the context of photography, "The thickening or increasing of
the opacity of the film of a Negative." OXFORD ENGLISH DICTIONARY (2d ed. 1989). The following passage from the Oxford English Dictionary seems particularly germane: "To become intense, to grow in intensity... intensifying ppl. a., esp. in intensifying screen, a fluorescent screen placed in contact with the film or plate when a radiograph is taken in order to increase the effect on it of the X-rays." Id.

Plaintiff draws the court's attention to the following definitions from technical treatises. The Chamber's Dictionary of Science and Technology defines "image intensifier" as "an electronic device screen for enhancing brightness of an image in fluoroscopy, at the same time reducing patient dose." (Airhart Decl. Ex. R at 290.) Similarly, the Principles of Radiographic Imaging states that "an image intensification tube is designed to electronically amplify the brightness of an image." (Id. at Ex. S at 294.) Accordingly, the ordinary meaning of the term "intensify" in the context of X-ray fluoroscopy is "to enhance the brightness of an X-ray image." (See, e.g., id.) An intensifier accomplishes that task. (Id.)

Turning to the specification, the patentees distinguish a prior art reference and explain:

the '867 Patent (prior art reference) is designed to be used in conjunction with ionized particle beams and heavy particle beams and also uses an image intensifier to intensify the television image of the X-ray. This type of system is not readily adaptable to proton therapy treatment as the use of an image intensifier would introduce image distortion and, therefore, errors into the calculation of patient position which would be unacceptable. Since the proton beams can have a significantly more harmful effect on tissue, it is important to very accurately locate the patient in front of the nozzle and, consequently, the errors introduced by an image intensifier would result in too many inaccuracies for use in a proton therapy system.

(Rosenberg Decl. Ex. 5, the '845 Patent at 2:55-68.) The court finds nothing in this patent specification, including the preferred embodiment, to alter the ordinary meaning of the words "intensify," "intensification," or "intensifier" as those terms are used in the context of X-ray fluoroscopy. (See id. at 2:44-13:19.) In addition, as the above quoted passage indicates, there is nothing in the prosecution history to suggest the ordinary meaning of the term was altered or limited by the patentees. (See id.; see also Rosenberg Decl. Ex. 12.) Accordingly, the term "intensify" means "to enhance the brightness of an X-ray image." It follows that "non-intensified" means "generated without the use of an image intensifier." However, it is equally clear from the face of the patent (Rosenberg Decl. Ex. 5, the '845 Patent at 2:55-68) and the prosecution history (Id. at Ex. 12 at 6-7) that the device described by the '845 patent does not use an image intensifier. As Defendant suggests Claim 14 and Claim 33 cannot be construed to include an intensifier. (See, e.g., id.)

1. "said second connecting edge being non-parallel to said first connecting edge"

The phrase "said second connecting edge being non-parallel to said first connecting edge" is used in claim 1 of the '298 Kuepper patent. KC contends that this language means "at least some portion of the second connecting edge being non-parallel to the first connecting edge." (doc. 150 at 41.) In support of its proposed construction, KC indicates that Figures 1 and 5 of the patent show that portions of the first (38) and second (40) connecting edges are parallel and also non-parallel. KC refers specifically to the generally horizontal lowermost portion of the second connecting edge nearest the body of the diaper. (doc. 150 at 42.) KC argues that it's construction clarifies the meaning of the non-parallel limitation by placing it in context with the specification and figures. In response, First Quality argues that the phrase should be given its ordinary and customary meaning, and thus no construction is necessary. (doc. 168 at 19.) Specifically, First Quality asserts that the additional phrase "at least some portion" improperly limits the claim to embodiments found in the specification. (doc. 168 at 20.) The evidence supports First Quality's position.

KC's proposed construction would expand the disputed claim term beyond what is specifically found in the claims and specification. As First Quality indicates, the language of both Claim 1 and 15 provide that "said second connecting edge being non-parallel to said first connecting edge." U.S. Patent No. 5,496,298, Claim 1 & 15 (emphasis added). This language is clear and unambiguous. If KC wanted to expand the scope of Claim 1, it could have done so by drafting the claim to require only a portion, and not the total of the second connecting edge to be non-parallel. In fact, KC demonstrated that is was capable of this by including expansive language in Claim 11 when it provided that "said distal edge is generally parallel to said proximal edge." U.S. Patent No. 5,496,298, Claim 11 (emphasis added). In addition, the specification further supports the contention that the claim language is unambiguous because in one other embodiment, depicted in Figure 2, it
provides that the "first connecting edge (38) and second connecting edge (40) are non-parallel." U.S. Patent No. 5,496,298, col. 3, ll 64-65. KC makes much of the patent drawings depicting, presumably, portions of the first and second connecting edges being parallel. However, patent drawings do not define the precise proportions of a patent element. See Hockerson-Halberstadt, Inc. v. Avia Grp. Int'l, Inc., 222 F.3d 951, 956 (Fed. Cir. 2000). While the drawings may indicate that portions of the first and second connecting edges are parallel, the claim and specification makes clear that these elements of the invention are to be non-parallel. 1 In contrast, First Quality proposes that the claim language essentially speaks for itself. We agree. Thus, we will construe "said second connecting edge being non-parallel to said first connecting edge" to mean that "the second connecting edge is non-parallel to the first connecting edge."

1 Neither party addressed the peculiar language of the specification that indicates the possibility of two "proximal" edges. The specification provides:

[w]e have included a proximal edge 34, an opposed distal edge 36, a first connecting edge 38, and a second connecting edge 40. As used herein, the proximal edge is that edge of the elastomeric ears 24 which is joined to lateral edges 42 of diaper body 44 defined by, in the illustrated embodiment [FIG. 1], outer cover 12 and bodyside liner 14. The distal edge 36 is that edge of elastomeric ear 24 which is opposite the proximal edge 34 moving in a direction outward from a central longitudinal axis of the diaper 10. The first and second connecting edges 38 and 40 connect the proximal edge 34 and the distal edge 36 thereby defining a body of elastomeric materials which at least partially define elastomeric ear 24.

U.S. Patent No. 5,496,298, col. 3, ll. 1-13 (emphasis added). This language indicates that, at least pertaining to Figure 1, that a different proximal edge is described. This embodiment does not show that portions of the first (38) and second (40) connecting edges are parallel and also non-parallel. Instead, it provides that the second connecting edge (40) connecting to a proximal edge (42) is non-parallel to the first connecting edge (38). Thus, it appears that KC's reliance on FIG. 1 is misplaced.

w. "Non-Resilient" (Claim 3)

133. This claim terminology is only used in Claim 3 to describe the lever moving element. During prosecution of the '656 patent, the Examiner rejected a number of the claims on the basis of prior art which showed a lever moving element operated by springs. PX 45, p. 60, 118. To distinguish over that prior art, the '656 patent applicants expressly limited the claim to exclude lever moving elements which were resiliently mounted by incorporating the modifying limitation "non-resilient". PX 45, p. 113, 130, 155, 173, 174, 198, 199. A patentee may not obtain, in an infringement suit, protection of subject matter that was relinquished in order to obtain allowance of other subject matter during prosecution. Modine Mfg. Co. v. U.S. International Trade Commission, 75 F.3d 1545, 1555 (Fed. Cir. 1996). Consequently, this term should be interpreted to exclude lever moving elements which are operated resiliently, i.e. by means of springs, since a spring is resilient as LaGard concedes. LaGard's Supplemental Reply to Mas-Hamilton's Opposition to LaGard's Summary Judgment Motion (DE # 142), p. 9.
the first reactant adsorbs on the semiconductor, and part of the non-semiconductor thin film to be formed.

Here, the dispute is whether the thin film to be formed can be a semi-conductor film. ASM argues that the word "non-semiconductor" should be interpreted as if it were repeated twice in the claim, so that the first reactant must contain a non-semiconductor element of the non-semiconductor thin film to be formed. Genus argues that the plain meaning of the claim language is that the first reactant must contain a non-semiconductor element, but that the thin film to be formed does not have to be a non-semiconductor.

Genus' construction follows the plain meaning of the claim language. ASM argues, however, that a review of the specification demonstrates that the invention was only directed to the creation of non-semiconductor films.

As ASM points out, the specification explains that "[a] continuing problem in the commercial manufacture of integrated circuits is the achievement of conformal deposition of dielectric (e.g., silicon dioxide, silicon nitride) or conducting (e.g., aluminium, titanium nitride) thin solid films over large area wafers[]." (‘365 patent 2:66-3:3.) The Oxford English Dictionary Online defines "dielectric" as "non-conducting." ASM thus contends that the invention is concerned only with conducting or non-conducting films, not semi-conducting films. The language quoted by ASM is not a description of the invention, however, but simply part of a discussion of then-current problems in the commercial manufacture of integrated circuits.

The specification also contains schematic drawings of three preferred embodiments of the invention, one of which is "suitable for the deposition of any film, conducting or non-conducting[]." (Id. 5:46-47.) ASM contends that this phrase, which does not mention semi-conductor films, also indicates that the invention is not directed towards the creation of semi-conductor films. Nothing in the surrounding text, however, indicates that ASM's reading of this phrase is the correct one. If one were attempting to exclude semi-conductor films, one would be more likely to use the phrase "any conducting or non-conducting film" or "any non-semiconductor film." The use of the phrase "any film" suggests that the drafter intended to include semiconductor films within the range of films from nonconducting to conducting. In other words, "any film" could easily mean "any film." It is a somewhat strained reading to interpret the phrase "any film, conducting or non-conducting" to mean "any non-semiconductor film."

ASM argues that because the specification contains a schematic drawing for a reactor "suitable for the deposition of films that are not electrically conducting" (id. 5:40-41) and another for a reactor "suitable for the deposition of any film, conducting or non-conducting," (id. 5:46-47) that the invention excludes the deposition of semi-conductor films. This argument fails for the same reason stated above.

A more reasonable reading is that one reactor is suitable only for deposition of non-conducting films, and that the other can be used for deposition of any film. There is no language in the specification that expressly excludes semi-conductor films from the scope of the invention, or that indicates that the preferred embodiments cannot be used for the deposition of semi-conductor films.

In fact, the specification begins by stating that "the present invention relates to methods and apparatuses suited to the low temperature deposition of solid thin films of one or more elements by the technique of sequentially exposing the object being coated with chemically reactive gaseous species." (Id. 1:5-9.) The specification also states later that "it is an object of the invention to facilitate the growth of thin films of any element by using a radical generator to make available highly reactive gases (radicals)." (Id. 5:34-36.) The specification also explains that "the process of this invention is unique in that it allows, for the first time, the deposition of perfectly conformal and very pure films of any composition at low temperatures." (Id. 9:34-37.) This repeated use of language that makes no attempt to describe or limit the conductivity or composition of the resulting thin film also suggests that when the specification uses the phrase "any film," it means "any film," not any non-semiconductor film.

ASM also argues that the examples listed at the end of the specification all describe non-conducting or conducting films. (Id. 7:29-9:50.) Again, however, nothing in the specification limits the types of films that the invention can create, or
indicates that the invention is not directed to the creation of semi-conductor films. As noted above, the specification specifically states that the invention facilitates the growth of thin films "of any element" (id. 5:34-36) or "of any composition" (id. 9:34-37). The Court rejects Genus' argument that the examples show the formation of semiconductor thin films, however. Examples 1 and 3 do discuss depositing a layer of elemental silicon, which is a semiconductor, but those layers are clearly stated to be only one layer in the formation of non-semiconductor thin films of materials such as silicon dioxide and tantalum/silicon/nitrogen. ( '365 patent 7:34-39; 8:18-27.) Claim 1 itself makes clear that the thin film to be formed is created only after the interaction of the second reactant. ( '365 patent 9:61-64.) Thus, examples 1 and 3 do not discuss the creation of semiconductor films, but only discuss the deposit of semiconductor layers which are used to create non-semiconductor films.

Moreover, the Court notes that "thin film" is used in two other places in claim 1, both times without any limitation on the type of thin film that is to be formed. The claim begins: "A process of growing a thin film ...." (Id. 9:52.) The claim also explains that after the second reactant gas is added to the chamber, the first reactant on the part is converted "to one or more elements, wherein a thin film is formed[.]" (Id. 9:63-64.) The repeated and conspicuous absence in the claim language of any limitation on the type of thin film that is to be formed demonstrates that no such limitation should be imported into the claim. There is nothing at all in the specification that demonstrates that the thin film to be formed must be a non-semiconductor film. In fact, the specification defines "thin film" by expressly noting that it can be "of any element" (id. 5:34-36) or "of any composition" (id. 9:34-37).

ASM argues that the Court should not interpret the claim language according to its plain meaning, and cites cases such as Cultor Corp. v. A.E. Staley Manufacturing Co., 224 F.3d 1328 (Fed. Cir. 2000) and SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337 (Fed. Cir. 2001). Those cases are distinguishable, however, because in both cases, the specification clearly showed that the claim language was being used more narrowly than its plain meaning would suggest. Here, however, nothing in the specification excludes semi-conductor films, and there is language in the specification that explicitly supports Genus' claim that the thin film to be formed can be any film.

The extrinsic evidence is unhelpful. Oldham states in his expert report that a person of ordinary skill in the art "would have understood that this claim language does not require that the thin film to be formed is 'a non-semiconductor.'" (Oldham '365 Expert Report at 8.) Glew states in his report that one of ordinary skill in the art would interpret this language to require that a non-semiconductor film be formed. (Glew Expert Report at 11.) The inventor testified that it was his intent to exclude all semiconductor films. (Gasner Decl., Ex. 14, Sherman Dep. 147:1-25.) The inventor's intent, however, does not control over the unambiguous language of the patent. The inventor cannot "by later testimony change the invention and the claims from their meaning at the time the patent was drafted and granted." Voice Technologies, 164 F.3d at 615.

Finally, ASM contends that the Court should construe the "thin film to be formed" to be a non-semiconductor film in order to preserve the validity of the claim. Although there has been no argument that claim 1 is invalid in light of prior art, ASM asserts that there is prior art that addresses the use of radicals to grow a gallium arsenide film, which is a semiconductor. Without having received any evidence or developed argument about these prior art references, the Court is no position to opine on their effect on the validity of the claims of the '365 patent.

It is true that, where possible, the Court should construe claims to preserve their validity, but "claims can only be construed to preserve their validity where the proposed claim construction is 'practicable,' is based on sound claim construction principles, and does not revise or ignore the explicit language of the claims." Generation II Orthotics Inc. v. Medical Technology Inc., 263 F.3d 1356, 1365 (Fed. Cir. 2001). The problem with ASM's argument here is that the plain language of the claim indicates that the "thin film to be formed" can be any film, and the specification explicitly states that "it is an object of the invention to facilitate the growth of thin films of any element" ( '365 patent 5:34-35 (emphasis added)), and "the process of this invention is unique in that it allows, for the first time, the deposition of perfectly conformal and very pure films of any composition at low temperatures." ( '365 patent 9:34-37 (emphasis added.).) The very first line of the specification after the abstract states that "the present invention relates to methods and apparatuses suited to the low temperature deposition of solid thin films of one or more elements," without limitation as to the type of thin film. There is nothing in the specification that limits the thin film to a non-semiconductor film. Thus, the only way for the Court to construe the claim language to exclude semiconductor films would be to rewrite the claim language, which it may not do.

Accordingly, the Court agrees with Genus that the phrase "including a non-semiconductor element of the thin film to be formed" should be construed according to its plain meaning: "including an element that is not a semiconductor and that will be contained in the thin film to be formed." The claim contains no limitation on the conductivity of the thin film that is to be formed, and thus does not exclude semiconductor thin films from the scope of the claim.

4. "non-sinusoidal"

This phrase is found in the '037 patent only, in claims 1, 8-9, 12-13, 16-17, 20, 22, 29-30, 33-34, 40-41, 43, 45-48, 52-53, and 55-75. See Joint Statement, '037 Patent. Plaintiffs contend that the proper construction to be given "non-sinusoidal" is "not S-shaped," while defendants and the intervenor all contend that the phrase should be construed to mean "not forming a continuously curved shape consisting of a pair of joined, opposed curved sections wherein each curved section has an arc of approximately 180 degrees or greater."

All parties agree that the term "sinusoidal" can be defined with reference to the '037 Patent specification, and that the term "non-sinusoidal" should therefore be construed with reference to the same. Turning, then, to the language of the specification, it is immediately apparent that it expressly and continuously refers to the term "sinusoidal" as "s-shaped." See, e.g., Joint Statement, '037 Patent at 4:17-18 ("A particularly preferred embodiment of the flexure means comprises a sinusoidal or S-shaped section"); id. at 4:20, 28 (repeatedly referring to the "sinusoidal or S-shaped" portions of the claimed design); id. at 10:48-50; 10:60-63 (describing illustrated depictions of "sinusoidal (or S-shaped)" portions of figures 9 and 10). This constant referral to "s-shaped" and to "sinusoidal" in the alternative, is a strong indication that "sinusoidal" is meant by the patent authors to be synonymous with "s-shape." By extension, therefore, plaintiffs' argument that "non-sinusoidal" should be construed as "not s-shaped" makes sense.

Defendants' and the intervenor's proposed construction, by contrast, is ultimately unpersuasive. They contend that, while the specification generally defines "sinusoidal" to mean "s-shape," it goes further than this, and specifically requires that the claimed "sinusoidal" elements be comprised of "joined [or adjoined] curved sections." See Joint Statement, '037 Patent at 4:39-41 ("the sinusoidal or S-shaped portion may be comprised of a pair of joined curved sections wherein each curved section has an arc of about 180 [degree]"); 4:45-47 ("Alternatively, the sinusoidal or S-shaped portion may be comprised of a pair of joined curved sections wherein each curved section has an arc of greater than 180 [degree]"); 4:48-51; 10:49-52; 10:66-11:1. This supports, in defendants' and the intervenor's view, the notion that the claimed "sinusoidal" elements must be comprised of a pair of joined curved sections, which must furthermore be continuously curved -- as supported by both the dictionary definition of the word "adjoined," and the rules of mathematics.

The language that defendants rely on for their argument, however, specifically refers to alternative possible embodiments of the "sinusoidal or S-shaped portions" that are claimed. See id. at 4:39-52 (noting that "the sinusoidal or S-shaped portion may be comprised of a pair of joined curved sections … [each with an arc of about 180 [degree]]" and "[a]lternatively… may be comprised of a pair of joined curved sections … [each with an arc of greater than 180 [degrees]]") (emphasis added).

These alternative embodiments are described in the specification subsequent to the specification's unequivocal statement that, while the sinusoidal or S-shaped portion is "not particularly restricted," it "generally takes the form of an 'S.'" Id. at 4:35-39. Thus, the only unequivocal statement to be gleaned from this language is that, while a "sinusoidal" portion of the claimed element may be comprised of pairs of joined curved sections consisting of arcs of about or greater than 180E, the sinusoidal portion will always generally take the form of an S.

Defendants and the intervenor respond to this by noting that the specification, properly read, actually limits all possible embodiments of the "sinusoidal or S-shaped portion" covered by the claims of the '037 Patent to the two alternative embodiments specifically described therein, see id. at 4:39-52. As such, all disclosed embodiments that contain "sinusoidal" elements must be comprised of joined curved sections -- a limitation that only defendants' and the intervenor's construction recognizes.

Even assuming this to be the case, however, defendants' and the intervenor's construction still includes a limitation for which the court can find no support in the specification -- i.e., the requirement that sinusoidal be construed as "continuously
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

curved," and that "non-sinusoidal" therefore be construed in part to mean "not forming a continuously curved shape."
Defendants and the intervenor claim that the "continuously curved" requirement follows naturally from applying the
dictionary definition to the specification's requirement that sinusoidal elements be comprised of "joined curved sections," or
"adjoined curved sections." See id. at 4:39-52; 10:48-50; 10:67. However, neither party points to anything in the
specification language itself that either supports this limitation, or in some other way suggests that the limitation should be
read into the meaning of "sinusoidal." Indeed, the court could find no mention of the phrase "continuously curved"
anywhere in the relevant specification language at all. Without any support for the claimed limitation, the court will not
voluntarily read it into the claim language itself. 4 See, e.g., Phillips, 415 F.3d at 1323.

4 Defendants' and the intervenor appear to have chosen the phrase "continuously curved" in order to clarify that the phrase
"sinusoidal" cannot include straight sections, a point with which plaintiffs take issue. This particular issue, however, need
not specifically be resolved by the court. Plaintiffs' proposed construction of "not S-shaped" contemplates only that
sinusoidal shall "generally take the form of an S." As such, regardless whether any portion of a design contains a straight
section or not, it will not qualify as sinusoidal if it does not generally take the form of an S.

In sum, therefore, and for the above reasons, the court finds plaintiff's proposed construction to be more consistent with the
intrinsic evidence of the '037 Patent. Accordingly, the court hereby adopts plaintiff's proposed construction, and construes
"non sinusoidal" to mean: "not S-shaped."

1. "Non-slip"

Microthin contends that "non-slip" means, "to reduce or prevent smooth sliding motion without being sticky to the touch."
SiliconeZone claims that "non-slip" requires no construction but should be construed according to the term's plain and
ordinary meaning in the context of the claim language.

Certainly, the plain and ordinary meaning of "non-slip" essentially includes something that reduces or prevents smooth
sliding motion. Therefore, the dispute in the meaning of "non-slip" stems from a disagreement regarding whether the
language of the patent requires a limitation of the term to surfaces that are not "sticky to the touch."

"[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in
question is not present in the independent claim." Phillips, 415 F.3d at 1314-15. In the '311 Patent, the only additional
limitation in claim 8 that depends from claim 1 is that "the non-slip surface is not sticky to the touch." Memorandum, Ex.
F(a), Patent No. 5,942,311, at 6:4-5. If claim 1 were to be construed to only cover surfaces "not sticky to the touch," claim 8
would be completely superfluous. Therefore, this Court notes the presumption that claim 1 does not contain the limitation
that the surface is non-slip without being sticky to the touch.

Based on the written specification, Microthin fails to overcome this presumption against the proposed limitation. Indeed,
from the very beginning, even in the abstract, the '311 Patent speaks of a surface with a "tacky" characteristic, which is a
term commonly understood to suggest something that is sticky to the touch. Memorandum, Ex. F(a), Patent No. 5,942,311,
at [57]; Merriam-Webster's Collegiate Dictionary 1199 (10th ed. 1996) (defining "tacky" as "somewhat sticky to the touch").
The Court recognizes that the specification does mention that the non-slip characteristic is accomplished without being
sticky to the touch in two separate places. Memorandum, Ex. F(a), Patent No. 5,942,311, at 1:6-10; 3:3-5. However, nothing
in the '311 Patent specifically requires that the surface be non-sticky. This Court reads those phrases as simply describing a
preferred embodiment of the patent rather than disclaiming surfaces that are sticky to the touch. Therefore, the presumption
that claim 1 is broader than claim 8, which specifically claims the limitation of a surface not sticky to the touch, has not
been rebutted. Therefore, "non-slip" means something that "reduces or prevents smooth sliding motion."

GO BACK
Claim 1 of the '311 patent states:

A non-slip mat or pad consisting of a transparent plastic sheet having an upper surface and a lower surface, a coating of one or more inks forming a design on the lower surface and adapted to show through the plastic sheet to be seen through the top surface, and a non-slip coating adhering to the lower surface and inked coatings to form a mat or pad having a thickness in the range of 1.0 to 30.0 mils.

'311 patent col.4 l.64-col.5 l.3 (emphasis added). Claim 1 of the '995 patent states:

A method for manufacturing a non-slip mat or pad, including the steps of providing a mat or pad formed of a plastic material, printing a design or logo to show on the upper surface of the mat, and applying a non-slip surface to the underside of the mat or pad with the total thickness of the mat or pad in the range of 1.0 to 30.0 mils.

'995 patent col.5 ll.4-9 (emphasis added).

The district court construed "non-slip" to mean "reduces or prevents smooth sliding motion." Opinion at 7, 12. Microthin challenges the district court's interpretation, arguing that "non-slip" means "to reduce or prevent smooth sliding motion without being sticky to the touch." To support its proposed construction, Microthin points to two places in the specifications where the patents discuss a non-slip surface that is not sticky to the touch. See '311 patent col.1 ll.6-10, col.3 ll.3-5; '995 patent col.1 ll.7-11, col.3 ll.7-11.

We agree with the district court that the plain and ordinary meaning of "non-slip" is "reduces or prevents smooth sliding motion" and does not distinguish between sticky and non-sticky characteristics. Claim 1 in each patent does not include any limitation suggesting that the non-slip surface must not be sticky to the touch. Moreover, dependent claim 8 of the '311 patent adds a single limitation to claim 1, "wherein the non-slip surface is not sticky to the touch." '311 patent col.6 ll.4-5 (emphasis added). "[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005) (en banc). In cases such as this, "where the limitation that is sought to be 'read into' an independent claim already appears in a dependent claim, the doctrine of claim differentiation is at its strongest." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). Hence, the claim language fully supports the district court's construction.

Microthin also cites the specification as indicating that the non-slip surface is not sticky. These statements do not, however, justify interpreting the term non-slip different from its plain and ordinary meaning. The patentee did not, in this case, act as his own lexicographer defining "non-slip" contrary to its plain and ordinary meaning. To be his own lexicographer, a patentee must use a "special definition of the term [that] is clearly stated in the patent specification or file history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1580 (Fed. Cir. 1996); see also CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 ("[T]he claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history."). Here, the specification contains no such clear definition of "non-slip." The preferred embodiment does indicate that the non-slip surface is not sticky to the touch. See '311 patent col.3 ll.1-5; '995 patent col.3 ll.7-11. Additionally, in the Technical Field of the patent there is also a mention of the non-slip surface not being sticky. See '311 patent col.1 ll.4-8 ("The invention disclosed . . . provides the required frictional characteristics to prevent slipping upon substantially any surface without being sticky to the touch."); '995 patent col.1 ll.7-11 (same). These references, however, do not amount to a clear definition of non-slip.

Likewise, the specification and prosecution history do not present a clear disclaimer such as the patents in SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, 242 F.3d 1337 (Fed. Cir. 2001). We have stated that "claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). In SciMed, the patents at issue related to balloon dilatation catheters containing passageways, or lumens. 242 F.3d at 1339. Only two types of lumen arrangements, dual (or adjacent)
and annular (or coaxial), were known and practiced in the prior art. Id. Although the asserted claims did not claim a particular lumen arrangement, see id. at 1340, we determined that the common specification of the patents "lead[s] to the inescapable conclusion that . . . the asserted claims read only on catheters having coaxial lumens." Id. at 1342. For example, the abstract identified the lumen as annular, the written description distinguished the prior art by discussing the disadvantages of dual lumen configurations, the "Summary of the Invention" described the invention numerous times as having an annular lumen, and a section describing preferred embodiments stated that "all embodiments of the present invention contemplated and disclosed herein" had an annular lumen arrangement. Id. at 1342-43. We stated that "[t]he words 'all embodiments of the present invention' are broad and unequivocal," and that they "cannot reasonably be interpreted as limited to the preferred invention." Id. at 1344.

In contrast, in Liebel-Flarsheim, we reversed the district court's construction of claims related to powered injectors used in medical applications. 358 F.3d at 900. Although none of the asserted claims expressly referred to a pressure jacket--a jacket that surrounds a syringe and prevents it from breaking under pressure from the injection fluid--the district court concluded that "the specification makes clear that the injector includes a pressure jacket." Id. at 901 (citation omitted). The Appellee made several arguments as to why the district court's construction was correct: (1) all the embodiments described in the specification featured pressure jackets, id. at 905; (2) the abstract described the invention as including a pressure jacket, id. at 908; (3) the Summary of the Invention described two objectives of the invention in terms of use with pressure jackets, id.; and (4) the Summary of the Invention also described a "principle[] of the present invention" in terms of use with pressure jackets, id. Although all the embodiments contained pressure jackets, we nonetheless determined that "the written description does not contain a clear disavowal of embodiments lacking a pressure jacket." Id. With respect to the language in the abstract, we stated that it "does not suggest that a pressure jacket is an essential component of the invention, nor is there any language in that passage, or elsewhere in the specification, that disclaims the use of the invention in absence of a pressure jacket." Id.

The language in the specifications of the '311 and '995 patents does not constitute a clear disclaimer of sticky non-slip surfaces. Here, two statements in the specification mention that the non-slip surface is not sticky to the touch--one in the Technical Field and one in the description of the preferred embodiment. The remainder of the disclosure describes the non-slip surface as "tacky." See, e.g., Abstract, col.2 ll.63-66, col.4 ll.54-60. The term "tacky" is commonly understood as "sticky to the touch." Opinion at 12 (citing Merriam- Webster's Collegiate Dictionary 1199 (10th ed. 1996)). Nowhere in the specification does it suggest that a non-sticky surface is "an essential component of the invention," nor does it clearly disclaim the use of a sticky surface. See Liebel-Flarsheim, 358 F.3d at 908. We conclude that the district court correctly construed the non-slip limitation by giving it the plain and ordinary meaning.

2. Construction of "bulb" and "socket" claim terms

Finally, defendants argue that the claim terms "standard bulb socket," "non-standard bulb socket," and "non-standard twinkle bulb" cannot be construed. Their only argument in this connection that merits any discussion is the argument that the '909 Patent encompasses an impermissible negative limitation. Relying on In re Schechter, 40 C.C.P.A. 1099, 205 F.2d 185, 188, 1953 Dec. Comm'r Pat. 323 (C.C.P.A. 1953), the defendants point to the fact that each of the bulb sockets and bulbs are defined as being of a type that receives or is received by one type of bulb or socket, while "not operatively receiv[ing]" or "not to be operatively received in" the other type.

In re Schechter has no relevance to the claims in the '909 Patent. In that case the claim attempted to cover all of a class of compounds except those shown in prior art. Id. There is no per se ban on the use of negative limitations, and In re Schechter does not suggest that one exists. See, e.g., In re Wakefield, 57 C.C.P.A. 959, 422 F.2d 897, 904 (C.C.P.A. 1970) (finding a claim still definite despite a negative limitation); see also SmithKline Beecham Corp. v. Apotex Corp., 403 F.3d 1331, 1363 (Fed. Cir. 2005) (suggesting patentees incorporate negative limitations such as "non-natural" or "non-human" into their claims); Animal Legal Defense Fund v. Quigg, 932 F.2d 920, 923 (Fed. Cir. 1991) ("The use of a negative limitation to define the metes and bounds of the claimed subject matter is a permissible form of expression."). The defendants have not shown that the use of negatives in the definitions in the '909 Patent's specifications creates any ambiguity or otherwise requires a finding of invalidity.

2. Language in dispute: "non-tapered distal end portion" 7

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

7 Defendants define the term "non-conical" as well as "non-tapered," however, Plaintiff does not address the meaning of "non-conical." The court therefore assumes that term is not disputed and adopts Defendants' proposed construction, interpreting "non-conical" to mean that the distal end portion does not have a conical shape anywhere along its length.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Does "non-tapered distal end portion" mean (1) a distal end portion that has a perimeter wall that does not become progressively smaller toward the distal end reducing the cross section area of the distal end portion, or does it more generally mean (2) a distal end portion that is not tapered anywhere along its length?

Answer: the court interprets the language to mean that the distal end of the catheter does not taper anywhere along its length.

The parties agree that the distal end portion of the catheter refers to the section of the first lumen (the return lumen) that extends from the second opening described in the claim language to the end of the catheter and is the end that is inserted into a patient. (Defs.' Brief at 25, Pl.'s Reply at 11.) The parties also agree that "tapering" refers to a shrinking of the cross section area of the distal end. Plaintiff disputes that the claim language requires that the distal end portion must remain uniform in cross section throughout its length, however, contending instead that the claim only dictates that the perimeter wall does not become progressively smaller as it nears the distal end. Defendants argue on the other hand that "non-tapered" means that the distal end portion is not tapered anywhere along its length.

On this issue, the court agrees with Defendants that the term "non-tapered" means that the distal end's cross section area does not change throughout its length. Claim 1 describes the distal end portion as "having a cross-sectional area smaller than the cross-sectional area of said proximal cylindrical portion." The use of the singular word "a" indicates only one cross-sectional area. The language from the specification indicating that "both lumens . . . are straight along their entire lengths" lends more support to the conclusion that the width of the distal end does not change anywhere along its length.

Plaintiff argues that the prosecution history supports his interpretation, and explains that "non-tapered" was added to distinguish his invention from that of a double lumen catheter designed by Dr. Geoffrey S. Martin, in which the cross section of the lumens "smoothly tapers to provide a circular cross-section at the tip." (Tr. 127, U.S. Patent No. 4,451,252, col. 4, lines 37-39, Ex. H to Pl.'s Brief.) Plaintiff contends that because he specifically represented to the Patent Office that he included the word "non-tapered" to distinguish his invention from Martin's, the court should only exclude Martin's description of a tapered end to the '155 patent. (Tr. 128.) The court, however, finds the Defendants' argument more convincing. As Defendants point out, there is nothing in the claim language that indicates Plaintiff was limiting his affirmative disclaimer to only the taper shown in Martin's patent, (Tr. 133), nor do the words chosen lend themselves to the very restrictive construction Plaintiff wants to give them. Plaintiff suggests that the patent language would have the meaning Defendant ascribes to it only if it stated that the distal end was to be "nonconical and nontapered anywhere along its length." (Tr. 143) (emphasis added.) The court believes the additional language Plaintiff urges as necessary would instead be superfluous. The logical conclusion one makes upon reading the negative claim language is that it means the distal end shall not be tapered anywhere along its length.

Plaintiff also argues that because the words "substantially uniform" are used in claim 7 to describe the cross section of the tube containing the distal end portion, then by implication "nontapered" must mean something different from "uniform." The court is not persuaded by this argument. As Defendants point out, the terms are used to describe two different things. "Substantially uniform" modifies the internal cross section of the tube. "Non-tapered," on the other hand, describes the outside appearance or shape of the distal end. If anything, the terms complement each other: if the distal end did taper, then the cross section of the tube would probably not be substantially uniform. For these reasons the court construes the term to mean that the distal end of the catheter does not taper anywhere along its length.

- 3175 -
B. "Non-textured"

Claim 1 of the '418 patent describes a sheet with two surfaces, "the first surface being non-textured, and the second surface being textured . . . ." Plaintiffs contend that "non-textured" means "smooth," while Gore contends that "non-textured" means "completely lacking macroscopic surface characteristics."

The '418 patent's specifications describe numerous individual villi and great irregularity of the surface of the material. See U.S. Patent No. 6,921,418 at 3:32-35. Such a description is consistent with the plain and ordinary use and understanding of the term "textured" because it considers the tactile characteristics of the surface. See Pl. Claim Constr. Mem., Ex. H, Random House Dictionary of the English Language Second Edition, at 1964 (defining "textured" as "the visual and especially tactile quality of a surface") (emphasis added). The phrase "great irregularity of the surface of the material" essentially states that one surface is not smooth, without regard to the visibility of the irregularity. Under Gore's proposed definition, a material would only be textured when it has visible characteristics on the surface. Therefore, Gore's definition would ignore the important tactile element included within the plain and ordinary understanding of the term "textured."

To support its position, Gore relies on the prosecution history of the '418 patent and the rejection of a dependent claim for a sheet that included holes. The Patent Office rejected claims covering a channeled sheet and holes for failure to comply with the written description requirement in 35 U.S.C. § 112. See Joint App., Ex. B at FH343. The Court recognizes it must interpret patents with reference to cancelled or rejected claims so that the claim construction process does not change the scope of a patent to cover claims previously eliminated from the patent. See Schriber-Schroth Co. v. Cleveland Trust Co., 311 U.S. 21, 220-21, 61 S. Ct. 235, 85 L. Ed. 132, 1941 Dec. Comm'r Pat. 802 (1940); On Demand Mach. Corp. v. Ingram Indus., Inc., 442 F.3d 1331, 1338 (Fed. Cir. 2006). However, the rejection of the design that included holes in the sheet did not alter or inform the meaning of the term "non-textured" in Claim 1. The rejection for failing to comply with the writing requirement does not mandate that the term "non-textured" can only describe the visible characteristics of the sheet without reference to the sheet's tactile qualities. Therefore, the Court finds that the term "non-textured" means "smooth."

3. "Non-thrombogenic material which provides long term non-thrombogenicity to the device portion during and after release of the biologically active material."

Consistent with the claim language and its ordinary meaning, 6 the specification 7 and the prosecution history, 8 the court construes this phrase as meaning "a material that does not promote thrombosis for a period of time that extends both during and after release of the biologically active material."

Footnotes

6 '536 patent, col. 13, 11. 23-24; Stedman's Medical Dictionary 1831 (27th ed. 2000) (defining "thrombogenic" as "causing thrombosis or coagulation of the blood"). In the background of the invention, the patentee refers to prior art with "thrombolytic agents." ('536 patent, col. 2, 1. 36) Something that is "thrombolytic" "break[s] up or dissolve[s] a thrombus." Stedman's Medical Dictionary 1831 (27th ed. 2000). Notably, the patentees used a more passive term to describe their invention and the court has construed it accordingly.

7 '536 patent, col. 2, 11. 30-46; col. 6, 11. 52-55. Defendants argue that construction of this limitation should include the instruction that there is a "significant reduction in thrombogenicity over that experienced with bare metal stents." (D.I. 307) There is nothing in the specification or prosecution history that the patentees intended the claim to be limited in this way.

8 D.I. 300, Ex. 9 at DFH 106.
Cordis asserts that the district court erred by declining to construe the "non-thrombogenic" limitation to require less thrombogenicity than an uncoated metal stent. Cordis argues that, according to the language of claim 8, the specification, and the prosecution history, the non-thrombogenic material must have an effect different from the stent's natural effect, and that the specification itself compares the invention to metal stents. Also, according to Cordis, Boston Scientific admits that "non-thrombogenic" is a relative term requiring a comparison, and it waived any argument that the comparison should be to rough, porous coatings as opposed to bare metal stents. Cordis also argues that the court should not have relied on dictionary definitions, especially of unclaimed terms. Cordis asserts that undisputed evidence showed that Cypher stents and bare-metal stents were equally thrombogenic, such that Cypher stents would not infringe under the correct claim construction. Although Cordis publicly declared that its stents were non-thrombogenic, seemingly meeting the claim language and thus infringing, Cordis argues that its public statements used the term in a different sense from the patent and that its stents do not infringe.

Boston Scientific responds that nothing in the specification or prosecution history requires a comparison with bare metal stents; any comparison is to other coatings that promote thrombosis, so even if the Cypher stent were more thrombogenic than a bare metal stent, it would still infringe. Indeed, Boston Scientific points out that the claim language allows some metal to be left uncoated, so that a comparison to bare metal stents would not make sense. According to Boston Scientific, the court's definition conforms with both the ordinary meaning and experts' definitions of "non-thrombogenic." Boston Scientific adds that the Cypher stent infringes claim 8 of the '536 patent under either the district court's claim construction or Cordis's proposed claim construction. Boston Scientific notes that Cordis admitted in FDA submissions and promotional literature that the Cypher coating is "non-thrombogenic." Boston Scientific also points out that Cordis uses toluene to smooth the surface and remove pores, preventing thrombosis, indicating that its stents are non-thrombogenic. Finally, according to Boston Scientific, a new claim construction would require a remand to allow Boston Scientific to present a new infringement case.

We review claim construction de novo on appeal. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). We agree with Boston Scientific that the district court reasonably construed the "non-thrombogenic" limitation to mean "a material that does not promote thrombosis for a period of time that extends both during and after release of the biologically active material." To determine the meaning of "non-thrombogenic," we begin by considering the language of the claims. See Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) (en banc). The language of claim 1 requires that the non-thrombogenic topcoat material "provide[] . . . non-thrombogenicity" to the stent, but it does not require a comparison to any other stent, either bare metal or coated. '536 patent col.13 ll.22-26. As the claims themselves provide no other insight into the meaning of "non-thrombogenic," we turn to the specification in order to determine if it provides a clearer indication of the scope of "non-thrombogenic."

"[C]laims must be read in view of the specification, of which they are a part." Phillips, 415 F.3d at 1315 (quotation marks omitted). The abstract of the invention states that the "non-thrombogenic surface . . . is provided with sites . . . which aid in . . . reduc[ing] thrombogenic activity." '536 patent abstract; see also id. at col.2 ll.36-46 (using heparin "to impart a non-thrombogenic surface to the material"). Thus, we can discern that the non-thrombogenic material must reduce thrombogenic activity because of its particular properties. This conclusion accords with the fact that stents are known to promote thrombosis, and the goal of the patent is to have the claimed stent promote thrombosis as little as possible, or not promote thrombosis at all. However, it is clear from the specification that the reduced thrombogenic activity is not necessarily reduced from that of bare metal stents. Indeed, the specification discusses various ways of formulating a topcoat and then states that "a top coat or surface coating modified . . . to make the surface more non-thrombogenic presents a distinct advantage." Id. at col.6 ll.49-55. Thus, the reduced thrombogenic activity is clearly reduced from that of other coated stents whose topcoats have not been so modified.

Cordis argues that the prosecution history precludes the district court's construction of "non-thrombogenic" and that the claimed device must have had a reduced risk of thrombosis over that of a bare metal stent. "[A] court should also consider
the patent's prosecution history, if it is in evidence. . . . Like the specification, the prosecution history provides evidence of how the [Patent Office] and the inventor understood the patent." Phillips, 415 F.3d at 1317 (citations and quotation marks omitted). During prosecution, the applicant added the "non-thrombogenic" limitation to overcome an anticipation rejection, explaining that the topcoat "renders the coated device non-thrombogenic" and arguing that the prior art did not provide the same benefit. However, the prior art device, according to the applicant, was directed to "drug containing coatings . . . for metal stents." Parties' Joint App. at A482 (prosecution history of '536 patent, amendment dated July 30, 1997). Thus, if the amendment required reduced thrombogenicity over anything, it would be reduced over the prior art stent that is coated, not the bare metal prior art stent. The applicant therefore could not have considered "non-thrombogenic" to require reduced thrombogenicity over a bare metal stent.

Cordis also argues that the district court should not have compared dictionary definitions of "thrombogenic" and "thrombolytic" because "thrombolytic" does not appear in the claim, and because it is treated synonymously with "non-thrombogenic" in the specification. We disagree. Courts may of course "rely on dictionary definitions when construing claim terms, so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents," Phillips, 415 F.3d at 1322-23, and the court here did not err in relying on dictionary definitions to inform the meaning of the claim terms. The district court here permissibly looked to the definitions of "thrombogenic" and "thrombolytic" to inform the meaning of "non-thrombogenic." Because the court's definition accords with the specification, prosecution history, and the dictionary definition of a related term, we affirm the district court's definition of the term "non-thrombogenic." We therefore need not address Cordis's arguments that, under a different claim construction, the Cypher stent does not infringe claim 8 of the '536 patent.

2. Construction of "Long Term"

Cordis also argues that the district court erred by construing "long term" to mean a "period of time" and abused its discretion in denying Cordis's motion for a new trial based on newly discovered data. According to Cordis, the district court's construction improperly erases the claim requirement of "long term" because the claim requires both "long term non-thrombogenicity" and that the non-thrombogenicity be provided "during and after release of the biologically active material," whereas the court's definition only required "a period of time that extends both during and after release of the biologically active material." Cordis argues that the court's claim construction lessened the significance of what the specification describes as an important objective of the invention. Moreover, according to Cordis, data that became available after the trial but before entry of judgment showed that its Cypher stent had long-term thrombosis risks, and Boston Scientific itself publicly stated that the Cypher stent had a higher incidence of late thrombosis than bare metal stents.

Boston Scientific responds that the "long term" requirement has not been read out of the claim because the district court's construction includes a time limitation. Neither the specification nor the prosecution history limits "long term" to the phenomenon of late stent thrombosis, which occurs more than one year after implantation. Moreover, according to Boston Scientific, Cordis has publicly stated that the same data it now relies on is flawed. Boston Scientific also argues that the data Cordis seeks to include is cumulative and existed before trial, so it is not new evidence.

We agree with Boston Scientific that the district court correctly construed the "long term" aspect of the "non-thrombogenic" limitation. Neither the specification nor the prosecution history defines the period of time that is "long term," other than to require that it be longer than two weeks, '536 patent col.7 ll.1-5, and the claim construction includes two time limitations, like the claim itself. The claim construction requires both "a period of time" and that the period "extends both during and after release of the biologically active material." Even assuming, as Cordis argues, that the specification describes long-term non-thrombogenicity as an important objective of the invention, it does not further elucidate the meaning of "long term" or require that those specific words be used in the claim construction. We thus affirm the district court's construction of the "non-thrombogenic" limitation, including the "long term" aspect.

2666

E. Non-uniform

1. Plaintiff's Interpretation
Plaintiff PMT asserts that "non-uniform" should be defined simply as it is stated in the claims: "the dopant concentration in the first semiconductor regions is greater near the first contact layer than near the second contact layer and the dopant concentration in the second semiconductor regions is greater near the second contact layer than near the first contact layer." (R.49 at 11-17) (referencing Chen Patent, col.8, In.8-14). PMT argues that basic English grammar rules tell us that the language following the comma after "non-uniform" is an explanation of that term. (R. 247 at 18-22). PMT denies that a specific dopant gradient is required, arguing that the specification explains that all that is needed is a sort of inverse doping so that dopant is more diffuse at the bottom of p columns than at the top, and more diffuse at the top of n columns than at the bottom, or vice versa (R. 50 at 17-22 (referencing Chen Patent, col. 3, In. 41-47); R. 51 at 7-13). Further, PMT asserts that claim 11 covers any varying dopant concentration, no matter the method that produces it, including conventional manufacturing techniques. (R. 54 at 9-14, R. 255 at 5-12). Finally, PMT argues that defendants' proposed definition requires the impermissible reading of limitations from a preferred embodiment into claim 11. (R. 50 at 23 to 51 at 3; R. 218 at 15-24) (referencing Chen Patent, col. 3, In 37-47).

2. Defendants' Interpretation

Defendants assert that "non-uniform" should be defined as "doped to add an additional impurity gradient to the original 'uniform' impurity concentration." 24 (Infineon Br. at 40). Defendants argue that there are two components to this limitation: (1) additional dopant must be added to the normal dopant distribution that results from a conventional manufacturing process, and (2) the resulting distribution must be graded in some direction. (R. 126 at 12-16; R. 135 at 17 to 136 at 10). In support of the first component, defendants remind the Court that the parties had previously agreed that "uniform" meant those "items whose measure is within normal manufacturing variations." 25(R. 124 at 21-23; R. 160 at 7-9 and ST slide # 18 (paraphrasing)). Defendants argue that, since "non-uniform" is understood in terms of something not "uniform," by definition it must mean "variations beyond those that would result from a conventional manufacturing process." (R. 124 at 24 to 125 at 13; R. 139 at 22-23). Defendants also contend that, since these variations occur during normal manufacturing, they would necessarily be present throughout the prior art of semiconductor devices; thus, this first component of the limitation is necessary to distinguish over such prior art, including the Coe Patent cited during prosecution. (R. 126 at 16-19; R.143 at 4 to 146 at 7; R. 147 at 1-21) (referencing Coe Patent, U.S. Patent No. 4,754,310).

24 Defendant ST's proposed definition varies only slightly: "doping apart from any normal manufacturing variations (such as random changes in doping concentration and cross-boundary diffusion), as well as an additional impurity gradient added to the original uniform impurity concentration." (R. 162 at 4-6 and ST slide # 21).

25 However, during its rebuttal at the Markman hearing, PMT retracted its agreement to the meaning of "uniform" because it contends that manufacturing techniques change over time, so the definition provides no certainty. (R. 218 at 2-8; R. 253 at 20-25). PMT proposes instead a definition from the AMERICAN HERITAGE DICTIONARY, "always the same, unchanging, unvarying, without fluctuation." (R. 258 at 21-22).

In support of the second component of their proposed definition, defendants argue that the specification implicitly describes "non-uniform" as a graded doping condition, that claim 11 incorporates the grading limitation by reference to "non-uniform", and that Chen included such condition specifically to distinguish over the Coe Patent. (R. 126 at 12-19; R. 139 at 7-19 and ST slides # 6-10) (referencing Chen Patent, col. 3, In. 38-47, col. 8 In. 6-14 and Amendment at 12, In. 27 to 13, In. 23). Specifically, defendant ST explains that, in claim 11, "non-uniform" is a separate limitation from the clause immediately following and that PMT's proposed definition ignores the prosecution history and the definition provided in the specification and would effectively read the "non-uniform" limitation out of the claims. (R. 152 at 15 to 154 at 18 and ST slides # 18-19). Both defendants point out that the specification describes only two doping conditions, the uniform one that results from normal manufacturing processes and a graded doping condition. (R. 125 at 2-18; R. 158 at 17-18) (referencing Chen Patent, In. 37-47). ST further argues that claim 11 would fail for indefiniteness if the limitation of a gradient were not included. (R. 158 at 19-25). ST continues that, since it is a law of claim construction that patent claims should be construed to uphold validity, this Court should adopt its narrower construction that would render the claim definite. (R. 159 at 1-13 and ST slide # 20) (citing Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir 1996)).
3. Recommended Interpretation

The Special Master recommends that "non-uniform" be given its plain meaning of "not uniform." Out of the multitude of different doping possibilities in the voltage sustaining layer, the particular type of non-uniform doping that is chosen, is recited by the clause immediately following the use of "non-uniform" in claim 11. (Chen Patent, col. 8, In. 8-14). That language explains that the non-uniformity indicated is a condition wherein the p and n regions in the voltage sustaining layer are inversely doped such that the dopant concentration in each region increases as it approaches the contact layer of the corresponding conductivity type. (Chen Patent, col. 8, In. 8-14). The benefit to be achieved from such a doping condition, as explained in the disclosure, Chen Patent, col. 3, In. 37-47, is that the on-resistance of the device is lowered using this specific non-uniform doping profile. (Chen Patent, col. 8, In. 40-41).

How the non-uniformity is achieved is not relevant to the interpretation of this term. The claims at issue in the patent are structural claims, and the specific steps or methods used to achieve that structure is not part of a structural claim. Nor does the specification in any way limit the range of possible methods that could be used to achieve the non-uniformity. Specifically, nothing in the patent precludes a non-uniformity of the specific type described that is realized through conventional semiconductor processing techniques. Therefore, it is simply left to one of ordinary skill in the art to determine how best to achieve the specific non-uniform doping profile in the voltage sustaining layer.

2667

Claim Construction

The district court construed the claims, and instructed the jury accordingly. We review the claim construction as a matter of law, including any fact-based questions relating to claim construction. Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 1456, 46 USPQ2d 1169, 1174 (Fed. Cir. 1998). See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 38 USPQ2d 1461, 134 L. Ed. 2d 577 (1996). Jury instructions are reviewed for correctness in their statement of the law, with due attention to their clarity, objectivity, and adequacy. United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1564, 41 USPQ2d 1225, 1232 (Fed. Cir. 1997).

Claim 1 of the Cooper patent is representative:

1. A submersible molten metal pump comprising:
   a pump casing having a cylindrical non-volute pump chamber defined therein, at least one inlet opening, and a tangential discharge opening;
   a rotor in said chamber sized to fit through said at least one inlet opening;
   a rotor shaft attached to said rotor and extending upwardly therefrom;
   at least one support post attached to said casing and extending upwardly therefrom in parallel with said rotor shaft; and
   superstructure positioned above said casing and including a mounting plate, means on said plate engaging said at least one support post, a motor mount attached to said plate,
   a motor on said motor mount, and coupling means for operatively connecting said motor to said rotor shaft.

The issues of infringement turned on the meaning and application of the claim element "cylindrical non-volute pump chamber." This element is defined in the Cooper patent in terms of the known spiral pump with increasing cross-section:

The pump chamber in the [prior art] casing generally defines a volute which is defined for the purpose of this application and as known in the art as a spiral casing for a centrifugal pump with an increasing cross sectional area viewed circumferentially as the outlet of the pump is approached.
Col. 2, lines 21-26. The district court instructed the jury, with respect to the definition of non-volute, as follows:

[A] non-volute pump chamber is a pump chamber that is not a volute pump chamber.

A volute pump chamber is . . . [a] three dimensional region wherein fluid is subjected to the force of an impeller, with a spiral casing, such that, when viewed circumferentially, the cross-sectional area of the chamber generally increases as the outlet of the pump chamber is approached.

"Viewed circumferentially," means viewed along the path that the liquid in the chamber follows; i.e., rotating around the chamber, in the direction of the outlet.

The "cross-sectional area," refers to the area defined that is between the pump chamber wall and the outer edge of the impeller.

"Generally increases," does not mean that the increase must be constant; however, the "widest" point must occur at the outlet of the pump, or as the outlet of the pump is approached, and the narrowest point occurs at the cutwater (or the other edge of the outlet).

Jury Instructions 28.

The definition of "volute" in the jury instruction is in accordance with the specification, which described its "non-volute" pump in comparison with the volute pumps of the prior art. The instruction has not been shown to be in error, and is confirmed.

D. "A Non-Woven Top Sheet"

There appears to be no dispute between the parties as to this definition. The '810 patent does not define "non-woven top sheet," although it names "wood pulp, rayon, cotton, polypropylene, polyester, lycra, or a combination thereof" as the elements of the non-woven material. In the absence of further clarification in the specification, the parties agree that various definitions of "non-woven" submitted as extrinsic evidence by Defendants are informative. The Court, borrowing from these definitions, construes "a non-woven top sheet" as a sheet, web or batt of fibers or filaments of wood pulp, rayon, cotton, polypropylene, polyester, lycra or a combination thereof that are bonded to each other by any of several means. Papers, wovens, knits and felts are specifically excluded. The parties each stressed qualifications to this generic definition, none of which was objected to by the other. The Court adopts these qualifications as incorporated into its construction: (1) there is no minimum thickness for the non-woven top sheet; (2) certain materials loosely defined as "felts," but not made of animal hair or paper, are not excluded from the definition of "non-woven" top sheet; and (3) a scrim, gauze, netting, yarn or other conventional sheet material may be added to one or both faces of the top sheet, or embedded within as reinforcement.

E. "the lower surface having no projections for connection to the seating surface;"

Plaintiff contends that this phrase must be construed in light of the prosecution history to mean "having no arms extend[ing] downwardly into the seating surface." (Claims Chart, p. 2, section 1.4.) In support of this construction, Plaintiff cites to the November 20, 1989 amendment in response to the examiner's prior art rejections. In this response, Plaintiff was forced to argue around the prior art disclosure of Postings and McMurry (U.S. Pat. # 2,831,457) when he stated: "[I]n both Postings and McMurry, the base member is physically secured to the ground surface via projections from its lower surface . . . . It therefore is not freely seated on the ground in either case. . . ." (Def's Exh. B at 37.) In conjunction with this argument, it appears that Plaintiff amended Claim 1 to include the above language, claiming a negative element of "no projections."
The Court does not agree with Plaintiff's contention that the prosecution history should be interpreted as limiting "no projections for connection to the seating surface" to "no arms extend[ing] downwardly into the seating surface." While Plaintiff's intention when drafting the amended claim may have been to only disclaim those projections which extended downwardly, he did not do so. It is a fundamental axiom in patent law that a Court may not redraft a claim, via construction, to encompass what the patentee intended to claim, or could have claimed. In a situation very similar to this one, where the patentee was relying on prosecution history to support construction of the term "permanently affixed" as meaning "affixed to prevent movement in at least a horizontal plane," the Federal Circuit stated:

To be sure, the prosecution history indicates that the applicant intended to amend the claims to avoid the "detachable" connection of the Johnson skate. The same history, however, indicates that the applicant chose to add the term "permanently" to the claims in order to achieve this result. That the applicant could possibly have added terms other than "permanently" to create a patentable distinction with the asserted prior art is simply irrelevant to our claim construction task. Courts do not rewrite claims; instead, we give effect to the terms chosen by the patentee. See, e.g., Texas Instruments v. United States ITC, 988 F.2d 1165, 1171, 26 U.S.P.Q.2d (BNA) 1018, 1023 (Fed. Cir. 1993) ("[T]o construe the claims in the manner suggested by TI would read an express limitation out of the claims. This, we will not do because courts can neither broaden nor narrow claims to give the patentee something different than what he has set forth" (quoting Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 396, 155 U.S.P.Q. (BNA) 697, 701 (Ct. Cl. 1967)).

Just as the court in K-2 refused to expand the scope of the phrase beyond that which was claimed, so must this Court. The distinction that the claim amendment here was a negative one, or specifically negating an element of the claim, does not distinguish K-2 from the present case. In this instance, reading "downwardly" into the claim would serve to expand the scope of Plaintiff's claim, because the claim would then encompass all projections not protruding "downwardly" - just as reading "permanently" to mean "affixed to prevent movement in at least a horizontal plane" would expand the scope of the K-2 claim to include fixation in methods outside the commonly understood definition of "permanently." Though a patentee is entitled to be his own lexicographer, "the words of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently." K-2, 191 F.3d at 1364 (quoting Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 951 (Fed. Cir. 1993). In this instance, Plaintiff has not demonstrated that the language used in the prosecution history is sufficient to overcome the ordinary meaning of the phrase. 4

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 American Heritage Dictionary defines "projection," as used in the context of the '448 patent, as: "a thing or part that extends outward beyond a prevailing line or surface." "Connect," the root of the word "connection," is defined as: "to join or fasten together."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

As such, "the lower surface having no projections for connection to the seating surface" shall be construed as "the lower surface having no parts extending outwardly for attachment or fastening to the seating surface."
The district court did not explicitly construe the terms in question--"normal plunger performance" and "predetermined plunger performance"--but has conflated claim construction and infringement issues in its analysis. In analyzing the claim limitation "assigning first values . . . which represent normal plunger performance," the district court noted that Special Master Williams did construe "values" to require at least two different values, defining a window of time or a time interval. See Special Master's Report at para. 156; Markman Report at 23. The district court then turned to an example in the specification and determined that "normal plunger performance" should be equated with a good window of plunger arrival. Special Master's Report at para. 156. From there, the district court examined the accused device, and determined that the APC 1000 operator entered only a single target time, TT, from which the system generated a second TT+1 time. Id. at para. 158. The district court concluded that the window, bounded by the time entered by the operator, TT, and the generated value, TT+1, "does not per se represent 'normal plunger performance.'" Id. at para. 159 (emphasis in original). Although the district court then found that an operator might select a one-minute good window, it still determined that there was no infringement, because it concluded that "the TT+1 value does not bear any relationship to 'normal plunger performance.'" Id.

The determination of infringement is a two-step process. First, the court construes the claims at issue to correctly determine their scope. Second, it compares the properly construed claims to the accused device. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454-56 (Fed. Cir. 1998) (en banc). Claim construction is a question of law that we review de novo. Id. A determination of infringement, whether literal or under the doctrine of equivalents, is a question of fact. Instituform Techs., Inc. v. Cat Contracting, Inc., 161 F.3d 688, 692 (Fed. Cir. 1998).

We begin our claim construction analysis with the words of the claim. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). "In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to use to 'particularly point[] out and distinctly claim[] the subject matter which the patentee regards as his invention.' 35 U.S.C. § 112, P 2." Interactive Gift Express, Inc. v. CompuServe, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001). In the absence of an express intent to impart a novel meaning to the claim terms, the words take on the full breadth of the ordinary and customary meanings attributed to them by those of ordinary skill in the art. See, e.g., Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources. Some of these sources include the claims themselves, see Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999); dictionaries and treatises, Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002); and the written description, the drawings, and the prosecution history, see, e.g., DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1324 (Fed. Cir. 2001).

Words often have different meanings to different people and in different contexts, accounting for the multiple ordinary meanings found in dictionaries. Dictionary definitions, while reflective of the ordinary meanings of words, do not always associate those meanings with context or reflect the customary usage of words by those skilled in a particular art. The words used in the claims must be considered in context and are examined through the viewing glass of a person skilled in the art. Tegal Corp., 257 F.3d at 1342. It is the use of the words in the context of the written description and customarily by those skilled in the relevant art that accurately reflects both the "ordinary" and the "customary" meaning of the terms in the claims of a patent. As set forth in Brookhill-Wilk 1:

In construing claim terms, the general meanings gleaned from reference sources, such as dictionaries, must always be compared against the use of the terms in context, and the intrinsic record must always be consulted to identify which of the different possible dictionary meanings is most consistent with the use of the words by the inventor. "Where there are several common meanings for a claim term, the patent disclosure serves to point away from the improper meanings and toward the proper meanings."

Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1300 (Fed. Cir. 2003) (quoting Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998)); see also Tex. Digital, 308 F.3d at 1203. The written description must also be examined in every case, because it is relevant to determine if the presumption of ordinary and customary meaning is rebutted. See Renishaw, 158 F.3d at 1250. Once the court has construed the claim limitations, the second step in the analysis is to compare the properly construed claims to the accused device. Cybor Corp., 138 F.3d at 1454-56.

As noted, the claim limitations at issue are "normal plunger performance" and "predetermined plunger performance." The parties do not dispute the meaning of the terms "plunger performance," so the initial focus of our analysis is on the terms "normal" and "predetermined" within the context of each of the claim limitations in question. Starting with the claim
As to claim three, the claim has been amended to specify that the plurality of normally downwardly hanging fingers follows:

amending the claim to add the reference to gravity the patent applicant noted the significance of the claim change as even more apparent by the fact that the patent was amended expressly for the purpose of adding the gravity element. After device where the primary reason for the downward direction Of the fingers is something other than gravity. This is made affected by gravity to some degree. To avoid such an unreasonable result the claim must be construed not to extend to a

Plaintiff's expert suggests that normally hanging downwardly by gravity requires only that gravity be one of the forces operating on the fingers. Defendants argue that gravity must be the sole force which causes the fingers to hang down. The language of the patent and its prosecution history clearly require rejection of plaintiff's proposed interpretation.

Plaintiff's proposed interpretation would essentially render the reference to gravity meaningless since all objects will be affected by gravity to some degree. To avoid such an unreasonable result the claim must be construed not to extend to a device where the primary reason for the downward direction Of the fingers is something other than gravity. This is made even more apparent by the fact that the patent was amended expressly for the purpose of adding the gravity element. After amending the claim to add the reference to gravity the patent applicant noted the significance of the claim change as follows:

As to claim three, the claim has been amended to specify that the plurality of normally downwardly hanging fingers
actually hang downwardly by gravity. Since the fingers of the French patent are fixed in position, and are not even in a
directly vertical position, there is no suggestion in the patent of applicant's type of fingers.

Given this explanation it is absurd to suggest that the reference to gravity is no more than a recognition of an ever-present
physical force.

Plaintiff places great emphasis on the fact that a special master in a prior suit involving this patent accepted its
to suggest that this unpublished opinion from a sister district court adopting a special master's conclusion operates as stare
decesis unless the cases can be factually distinguished. Plaintiff's reply brief in support of its summary judgment motion at
page 4. This not only indicates a fundamental misunderstanding of the doctrine of stare decisis by plaintiff but a direct
disregard for the Federal Circuit's exposition of the doctrine in Mendenhall v. Cedarapids, Inc., 5 F.3d 1557, 1570 (Fed. Cir.
1993)

Stare decisis in essence "makes each judgment a statement of the law, or precedent, binding in future cases before the
same court or another court owing obedience to its decision." Thus, stare decisis could be invoked by a district court or by
this court based on a prior decision of this court, but the opinion of one district court is entitled only to comity in another
district court.

While it is true that the judgment of the district court was ultimately affirmed by the Federal Circuit it was affirmed not on
its merits but on the basis that the defendant appellant had waived its right to object to the use of a special master or to
challenge the special master's conclusions. Accordingly, the decision of the court in the Northern District of California is
persuasive only to the extent that the Court finds its reasoning to be so, which it does not.

III. The '325 Patent

Claim 1 of the '325 patent reads as follows:

In a sheet handling device:

(a) a conveyor for conveying a plurality of sheets in succession,

(b) a nip disposed at the discharge end of the conveyor for passing sheets therethrough,

(c) a sheet stacker disposed downstream of said nip for receiving and stacking said sheets

(d) and stop means disposed between said nip and said stacker for guiding the longitudinal sheet edges in a manner to
prevent transverse shifting of said edges as the sheets pass from said nip to said stacker, said stop means comprising:

(1) an elongated mounting element disposed above the path of the traveling sheets and extending transversely thereof and
outwardly beyond the said longitudinal sheet edges,

(2) and a plurality of fingers normally hanging downwardly by gravity and arrayed along said mounting element,

(3) a first portion of said fingers being disposed in the path of said sheets and engageable thereby so that said first portion
of fingers are swung forwardly and upwardly about a transverse axis and rest on the sheets,

(4) and a second portion of said fingers remaining out of the path of the traveling sheets and hanging downwardly to
guide the said longitudinal sheet edges.

(emphasis added).
The district court interpreted "hanging downwardly by gravity" as requiring that gravity be the "primary reason for the downward direction of the fingers." Marquip asserts that the phrase only requires that gravity act on the fingers, rather than that the gravity causes the downward hang. However, to interpret the phrase as Marquip contends would read the "by gravity" limitation out of the claim. Gravity acts on everything within our physical frame of reference. Therefore, the term must mean something beyond the universal action of gravity. Moreover, the prosecution history discloses that the applicant added the "by gravity" language to the claim after a rejection. Therefore, this court must assume that this limitation was significant. Thus, this court adopts the district court’s interpretation.

CLAIM 8

Claim 8 reads as follows, with the language at issue in italics:

8. A filter for removing air from fuel received from a fuel tank prior to delivery to an engine comprising: [issue # 1]

- a substantially enclosed vessel including a fuel inlet, a fuel outlet leading to the engine, and a fuel return line leading to said storage tank, said vessel including a normally upright tube presenting a substantially open upper margin defining an operating fuel level within said vessel, said vessel further including means in direct fluidic communication with said outlet for detachably mounting a cartridge thereon; [issue # 2] and

- a (sic) air removal filter cartridge detachably received within said vessel, said cartridge being positioned below said operating fuel level for allowing air bubbles separated by said cartridge to float upwardly to said fuel level and be discharged through said fuel return line. [issue # 3]

Claim 8; Issue 1 - The Preamble

The first issue in claim 8 again pertains to the construction of the preamble. As above, Plaintiffs assert that the preamble merely states a purpose or intended use of the invention and thus does not limit the claim. Defendants, on the other hand, again assert that the term "filter" must be construed as "a filter for removing air which allows fuel to pass but not air" in order to distinguish the "air removal filter cartridge" from prior art, citing to its prior arguments related to "filter media" in claim 1.

As Plaintiffs correctly note, however, if nothing in the claim preamble serves to distinguish prior art, the claim preamble is not a limitation. Compare STX, LLC v. Brine, Inc., 211 F.3d 588, 591 (Fed. Cir. 2000) (preamble not a limitation when used only to state a purpose or intended use of the invention and thus does not limit the claim. Defendants, on the other hand, again assert that the term "filter" must be construed as "a filter for removing air which allows fuel to pass but not air" in order to distinguish the "air removal filter cartridge" from prior art, citing to its prior arguments related to "filter media" in claim 1.

As Plaintiffs correctly note, however, if nothing in the claim preamble serves to distinguish prior art, the claim preamble is not a limitation. Compare STX, LLC v. Brine, Inc., 211 F.3d 588, 591 (Fed. Cir. 2000) (preamble not a limitation when used only to state a purpose or intended use of the invention and thus does not limit the claim. Defendants, on the other hand, again assert that the term "filter" must be construed as "a filter for removing air which allows fuel to pass but not air" in order to distinguish the "air removal filter cartridge" from prior art, citing to its prior arguments related to "filter media" in claim 1.

In any event, for the reasons set forth above with respect to claim 1, the Court finds that the construction of the term "filter for removing air from fuel" suggested by Defendants is not supported by either the language of the claim itself, which clearly references "air bubbles separated by said cartridge," or the specification. See col. 7, lines 4-8.

Claim 8; Issue 2 -- The Vessel & Upright Tube

The parties agree that for the most part, the terms in the first element of claim 8 are not ambiguous. Plaintiffs assert that the language in the last clause referencing a "means . . . for detachably mounting a cartridge thereon" is a means-plus-function claim, and Defendants do not contend otherwise. The Court agrees. The structure described in the specification is a threaded coupling. See col. 2, lines 5-9; col. 4, lines 33; col. 7, lines 3-5. Thus, this portion of the claim is defined as "a threaded coupling or equivalents thereof for detachably mounting a cartridge which is in direct fluidic communication with such outlet, allowing fluid to travel directly between the cartridge and the outlet."
Defendants' arguments with respect to the vessel in Claim 8 center on the "normally upright tube." Defendants asserted at the hearing that the tube 88 is an "overflow tube." As the courts have recognized, claims are part of a "fully integrated written instrument," consisting principally of the specification, and "must be read in view of the specification, of which they are a part." Phillips, 415 F.3d at 1315 (quoting Markman, 52 F.3d at 978, 979). While language is normally given its ordinary meaning, the patentee may serve as his own lexicographer, and subscribe a meaning to a term in the specification that differs from or is more limited than the meaning it would otherwise have, and in such instance, "the inventor's lexicography governs." Phillips, 415 F.3d at 1316.

Throughout the specification, both in defining the invention itself and the preferred embodiment, the patentee has invariably described the upright tube as an "overflow tube." See col. 1, lines 68; col. 2, lines 24; col. 2, lines 31; col. 4, lines 20-21; col. 5, lines 41-42. Likewise, the Abstract described that the trapped bubbles float upward to the fuel level and "then spill over the upper margin of an upright tube within the vessel" leading to the fuel return line. Nowhere is the upright tube described in any other fashion. Accordingly, the Court finds that the substantially upright tube is defined to be "a substantially upright overflow tube." See Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1273 (Fed. Cir. 2001) (patentee "defined the term 'mode' by implication through the term's consistent use through the patent specification").

Defendants further assert that as described in the claim, the "normally upright tube" is not structurally or functionally connected to any element within the vessel. Plaintiffs do not suggest any such connection in the claim language itself, but assert that Defendants' argument is essentially one of invalidity rather than claim construction. The Court agrees, and will address Defendants' argument in connection with their motion for partial summary judgment.

Accordingly, the Court finds that one ordinarily skilled in the art would understand the challenged language pertaining to the vessel to be defined as follows:

"a substantially enclosed vessel that includes a fuel inlet, a fuel outlet leading to the engine, and a fuel return line leading to the fuel storage tank. The vessel includes a normally upright overflow tube that presents a substantially open upper portion, which defines an operating fuel level with the vessel. The vessel further includes a threaded coupling or equivalents thereof for detachably mounting a cartridge which is in direct fluidic communication with such outlet, allowing fluid to travel directly between the cartridge and such outlet."

Cone, Nose, Flank, and Shoulder Region

Claims in the '249, '715, and '631 Patents contain the terms "cone" or "cone region," "nose" or "nose region," "flank" or "flank region," and "shoulder region." The parties dispute whether these regions extend around the circumference of the drill bit face or are limited to the blades of the drill bit face. The parties further dispute the construction of these regions with respect to each other.

Whether the Regions Extend Around the Circumference of the Drill Bit Face

Baker Hughes contends "cone," or "cone region," means "the area or region extending around the entire circumference on the drill bit face and which is located radially closest to the centerline or longitudinal axis of the drill bit body (and which is shaped more or less like an inverted cone)." Baker Hughes proposes similar constructions for the other claim terms and contends these regions extend around the entire circumference of the bit face.

ReedHycalog contends "cone," or "cone region," means the "region, defined by the blades of the bit, radially between the nose and the center longitudinal axis of the bit." ReedHycalog proposes similar constructions for the other claim terms and claims these regions are defined by the drill bit blades and do not extend around the entire circumference of the bit face.

The specifications of the '249, '715, and '631 Patents support a construction that limits the "cone," "nose," "flank," and "shoulder" regions to the blades. The '249 and '715 Patents refer to the "cone," "nose," "flank," and "shoulder" regions as being regions within the bit profile. '249 Patent col. 5:66-col. 6:1; '715 Patent col. 9:34-39. As the blades define the bit
profile, and each of these regions are located in the bit profile, the blades likewise define the "cone," "nose," "flank," and "shoulder" regions.

Second, figures in the '249, '715, and '631 Patents confirm that these regions are limited to the area defined by the drill bit blades. Fig. 10 of the '249 and '715 Patents, displayed in Appendix C and annotated, shows the "cone," "nose," "flank," and "shoulder" regions along the bit profile. Fig. 13 of the '715 Patent, a quarter-sectional side view of the three-region embodiment of the claimed drill bit, similarly shows the disputed regions along the bit profile. '715 Patent Fig. 13. Figs. 14A and 14B of the '631 Patent, reproduced in Appendix C and annotated, show the "cone," "nose," "flank," and "shoulder" regions on the blades of the drill bit. While Fig. 14C of the '631 Patent, annotated and shown in Appendix C, tends to support Baker Hughes's contention that the "cone region" extends circumferentially around the drill bit, the above intrinsic evidence more clearly shows that this region, in addition to the "nose," "flank," and "shoulder" regions, is limited to the drill bit blades. Thus, the Court construes these terms to only extend on the blades of the drill bit.

Radial Location of Each Region With Regard to Other Regions

Baker Hughes and ReedHycalog additionally dispute the definition of each region on the drill bit in relation to the other regions. In short, Baker Hughes defines "cone" as "... located radially closest to the centerline or longitudinal axis of the drill bit body ..." and subsequently defines "nose" as the area or region radially between the cone and the "flank," which includes the leading most point on the drill bit body. Similarly, Baker Hughes defines "flank" as the area or region radially between the "nose" and the "shoulder" or "gage," and "shoulder region" as the area or region radially between the "flank" and the "gage," although in a given drill bit, the "flank" and "shoulder" regions may be the same part of the bit.

ReedHycalog's constructions are similar, except that ReedHycalog starts with the "nose," which it construes as "extending radially and proximately about the leading-most point." ReedHycalog defines "cone" as the region radially between the "nose" and the longitudinal axis of the drill bit body, "flank" as the area or region radially between the "nose" and the "shoulder region," and the "shoulder region" as radially proximate the "gage."

Nose

Similarly, there is little difference between the parties' constructions of "nose" and "nose region." The '249, '715, and '631 Patents specifications refer to the "nose," or "nose region," as part of "an outer region," as a "radially intermediate portion" of the bit face between the "cone" and the "flank" and "shoulder" regions, or as "more radially distant" from the centerline than the "cone." '249 Patent col. 8:14-18; '715 Patent col. 3:11-18, 36-45; '631 Patent col. 4:37-43, col. 5:37-43. This language in the specifications supports Baker Hughes's contention that the "nose," or "nose region," is located radially between the "cone" and the "flank" regions. Further, as the parties agree, all embodiments of the invention show the leading-most point of the bit within the "nose" or "nose region." '249 Patent Fig. 10; '715 Patent Figs. 10, 13; '631 Patent Figs. 15A, 15, 16, 17.

The Court slightly modifies Baker Hughes' construction. Thus, "nose," or "nose region," means "region, defined by the blades of the bit, located radially between the cone and flank regions, and includes the leading-most point on the blades, labeled 232 in Fig. 10 of the '249 and '715 Patents." 7

2675

5. "Nose Feature"

Hoodlums defines "nose feature" as "[t]he part of the face used for breathing and smelling, including but not limited to the
nose features shown in Figures 5 through 9 of the '972 patent." (Doc. 37, Ex. B at 5.) Redtail defines "nose feature" as "prominent and distinctive characteristics of the organ forming the nostrils used for smelling and breathing." (Id.)

The term "nose feature" closely resembles the previously defined terms "skull facial features" and "facial features." In this case, "nose feature" is only found in claim 1, and the specification and the prosecution history do not provide any particular meaning to the term. The dictionary defines "nose" as "the organ for breathing and smelling." New Webster's Dictionary and Thesaurus, 261. This definition captures the ordinary and customary meaning of the word "nose." However, the addition of the word "feature" strongly suggests that the term "nose feature" includes more than just the definition of "nose." See Phillips, 415 F.3d at 1314.

Looking to the claims, the specification, Federal Circuit law, and the dictionary, the court defines "nose feature" as "the part of the face used for breathing and smelling, including, but not limited to, the nose features shown in Figures 5 through 9 of the '972 patent."

E. Nose Segment

The term "nose segment" is recited in Claim 3(d) of the '649 patent which reads: 17 "said cutting head assembly further including a nose segment structured to applanate the cornea to be cut; said nose segment structured to move in unison at substantially all times with said cutting head assembly in both a forward and a reverse direction over said positioning ring along said generally arcuate path defined by said guide assembly." Defendants support the following construction: "the separable forward part of the cutting head assembly," (Court Reference Sheet at 1), and plaintiff proposes the following: "the forward section on the cutting head that applanates the cornea," (id. at 2). Thus, the key dispute is whether the piece is separable, as proposed by defendants, or integral, as argued by plaintiff.

Defendants argue that the nose segment must be separable or the claim would not specify that it "moves in unison at substantially all times with said cutting head assembly." In other words, if the nose segment was fully integrated with the cutting head assembly, there would be no need to point out that it moved in general unison with the cutting head assembly. This is a powerful argument, for if the nose segment is to be integrated, the last part of the claim would be wholly redundant.

Defendants further contends that any ambiguity is resolved by the specification of the '649 patent which reads: "Preferably, the depth adjusting means 75 comprise a separate nose segment 76, which is structured to be securely, yet removably interconnected with housing 51 by way of a conventionally known fasteners 74 such as a screw, bolt, etc." Col 10, ln. 60 - Col. 11, ln. 3 (emphasis added). Thus, the specification describes a separate piece. While it is clear that the patentee is not mandated to describe in the specification every possible embodiment, see Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1344 (Fed. Cir. 2001), one may turn to the written description to define a term already in a claim limitation because a claim must be read in view of the specification of which it is a part, Renishaw PLC v. Marposs Societa Per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998).

Plaintiff relies on Rexnord in which the Court of Appeals held that the term "portion" embraced structure that may be either integral or separate. 274 F.3d at 1345. Plaintiff analogizes "segment" to "portion," which shares a similar dictionary definition. The Rexnord court, however, found it significant that the specification described more than one embodiment. See id. The inventor had also specifically noted that the invention could be carried out in a number of ways. See id. Here, the specification describes only an embodiment of a separate nose segment which is secured to the cutting head assembly and removable therefrom. Therefore adopt defendants' proposed construction for the term nose segment: "the separable forward part of the cutting head assembly."
Plaintiffs contend that the phrase "each flange itself not being a magnet, including a magnetic material" means "(respecting the flanges) . . . that a portion or segment of each flange is a magnetically attractive substance, such as, for example, a magnet; but the entirety of the flange cannot be a magnet. The magnetic material may be embedded in or secured to the remaining portions of each flange." JS, Exh. A at 11.

Conversely, Defendant construes the entire phrase in question to mean that "the flange is not a magnet, but it includes magnetic material, specifically a magnet." JS, Exh. C at 107.

In examining the language of the claims, the Court agrees with Plaintiffs that the use of both "magnet" and "magnetic material" in the language of claim 12 counsels against limiting the phrase "magnetic material" to a "magnet." Pls.' Opening at 17:24-27. However, this fact, in and of itself, is not dispositive. Additionally, and as stated above, see supra section "III B 2 a (4)," the plain meaning of the term "magnetic" is "having the properties of a magnet and capable of being magnetized or of being attracted by a magnet." Having considered the language of the claims, the Court now turns to the specification.

In the "Detailed Description of the Preferred Embodiment" section of the '747 Patent, the patentee states that when there is a magnetic attraction between the primary and auxiliary frames, it is achieved through the engagement of magnets as depicted in Figure 3. See the '747 Patent, Koo Decl., Exh. C at 19 and 20, Col. 2, 11. 56-60 and 65-67. However, the references to magnets in the descriptions of the preferred embodiment are not claim limitations. Laitram Corp., 863 F.2d at 865. The Court next turns to the prosecution history.

In this case, the Sadler Patent was cited by the applicant in his Information Disclosure Statement ("IDS"), 19 which was filed with the PTO during the prosecution of the '747 Patent. 20 See IDS, Prosecution History of the '747 Patent, Koo Decl., Exh. F at 739. As discussed above, see supra section "III B 2 a (4)," the Sadler Patent defines the phrase "magnetic member" to be a permanent magnet or a ferromagnetic member, but at least either the first or second magnetic members must be a permanent magnet. Therefore, and consistent with the Court's analysis with regard to similar claim language in the '545 Patent, the Court construes the phrase "magnetic material" to mean a permanent magnet or ferromagnetic material, but at least either the magnetic material in the primary frame or in the auxiliary frame is a permanent magnet.

Therefore, the Court construes the phrase "each flange itself not being a magnet, including a magnetic material" to mean each flange is not a magnet, but it includes a permanent magnet or ferromagnetic material, and at least either the magnetic material in the primary frame or in the auxiliary frame is a permanent magnet.
even partly covers the "axial peripheral lip": for instance, where the panel lies only halfway up the side of the lip, but does
not rise over the top of the lip. Lacks argues, however, that the "not cover" limitation only teaches away from those
inventions where the panel covers the projecting top of the "axial peripheral lip." The ordinary meanings of "cover" permit
both constructions. 7

7 Webster's Third New International Dictionary (1986) ("Webster's") defines the verb "cover" to mean, among other things,
"to lie over; spread over; be placed on or often over the whole surface of" and "to appear here and there on the surface of."
Even though a dictionary is technically extrinsic evidence, the U.S. Court of Appeals for the Federal Circuit ("Federal
Circuit") has determined that judges may consult a dictionary "at any time" when construing claim terms, so long as the
dictionary's definition does not contradict the definition supplied by the intrinsic evidence of the patent. Vitronics, 90 F.3d at
1584, n.6. As will become clear, there is no contradiction.

Claim 1 states that the "ornamental panel" is "shaped to cover said entire wheel face outer surface and not cover said axial
peripheral lip." '809 patent, col. 11, lines 9-11. In order to be consistent with my construction of "axial peripheral lip" and
"wheel face outer surface," the "not cover" limitation must mean what defendants propose: that the panel cannot cover any
portion of the axial peripheral lip structure. Furthermore, reason alone dictates that the "not" negates all possible ordinary
meanings of "cover," absent a specific direction to the contrary in the specification or the prosecution history. See id. at
1582.

No such direction exists in the specification. Instead, cross-sectional drawings of the preferred embodiments (Figures 3 and
5) show the panel fitting snugly into the base of the shoulder of the axial peripheral lip. These drawings do not teach partial
coverage of the axial peripheral lip structure.

With respect to the prosecution history, Lacks argued at the hearings that it had amended claim 1 and inserted the "not
cover" limitation solely to distinguish the scope of claim 1 from prior art that taught a cladding panel that went over the top
of the "axial peripheral lip." In making that argument, Lacks has essentially asserted that it did not intend for the "not cover"
limitation to teach away from all forms of coverage, but only to teach away from coverage of the top of the lip. While this
may have been Lacks' intent, the prosecution history before me offers no persuasive evidence to support this argument.

Even if true, Lacks' contention about the purpose of the "not cover" limitation could not overcome the strong evidence of
the claim language and the specification. I conclude therefore that a person of ordinary skill in the art of cladded wheels
would understand the "not cover said axial peripheral lip" limitation of claim 1 to mean that the cladding panel cannot cover
any portion of the "axial peripheral lip." Because the intrinsic record of evidence has resolved any ambiguities as to the
meaning of the "not cover" limitation, I find it unnecessary to examine any extrinsic evidence on this issue (with the
permissible exception of Webster's). See id. at 1583.

11. Not Directed, Non Laminar Stream

The claim term "not directed, non laminar stream" appears twice in Claim 35. 7 Erbe defines the terms "not directed…
stream" and "non laminar stream" separately. Canady defines the terms together.

Erbe's Proposed Definition of "not directed…stream": A gas stream that is not necessarily oriented toward the surface of
the tissue to be coagulated.

Erbe's Proposed Definition of "non laminar stream": A diverging gas stream that allows an inert gas atmosphere to form.

Canady's Proposed Definition of "not directed, non laminar stream": A turbulent, diverging gas stream.
(Docket No. 42, p. 15, 16; Docket No. 66, pp. 34-49). After a review of the claim language, I find that the terms should be read in relation to each other since they are always together in the claim language and describe the type of stream that the invention envisions.

7 Claim 35 provides, in relevant part, as follows:

35. A method for coagulating tissue during endoscopic surgery comprising the following steps:...supplying the inert gas from the source of said gas thorough the tube to the distal end opening of said tube with such a low flow rate, that gas exiting through said distal end opening is a not directed, non laminar stream but forms an inert gas atmosphere between the distal end of the tube and the region of the tissue to be coagulated.....supplying an electric current by means of a plasma jet as a function of the direction of said electric field and the electric conductivity of the tissue surface to be coagulated, and coagulating an area of the tissue sidewardly of the extended longitudinal axis of the protruding end of the tube while the distal end opening of the tube is maintained in a substantially stationary position at a predetermined distance from the tissue to be coagulated, and while the ionized gas is being supplied through the distal end opening of the tube as a not directed, non laminar stream with a low flow rate.

Docket No. 63, Ex. 1, col. 15, ll. 53-58, and col. 16, ll. 3-14 (emphasis added).

8 Erbe changed its proposed definition to eliminate the term "turbulent," because upon further reflection, the term "turbulent" was "inadvertent and incorrect." (Docket No. 68, p. 24). Consequently, I will delete this term from Erbe's proposed definition.

In defining the claim terms, both Erbe and Canady propose some similar language: A diverging gas stream. I agree with the parties that "a diverging gas stream" should be included within the definition. See, Docket No. 63, Ex. 1, col. 8, ll. 31-33. I do not agree with Erbe, however, that the additional language "that allows an inert gas atmosphere to form" should be included. Such language would not make sense when read where the claim term appears for the first time in Claim 35. See, Docket No. 63, Ex. 1, col. 15, ll. 53-58. See, Footnote No. 8. Furthermore, I cannot agree with Canady, that the term "turbulent" should be included in the definition. To read "turbulent" into the construction would be placing a limitation set forth in the specifications into the claim, which is not permitted. Phillips, 415 F.3d at 1323, citing Comark Communs. v. Harris Corp., 156 F.3d 1182, 1186-87 (Fed.Cir.1998).

I do agree with Erbe, however, that I must give all terms, to the extent possible, meaning. Thus, I do not believe that the word "diverging" conveys the entire meaning of the term "not directed, non laminar stream." "Not directed" must be given some meaning. As such, I turn to the specifications which states that "the surgeon needs not take exactly aim" at the tissue to be coagulated. Docket No. 63, Ex. 1, col. 7, ll. 19-20. The specifications further state that [i]n many cases it is not necessary to direct the axis of the orifice 9 of the tube 2 or the attachment 11 to the surface to be coagulated, as shown in FIG. 15, since the ionization of the gas stream 17 is normally automatically directed to the adjacent surface of the tissue 18, even if the tissue 18 is in a position as shown in FIGS. 3, 4, 6, 7 and 9 to 12, whilst the axis of the tube 2 or the attachment 11 is oriented as shown in FIGS. 2, 5 and 8. Consequently, I construe the term "not directed, non laminar stream" as a diverging gas stream which need not be specifically aimed at the tissue to be coagulated:

**2680**

vii. Not parallel to the frontal plane

Plaintiffs construe the phrase "not parallel to the frontal plane" to mean "not on the front portion of the bridge, but on the top and bottom of surfaces of the bridge, in some cases perpendicular to the frontal plane." Defendant interprets the phrase "not parallel" to mean, simply, that the planes do intersect and objects to limiting the phrase to encompass coupling only at
"the top and bottom... surfaces of the bridge."

First, the court finds (and the parties appear not to contest) that "not parallel" means "substantially perpendicular." The language of Claim 2 states that "an eyeglass device as recited in claim 1 wherein the coupling occurs at a coupling surface on the second frame that is substantially perpendicular to the frontal plane." Therefore, "not parallel," read in the context of other relevant claim language, means "substantially perpendicular."

With respect to Plaintiffs' interpretation that coupling must be done "on the top and bottom of surfaces of the bridge," Defendant argues that, even if one of the non-parallel planes, such as the frontal plane, is vertically aligned, the other plane need not be horizontally aligned, and could in fact also be vertically aligned and still be substantially perpendicular. Defendant cites, as an example, a typical six-sided die; as Defendant points out, for any given side of a die, there are four sides that are perpendicular to it, two of which are horizontally aligned and two of which are vertically aligned. Therefore, Defendant contends, there is no basis for restricting the phrase "not parallel to the frontal plane" only to "the top and bottom of surfaces of the bridge."

The court agrees with Defendant. Plaintiffs cite prosecution history from the related '054 Patent as support for its interpretation, but the language Plaintiffs cite do not preclude Defendant's interpretation. Therefore, the court construes "not parallel to the frontal plane" to mean "substantially perpendicular to the frontal plane" without any limitation that coupling occur on the top and bottom of surfaces of the bridge.

II. "a notch through the entire thickness of the strip"

Lifescan proposes "a small cut through the entire thickness of the strip," while Roche proposes "a small cut into a lateral edge of the strip, such as the notches A, B, or C circled below [with three drawings]." The three drawings are based on Fig. 12 of the '420 patent ("Notch A"), Fig. 8 of Australian Provisional Application No. PN6619 2 ("Notch B"), and Fig. 3i from the Crismore '817 patent 3 ("Notch C"). According to Roche, the drawings are "genericized" versions of these figures; the drawings are not exact reproductions of those figures.

The Court declines to define the relatively simple term "notch" by reference to Roche's figures. Roche does not provide any legal or factual support for using its own drawings, based on one figure from the patent-in-suit and two figures from other sources, to construe "notch." Both parties agree that "notch" means "a small cut," and the Court finds that this construction is sufficient.

5. Notches

. Plaintiff's proposed construction: Angled or shaped portions in the lower edge surface of the helmet shell for preventing flexible members from freely sliding.

. Defendant's proposed construction: Concave or V-shaped cuts or indentations formed in the lower edge of a helmet shell.
The parties' dispute focuses on the expanse of a notch. Plaintiff asserts that notches are angled portions of the lower edge of the helmet shell and defendant contends that they are concave or V-shaped indentations in the lower edge of the shell. Defendant's construction of notch better reflects both the claim and specification language.

The specification says that "notches 107, 108 are generally V-shaped notches; however, other shapes of notches, if desired, could be utilized." '971 patent, col. 9, lns. 15-17. It also states that "the notches 107, 108 of chin protector connector 34 serve to provide improved stability of the lower chin straps, or flexible members 104, by preventing the lower strap 104 from being free to slide around the outer wall surface of ear flaps 32." Id., col. 9, lns. 59-63. The specification and diagrams show that "notches" are smaller indentations or cut outs and not large angled portions in the lower edge of the helmet. Instead of being merely angled, the lower edge of the shell is interrupted by an indentation of some sort.

Although defendant's construction of the word is more accurate, it is too narrow because it appears to limit notches to only two shapes: concave and V-shaped. Concave is defined as "arched in" or "curving in," implying a U shape. Merriam-Webster's Online Dictionary, accessed at http://www.merriam-webster.com/dictionary/concave (visited July 10, 2009). Therefore, I find that "indentations of any shape" better defines the claim term.

I conclude that the term "notches" as used in claims 42-47 of the '971 patent means indentations of any shape in the lower edge of the helmet shell that prevent the lower chin straps from moving.

2683

1. "A Number of Apertures"

In the preliminary injunction pleadings, Bradley argued that claim 6 requires more than one set of cold fluid apertures.Defs.' Br. in Opp'n to Pl.'s Mot. for Prelim. Inj. at 44 ("Def.' Prelim. Inj. Opp'n Br."). In fact, Bradley argued that one set of apertures was necessarily located within the shuttle bore (the portion of the valve liner in which the shuttle valve moves, '531 Patent, col. 14, ll. 14-15). Defs.' Prelim. Inj. Opp'n Br. at 44 (citing Ballanco Aff. P 8).

In contrast, Lawler argued that only one set of openings is all that claim 6 requires. Pl.'s Reply Br. in Supp. of Mot. for Prelim. Inj. at 19 ("Pl.'s Prelim. Inj. Reply Br."). Moreover, reading a requirement of two sets of openings, a set of apertures and a set of slots, into claim 6 would render claim 7 superfluous. Therefore, Lawler argues that pursuant to the doctrine of claim differentiation, claim 6 could not require two sets of apertures. Id. at 20 (citing Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991)).

The Court agrees with Lawler. There is nothing in the language of the claims or in the specification that requires more than "a number of apertures." Use of the plural form of aperture does imply that more than one aperture should be present, or implies a set of apertures, however, there is nothing that specifies that the number of aperture sets need be more than one. In addition, as Lawler points out, requiring more than one set of apertures in claim 6 would render claim 7 superfluous. Claim 7 states:

The thermostatic mixing valve of claim 6, wherein:

    said valve liner defines a number of slots in communication between said first source and said shuttle bore; and

    said shuttle valve is configured to variably restrict the flow of liquid through said number of slots into said shuttle bore in response to movement of said thermostat actuator.

'531 Patent, col. 14, ll. 20-26. Claim 7 clearly adds a requirement that the valve liner also define a number of slots between the cold liquid source and the shuttle bore. In other words, claim 7 adds a second set of apertures for the cold liquid source. If claim 6 required a second set of apertures, this portion of claim 7 would be repetitive and unnecessary.

Moreover, it appears that Bradley's argument that the specification supports a requirement that the valve described by claim 6 have at least two sets of apertures impermissibly imports a claim limitation from the description of the preferred embodiment. Bradley points to language in column 8 that describes the shuttle valve and its function of closing the cold
liquid bypass slots defined by the valve liner. Id. col. 8, ll. 4-14. The '531 Patent goes on to describe the cold liquid apertures, also defined by the valve liner. Id. col. 9, ll. 20-25. See also id. col. 7, ll. 46-50 ("Cold liquid apertures 77 are formed around the outer circumference of the liner and communicate directly with the shuttle bore 74. Likewise, cold bypass slots 78 are cut into the liner 70 above the cold liquid apertures 77.") However, this is a description of the preferred embodiment described by the patent. A court will not import a limitation into a claim from the specification absent means-plus-function language. Laitram, 163 F.3d at 1348. There is no such language in claim 6, nor did Bradley argue that the claim was written such that the Court should interpret the claim using a mean-plus-function limitation.

Therefore, the language of claim 6 itself has no requirement that the liner define a set of apertures and a set of slots. Claim 6 only requires that the valve liner define some number of apertures that communicate with the cold liquid chamber and have an orientation relative to the other parts as further described by the claim.

Bradley also appeared to argue at the preliminary injunction stage that apertures in claim 6 were limited to holes. In other words, slots were not apertures. However, the word apertures clearly means opening without limitation on shape. In addition, reading the word in the context of the claims and specification does not require that the apertures be of any particular shape, only that they are in communication with other parts of the valve assembly. For instance, at column 2, lines 53 to 57, the '531 Patent states: "The vane [sic] liner includes a plurality of cold liquid apertures circumferentially disposed around the liner. In one embodiment, the apertures serve as the primary flow path for the cold water to be mixed with incoming hot water." The description also states: "Cold liquid apertures 77 are formed around the outer circumference of the liner and communicate directly with the shuttle bore." Id. col. 7, ll. 46-48. None of this language limits the shape of the apertures to holes.

In one part of the specification, the preferred aperture shape is discussed. The patent states:

Preferably, each of the valve liners 70 includes 6-8 apertures 77 uniformly distributed around the circumference of the valve liner 70. In a specific embodiment, these apertures have a diameter of about 1/8 inch to ensure adequate cold flow at all times.

Id. col. 11, ll. 9-13. This part of the description implies that the inventor thought that holes with an 1/8 inch diameter would best perform the function of ensuring adequate cold liquid flow. But, the description of the preferred embodiment was not meant to limit the patent claims. In addition, the patent specification uses apertures and slot interchangeably when describing an alternative embodiment of the invention. The patent states: "In one specific embodiment, only four such apertures are provided so that about two-thirds of the cold flow is provided through the bypass apertures. Even in this embodiment, the bypass slots can still be shut off by the shuttle valve." Id. col. 12, ll. 53-58 (emphasis added).

Finally, as discussed briefly in the Preliminary Injunction Order, the plain meaning of the term apertures is not limited to holes. Prelim. Inj. Order at 47 n.9. Bradley's expert, Julius Balanco ("Balanco") admitted as much during the preliminary injunction hearing. Prelim. Inj. Hr'g Tr. at 572-73, Ballanco-Cross.

The Court finds that apertures in the context of the '531 Patent means openings of any shape or dimension. This definition includes, but is not limited to, holes and slots.

10. The claims in issue require asbestos free glass cloth held in place by fasteners which are "two woven nylon, hook and loop mating strips." Transco's fasteners have a Nomex(R) base and loops and a second strip of Nomex(R) base with stainless steel hooks.

11. At the time that the Pinsky patent application was filed in 1973, Nomex(R) was known generically as high temperature resistant nylon, as described in column 2, lines 51 through 60 of the Pinsky patent.

12. "Velcro"(R) hook and loop fasteners are made of woven simple nylon or Nomex(R) nylon strips. Either loop
components or hook components extend upwardly from the woven nylon strips. The hooks may be of stainless steel or simple nylon, and are stiff little hooks. The loops are tiny soft loops and may be of simple nylon or Nomex(R) nylon.

13. Simple nylon hooks are not suitable for containment areas because they cannot withstand gamma radiation levels in a containment unit. (Pinsky Tr. 506, 554.) Mr. Pinsky learned this in 1977.

14. I reject as did Judge Shadur, and for the same reasons, the argument that "nylon" in the sentence in claim 1 of the Pinsky patent that states that "the fasteners are two woven nylon, hook and loop mating strips" refers only to the mating strips without the hooks or loops. Velcro(R) mating strips are comprised or made up of hooks and loops. 813 F. Supp. at 622.

15. Since stainless steel hooks are suitable for nuclear containment areas and nylon hooks are not, stainless steel hooks are not the equivalent of nylon hooks.

The two claims of the '735 patent that the district court found relevant are claims 1 and 4, which read:

1. Readily removable and replaceable rewetable thermal insulation for use on vessels and piping within reactor containment areas of nuclear power plants comprising high temperature resistant mineral fiber or glass fiber encapsulated within rewetable, high temperature resistant, asbestos free glass cloth held in place with a plurality of spaced quick release and engage fasteners, wherein the glass cloth can withstand repeated wettings from spray systems within the reactor containment areas of nuclear power plants and wherein the fasteners are two woven nylon, hook and loop mating strips, wherein the glass cloth has a finish of a leachable, organic silicate carried in a fatty and mineral oil vehicle.

4. Thermal insulation according to claim 1 wherein the strips comprise a hook strip covered with stiff little hooks and a loop strip covered with tiny, soft loops.

Performance Contracting asserts that five general configurations of insulation blankets made by Transco infringe the '735 patent. The only dispute on appeal concerning infringement is whether the fasteners used by Transco in the five configurations of blankets meet the claim limitation "two woven nylon, hook and loop mating strips" of claim 1.

The types of fasteners used in the industry are marketed under the trademark Velcro nylon is a more durable nylon that can withstand higher temperatures, such as those in a nuclear containment area, than simple nylon without degrading. The district court found that the hooks of such fasteners, however, must be made of either simple nylon or stainless steel because Nomex (R) cannot be formed into monofilaments to create the hooks. See Transco Products, Inc. v. Performance Contracting, Inc., 1996 U.S. Dist. LEXIS 4027, No. 89 C 8001, 1996 WL 153676, at *5, P 30 (N.D. Ill. April 1, 1996).

The district court concluded that the '735 patent was invalid under 35 U.S.C. § 101 because it was inoperable, since its disclosed structures were not "useful." The district court determined that the claims of the '735 patent were directed to nuclear power plant containment areas only, and found as a matter of fact that simple nylon hooks are not suitable because they cannot withstand gamma radiation levels in such a containment area. Id. at *2, P 3, and *4, P 13. The district court further found that:

The [‘735] patent disclosed fastener(s) made of woven nylon. However, the patented insulation is only suitable for reactor containment areas of nuclear power plants if the fasteners are made of Nomex (R) material and stainless steel.

Id. at *5, P 29.

The district court noted that a patent is invalid because of inoperability "if the described result cannot be obtained by the described means." Id. at *11, P 66 (quoting Raytheon Co. v. Roper Corp, 724 F.2d 951, 958, 220 U.S.P.Q. (BNA) 592, 598 (Fed. Cir. 1983) (quoting Mitchell v. Tilghman, 86 U.S. 287, 397, 22 L. Ed. 125 (1873)), cert. denied, 469 U.S. 835, 83 L. Ed. 2d 69, 105 S. Ct. 127 (1984)). Therefore, based on these findings, the district court declared the '735 patent invalid because "the product disclosed in the [‘735] patent cannot survive in the containment area of the nuclear power plant unless the fastener(s) are Nomex (R) material and stainless steel. Because this crucial structure is not shown or discussed in the
The district court also held, alternatively, that none of the five configurations of Transco's products infringed the '735 patent either literally or by the doctrine of equivalents. The district court found that the phrase "two woven nylon, hook and loop mating strips" defining "fasteners" in claim 1 must be interpreted, by clear English construction, to mean "two woven nylon" modifies the entire phrase "hook and loop mating strips." Therefore, the district court rejected Performance Contracting's argument that "nylon" modifies only "mating strips" and not "hooks and loops," because Velcro (R) mating strips are comprised of hooks and loops. See id. at *4, P 14. The district court concluded, the whole construction of the quick release and engage fasteners must be made of nylon, such as simple nylon or Nomex (R), including the hooks and loops as well as the mating strips, to infringe claim 1.

The district court found that in all five of Transco's blanket configurations, Transco used fasteners that have a Nomex (R) base and loops and a second strip of Nomex (R) base with stainless steel hooks. Id. at *3, P 10. Because claim 1, as interpreted by the district court, literally calls for the hooks to be made of nylon, the district court found that Transco's five blanket configurations that all use stainless steel hooks do not literally infringe claim 1, the only independent claim of the '735 patent. Id. at *11, P 62.

The district court also found, based on its inoperability determination that "since stainless steel hooks are suitable for nuclear containment areas and nylon hooks are not, stainless steel hooks are not the equivalent of nylon hooks." Id. at *4, P 15. Based on this finding of fact, the district court held that the five Transco configurations did not infringe any claim of the '735 patent based on a doctrine of equivalents analysis. Id. at *11, P 62. 1

Discussion

The two issues in this appeal, claim interpretation and operability, are inextricably linked. In determining utility, we must assess the claimed subject matter. Raytheon, 724 F.2d at 956, 220 U.S.P.Q. (BNA) at 596. While utility is a question of fact subject to the clearly erroneous standard of review, id., claim construction is a legal question subject to de novo review, Markman v. Westview Instruments, Inc., 134 L. Ed. 2d 577, 116 S. Ct. 1384, 1387, 38 U.S.P.Q.2D (BNA) 1461, 1463 (1996), affg 52 F.3d 967, 34 U.S.P.Q.2D (BNA) 1321 (Fed. Cir. 1995).
A. Claim Construction and Literal Infringement

Performance Contracting challenges the district court's claim construction with respect to the phrase "two woven nylon, hook and loop mating strips" describing the fasteners in claim 1 of the '735 patent. Performance Contracting makes two arguments attacking the district court's claim construction. First, Performance Contracting asserts that when the phrase is read in light of the specification, it is clear that "nylon" modifies only "strips."

The written description of the '735 patent at column 2, lines 53-56, describes the hook and loop tape fasteners as "woven and [comprising] two mating strips. The hook or male section is covered with stiff little hooks and the loop or female section is covered with tiny, soft loops." Because the written description describes hooks covering the two mating strips, Performance Contracting asserts that the strips and hooks are separate and can be, and are, made of different materials.

Performance Contracting's second argument attacking the district court's claim construction applies a well known principle of claim construction that an ambiguous claim should be construed to preserve its validity. See, e.g., Texas Instruments, Inc. v. United States Internat'l Trade Comm'n, 871 F.2d 1054, 1065, 10 U.S.P.Q.2D (BNA) 1257, 1265 (Fed. Cir. 1989). Performance Contracting asserts that the term nylon should not be construed to modify the phrase "hook and loop" because the district court has held that claim 1 is invalid for inoperability based on its claim interpretation requiring the hooks to be made of simple nylon. For these reasons, Performance Contracting asserts that claim 1 is literally infringed by Transco's five products because stainless steel hooks are within the scope of claim 1 as properly construed.
Transco counters these arguments by asserting that extrinsic evidence, such as a brochure describing Velcro (R) fasteners and the testimony of Mr. Pacella, the attorney who prosecuted the '735 patent, supports the district court's claim construction. For instance, Transco states:

As the VELCRO (R) brochure illustrates, the two hook and loop mating strips are each unitary structures woven from nylon, and the hooks and loops are thus woven from nylon. This was consistent with the understanding of the patent attorney (Pacella) drafting the claim language, who believed that VELCRO (R) hooks and loops could only be made with nylon or some other plastic.

Also, Transco counters Performance Contracting's argument that the claim should be construed to preserve validity by asserting that if two equally plausible claim interpretations exist, the claim should be construed narrowly, citing Athletic Alternatives, Inc. v. Prince Manufacturing, Inc., 73 F.3d 1573, 1581, 37 U.S.P.Q.2D (BNA) 1365, 1372 (Fed. Cir. 1996) ("Where there is an equal choice between a broader and a narrower meaning of a claim, and there is an enabling disclosure that indicates that the applicant is at least entitled to a claim having the narrower meaning, we consider the notice function of the claim to be best served by adopting the narrower meaning.").

In construing a claim, "the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996) (citation omitted) (citing Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 U.S.P.Q.2D (BNA) 1321). When reviewing the file history, the court may examine the prior art cited therein. When such a review of the intrinsic evidence of the patent, which constitutes the public record, unambiguously describes the scope of the patent right, it is improper to rely on extrinsic evidence. Id. at 1583, 39 U.S.P.Q.2D (BNA) at 1577; see also Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1555, 42 U.S.P.Q.2D (BNA) 1737, 1742 (Fed. Cir. 1997). We find that the intrinsic evidence unambiguously determines the meaning of the claim limitation "two woven nylon, hook and loop mating strips." The written description of the '735 patent describes the hook and loop mating strips at column 2, lines 46-60, as follows:

Any quick release fasteners can be employed in this invention. These fasteners include metal hooks, metal snaps, tape fasteners and the like. An important point here is the use of quick release fasteners that require no accessory tools to be engaged or disengaged.

Hook and loop tape fasteners made of nylon are preferred. High temperature resistant nyons generally are employed. The tape fasteners are woven and comprise two mating strips. The hook or male section is covered with stiff little hooks and the loop or female section is covered with tiny, soft loops. When pressed together the hooks and loops engage, creating a secure closure. To open, the two strips simply are peeled apart. These tape fasteners can be opened and closed many thousands of times.

The drawings of the fastener are described at column 3, lines 12-21, as a "hook and loop tape fastener 6 . . . shown in FIG. 3 with hook strip 22 partially peeled apart from loop strip 24." Figure 1 shows where the hook and loop tape fastener 6 is positioned on the insulation blanket.

In describing the preferred embodiment of the fasteners, the specification indicates that the entire fastener, i.e., "hook and loop tape fastener," is preferably made of nylon. The description of the hooks and loops "covering" the two strips is merely an explanation of the construction of the entire fastener, which is described as woven and comprising two mating strips. From the written description it is clear that the entire fastener must be made of nylon. We hold that the district court correctly interpreted this limitation of claim 1 to require nylon to modify "hook and loop" as well as "mating strips."
ring elements." (Id.)

amended Claim 71, ICU stated, "the Examiner's attention is respectfully drawn to Figure 9 which illustrates a plurality of O-

'of a plurality of ringed wall portions 94 that expand and collapse in an accordion like fashion.'" (Id.) With regard to

made up the seal. (D.I. 120, Ex. D, at 1236.) ICU clarified that the O-ring elements form a portion of the seal, and further

claims 2 and 3) for indefiniteness because it was unclear whether the "at least two O-ring elements" were on the seal or

During the course of the '862 Patent's prosecution, the Examiner rejected claims 70 and 71 (which ultimately issued as

The prosecution history of the '862 Patent provides additional confirmation that RyMed's more limited construction is

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

2 In the '866 and '592 Patents, the term "O-ring elements" appears in an identical phrase: "a series of O-ring elements

stacked together and connected to form a unitary structure." '866 Patent, col. 15: 52-54; '592 Patents, col. 15: 63-65. In the

'862 patent, the term appears in the following phrase: "wherein said seal has at least one groove defined by at least two O-

ring elements forming a portion of said seal[.]" '862 Patent, col. 16, 17-19.

- - - - - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - -

RyMed responds that ICU's emphasis on the word "elements" in construing the claim term "O-Ring elements" is

inappropriate, (See D.I. 232, at 50:11-14), because it allows ICU to construe "O-ring elements" significantly more broadly

than the actual term "O-ring." (D.I. 116, at 21.) RyMed also argues that ICU's construction is confusing, unclear, and will be

unhelpful to the jury. (Id.) RyMed contends its construction is appropriate because it reflects the ordinary meaning of "O-

ring," and is consistent with the patent disclosure. (Id. at 20.)

Both parties agree as to the ordinary meaning of O-ring. (Compare D.I. 232, at 52:7-10 (RyMed stating that an O-ring is a

"circular torus or doughnut-shaped ring") with id. at 83:23-25 (ICU stating "we agree an O-ring is like a doughnut").) The

issue is whether the term "O-ring elements" has a different meaning than "O-ring," namely as a description of the seal's

appearance rather than as a description of its structure. The Court is persuaded that ICU's construction is more appropriate

because support for their position can be found in the Common Specification and prosecution history.

There is limited use of the term "O-ring elements" in the Common Specification. The Summary of the Invention states, "[a]

preferred embodiment of the seal comprises a series of O-ring elements stacked together and connected to form a unitary

structure." '866 Patent, col. 3: 63-66. A description of a preferred embodiment can help define what is claimed, but without a

specific declaration, it does not limit what the patent claims. See Liebel-Flarsheim Co., 358 F.3d at 906. In fact, both

Figures 9 and 13 illustrate features of the preferred embodiment. See '866 Patent, col. 5: 19-20, 47-48, 58-59. Figure 9

displays a "seal wall consisting of a plurality of ringed wall portions 94 that expand and collapse in an accordion like

fashion." Id. at col. 12:4-5. Figure 13 displays a seal with a "wall 150 comprised on circular tires 100 stacked in a series one

on top of an adjacent larger diameter tire." Id. at col. 12:47-49. Therefore, ICU's contention that "O-ring elements" should

not be construed as merely a device of actual O-rings is supported in the Common Specification.

The prosecution history of the '862 Patent provides additional confirmation that RyMed's more limited construction is

unsupported. "In order to disavow claim scope during prosecution 'a patent applicant must clearly and unambiguously

During the course of the '862 Patent's prosecution, the Examiner rejected claims 70 and 71 (which ultimately issued as

claims 2 and 3) for indefiniteness because it was unclear whether the "at least two O-ring elements" were on the seal or

made up the seal. (D.I. 120, Ex. D, at 1236.) ICU clarified that the O-ring elements form a portion of the seal, and further

stated that "[s]upport for amended Claim 70 can be found on page 15, lines 27-29, which disclose that the 'seal wall' consists

'of a plurality of ringed wall portions 94 that expand and collapse in an accordion like fashion.'" (Id.) With regard to

amended Claim 71, ICU stated, "the Examiner's attention is respectfully drawn to Figure 9 which illustrates a plurality of O-

ring elements. . ." (Id.)
Although RyMed contends these statements were irrelevant to the indefiniteness rejection, the prosecution history, at a minimum, demonstrates that the ICU patentee did not explicitly disavow the claim scope currently advocated by ICU's proposed construction. In sum, nothing in the Common Specification or prosecution history supports a reading of "O-ring elements" which gives no meaning to "elements," a word included in the disputed term. Thus, the Court concludes "O-ring elements" means "portions having a circular outer surface that is wider at the middle than at the top or bottom."

10. Object

Defendants' Proposed Construction: An "object" is any article having three dimensions.
Plaintiff's Proposed Construction: Leave undefined.
The Court's Claim Construction: An "object" is any article having three dimensions.

MPT does not dispute Defendants' definition of object. Instead, it claims that it would confuse the jury to provide a definition for this non-technical term. However, the Court perceives no harm in providing this definition to the jury and adopts Defendants' definition.

GO BACK

2688

1. object(s)

The term "object(s)" appears in claims 1 - 24 of the '874 patent, claims 1 - 20 of the '786 patent, and claims 26 - 28 and 40 - 43 of the '213 patent. The plaintiff proposes a construction of "a physical thing capable of being grasped in a human hand." The defendant's counter-construction is "a block," and the defendant further argues that the term "'object' does not include keyboards, mice, pens, wands, instruments for writing or hand signing on graphic tablets or touch screens, or other devices not specifically adapted for a child's use." The court finds the defendant's arguments unpersuasive.

The defendant argues that the patentees' repeated use of the term "block" within the written description to describe certain preferred embodiments of the invention limits the construction of the term "object" to "block." In support of its argument, the defendant cites isolated claim construction canons from SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001), Genzyme Corp v. Transkaryotic Therapies, Inc., 346 F.3d 1094, 1099 (Fed. Cir. 2003), and other Federal Circuit cases. These cases are inapposite. 2 As the Federal Circuit has stated, "[w]hether an invention is fairly claimed more broadly than the 'preferred embodiment' in the specification, the context in which the embodiment is described, the prosecution history, and if appropriate the prior art ... ." Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999).

2 As the Federal Circuit has stated, "[a]lthough precedent offers assorted quotations in support of differing conclusions concerning the scope of the specification, these cases must be viewed in the factual context in which they arose." Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). "All rules of construction must be understood in terms of the factual situations that produced them, and applied in fidelity to their origins." Modine Mfg. Co. v. US. Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996). "[W]hen the preferred embodiment is described in the specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment." Id. (emphasis added).

A review of the patentees' specification reveals that although many of the embodiments described in the written description use the term "block," other embodiments in the specification, including the written description, fail to use such limiting term. For example, the original claims, filed as part of the specification of the parent '437 application, use the term "object"
in contrast to the use of the more limiting term "block." Opening Brief of the Plaintiff, Exhibit 6 at 22-23. Additionally, the specification supports a broader construction of the term "object." For example, the specification describes "objects" as "computer-recognizable characters." See '874 patent at 1:12-19, 3:1-5. In light of the intrinsic evidence contained in the specification, the court concludes that the term "object" is not limited to a "block."

Next, the defendant argues that the term "object" does not include "keyboards, mice, pens, wands, instruments for writing or hand signing on graphic tablets or touch screens, or other devices not specifically adapted for a child's use." Brief of the Defendant at 19. In support of its position, the defendant asserts that the patentees disclaimed the above subject matter during prosecution before the patent office. 3

Footnotes - - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

End Footnotes - - - - - - - - - - - - - -

The defendant's argument is misplaced. The cited portions of the prosecution history are consistent with the specification as originally filed. For example, the patentees' statements during prosecution are consistent with the following statement by the patentees in the Background of their specification: "young children have not yet developed the mental capabilities or the motor skills to interact well with conventional computers, which require data to be entered, for example via the keyboard or mouse, in a fixed format," as well as the following phrase in the plaintiff's reply brief: "[t]he kinesthetic activities of typing, manipulation of a mouse, or handwriting or hand signing are not covered by [this] invention." '874 patent at 1:33-36; Reply Brief of the Plaintiff at 11. Additionally, the specification contemplates that "objects" may be used by an adolescent or an adult. See '874 patent at at 3:13-16, 9:48-57 (describing embodiments for learning braille and playing board games).

For the foregoing reasons, the court rejects the defendant's attempt to limit this term and concludes that the term "object" means "a physical thing (or item)."

2689

A. "An Object to Be Magnetically Heated Including an Induction Heatable Element and an RFID Tag"

The parties dispute the proper construction of the term "an object to be magnetically heated including an induction heatable element and an RFID tag," which object is included in the apparatus claimed in the '585 Patent. TSI argues that the term means an object that includes an induction heatable element and an RFID tag; defendants argue that the term should be construed to mean a food delivery container made of a non-inductively heatable material that includes an element and an RFID tag; but not a temperature sensor. Thus, TSI essentially repeats the claim language, while defendants define "object" in the claims to include three limitations not found in the claim language: (1) the object is a food delivery container (2) that is made of non-inductively heatable material and (3) that cannot include a temperature sensor. Defendants do not rely on any express definition of "object" or disclaimer or disavowal of claim scope in the patent; rather, defendants rely on the Microsoft standard, discussed above, which allows the claim scope to be limited if the patent "repeatedly and consistently" describes the scope of the invention (and not a mere embodiment) as limited. 3

Footnotes - - - - - - - - - - - - - -
3 The Court does not agree with defendants' argument that reference to the '585 Patent's specification is required here to provide context because "object" is a common, non-technical word that necessarily requires limitation. The word is not ambiguous, and the claims themselves provide sufficient context and limitations to ensure that not every conceivable "object" in the world is claimed in the patent. Because there is no clear disclaimer or disavowal of claim scope here, TSI is entitled to the entirety of its patent claims, subject to limitations imposed by consistent and repeated descriptions of the invention under Microsoft. Any argument that the patent's claims are impermissibly broad must await later proceedings, as only the construction of the patents is presently before the Court.
With respect to the first limitation urged by defendants, the Court concludes that the '585 Patent's specification does repeatedly and consistently describe the invention as a whole as a "food delivery system" involving a "food container". The title of the patent is "Temperature Self-Regulating Food Delivery System." The first sentence of the patent's Abstract states that "[t]emperature self-regulating food delivery systems are provided." The Background of the specification begins as follows:

The present invention is broadly concerned with food delivery systems designed to maintain food at a selected temperature over relatively long periods of time. More particularly, the invention pertains to such food delivery systems which include a magnetically heatable thermal storage device within a food-holding container . . . .

('585 Patent at 1:11-18.) The Background section concludes as follows:

There is accordingly a need in the art for an improved food storage and delivery system which will permit the purveyor to maintain the food products at or near a desired temperature over sustained periods, while also allowing delivery under conditions to substantially maintain this temperature. An effective hot food storage and delivery system thus requires a lightweight delivery container . . . .

(Id. at 2:5-11.) Similarly, the Summary of the Invention in the specification begins with the following statement:

The present invention overcomes the problems outlined above [in the Background] and provides a food delivery system broadly including a food delivery container equipped with a thermal storage device with the latter being heated while in the container by a magnetic induction charging station.

(Id. at 2:18-22.) The specification's Detailed Description of the Preferred Embodiments begins as follows:

The present invention provides a food delivery system broadly comprising a food delivery container . . . . As explained above, one type of food item requiring temperature maintenance during delivery is pizza, and accordingly certain embodiments of the invention are specific to this problem. However, it should be understood that the invention is not limited to pizza temperature maintenance, but rather relates to any type of food delivery system for virtually all food items which require or may be rendered more palatably by temperature maintenance.

(Id. at 5:25-38.)

Thus, contrary to TSI's argument, the patent's specification does not describe an invented heating system that can, among other things, be used to solve food delivery problems. Rather, the patent repeatedly and consistently describes the invention as a whole, and not a mere embodiment of the invention, as a food delivery system involving a food delivery container. Even the specification's language that attempts to ensure a construction broader than the mere embodiments, quoted above, describes the invention as a food delivery system (as opposed to the pizza delivery system described as the preferred embodiment). Accordingly, the Court agrees with defendants that the object described in the claims should be limited to a food delivery container.

TSI argues that application of the Microsoft standard is not appropriate here, despite the quoted descriptions of the invention as a food delivery system, because the claim refers to an "object" and not the more specific "container", and thus the required "consonance" between the claim and the specification is missing here. The Court rejects this argument, as there is no authority for limiting the Microsoft standard in this way. As explained above, claims are properly limited to the repeated and consistent description of the actual invention. TSI's citation to this Court's decision in MGP Ingredients, Inc. v. Mars, Incorporated, 494 F. Supp. 2d 1231 (D. Kan. 2007), is inapt, as that case did not involve application of the Microsoft "repeated and consistent description" standard. See id. at 1236-39.

TSI also argues, based on the doctrine of claim differentiation, that "object" in the independent claims of the patent must be broader than food delivery containers in light of dependent claims 2 and 5 in the patent, which claim the apparatus and method of independent claims 1 and 4 "with said object comprising a food holding container." The Federal Circuit has stressed, however, that the presumption that dependent claims must be narrower than their independent claims is rebuttable,
and the presence of such dependent claims is therefore not dispositive:

[While it is true that dependent claims can aid in interpreting the scope of claims from which they depend, they are only an aid to interpretation and are not conclusive. Indeed the presumption created by the doctrine of claim differentiation is not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history.

Regents of Univ. of Calif. v. Dakocytomation Calif., Inc., 517 F.3d 1364, 1375 (Fed. Cir. 2008) (internal quotations and citations omitted). In this case, the specification's clear description of the claimed invention (and not merely an embodiment) as a food delivery system involving a food container dictates the construction urged by defendants and overcomes any presumption raised by the dependent claims. See Sprint v. Big River, 2009 U.S. Dist. LEXIS 58161, 2009 WL 1992537, at *12-13 (concluding that consistent and repeated description of invention as limited rebutted presumption raised by dependent claims).

Defendants have not pointed to any portions of the patent's specifications in which the invention is consistently and repeatedly described with the second and third limitations urged by defendants in their construction of "object" (relating to non-inductively heatable material and the absence of a temperature sensor). Thus, there is no basis to construe the term "object" to include those limitations.

Accordingly, the Court construes the term "an object to be magnetically heated including an induction heatable element and an RFID tag," found in the claims of the '585 Patent, to mean a food delivery container to be magnetically heated that includes an induction heatable element and an RFID tag.

2690

d. '314 patent, claim 1, element 3: "objective lens means disposed on said surgical microscope positioned within said three-dimensional space." 27

27 Same construction for '314 patent, claim 14, element b.

This element is construed to cover an objective lens positioned within stereotactic three-dimensional space. The only dispute on this element is whether the objective lens must be attached to a stereotactic frame. The Court concludes that it does not because such a requirement would exclude potential embodiments not using a stereotactic frame. Drawings and passages in the specification support this interpretation. See '314 patent, col. 14, ll. 22-26 & Fig. 39.

2691

The Defendants raise four objections to the constructions by the SM of the '118 patent. The objections raised center upon claim 1 of the '118 patent which reads:

A load bearing deck structure comprising:

at least one sandwich panel formed of a polymer matrix composite material, said sandwich panel comprising a plurality of substantially hollow, elongated core members having side walls, said core members being provided with an upper facesheet and a lower facesheet wherein said facesheets are formed integrally with the side walls of the core members, and wherein at least one of the side walls is disposed at an oblique angle to one of the upper and lower facesheets such that the side walls and facesheets define a polygonal shape when viewed in cross-section.
The Defendants object to the construction recommended by the SM as to the term "oblique angle." The SM recommended that this term be construed as "an angle that is neither a right angle nor a multiple of a right angle." SM Report, p. 176. The Defendants disagree with this construction presenting several arguments.

First, the Defendants argue that the inventors meant such term "to describe an angle that is formed when two walls connect or intersect." Defendants' Obj., p. 8. The SM disagreed with this construction concluding that the claim language only required that one side wall be disposed at an oblique angle in order to define a polygonal shape in viewing the side walls and facesheets in "cross-section." SM Report, p. 161. The SM went on to review the specification and conclude that a specific measure of angle is not required for the oblique angle within this invention. SM's Report, pp. 170-172. The SM further analyzes the issue of connection or intersecting to form the oblique angle in claim 1, but the SM finds that the Defendants' true issue is with the word "disposed" and if the patentee wanted to claim an intersection between a side wall and an upper or lower facesheet at an oblique angle to define a polygonal shape, language to this effect would be within the claim. SM's Report, p. 174.

Second the Defendants argue that an angle "is only formed when two lines come together at a point" and that the side wall disposed at an oblique angle to the facesheets naturally must connect with a facesheet to form this angle. Defendants' Obj., p. 9. In evaluating the second argument, the Court agrees with the conclusions of the SM. In particular, the Court observes in addition to the SM's reasoning that the positioning of the side walls with respect to the upper and lower walls can be "in a variety of shapes angles with respect to the upper and lower walls." '118 Patent, col. 5, lines 24-25. Furthermore, the presence of the oblique angle "[proportional]" is shown within figure three of the '118 patent and it is present within the elongated core member without the attachment of the facesheets. This is explained by the SM at page 165 of the SM's report and in particular the citation of the specification in the following language: "The oblique angle "[proportional]" of the side wall 48 with respect to the upper wall 64 is preferably 45 [degrees], but angles between about 30 [degrees] and 45 [degrees] can be provided in alternative embodiments." '118 patent, col. 10, lines 5-8. Reading this portion of the specification with the preferred embodiment in figure three (see page 8, infra) demonstrates the existence of angle "[proportional]" independent of the integral formation of the sandwich panel as defined in the patent. The specification presents more relevant evidence demonstrating the existence of angle "[proportional]" independent from the integration of the core members with the facesheets: "When normalized by weight, the trapezoidal tube 46 with at least a 45 [degrees] angle between the sidewall 48 and the upper wall 64 and the lower wall 65 has a transverse shear stiffness 2.6 times that of a tube with a square cross-section. Alternatively, for a tube with an oblique angle of about 30 [degrees], the transverse shear stiffness is 2.2 times that of a tube with a square shaped cross-section." '118 patent col. 10, lines 31-37. To repeat the analysis of the SM, the language of the claim uses the words "disposed at", in reference to the placement of the sidewall in reference to the facesheet and does not use any words such as "connecting at", "intersecting at" or "forming" which would indicate the meeting of a sidewall and a face sheet to form the oblique angle. Furthermore, the disposal of the sidewall at the oblique angle is to achieve the purpose of having "the sidewalls and facesheets define a polygonal shape when viewed in cross-section" '118 patent col. 24, lines 12-14. The defining of the polygonal shape is obtained when viewing this sandwich panel, as defined, in a cross-section. However, a polygon is formed by the shape of the core member, not by its integration with the facesheets. The specification language describing the preferred embodiment makes this clear:

The core members are shown as hollow tubes of trapezoidal cross-section (FIGS. 2, 3 and 7). Each of the trapezoidal tubes includes a pair of sidewalls 48, 49. One of the sidewalls 48 is disposed at an oblique angle a to one of the upper and lower facesheets 35, 40 such that the sidewalls 48, 49 and the upper wall 64 and lower wall 65, when viewed in cross-section, define a polygonal shape such as a trapezoidal cross-section (FIG 3).
Third, the Defendants argue that with the integral formation of the facesheets and the sidewalls with one sidewall disposed at an oblique angle, a polygonal shape is defined and that any sort of "open shapes" similar to that suggested by the SM is not what was intended by the inventors. Defendants' Obj., pp. 10-11. Fourth, the Defendants argue that the oblique angle described in the '118 patent is "important to the invention, [and] increases the likelihood that the patent claims covering the invention were intended to include that important feature as it was described" and that such angle is formed from a sidewall and facesheet. Defendants' Obj., pp. 12, 11.

While the Court agrees with the SM's conclusions as to the matters concerning the Defendants' third argument, the Court understands the Defendants' concern within its third argument regarding the SM's discussion of the word "define" and his conclusion that five lines that do not intersect or connect and the drawing of the five lines on page 175 of the SM's Report define a polygonal shape (a pentagon in this instance), but not a polygon. While the Court does not adopt the SM's analysis on this matter, it understands that this exercise on page 175 of his report was meant to make a point of the exercise of claim construction. The Court takes this opportunity to explain its analysis on this matter and present its own analysis that arrives at the same claim constructions of the SM while simultaneously addressing the Defendants' third and fourth arguments presented above and touching upon issues related to the first and second arguments.

The claim language reads "wherein at least one of the sidewalls is disposed at an oblique angle to one of the upper and lower facesheets such that the sidewalls and facesheets define a polygonal shape when viewed in cross-section." '118 patent, col. 24, lines 11-14. The SM stated that "The following may be reasonably said to 'define' a 'polygonal shape,' i.e., one that identifies the essential qualities of a polygonal shape:

[SEE ILLUSTRATION IN ORIGINAL]

even though the lines do not intersect and the figure is not, therefore, a polygon per se, although it is a polygonal shape." SM's Report, p. 175.

The Court agrees that in the Defendants' third argument that the inventors never intended that the "polygonal shapes," which are defined when obtaining a cross-sectional view of the sandwich panel, included the "open" shapes as suggested by the SM. The SM used the term "define" as quoted above in the context of "identifies the essential qualities of." The word "define" has multiple meanings in the English language one of which is "to describe the nature or basic qualities of" and other meanings include "to delineate the outline or form of" and "to specify or fix distinctly." WEBSTER'S II NEW COLLEGE DICTIONARY 296 (2001). The Court agrees with the Defendants' argument that defining a polygonal shape, as those terms were used in claim 1 of the '118 patent, does not mean that a polygonal shape can be defined through a form that includes lines that never intersect or connect. Rather, the word "define" as the Court interprets it and will use within the following analysis, is in the sense of delineating the form of a shape, in this instance a polygon. At the risk of sounding redundant, the word "define" requires a definiteness to it; a certainty in its form. This is clear from the specification language which refers to figure three of the '118 patent. '118 Patent, col. 9, lines 65-67, col. 10, lines 1-5. This is apparent from figure three of the '118 patent:

GET DRAWING SHEET 3 OF 16

Nowhere is the trapezoidal shape of the core members defined by non-intersecting lines. The Court therefore finds that the language of the specification and the non-technical meaning of the word "define" is understood to have the same meaning in this instance: delineating the form of a shape. In this example, the shape is a trapezoid.

However, the Court still agrees with the SM as to the issue that one of the sidewalls and the upper and lower facesheets never connect, intersect or meet to create the oblique angle, contrary to the Defendants' contentions. The claim language requires integral formation of a sandwich panel, as defined by the inventors, that when viewed in a cross-section defines a polygonal shape. Figure three of the '118 patent illustrates the exploded view of a sandwich panel described in that patent, but not yet integrally formed with the trapezoidal shaped elongated core members. Figure seven of the '118 patent demonstrates a cross-sectional view of two sandwich panels after integral formation that are being joined with a key lock:

GET DRAWING SHEET 5 OF 16

The view of the trapezoidal shape is apparent after the integration of the facesheets and core members. To further explain
the Court's reasoning, the following illustration is made by the Court:

[SEE ILLUSTRATION IN ORIGINAL]

In the Court's illustration, the facesheets and the upper and lower walls of the core members are assumed to be formed integrally and the sandwich panel exists after this integration. In View 1 above, the areas labeled as "1" and "2" have the form of trapezoids having a common side and they have such a polygonal shape because of the form of the core members that were integrated with the facesheets to form the sandwich panel. The areas "1" and "2" are formed based upon the shape of the trapezoidal core members, not because of the integration of the facesheets with the core members. That is to say, the addition of the upper and lower facesheets does not add a missing side or piece that create the trapezoidal form shown in the preferred embodiment of figures three or seven in the '118 patent. It is clear from the language of the claim and specification and the illustrations above that the use of the word "disposed" within claim 1 sets forth a different purpose that is not the formation of a trapezoidal or other polygonal shape, but is for the purpose of ensuring proper formation of the sandwich for the deck described in the '118 patent.

It has been noted above that trapezoids and other polygonal shapes may be used to provide a form to the elongated core members. '118 patent, col. 10, lines 40-47. The core members are noted as being "substantially hollow" and it is apparent from this design that the description of the core members as "having sidewalls" that the core members are in the shape of a polygon, which is a form that is enclosed. Claim 1. Thus, the idea of a polygonal shape is rooted within the design of the elongated core members. The language of the specification proves this: "The core members 46 are shown as hollow tubes of trapezoidal cross-section (FIGS. 2, 3 and 7)."... "a variety of sizes, shapes and configurations of the elongated core members can be provided. Various other polygonal cross-sectional shapes can also be employed, such as quadrilaterals, parallelograms, other trapezoids, pentagons, and the like." '118 patent col. 9, lines 65-66, col. 10, 40-44. However, the core members are not the sandwich panel in and of themselves.

The Court finds the claim language, specifically the second "wherein" clause of claim 1, which includes the "disposed at an oblique angle..." language, is the basis for evaluating the proper integration of the core members with the facesheets to create the sandwich panel and not a description of how the oblique angle is formed. For instance, if one were to attempt to form the sandwich panel, but not follow the claim language and attach the facesheets to the core members while still having one of the sidewalls disposed at an oblique angle to the facesheets, the resulting structure would appear like View 2 in a cross-section because the facesheets could only attach to the core members in one alternative manner, that is by attaching to the sidewalls, instead of the upper and lower walls:

[SEE ILLUSTRATION IN ORIGINAL]

This resulting formation would be contrary to the claim language and clearly not covered by the patent. In View 2, a polygonal shape of a trapezoid is defined, but not in accordance with the claim language, which requires that the polygonal shape be defined by the sidewalls and the facesheets. Here one facesheet (as integrated with a sidewall), one sidewall of a core member (disposed at an oblique angle), and the upper and lower walls of a core member define the polygonal shape of a trapezoid. When compared with this view, the claim language is understood as requiring a sandwich panel that when properly formed, through whatever process instructed by the patent, presents a polygonal shape through the integration of core members with facesheets such that "wherein at least one of the sidewalls [of a core member] is disposed at an oblique angle to one of the upper and lower facesheets such that the sidewalls and facesheets define a polygonal shape when viewed in cross-section." '118 patent col. 24, lines 10-14 (Claim 1). View 1 above clearly comports with the claim language whereas View 2 does not. View 1 presents a polygonal shape as defined by facesheets (as integrated with the upper and lower walls) and the sidewalls. As the SM concluded, the definition of the term "disposed" is what the Defendants are truly arguing against when they attempt to argue that having a sidewall disposed at an oblique angle to a facesheet thereby establishes a "natural conclusion" that a connection, intersection or meeting exists between the sidewall, disposed at an oblique angle, and a facesheet. Such is not the case in the '118 patent when one follows the claim language and the specification language in attempting to create the sandwich panel as patented. The Court is therefore in agreement with the SM's analysis on this point. SM's Report, p. 175.

The Court further concludes that the integrated core members' sidewalls and facesheets, define, that is delineate the outline of, a polygonal shape when viewing the sandwich panel in a cross-section. However, the Court understands that the SM's discussion of non-intersecting lines that define a polygonal shape added confusion to his analysis on the issue of defining
the claim's phrase "disposed at an oblique angle" when it is clear from the language in the specification that the core members when viewed from the side are in the shape of a polygon, and the "core members being provided with an upper and a lower facesheets wherein said facesheets are formed integrally with the sidewalls of the core members, and wherein at least one of the sidewalls is disposed at an oblique angle…such that the sidewalls and facesheets define a polygonal shape when viewed in a cross-section." '118 patent, col. 24, lines 7-14. Reading this claim in context, it is apparent that the two "wherein" clauses direct the manner in which the core members are "provided" facesheets, specifically the placement of the facesheets and what a resulting cross-section of a properly integrally formed sandwich panel would appear like to the naked eye.

While the Defendants are correct that the oblique angle is the key to the strength produced in this sandwich panel, and deflection of the facesheet is created by this form, the oblique angle is not created by the connection of one of the sidewalls with the facesheets. It is clear from the specification that the oblique angle exists and is intact within an elongated core member prior to integration of the facesheets and core members as a sandwich panel.

II. Compliance with Phillips

The Defendants' next objection relates to the manner in which it views the SM's report as not complying with the requirements for claim construction set forth in Phillips v. AWH Corp., et al., 415 F.3d 1303 (Fed. Cir. 2005). In accordance with Phillips, a court construing claim terms is to avoid construction of terms in a broad manner by relying upon the meaning of the terms which derive from the patent itself; to achieve this result, the Court of Appeals for the Federal Circuit found that claim construction must rely primarily on intrinsic sources, in particular, the language of claim itself, and the specification which assists in defining claim terms and that placing primary reliance upon extrinsic sources such as dictionaries and treatises in order to establish the meaning of a claim term rather than use of intrinsic sources is incorrect when such extrinsic sources contradict the claim and specification language. Phillips at 1320-1324. However, the Court of Appeals did not establish a specific form for claim construction and recognized that the use of different sources in various sequences of analysis is permitted so long as no preference is made for construction of terms that would contradict an unambiguous construction derived intrinsic evidence, such as the specification. Phillips at 1324.

A review of the SM's Report reveals that the SM has complied with the manner of construing patent claims as set forth in Phillips. While the SM does refer to extrinsic evidence at times, such as dictionaries and different internet world wide web sites, such use of extrinsic evidence did not violate the dictates of Phillips. The SM consistently gave the intrinsic evidence, particularly the language of the claim and the specification, due deference. Although the references to extrinsic evidence may be in an order of presentation which one may find to be indicative of primary reliance on such sources, a specific order of presentation or review of evidence is not mandated by Phillips. Phillips at 1324. The SM gave proper weight to the intrinsic evidence in relation to any extrinsic evidence. The Court will now address specific references to the SM's Report in regard to the Defendants' objections on this matter.

While it is clear that the SM utilized common dictionary definitions in his analysis of the terms "disposed at an oblique angle," this use of dictionary terms was not inappropriate, but consistent with the claim language. SM's Report, pp. 160-176. In the beginning of the SM's discussion concerning the "disposed" issue, he relies upon the claim language but recognizes that the common dictionary definition of "disposed" presents the same meaning as the sense that word is used in the claim language and therefore cites to the specification language to buttress this conclusion. SM's Report, p. 160. The SM then dissects the idea of "oblique angle" and begins with the claim language, considers the idea of "customary' meaning," that is the meaning understood by one familiar in the art after considering the patent language and then moves onto the specification language and if that language provides interpretation of the claim term as it would be customarily understood in the patent's claim. SM's Report, pp. 161-164; Phillips at 1321. The SM further evaluates the specification language and embodiments and related patents as well as specialized and common dictionary meanings and the language of claim 1 again. SM's Report, pp. 165-172. The SM concludes that the meanings of "oblique angle" are the same whether one considers the patent language, or the common English or customary definition within the art meanings of that term and this is not contrary to the precedent in Phillips. SM's Report, pp. 172-173. Furthermore, the SM relies on the language of claim 1 to address the Defendants' concern regarding the construction of the term "disposed." SM's Report, p. 175. Aside from the exercise with the word "define" and the analysis thereon made by the SM, and the substituting of the Court's analysis on that matter for the SM's analysis of the word "define," the SM complied with the dictates of Phillips in the manner in which he conducted his construction contrary to the Defendants' objections. Defendants' Obj., pp. 13-16; SM's Report, pp. 175-176. These objections are denied.
Contrary to the Defendants' contention, the angle at issue in claim 1 of the patent is not formed when two structures come together, but the angle is formed by the inherent nature of the core member and the intersection of one of its sidewalls and upper or lower walls. Defendants' Obj., pp. 16-17. The "disposal" or arrangement of the sidewall to the facesheet establish the proper formation of the sandwich panel. In light of the Court analysis above, this will not be addressed again. These objections are denied.

The Defendants' remarks as to the disparagement of triangles has also been evaluated closely and again the Court agrees with the SM. See Defendants' Obj., pp. 17-18. The Defendants' contend that triangular shaped core members are not included within the patent, but the SM disagreed finding no such limitation within the patent. SM's Report, pp. 167-170, 171 n.37. The Defendants' quotations on page 17 and 18 of its objections point to an issue with regard to use of the triangular shape in the sandwich panel, specifically with regard to the language: "with composite materials has presented problems of failure in the resin bonded nodes of the triangular shape. Therefore, a modular structural composite component for structural supports is needed which overcomes this problem." '118 patent col. 3, lines 38-44. Without re-quoting the next quotation used by the Defendants, it is important to read the Defendants' quotation with the unquoted preceding sentence which reads: "It is believed that such forming overcomes the problem of node failure experienced in forming triangular shapes with composite materials." '118 patent col. 11, lines 18-20. Reading this sentence in context with the surrounding language reveals that this specific problem with node failure in triangular shapes of composite materials can be overcome through the manner of hand layup described in the preceding paragraph. '118 patent col. 11, lines 9-28. Therefore, the disparagement of triangular shapes is made in the context of the manner of using such shapes in the formation of the core members. This objection is denied.

To address the Defendants' argument that no recommendation has been made as to the issue of whether a "connection/intersection/meeting" between the sidewall disposed at an oblique angle and upper and lower facesheets, the Court finds that such sidewall is not required to be connected to, intersected with or meet with the upper and lower facesheets. See Defendants' Obj., p. 18. It is clear from the SM's Report that this issue was addressed and was found to require no connection between the sidewall and facesheets. SM's Report, pp. 160-161. The SM addressed this issue again in response to the Defendants' comments and the Court need not repeat that response here. SM's Report, pp. 173-176. The SM's recommendation did not include language referring to any "connection/intersection/meeting" because his analysis did not find that the language of the claim regarding "disposed at an oblique angle" was intended to mean or refer to such a meaning-this is clear from the SM's analysis. This objection is denied.

A suggested construction of the phrase "oblique zone" was given by the magistrate judge in addressing the related phrase, "a second oblique zone offset angularly from said first zone," which is found in the '525 patent. ADE Corp., 220 F. Supp. 2d at 315-19. Pursuant to Federal Rule of Civil Procedure 72, ADE has objected to the recommendation of the magistrate judge on that point. 18 (D.I. 533 at 15-22.) KLA, of course, urges the Court to adopt the construction suggested by the magistrate judge. (D.I. 615 at 1-12.) The Court takes this opportunity to deal with the term "oblique zone" as used in the '259 patent to simultaneously address ADE's objection to the magistrate judge's recommendation regarding the related phrase in the '525 patent. The following analysis is thus based not only on the parties' submissions with respect to the '259 patent but also on a de novo review of the evidence and arguments presented to the magistrate judge with respect to the phrase "second oblique zone offset angularly from said first zone" as found in the '525 patent claims.
18 Since patent claim construction is a question of law under Markman, even though not case dispositive, the magistrate judge's opinion is subject to plenary review. See, e.g., Haines v. Liggett Group, Inc., 975 F.2d 81, 91 (3d Cir. 1992) (district court exercises plenary review of magistrate judge's rulings of law).

The magistrate judge observed that the phrase "second oblique zone offset angularly from said first zone" first appeared in the prosecution history of the '525 patent "after being added almost two years into prosecution." Id. at 317. Although ADE argued that the inventors did not intend for the phrase to have a specialized meaning and that "those skilled in the art would readily comprehend what is meant[,]" id., ADE was unable to offer any pertinent art reference that would explain the meaning of the phrase. Id. at 317. Instead ADE urged the Court to apply a dictionary definition of "oblique" as modifying a dictionary definition of the word "zone." Id.

Turning to the specification and prosecution history of the '525 patent for assistance, the magistrate judge stated that the separate collection of forward, central, and backward scattered light was consistent with the "internal logic" of the '525 patent disclosure and it was also consistent with the applicants' arguments during patent prosecution. Id. at 318-19. In light of the record, she construed the phrase "second oblique zone offset angularly from said first zone" to mean "a second collection zone differing in polar angle from the central collection zone that does not collect the same light being collected by the 'central zone' but, instead, collects either forward or backward scattered light but does not collect both simultaneously." Id. at 319. The magistrate judge reached that conclusion by reasoning that, in prosecuting their application, "the inventors predicated patentability on separate collection of forward and/or backward scattered light … in addition to collection of light scattered generally in the normal direction." Id.

1. ADE's Position

ADE devoted most of its Opening Claim Construction Brief (D.I. 595) to a discussion of the relevance and importance of the "oblique zone" claim limitation. It argues that Federal Circuit precedent requires the Court to first assess the ordinary meaning of individual claim terms such as "oblique" and "zone" before considering the remainder of the intrinsic record to arrive at a construction for a disputed claim phrase. (Id. at 14-16.) According to ADE, the magistrate judge failed to follow that course and was instead persuaded by KLA to read the preferred embodiment of the invention into the construction of "oblique zone," which "resulted in the incorporation of the extraneous limitation that the oblique zone collects 'either forward or backward scattered light but does not collect both simultaneously.'" (Id. at 16-17.) The correct course, says ADE, is for the Court to consider the dictionary definition of the word "oblique" because it has a plain and ordinary meaning which, when combined with the common word "zone," gives the phrase "oblique zone" a plain and ordinary meaning as well. (Id. at 18-21.) The construction that ADE proposes be adopted would define "oblique zone" as "a light collecting zone positioned to collect light generally scattered obliquely (i.e., neither parallel nor perpendicular to the workpiece surface), and that is offset angularly from the central zone in the polar direction". (Id. at 3.)

ADE also asserts that the doctrine of claim differentiation supports its proposed construction for "oblique zone," since dependent claims 3, 4, 5, and 6 of the '259 patent "specify forward and backward limitations, reinforcing the breadth of claim 1." (Id. at 22.) In other words, ADE contends that since there are dependent claims that do have explicit limitations on the separate gathering of forward and backward scattered light, it is error to read claim 1, from which those later claims depend, to include such a limitation. (See id.)

Finally, in an attempt to rebut efforts by KLA to focus the Court's attention on the prosecution history of the patent, ADE argues that the intrinsic record is not clearly inconsistent with its proposed construction and does not evidence a clear and unambiguous disavowal of claim scope. (Id. at 22-27.)

2. KLA's Position

As earlier noted, KLA asserts that the magistrate judge properly construed the phrase "oblique zone" and, therefore, the construction given the phrase in connection with the '525 patent should apply to the '259 patent as well. 19 (D.I. 615 at 3.) In support of the approach taken by the magistrate judge, KLA points out that the magistrate judge first concluded that the phrase "oblique zone" has no ordinary or pertinent art meaning before she examined the remainder of the intrinsic record for guidance, all of which was and is consistent with Federal Circuit precedent. (Id. at 3-6.) Finally, KLA argues that an
Similarly, in Schumer v. Lab. Computer Sys., Inc., 308 F.3d 1304 (Fed. Cir. 2002), the Court held that the lower court's

because both possible constructions were viable, given the intrinsic record before the Court. Id. at 1379-82.

The Court then reversed the lower court for adopting only one of the two applicable meanings of the intrinsic record to "determine whether the specification or prosecution history clearly demonstrates that only one of the multiple meanings was intended." Id. at 1378-79 (citing Renishaw PLC v. Marposs Societa per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998)). The Court then commented that the word "on" had a special form of extrinsic evidence that it had not been defined by the specification or prosecution history, thus leading the Court to construe the remainder of the phrase in which the word appeared. Id. at 1378. The Court then used that definition in its construction of the remainder of the phrase in which the word appeared. Id.

For example, in Inverness Medical Switzerland v. Princeton Biomeditech Corp., 309 F.3d 1365, (Fed. Cir. 2002) ("Inverness I"), a case cited by ADE in support of its argument, the parties disputed a claim phrase containing the word, "mobility." 309 F.3d at 1369. The meaning of that word, reasoned the Court, was not disputed by the parties but was central to the controversy. Id. The Court, therefore, looked in a dictionary and chose, of the multiple dictionary definitions of "mobility," the one most appropriate in view of the intrinsic evidence before the Court. Id. at 1369-70. The Court then used that definition in its construction of the remainder of the phrase in which the word appeared. Id.

In Inverness Medical Switzerland v. Warner Lambert Co., 309 F.3d 1373 (Fed. Cir. 2002) ("Inverness II"), which ADE also cites, the Court "looked … to the dictionary definitions of the claim terms 'on' and 'onto' as of the date the patents issued." 309 F.3d at 1378. Reasoning that the definition of the word "onto" referred to the word "on," the Court concluded "that both prepositions are properly addressed through the interpretation of 'on'" Id. The Court then commented that the word "on" had been used to describe into the claims will be more easily avoided.”).

ADE would have this Court first recite a dictionary definition for each word in a contested patent claim phrase, add those definitions together, and adopt the resulting amalgamation as the Court's construction before proceeding to any consideration of the remainder of the intrinsic record. The cases cited by ADE, however, do not require the cataloguing of dictionary definitions before construing disputed claim phrases, nor do they require the adoption of a definition equal to the sum of the individual definitions of the words in a contested phrase.

For example, in Inverness Medical Switzerland v. Warner Lambert Co., 309 F.3d 1373 (Fed. Cir. 2002) ("Inverness II"), which ADE also cites, the Court "looked … to the dictionary definitions of the claim terms 'on' and 'onto' as of the date the patents issued." 309 F.3d at 1378. Reasoning that the definition of the word "onto" referred to the word "on," the Court concluded "that both prepositions are properly addressed through the interpretation of 'on'" Id. The Court then commented that the word "on" had been used to describe into the claims will be more easily avoided.”).

While it praises the magistrate judge's opinion on this particular issue, KLA too has filed objections to the opinion (D.I. 531), thus upholding the time-honored tradition of a party's accepting a court's conclusions only when they are in full agreement with the party's own.
"construction contradicts the plain meaning of the word 'or' in the claims." 308 F.3d at 1311. The Court then looked to a dictionary to define this ordinary word and compared that definition to the intrinsic record and held that the intrinsic record did not compel a construction different from the ordinary meaning of the word. Id. at 13-14.

Therefore, in contrast to what ADE seems to urge, the case law demonstrates that claim construction does not conclude with the shutting of a dictionary. If a court opts to use a dictionary when construing claims, it must still proceed to a consideration of remaining claim language and the remainder of the intrinsic record to determine whether the disputed claim language is used consistently with any ordinary meaning the claim language may have. A narrow approach to patent claim construction that focuses on summing dictionary definitions may well lead a court to adopt an inappropriate construction, one that is inconsistent with the pertinent art and the intrinsic record of the patent in suit. That danger is exacerbated when a phrase, rather than a single word, is at issue. The meaning of a phrase is often greater than the sum of the individual words. Ordinary experience with idiomatic phrases, particularly when translating them from one language to another, demonstrates the difficulties and misunderstandings that a literal, word-for-word translation can produce. A dictionary, encyclopedia, or treatise may also contain several definitions for the same word. In short, context is critical, and the import of the intrinsic record cannot be ignored. See Springs Window Fashions, LP v. Novo Indus., L.P., 323 F.3d 989, 2003 U.S. App. LEXIS 2681, Nos. 02-1309, 02-1347, 2003 WL 297500, *4-*6 (Fed. Cir. Feb. 13, 2003) (noting that a patentee is held to what was said during patent prosecution when distinguishing prior art even though there is no explanation in the prosecution history for particular claim language because competitors must be able to look to the intrinsic record and rely upon it).

As previously noted, 2003 U.S. App. LEXIS 2681, [WL] at 23-25, the magistrate judge reviewed the phrase "oblique zone" as part of the larger phrase "second oblique zone offset angularly from said first zone." ADE asserts that the magistrate judge read a limitation into the construction of "oblique zone" from the preferred embodiment. (D.I. 595 at 16-17.) In fact, however, the magistrate judge merely acknowledged the difficulties in construing the phrase "oblique zone," stating that the Court was "well aware … that a preferred embodiment does not, necessarily, define the claimed invention as detailed by the language of the claims." ADE Corp., 220 F. Supp. 2d at 318. The magistrate's Report and Recommendation went on to reason, in effect, that the phrase "oblique zone" was not clear on its face and that the inventors had failed to provide clues to its correct interpretation except through the intrinsic record and whatever further understanding could be gleaned from the description of the preferred embodiment. Id. at 318-19 (citations omitted). That conclusion about the phrase in the '525 patent is sound and is equally true with regard to the term "oblique zone" as used in the '259 patent. Cf. Schumer, 308 F.3d at 1312 ("It is well established that statements made during prosecution are used to interpret the scope and meaning of ambiguous claim terminology.") (citing Vitronics, 90 F.3d at 1582); E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1438 (Fed. Cir. 1988), cert. denied, 488 U.S. 986, 102 L. Ed. 2d 572, 109 S. Ct. 542 (1988) ("Arguments made during prosecution history are relevant in determining the meaning of the terms at issue. Those arguments … must be examined to ascertain the true meaning of what the inventor intended to convey in the claims.") (citations omitted); ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1580 (Fed. Cir. 1988), aff'd, 899 F.2d 1228 (1990) (rejecting patentees' proposed construction of disputed claim term as inconsistent with prosecution history).

The phrase "oblique zone" was first added to the claims of the '525 patent by amendment after an interview with a PTO examiner. (D.I. 627, '525 Patent Prosecution File History, Applicants' Response to Office Action mailed Oct. 28, 1999 at 4.) Under 37 C.F.R. § 1.133(b), it is the patentee's responsibility to complete a written statement as to the substance of that interview. See also 37 C.F.R. § 1.2; Manual of Patent Examining Procedure § 713.04 pp. 700-166 to 700-168 (8th ed., Aug. 2001). Failure to adequately explain why an examiner approved of that language does not erase the preceding prosecution history, which includes prior art citations that the examiner viewed as rendering the invention obvious. See Tate Access Floors, Inc. v. Interface Architectural Res., Inc., 279 F.3d 1357, 1372 n.4 (Fed. Cir. 2002) (prior art cited by an examiner in the prosecution history is part of the intrinsic record of the patent). That prosecution history clearly weighs against the interpretation sought by ADE.

In an Office Action mailed June 5, 1998, an examiner at the PTO rejected the applicants' original claims in the application leading to the '525 patent because, as written, those claims were obvious under Section 103(a). (D.I. 627 at '525 Patent Prosecution File History, Office Action mailed June 5, 1998 at 1-3.) Specifically, the examiner explained that a particular prior art reference known as "Quackenbos" made the claimed invention obvious:

Quackenbos teach [sic] of using a light beam … to send light to surface … of a disk … which is moved and rotated … to scan the entire surface in two directions. The perpendicular scattered light, caused by pits … is detected … and the other scattering angles, both back scattered light and forward scattered light … is detected using [a] sensor … The two detected
intensities are compared in [a] comparator … and then the system determines if the sensed region is a particle or pit where only the pits on the surface are mapped ….

(Id. at 3.) The examiner then explained that another prior art reference called "Wells" could, like the applicants' invention and unlike the Quackenbos reference, "be used to determine … the sensing of a defect/particle … either a pit or particle[.]") thus, rendering the applicants' invention obvious in light of the combination of those two references. (Id. at 3-4.)

There is little question from the quoted remarks that the examiner understood the pertinent art as disclosing a system that employs two detectors in which normally (or perpendicularly) scattered light is collected in one sensor and, in the other sensor, both forward and backward scattered light are collected for detecting defects on the surface of a silicon wafer or other workpiece. In Quackenbos, as depicted below in Figure 3 from that patent, the two sensors are conically shaped and depicted as item 28, which is capable of collecting perpendicularly scattered light, and as item 48, which is capable of collecting forward scattered light, back scattered light, and other light scattered in a 360 degree azimuthal range.

GET DRAWING SHEET 1 OF 4

(D.I. 626 at U.S. Patent No. 4,794,264 (issued Dec. 27, 1988), Figure 3.)

On August 26, 1998, the PTO received the applicants' response to the examiner's June 5, 1998 Office Action. (D.I. 627 at '525 Patent Prosecution File History, Applicants' Response to Office Action mailed June 5, 1998.) In that response, the applicants twice distinguished their invention from the Quackenbos reference by stating that "Quackenbos … does not separately collect back-scattered and forward-scattered light …." (Id. at 5 (emphasis in original).) The applicants also characterized their invention as employing "a plurality of collectors arranged at different angular positions … for collecting back-scattered, forward-scattered, and perpendicularly scattered light." (Id. at 2.) In addition, the applicants asserted that in Quackenbos "there are not truly any 'back-scatter' or 'forward-scatter' directions. Rather, light is scattered by a defect in a conical volume." (Id. at 5.) After making the foregoing statements with regard to their invention and the prior art, the applicants proceeded to a discussion of original claims 1 and 12. 20 (Id. at 7.) As to those two claims, the applicants argued that neither Quackenbos nor Wells teaches or even suggests the additional recitation in claim 12 of separately collecting perpendicularly and back-scattered light. (Id. at 7-8.) Moreover, asserted the applicants, "neither of the references teaches or suggests comparing scattered light intensities in different angular locations." (Id.) The applicants thus predicated the patentability of their invention on the separate collection of forward, backward, and perpendicularly scattered light.

20 See supra note 12.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

In addition to the prosecution history that weighs heavily against ADE's proposed construction, there is a significant question as to whether the invention would be enabled if ADE's construction of "oblique zone" were adopted. Figure 16 and column 12 lines 19-36 of the '259 patent written description disclose a mathematical algorithm for comparing the center channel signal to either or both of the forward channel signal or the back channel signal. 21 This signal comparison algorithm is suited for comparing signals generated from forward, backward, and center "segmented" collection/detection apparatuses. The algorithm is not designed to process light signals produced from a center collection/detection apparatus and a single axisymmetric collection/detection apparatus that collects both forward and backward scattered light in a 360 degree azimuthal range. Granted, the mathematical algorithm taught by the inventors is qualified by the following language in the specification:

It should be apparent to those of skill in the art from this illustration that the present invention is not limited to the particular algorithm described herein, and that other approaches and other specific algorithms may be used to process the data obtained from the various detectors and to distinguish between pits and particles in accordance with the present invention.

(D.I. 627, '259 Patent Prosecution File History, '259 Patent at col. 12 II. 43-49 (emphasis added.) The Court is bound by what is disclosed. Those of ordinary skill in the art may be able to conceive of different algorithms to use in the '259
invention, however, those algorithms must work in accordance with the disclosed invention, which processes distinct signals gathered from separate collectors. (Id.)

21 See supra note 5.

The disclosed algorithm processes signals from three different sources, a forward channel collector/detector, a back channel collector/detector, and a center channel collector/detector. An algorithm that can process separate signals for comparison is, it would seem, a much different endeavor then a mathematical algorithm that can be used to analyze a single signal representing light collected in a forward and backward scatter region generated by a single collector/detector and then compare the scattered light pattern of the forward and backward scattered light to the light collected in a central region to determine whether the collected light in those regions is characteristic of a pit or particle defect. Such an algorithm, one capable of processing axisymmetric collected light, would be required to render the invention operable if ADE's construction of "oblique zone" was adopted by the Court, since ADE's construction would permit collection of forward and backward scattered light in one collector/detector positioned to collect light 360 degrees in the azimuthal range. There is, however, no disclosure in the '525 or '259 written descriptions or drawings supporting such an algorithm.

If the argument were made that the algorithm need not differentiate between forward and backward scattered light collected in a single apparatus because that is accomplished by the apparatus which collects the light from the two regions, then the '259 and '525 inventions do not teach a single collector/detector for capturing forward and backward scattered light and do not enable a single collector/detector that can perform such a function. Yet ADE's proposed construction of "oblique zone" would encompass just such a single conical or axisymmetric collector/detector, capable of capturing forward and backward scattered light and comparing the forward and backward collected light to light collected in a center channel collector/detector. Again, there is no teaching in the '525 or '259 written descriptions or drawings for such a device. ADE's proposed construction of "oblique zone" is simply not supported by the '525 or '259 intrinsic record before the Court. Indeed, as noted by ADE's efforts to distinguish Quackenbos and Wells, the record is contrary to ADE's position.

ADE, though, points to dependent claims 3, 4, 5, and 6 of the '259 patent in support of its argument for a broad construction of the phrase "oblique zone." ADE argues that the doctrine of claim differentiation requires the broader interpretation of claim 1 that it seeks. (D.I. 595 at 22.) The argument, however, ignores the Federal Circuit's warning that, "the dependent claim tail cannot wag the independent claim dog." North Am. Vaccine, Inc., 7 F.3d at 1577. Again, ADE's proposed construction of "oblique zone" was "disclaimed" by the inventors during patent prosecution in their effort to distinguish the Quackenbos and Wells references cited by the examiner. (See, e.g., D.I. 627 at '259 Patent Prosecution History, Applicants' Response to Office Action mailed June 5, 1998 at 2-3 ("Quackenbos and Wells wholly fail to teach or even remotely suggest the importance of … collecting scattered light in the backward, center, and forward-scattered regions, and comparing the intensities in these three regions to discriminate pits from particles.").)

The Court, therefore, adopts the magistrate judge's construction of "oblique zone" and will also apply it to the claims of the '259 patent. Accordingly, "oblique zone" means a collection zone that differs in polar angle from the central collection zone and that does not collect the same light being collected by the central zone but, instead, collects either forward or backward scattered light but does not collect both simultaneously. ADE's objection to the magistrate judge's construction of "second oblique zone offset angularly from said first zone" in the '525 patent is overruled.

**Claim 1 of the '602 patent has four elements:**

I. A method for diagnosing viral infection in a susceptible host, said method comprising:

II. obtaining a physiological specimen from said host; and
III. determining the presence of feline T-lymphotrophic virus [FIV] or antibodies to [FIV]

IV. in a physiological specimen from said host.

See '602 patent, attached as exh. A to Consalvi Declaration (paragraph numbers added to comport with the parties' referencing system). Defendants claim that their activities do not meet the second element -- obtaining a physiological specimen from said host. They accede that their activities otherwise fall within the language of claim 1.

1. Element II

It is undisputed that Dr. Hansen performs IFA assays on cat blood or serum samples sent to him by other veterinarians and laboratories. The parties dispute whether receiving samples from others meets the test of "obtaining a physiological specimen from said host." Defendants claim, however, that element II requires a positive, active step of obtaining a specimen and that Dr. Hansen did not meet this step because people sent him specimens rather than Dr. Hansen collecting them himself.

Defendants appear to draw the language of requiring a "positive, active step" from Ex Parte Erlich, 3 U.S.P.Q.2D (BNA) 1011, 1016 (Bd. Pat. App. & Interf. 1987). They interpret the language out of context. Under Erlich, "a method claim should at least recite a positive, active step(s) so that the claim will 'set out and circumscribe a particular area with a reasonable degree of precision and particularity' and make it clear what subject matter these claims encompass, as well as making clear the subject matter from which others would be precluded." See id.

Interpreting element II to mean "taking possession of a physiological specimen from said host" meets the goals of 35 U.S.C. § 112 and of Erlich. The subject matter is clear -- a physical specimen from a cat. The use of the patent is similarly clear -- diagnosing a viral infection in a host by taking a physical specimen from the host. How possession is gained is not important to either 35 U.S.C. § 112 or to the Erlich decision. Defendants try to twist the language of Erlich to make "active" mean that the person practicing the claim has to go out and draw the blood or serum themselves. The reasoning behind Erlich does not require such a narrow interpretation.

When construing a claim, the court must look to the intrinsic evidence including the claim itself and the specification. 6 See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581 (Fed. Cir. 1996). To meet the purpose of the patent claim, the court need not narrowly interpret "obtain." The patent claim shows a method for diagnosing viral infection in a susceptible host. Who gathers the specimen is not important to the diagnosis. Furthermore, nothing in the specification supports a narrow interpretation of "obtain." The specification states that FIV may be isolated "from the sera of infected cats." See '602 patent, col. 3, attached as exh. A to Consalvi Declaration. Sera can be isolated from blood. See id. FIV may also be "obtained from other specimens particularly from the lymph tissues of infected animals." Id. at 4. Nowhere does the specification require that the person using the method for diagnosing the infection must be the one who gathers the sera, blood, or lymph.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
6 The specification is the term given to the portion of the printed patent which precedes the claims. The specification included written descriptions of the invention or discovery and the matter and process of making and using it.

The dictionary definition of "obtain" is "to gain or attain possession or disposal of, usually by some planned action or method." See Webster's 3rd New World International Dictionary, unabridged edition, G + C Meriam & Co, 1976. The court sees no reason to limit the ordinary definition. The dictionary definition is consistent with the case law, the statute, the language of the claim itself, and the specification. Consequently, the court interprets "obtain" in this context to mean take physical possession of the physiological specimen.

2694

7. "Obtaining Said Sample"

Although the parties do not agree about the meaning of the term "obtaining said sample" (claim 12), their definitions are similar. Plaintiffs think that this term refers to withdrawing blood or collecting urine, and rely on information in the patent indicating that samples are "drawn." See '103 Patent Specification at Fig. 5, 11:50-54. Nevertheless, these references are merely illustrative of particular applications of the patent, and do not claim to be exclusive of other methods. See id. at 11:44-46 ("Figs. 5 to 9 are flowcharts illustrating a specific method according to the present invention which is explained in detail below."). Intema argues that this phrase refers to obtaining a sample of any kind (including blood, urine, or cells). Indeed, the specification refers to "serum or plasma or urine or cells" as types of "biochemical samples." Id. at 5:27-28. Intema's interpretation is also consistent with the plain meaning of the terms, because "obtaining" could include receiving a sample from someone else who collected it, and "sample" need not be limited to blood and urine. Accordingly, I adopt Intema's construction.

2695

c. "an obtuse angle is formed between the strut and the guidewire"

The phrase "an obtuse angle is formed between the strut and the guidewire" appears in the '682 Patent. The Court construes this phrase as "an angle of more than 90 degrees and less than 180 degrees formed between the strut and the guidewire."

2696

E. Term 6: "occluding"

The Court construes the term "occluding" in claim 1 of the '291 patent to mean "blocking or obstructing."

The core of the parties' dispute over this term is whether "to occlude" means "to block completely" or instead means "to block partially or completely." See AGA Opening Br. at 37-38; Univ. Opening Br. at 35-37. AGA contends that the "occluding disk" identified in claim 1 of the '291 patent must be "sufficiently impermeable to stop the flow of blood through a defect within an acceptably short period of time." Am. JCCS Sched. B at 19. This is a lot to pack into a single word, and AGA has not provided any evidence that a person of ordinary skill in the art would construe "occluding" to mean, in effect, "totally occluding." Instead, AGA supports its proposed construction with evidence that "occluding" is used in the specification interchangeably with "closing" or "closure." AGA Opening Br. at 37-38.

This is true as far as it goes. 14 And it is also true that the purpose of the claimed invention is to stop completely -- though not immediately -- the flow of blood. See '291 patent col. 10:8-11. But it does not follow that "occlude" necessarily means "occlude completely," any more than "close" necessarily means "close completely." Put another way, a closure device that
blocks most of the blood flowing through a defect is obviously less effective than one that blocks all of the blood. But a leaky plug is a plug nonetheless. And there is no reason, in the abstract, why a device could not both infringe a patent and be less effective for its purpose than other embodiments of the patented invention. The '291 patent itself therefore does not establish that "occlude" means "occlude completely."

14 See '291 patent col. 1:11-16 ("The present invention generally relates to devices and methods for occluding septal defects . . . . In particular, the present invention provides a device for closing such defects . . . . and a method for delivering and deploying that device to close off the defect.") (emphasis added); id. col. 1:45-50 ("[A]n occluding device is delivered through a catheter. Once the closure device is positioned adjacent the defect, it must be attached to the rest of the septum in a manner which permits it to effectively block the passage of blood through the defect.") (emphasis added).

15 The evidence, such as it is, thus supports construing "occluding" to mean "blocking or obstructing." as proposed by the University.

16 The University actually proposes to construe "occluding" to mean "blocking or obstructing blood flow through a septal defect." Am. JCCS Sched. B at 19. But given that claim 1 of the '291 patent is already directed to a "septal defect closure device," the Court sees no reason to state, in its claim construction, the obvious fact that the device occludes blood flow through a septal defect.
percutaneous transluminal coronary angioplasty is used to open an occlusion of a coronary artery. Id., 88-89.

In contrast to procedures for removing an occlusion, the inventions of the '136 Patent are methods and devices for deliberately forming an occlusion to treat malformations within the vascular system.

The "Background of the Invention" section of the patent states that creation of an "occlusion" to block off vascular malformations was known at the time of the invention. The "Background" discusses intracranial aneurysms as examples of a vascular malformations which physicians sought to treat by "occluding" them in various ways. The "Background" discusses endovascular and extra-intravascular prior art methods for "occluding" intracranial aneurysms by inserting objects such as balloons or injecting coaggulants within them:

In such [endovascular] procedures a balloon is typically attached to the end of the microcather and it is possible to introduce the balloon into the aneurysm, inflate it, and detach it, leaving it to occlude the sac and neck with preservation of the parent artery.

('136 Patent, Col. 1:51-55.)

In the extra-intravascular approach, an aneurysm is surgically exposed or stereotaxically reached with a probe. The wall of the aneurysm is then perforated from the outside and various techniques are used to occlude the interior in order to prevent it from rebleeding.

('136 Patent, Col. 2:11-16.)

The "Background" also discusses prior art methods for forming a thrombus in an aneurysm as a means for occluding the aneurysm:

In the use of electrothrombosis for extra-intravascular treatment the tip of a positively charged electrode is inserted surgically into the interior of the aneurysm. An application of the positive charge attracts white blood cells, red blood cells, platelets and fibrinogen which are typically negatively charged at the normal pH of the blood. The thrombic mass is then formed in the aneurysm about the tip. Thereafter, the tip is removed.

('136 Patent, Col. 2:19-26.)

The disputed language under consideration appears in the Preamble of Claim 1, which states that the invention is a method "for forming an occlusion within a vascular cavity." The Summary of the Invention section of the '136 Patent discloses that the method is practiced by forming a thrombus in the vascular cavity:

A method for forming a thrombus within a vascular cavity comprising the steps of endovascularly disposing a guidewire near an endovascular opening into the vascular cavity. A distal tip of the guidewire is disposed into the vascular cavity. An electrical signal is applied to the distal tip within the vascular cavity to form a thrombus within the vascular cavity about the distal tip. The distal tip is detached from the guidewire to leave the distal tip within the vascular cavity and the thrombus electrically formed within the vascular cavity.

As a result, electrical formation of a thrombus is completely endovascularly formed. ('136 Patent, Col. 4:1-14.)

However, the language of Claim 1 does not limit "formation of an occlusion" only to formation of a thrombus. The Claim discloses that the vascular cavity is occluded by a thrombus and the distal tip:

whereby 3 said vascular cavity is occluded by said distal tip, and any thrombus formed by use of said tip.

Therefore, construction of the subject phrase must be broad enough to cover occlusion by the distal tip and any associated thrombus.
This language is taken from a "whereby clause." As discussed in Discussion Section I.A.3, below, the "whereby clause" of Claim 1 is limiting because it imposes a limitation on the composition of the occlusion.

In the area of vascular medicine concerned with removal of an occlusion formed due to disease, a vessel may be described as "occluded" if it is partially blocked. An additional aspect of the dispute over the construction of the subject phrase is whether the inventors intended the word "occlusion" to mean a blockage which completely obstructs the vascular cavity or whether a partial obstruction was intended to be included in the definition of "occlusion."

On its face, Claim 1 does not state what amount or degree of blockage is meant by "formation of an occlusion." In general, if a claim does not contain a limitation on the extent of a disclosed parameter, the Court should not add such a limitation. See Modine Manufacturing Co. v. U.S. International Trade Commission, 75 F.3d 1545, 1551 (Fed. Cir. 1996).

The written description discloses three embodiments of the invention. With respect to the first embodiment, the inventors discuss that in using that embodiment of the invention, a thrombus or blood clot is formed, but they do not specify any extent to which the thrombus occludes the aneurysm:

The positive charge on secondary coil 28 within the cavity of the aneurysm causes a thrombus to form within the aneurysm by electrothrombosis.

('136 Patent, Col. 6:52-55.) Similarly with respect to the second embodiment, no specification of an extent of occlusion is disclosed:

The embodiment of FIG. 2 is utilized in exactly the same manner as described above in connection with FIG. 1 to form a thrombic mass with an aneurysm or other vascular cavity.

('136 Patent, Col. 7:12-15.)

However, in a discussion of a third embodiment the inventors disclose circumstances under which the method results in the vascular cavity being "completely occluded:

Turn now to the third embodiment of the invention as shown in FIG. 3.

* * *

After the thrombus has been formed and the aneurysm completely occluded, tip 58 and coil 56 are detached from guidewire 42 by electrolytic disintegration of at least one portion of stainless steel coil 46.

* * *

After separation by electrolytic disintegration, guidewire 42, microcatheter 44 and the remaining portion of coil 46 still attached to guidewire 42 are removed from vessel 66, leaving aneurysm 64 completely occluded as diagrammatically depicted in FIG. 5 by thrombus 74.

('136 Patent, Col. 7: 42-43; 8:16-19, 26-30.)

There is no discussion in the extrinsic evidence that only complete occlusion would fulfill the medical purpose of the invention. Thus, in light of the inventors' choice of words, i.e., using "completely occluded" with only one embodiment, the Court declines to adopt a construction of "an occlusion" which requires that it completely block the vascular cavity because the construction arguably would not read on the first two embodiments. See SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005).

The Court construes "forming an occlusion within a vascular cavity" as it is used in the Preamble to Claim 1 of the '136 Patent.
Patent to mean:

forming a blockage within a vascular cavity. The vascular cavity does not have to be completely occupied by the blockage to be occluded.

2698

D. "Case occupies substantially the entire drive bay slot"

Comaper's proposed construction of "case occupies substantially the entire drive bay slot" is "when installed, the case occupies the slot leading to a drive bay." (Pl.'s Constr. Mem. at 6; Pl.'s Reply Mem. at 11.) According to Comaper, when installed, the case does not share, to any significant degree, the opening in the computer enclosure with other devices. Comaper supports this position with the intrinsic record. Comaper contends that this language was added to distinguish the '955 patent from the device at issue in Pollard because the Pollard device was "a minor integrated component of a drive" and not a dedicated system. (Pl.'s Constr. Mem. at 6.)

The Court constructs the above claim to mean "when installed, the case occupies almost entirely the slot leading to a drive bay." It is clear to the Court that this term was added to distinguish the '955 Patent from the Pollard invention. The invention in Pollard was not a dedicated system for cooling a computer's drive bay region - it was merely a subcomponent of a larger drive. As noted above, the '955 Patent is a dedicated system. It is the opinion of this Court, that during prosecution Comaper sought to distinguish its invention from Pollard. As a result the Court will adopt Plaintiff's construction, with some amendment.

2699

6. occurrence of contact; occurrences of contact

The term "occurrence of contact" appears in claims 25 - 53 of the '213 patent, and the term "occurrences of contact" appears in claim 39 of the '213 patent and in claims 10 - 12 of the '283 patent. The plaintiff's proposed construction is "the act of causing contact to occur at a location on the work platform." The defendant counters with "occurrences of physical contact with the surface of the work platform." The crux of the disagreement with respect to this term is whether or not an "occurrence of contact" includes a moving contact with the work platform (the defendant's position), or, in contrast, includes solely a stationary, location-based contact (the plaintiff's position).

In light of the intrinsic evidence, the court agrees with the plaintiff and concludes that this term means "the act of causing contact to occur at a location on the work platform."

2700

1. The term "of size to fit into the grate frame" (claims 6 and 9). 2

2 In claim 6, the phrase "of size to fit into the grate frame" modifies one noun phrase ("open top receptacle"), whereas in claim 9 the phrase "being of size to fit into the grate frame" modifies a different noun phrase ("erosion control housing"). The parties treat "of size to fit into the grate frame" and "being of size to fit into the grate frame" as if they are different claim terms. Joint Claim Const. Stmt. ("JCCS") at 1, 3 [Docket No. 17]. In fact, both phrases include the same term ("of size to fit into the grate frame"). Claim 9 merely makes explicit (with the word "being") what is implicit in claim 6: The modified noun phrase ("open top receptacle" in claim 6; "erosion control housing" in claim 9) has the property of being "of
size to fit into the grate frame." Accordingly, the Court treats the phrase "of size to fit into the grate frame," and not the phrase "being of size to fit into the grate frame," as the term to be construed, and gives the phrase the same meaning in both claim 6 and claim 9.

The Court construes this term to mean:

of a size to fit reasonably accurately into the grate frame.

WIMCO argues that this term does not need to be construed. Joint Claim Const. Stmt. (“JCCS”) at 1, 3 [Docket No. 17]; Pl. Claim Constr. Br. at 8-10. Lange proposes construing it to mean "of a size to conform correctly to the shape or size of the grate frame." Def. Claim Const. Br. at 27-28 [Docket No. 28]. Based on the patent specification, the Court adopts a position close to Lange's.

The word "fit" is at once ordinary and imprecise; its meaning varies significantly depending on the context in which it is used. In some contexts, object A "fits" inside object B if A is smaller than B, regardless of how much smaller. For instance, if a store clerk asks a customer if her new television will "fit" into the trunk of her car, the customer will answer "yes" as long as the trunk is larger than the television. It will make no difference whether the television will take up all of the room in the trunk or only a small portion of it; in either case, the customer will say that the television "fits" into the trunk. But if a mechanic is asked whether a nut "fits" onto a bolt, he will not say "yes" unless the threads on each are cut to match and the outer diameter of the bolt is nearly identical to the inner diameter of the nut, so that the threads on the nut will engage properly with the threads on the bolt. If the nut is so large that the bolt passes through without engaging, the mechanic will say that the nut does not "fit." In light of the protean nature of the word "fit," to leave the phrase "of size to fit into the grate frame" entirely undefined (as WIMCO suggests) would not give sufficient guidance to the jury that will have to decide infringement.

It is clear that, in the '207 patent, "fit" means something like the fit of a nut onto a bolt rather than the fit of a television into a car trunk. In several ways, the '207 patent specification indicates that the outer edges of the patented basin must fit fairly closely to the inside edges of storm-sewer grate frame. First, all of the patent drawings depict a basin that fits entirely within an existing storm-sewer grate frame, with neither significant gaps nor significant overlaps. In particular, Figure 2 shows a basin inside a grate frame and a grate inside that basin -- that is, it depicts a basin sized to accommodate the exact same grate that is accommodated by the grate frame itself. Second, in describing the preferred embodiments, the patent provides: "Storm sewer frame castings are available in many shapes and sizes, and each erosion control basin then would be designed to fit into the frame with which it is used." '207 Patent col. 3:12-15. This language assumes a close fit between the basin and the grate frame, because it suggests that basins should be customized to particular grate-frame designs. Finally and most importantly, the sole purpose of the basin is to catch debris before it enters the storm sewer below the basin. The basin cannot fulfill its purpose if there are substantial gaps between the basin and the grate frame through which debris may flow.

In light of this evidence from the '207 patent, the Court finds that the claimed basin is "of size to fit into the grate frame" only if it fits reasonably accurately into the grate frame. This construction is admittedly not very precise, but it is as precise as the intrinsic evidence permits, and it serves to exclude from coverage those basins that fit so poorly within grate frames that they fail of their purpose.
1. The '600 Patent

Claims 1 and 9 of the 600 patent describes a "second trough defining means for defining a substantially vertical trough extending the height of said panel . . . said vertical trough disposed offset from said horizontal trough defining means and located proximate said horizontal trough rear portion." Similarly, Claim 11 describes a "means for defining a vertical trough . . . said vertical trough-defining means lying in a plane parallel to and spaced apart from said horizontal trough-defining means . . . ." Defendants contend that this language, when read in the context of the patent specification, requires that there be absolutely no overlap between the space occupied by the vertical troughs and the space occupied by the intermediate horizontal troughs. The Court does not agree.

On their face, the claims do not require that the vertical trough and horizontal troughs have absolutely no overlap. In common parlance, "offset" means merely that the two objects are not perfectly aligned. 5 Similarly, "lying in a plane parallel to and spaced apart from" does not require the troughs to be completely offset. An entire object, with depth, cannot occupy a single plane, which, by definition, has no depth. Typically, however, an object is thought to "lie in the plane" which passes through its center. Thus, for the vertical and horizontal troughs to lie in parallel but separate planes, their center planes cannot be aligned.

--- Footnotes ---

5 Neither side has suggested that "offset" has a particular meaning within the telecommunications equipment field which differs from the common usage of the term. ADC has noted, however, that, in advertisements, T&B has used the term "offset" to describe the relationship between horizontal and vertical troughs in the allegedly infringing device—a device in which there is overlap between the horizontal and vertical troughs. The Court, however, need not consider this extrinsic evidence of the claim meaning to reach the conclusion that "offset," given its ordinary meaning, does not mean entirely without overlap.

--- End Footnotes ---

Defendants argue that the language used to describe the preferred embodiment of the invention suggests that Plaintiff intended a more narrow definition of "offset" and "spaced apart from." Specifically, Defendants quote the following language: "No interference is provided by the vertical troughs. Accordingly, a horizontal run is unrestricted between a plurality of side-by-side bays." U.S. Patent No. 5,220,600, col. 4, ll. 23-26.

"It is entirely proper to use the specification to interpret what the patentee meant by a word or phrase in the claim. But this is not to be confused with adding an extraneous limitation appearing in the specification, which is improper." See E.I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988) (citations omitted). The language quoted by Defendants accurately reflects the spatial relationship between the vertical and horizontal troughs in the preferred embodiment, but the specification goes on to note that the preferred embodiment is not intended to serve as a limitation on the claims themselves. The Court cannot construe the claim language as limited to devices having the exact characteristics of the preferred embodiment, specifically "no interference" by the vertical trough and an "unrestricted run" through the horizontal troughs.

It is true that the specification makes clear that the vertical trough must be positioned in such a way as to allow jumper wires to run through a series of horizontal troughs without getting tangled in vertical wires. The background section of the patent notes the problems in the prior art: "The common planar arrangement of the horizontal and vertical troughs of the [prior art bays] results in interference of wires passing through tho [sic] intersection of horizontal and vertical troughs. . . . It is desirable for a wire to pass from one bay to other bays in the installation." U.S. Patent No. 5,220,600, col. 1, ll. 51-61. However, this function is not inconsistent with an arrangement of offset but overlapping vertical and horizontal troughs. So long as some portion of the horizontal troughs does not overlap with the vertical troughs, there is unrestricted access between horizontal troughs of different bays. Thus, to the extent that the specification discusses the purpose for having the vertical and horizontal troughs offset or in different planes, that specification does not suggest any limitation beyond the plain meaning of the claim language.

The Court concludes that the proposed claim construction of the Defendants unduly narrows the scope of the 600 patent. The claims should be read and construed as they are written, to require that the vertical and horizontal troughs not be
perfectly aligned so that there is some measure of unrestricted passage between horizontal troughs of different bays. The claims should not be limited to devices in which there is absolutely no overlap between horizontal and vertical troughs.

Claim 1 of the '427 Patent provides:

An altitude accumulator for selectively accumulating altitude changes, comprising:

receiver means for receiving a pressure signal representing atmospheric pressure; computer means for computing altitude based upon said received pressure signal; and accumulator means for selectively accumulating and providing an accumulated altitude signal representing accumulated altitude changes which reach a first accumulation threshold in a first direction from a reference altitude, said altitude changes being based upon said computed altitude, wherein altitude changes in a second direction which do not reach a second accumulation threshold offset subsequent altitude changes in said first direction, and further wherein altitude changes in said second direction which do reach said second accumulation threshold cause said reference altitude to change in accordance therewith.

a. "offset subsequent altitude changes in said first direction"

The parties dispute the meaning of the phrase "offset subsequent altitude changes in said first direction."

In the background section of the specification, the inventor discussed some of the desired features of the invention as follows:

"It is desirable to have an accumulating altimeter which can selectively accumulate altitude changes such as gains, while selectively ignoring some, but not all, opposing altitude changes such as losses. In other words, it would be desirable to have an accumulating altimeter that can selectively ignore insignificant altitude changes, due to such things as mechanical vibration, slightly rolling terrain or highway overpasses, while at the same time being capable of recognizing significant altitude changes, due to such things as riding over a hill or into a valley."

('427 Patent, Col. 1:58-68.)

This discussion of "selectively ignoring" opposing altitude changes describes the effect of an "offset." However, it does not define how an "offset" occurs.

The written description uses the word "offset" as follows:

As the user ascends 30 feet to point D, the display 20 now indicates an accumulated altitude gain of 30 feet, since the altitude gain has now reached the non-opposing accumulation threshold of 30 feet, relative to the latest reference altitude of -10 feet at point C. As the user continues to travel up the rise another 20 feet to the next peak at point E, the altitude gained continues to be accumulated, resulting in an accumulated altitude gain of 50 feet.

As the user descends 20 feet to point F, the accumulated altitude does not change since no further altitude gains have yet been made. Furthermore, since the descent is only 20 feet, i.e. less than the opposing accumulation threshold of 30 feet, a new reference altitude is not established at point F. This descent of less than the opposing accumulation threshold will be used to offset subsequent non-opposing altitude changes, i.e. altitude gains.

As the rider ascends to point G, this 20 foot gain is offset, or cancelled out, by the preceding descent of 20 feet between points E and F. As the user ascends 10 feet further to point H, an additional 10 feet of altitude gain is accumulated, i.e. 60 feet of altitude gain have now been accumulated and can be displayed.

('427 Patent, Col. 4:16-39.)

Thus, the word "offset" and the phrase "cancelled out" are used synonymously. However, neither "offset" nor "cancelled
"offset" is defined in the written description. Furthermore, the written description does not indicate that a person having ordinary skill in the art would understand the terms "offset" or "cancelled out" to have a special meaning. Thus, the Court interprets the subject phrase by giving the word "offset" its ordinary meaning.

In ordinary use, "cancelled out" is defined as "to match in force or effect." See WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY 200 (1991). In ordinary use, "offset" is defined as "to counterbalance or compensate." Id. 820. Thus, the Court finds that "offset" means "to counterbalance, compensate, or match in force and effect."

Accordingly, as it is used in Claim 1 of the '427 Patent, the Court construes the phrase "offset subsequent altitude changes in said first direction" to mean:

- to counterbalance, compensate, or match in force and effect subsequent altitude changes in said first direction.

Construing the meaning of "on" and "onto":

As indicated above, the Court is asked to construe two disputed and undefined prepositions, "on" and "onto."

When construing a patent claim, the Court first looks to the "intrinsic" evidence of record, including the language of the claims themselves, the specification, and the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996); see also Markman, 52 F.3d at 979. This intrinsic evidence is "the most significant source of the legally operative meaning of disputed claim language." Vitronics, 90 F.3d at 1582-83. "In most situations, an analysis of the intrinsic evidence alone resolves any ambiguity in a disputed claim term." Id. If a review of the intrinsic evidence reveals no ambiguity, it is improper for the Court to use or rely on extrinsic evidence when construing the claims. Bell & Howell Document Management Products v. Altek Systems, 132 F.3d 701, 705 (Fed. Cir. 1997); Vitronics, 90 F.3d at 1583-1584. The claims are considered alone and not in light of the accused product or any other physical device. See S.R.I. Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1118 (Fed. Cir. 1985). At oral argument, the parties agreed that claim construction may proceed in this case based upon intrinsic evidence.

1. Plain meaning

A review of the intrinsic evidence begins with a plain meaning construction of the claim language, which defines the scope of the claim. York Prods., Inc. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996). According to the claim language: "said labelled reagent is dry on said test strip prior to use" and mobilization of that labelled reagent is facilitated by "drying said labelled reagent onto a portion of said test strip." In analyzing the claim language the Court must employ "normal rules of syntax," Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1553 (Fed. Cir. 1997), and must read the claims in accordance with their ordinary dictionary meaning absent some contrary expression in the specification. Northern Telecom Ltd. v. Samsung Electronics Co., 215 F.3d 1281, 1295 (Fed. Cir. 2000).

The preposition "on" is "used as a function word to indicate position in contact with and supported by the top surface of" or the "outer surface," according to Merriam Webster's Collegiate Dictionary (10th ed.1997). The term "onto" means "to a position on." Id. Substituting this plain dictionary meaning, the claim language would read: "said labelled reagent is dry in a position in contact with the top or outer surface of said test strip prior to use" and "drying said labelled reagent to a position in contact with the top or outer surface of a portion of said test strip."

Plaintiff disagrees. As defined by Webster's Third New International Dictionary, "on" includes the term "within," as in "rode there on a train" or "booked passage on an ocean liner." Thus plaintiffs argues for an alternative claim construction that would read that the "labelled reagent is dry on and within said test strip prior to use" and mobility of the labelled reagent is facilitated by "drying said labelled reagent onto and within a portion of said test strip."

In considering this construction, it is significant to note that the language of Claim 1 describes an invention "wherein mobility of said labelled reagent within said test strip is facilitated by . . . drying said labelled reagent onto a portion of said test strip." Plaintiff's construction would use "on" and "onto" interchangeably with "within" and thereby require the Court
impermissibly to construe different words used in the claims so they have identical meanings. See Senmed, Inc. v. Richard-Allan Medical Indus., 888 F.2d 815, (Fed. Cir. 1989)(when two terms are clearly intended to have "different meanings within the context of the claim language," it is impermissible to construe these terms to have the same meaning).

Moreover, and contrary to plaintiff's construction, the patent specification reinforces the use of "on" and "onto" as position words being used here to describe something in contact with a surface.

2. Patent Specification:

Patent specification is one of source of intrinsic evidence used to give context to the claim language. As the Federal Circuit explained in Vitronics, 90 F.3d at 1582:

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication . . . . As we have repeatedly stated, "claims must be read in view of the specification, of which they are part." . . . The specification contains written description of the invention which must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Thus, the specification is always relevant to the claim construction analysis. Usually, it is dispositive: it is the single best guide to the meaning of the disputed term.

Id. The specification in the May patents supports only one of the possible meanings for "on." In each of three instances, the specification clearly describes the labelled reagent as applied on the surface of the test strip.

Column 6 of the specification reads as follows:

To assist the free mobility of the labelled reagent when the porous carrier is moistened with the sample, it is preferable for the labelled reagent to be applied to the carrier as a surface layer, rather than being impregnated in the thickness of the carrier. This can minimize interaction between the carrier material and the labelled reagent. In a preferred embodiment of the invention, the carrier is pre-treated with a glazing material in the region to which the labelled reagent is to be applied. Glazing can be achieved, for example, by depositing an aqueous sugar or cellulose solution, e.g. of sucrose and lactose, on the carrier at the relevant portion, and drying.

Column 6, line 48 - Col. 7 line 3 (emphasis added). The ordinary meaning of "on" requires contact with the top or outer surface, and the specification reinforces this meaning by affirmatively stating that the labelled reagent should be applied to the test strip as a surface layer, rather than being impregnated within the test strip.

The application of the labelled reagent as a surface layer is also referred to in Column 13 where the specification diagram is described:

A portion of the test strip surface opposite the backing strip 511 and adjacent the porous receiving member 506, carries a glaze 519 on which is deposited a layer 520 of labelled specific binding reagent. . . . . The essential objective of reducing any interaction between the labelled reagent and the carrier material forming the strip will be achieved.

Col. 13, lines 45-48. Again, the labelled reagent is deposited on a glaze and this achieves the "essential objective of reducing any interaction" between the labelled reagent and what the test strip is made out of.

Finally Column 17 describes the process of using an airbrush to apply the layer of sugar substance, and then a layer of labelled antibodies on top of the sugar layer as follows:

Prior to the deposition of dye labelled antibody, a sublayer of, for example, 60% w/v of sucrose in distilled water is applied by airbrush . . . . Then several passes (e.g. three) of dye labelled antibody . . . are applied by airbrush directly on top of the sublayer.

Col. 17, line 63 - Col. 18, line 6.

Each of the above excerpts from the specification describe what is the preferred embodiment of the May patent and clarify and strengthen the contextual meaning of the terms "on" and "onto."
In opposing this construction, plaintiff correctly states that claims are not construed to cover only a particular embodiment or example -- even if that embodiment is "preferred," Northern Telecom Ltd. v. Samsung Electronics Co., 215 F.3d 1281 (Fed. Cir. 2000), and offers three embodiments, also in the specification, to support a construction in which "on" means "within."

First plaintiff cites Column 8, which describes an embodiment in which the test strip area in question, Zone 12, is "loaded with a first antibody bearing a visible ('direct') label . . . . This reagent can freely migrate through the test strip in the presence of a liquid sample." Col. 8, lines 52-55. Plaintiff argues that the term "load" should be defined as "to put a load in or on (a means of conveyance); to fill with material, animals, or passengers to be transported (had loaded the moving van by noon)." Webster's Third New International Dictionary, Unabridged, Merriam Webster Inc., (1993). But plaintiff fails to point out that the very next line in the patent, Col. 8, lines 55-56, describes Zone 14, the test result zone, in which a second antibody is "impregnated" in the test strip. As defendant correctly argues, the reference to "loaded" when read in context with the reference to "impregnated" does not support plaintiff's construction. Instead it bolsters a construction that distinguishes between the zones containing impregnated immobilized antibodies and the labelled antibody zone, presumably not impregnated.

Plaintiff's second reference to the specification identifies language from Column 13:

The thickness of these two layers as depicted in FIG. 10 is grossly exaggerated purely for the purpose of illustration. It will be appreciated that in practice, the glaze may not form a true surface layer and the glazing material will penetrate the thickness of the strip to some extent. Similarly, the subsequently applied labelled reagent may also penetrate the strip.

"871 Patent, Col. 13, lines 49 - 55. But this is excerpted from the specification defendant points to, discussed above: "a portion of the test strip surface . . . carries a glaze on which is deposited a layer of labelled specific binding reagent." '871 Patent, Col. 13, lines 45-48, to achieve the "essential objective of reducing any interaction between the labelled reagent and the carrier material forming the strip." '871 Patent, Col. 13, lines 55-57. The fact that the glaze with the labelled reagent might "to some extent" penetrate the thickness of the strip is clearly in contrast with specification language describing antibodies in the test result zone as "impregnated throughout the thickness of the carrier." '871 Patent, Col. 7, lines 37-42. If the patent drafter intended to include labelled antibodies "within" the test strip, this language does not express it.

Plaintiff also cites to language in Column 18, which reads: "In another embodiment, the label may be dispensed/deposited into/on a restricted zone before cutting up the liquid-conductive material into strips." '871 Patent, Col. 18, lines 18-20, offering the term "dispensed into" to support its construction that the labelled reagent and sugar material can be dried "within" the test strip. But, once again, this reference is surrounded by language describing the labelled reagent as "applied . . . directly on top of the sublayer." '871 Patent, Col. 17, line 63 - Col. 18, line 1. The fact that the labelled reagent could be dispensed into a "zone" does not mean it is dried into or within the thickness of the test strip.

3. Final Claim Construction (Resolving "On" and "Onto")

The claim language is construed by the Court to define an invention that uses an undefined sufficient amount of material, of which sugar is an ingredient, to reduce the mutual action between the labelled reagent and the test strip by either coating the test strip with the material or drying the labelled reagent and this material together onto the surface of a portion of the test strip upstream from the test result zone. The claim is further construed to mean that the presence of this sugar material on the surface of the test strip will help or improve the release of the labelled reagent when the liquid biological sample is applied to the strip.

b. "Stops on the cable"

Claim 26 recites in relevant part "stops on said three cables whereby a manual exercising force applied [to one of the cables associated with the exercise unit in use] responsively tensions said first cable and applies a force tending to move said load." '572 patent 11:64-12:19.
The court has already construed the term "stops" to include both "ball" and "mechanical"-type structures. Defendants argue, however, that the stops on the accused products' butterfly units fail to satisfy the limitation that the stops be directly "on" on the cable. Plaintiff disagrees that the limitation requires the stop to be directly "on" the cable.

Since the term "on" is not further defined in the claim itself, the court looks to extrinsic evidence for guidance. Webster's defines "on" to mean "so as to be attached to or unified with." Webster's Encyclopedic Unabridged Dictionary 1005 (1989). Using this definition, the stops associated with the butterfly units are "on the cable." While the stops do not come into direct contact with the cable, the cable is "attached to" or "unified with" the mechanical structure that functions as the units' stop.

2706

4. On

a. **Depositing a Titanium Film Containing Nitrogen Atoms on a Semiconductor Substrate**

The titanium film containing nitrogen atoms must be deposited directly on a semiconductor substrate.

b. **Forming a Titanium Nitride Film on the Semiconductor Substrate**

The titanium nitride film must be directly on the titanium silicide film, which in turn must be directly on the semiconductor substrate.

2707

2. "Provided on an Exterior of the Housing"

One of the most important issues with respect to Claim 1 of the '559 Patent is the meaning of "provided on an exterior of the housing," element 1(n), in reference to the "on/off switch." All three parties agree that an "on/off switch," element 1(m), is "a switch that moves between at least an on position and an off position." Claim 1 states that the "on/off switch" is "provided on an exterior of the housing and electrically coupled to the motor of the shredder mechanism." Fellowes construes this to mean that "the on/off switch is located at least in part outside the housing so that it can be operated by the user." Fellowes' Opening Br. on Claim Construction 27 [Doc. No. 40] (emphasis added). Michilin, relying upon the prosecution history, urges the Court to find that the "on/off switch" is located, apparently exclusively, on the "exterior of the housing." Intek proposes that "the on/off switch is in contact with and supported by an exterior surface of the housing." The parties do not dispute that the "housing," element 1(c), is a "shell that houses components of the shredder."

Notwithstanding the parties' efforts to extract meaning from the words "provided on," the Court finds this phrase to be ambiguous as to whether the "on/off switch" is located entirely on the exterior of the housing, partially on the exterior, or on the interior. The Court finds the matter easily resolved, however, by looking to the rest of the claim itself and the preferred embodiments. Claim 1 teaches that the "on/off switch" is "electrically coupled to the motor of the shredder mechanism" and "includes a manually engageable portion." '559 Patent, col. 6, lines 46-50. The preferred embodiments clearly show that parts of the "on/off switch" are located on the interior of the housing, while other parts are located on the exterior. See id. figs. 2 (outside view) & 5-6 (inside view); id. at col. 3, lines 36-40 (the "on/off switch 42 includes a switch module 44 . . . mounted to the top wall 24 underneath the recess 38 by fasteners 45, and a manually engageable portion 46 that moves laterally within the recess 38"). Figure 2 shows a "manually engageable portion" on the exterior of the housing, and the "switch module" on the interior of the housing. If the claim were construed as limiting the location of the "on/off switch" to the exterior of the housing, as Michilin argues, the preferred embodiment in Figure 2 would not fall within the scope of the patent claim, a result which is untenable. See SanDisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1285 (Fed. Cir. 2005) ("A claim construction that excludes a preferred embodiment . . . is rarely, if ever, correct.") (quoting Vitronics, 90 F.3d at 1583). Finally, Michilin's construction of "provided on an exterior of the housing" in Claim 1 is inconsistent with the plain meaning of Claim 19, which is dependent upon Claim 1. "A claim term used in multiple claims should be construed
Michilin and Intek make much of the fact that during the prosecution of the '559 Patent the patentee amended its application to add "provided on an exterior of the housing" in order to distinguish Claim 1 from the prior art. On September 20, 2005, the USPTO issued an Office Action in which it rejected Claim 1, among other claims, as unpatentable under 35 U.S.C. § 103(a) over the admitted prior art, namely Patent No. 6,274,828 ("the Chu patent") or "the '828 Patent"). The Chu patent disclosed an electric power hand tool that included a "lock for preventing unintentional closing." '828 Patent, Intek's Am. Br. in Supp. of its Proposed Claim Construction, Ex. 12 ("Intek Br.") [Doc. No. 85]. 4 The USPTO found that a paper shredder having a "switch lock" to prevent operator injury was "obvious" in light of the Chu patent. '559 Patent, FE 000159. In response to the USPTO's rejection, on November 2, 2005, the patentee added amendments to its claim, including the phrase "provided on an exterior of the housing" after the term "on/off switch." Id. at FE 000165. In addition to the amendment, the patentee argued to the USPTO that "the 'on/off switch' and the 'manually engageable portion' of the 'switch lock' are both distinctly provided on an exterior of the housing." See id. at FE 000175. Following these amendments, the USPTO allowed the '559 Patent to issue. The Court sees no sufficient basis for applying prosecution disclaimer on these facts. Even assuming that the "on/off switch" must be "provided on an exterior of the housing" in order to overcome the Chu patent, Fellowes' construction--placing the "on/off switch" "at least in part" on an exterior of the housing--is entirely consistent with the patentees' amendment and supporting arguments to the USPTO. Intek is therefore incorrect in its assertion that Fellowes' construction, if adopted, would "render[] meaningless" the phrase "on an exterior of the housing." Intek Br. 23. The Court finds no "clear and unmistakable" disavowal of Fellowes' construction in the prosecution history. See Omega, Eng'g, 334 F.3d at 1325-26. The Court refuses, however, to add surplusage to the claims, and sees no value in adding Fellowes' phrase "so that it can be operated by the user."

4 Michilin directs the Court's attention to Figure 6 of the Chu patent. Figure 6 "is a cross-sectional side view of an electrical power hand tool incorporating the [on/off] switch of FIG. 1." '828 Patent, col. 2, lines 23-24. In Michilin's view, which the Court does not necessarily share, the "on/off switch" in Figure 6, depicted as element 100, is "in a housing." Markman Hr'g Tr. 42.

The only remaining issue is whether to adopt Intek's position that the "on/off switch is in contact with and supported by an exterior of the housing." Intek points to Figure 2 of the '559 Patent, which depicts a "perspective view" of the shredder without the container and with the switch lock in the releasing position thereof." '559 Patent, col. 1, lines 54-56. According to Intek, Figure 2 shows that a "switch recess 38 formed in an exterior of the surface, top wall 24, of the housing 14 receives the on/off switch 42. Thus, on/off switch 42 is provided on (in contact with and supported by) an exterior surface of the housing." Intek Br. 21; see Stern Decl., Intek Br., Ex. 14, 9 P 41. The Court is not convinced by Intek's argument. Nowhere in the patent claims or specifications is the "on/off switch" described as being "in contact with and supported by" an exterior of the housing. The notion that the "on/off switch" is "supported by" the "exterior of the housing" is seemingly irreconcilable with the specifications' description of the "on/off switch" as "includ[ing] a switch module 44 (FIGS. 4A-6) mounted to the top wall 24 underneath the recess 38 by fasteners 45, and a manually engageable portion 46 that moves laterally within the recess 38." '559 Patent, col. 3, lines 36-40 (emphasis added). See SanDisk, 415 F.3d at 1285 ("A claim construction that excludes a preferred embodiment . . . is rarely, if ever, correct.") (quoting Vitronics, 90 F.3d at 1583).

Intek argues, and Fellowes disputes, that "[t]here is not a single embodiment or description that shows an on/off switch can be 'outside the housing' but not in contact with and supported by an exterior surface of the housing." Intek Br. 23; Fellowes' Resp. to Intek's Br. 4 [Doc. No. 88] (citing '780 Patent, fig. 11B). Whomever is correct on this particular point, the specifications make clear that the embodiments in the '559 Patent "have been provided solely for the purposes of illustrating the structural and functional principles of the present invention, and should not be considered limiting. To the contrary, the present invention is intended to encompass all variations, modifications, and alterations within the spirit of the appended claims." '559 Patent, col. 6, lines 27-34. In light of the specifications and the claim itself, the Court finds no basis to graft "in
support of and in contact with" onto its construction. Finding no need to address Fellowes' additional arguments on this point, the Court FINDS that the phrase "provided on an exterior of the housing," element 1(n), means simply that "the on/off switch is located at least in part outside the housing."

2708

I. "on at least one of said surfaces"

TLI argues that the term "on at least one of said surfaces" means "on at least a portion of either or both the inside and outside enclosure surfaces" and this definition comports with the ordinary and customary meaning of the terms. See TLI's Br. at 21. The dispute concerning this issue is limited since Sylvania contends that the specification of the '017 patent states that the coating "preferably extends over at least about 90 percent of the exterior surface of the lamp envelope." … col. 19, Ins. 36-37." See Sylvania's Br. at 20. Accordingly, Sylvania asserts TLI's proposal to include the phrase "at least a portion of" should not be accepted. However, to the extent that a qualifier is included, it must be quantified to be at least about 90 percent covered. Id.

Both parties agree, for purposes of the present litigation that the definition of a lamp envelope is one "having an interior surface and an exterior surface[.]" See Joint Statement at p. 3. Under the plain meanings of these terms, I find that the claim term "said surfaces" from the phrase "on at least one of said surfaces" refers to the inner surface and outer surface of the lamp envelope requiring no specific limitation. There is no specific limitation in either the claim or the specification directing that the coating must be disposed on at least one entire surface. See refs. 620, 642, 644, 646, 648 of Figure 20 of U.S. Patent 5,666,017.

2709

CLAIM 1 OF THE 113 PATENT

Claim 1 of Somfy's 113 patent claims the following:

[A] A device for winding at least one suspension cord of a blind comprising a [B] winding drum, [C] one end of said suspension cord attached to said winding drum [D-E] an auxiliary drum means on said winding drum for ensuring that the cord is wound in even turns without overlapping, said auxiliary drum means having a smooth drum portion having a diameter which is greater than the diameter of the winding drum and located at a distance from the cord end, [F] a shoulder means on one end of said auxiliary drum means for moving successive cord windings axially away from the shoulder means and onto the auxiliary drum means, and [G] guide means for guiding the cord to be wound onto the shoulder means so that the successive cord windings are formed on the auxiliary drum means and are pushed off the opposite end of the auxiliary drum means onto the winding drum under the effect of the shoulder means on the cord.

The parties offer conflicting interpretations of elements C, D, E, F, and G in Claim 1 of the 113 patent. Before construing these elements, we will set forth the background and standards guiding our construction of Claim 1.

ANALYSIS

Congress enacted the Patent Act ("the Act") to encourage scientific advancement by granting inventors "the right to exclude others from making, using, offering for sale, selling, or importing the patented invention," in exchange for full disclosure of an invention. Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1387, 134 L. Ed. 2d 577 (1996). This protection is not without its boundaries; although the Act affords protection for a specified process, machine, or design, a patent never shields the result achieved by that design. 116 S. Ct. at 1388. Accordingly, the burden lies with the inventor to fully disclose "the exact scope of an invention and its manufacture to 'secure to [the patentee] all to which he is entitled, [and] to apprise the public of what is still open to them.'" Id. at 1387 (quoting McClain v. Ortmayer, 141 U.S. 419, 424, 35 L. Ed. 800, 12 S. Ct. 76 (1891)).
A plaintiff satisfies its burden of proving infringement by demonstrating that every claim limitation is present in the accused device. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1535 (Fed. Cir. 1991) ("the failure to meet a single limitation is sufficient to negate infringement of the claim"). Courts also recognize that devices that do not literally infringe a patent may do so under the doctrine of equivalents. The doctrine of equivalents "functions to forbid not only exact copies of an invention, but products that go to 'the heart of the invention but avoid the literal language of the claim by making a noncritical change.'" Markman, 116 S. Ct. at 1388 (quoting H. Schwartz, Patent Law and Practice I, 82 (2d ed. 1995)).

Resolving an infringement dispute is a two-step process. First, the Court must construe the patent claim. In determining its proper meaning, we begin with the claim language. Claim construction also requires us to consult the patent's written description and specification, and, when available, the prosecution history. Spectrum Int'l Inc. v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998). Courts should resort to extrinsic evidence, such as treatises, technical references, and expert testimony, only when the intrinsic evidence fails to clearly reveal the meaning of the patent claim language. Id. It is only after the Court has determined the meaning and scope of the claim that the Court compares the accused device to the properly construed claim.

While the parties offer competing interpretations of elements C, D, E, F, and G, 1 we limit our discussion to the element F, because we find that our interpretation of element F precludes a finding of literal infringement. 2 Interstore Transfer Sys., Ltd. v. Hanger Management, Inc., 1997 U.S. Dist. LEXIS 1497, 1997 WL 106109, *6 (N.D. Ill. Feb. 10, 1997) ("Having found that the accused device fails to meet one limitation set forth in the asserted claims and thus does not literally infringe, the Court has limited its analysis accordingly, Laitram, 939 F.2d at 1535, and will not rule on issues presented in other subparagraphs of the asserted claims.").

--- Footnotes ---

1 To the extent that the parties disagree about the remaining elements, the Court finds as follows:

Element C: The plain language of element C, the specification and embodiments, and the inventor's testimony (Perache Dep. at p. 132) requires the cord to be attached, or affixed, to the winding drum.

Elements D and E: Nothing in the plain language of these elements requires the corresponding "drum" structures to be limited to constant-diameter cylinders.

Element G: The plain language of element G and the specification and embodiments requires the guide means to guide the cord (after the initial turns onto the drum) to come into contact with the shoulder means.

2 The Court acknowledges that this finding exceeds the scope of its present assignment, claim construction. However, because we find that the Somfy patent requires contact between the shoulder means and the auxiliary drum means -- a requirement that the Springs' device clearly does not satisfy -- the Springs' device could not be an equivalent of the Somfy shoulder means under 35 U.S.C. § 112, P6.

--- End Footnotes ---

Element F

a. Means-Plus-Function Format

The parties' dispute centers principally on the interpretation of the "shoulder means" in element F. Element F claims "a shoulder means on one end of said auxiliary drum means for moving successive cord windings axially away from the shoulder means and onto the auxiliary drum means as the cord windings are formed." This claim is largely written in a mean-plus-function format, and is therefore subject to the requirements of 35 U.S.C. § 112. Section 112, sixth paragraph states:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, materials, or acts described in the specification and equivalents thereof.
This provision enables inventors to draft claims without disclosing a definite structure by expressing limitations in a "means-plus-function" format, B. Braun Med. Inc. v. Abbott Labs, 124 F.3d 1419, 1424 (Fed. Cir. 1997). "The quid pro quo for the convenience of employing § 112," is that the specification must clearly show what the limitation means. Id; see also Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996) (rejecting the patentee's broad interpretation of the claim because the patentee particularly pointed out and distinctly claimed only the narrower interpretation). "Section 112 thus permits means-plus-function language in a combination claim, but with a 'string attached.' The 'attached string' limits the applicant to the structure, material, or acts in the specification and their equivalents. Indeed the section operates more like the reverse doctrine of equivalents than the doctrine of equivalents because it restricts the coverage of literal claim language." Valmont Indus. Inc. v. Reinke Mfg. Co., 983 F.2d 1039, 1042 (Fed. Cir. 1993) (quoting Johnston v. IV AC Corp., 885 F.2d 1574, 1580 (Fed. Cir. 1989)).

Because "the 'means' term in a means-plus-function limitation is essentially a generic reference for the corresponding structure disclosed in the specification," the Court must look to the specification to determine the corresponding structure and the equivalents thereof. Chiuminatta Concrete Concepts, Inc. v. Cardinal Indus. Inc., 145 F.3d 1303, 1308 (Fed. Cir. 1998). First, however, we will set forth element F's function. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448 (Fed. Cir. 1998) (finding that a determination of a claimed function is a question of law).

b. Claim Interpretation

The function expressed in element F is to move successive cord windings axially away from the shoulder means and onto the auxiliary drum means as the cord windings are formed. The drafter did not stop there, however, and included additional limitations that must be incorporated into the construction of the element. See O. I. Corp. v. Tekmar Co. Inc., 115 F.3d 1576, 1580-81 (Fed. Cir. 1997). The drafter further defined this function by referencing a shoulder. Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311, 1319 (Fed. Cir. 1998) (finding that "spring means tending to keep door closed" is within the ambit of § 112 even though the claim recites a "spring", which is clearly structural language, because the recitation of this structure merely served to further specify the function of the means). Instead of reciting pure structure, the inventor's reference to the shoulder merely elaborates how the means works -- the means moves the cord by blocking (or shouldering) the cord, and preventing the cord from winding beyond the auxiliary drum. Laitram, 939 F.2d at 1536 (finding that the recitation of some structure in a means-plus-function element does not preclude the applicability of 35 U.S.C. § 112, P 6 when it merely serves to further specify the identified function).

The inventor further limited element F by describing the shoulder means as being "on one end of said auxiliary drum means." The parties' conflicting interpretations of "on one end" lies at the heart of this litigation. Springs argues that "on one end" requires the shoulder means to contact the auxiliary drum, while Somfy's interpretation indicates proximity as opposed to physical contact. Both parties have submitted equally compelling dictionary definitions to support their respective interpretations. WEBSTERS NINTH COLLEGIATE DICTIONARY (Merian-Webster, Inc. 1990) (Springs relies on definition b: "used as a function word to indicate position on or in contact with an outer surface" and Somfy relies on definition c: "used as a function word to indicate position in close proximity with (a village on the sea).". Because "on one end" is susceptible to two equally plausible definitions, we must proceed to examine the remaining intrinsic evidence to properly construe the claim.

The patent clearly discloses a structure that corresponds to the function described in element F. Consistent with the proffered definitions of a shoulder, the disclosed device is a "step-like change in the contour of [the drum], for opposing or limiting motion along it, for an abutment, etc." The rounded device displayed in the embodiments has a diameter that is greater than the diameter of the auxiliary drum.

--- Footnotes ---

3 The RANDOM HOUSE DICTIONARY OF THE ENGLISH LANGUAGE (1980). See also DICTIONARY OF MECHANICAL ENGINEERING by G.H.F. Nayler (4th ed.): "That portion of a shaft or of a flanged structure where a sharp increase of diameter or other dimension occurs."

--- End Footnotes ---
We note that each embodiment in the specification and drawings depicts a shoulder in contact with the auxiliary drum; if there is any space between the shoulder and the drum, it is invisible to the human eye. Hoganas AB v. Dresser Indus., 9 F.3d 948, 951 (Fed. Cir. 1993) (finding that the claim must put "competitors on notice of the scope of the claimed invention."). However, only one of the embodiments demands that the shoulder be in contact with the auxiliary drum, because this embodiment (Figure 7) teaches that the shoulder means and the drum means "may be made in a single piece." Col. 4, lines 23-26. Because Springs does not argue that the shoulder and the drum must be made in a single piece, but merely that the two contact each other, the specification language fails to conclusively support either parties' position. 4

--- Footnotes ---

4 Somfy attempts to rely upon claim differentiation to bolster its position that the shoulder need not contact the auxiliary drum. The doctrine of claim differentiation provides that different claims should be presumed to cover different inventions; i.e., the Court should not interpret one claim so that it would read like another. However, the two claims that Somfy relies upon, Claim 5 ("the winding device as claimed in claim 2, wherein the lateral face of the shoulder means facing the auxiliary drum means is conical.") and Claim 6 ("the winding device as claimed in claim 5, wherein the conical lateral face (9a) is joined to the smooth drum portion (8') by a rounded portion (16) having a radius of the section of the cord to be wound") do not disclose that these are the only claims in which the shoulder and the drum may be joined. Rather, they merely disclose a different design or method for joining the shoulder and drum means. Therefore, this argument is without merit.

--- End Footnotes ---

The patent's language is consistent with an interpretation requiring contact between the shoulder and the drum. The 113 patent's abstract states that the auxiliary drum is "limited by a shoulder." Similarly, Plaintiff addressed the Patent Office's questions regarding patentability over prior art by explaining that "none of the prior art references teach the auxiliary drum having a shoulder means on one end and a free end on the other end." Somfy fails to adequately explain how the drum means would be "limited by" the shoulder means if there was no contact between the two structures. We find, however, that even this language does not conclusively establish that the phrase "on one end" and the term "shoulder" require contact between the drum and the shoulder.

Because the intrinsic patent evidence (while favoring the Defendants' interpretation) is inconclusive, we turn to the extrinsic evidence. Beginning with the inventor testimony, we note that while the inventor insisted that the shoulder need not contact the drum means, he conceded that the patent did not disclose such a teaching. On the contrary, every embodiment reveals a shoulder directly contacting the auxiliary drum. The inventor agreed that "the patent also doesn't teach how you would design a unit that had a shoulder means that's not in contact with the auxiliary drum." Perache Dep. at p125. And when asked if "the shoulder that's disclosed in the patent and that was used in the Somfy devices as of 1994, the shoulder rotates with the auxiliary drum, correct?" A: "From -- in '94?" Q: "Right", the inventor responded: "Beginning of '94, yes." Id. at p 56. Finally, the inventor admitted that Somfy had tinkered with a prototype incorporating a shoulder spaced away from the drum. However, the inventor neither disclosed this embodiment to the Patent Office or the attorneys preparing his claim, nor did Somfy incorporate this embodiment into any of its initial designs.

In addition, Springs has introduced evidence that its device was based a design patented after and over the Somfy 113 patent -- the Domel patent. During the patent application process, Domel distinguished his device from the Somfy patent on the grounds that his invention utilized a stationary finger placed above the drum and not a shoulder attached to and rotating with the drum. This allegedly allowed the inventor to reduce the friction created by Somfy's patented design. The patent examiner accepted these differences between the two devices as significant and granted Domel's patent application.

Springs' device, however, is not an exact replica of the Domel design -- while the Springs' device utilizes two fingers, the Domel design utilized only one. Nevertheless, the Springs device differs from the Somfy device in the same manner that the Domel device does: the Springs device utilizes fingers spaced away from the auxiliary drum and is stationary. This evidence strongly suggests not only that the Somfy 113 patent is not entitled to the broad interpretation proffered by Somfy, but also that the difference between the Somfy and Spring devices is substantial enough to avoid a finding of infringement.

Upon review, the Court finds that both the intrinsic and extrinsic evidence favor Defendants' interpretation of element F. In drafting its patent, Somfy bore the burden of distinctly claiming its invention in order to put competitors on notice. This
requirement "guard[s] against unreasonable advantages to the patentee and disadvantages to others arising from uncertainty
899 (1938). In failing to clearly disclose that the shoulder need not contact the drum, Somfy abandoned its right to
protection for such a broad interpretation of its patent. Athletic Alternatives, 73 F.3d at 1581 ("Were we to allow [plaintiff]
successfully to assert the broader of the two senses of 'between' against [defendant], we would undermine the fair notice
function of the requirement that the patentee distinctly claim the subject matter disclosed in the patent from which he can
exclude others temporarily."). Because the enabling disclosure reveals a shoulder contacting the auxiliary drum and because
the plain language of the claim fails to teach a broader interpretation, we find that the shoulder means must be in contact
with the drum means.

5. "on or in-line with"

This phrase is used in claim 15 of the '607 and '967 Patents. WG seeks to construe this term as "attached externally to or in-
line with." Ion seeks to construe the term as "attached to or in-line with."

In construing the word "on" as "attached externally to," WG seeks to distinguish between those devices that are attached
externally to streamers from those are in-line with, or part of the linear of, the streamer, as is WG's Q-Marine. WG also
argues that the plain meaning of the word "on" implies an external connection, rendering it appropriate to explicitly add
the word "external" to the construction of the term. Ion, however, takes issue with this "external vs. in-line with" dichotomy,
and argues that there are certain devices that are "hybrid" in that they contain a component that is in-line with the streamer
as well as a part that is attached externally. Ion also points out that the term "externally" appears nowhere in either the claim
language or the specification. Ion therefore seeks to construe this phrase without this limitation.

The Court notes that WG relies only on external evidence to establish the purported distinction between devices that are on,
and those that are in-line with, the seismic streamers. Ion apparently disagrees that this is binary framework is as exact as
WG avers. The Court will not rely on only external evidence to construe this term so as to create the binary distinction as
WG advocates.

In addition, the Court notes that to the extent that the word "on" implies a connection that is different from "in-line," this
difference is made apparent by the fact that the terms are separated with the word "or." Therefore, the Court holds that the
phrase "on or in-line" is sufficiently clear that it needs no construction. Any fact-finder can be trusted to understand the
plain and ordinary meaning of the word "on" such that the Court need not impose a construction, particularly one that finds
no support in the intrinsic evidence. A district court is not obligated to construe terms with ordinary meanings, lest trial
courts be inundated with requests to parse the meaning of every word in the asserted claims. O2 Micro Intern. Ltd., 521 F.3d
at 1360; see also Biotec Biologische Naturverpackungen GmbH & Co. KG v. Biocorp, Inc., 249 F.3d 1341, 1349 (Fed. Cir.
2001) (finding no error in non-construction of "melting"); Mentor H/S, Inc. v. Med. Device Alliance, Inc., 244 F.3d 1365,
1380 (Fed. Cir. 2001) (finding no error in the lower court's refusal to construe "irrigating" and "frictional heat").
oxide layer. We disagree with the district court's claim interpretation. The prosecution history shows that the claimed invention was distinguished from the relevant prior art on the basis that the claimed invention involves the deposition of a metal film directly onto the glass surface, whereas the prior art teaches the deposition of a metal film only after a distinct adhesive film is first applied intentionally to the glass surface. The '728 patent claims contain no limitation that the interface between the metal film and the glass sheet be devoid of unintended intermediate material, oxide or otherwise. The presence of an intermediate oxide layer in the PPG products thus does not alone render the accused devices noninfringing.

A. Claim Construction

Claim 7 of the '755 Patent is representative:

7. A food processor comprising:

   a housing having a first opening for introduction of food products and a second opening for discharging processed food products;

   a cutting member rotatably mounted within said housing, said cutting member comprising:

   a plastic hollow blade holder having a central axis of rotation, a closed end having an integrally formed driven member and an open end and a plurality of arcuate wall sections extending from said closed end to said open end and spaced circumferentially about said axis of rotation;

   at least one metal cutting blade member integrally and permanently molded into said blade holder between said arcuate wall sections and having openings through which processed items pass into the hollow interior of said holder;

   means on said housing for supporting said blade holder proximate its open end;

   means for rotatably driving said cutting member whereby food products are processed and discharged through said open end of said holder. [Emphasis added.]

In Markman v. Westview this court held that the appellate court must construe, de novo, the meaning and scope of disputed terms in the claims. F.3d at , 34 USPQ2d at 1329. This court on appeal will interpret the meaning and scope of the claim term as a matter of law. Id.

Black & Decker argues that the '755 Patent claims should be interpreted to require a structure distinct from the housing for supporting the open end of the cutting member. Such an interpretation could avoid infringement by the HSS-60, wherein a lip on the housing provides support for the open end of the cutting member. We do not agree with this view. The supporting structure in the '755 Patent is claimed in "means-plus-function" form in claims 7 and 8, and in descriptive form in claim 14. In claim 7 the term is "means on said housing for supporting said blade holder proximate its open end." In claim 8 the term is "housing farther having means for supporting the cutting member proximate the second opening of the housing." In claim 14 the term is "support member at the second opening of the housing," not in means-plus-function form. Although different usages in different claims are presumed to have different meanings, Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023, 4 USPQ2d 1283, 1288 (Fed. Cir. 1987), and each claim must be construed independently, in this case any difference in the meaning of the supporting means or support member in the several claims does not affect our conclusion.

Claims 7 and 8 are written in the means-plus-function form authorized by 35 U.S.C. § 112 P 6. Literal infringement is made out when an accused device performs the function stated in a claim clause written in means-plus-function form, by means of structure, material, or acts described in the specification or an equivalent thereof. Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1562, 231 USPQ 833, 834-35 (Fed. Cir. 1986). The supporting means described in the '755 specification is a retaining ring that is attached to ridges in the housing. Presto argues that this description means that the cutting member is directly supported by the retaining ring and indirectly supported by the housing. Black & Decker argues that the '755 claims should be construed to require that the supporting structure on the housing is separate from the
housing, and therefore that the claims can not reach Black & Decker's HSS-60 wherein the supporting means is a lip of the housing on which the cutting member rests, while a retaining ring holds the cutting member within the housing. Black & Decker argues that because claim 7 requires a supporting means "on said housing", only a support not attached to the housing can be "on" the housing.

We do not share Black & Decker's interpretation of the term "on". Neither the specification nor the prosecution history requires or suggests that the support "on" the housing is a separate entity from the housing. Applying the ordinary meaning of words, a supporting means "on" a housing may be integral with or attached to the housing. See ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579, 6 USPQ2d 1557, 1560 (Fed. Cir. 1988) ("terms of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently.") Indeed, both sides acknowledge that being "on" does not necessarily mean separate entities.

We conclude as a matter of law, see Markman, supra that the correct interpretation is that the supporting means on the housing need not be a separate entity from the housing.

The second issue of claim construction raised by appellants is that the district court incorrectly construed the phrases "said labelled reagent is dry on said test strip" and "drying said labelled reagent onto a portion of said test strip." Opinion at 12. Appellants argue, however, that the phrase should be more broadly construed to include disposition of the labelled reagent within the test strip.

We begin claim construction analysis with the ordinary meaning of the disputed claim term. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567, *1, No. 02-1032 (Fed. Cir. Oct. 16, 2002); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996). It is well settled that dictionary definitions provide evidence of a claim term's "ordinary meaning." Tex. Digital Sys., 2002 U.S App. LEXIS 21567 at *1; CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 USPQ2d 1658, 1662 (Fed. Cir. 2002) (citing Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1344, 60 USPQ2d 1851, 1855 (Fed. Cir. 2001)). Potentially relevant dictionaries include dictionaries of the English language (providing general definitions and usages) and technical dictionaries, encyclopedias, and treatises (providing specialized meanings as used in particular fields of art). The parties here do not argue that the terms "on" and "onto" have established specialized meanings, and we agree that "on" and "onto" have no such specialized meanings. Accordingly, standard dictionaries of the English language are the proper source of ordinary meaning of the phrase.

We may look, therefore, to the dictionary definitions of the claim terms "on" and "onto" as of the date the patents issued. 2 Webster's provides the relevant definition of "onto" as "to a position or point on or upon . . . in position on." Webster's 3d Int'l Dict. 1577 (1968) ("Webster’s"). The Oxford English Dictionary provides a substantially identical definition, "to a position on or upon." 2 The Shorter Oxford English Dictionary 1371 (3d ed. 1947) ("OED"). The definition of "onto," therefore, refers to the word "on" as part of its definition, such that both prepositions are properly addressed through the interpretation of "on."

We do not share Black & Decker's interpretation of the term "on". Neither the specification nor the prosecution history requires or suggests that the support "on" the housing is a separate entity from the housing. Applying the ordinary meaning of words, a supporting means "on" a housing may be integral with or attached to the housing. See ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579, 6 USPQ2d 1557, 1560 (Fed. Cir. 1988) ("terms of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently.") Indeed, both sides acknowledge that being "on" does not necessarily mean separate entities.

We conclude as a matter of law, see Markman, supra that the correct interpretation is that the supporting means on the housing need not be a separate entity from the housing.

The second issue of claim construction raised by appellants is that the district court incorrectly construed the phrases "said labelled reagent is dry on said test strip" and "drying said labelled reagent onto a portion of said test strip." Opinion at 12. Appellants argue, however, that the phrase should be more broadly construed to include disposition of the labelled reagent within the test strip.

We begin claim construction analysis with the ordinary meaning of the disputed claim term. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 2002 U.S. App. LEXIS 21567, *1, No. 02-1032 (Fed. Cir. Oct. 16, 2002); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996). It is well settled that dictionary definitions provide evidence of a claim term's "ordinary meaning." Tex. Digital Sys., 2002 U.S App. LEXIS 21567 at *1; CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 USPQ2d 1658, 1662 (Fed. Cir. 2002) (citing Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1344, 60 USPQ2d 1851, 1855 (Fed. Cir. 2001)). Potentially relevant dictionaries include dictionaries of the English language (providing general definitions and usages) and technical dictionaries, encyclopedias, and treatises (providing specialized meanings as used in particular fields of art). The parties here do not argue that the terms "on" and "onto" have established specialized meanings, and we agree that "on" and "onto" have no such specialized meanings. Accordingly, standard dictionaries of the English language are the proper source of ordinary meaning of the phrase.

We may look, therefore, to the dictionary definitions of the claim terms "on" and "onto" as of the date the patents issued. 2 Webster's provides the relevant definition of "onto" as "to a position or point on or upon . . . in position on." Webster's 3d Int'l Dict. 1577 (1968) ("Webster’s"). The Oxford English Dictionary provides a substantially identical definition, "to a position on or upon." 2 The Shorter Oxford English Dictionary 1371 (3d ed. 1947) ("OED"). The definition of "onto," therefore, refers to the word "on" as part of its definition, such that both prepositions are properly addressed through the interpretation of "on."

We do not share Black & Decker's interpretation of the term "on". Neither the specification nor the prosecution history requires or suggests that the support "on" the housing is a separate entity from the housing. Applying the ordinary meaning of words, a supporting means "on" a housing may be integral with or attached to the housing. See ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579, 6 USPQ2d 1557, 1560 (Fed. Cir. 1988) ("terms of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently.") Indeed, both sides acknowledge that being "on" does not necessarily mean separate entities.

We conclude as a matter of law, see Markman, supra that the correct interpretation is that the supporting means on the housing need not be a separate entity from the housing.

3234

2 Our decisions have not always been consistent as to whether the pertinent date is the filing date of the application or the issue date of the patent. Compare Tex. Digital Sys., 2002 U.S. App. LEXIS 21567 at *1, with Schering Corp. v. Amgen, Inc., 222 F.3d 1347, 1353, 55 USPQ2d 1650, 1654 (Fed. Cir. 2000). No party here has suggested that the pertinent dates changed between the application and issuance dates.
In reaching its construction of the word "on" the district court referred to the definition "used as a function word to indicate position in contact with and supported by the top surface of." Opinion at 12 (citing Merriam Webster's Collegiate Dict. (10th ed. 1997)). The standard dictionaries provide a number of definitions of "on" in positional, functional, and temporal contexts. "Where there are several common meanings for a claim term, the patent disclosure serves to point away from the improper meanings and toward the proper meanings." Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250, 48 USPQ2d 1117, 1122 (Fed. Cir. 1998); see also Tex. Digital Sys., 2002 U.S. App. LEXIS 21567 at *1. It is simple to rule out many of the definitions of "on" as contextually irrelevant, e.g., "occurrence during the course of a specified day." Webster's at 1574. Here there are two possibly pertinent definitions. One is the definition supported by appellee and adopted by the district court: "used as a function word to indicate position over and in contact with that which supports from beneath." Id.; The other is a definition of the term "on" encompassing internal positioning, providing: "used as a function word to indicate presence within." Webster's at 1574.

In such situations, a word that has an ordinary meaning encompassing two relevant alternatives may be construed to encompass both alternatives. Rexnord, 274 F.3d at 1343, 60 USPQ2d at 1855 (holding that the claim term "portion" may be interpreted to encompass both "separate" or "integral"). However, before finally concluding that the term encompasses both meanings, we must determine whether the specification or prosecution history clearly demonstrates that only one of the multiple meanings was intended. See Renishaw, 158 F.3d at 1250, 48 USPQ2d at 1122. 

Appellee asserts that the specifications of the patents-in-suit show that the term "on" was used in a limited sense to mean only surface deposition. Specifically, appellee argues that:

the specification clearly shows by Fig. 10 and otherwise describes the labelled reagent dried on the test strip as a surface layer in the presence of sugar: "The labelled reagent [is] applied to the carrier as a surface layer" (A70, col. 6, lns. 58-63); "the test strip surface . . . carries a glaze 519 on which is deposited a layer 520 of labelled . . . reagent" (A74, col. 13, lns. 45-48); "labelled antibody . . . [is] applied . . . directly on top of the [sugar] sublayer" on the test strip (A76, col. 17, ln. 63 to col. 18, ln. 4).

Appellee's Br. at 31. In effect, appellee argues that only surface deposition was disclosed, and that therefore, only surface deposition could have been intended by the use of the word "on."

The surface layer disposition is disclosed as a preferred embodiment of the invention, however, it is not the sole embodiment disclosed. Impregnation within the thickness of the test strip is also disclosed. The specification states, "it is preferable for the labelled reagent to be applied to the carrier as a surface layer, rather than being impregnated in the thickness of the carrier." '871 patent, col. 6, ll. 59-62 (emphasis added). 4 It is improper to limit the claim based on a preferred embodiment of the invention. Turbocare v. Gen. Elec. Co., 264 F.3d at 1111, 1123, 60 USPQ2d 1017, 1026 (Fed. Cir. 2001) (citing Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 USPQ2d 1289, 1299 (Fed. Cir. 1988), cert. denied, 490 U.S. 1068, 104 L. Ed. 2d 634, 109 S. Ct. 2069 (1989) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations.").

The patent also discloses that the labelled reagent, even if provided as the preferred surface layer, "may also penetrate the
strip." 871 patent, col. 13, ll. 54-55. We find this particular reference to be unhelpful because it is ambiguous as to whether it is referring merely to incidental penetration or to impregnation.

Appellee also cites to the prosecution histories of the patents as suggesting a limited use of the words "on" and "onto." Appellee argues that "in rejecting broader claims, the examiner stated that the only enablement for mobilizing the labelled reagent was 'as a surface layer by means of soluble glazing techniques as instantly described.'" Appellee's Br. at 36.

Appellee asserts that in response to this rejection the patentee amended the claims to require "wherein mobility of said labelled reagent within said test strip is facilitated by at least one of 1) coating at least a portion of said test strip with, and 2) drying said labelled reagent onto said test strip in the presence of, a material comprising a sugar." Appellee's Br. at 36.

Appellee effectively argues that by amending the claim in response to the examiner's rejection, which stated that only the glazing method was enabled, appellants disclaimed any interpretation broader than the enabled glazing embodiment.

To be sure, failure to object to an examiner's interpretation of a claim ordinarily disclaims a broader interpretation. See Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 979, 52 USPQ2d 1109, 1113-14 (Fed. Cir. 1999), cert. denied, 529 U.S. 1066, 146 L. Ed. 2d 482, 120 S. Ct. 1672 (2000) (holding that failure to respond to an examiner's reason for allowance functioned as a disavowal of a different interpretation of the claim). The passage from the prosecution history cited by appellee, however, was not the entirety of the examiner's rejection, which continued:

Thus, the disclosed glazing method of providing particulate labelled reagent is required for resolubilization and mobilization of the dried particulate labelled reagent. (In the alternative, Applicant is invited to provide evidence that the prior art recognized a number of equivalent pretreatment/application techniques for providing mobilizable/ resolubilizable dried particulate labelled reagents in a conventional porous test strip capable of capillary transport).

Office Action of Dec. 16, 1994 at 5 (emphasis added). 5 Based on the underscored language, during oral argument appellants asserted for the first time an alternative interpretation of the prosecution history.

5 When the claim was amended the applicant quoted the examiner's rejection and stated that the claims were amended in response thereto, stating that:

According to the examiner,

the disclosed glazing method of providing particulate labelled reagent is required for resolubilization and mobilization of the dried particulate labelled reagent. . . .

In response, claims 39, 70, and 75 have been amended hereinabove . . .

In making the rejection under § 112, first paragraph, the Examiner has correctly noted an existing problem within the art. That is, it is true that particle mobility may be constrained by interactions between the particles and the surrounding surfaces. Consequently, to achieve optimal particle mobility it is important to reduce any interaction between the particulate labelled reagent and the material forming the strip. In seeking to address this problem in the instant immunoassay invention, the inventors discovered unexpectedly that sugars were effective in avoiding those interactions.

Amendment of June 9, 1995, to the '313 application at 15.

On September 3, 2002, appellee filed a motion to preclude consideration of the argument on the ground that appellants failed to raise the argument before the district court or in its briefs on appeal or, in the alternative, "[to] consider its response contained in the . . . motion." (Appellee's Mot. at 19.) "[A] waiver may occur if a party raises a new issue on appeal, as by, e.g., presenting a new question of claim scope. . . . A waiver will not necessarily occur, however, if a party simply presented new or additional arguments in support of the scope of its claim construction, on appeal." CCS Fitness, 288 F.3d at 1370-
As we understand it, appellants' theory is as follows: at the time of the examiner's rejection of the claim it failed to recite a sugar glaze as an element of the claimed device, without which the examiner determined the claims were not enabled. While the examiner interpreted the sugar glaze as the only enabled embodiment, he invited the applicant to provide evidence of art-recognized equivalents. In amending the claim language to include the two methods finally claimed, the applicant was making reference to two prior art methods, those disclosed in European Patent No. 0 183 442 to Stiso ("Stiso") and U.S. Patent No. 5,120,643 to Ching et al. ("Ching").

The Stiso and Ching patents were cited by the examiner as prior art to the patents-in-suit in the Office Action just prior to the amendment in question. Stiso teaches that a disclosed testing device "can be coated with a wide variety of materials . . . [which] may include . . . sugars or the like, which are used particularly to enhance the stability of the materials . . . ." Stiso at 20-21. Appellants argue that the first alternative recitation, which provides for the "coating . . . said test strip," corresponds to the prior art coating method of Stiso. The abstract of Ching provides:

impregnation of solid substrate materials with labile protein materials including colloidal particle and enzyme labelled reagents in the presence of meta-soluble proteins provides for the rapid resolubilization of such materials which have been dried onto such substrate materials.

(emphasis added). This passage of Ching equates the use of the phrase "impregnation . . . [of] labelled reagents in the presence of meta-soluble proteins" with being "dried onto [the] substrate materials." Appellants argue that the prior art teaching of Ching corresponds to the second alternative recitation in the claim, which provides for the reagent being "dried onto [the] substrate."

Appellants argue that the examiner's rejection referred to a single enabled embodiment, but the patentee expressly amended the claim to recite two distinct embodiments, "coating at least a portion of said test strip" or "drying said labelled reagent onto a portion of said test strip." Appellants urge that the first recitation clearly corresponds to the glazing method referred to by the examiner, and that the second recitation is distinct in language from the first and is properly construed as reciting a different aspect of the invention, namely impregnation. See CAE Screenplates Inc. v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308, 1317, 55 USPQ2d 1804, 1810 (Fed. Cir. 2000) ("In the absence of any evidence to the contrary, we must presume that the use of these different terms in the claims connotes different meanings.").

Although we are not convinced that the appellants' reading of the history is the only plausible reading, 6 we are also not convinced that the prosecution history demonstrates that the patentee clearly was using the disputed language in a limited sense that would foreclose the broader dictionary definitions that encompass both surface and internal positioning. It is inappropriate to limit a broad definition of a claim term based on prosecution history that is itself ambiguous. As we recently said in Schwing, "although prosecution history can be a useful tool for interpreting claim terms, it cannot be used to limit the scope of a claim unless the applicant took a position before the PTO that would lead a competitor to believe that the applicant had disavowed coverage of the relevant subject matter." Schwing GmbH v. Putzmeister Aktiengesellschaft, 305 F.3d 1318, 2002 U.S. App. LEXIS 20205, *1, No. 01-1615 (Fed. Cir. Sept. 24, 2002) (citations omitted).

--- Footnotes ---

6 As noted above, there is another plausible reading of the claim language as encompassing two alternative embodiments of surface positioning. Ante at n.3.

--- End Footnotes ---

---
Accordingly, the plain meaning of the recitations "on" and "onto" must control, whereby disposition of the labelled reagent "on" or "onto" the test strip means disposition as a surface layer or within the test strip. The claim construction used by the district court in reaching summary judgment of non-infringement having been incorrect, the judgment is vacated. The case is remanded to the district court for consideration of any remaining issues including issues of claim construction not addressed in this opinion and issues of validity and infringement of the claims as correctly construed.

The most basic of the 158 Patent's disputed terms is the term "on" in the following limitation: "at least one top horizontal
Thermal claims that "on" signifies that the top horizontal baffle is supported by the horizontal rack structure. (Doc. 69 at 10-11). Dade counters that "on" need not mean that those items touch one another; rather, "on" may signify that the top horizontal baffle is elevated above but in close proximity to the horizontal rack structure. (Doc. 67 at 10).

The full ordinary meaning of a term is presumptively the meaning the term carries in a patent. See Johnson Worldwide Assocs., Inc., v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999). Among the foregoing interpretations of the term "on," Thermal's uses the ordinary meaning, and Dade's uses a figurative one. To support its interpretation, Dade argues that "vertical seals" positioned beneath the top horizontal baffle could provide independent support for the baffle. (See Doc. 68, Ex. 2, fig. 1, items 26-27). Yet the Claim itself provides no structure for, nor does it even mention, vertical seals. Instead, the vertical seals to which Dade refers are described in the 158 Patent's specification as extending down from the top horizontal baffle, 7 and all relevant indicators suggest that those vertical seals are themselves supported by the horizontal rack structure. 8 Dade's construction is strained to say the least. The top horizontal baffle is not simply near the horizontal rack structure.

The term "on" in Claim 1 means "on, that is, supported by,..."

To put the top horizontal baffle in perspective, at least one pressurizer (fan) 9 rests centrally on the top horizontal baffle, (Doc. 68, Ex. 2, claim 11); the baffle, itself, rests centrally on the horizontal rack structure, (id. cl.1k); the horizontal rack structure spans between, and rests on, at least two rack pillars, (id. cl.1j); the horizontal rack structure is thereby suspended vertically above an area of space between the rack pillars, separated wide enough to receive two pallets juxtaposed on opposite sides of a "central circulation section," (id. cls. 1g,j). Consistent with these structural limitations, the top horizontal baffle, and pressurizer(s), are centrally suspended above a "central circulation section." The term "on" in Claim 1 means "on, that is, supported by,..."

9 Dade indicates that a "pressurizer" is a fan. (Doc. 67 at 11)

We agree with Outlast that the district court erred in its construction of the asserted claims. First, we do not think that the patentees clearly disclaimed impregnated materials or materials made by an impregnation process 4 during prosecution of the '801 patent. It is true that in distinguishing Woo the patentees stated that the present invention is a coating that is applied to the surface or the substrate (i. e., the fabric or the fiber) and is intended to remain on the surface.

Summary Judgment, 298 F. Supp. 2d at 1122. However, as already noted, the patentees went on to state that

- 3239 -
in the present invention, the microcapsules are placed on the surface of the substrate as well as within the interstices of the substrate, should there be any such interstices.

Id. These seemingly contradictory statements do not unequivocally or unambiguously disclaim articles in which the microcapsules are impregnated within the interstices of the substrate. On the contrary, such contradictory statements are indicative of ambiguity. 5

4 We note that, absent clear and unambiguous evidence to the contrary, a product claim is not limited to, or does not exclude, products made by a particular process. See Vanguard Prods. Corp. v. Parker Hannifin Corp., 234 F.3d 1370, 1372 (Fed. Cir. 2000).

5 Contrary to Frisby's contention, our decision in Springs Window, supra, in no way suggests that we should ignore the second of two conflicting statements in the prosecution history.

The district court ignored the second statement on the ground that it could not overcome the substantive effect of the prior statement. Id. The court indicated that this was because, after the patentees amended the claim to overcome the first obviousness rejection, "the examiner found that application of microcapsules by impregnation was obvious under Woo, and the patentees were required following the second rejection to give up application by impregnation to gain patentability." Id. This, however, is not necessarily true. Woo appeared to disclose an article in which all of the microcapsules were impregnated within the fabric, i.e., no microcapsules remained on the surface of the fabric. The patentees' statement can consequently be interpreted as distinguishing Woo on that ground, i.e., on the more limited ground that, unlike Woo, in the claimed invention microcapsules are not only dispersed within the interstices of the fabric but also on the surface of the fabric. Indeed, in the same paragraph in which the patentees stated that the microcapsules were intended to remain on the surface of the fabric, they also stated that

the present invention allows a much greater quantity of microcapsules to be located on the substrate since the entire surface and not only the interstices between fibers is available for capsule loading.

(J. A. at 211.) In short, the prosecution history does not provide unambiguous evidence that the patentees disclaimed all impregnated fabrics or fabrics made by an impregnation process.

Second, we are also not persuaded by Frisby's argument that the plain language of the claim requires the article to consist essentially of a surface coated fabric or fiber. The claim does require that the article consist essentially of a base material and a coating. However, with respect to the coating, the claim expressly states that the coating must merely cover "at least a portion of the surface of said base material." '801 patent, col. 5, ll. 40-41 (emphasis added). Nor does the fact that the base material limitation is written in Markush format have a material effect on our construction because it merely requires the base material to consist of a fabric or a fiber. Therefore, if the base material is fabric, the claim requires at least a portion of the fabric's surface to be covered by the coating. However, it does not preclude the coating from also being dispersed within the interstices of the fabric.

In sum, we hold that "on the surface of said base material" does not exclude articles in which microcapsules are dispersed within the fabric, whether by impregnation or some other process. The limitation simply means that the coating (i.e., the mixture of microcapsules and polymeric binder) is dispersed on at least a portion of the surface of the base material, irrespective of whether the coating is also dispersed within the interstices of the base material.
Microthin argues that "printing a design or logo to show on the upper surface of the mat" means "a design or logo reverse printed on the lower surface of the mat such that it can be seen through the mat on the upper surface and can be viewed correctly through the upper surface." SiliconeZone contends that the phrase requires no construction and urges the Court to accept the plain and ordinary meaning in the context of the claim language.

For the reasons discussed in relation to the '311 Patent above, the Court will not read into the claim that the image must be "reverse-printed" such that it may be "correctly viewed" through the upper surface. However, the written description at least requires the printing to be on the lower surface such that the image may be seen through the upper surface. Therefore, "printing a design or logo to show on the upper surface of the mat" means "printing a design or logo on the lower surface of the mat such that it can be seen through the mat on the upper surface."

1. Claim Term One - "One End"

The term "one end" is found in all of the disputed claims. Plaintiff asks this Court to construe the term as encompassing any free end of the rod, not limited to a single end. Plaintiff bases its argument on dictionary definitions from Miriam Webster's Ninth New Collegiate Dictionary and The New Shorter Oxford English Dictionary, as well as the specific claims and figures in the '704 and '057 patents. Plaintiff also introduces extrinsic evidence in the form of the Federal Circuit's November 18, 2003, decision and expert testimony from R. Lee Rawls.

Defendant asks this Court to construe the term as limited to a single tip of the rod. Defendant bases its argument on a dictionary definition from Merriam Webster's Ninth New Collegiate Dictionary, as well as the specific claims and figures in the '704 and '057 patents. Defendant also introduces extrinsic evidence in the form of Judge Pechman's October 6, 2003, Order Granting Summary Judgment of No Infringement Under the Doctrine of Equivalents, and expert testimony from Evan R. Flavell.

The Court finds plaintiff's argument more persuasive. The patent claims:

In an exercise machine: a base, a plurality for resilient rods mounted on the base in cantilevered fashion with one end of each of the rods being free, a flexible cable adapted to be pulled upon by a person using the machine, and means for connecting the cable selectively to one or more of the rods so that the rods to which the cable is connected bend in bow-like fashion and thereby produce a force which opposes the pull on the cable, the magnitude of the force depending at least in part upon the number of rods to which the cable is connected.

'057 Patent at 7:50-60 (emphasis added). The pertinent language is also used in the '704 patent claims. '704 Patent at 7:30-33. In the context of the patent, the Court finds that the term "one end" means one portion or section of a rod that includes one of the rod's two extremities. Both parties have presented the same dictionary definition of "one" which means "a single particular unit." Merriam Webster's Ninth New Collegiate Dictionary, at 824 (1990). However, plaintiff also points to the definition of the word "end" meaning "a part of anything which includes either of its two extremities." The New Shorter Oxford English Dictionary, at 815 (1993). In this case, a broader definition of "one end" is the most consistent with the use of the words by the inventor. See Tehrani v. Hamilton Medical, Inc., 331 F.3d 1355, 1361 (Fed. Cir. 2003). In the detailed description portion of the patent, the inventor envisions rods with free ends that allow the rods to bend in a bow-like fashion in order to produce resistance. '704 Patent at 3:58-4:10 and '057 Patent at 3:31-54. This description does not preclude rods that have more than one free end.

Furthermore, this broader definition is consistent with the Federal Circuit's prior ruling in this case, in which that Court explained that a rod with two free ends literally includes one free end, and therefore, the limitation of the term requires only at least one free end. (Dkt. # 243, Ex. 1 at 6). Finally, plaintiff's expert, Mr. Rawls, has testified that a person of ordinary skill in the art would understand the term "one" to mean one or more than one. (Dkts. # 303 at 5 and # 316 at 5-6).

Accordingly, this Court construes the term "one end" to encompass a rod with two free ends, and the term "end" to encompass a portion of the rod that includes either of its two extremities.
C. The "One of" Limitations

Claim 6 claims:

An energy-absorption system comprising:

a terminal including an impact head ["Limitation 1"]; and

a cutable member having an axis ["Limitation 3"]; said energy-absorption terminal including one of the cutting section and cutable member ["Limitation 4"]; said one of said cutting section and cutable member being positioned in the energy-absorption terminal aligned with the impact head and the other of said cutting section and cutable member ["Limitation 5"]; said energy-absorbing terminal including one of the cutable member and the cutting section aligned with each other wherein the cutable member, and cutting section are forced together when the impact head of the energy-absorbing terminal is impacted by a vehicle ["Limitation 6"]; said cutting section including cutting means positioned to cut said cutable member as the cutable member and cutting section are moved with respect to each other by the impact head ["Limitation 7"].

('003 Patent, col. 9, ln.50-col. 10, ln.2).

The parties dispute the construction of Limitations 4, 5, and 6. As to Limitation 4, KEI contends that the "energy absorbing terminal" must include at least one or both of the "cutting section" or the "cutable member." (Docket Entry No. 75, p. 18). Trinity contends that the "energy absorbing terminal" includes either the "cutting section" or the "cutable member." (Docket Entry No. 76, p. 10). As to Limitations 5 and 6, KEI contends that at least one or both of the "cutting section" and "cutable member" must be positioned in the "energy absorbing terminal." (Docket Entry No. 75, p. 18). Trinity proposes that this court construe these limitations as requiring either the "cutting section" or the "cutable member" be positioned in the "energy-absorption terminal" and that the "energy absorbing terminal" include either the "cutable member" or "cutting section." (Docket Entry No. 76, p. 11).

The plain language of the limitations is imprecise. Claim 6 uses the term "comprising," which "signifie[s] that the claims do not exclude the presence in the accused apparatus of or method of factors in addition to those explicitly recited." Vivid Techs., Inc. v. American Science & Eng'g, Inc., 200 F.3d 795, 811 (Fed. Cir. 1999); Stiftung v. Renishaw PLC, 945 F.2d 1173, 1178 (Fed. Cir. 1991)(a claim "which uses the term 'comprising' is an open claim which will read on devices which add additional elements"). KEI contends that the limitation that the energy-absorption terminal include "one of the cutting section and cutable member" does not exclude the possibility that the terminal will include both the cutting section and cutable member.

Limitations 4, 5, and 6 also use the term "one of." Trinity contends that the phrase "one of said cutting section and cutable member" should be construed to mean that the terminal contains either the cutting section or cutable member, but not both. Trinity argues that the definition of the word "one" as "being a single unit or entire being and no more" supports this construction. (Docket Entry No. 77, Ex. F at T03027).

Trinity cites WMS Gaming, Inc. v. Int'l Game Tech., 184 F.3d 1339 (Fed. Cir. 1999) in support of its proposed construction of the "one of" limitations. WMS Gaming involved a patent on a type of electronic slot machine that could decrease the probability of winning through electronic circuitry. Each symbol or "stop position" on the reels of the slot machine was assigned one or more random numbers. The electronics would select a number at random from the list of randomly assigned
A person of ordinary skill in the art might select the cutting section to include in the terminal to satisfy Limitation 4, which requires that the terminal "include one of the cutting section and cuttable member." The phrase "said one of said cutting section and cuttable member" of Limitation 5 refers to the cutting section in this example. This makes "the other" element of Limitation 5 the cuttable member. In this example, the cutting section is placed in the terminal aligned with the impact head and the cuttable member. The cuttable member may or may not be included in the terminal. Limitations 4, 5, and 6 do not require that in this example the cuttable member be included in the terminal, but they do not exclude the possibility that the cuttable member is also included in the terminal.

This interpretation is consistent with the specification. The guardrail or structural pipe serving as the cuttable member could be notched at the places where the cutting section will cut on impact, and the cutting section and cuttable member could be fit snugly together, or perhaps even spot-welded together, such that both the cuttable member and the cutting section are included in the terminal. Figure 10 of the '003 Patent shows an example cuttable member with three slots into which the cutters of the cutting section fit. The cuttable member and the cutting section each starts within the terminal, but only the cutting section is attached to the impact head, such that on impact, the impact head and the cutting section move relative to the cuttable member and the cutting section cuts the cuttable member.

This court construes the limitation stating that "said energy-absorption terminal including one of the cutting section and cuttable member" as requiring that the energy-absorption terminal include either the cutting section or the cuttable member, and that the terminal may include both the cutting section and the cuttable member. Similarly, the limitation "said energy-absorbing terminal including one of the cuttable member and the cutting section numbers to determine which position would be the stop position for a given use, that is, which symbol would appear after the user pulled the slot. The patent contained a limitation that claimed a "means for randomly selecting one of said plurality of numbers," which described the step in which the electronics picked a number from the list of randomly selected numbers to determine which symbol would appear. The WMS Gaming court stated that the limitation -- "means for randomly selecting one of said plurality of numbers" -- claimed a step in which the random number generator randomly selected a single number from the list of numbers. Id. at 1349. Citing WMS Gaming, Trinity asserts that the phrase "said energy-absorption terminal including one of the cutting section and cutting member" in the '003 Patent must be construed as including either the cutting section or the cuttable member, but not both.

WMS Gaming is distinguishable and does not apply to the facts of this case. WMS Gaming involved the construction of means-plus-function claims, which are not present in this case. It was clear from the invention in WMS Gaming that a single number was being selected; the court did not engage in an extensive construction of the term "one of." The claim in WMS Gaming would make no sense if it was construed as meaning that the claimed function could select more than one number; once a single number was selected and a stop position determined, the function was complete. By contrast, it would be possible for the terminal to contain both the cutting section and cutting member. Limitation 4 requires only that one of the cutting section or cuttable member be present in the terminal; it does not exclude the possibility that both are present in the terminal.

Limitation 4 requires that "said energy-absorption terminal" include "one of the cutting section and cutting member." Limitation 5 states that "said one of said cutting section and cuttable member being positioned in the energy-absorption terminal aligned with the impact head and the other of said cutting section and cuttable member." The term "said one of said cutting section and cuttable member" refers back to Limitation 4. Limitation 4 is a list: the energy-absorption terminal must include one of the cutting section and cuttable member. The person of ordinary skill in the art must select one of the cutting section and cuttable member to include in the terminal. Limitation 5 instructs the person of ordinary skill in the art to take whichever of the cutting section and cuttable member he or she selected as having to be in the terminal and position that item in the terminal such that it is "aligned with the impact head (also a part of the terminal per the language of claim 6) and the other of said cutting section and cuttable member." "The other of said cutting section and cuttable member" refers to whichever of the cutting section and cuttable means the person of ordinary skill in the art did not select as having to be in the terminal. That element could be positioned in the terminal, but the claim limitations do not require that result. The claim limitations only require that "the other" element, which the person of ordinary skill in the art chooses not to include in the terminal, must be aligned with the element that the person did choose to be in the terminal.

Similarly, the limitation "said energy-absorption terminal including one of the cutting section and cuttable member" as requiring that the energy-absorption terminal include either the cutting section or the cuttable member, and that the terminal may include both the cutting section and the cuttable member. Similarly, the limitation "said energy-absorbing terminal including one of the cuttable member and the cutting section
aligned with each other wherein the cutable member, and cutting section are forced together when the impact head of the energy-absorbing terminal is impacted by a vehicle" requires that either the cutting section or cutable member must be present in the terminal, and both may be present in the terminal.

To summarize, Limitations 4, 5, and 6 do not exclude a configuration in which both the cutting section and cutable means are included in the terminal.

2720

G. Wherein a predefined one of the positions on the riser card has both ISA type and PCI type expansion connectors associated therewith

1. Parties' positions

The parties dispute whether this phrase limits the number of combi-connectors to one, and only one, or whether it is merely a requirement that there be at least one combi-connector. Tulip's proposed construction is that the disputed phrase means that "at least one position on the riser card is a combination slot (or combi-connector) that has both an ISA type connector and a PCI type connector." 124 Dell argues that "the phrase requires one and only one expansion position on the riser card that includes a combination of both an ISA type and a PCI type expansion connector." 125

Tulip suggests that the disputed phrase requires that there be a combi-connector on the riser card but does not limit the invention to including only one combi-connector. Tulip contends that Dell's proposed construction has the effect of adding the words "and only one" to the claims. Tulip argues Dell's construction reads an improper unstated limitation into the language of the claims. Furthermore, Tulip insists that maintaining the effect of the applicant's open transitional language is particularly appropriate here, as Tulip never amended its claims to limit the invention to having a single combination connector and there is no prior art in the prosecution history having multiple combination connectors on a riser card that a limitation to a single combi-connector would avoid.

Dell states the clear meaning of the word "one" limits the meaning of the disputed phrase to "one and only one," 126 and therefore, the disputed phrase limits the claimed invention to one and only one combi-connector. Dell disputes Tulip's assertion that the prosecution history does not distinguish the '621 invention from prior art based on the number of combination connectors on the riser card. During prosecution, Tulip stated that "independent claim 4 [claim 1 of the '621 patent as issued] … contains suitable recitations directed to the distinguishing aspects of the present invention--with those recitations being shown in bolded type." 127 The phrase "wherein a predefined one of the positions" was among the bolded type. 128 Dell contends this shows that Tulip considered "a predefined one" combi-connection to be one of its invention's distinguishing characteristics. Dell also notes that the claims at issue demonstrate that when Tulip contemplated more than one slot of a particular type on the riser card it drafted language to so provide. Both claims 1 and 2 include the language:

wherein a predefined one of the positions on the riser card has both ISA type and PCI type expansion connectors associated therewith and situated one above another so as to accommodate either an ISA type or a PCI type expansion board in said predefined one position, wherein said predefined one position is located on the riser card below at least one of the positions having the ISA type expansion connector and above at least one of the positions having the PCI type expansion connector. 129
Dell contends that Tulip is now attempting to broaden its claim by effectively adding the words "at least" before its reference to the "predefined one" combination connector. Dell also disagrees with Tulip's statement of the affect of the open transitional phrases in the claims at issue. Dell argues that Tulip's use of restrictive claim language with respect to one combi-connector trumps the transitional phrases "comprising" and "having."

--- End Footnotes ---

2. Court's construction

The parties are in agreement that the disputed phrase refers to a combi-connector. They disagree over whether the phrase limits the invention to a single combi-connector. The claim elements unambiguously make a distinction between the "predefined one" combi-connector position and "at least one" position for ISA and PCI connectors located above and below the "predefined one" combi-connector position. The word "one" is an adjective describing "a single unit." 130 A "predefined one of the positions on the riser card having both ISA type and PCI expansion connectors [a combi-connector]" would ordinarily be understood to mean a single combi-connector. This understanding is reinforced by claim language describing the location of ISA connectors and PCI connectors relative to the combi-connector which makes it absolutely clear that the invention is not limited to a single dedicated ISA connector and a single dedicated PCI connector. After the "predefined one" combi-connector position is defined as "having both ISA type and PCI type expansion connectors associated therewith and situated one above another so as to accommodate either an ISA type or a PCI type expansion board", that "predefined one position" is described as being located "below at least one of the positions having the ISA type expansion connector and above at least one of the positions having the PCI type expansion connector."

--- Footnotes ---
130 WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 1575 (1993).
--- End Footnotes ---

Tulip's proposed construction would broaden the claims to read "at least one predefined" position would have a combi-connector. Unlike the court's earlier determination that the phrases "peripheral side edge" and "side edge" have the same meaning because they clearly reference the same area on the motherboard, here, the "predefined one" combi-connector position and "at least one" position having an ISA connector and "at least one" position having a PCI connector all refer to different areas on the riser card. It would be inappropriate, therefore, for the court to construe "one" to mean the same thing as "at least one." Contrary to Tulip's assertion, Dell's proposed construction, that "a predefined one" combi-connector position means "one and only one" combi-connector position, is not improperly imposing an unstated limitation on the claims at issue. 131 Dell's proposed construction merely applies the ordinary and accustomed meaning to the phrase. One means a single unit. One means one.

131 See Northern Telecom Ltd. v. Samsung Electronics Corp., 215 F.3d 1281, 1290 (Fed. Cir. 2000). ("This court has repeatedly and clearly held that it will not read unstated limitations into claim language."); Kemco Sales, Inc. v. Control Papers Co., Inc., 208 F.3d 1352, 1362 (Fed. Cir. 2000) ("We are fully cognizant of the need to avoid reading limitations into

- 3245 -
Tulip nevertheless argues that because the claims contain open transitional phrasing ("comprising" and "having"), it would be improper to construe the disputed phrase so as to limit the invention to having a single combi-connector. It is true that claims containing open transitional phrasing are not limited to covering only the elements specifically recited in those claims. 132 Acknowledging that Tulip's patent may cover products having additional elements not recited in its claims is different than agreeing that its claims cover more than the specific number of combi-connector positions claimed, i.e., one. 133 The court does not agree with Tulip's assertion of the effect of open transitional language (that "a predefined one" combi-connector means "at least one" combi-connector) because such interpretation means the words "at least" have no separate meaning when the claims refer to "at least one" ISA connector and "at least one" PCI connector. Having determined that the ordinary and accustomed meaning of the word "one" is a single unit, and that the use of transitional phrasing does not eliminate a self-imposed numerical limitation, the court must consider whether the specification or prosecution history eliminate this limitation.

132 See Crystal Semiconductor Corp., 246 F.3d 1336, 1348 (Fed. Cir. 2001) ("When a patent claim uses the word 'comprising' as its transitional phrase, the use of 'comprising' creates a presumption that the body of the claim is open. In the parlance of patent law, the transition 'comprising' creates a presumption that the recited elements are only a part of the device, that the claim does not exclude additional, unrecited elements. The transition 'having' can also make a claim open.") (citations omitted).

133 Innovad Inc. v. Mirocoft Corp., 260 F.3d 1326, 1333 (Fed. Cir.2001) (finding that "the term 'single,' … precludes the use of multiple switches to perform [a specifically recited function]" even where the preamble recited the transitional phrase "comprising"); see also Novo Nordisk A/ S v. Eli Lilly & Co., 1999 U.S. Dist. LEXIS 18690, No. Civ. A. 98-643 MMS, 1999 WL 1094213, at *12-13 (D.Del. Nov. 18, 1999) (The Novo Nordisk court construed a claim reciting two zinc ions to be limited to two and only two even with transitional phrase "comprising." The court noted that within the same claim the words "at least" preceded "three phenolics" and that "the expression of a limitation in one element of a claim implies the exclusion of that term in other elements of the claim …. In order to give meaning to the choice to use the term 'at least' to modify only 'three phenolics,' claim 1 must mean that a hexamer complex can contain more than three phenolics but not more than two zinc ions per hexamer.").

The language of the specification repeats the same limitation on the number of combi-connectors to "one position" and consistently recites that there is "at least one" ISA connector above "that one position" for a combi-connector and/ or "at least one" PCI connector below "that one position" for a combi-connector. 134 The language of the specification reinforces the plain language of the claims and provides no basis to broaden the scope of those claims. Likewise, nothing in the prosecution history indicates that the court should construe the "predefined one" combi-connector position to mean "at least one" combi-connector position.

134 See 621 at 3:3-13 ("the riser card has one position where either an expansion card of the ISA type or an expansion card of the PCI type can be arranged in that, at that position, a connector of the ISA type and a connector of the PCI type are arranged above each other and parallel to each other; and the riser card comprises above that position at least one position for an expansion card of the ISA type, at which position a connector of the ISA type is arranged, and/ or under that one position at least one position for an expansion card of the PCI type, at which position a connector of the PCI type is arranged"); Id. at 4:6-16 (same).
argument that its invention taught a riser card having only a single combi-connector. Although the court agrees it did not make that argument, that fact is irrelevant. 135 The fact that Tulip did not make that argument means that the court would not otherwise limit the '621 patent's coverage to single combi-connector riser cards had the claim language itself not so limited the patent's scope of coverage. The opposite does not follow. Just because Tulip did not need to distinguish its invention based on a particular claim element does not mean that its patent claims are entitled to broader coverage than the limitations clearly recited in those claims.

--- Footnotes ---

135 Dell's contention that the prosecution history reveals that Tulip did limit its claims to a riser card with a single combi-connector position because "a predefined one of the positions" was among bolded type used by Tulip to designate the distinguishing aspects of its invention is misleading. The entirety of the disputed phrase is bolded. That phrase is not otherwise defined in the prosecution history and the task of determining the meaning of the phrase now rests with this court.

--- End Footnotes ---

The ordinary and accustomed meaning of the word "one" is a single unit. Nothing in the specification or prosecution history contradict this ordinary meaning. Consequently, the court construes the phrase "wherein a predefined one of the positions on the riser card has both ISA type and PCI type expansion connectors associated therewith" to mean that the riser card has a single expansion position having a single combi-connector.

--- Footnotes ---

29 The phrase "one or more converters" is used in claims 1, 21, 25, 29, and 30 of the '259 patent.

--- End Footnotes ---

1. ADE's Position

ADE argues that "one or more converters" should be construed according to its plain meaning to mean "one or more components for converting light collected by the collectors into signals, typically electronic signals, which correspond to the amount of light, e.g., PMTs or photodetectors." (D.I. 613 17-18.) ADE further asserts that KLA, once again, attempts to read improper limitations into the construction of this claim language. (Id.) ADE then avers that a patent specification need not "catalogue and describe every possible embodiment [or arrangement of an invention] covered by the [patent] claims …." (Id.)

2. KLA's Position

KLA, on the other hand, argues that "one or more converters" "should be construed to mean: 'one or more separate detectors, each being in optical communication with a separate one of the first and second collectors.'" (D.I. 594 at 19.) KLA directs the Court to the '259 specification in urging adoption of this construction. (Id. at 19-20.) In particular, KLA refers to portions of the '259 specification describing that "each collector must have a converter associated with it." (Id. at 19.) In other words, argues KLA, "the specification describes a one-to-one correlation between collectors … and their respective detectors" and this "one-to-one correlation … is necessary to practice the claimed invention." (Id. at 20.)

3. Analysis

The '259 specification does not specifically define what is meant by a "converter." The claims in which the phrase "one or more converters" appears, however, do give guidance as to the proper construction. Claim 1 of the '259 patent is representative. The fifth element of that claim states that the invention covered by claim 1 employs "one or more converters
for converting the collected light components into respective signals representative of the light scattered into the central zone and oblique zone." (D.I. 627 at '259 Patent col. 12 II. 32-35.) It is clear, therefore, that the "converter" must be capable of transforming collected light into signals that represent the light that was collected. Given this, a person of ordinary skill in the art would reference the specification to determine what physical structures operating in combination could perform such a task, i.e., what did the inventors intend when they used the word "converter" to define their invention.

Both parties directed the Court to a specific passage in the specification to aid its interpretation. (JCCS at 7.) A portion of that passage provides that:

The dark channel detector … further includes a forward channel detector … a center channel detector … and a back channel detector … each respectively positioned in optical communication with a corresponding collector … and means electrically connected to the forward, center and back channel detectors … and responsive to electrical signals from said detectors for determining the presence of a particle [or pit] on the surface … of a workpiece …. The determining means of the collector is preferably electronic signal discrimination circuitry … and understood by those skilled in the art, which receives signals representative of collected light from the light channel detector … and the dark channel detector ….

(D.I. 627, '259 Patent Prosecution File History, '259 Patent at col. 7 II. 46-60.) It appears from the foregoing passage and the claim language surrounding the phrase "one or more converters" that a converter is a detector in optical communication and electrically connected to a corresponding collector. The Court, therefore, construes "converter" to mean a detector in optical communication and electrically connected to a corresponding collector. Accordingly, the phrase "one or more converters" means one or more such detectors in optical communication and electrically connected to one or more corresponding collectors.

---

1. "One Piece Lever"

As demonstrated above, various iterations of the phrase "one-piece lever" appear in claims 19 and 21 to indicate a lever that is operatively associated with a piston inside a master cylinder. The lever engages the brake by moving between a rest position and an actuated position. According to SRAM, this term does not need to be construed. Formula disagrees and argues that the term means "a lever consisting of only one piece."

As SRAM points out, the phrase "consisting of" has special meaning when used in a patent: It excludes any unrecited claim element and the reach of a claim using the term is correspondingly very narrow. See CIAS, Inc. v. Alliance Gaming Corp., 504 F.3d 1356, 1360-61 (Fed. Cir. 2007). The ill-considered use of this phrase within a patent claim can have drastic consequences for the scope of the protection afforded to the inventor. See Immunocent, LLC v. Fullbright & Jaworski, LLP, 504 F.3d 1281, 1283 (Fed. Cir. 2007). Consequently, it would be inappropriate to import such a limitation into the claim in the course of litigation when neither the inventor nor the patent examiner deemed it necessary to do so.

Formula also proposes that we construe the term "one piece" to mean "only one piece" but does not offer any persuasive reason why the additional word is necessary. Formula's arguments appear more directed toward a determination of whether specific levers can be considered to be made of one piece or not. Our task at this point of the litigation is to construe the meaning of the claims as a matter of law, not to apply those meanings in particular contexts. See, e.g., Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 1454 (Fed. Cir. 1998). Accordingly, we conclude that the term "one piece" as used in these two claims is not in need of greater elaboration for purposes of claim construction. See Biotec Biologische Naturverpackungen v. Biocorp, Inc., 249 F.3d 1341, 1349 (Fed. Cir. 2001).

---

5. "One-piece" (422 Patent, Claim 1)

"One-piece" is construed as "having no parts that separate from the unit during normal operation and containing no parts
that are not integrally formed."

When both terms are given their ordinary meaning, the term "one-piece" is the equivalent of "integral." See, e.g., Rexnord Corp. v. Laitram Corp., 274 F. 3d 1336, 1341, 1344-45 (Fed. Cir. 2001) (equating "integral" with "one-piece"; distinguishing "two-piece structure" from "an 'integral' structure"); Knorr-Bremse Systeme Fuer Nutzfahrzeuge GmbH v. Dana Corp., 133 F. Supp. 2d 833, 840 (E.D. Va. 2001) (construing "one piece caliper" as "a caliper constructed or formed as a single, integral piece"). At the claim construction hearing, the parties agreed that when one part of a device is "integrally formed" with another part of the device, the two parts are not connected with mechanical joints. Such definition is consistent with the ordinary meaning of "integral" as distinguished from "two-piece," or "separate." See Rexnord Corp., 274 F. 3d at 1345 (noting "the other two embodiments do not describe two-piece, or separate, constructions"; further noting "words that connote a quality of being 'separate'" include "attachment"); compare 422 Patent, col. 4, II. 65 - col. 5, II. 37 (claiming "one-piece holder" comprising exclusively "integrally formed" parts), with id., col. 6, II. 1-18 (claiming "combination money clip and card holder" comprising both "integrally formed" parts and "pivotally attached" part).

6. "One-Piece Holder" (230 Patent, Claims 1, 7, 13)

"One-piece holder" is construed as "a holder having no parts that separate from the unit during normal operation and containing no parts that are not integrally formed."

A. Claims One and Six

With reference to claims one and six, Danek contends there is neither literal infringement nor infringement under the doctrine of equivalents. AcroMed relies solely on literal infringement, thus the motion is limited thereto.

The infringement issue centers around similar "one-piece" language in claims one and six. Claim one claims, inter alia, that the apparatus used to obtain the desired spatial relationship is comprised of a bone screw, rod, "and a one-piece connector means" used to connect the rod and bone screw. (PX A at column 8, lines 54-55.) (Emphasis added.) Claim six claims an apparatus is used to obtain the desired spatial relationship, comprised of a bone screw, rod, and "a one-piece L-shaped connector member" used to connect the rod and bone screw. (Id. at column 9, lines 42-43.) (Emphasis added.) Danek contends that none of its products contain a "one piece" connector.

The patent description notes "the connector member…is formed from one piece of biocompatible material…." (Id. at column 4, lines 46-47.) The prosecution history further defines "one piece."

The original patent application was received by the PTO on July 24, 1990. The proposed claims in that application did not contain the term "one piece." (DX D at 41-46.) 4 On June 6, 1991, all claims then pending in the application were rejected by the patent examiner. (Id. at 73-76.) The claims were rejected under 35 U.S.C. § 102(e) "as being anticipated by Frigg." (Id. at 74.) The examiner noted specifically that, among other disclosures, Frigg disclosed a connector means, or a connector member. (Id. at 74-76.)
4 Defendants' exhibit D was not paginated. It has been consecutively paginated.

An amended application was filed with the PTO on September 20, 1991. It added the language "a one-piece" to one of the claims. It added the phrase "a one-piece L-shaped connector member" to another claim. (Id. at 78.) In the accompanying remarks, Frigg was distinguished as follows:

In Frigg, a three-piece connector means 9 (Fig. 1) or a two-piece connector means (Fig. 6), interconnects a fastener 12 [bone screw] and a longitudinal member 10 [rod]. The three-piece connector means 9 (Fig. 1) comprises an upper jaw section 14, a lower jaw section 16 and a hook 20. The two-piece connector means (Fig. 6) comprises a block 50 and a hook 20. Accordingly, claim 18 which recites a one-piece connector clearly distinguishes over the prior art and is allowable.

(Id. at 81.)

On January 22, 1992, the patent application was allowed. (DX D at 84-86.) One of the reasons for allowing the patent was as follows:

In accordance with Applicant's definition of "one-piece" [above quoted]...Frigg fails to disclose or suggest a "one-piece" apparatus.

(Id. at 85.)

AcroMed's expert concludes that the "term 'one-piece connector means' requires that the lateral adjustability provided by the connector be accomplished by a single piece (in conjunction with a bone screw)." (PX C at P8.) He does not mention the prosecution history.

In summary, the meaning and scope of claim one requires that the connector, which provides lateral adjustability, be one piece, as distinguished from the two-piece and three-piece connectors disclosed in Frigg.

10. One-Way Snap Lock

The Court now considers the construction of the term "one-way snap lock" that appears in claims 1, 13, 14, 26, and 27 of the '410 patent. The Plaintiffs contend that the term means "a fastening device that closes with a catch and that once closed, cannot be opened by applying the reverse of the motion used to close the device." (Pls.' Open. Br. 35-36.)

Pergo asserts that one-way snap lock means "a lock in which two panels, having abutting vertical surfaces on their locking elements and locking groove, are snapped together by moving one panel horizontally toward the other, and once joined cannot be pulled apart without damaging the joint." (Unilin's Open. Br. 47.) In proposing its definition, Pergo relies on claim 1 of the '410 patent which states "said locking means being constructed so as to operate in as a snap lock in said horizontal direction during assembly of the panels." (Id. (quoting '410 patent, 10:58-60).) Pergo also relies upon the specification statement that "the locking surface 10 of the locking element 8 serves as a stop with respect to the surface of the locking groove 14 closest to the joint edge 4." (Id. (quoting '410 patent, 7:37-39).) Pergo asserts that if one or more surfaces are not vertical, the joint may be pulled together by a horizontal force.

The Plaintiffs' proposed definition is consistent with the claim language and the ordinary meaning of the terms "one-way snap lock." Pergo's suggestion that "vertical" should be included in the definition would improperly read language from the specification describing the preferred embodiment into the claim and is rejected. See Phillips, 415 F.3d at 1323. One-way means permitting in one direction only. Webster's II New Riverside University Dictionary 821. "Snap" means to open or close with a click. Id. at 1100. Considering these ordinary definitions in the context of the claims and specification as a whole, the Court construes "one-way snap lock" as meaning "a fastening device that closes with a catch and that once
I. Literal Infringement

Claim 3, Step 3 recites the step of supplying a dose of respirating gas "only for the duration T[1]." The meaning of Claim 3 and this limitation, in particular, are clear and unambiguous, in view of the claim language itself and other intrinsic evidence. The specification states, in pertinent part, "thus, no respirating gas is applied to the patient during expiration." Resort to extrinsic evidence to interpret Claim 3 in this regard would therefore be improper. Bell & Howell, 132 F.3d at 706; Vitronics, 90 F.3d at 1584-85.

The ImPulse Select device, however, like the Stewart device and the Invacare Venture device, can and does supply a dose of oxygen when a patient exhales. Dkt. no. 84, at 35 et seq. Although very few patients ever experience a pulse of oxygen during exhalation, the fact remains that the ImPulse Select is capable of delivering such a pulse, something the '303 patent states should never happen. I therefore conclude that the ImPulse Select does not meet the claim limitation that T[1] be less than T[2]. The dosing method of the ImPulse Select is simply not the same as the claim limitation of claim 3. Thus, the accused method omits at least one claim limitation recited in Claim 3 and there is no likelihood of literal infringement of that claim. Becton Dickinson, 922 F.2d at 796.

Plaintiff, however, argues that merely pointing out certain operating conditions under which the device may not infringe is insufficient to avoid liability if the device infringes under other circumstances. Canon Computer Sys., Inc. v. Nu-Kote Int'l, Inc., 134 F.3d 1085, 1089, 45 U.S.P.Q.2d (BNA) 1355 (Fed. Cir. 1998). As a general principle, this is unassailable. Simply because, under certain operating conditions, a device does not infringe is not persuasive evidence for defendant because "this has little bearing on whether [the accused infringer's device] will avoid infringement under other foreseeable operating conditions." Id. Rather, "for a manufacturer [of a device], infringement is determined by the use to which the device may reasonably be put or of which it is reasonably capable." Huck Mfg. Co. v. Textron, Inc., 1975 U.S. Dist. LEXIS 12539, 187 U.S.P.Q. (BNA) 388, 408, 1975 WL 21108 (E.D. Mich. 1975).

741 The fact that an accused device that only infringes during certain times of operation nonetheless infringes has been long accepted. If devices "were designed so that they could be operated normally in an infringing way, it would seem to be immaterial that some customers did not choose at times to operate them in that manner." Stearns-Roger Mfg. Co. v. Ruth, 87 F.2d 35, 38 (10th Cir. 1936). "[A] machine that infringes part of the time is an infringement, although it may at other times be so operated as not to infringe." Wright Co. v. Herring-Curtiss Co., 211 F. 654, 655 (2d Cir. 1914).

making a device capable of infringing use constitutes infringement even though it may be capable of some noninfringing use, see Bell Comm. Research, Inc. v. Vitalink Comm. Corp., 55 F.3d 615, 622-23, 34 U.S.P.Q.2d (BNA) 1816 (Fed. Cir. 1995); Kustom Signals, Inc. v. Applied Concepts, Inc., 52 F. Supp. 2d 1260, 1279 (D. Kan. 1999) (citing Bell, 55 F.3d at 622-23), and "it is of no moment that in certain modes of operation . . . [the accused infringing device] may not operate in a way that would infringe the . . . patent. It matters only that the insured device operate in an infringing way at some time]." Interspiro USA, Inc. v. Figgie Int'l, Inc., 815 F. Supp. 1488, 1512, 27 U.S.P.Q.2d (BNA) 1321 (D. Del. 1993), aff'd, 18 F.3d 927, 30 U.S.P.Q.2d (BNA) 1070 (Fed. Cir. 1994). But while true as a basic precept, plaintiff's argument based on this body of law fails to recognize the express claim limitation that the duration T[1] is "less than the duration T[2]," which was reinforced by the patentee's statement in the prosecution history that "gas supply can never last longer than the patient's inspiratory effort." The patentee having limited his claim by the express use of the inequality "less than"--confirmed as a matter of claim construction by the use of the word "never" in the prosecution history--Sunrise as assignee cannot now rely on the above-referenced general authorities to assert that this limitation should be of no effect and that infringement should be found merely because most users experience no oxygen flow during expiration.

For this reason, Canon is distinguishable. There, the claim at issue required an airflow passage and a "first chamber" in the
cartridge, while the accused device had a groove in the cartridge that the plaintiff contended acted as the air flow passage. Defendant submitted that under certain circumstances, the groove did not act as an air flow passage and the accused device did not infringe, although in other foreseeable operating circumstances the device could infringe. But there, the patent did not have limitations in the claim or language in the specification supporting a limitation that would exclude the accused device. In addition, there was no prosecution history in which the patentee specifically excluded certain devices or methods by distinguishing them over the prior art and by using the word "never."

Claim 3 further recites, in Step 2, that the duration \( T[1] \) is "less than the duration \( T[2] \)." The meaning of this limitation is clear from the claim language itself and from the specification. As the patentee states,

an object of this invention is to provide a respirator apparatus and method of operating same wherein respirating gas is supplied to a patient substantially at the beginning of an inspiration and for a time period thereafter which is a fraction of the duration of inspiration.

When in use, the accused device's pulse dose interval can be less than, equal to, or greater than \( T[2] \). Thus, for this additional reason, it is unlikely that there is literal infringement of Claim 3.

D. "For Initiating the Heating of Said Object Only upon . . ."

The parties' next dispute concerns the following term from the claims of the '585 Patent: "for initiating the heating of said object only upon placement of said object proximal to said heater and in a position for RF communication between said tag and said reader." Defendants seek to construe the term to mean the microprocessor will initiate heating of the object when the object is placed (i) proximal to said heater and (ii) in a position where RF communication between said tag and said reader, but not before both (i) and (ii) occur. TSI argues that no further construction is necessary for this term.

By their construction, defendants would limit the scope of the claims to require that two particular steps (placing the object in proximity to the heater and in a certain position to allow RF communication) and nothing more be completed for the heating to commence. Defendants argue that requiring more than a single step promotes safety and efficiency, while requiring only two steps furthers the goal of having an easy auto-start function. TSI responds that the claim language, which provides that heating will be initiated "only" upon placement of the object in proximity and in the proper position, requires
both steps but does not preclude a system in which more than those two steps are required for heating to commence.

Defendants cite only a single excerpt from the patent's specification in support of their urged limitation. That excerpt, however, refers to the completion of the two steps "permitting commencement of the heating cycle." See '585 Patent at 7:5-10. Thus, the specification does not preclude having additional required steps as well. Defendants also cite to the provisional application for the patent and to an affidavit from the inventor that refer to the ease of starting the process, but neither document states that no additional requirements could ever be imposed.

Defendants have not identified any disclaimer or disavowal of claim scope to support this limitation, and thus appear to rely solely on the Microsoft standard here. The specification does not contain any description of the invention as limited in this way, however. Accordingly, the Court rejects defendants' proposed construction and concludes that this term need not be construed further.

2730

B. Infringement

OSI argues that the district court erred in interpreting claim 1 of the '898 patent to cover gamma units with radiation sources and beam channels located between 0 degrees and 30 degrees. OSI asserts that the claim language "only within a zone extending between latitudes 30 degrees-45 degrees" unambiguously excludes gamma units with radiation sources between 0 degrees and 30 degrees. OSI contends that, even though the preferred embodiment discloses radiation sources between 0 degrees to 45 degrees, claim 1 should be limited to gamma units with radiation sources located exclusively between 30 degrees to 45 degrees because the scope of Elekta's right to exclude is governed by the language of the claims, not by the written description. OSI thus asserts that the district court erred in concluding as a matter of law that its RGS device literally infringes claim 1. Moreover, OSI argues that Elekta is barred by prosecution history estoppel from arguing infringement under the doctrine of equivalents, because coverage of gamma units with radiation sources in the range of 0 degrees to 30 degrees was surrendered in response to an obviousness rejection.

Elekta responds that the district court properly construed claim 1 as covering gamma units with radiation sources that are in a zone having an upper boundary between 30 degrees to 45 degrees. Elekta argues that the plain meaning of the term "extending" is "reaching," which includes 0 degrees to 30 degrees, and that the district court's claim construction is the only interpretation that is consistent with the claim language, the written description, and the prosecution history. Elekta contends that OSI's proposed interpretation is inconsistent with the drawings and the written description, and should not be adopted because it fails to cover the preferred embodiment and would render the claim invalid. Elekta further contends that the district court properly concluded as a matter of law that OSI's RGS device literally infringes claim 1 of the patent.

In interpreting claims, a court should rely upon "the claim language, the written description portion of the specification, the prosecution history, and if necessary to aid the court's understanding of the patent, extrinsic evidence." Gentry, 134 F.3d at 1476, 45 U.S.P.Q.2D (BNA) at 1500. "While we have held many times that a patentee can act as his own lexicographer to specifically define terms of a claim contrary to their ordinary meaning," the written description in such a case must clearly redefine a claim term "so as to put a reasonable competitor or one reasonably skilled in the art on notice that the patentee intended to so redefine that claim term." Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357, 52 U.S.P.Q.2D (BNA) 1029, 1033 (Fed. Cir. 1999). Absent an express intent to impart a novel meaning, claim terms take on their ordinary meaning. See Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249, 48 U.S.P.Q.2D (BNA) 1117, 1121 (Fed. Cir. 1998).

We agree with OSI that the district court erred in interpreting claim 1 to include gamma units with radiation sources and beam channels located "beginning at the edge of the helmet (0 degrees) and extending to a point between 30 degrees-45 degrees." The district court erred in its claim construction because it did not accord the claim language its ordinary meaning. Claim 1 explicitly provides that the radiation sources and the beam channels in the gamma unit are located "only within a zone extending between latitudes 30 degrees-45 degrees, as seen from the diametrical plane." '898 patent, col. 3, ll. 26-27 (emphasis added). When given their ordinary meaning, the terms "only" and "extending between" unambiguously limit claim 1 to gamma units with radiation sources and beam channels located in a zone stretching exclusively in the space separating the latitudes 30 degrees and 45 degrees. See, e.g., Webster's New World Dictionary 947 (3d ed. 1988) (defining
"only" as "solely; exclusively"; see id. at 480 (defining "extending" as "to stretch out"); see id. at 134 (defining "between" as "in or through the space that separates (two things)"). While Elekta argues that "extending" should be interpreted as "to reach" rather than "to stretch," we conclude that the key word is "between," and that the ordinary meaning of the phrase "only within a zone extending between" is inescapable. The claim only encompasses 30 degrees-45 degrees. Any other conclusion renders the reference to 30 degrees superfluous.

The written description does not convince us otherwise. It is true that, while "one may not read a limitation into a claim from the written description, . . . one may look to the written description to define a term already in a claim limitation, for a claim must be read in light of the specification of which it is a part." Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120. The parties do not dispute that the written description discloses a gamma unit with radiation sources and beam channels located between the latitudes of 0 degrees and 45 degrees. See, e.g., '898 patent, col. 2, ll. 16-22; id. at col. 2, l. 64 to col. 3, l. 3. However, the unambiguous language of the amended claim controls over any contradictory language in the written description.

OSI also argues that the prosecution history provides another reason why claim 1 should be limited to gamma units with radiation sources and beam channels located exclusively between 30 degrees and 45 degrees. Claims that have been narrowed in order to obtain issuance over the prior art cannot later be interpreted to cover that which was previously disclaimed during prosecution. See Graham v. John Deere Co., 383 U.S. 1, 33, 15 L. Ed. 2d 545, 86 S. Ct. 684 (1966); Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995). During prosecution, the examiner initially rejected claim 1 for obviousness, stating that:

Applicants [sic] stated point of novelty is only the elimination of the radiation sources which are located within a zone that is near or on the longitudinal plane of the patient. Applicant claims his sources within a zone of latitudes from 30 degrees-45 degrees. But the prior art gamma units have sources which are located within a zone which includes 30 degrees-45 degrees. Applicant does not claim the zone which is exclusively 30 degrees-45 degrees or that his sources specifically are not at latitudes near the longitudinal plane of the patient.

Paper No. 10 at 3. In response to the examiner's rejection, the applicant amended claim 1 as follows, with additions indicated by underlining and deletions indicated by brackets:

1. (Amended) An arrangement in a gamma unit, . . . the radiation sources [(9)] and the beam channels [(6, 19)] . . . located, in relation to the diametrical plane [through] extending across the opening to said face, only within a zone extending [to] between latitudes 30 degrees-45 degrees, as seen from said diametrical plane.

Paper No. 14 at 1.

Elekta argues that those amendments were made to address the examiner's concern that the original claims did not incorporate the point of novelty stated in the written description - the elimination of radiation sources near the longitudinal plane of the patient (90 degrees), not the elimination of radiation sources between 0 degrees and 30 degrees. While this may explain why the term "only" was added to the claim, Elekta's explanation fails to adequately address the change from the word "to" to "between." OSI responds that the word "to" was changed to "between" in response to the examiner's statements that "prior art gamma units have sources which are located within a zone which includes 30 degrees-45 degrees," and that "Applicant does not claim the zone which is exclusively 30 degrees-45 degrees." Paper No. 10 at 3. We agree. In view of these statements from the examiner, a person of skill in the art would understand that the term "to" was changed to "between" in order to respond to the examiner's statement and to distinguish the prior art by claiming exclusively the range of 30 degrees-45 degrees. We therefore agree with OSI that claim 1 is susceptible of only one reasonable construction, and is limited to gamma units with radiation sources located exclusively between 30 degrees-45 degrees.

Elekta argues that OSI's proposed claim construction should not be adopted because it would exclude the preferred and only embodiment disclosed in the specification. We have previously stated that "such an interpretation is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1578 (Fed. Cir. 1996). That proposition is correct. However, in light of the prosecution history and the unambiguous language of the amended claim, we conclude that this is the rare case in which such an interpretation is compelled.
Elekta further argues that OSI's interpretation would render claim 1 invalid, because a gamma unit with radiation sources solely between 30 degrees-45 degrees would be inoperative. We do not reach the issue of invalidity, and we note that the record is unclear as to whether such a device would be inoperative. Moreover, having concluded that the amended claim is susceptible of only one reasonable construction, we cannot construe the claim differently from its plain meaning in order to preserve its validity (upon which we do not opine). Cf. Process Control, 190 F.3d at 1357, 52 U.S.P.Q.2D (BNA) at 1033 ("Where, as here, the claim is susceptible to only one reasonable construction . . . we must construe the claims based on the patentee's version of the claim as he himself drafted it.").

5. "onto each other"

Read in context, the pertinent claim language discusses the "imaging [of] mask alignment marks and substrate alignment marks onto each other by the projection system." Specification language suggests that "onto each other" means to be placed with a substantial degree of overlap. See '832 Patent at 10:20-43. In so suggesting, the specification language implies that the imaging can occur in a unidirectional manner; i.e., the first pair of marks and the second pair of marks need not both be imaged onto the other so long as one pair is so imaged onto the other. Id. Congruent with this intrinsic evidence, the court thus construes "onto each other" to mean "projecting mask alignment marks and substrate alignment marks to a substantial degree of overlap."

7. Introducing Onto

The meaning of the term "introducing…onto" is in dispute. It appears in the following context: "introducing concentrated detergent solution having a concentration level in the range of 0.5 to 12% by weight onto said fabric as said fabric is tumbling." ('370 patent, claims 8,15.)

Whirlpool seeks the following construction: "This claim step means that concentrated detergent solution in the range of 0.5 to 12% by weight is introduced into the wash chamber by directing the concentrated detergent solution onto (i.e., on top of) the fabric as the fabric is tumbling in the wash chamber."

LG argues for the following construction: "Introducing concentrated detergent solution… onto the fabric in a wash chamber that does not contain a pool of detergent solution as the fabric is tumbling in the wash chamber. Introducing onto said fabric is not limited to introducing solution to only the top of the fabric."

The dispute is whether "introducing solution onto fabric" requires that the solution originate at a point vertically above the fabric. Whirlpool argues that the ordinary meaning of "onto" means "on top of, upon," AMERICAN HERITAGE DICTIONARY and thus the claim requires that the solution be introduced from above the clothes. LG counters that a definition of "upon" is "used to indicate contact with or extent over (a surface) regardless of position," which suggests that the contact may occur from any direction. AMERICAN HERITAGE DICTIONARY. The Court finds the dictionary definitions ambiguous and that the ordinary meaning of "onto" does not require movement from top to bottom. For example, someone painting his living room ceiling would be "introducing" paint "onto" the ceiling, but of course would do so from bottom to top. Thus, the Court construes the terminology to encompass contact from any direction. See Inverness Med. Switzerland v. Warner Lambert Co., 309 F.3d 1373, 1379 (Fed. Cir. 2002) ("A word that has an ordinary meaning encompassing two relevant alternatives may be construed to encompass both alternatives.").

Accordingly, the Court adopts LG's proposed construction of "directing…solution…onto said fabric."
E. "so that at least a portion of the fallopian tube is open"

The final disputed phrase from the '361 patent is "so that at least a portion of the fallopian tube is open" from claims 37 and 38. Proposed constructions are shown below.

**CONCEPTUS'S PROPOSED CONSTRUCTION**

"so that at least a portion of the fallopian tube is not completely occluded"

**HOLOGIC'S PROPOSED CONSTRUCTION**

Indefinite subject to 35 U.S.C. 112.

Otherwise:

"that there is no obstruction in the fallopian tube preventing the meeting of sperm and ovum"

As a preliminary matter, Hologic's indefiniteness argument must be rejected. As the analysis below illustrates, this phrase is amenable to construction in light of the specification. Given this conclusion, the phrase is not indefinite. See Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1374 (Fed. Cir. 2001).

This construction boils down to the differences between complete (or total) occlusion of the fallopian tube and "functional occlusion" of the fallopian tube. As explained in the summary of the invention, while the contraceptive device in the asserted patent "will generally result in occlusion, it need not completely occlude the fallopian tube to prevent the meeting of the sperm and ovum" (col. 3:22-24) (emphasis added). "[C]ontraception can be provided by disrupting the architecture and/or function of the fallopian tube, despite the presence of an open lumen" (col. 3:27-29) (emphasis added). "This concept is referred to herein as 'functional occlusion'" (col. 3:29-30). In other words, the specification clearly taught that the intrafallopian contraceptive device need not block the entire lumenal cavity to provide effective contraception (see cols. 4:29-34, 11:27-34). Despite the presence of an open lumen, the device may still provide effective contraception so long as there is "functional occlusion" to "inhibit fertilization and/or conception" (col. 3:30-34).

With this definition of "functional occlusion" from the specification, the claims provide all the information necessary to properly construe this disputed phrase. Specifically, claim 40 -- which is not asserted in this action -- covers "[a] method as claimed in claim 36, wherein permanently affixing the resilient structure with the fallopian tube provides functional occlusion of the fallopian tube." Given that "functional occlusion" is only necessary when the fallopian tube is not completely occluded, this necessarily implies that the fallopian tube in claim 36 has this feature. Indeed, this is exactly what a person having ordinary skill in the relevant art at the time the patent was filed would have understood "so that at least a portion of the fallopian tube is open" to mean.

Moreover, asserted claims 37 and 38, which cover "tissue ingrowth," would also be meaningless if the fallopian tube in claim 36 were already completely occluded (see col. 4:21-22). Indeed, the specification stated that "[i]n many embodiments, the presence of the contraceptive device in combination with [] tissue reaction can provide effective contraception without having to rely on total occlusion of the fallopian tube" (col. 4:30-34) (emphasis added). Stated differently, the promotion of tissue ingrowth into the device (claim 37) can produce sufficient ingrowth to inhibit contraception (claim 38), despite the fact that the fallopian tube was not completely occluded when the contraceptive device was initially affixed (claim 36).

As such, Conceptus's proposed construction is correct, and the phrase "so that at least a portion of the fallopian tube is open" from claims 37 and 38 patent shall mean "so that at least a portion of the fallopian tube is not completely occluded."

b. "said first end cap being an open airflow inlet"

The phrase "said first end cap being an open airflow inlet" appears in claim 7 of the '712 Patent. 4 Donaldson asserts that the phrase has a meaning readily understood by one of skill in the art and construction of the language is not necessary. Baldwin asserts that "said first end cap being an open airflow inlet" should be construed as "the first end cap having an opening and being assembled as part of a reverse flow air filter arrangement including a housing and an air flow direction arrangement." Baldwin argues that requiring an airflow inlet places an express structural limitation on the claimed device that cannot be
met by the filter element alone. Specifically, Baldwin submits that an end cap defines an inlet only if the claimed device is a combination of the overall air filter arrangement (housing, filter, and air flow direction arrangement). In part, Baldwin argues that a user cannot identify which end of the air filter is an inlet without reference to the housing and air flow direction arrangement. In the alternative, Baldwin argues that "said first end cap being an open airflow inlet" should be construed as "the first end cap having an opening" or at most "the first end cap having an opening capable of being used as an inlet." Baldwin submits that if the housing and air flow direction arrangement are not included in the claim, being an inlet is only an intended use because the opening standing alone (without being part of a reverse flow arrangement) is neither an inlet nor an outlet.

--- Footnotes ---

4 Also at issue is the phrase "defining an air inlet aperture" in claim 1 of both the '366 and '009 Patents. Baldwin argues that those claims require the same construction as "open airflow inlet" in claim 7 of the '712 Patent.

--- End Footnotes ---

Baldwin relies on Cross Medical Products, Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293 (Fed. Cir. 2005), in arguing that the "inlet" imposes an express structural limitation on the claim. The Court finds such reliance unpersuasive. In Cross Medical, the Federal Circuit reviewed the district court's construction of the term "operatively joined" in a patent concerning orthopedic surgical implants used to stabilize and align spinal bones. 5 424 F.3d at 1305-06. Although the claim does not "state explicitly whether 'the bone interface' and the 'bone segment' must be in contact," the Federal Circuit reasoned that use of the word "joined" indicates that the interface and the bone must be connected. Id. at 1305. The Federal Circuit concluded that the "lower bone interface [is] operatively joined to said bone segment" when the interface and the bone segment are connected and in contact such that the device is effective to perform posterior stabilization." Id. at 1306. In its infringement discussion, the Federal Circuit explained that the claim has a structural limitation that the "anchor seat be in contact with the bone." Id. at 1311. Cross Medical is distinguishable from the present case because the text of claim 7 of the '712 Patent does not provide that the air filter element is "joined" with a housing or an air flow direction arrangement.

--- Footnotes ---

5 The claim language recites an "anchor seat means which has a lower bone interface operatively joined to said bone segment."

--- End Footnotes ---

The Court determines that the phrase "said first end cap being an open airflow inlet" has not acquired the meaning proposed by Baldwin. Looking to the claim language, the Court notes that none of the structure that Baldwin requests be included in the claim forms a part of an end cap that is an inlet. The claim does not recite a housing or an air flow direction arrangement. Nor does it recite a detailed description of a housing's or an air flow direction arrangement's physical characteristics. Further, the Court declines to adopt Baldwin's alternative proposed construction. Doing so would improperly eliminate language essential to the claim. See Playtex Prods., Inc. v. Procter & Gamble Co., 400 F.3d 901, 908 (Fed. Cir. 2005) ("We think this view reads out the essence of the claim limitation 'substantially flat' as it equates 'flattened' to 'flat.'"). The claim language and the specification both describe an end cap with an inlet. See '712 Patent, col. 5, ll. 29-31 ("That is, end cap 23 includes a large inlet aperture 28 (FIG. 4) therein, for introduction of air to be filtered into filter element interior 35."). In addition, a reading of the claims by one skilled in the art would indicate which end of the air filter has the inlet and which end has the outlet. Specifically, claim 7 of the '712 Patent recites in part: "said first end cap being an open airflow inlet;" "said second end cap comprising molded polymeric material and having an outer surface;" with "said second end cap having a circular sealing trough." One skilled in the art could read the claims and understand that the inlet end of the filter is opposite the end with the circular sealing trough. Thus, it is unnecessary to read a housing or an air flow direction arrangement into the claim to understand the air inlet structure of the first end cap of the claimed filter. Accordingly, the Court declines to adopt Baldwin's proposed constructions and does not construe the phrase "said first end cap being an open airflow inlet."
6 In addition, one skilled in the art could read the claims of the '366 and '009 Patents and discern that the end caps of the air filter are structurally different.

(D) Open Channel

The term "open channel" appears in claim 12 of the '433 Patent, where it is described as "said plurality of ribs extend to a location below said upper edge, said ribs forming an open channel extending between said first and second ends of said body between said upper edges of said sidewalls and said plurality of ribs." Pl's Markman Br. Ex. F. col. 17 ll. 63-67. Defendants requests that the court determine that the term is not amenable to construction because it is indefinite.

Innovative responds that the prosecution history clarifies that "open channel" is an unobstructed channel or pathway between the first and second end bodies. See Pl's Resp. Markman Br. pp. 24-25 (citing the prosecution history of the term "open channel").

Defendants do not meet the high hurdle for declaring a claim term indefinite.

According to the Federal Circuit, clear and convincing evidence is required to invalidate a patent because patents are presumptively valid:

Only claims not amenable to construction or insolubly ambiguous are indefinite….If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds. In this regard it is important to note that an issued patent is entitled to a statutory presumption of validity. By finding claims indefinite only if reasonable efforts at claim construction prove futile, we accord respect to the statutory presumption of validity and we protect the inventive contribution of patentees, even when the drafting of their patents has been less than ideal.

Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347-48 (Fed. Cir. 2005) (finding that the claim term "aesthetically pleasing" failed as indefinite) (internal citations omitted). Since one ordinarily skilled in the art would understand the claim term "open channel," the court will not find that it fails as indefinite. "Open channel" means "an unobstructed channel or pathway in the area defined in claim 12."

(1) Open-lattice sidewall structure.

Consistent with the claim language and its ordinary meaning, the court construes this limitation to mean "regular geometric pattern of openings in the side wall of the stent."

(3) Open-pore Microporous Material (Claims 9 and 15 37)

Microporous material is also referenced in claims 10 and 14.
Plaintiffs define open-pore microporous material as "material having a microcellular structure forming pores, the average size of which is 0.1 microns or less," "in which essentially all pores are open intercommunicating pores." 38 At the hearing, Plaintiffs refined its definition to comport with the National Insulation Association's Insulation Science Glossary (2004) definition of microporous material: "material with an average interconnecting pore size comparable to or below the mean free path of air molecules at standard atmospheric pressure." 39 Citing to the specification, Plaintiffs define "open-pore" as "where open intercommunicating pores represent essentially all pores contained in the microporous structure." 40

38 Plaintiffs' Opening Claim Construction Brief, Docket Entry No. 22, p. 10.

39 Plaintiffs' Markman hearing arguments.

40 Id.

Defendant offers a less complicated definition of "open-pore microporous material" as referring to "a material having very fine pores, essentially all of which are open and intercommunicating." 41 Despite using the words "essentially all" in its own definition, Defendant expressed some concern at the hearing that "essentially all" is not sufficiently descriptive for independent claim 9 because it contains the further limitation that eighty-five to ninety-five percent of the total pore volume must be open-pore.

41 Defendant's Brief on Claim Construction, Docket Entry No. 23, p. 10.

The patentee defined open-pore in the specification as follows:

Those skilled in the art will recognize that porosity is said to be open where open intercommunicating pores represent essentially all pores contained in the microporous structure, that is in practice in the range of 85 to 95% by volume based on total pore volume, which is itself close to 80% of apparent volume. 42

The court accepts this definition. As for the definition of "microporous material," the court finds no reason to strike out on its own when the parties agree. Because Defendant raised no objection to the definition provided by Plaintiffs from the National Insulation Association's Science Glossary 43 and the definition harmonizes with the specification, 44 the court adopts that definition. 45

42 547 patent at 3:1-6.

43 Plaintiffs represented to the court that the definition in 1996 would have not differed from the National Insulation Association's 2004 definition. As the representation was made without objection, the court accepts it as true.

45 Plaintiffs also mentioned that the microporous material may contain opacifiers to reduce the amount of radiant heat transmitted. Plaintiffs' Markman hearing arguments. Defendant objected to including this remark in the definition in light of claim 15, which further defines ingredients of the microporous material. Defendant's Markman hearing arguments. The court addresses Defendant's point about claim 15 in a subsequent section. However, the court agrees that whether the microporous material may or may not contain opacifiers is a gratuitous addition to the definition that could interfere with consistent construction of the term open-pore microporous material.
Combining the definition of "open-pore" with that of "microporous material," the court recommends that the term be defined as material with an average interconnecting pore size comparable to or below the mean free path of air molecules at standard atmospheric pressure in which the intercommunicating open pores represent essentially all pores contained in the microporous material.

This definition is subject to the more specific limitation of claim 9, in which the portion of open pores of the material "is 85 to 95% based on total pore volume, with an average pore diameter less than or equal to 0.1 μm." The court finds this limitation sufficiently clear on its face.

GO BACK

1. An "open space" is a space for the performance of a surgical procedure, which is not occupied by a bladder or other device, or by tissue.

GO BACK

2. Specification and Prosecution History

The Defendants' proposed construction is "the cross-sectional area spanning the circumference of the top of the container including the rim to its outer diameter and all portions therein." Sunbeam's proposed construction is "a portion of the container opposite the closed bottom portion of the container, said portion having an interface and an area that is not closed." Thus, the parties dispute whether the term necessarily includes an interface.

1. Words of the Claim

Claim 4 of the '592 patent includes the disputed claim term, in the following context:

A beverage container assembly for use with a blender, comprising:

   a beverage container having an open top portion and a closed bottom portion;

   a first removable cover for selectively covering said top portion of said container, said first cover adapted to be removably mountable on and off a blender and comprising an adapter portion for mounting said container on a blender; and

   a second removable cover for selectively covering said open top portion of said container, said second cover comprising a cap, and wherein said first and second covers are interchangeable on said container.

'592 Patent at 20:50-63 (emphasis added). Claim 8 also references the disputed claim term, by claiming "[t]he assembly of claim 4, wherein said first and second cover each comprises a screw thread for engaging said open top portion." Id. at 21:3-5 (emphasis added).

2. Specification and Prosecution History
The specification and prosecution history say virtually nothing about "open top portion." It is not surprising that the patent's authors saw no need to define this self-explanatory term. The Defendants deceptively assert several figures showing an opening on the top of a container, proffering them as examples of an "open top portion" with misleading captions designed to make it appear as if the figures in the original patent were so captioned. However, the language of the specification does not discuss an "open top portion" as such, and, indeed, the Defendants set forth figures of a "blender jar" that is not the single-serving "beverage container" in question.

3. Extrinsic Evidence

Neither party has provided any extrinsic evidence on the term "open top portion."

4. Proper Construction of "Open Top Portion"

The open top portion must contain a screw-on interface. This is implicit in the overall language of the claim, which notes in numerous places that the interface by which the beverage container attaches to both the blender base and the various caps is of the screw-on variety. Thus, Sunbeam's construction is the proper one, and is adopted here: "a portion of the container opposite the closed bottom portion of the container, said portion having an interface by which a cap screws onto the beverage container and an area that is not closed."

B. "Opened"

The jury found infringement of claims 1-4 of the '018 patent in terms of the doctrine of equivalents. The only claim limitation presented for jury consideration of equivalency was the holder drive gear. Daewoo does not challenge the jury's finding of equivalency of the holder drive gear. However, Daewoo argues that the district court erred in its determination on summary judgment that the "opened" limitation was literally infringed, and that infringement under the doctrine of equivalents cannot be found because of prosecution history estoppel as to the "opened" limitation.

Daewoo argues that the court erred as to the "opened" limitation by focusing only on the status of the door upon movement of the cassette holder to the initial position, without also accounting for the claim's requirement that the VCR door is opened before the cassette holder moves from the play position. Daewoo states that in its VCRs the door is opened only after the cassette holder has moved two millimeters. The district court held that: "It does not matter that the door does not move before the holder shifts from the play position to the intermediate position. The critical point, not disputed by the parties, is that when the holder is moved towards the initial position from the intermediate position, the door has already begun its opening motion." Funai, 2006 U.S. Dist. LEXIS 93132, 2006 WL 3780715, at *8. Funai states that the district court correctly construed the "opened" limitation to mean "moved from a closed position such that the door has cleared the cassette so that ejecting the cassette will not interfere with the door." Funai, 2006 U.S. Dist. LEXIS 98055, 2006 WL 6130993, at *7. We agree that this claim construction is correct, for it is as described in the specification. This construction, and the summary judgment based thereon, have not been shown to be in error. The court's ruling that the "opened" limitation is literally met by the accused products is sustained. On the entirety of the claim, the jury verdict of infringement is supported by substantial evidence, and is affirmed.

iii. "opening"

180s argues for construing "opening" as "open space serving as a passage or gap." Considering its construction of "an opening that communicates with the receptacle, the opening being disposed proximate the interior side of the frame," Gordini seems to urge construing "opening" as "a port that is positioned near and within the inside surface, i.e., the surface closest to the user's head when worn." 13 Gordini also seems to urge a further limit that the "opening" be "unimpeded."
13 Matching Gordini's constructions with particular claim terms or language, especially for the '645 patent, is a difficult endeavor, in part because Gordini construed longer phrases and not individual words. For example, Gordini may actually be urging the Court to define "disposed proximate the interior side" when it urges the construction "near and within the inside surface, i.e., the surface closest to the user's head when worn." That said, the outcome of these claim constructions would remain the same regardless of where this opinion discusses each of Gordini's proposed constructions.

I construe "opening" as an "open space serving as a passage or gap." This definition is consistent both with the embodiments in the specification and the widely accepted understanding of the term and. To be sure, the "opening" must be "disposed proximate" the "interior" side of the ear warmer frame. However, any required proximity to the "interior side" is not found within the term "opening," but rather within terms "disposed proximate" and "interior." See infra Section II.B.v (construction of "disposed proximate"). Further, Gordini's "unimpeded" limitation is unnecessary and imprecise. If Gordini believes, as 180s suggests, that "unimpeded" means "unblocked to provide continuous access by the user," such a limitation is simply not found in the claim language or specification. For example, an "opening" that is somewhat impeded by fabric, but nonetheless allows access to the "connector," would in fact, I believe, still be considered an "opening" under this claim language. (See, e.g., Pls.' Mem., Ex. B. at col. 4, ll. 50-58 (specification describing an embodiment in which the "connector" is not stored within the "receptacle," but is protruding out of the "opening" such that the user need not have unimpeded access through the "opening" and into the "receptacle").)

In accordance with the invention, an improved cup construction and valve assembly is provided which provides an extremely secure seal against accidental liquid flow from the cup spout. Further to the invention, a user places his or her mouth against the spout of the cup assembly to suck liquid out of the cup when desired. The act of sucking at the spout of the cup creates negative pressure or a partial vacuum against a valve in the cup spout, causing the valve to invert, or turn inside out, either partially or totally, thereby unblocking an opening such as an orifice or slit in the valve. Once the opening is unblocked, liquid can flow freely through the valve and spout.

In contrast, when not in use, the valve sits in a resting, closed position, with the valve pressed against the center seal-off, thereby sealing off the opening or slit in the valve assembly. Thus, in its relaxed state, with no negative pressure applied, the valve sits in a closed position with the fluid opening sealed by the center seal-off. Moreover, in accordance with the dual valve nature of the device in the preferred embodiment, an adjacent valve similarly seals when no negative pressure is applied, thereby blocking off the air vents in the cover of the cup, and further preventing the possibility of fluid flow. Consequently, the closed position provides an extremely secure seal against fluid leakage, such that inadvertent spills or even deliberate attempts to force liquid outside of the cup, such as by turning the cup upside down, or shaking the cup, are ineffective.

During patent prosecution Hakim described his distinctions from the cited references as follows:

Thus two separate mechanisms are both used to close off the passage of liquid through the valve when not in use. The
first mechanism involves an inverting, flexible valve material which has a slit therein and responds to suction. The second mechanism involves the use of a blocking element, which is impenetrable to the passage of liquid. The slit sits against the blocking element, sealing or blocking off the slit, to yet further prevent the passage of liquid through the valve.

. . . . By providing both the elastomeric member with a slit and a blocking element, a sealing mechanism is provided which reduces spillage beyond that of either mechanism alone. None of the references cited in the Office Action [Robbins III, Bachman, and Belcastro] teach or suggest such a no-spill mechanism having a slit sitting against a blocking element such as is recited in all of the pending claims.

'931 Application Response, Oct. 2, 2000 (emphases added). Thus during prosecution the presence of the slit in the flexible valve material was emphasized as distinguishing all of the claims from the cited references.

Avent's accused drinking cup has a valve with a flexible diaphragm having a central opening, but the opening is not a slit that opens and closes, but simply a hole in the diaphragm. The diaphragm rests against a plastic mount that has a conical head that seals the hole. Upon suction by a person seeking to drink, the diaphragm is lifted off the conical head, exposing the hole and permitting fluid to flow from the cup to the drinking spout.

The district court held on summary judgment that Avent's device did not infringe the '931 claims, based on the claim construction that limited the '931 claims to a sealing mechanism that includes a flexible valve material or diaphragm having a slit. Hakim I, 2005 U.S. Dist. LEXIS 16830, [WL] at *1 (“For the reasons contained in the Report and Recommendation of the Magistrate Judge previously filed herein, and after a de novo review of the entire record and the written objections filed herein, and concurring with the Magistrate Judge's findings under the applicable law”; summary judgment was granted.) Mr. Hakim argues that the claim construction is excessively constricted and that all of the '931 claims do not require a slit that opens and closes with pressure, for claims 1 and 2 use the word "opening," not "slit," for the aperture in the diaphragm. Claim 1 is as follows:

1. An apparatus for use in a no-spill drinking cup, said apparatus comprising:

   a valve holder, such valve holder comprising at least one valve and a blocking element, said valve comprising a flexible material, said blocking element comprising an area of material which is impenetrable to the flow of liquid, said valve further comprising an opening through said flexible material, said valve having a resting position wherein said flexible material sits with said opening against said blocking element such that said valve is closed to the passage of liquid through said valve, said valve moving into an open position for the passage of liquid through said valve upon the application of negative air pressure to the top of said valve, said open position being a position wherein said flexible member comprising said opening lifts off of said blocking element.

(Emphasis added.) The word "opening" was placed in claims 1 and 2 when Hakim filed a continuation application after receiving a notice of allowance for claims wherein the word "slit" appeared instead of "opening." The filing of the continuation was accompanied by an attorney letter stating that Hakim was broadening claims 1 and 2, and an amendment changing "slit" to "opening" in claims 1 and 2. The continuation claims were allowed without any comment or rejection by the examiner. However, in construing the claims of the continuation patent, the district court held Hakim to his arguments in the parent application that the invention includes the presence of a slit in the flexible material. The court stated: "Because Hakim did not retract any of his arguments distinguishing the prior art, he is held to the restrictive claim construction he argued during prosecution of the patent." Hakim I, 2005 U.S. Dist. LEXIS 16830, [WL] at *5 (adopted Magistrate's Report).

Hakim argues that the district court improperly relied on the argument in the abandoned parent application. Hakim states that by re-filing the application with broader claims, he avoided any unnecessary restriction that may have crept into the prior prosecution. He states that he informed the examiner that the new claims were broader than those previously allowed, and that when the examiner allowed the new claims without rejection, there is a presumption that the examiner had assured himself of the patentability of the new claims. See United States v. Chemical Foundation, 272 U.S. 1, 14-15, 47 S. Ct. 1, 71 L. Ed. 131 (1926) ("The presumption of regularity supports the official acts of public officers, and, in the absence of clear evidence to the contrary, courts presume that they have properly discharged their official duties.") Hakim states that he did what was appropriate when he flagged this change to assist the examiner, and that the claims as granted should not be unnecessarily narrowed by the court.
Avent states that the totality of the prosecution history nonetheless limits Hakim to the embodiment with the slit, for the magistrate judge found: "The prosecution history makes perfectly clear that Hakim specifically distinguished his invention from the prior art by limiting it to an apparatus with (1) a slit which closes when suction is not applied, and (2) a second closure consisting of a blocking element which the slit rests against." Hakim I, 2005 U.S. Dist. LEXIS 16830, [WL] at *5 (adopted Magistrate's Report). Avent states that this was and is the distinction from the prior art, and that the claims are properly limited to this feature whether they use the word "slit" or the word "opening." Avent stresses that when Hakim wrote to the examiner that he was broadening the claims, he did not specifically point out that he no longer intended to be limited to the specific mechanism that he had previously argued was the distinguishing feature of his invention.

Hakim points out that a patent applicant is not precluded from filing a continuation application with broader claims. It is recognized that an applicant can broaden as well as restrict his claims during the procedures of patent examination, and that continuing applications may present broader claims than were allowed in the parent. Cf. Symbol Technologies, Inc. v. Lemelson Medical, Education & Research Found., 422 F.3d 1378, 1385 (Fed. Cir. 2005) ("Commonly, and justifiably, one might refile an application to add subject matter in order to attempt to support broader claims as the development of an invention progresses, although entitlement to an earlier filing date for any claimed subject matter may of course be necessary to avoid a statutory bar created by intervening events outlined in 35 U.S.C. §§ 102 and 103.").

Hakim had the right to refile the application and attempt to broaden the claims. See id. at 1385 ("One may also refile an application even in the absence of any of these reasons [refiling an application in response to a requirement for restriction; refiling in order to present evidence that may not have previously existed; or refiling to support broader claims as the development of an invention progresses], provided that such refileing is not unduly successive or repetitive.") However, an applicant cannot recapture claim scope that was surrendered or disclaimed. The district court did not err in holding that the examiner's action in allowing the continuation claims without further prosecution was based on the prosecution argument in the parent. See Omega Engineering, Inc. v Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003) ("The doctrine of prosecution disclaimer is well established in Supreme Court precedent, precluding patentees from recapturing through claim interpretation specific meanings disclaimed during prosecution."). (citing Schriber-Schroth Co. v. Cleveland Trust Co., 311 U.S. 211, 220-21, 61 S. Ct. 235, 85 L. Ed. 132, 1887 Dec. Comm'r Pat. 185 (1940), Crawford v. Heysinger, 123 U.S. 589, 602-04, 4 S. Ct. 399, 31 L. Ed. 269, 1888 Dec. Comm'r Pat. 185 (1887), and Goodyear Dental Vulcanite Co. v. Davis, 102 U.S. 222, 227, 26 L. Ed. 149, 1881 Dec. Comm'r Pat. 131 (1880)). Although a disclaimer made during prosecution can be rescinded, permitting recapture of the disclaimed scope, the prosecution history must be sufficiently clear to inform the examiner that the previous disclaimer, and the prior art that it was made to avoid, may need to be re-visited. See Springs Window Fashions LP v. Novo Indus., L.P., 323 F.3d 989, 995 (Fed. Cir. 2003) ("The public notice function of a patent and its prosecution history requires that a patentee be held to what he declares during the prosecution of his patent. A patentee may not state during prosecution that the claims do not cover a particular device and then change position and later sue a party who makes that same device for infringement.").

The district court correctly ruled that the word "opening" is not correctly construed to eliminate the sealing mechanism provided by the slitted diaphragm. On this construction, the summary judgment of noninfringement of the '931 patent was correct, and is affirmed.

GO BACK
Each time the term "opening" is used in the specification, it refers to a hole, breach, or aperture in the camera cover, either by textual description or by reference to the patent figures. In support of its broader claim construction, Fuji points to a sentence from the specification that describes the lens hole in the front cover as being "defined by a circular boss 37a." '168 patent, col. 5, ll. 27-29. Because the circular boss consists of a hollow bulge in the front cover section, and because the specification states that the hollow bulge is "for receiving therein the taking lens," Fuji argues that the term "opening" must be interpreted to include an open space such as is created by a bulge in the camera cover.

Significantly, the sentence on which Fuji relies does not refer to the circular boss as an "opening." Nor is the circular boss ever referred to as an opening. To the contrary, the specification characterizes the lens hole as being "defined by" the circular boss, and it characterizes the lens hole as an "opening." See '168 patent, col. 6, ll. 56-62. The sentence cited by Fuji thus does not support Fuji's argument at all, but in fact indicates that what the patent refers to as an "opening"--the lens hole--is different from what the patent refers to as the "boss" that surrounds and defines the opening. We therefore agree with the Commission that the claimed "front cover section being formed with at least one opening" uses the term "opening" to refer to a hole, breach, or aperture.

2. Openings & Holes

Plaintiff argues that "opening" should be defined as "unthreaded space, open on both ends, serving as a passage" and "hole" as "a threaded space that has a finite depth." Defendants suggest defining "opening" as "an open space, a breach, an aperture" and "hole" as a "cavity that can extend completely through a solid body, but is not required to do so."

Figure 4 of the '451 Patent, shown above, depicts both openings (in 34) and holes (in 31).

Defendants argue that "holes" and "openings" are synonymous, noting that the American Heritage Dictionary gives "opening" as one definition of "hole." The American Heritage Dictionary of the English Language 837 (Houghton Mifflin Co., 4th ed. 2004). Plaintiff responds by pointing to the presumption that when two similar terms are used in one claim, the terms have different meanings. CAE Screenplates, Inc. v. Heinrich Fiedler GmbH & Co. K.G., 224 F.3d 1308, 1317 (Fed. Cir. 2000). However, "the use of two terms in a claim requires that they connote different meanings, not that they necessarily refer to two different structures." Applied Med. Res. Corp. v. U.S. Surgical Corp., 448 F.3d 1324, 1333 n.3 (Fed. Cir. 2006) (citing CAE Screenplates, 224 F.3d at 1317).

There is no evidence to support Plaintiff's contention that an opening must be unthreaded or that a hole must be threaded. The claims make no reference to such properties. Plaintiff bases its argument on the fact that the specification states that fasteners can be "inserted through openings in flanges and into threaded holes," explicitly describing holes as threaded, whereas the specification attaches no adjective to "opening." '451 Patent col. 3, ll. 16-17. Once again, this is an inappropriate attempt to import limitations from the specification into the claim. Defendants' reference to a "solid body" is likewise not grounded in the claim language.

The only distinction found in the claims between "opening" and "hole" is that the fasteners are inserted "through openings" and "into holes." '451 Patent col. 4, ll. 40-41 (emphasis added). The fact that something can be inserted through an opening indicates that the opening has both an entrance and an exit. The fact that something can be inserted into a hole implies that the hole has an entrance, but not necessarily an exit.

The specification supports this distinction. Like the claims, the specification also states that fasteners are "inserted through openings in flanges and into threaded holes." '451 Patent col. 3, ll. 16-17. Thus the specification also indicates that a fastener can be inserted through an opening and then into a hole, meaning that the opening must have both an entrance and an exit to allow the fastener to enter the hole.

This distinction is consistent with at least one of the dictionary definitions of the terms. The American Heritage Dictionary gives "an open space serving as a passage or gap" as one definition for "opening" and "a hollowed place in something solid;
a cavity or pit" as one definition of "hole." The American Heritage Dictionary of the English Language, supra, at 1232, 837. The distinction also satisfies the presumption that the two claim terms have different meanings.

As used in claims 1, 6, and 10 of the '451 Patent, therefore, "opening" means an open space, breach or aperture with an entrance and an exit, and "hole" means an open space, breach or aperture with an entrance, but not necessarily an exit.

D. "Opening"

Mitek argues that the term "opening" should be limited to a "closed-end socket" in both the '477 and the '529 Patents. Mitek asserts that the claims describe and illustrate only closed-end sockets in the first clause which includes "forming an opening in a femur, the opening having an entrance facing a joint of the knee." Mitek cites to Claim 1 where it refers to "a tunnel in the tibia" and argues when Arthrex needed to use the term "tunnel" it did so elsewhere in the patents. Mitek also indicated that the term "opening" is not mentioned in the specification to refer to the longitudinal femoral hole. A court may look to other terminology in the specification which describes the same term as used in the claim if the exact term is not found in the specification. Network Commerce, Inc. v. Microsoft Corp., 422 F.3d 1353, 1361 (Fed. Cir. 2005) (when the term in the claim "download component" was not found in the specification, the court relied on the term "download file" in the specification which appeared to have the same function and description as the term "download component" had in the claim). Mitek asserts that the drawings all show a closed-end socket, and the Abstract refers to a longitudinal socket. (Doc. 140, Exh. 1, Abstract).

Mitek indicates that during the prosecution of the related U.S. Patent No. 5,918,604 ('604), the Patent Office rejected certain claims over prior art because the claims were not limited to a "blind hole or partial hole". (See, Doc. 140, Exh. 18, and Exh. 7, page 3). Arthrex amended these claims and specifically used the word "socket." (Doc. 140, Exh. 8, pgs. 2-3). Mitek argues that Arthrex distinguished its invention from prior inventions by having a socket form in the bone rather than a tunnel or hole. (See, Doc. 140, Exh. 8, p. 5).

Arthrex argues that the specification allows for either a femoral socket or a femoral tunnel. It cites to the language in the Summary of the Invention which states "[a]ccording to the present invention, forming the socket is preferred to forming a tunnel through the lateral femoral cortex." (Doc. 140, Exh. 1, 2: 42-44). Further, another part of the specification discusses "femoral tunnels" when describing the openings in the femur. (Doc. 140, Exh. 1, 3:30). In the Detailed Description of the Preferred Embodiments, a "femoral tunnel" is used to describe where the wire forms a loop. (Doc. 140, Exh. 1, 4:24-27). In this same section, the term "femoral tunnel" is used to state that the tendons must fit snugly within it, however later in the sentence the term "femoral socket" is also used. (Doc. 140, Exh. 1, 6:22-25).

Arthrex adds that it is improper to import a limitation to a claim from the language of the specification citing Ethicon Endo-Surgery, Inc., 93 F.3d 1572, 1578 (Fed. Cir. 1996). Arthrex asserts that it used specific language in the claim regarding the "transverse hole" that extends across the femur so that the flexible strand may be inserted, but did not use this type of limiting language when describing the opening in the femur, so that either a femoral socket or a femoral tunnel could be used. Arthrex indicates that the claim has no limiting language as to the type of "opening."

From the prosecutorial history, Arthrex asserts that the provisional patent '610, had the language in claim 1 of "forming a hole in a bone", and then in claim 4, stated the hole in claim 1 "is closed at one end." (Doc. 143, Exh. 1, p. 12). Claim 4 would be meaningless, Arthrex argues, if the hole in claim 1 was only a closed end hole. Arthrex argues that one claim cannot vitiate the meaning of another, and therefore, hole or opening in the '477 patent is not limited to being a socket, citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d. 898, 910 (Fed. Cir. 2004). Arthrex also argues that it never limited the term "opening" in the '604 patent to a socket.

To determine how a person of ordinary skill in the art would construe the term "opening," the Court will begin by reviewing the language of the claim itself, and the specification. The term "opening" is used in the claim as follows: "forming an opening in a femur, the opening having an entrance facing a joint of the knee." (Doc. 140, Exh. 1, 6:34-36). The claim language does not limit the meaning of the term "opening." Upon review of the specification, the term "opening" is not used. In the Summary of Invention, the term "femoral socket" is used repeatedly to describe the longitudinal hole in the
femur. (Doc. 140, Exh. 1, 2:41, 43, 45, 48, 50, 63, 64, 3:2). However, the term "femoral tunnel" is also used, although less frequently, to describe the opening in the femur. (Doc. 140, Exh. 1, 3:30, 4:24-27). In one clause of the Summary of the Invention, the following language is used: "[a]ccording to the present invention, forming the socket is preferred to forming a tunnel through the lateral femoral cortex. Advantageously, the diameters of the tibial tunnel and femoral socket are made just large enough to accommodate the graft in a snug fit." (Doc. 140, Exh. 1, 2:42-44).

Case law cautions that claims may not be broader than the scope of the invention that is set forth in the specification, yet the language of the specification may not import limitations on the claims. See, Varco, L.P. v. Pason Systems USA Corp., 436 F.3d at 1373, and On Demand Machine Corp. v. Ingram Industries, Inc., 442 F.3d at 1373. The patent as a whole must be consistent. Pfizer, Inc. v. Teva Pharmaceuticals USA, Inc., 429 F.3d at 1373. Reviewing the patent as a whole, it is clear that the preferred method is to have the "opening in the femur" be a femoral socket. The term "opening" is not used in the specification. However, the term "femoral socket," which is used to describe the opening in the femur, is used repeatedly throughout the specification. Even though "femoral socket" is used more frequently, the term "femoral tunnel" is also used in the specification to describe the "opening in the femur." In the Summary of the Invention, the patents provide that the preferred method is a femoral socket, however, a femoral tunnel is not specifically disavowed. The description of the invention contemplates the use of a femoral socket, but it also anticipates the use of a femoral tunnel by some and cautions that a femoral socket is the better practice. The purpose of the specification is to "teach and enable those of skill in the art" to use the invention and to provide the best method of using the invention. Phillips v. AWH Corporation, 415 F.3d at 1323. Even though the preferred embodiment uses a femoral socket, a claim is not limited to a preferred embodiment. See, Bell Atlantic Network Services, Inc. v. Covad Comm'cns Group, Inc., 262 F.3d at 1273.

The prosecution history is less useful for the term "opening" than the specification because it lacks the clarity of the specification. See, Phillips v. AWH Corporation, 415 F.3d at 1317. The provisional patent '610 does not use the term "opening." Rather, it does contain the clause that the "hole is closed at one end," however this modifies the term in claim 1 which states that the procedure is "forming a hole in a bone." (See, Doc. 143, Exh. 1, p. 12). If "forming a hole in a bone" meant a closed end socket, then the language "hole is closed at one end" would be superfluous. After the provisional patent '610, the later patents went through many amendments and modifications before the '529 and '477 patents were granted. Likewise, in the '604 patent which was cited by Mitek, the term "opening" does not appear. Mitek also cites to the prosecution of the '604 patent which modified the language in the patent based upon comments of the Patent Examiner. (See, Doc. 140, Exh. 7, p. 3). The comments of the Patent Examiner regarding the term "socket" are not clear in that he states, "[s]ince the 'socket' (a blind hole or a partial hole through the bone) is not claimed in these claims, they therefore reads [sic] on any strand that has been intersected and passing though a hole through the bone." (Doc. 140, Exh. 7, p. 3). The Court finds no support in limiting the term "opening" from these comments. Mitek also cites to a deposition of the inventor, Dr. Jeffery Whelan in support of its position, however, the subjective intent of the inventor is not appropriate to construe terms in the claim. Superior Fireplace Co. v. Majestic Products Co., 270 F.3d 1358, 1375 (Fed. Cir. 2001).

Relying mainly on the claim language itself, and the specification, the Court determines that "a person of ordinary skill in the art" would construe the "ordinary and customary meaning" of the term "opening" as being either a femoral socket or a femoral tunnel. Both femoral socket and femoral tunnel are mentioned in the specification for the '529 and '477 patents, and even though the femoral socket is the preferred embodiment, the femoral tunnel is also an option for the procedure.

"Opening"

In my February 24, 2003 Memorandum Opinion and Order, I provided a construction of the limitation "said housing having an opening in the bottom thereof." I noted that "no particular type of housing opening is required" and that "this element is not disputed so further discussion is unnecessary." Because there was no particular significance to the term "opening" raised by Krippel's summary judgment motion, I did not discuss or analyze the meaning of the term "opening" in the housing opening limitation. Ford now asks that the term "opening" in claim 2 be construed as "an unobstructed hole in the housing."

It is presumed that a claim term carries its ordinary meaning. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). To determine the ordinary meaning of claim terms, I may consult relevant dictionaries. Texas Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1202-03 (Fed. Cir. 2002). Ford claims that the ordinary meaning of "opening" is "an open
space serving as a passage or gap;" "a breach or aperture." While Exhibit Q does define "opening" as a "breach" or "aperture," I do not see Ford's basis for "an open space serving as a passage or gap." This must be an inadvertent mistake. I do see the following definition: "something that is open."

Nonetheless, regardless of which definition one chooses, I see no basis for using Ford's additional term "unobstructed." More than merely adding an additional word, using the word "unobstructed" adds the additional meaning that an opening must be unobstructed in order to qualify as an opening under the claim. Under such a construction, even a partial obstruction of some type may prevent something from being considered an "opening" within the meaning of the term. Such a limitation, however, is not explicitly stated in the claim and, more importantly, goes beyond the ordinary meaning which Ford concedes I should use. Accordingly, the term "opening" will be construed as "something that is open; breach; aperture." 5

5 As Ford acknowledges, my construction of the term "opening" has no effect on my previous holding that the lens in the opening of the Ford Lighting Device is an additional element. If, at some point during the course of this litigation, Ford argues that this construction has some effect on this ruling, then I will revisit the construction of the term as opposed to the ruling.

2. Interpretation

Claims 1 through 20, 27, and 29 of the '709 reissue patent and all of the claims of the '397 patent require a housing that has an "opening." See, e.g., '709 reissue patent, col. 7 et seq., Exh. A to Clark Decl.; '397 patent, col. 5 et seq., Exh. B to Clark Decl. Claim 7 of the '709 reissue patent is representative in pertinent part 1: "A lighting system comprising a structurally supportive housing having a first opening; . . ." '709 reissue patent, col. 7, lines 9-11.

1 Defendant's Exh. A omits columns 5 and 6 of the '709 reissue patent. The Court relies on Exh. A of the First Amended Complaint for a complete copy of the '709 reissue patent.

The key dispute of the parties over the interpretation of these claims hinges on whether the "opening" referred to pertains to a structural element of the fixture or indicates that the overall lighting fixture be open upon assembly such that water and air can flow through the housing. Defendant alleges that the lighting assembly of the patents in suit allows air and water to flow through the fixture housing to cool the lamp assembly. To this end, both of the patents in suit claim a lighting assembly that is open to the weather.

Defendant supports its interpretation by considering the Background and Summary of the Invention of the patents in suit describing the problems with conventional outdoor lighting systems: "Conventional systems are especially vulnerable to the destructive effects of corrosive soils. . . . Conventional systems are also vulnerable to moisture and water intrusion." '709 reissue patent, col. 1, lines 20-29. The patents then describe how conventional outdoor lighting systems have approached such problems by employing "a fully sealed system of structural material," and the resulting disadvantages with such an approach: "Because of requirements to completely seal the outdoor systems, such devices are expensive, difficult to repair and difficult to cool." Id. at lines 31-32; 38-41.

According to Defendant, the Summary of the Invention suggests that Plaintiff's solution to this problem is, in part, to have a housing that allows air and water to enter.
The present invention contemplates an exterior housing to protect the system from corrosive soil conditions and to provide support and structural protection for the internal components. Components not capable of withstanding moisture and corrosive conditions may be positioned and sealed from moisture entry within the housing.

Id. at col. 1, line 66 - col. 2, line 4.

The Summary of the Invention goes on to state:

In a further aspect of the present invention, a face ring may be provided as an external cover that is contiguous with the lamp assembly and the housing. This external face ring is slotted to allow entry of air and water to dissipate heat away from the lamp. Both the lens and the face ring may be designed to support human foot traffic, allowing precise placement of the light assembly.

Id. at col. 2, lines 18-25. It then concludes:

Employing the foregoing features, both airflow and water in the housing may be used to cool the lamp. This provides improved thermodynamic characteristics for efficient operation of the lamp, enabling more design latitude. The use of a face ring can be advantageous because it can be easily removed to gain access to the interior of the housing as simple attachment mechanisms may be used to hold the face ring to the housing.

Id. at col. 2, lines 32-39. Defendant alleges that the face ring is a "further" aspect of the invention for the purpose of providing a contiguous surface to support human foot traffic and allow easy access to the housing. Additionally, Defendant contends that the slots are provided in the face ring to preserve the openness of the housing so that air and water can enter to cool the lamp assembly and other electrical components in the housing. 2

2 "Cooling is accomplished . . . through the multiple openings 82. As can be appreciated, water can enter and even fill up the housing 10 through these multiple openings 82. Thus, either air or water may provide the cooling medium for the components." '709 reissue patent, col. 5, lines 57-62.

In dispute, Plaintiff maintains that the claims neither state that the assembly has an opening nor state that the structurally supportive housing is open in the assembled state. Rather, the claims literally state that a component -- the structurally supportive housing -- has a first opening. According to Plaintiff, the fact that there is an opening in an element of a fixture does not require that an opening be found in the assembled fixture. It is the face ring and not the housing that provides and controls openings into the interior of the fixture. 3 Plaintiff asserts further that of claims 1 through 20 and 29 of the reissue patent and of all claims of the '397 patent, only claims 12 and 20 of the reissue patent -- not at issue here -- define openings that are open in the assembled fixture. See Pl. Opp., pp.5-6. As such, whether the entire assembly is open or closed is not recited in the language of the claims at issue.

3 "A structurally supportive housing 10 is illustrated. . . .One end of the housing 10 is open. This opening 20 is surrounded by an upper rim 22 of the housing 10 which is preferably arranged at approximately ground level 24. . . .Located at the opening 20 is a lamp assembly, generally designated 40. . . .Positioned over the space to span between the rim 22 and the lamp assembly 40 is a face ring 80. The face ring 80 has multiple openings or holes 82 which allow for the passage of water and air. These holes provide for cooling of the entire assembly." '709 reissue patent, col. 3, lines 8-20, 35; col. 4, lines 19-23.

The Court and Defendant agree with Plaintiff that only claims 12 and 20 define an open fixture. 4 But the Court finds that the only distinguishing feature of these claims from other claims in the patents is the recitation that the fixture includes a face ring with openings. The face ring with "openings" in claims 12 and 20 of the reissue patent could not result in an open
fixture unless a fixture lacking that face ring but having an "opening" in the housing as also recited in the claims, is open. It is not the face ring that provides and controls openings into the interior of the fixture and thus determines whether it is open or closed. Rather, the openings in the face ring can perform their function of admitting air and water to cool the lamp in the housing only if the "opening" in the housing is at least as large and as unobstructed as the "openings" in the face ring. Plaintiff's patent claims necessarily contemplate that the "opening" in the housing allows entry of air and water into the fixture at least as much as, if not more than, the "openings" in the face ring.

4 Claims 10 and 12 provide as follows:

10. A lighting system comprising

a structurally supportive housing having a first opening;

a lamp assembly having a socket enclosure and a lens, said socket enclosure with said lens defining a lamp cavity separately sealed from said housing;

a junction box affixed to said housing and having an access port into said housing, said junction box being sealed at said access port from the interior of said housing;

electrical lighting elements including a transformer in said housing electrically coupled between said junction box and said lamp assembly, said elements being sealed from the interior of said housing, from said lamp assembly and from said junction box.

12. The light assembly of claim 10 further comprising a face ring with multiple openings therethrough, said face ring being attached to said housing at said first opening, said lamp assembly and said housing providing an annular space therebetween at said first opening, said face ring spanning said annular space between said housing and said lamp assembly.

'709 reissue patent, col. 7, lines 9-23; 27-33.

Additionally, while one of the functions of the opening is, as Plaintiff asserts, to provide access to the lamp assembly and electrical lighting elements for servicing, an equally evident function of the opening is to admit air and water. The Court notes that Plaintiff's interpretation trivializes the claim limitation of an "opening" in the housing to the point of rendering it meaningless. The Court believes that all lighting fixture housings must have an opening at some point in the assembly process to permit the placement of the lamp assembly and electrical lighting elements in the housing. If this interpretation is all that Plaintiff meant by an "opening" in the housing, such a claim limitation would not distinguish the prior art or add in any meaningful way to the definition of Plaintiff's invention. The Court thus finds as a matter of law that the "opening" referred to in the claims in question refers to an opening in the assembled lighting fixture that deliberately allows air and water to enter for use in cooling.

B. "Syringe Receiving Opening" or "Opening"/Requirement of a Pressure Jacket

In this motion for partial summary judgment, L-F requests that the Court interpret the terms "syringe receiving opening" and "opening" as they appear in the asserted claims of the 669 and 261 patents. As the following analysis demonstrates, the construction of these terms is closely intertwined with L-F's contention that the injector referenced in the asserted claims of the 669 and 261 patents does not require a pressure jacket. The Court will, therefore, analyze these issues together.
The asserted claims are 10-11, 13, 16-19 of the 669 patent and 1, 8, 9, 11-13, 15-16, 18, 22, 27-28, 30-32, 34-37 of the 261 patent.

L-F proposes that the terms "syringe receiving opening" and "opening" refer to "an opening in an injector for receiving a syringe." (Doc. No. 164, p. 1). Medrad contends that the terms refer to the "open end of a pressure jacket." (Doc. No. 172, p. 16).

The difference in the parties' interpretations of these terms is significant. On the issue of non-infringement of the asserted claims, Medrad argues that the accused products do not infringe the 669 and 261 patents because both patent specifications describe an injector that requires a pressure jacket. 8 (Doc. No. 57, p. 19). Medrad's accused injectors are jacketless. L-F, on the other hand, argues that the term "pressure jacket" does not appear in the asserted claims, and thus, the claims do not describe an injector that requires a pressure jacket. (Doc. No. 164, p. 23). In response, Medrad has argued that the asserted claims contain the terms "syringe receiving opening" or "opening," which, in order to preserve the validity of the patents, must be interpreted as the opening of a pressure jacket. (Doc. No. 57, p. 18). Therefore, according to Medrad, the claims describe a device that requires a pressure jacket. (Id.).

8 It should be noted that the 669 and 261 patents do not claim the invention of a front-loadable injector. Rather, the 669 patent claims a method of front loading an injector and injecting fluid and the 261 patent claims a device of a front-loadable syringe. However, the claims of the 669 and 261 patents describe the injector with some specificity.

The Court begins its analysis where all claim construction begins -- the language of the claim. See Interactive Gift Express, 256 F.3d at 1331. With respect to the asserted claims, "syringe receiving opening" and "opening" are described as follows:

"a syringe receiving opening with a generally circular periphery therein adapted to receive a rearward end of a syringe having a generally circular rim"

669 patent, Claim 10

"an opening at the front end of the injector dimensioned to receive the back end of a disposable syringe…"

669 patent, Claim 19

"a circular syringe receiving opening therein bounded by a circular annular periphery…"

261 patent, Claim 11

"a circular syringe receiving opening bounded by a circular annular periphery…"

261 patent, Claim 30

(Doc. No. 30, Exhs. 1, 2). Clearly, this language describes a circular opening sized to accommodate the rear end of a syringe. Moreover, such a construction is supported by the ordinary dictionary definition of the terms. Webster's defines a "syringe" as "a device used to inject fluids into or withdraw them from the body or its cavities…" Webster's Third New International Dictionary at 2322 (1971). "Receive" is defined as "to take in: act as a receptacle or container for…", and "opening" is defined as "something that is open: as a (1) : BREACH, APERTURE … (2) : an open width : SPREAD, SPAN…." Id. at 1580, 1894. Thus, the dictionary definition of a "syringe receiving opening" is an open width able to take in a device used to inject fluids into or withdraw them from the body. The language of the claims requires that this "open width" be circular.

- 3271 -
The real issue dividing the parties is not the characteristics of a "syringe receiving opening" or "opening" but rather the location of such an opening. L-F, by asking the Court to conclude that the asserted claims involve an injector that does not require a pressure jacket, is asking the Court to conclude that the "syringe receiving opening" may be located anywhere, including the front-end of a pressure jacket. Medrad argues, on the other hand, that the injector described in the asserted claims requires a pressure jacket; therefore, the "syringe receiving opening" must be located at the front-end of the required pressure jacket.

Based on the language of Claim 19 of the 669 patent ("an opening at the front end of the injector), it appears, at the very least, such an opening would be somewhere on the front of the injector.

The parties do not dispute that the asserted claims do not contain the term "pressure jacket". However, the absence of the term "pressure jacket" does not necessarily lead to the conclusion that the injector referred to in the asserted claims does not require a pressure jacket. While the claim language does not explicitly require a pressure jacket, neither does it explicitly describe a jacketless injector. Because the claim language is ambiguous with respect to the requirement of a pressure jacket, the Court must conduct a review of all the intrinsic evidence (the claim language, the specification, and the prosecution history) to determine whether the injector described in the asserted claims requires a pressure jacket. See Interactive Gift Express, 256 F.3d at 1331.

Even the most cursory reading of the specification of the 669 and 261 patents reveals that the injector described in the specification includes a pressure jacket:

An animal fluid injector, replaceable syringe and method of replacement of the syringe in the injector are provided in which the syringe is loadable and unloadable into and from the injector through the open front end of a pressure jacket of the injector . . .

669 patent and 261 patent, Abstract

It is an additional objective of the present invention to provide an injector wherein a used syringe can be removed and a new one inserted in the injector without retraction of the drive from the pressure jacket in most applications. It is a further objective of the invention to allow for the removal of the used syringe from the jacket without disconnection of the injector tube from the syringe nozzle.

669 patent, col. 2, lines 32-39

261 patent, col. 2, lines 30-37

(Doc. No. 30, Exhs. 1, 2)(emphasis added). Not only does the specification contemplate an injector that includes a pressure jacket, a pressure jacket appears to be an essential component of the injector. According to the specification, the purpose of the pressure jacket is to reinforce the walls of the syringe used in the injector against pressures placed upon it by the injector:
The syringe 32 is disposable, and includes walls which will withstand only moderate or low pressure. The walls are usually outwardly deformable under operating pressures, particularly pressures of 300 psi or more. Such higher pressures are necessary to overcome pressure drops through the injection tubing at higher flow rates, which are often desirable. The jacket 31 is made of a stronger transparent material that will withstand the operating pressures. When the syringe 32 is contained in the jacket 31, it is surrounded by the jacket 31 and supported by the jacket 31 against expansion caused by the fluid pressure within as the syringe 32 expands against the jacket wall.

669 patent, col. 7, lines 15-26
261 patent, col. 7, lines 10-21
* * *

The pressure jacket 31 has a generally cylindrical inner bore . . . The bore 33 is dimensioned so as to receive through the remote end 35 the disposable syringe 32 and to support the syringe against expansion from fluid pressure within such fluid pressure may range to more than a thousand psi.

669 patent, col. 7, lines 26-33
261 patent, col. 7, lines 22-29
* * *

To provide this front end loadable feature, the syringes of the preferred and illustrated embodiments of the present invention are provided with a front wall that is pressure restraining, that is, of sufficient strength to support the front of the syringe against the expected pressures within the syringe, and that is securable to the front end of the pressure jacket so as to complete the pressure restraining enclosure of the syringe within the pressure jacket and hold the syringe in the jacket.

669 patent, col. 3, lines 1-9
261 patent, col. 2, lines 65-67 to col. 3, lines 1-7

(Doc. No. 30, Exhs. 1, 2)(emphasis added). Furthermore, the pressure jacket is an integral component of the injector described in the specifications. Other features of the injector, including the syringe used in the injector, rely on the existence of a pressure jacket, and the specification does not describe how such features would work without the existence of a pressure jacket. (Doc. No. 30, Exh. 1, 669 patent: col. 2, lines 53-56; col. 3, lines 1-9; col. 7, lines 35-48; col. 8, lines 45-65; col. 9, lines 45-55; col. 10, lines 45-51). Quite simply, the specification fails to describe the components, design, or operation of an injector that does not include a pressure jacket.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

11 As explained in detail in footnote 2, the 669 and 261 patents have the same specification.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

In light of the specification, the fact that the asserted claims do not mention a pressure jacket simply does not support the conclusion that the asserted claims describe a jacketless injector. In SciMed Life Systems, 242 F.3d at 1341, the court concluded that:

where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question.

In the present case, the opposite is true. The specification makes clear that the injector includes a pressure jacket. Accordingly, the Court concludes that the asserted claims do not cover a jacketless injector, even though the asserted claims
might be considered broad enough to disclose a jacketless injector when read without reference to the specification. See also, Watts, 232 F.3d at 882-83 (claim that described pipe joints that could be "sealingly connected" limited to a misaligned taper angle connection method because specification discussed "the present invention" only in terms of the misaligned taper angle connection method); Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1382 (Fed.Cir. 1999) (court limited a computer system claim term ("frame") to character-based systems noting that the "only system that is described and enabled in the [patent] specification uses a character-based protocol" and that "references to other known protocols [did] not describe them as included in the applicant's invention, and that the specification would not be so understood by a person skilled in the field of the invention.").

Although L-F does not appear to disagree with the conclusion that the specification describes an injector that includes a pressure jacket, it maintains that a pressure jacket is not a required element of the injector described in the asserted claims. (Doc. No. 164, pp. 18-19). L-F argues that the specification of the 669 and 261 patents merely discloses a preferred embodiment of a front-loadable injector that includes a pressure jacket. (Id.). L-F points to the following excerpt, which appears immediately prior to the claims of the 669 and 261 patents:

the invention has been described in the context of its preferred embodiments. It will be appreciated by those skilled in the art that variations and alternatives to the embodiments described may be employed without departing from the principles of the present invention. Accordingly, this patent is not intended to be limited except by the scope of the following claims: . . .

669 patent, col. 13, lines 52-58
261 patent, col. 13, lines 54-60

(Doc. No. 30, Exhs. 1, 2). L-F correctly notes that a patent's claims are not limited to the preferred embodiment included in the specification, unless the language of the claims so limits them. See Karlin Technology, 177 F.3d at 973; see also SRI Int'l, 775 F.2d at 1122 (quoting Smith v. Snow, 294 U.S. 1, 11, 79 L. Ed. 721, 55 S. Ct. 279 (1935)). Because the asserted claims do not mention a pressure jacket, L-F argues that the limitation of a pressure jacket cannot be read into the asserted claims of the 669 and 261 patents. (Doc. No. 164 at 18-19).

However, as Medrad correctly argues, a review of the specification reveals that every embodiment disclosed in the asserted patents requires a pressure jacket. An injector that includes a pressure jacket is not a preferred embodiment of the injector. As the following excerpt demonstrates, the only injector contemplated by the specification is an injector with a pressure jacket:

According to the principles of the present invention, there is provided an angiographic injector having a front end loadable syringe that can be loaded into and removed from the injector pressure jacket through an opening that is provided in the front end of the pressure jacket. To provide this front end loadable feature, the syringes of the preferred and illustrated embodiments of the present invention are provided with a front wall that is pressure restraining . . . and that is securable to the front end of the pressure jacket . . .

669 patent, col. 2, lines 64-67 to col. 3, lines 1-4
261 patent, col. 2, lines 61-67 to col. 3, line 1

(Doc. No. 30, Exhs. 1, 2)(emphasis added). Thus, a pressure jacket is a required element of the injector described in the asserted claims. See Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed.Cir. 1996), cert. denied, Showa Aluminum Corp. v. Modine Mfg., 518 U.S. 1005, 135 L. Ed. 2d 1048, 116 S. Ct. 2523 (1996)("When the preferred embodiment is described in the specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment."); Wang Labs, 197 F.3d at1382-83 (scope of claims limited to the only embodiment described in the specification).

The prosecution history also supports the conclusion that the asserted claims of the ' 669 and 261 patents involve an injector that requires a pressure jacket. The original applications which led to the 669 and 261 patents were filed on November 30, 1993 and April 6, 1995, respectively. (Doc. No. 57, Exhs. 23, 25). In the applications, all the independent claims included a pressure jacket and no dependent claims provided for the removal or elimination of the pressure jacket.
On September 12, 1994, L-F amended certain claims of the application that resulted in the 669 patent. (Doc. No. 57, Exh. 22). L-F removed the references to the pressure jacket in those claims. (Id.; Doc. No. 57, Exh. 2). Similarly, on April 6, 1995, L-F amended certain claims of the application that resulted in the 261 patent. (Doc. No. 57, Exh. 26). Again, L-F removed the references to the pressure jacket in those claims. (Id.; Doc. No. 57, Exh. 3). The specifications for the 669 and 261 patents remained the same.

It is undisputed that L-F amended the claims after it learned of Medrad's invention of a jacketless injector. Regarding the amendment of claims in light of a competitor's product, the Federal Circuit has held that:

there is nothing improper, illegal or inequitable in filing a patent application for the purpose of obtaining a right to exclude a known competitor's product from the market; nor is it in any manner improper to amend or insert claims intended to cover a competitor's product the applicant's attorney has learned about during the prosecution of a patent application. Any such amendment or insertion must comply with all statutes and regulations, of course….

Kingsdown Medical Consultants, Ltd. v. Hollister Inc., 863 F.2d 867, 874 (Fed.Cir. 1988), cert. denied, 490 U.S. 1067, 104 L. Ed. 2d 633, 109 S. Ct. 2068 (1989)(citing State Indus., Inc. v. A.O. Smith Corp., 751 F.2d 1226, 1235 (Fed.Cir. 1985)). Thus, despite Medrad's argument to the contrary, L-F did nothing improper in amending the claims submitted in the original applications.

Although the fact that the original claims of the 669 and 261 patents were amended has no bearing on the Court's analysis, the substance of the original claims is relevant to its analysis. The original claims described an injector that required a pressure jacket. The specification was drafted for claims that disclosed an injector that required a pressure jacket, and this specification was not amended when the original claims were amended. It is unlikely that the specification, which was drafted for claims that included a pressure jacket, would describe an injector that does not require a pressure jacket, much less enable one skilled in the art to make and use such a device.

L-F argues that the prosecution history actually supports a conclusion that the injector described in the asserted claims does not require a pressure jacket. In an April 22, 1996, amendment to the 261 patent, L-F stated:

In the claims as amended herein, the locking structure is not necessarily at the front end of the syringe, nor is there necessarily a pressure jacket . . .

(Doc. No. 84, Exh. 4(b), MED 000189). Based on this excerpt alone, L-F argues that "the Patent Office Examiner understood that the claims of the 261 patent were directed to the syringe/injector locking structure either at the front or the rear of the syringe and with or without a pressure jacket." (Doc. No. 164, p. 20). This Court cannot accept such an argument. When faced with a similar argument in DeMarini Sports, 239 F.3d at 1326, the court held that "drawing inferences of the meaning of claim terms from an examiner's silence is not a proper basis on which to construe a patent claim . . ." As in DeMarini Sports, it is L-F, not the Examiner, who commented on the absence of a pressure jacket. The Examiner did not comment either way on the existence of a pressure jacket.

Finally, L-F proposes that the doctrine of claim differentiation prevents the Court from interpreting the asserted claims as requiring pressure jackets. (Doc. No. 164, pp. 16-18). The doctrine of claim differentiation is based "on the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Karlin Technology, 177 F.3d at 971-72. However, courts cannot use the doctrine of claim differentiation to "broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence." Multiform Desiccants, 133 F.3d at 1480. The doctrine of claim construction "only creates a presumption that each claim in a patent has a different scope; it is 'not a hard and fast rule of construction.'" Kraft Foods, 203 F.3d at 1368 (quoting Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed.Cir. 1998)); Karlin Technology, 177 F.3d at 972 (stating that the doctrine of claim differentiation is not a rigid rule).

According to L-F, the doctrine of claim differentiation precludes the Court from reading a pressure jacket requirement into claims 10 and 19 of the 669 Patent, as this requirement expressly appears in claim 14 which depends from claim 10. 12 (Doc. No. 164, p. 16-18). Likewise, L-F asserts that claim differentiation precludes the Court from reading a pressure jacket requirement into claims 1 and 18 of the 261 patent as this requirement expressly appears in dependent claims 2 and 19. 13

12 Claim 14 of the 669 patent provides as follows:

The method of claim 10 wherein:

the injector includes a hollow pressure jacket projecting therefrom having an open front end, the opening being located at the front end of the pressure jacket, the jacket having an internal cross-section dimensioned to surround and provide pressure restraining exterior support to the body of a syringe, inserted in the jacket through the opening, between at least the rearward end of the body to the rim;

the peripheral rim of the syringe is located at the forward end thereof;

the syringe inserting step includes the step of translating the syringe rearwardly and inserting thereby the body of the syringe, from the rearward end to the rim, into the jacket; and

the rotating step includes the step of locking the forward end of the syringe to the front end of the jacket.

13 Claim 2 of the 261 patent provides as follows:

The disposable replacement syringe of claim 1 for use with an injector having a pressure jacket extending forwardly therefrom, the jacket having a cylindrical bore therein, the opening of the injector being the hollow bore of the jacket, and wherein the internal sections are fixedly located on the inside of the jacket, wherein:

the radially extending mating sections of the locking structure comprise mating sections positioned in a plane perpendicular to the axis of the body of the syringe so as to align with the internal sections on the jacket when the syringe is inserted in the jacket and to lock the syringe to the jacket.

Claim 19 of the 261 patent provides as follows:

The injector of claim 18 wherein:

the injector has a pressure jacket extending forwardly from the housing, the jacket having a cylindrical bore therein, the syringe receiving opening of the injector being in the bore of the jacket; and

the mating sections at the opening are fixedly located on the jacket, whereby the radially extending sections of the locking structure lock the syringe to the jacket.

(Doc. No. 30, Exhs. 1, 2).

L-F is applying the doctrine of claim differentiation in an attempt to broaden the asserted claims beyond their scope determined in light of the specification. See Multiform Desiccants, 133 F.3d at 1480. The specification does not contemplate a jacketless injector or instruct on the concept, design, or use of a jacketless injector. Thus, the Court cannot conclude simply because the term "pressure jacket" was explicitly used in dependent claims and not in the asserted claims, that the patents disclose a jacketless injector. As stated above, claim differentiation only creates a presumption that each claim has a different scope. "Claims that are written in different words may ultimately cover substantially the same subject matter." Multiform Sesiccants, 133 F.3d at1480; see also, Tandon Corp. v. U.S. Int'l Trade Comm., 831 F.2d 1017, 1023 (Fed.Cir. 1987)("Practice has long recognized that 'claims may be multiplied . . . to define the metes and bounds of the invention in a variety of different ways'.") (quoting Bourns, Inc. v. United States, 210 Ct. Cl. 642, 537 F.2d 486, 492 (Fed.Cir. 1976)).

Accordingly, the Court concludes that the terms "syringe receiving opening" and "opening" refer to a circular width of a size
to accommodate the back end of a syringe. Furthermore, the Court concludes that the injector described in the asserted claims of the '669 and '261 patent requires a pressure jacket and that the syringe receiving opening/opening is located at the front of this pressure jacket.

Claim 10 of the '669 patent is representative of the asserted claims of the '669 and '261 patents. It provides as follows:

A method of loading a tubular replacement syringe into a high pressure power injector for injecting fluid into an animal, the method comprising the steps of:

providing a power injector having:

a syringe receiving opening with a generally circular periphery therein adapted to receive a rearward end of a syringe having a generally circular rim,

a ram and a motor linked to the ram and operable to reciprocate the ram along a segment of a line projecting through the opening; and providing a hollow tubular syringe that includes:

a cylindrical body having an axis, a generally circular rim, a rearward end and a closed forward end with a fluid discharge orifice therein, and

a plunger axially slidable in the body, the syringe body being structurally capable of withstanding, at least from the rim to the orifice, fluid at an operating pressure of at least 100 psi within the interior thereof;

then:

inserting into the opening, by generally rearward axial movement of the syringe, the rearward end of the body;

rotating the syringe in the opening a fraction of a turn to thereby lock the body around the rim to the injector around the periphery of the opening; and

engaging the plunger with the ram;

then:

energizing the motor and thereby driving the ram forward along the line and parallel to the axis to move the plunger axially forward at a programmed speed to inject the fluid at the operating pressure from within the syringe and through the orifice at a programmed rate into the animal.

Neither claim 10 of the '669 patent nor any of the other asserted claims recites a pressure jacket. The district court, however, construed the claims to require pressure jackets by focusing on the "syringe receiving opening" limitation in claim 10 (and similar language used in the other asserted claims). After finding that limitation to be ambiguous with respect to the location of the opening, the court looked to the specification and concluded that, because the syringe-receiving opening in each of the embodiments of the invention was located at the front end of a pressure jacket, the "opening" referred to in each of the asserted claims had to be located at the front end of a pressure jacket. Medrad embraces the district court's claim construction analysis and makes the more general argument that because the "pressure-jacketed injector" is the only subject matter described in the specification, that subject matter constitutes the invention itself, not simply a preferred embodiment of a broader invention.

We have had many occasions to cite one or both of the twin axioms regarding the role of the specification in claim construction: On the one hand, claims "must be read in view of the specification, of which they are a part." Markman v.
Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). On the other hand, it is improper to read a limitation from the specification into the claims. Arlington Indus., Inc. v. Bridgeport Fittings, Inc., 345 F.3d 1318, 1327 (Fed. Cir. 2003); Gart v. Logitech, Inc., 254 F.3d 1334, 1343 (Fed. Cir. 2001). Although parties frequently cite one or the other of these axioms to us as if the axiom were sufficient, standing alone, to resolve the claim construction issues we are called upon to decide, the axioms themselves seldom provide an answer, but instead merely frame the question to be resolved. We have recognized that "there is sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification." Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186-87 (Fed. Cir. 1998); accord Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1307 (Fed. Cir. 2003). As we have explained, "an inherent tension exists as to whether a statement is a clear lexicographic definition or a description of a preferred embodiment. The problem is to interpret claims 'in view of the specification' without unnecessarily importing limitations from the specification into the claims." E-Pass Techs., Inc. v. 3COM Corp., 343 F.3d 1364, 1369 (Fed. Cir. 2003); accord Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204-05 (Fed. Cir. 2002). That problem can present particular difficulties in a case such as this one, in which the written description of the invention is narrow, but the claim language is sufficiently broad that it can be read to encompass features not described in the written description, either by general characterization or by example in any of the illustrative embodiments.

At the outset, we reject the district court's conclusion that the term "opening" should be defined as limited to an opening in a pressure jacket. The specification does not define "opening" restrictively, nor is there anything in the specification that supports the district court's conclusion that the term is ambiguous. The asserted claims refer to the "syringe receiving opening," or simply the "opening," as having various characteristics, but none of the asserted claims state, explicitly or by necessary implication, that the opening must be formed in or in conjunction with a pressure jacket. Claim 10 of the '669 patent, for example, requires "a ram and a motor linked to the ram and operable to reciprocate the ram along a segment of a line projecting through the opening." The claim further provides that the rearward end of the syringe will be inserted into the opening and rotated in the opening to lock it in place. Thus, the "opening" must be located so that the ram reciprocates along a segment of a line projecting through the opening and so that the rear end of the syringe can be inserted into the opening and affixed to the injector at that point. But the claim language does not suggest that the "opening" must also be located at the front end of a pressure jacket.

Other asserted claims likewise refer to the location of the opening without referring to the location of the opening vis-a-vis a pressure jacket. For example, claim 19 of the '669 patent identifies the location of the opening as being "at the front end of the injector," and claims 1, 8, and 15 of the '261 patent refer, respectively, to the opening as being located "on the front [of the injector]." "at the front of the injector," and "on" the injector. Claim 27 of that patent refers to the injector housing as having "a tubular member extending forwardly from the front thereof and having a cylindrical bore therein forming the syringe receiving opening." In each case, the claim specifies the location and structure of the opening while making no mention of a pressure jacket.

In common usage, an opening is simply an aperture, and nothing in the '669 and '261 patents indicates that the term "opening" should be understood to carry with it the requirement that it must always be located in the front of a pressure jacket. Accordingly, contrary to the district court, we find no ambiguity in the term "opening" and no reason to resolve the purported ambiguity by reading that term restrictively. We therefore turn to Medrad's more general argument that the specification and the prosecution history demonstrate that the invention as a whole was limited to an injector system using a pressure jacket.

1. "An opening" and "closed base"

Claim 9 includes "a battery holder shaped for containing a battery having first and second terminals, the battery holder having an opening at one end and a generally closed base at the other end. . . ." '900 Patent col.11 1.32-35 (emphasis added). Invisible Fence asserts that the term "an opening" means "an opening of the battery holder at an end opposite the generally closed base," and the term "closed base" means "an end of the battery holder that is opposite the opening." (Joint Statement 3.) Perimeter, however, submits that "an opening" is defined as "the open end of the cup-shaped battery holder through which the battery is inserted," and "closed base" is defined as "the end of the single-piece cup-shaped battery holder that is
opposite the open end through which the battery is inserted." (Joint Statement 3.)

Perimeter argues that the opening and the closed base are at opposite ends of a cup-shaped battery holder, while Invisible Fence counters that the claim language does not limit the battery holder to being cup-shaped. Perimeter supports its proposed construction by citing the Description, which provides that "the battery holder . . . is generally cup-shaped having a generally tubular sidewall . . . and a hollow interior with an opening at one end and a closed base . . . at the other." '900 Patent, col.6 1.8-11. Perimeter additionally cites to the Summary of the Invention ("Summary"), asserting that the following language necessarily depicts a cup-shaped battery holder: "The battery pack . . . includes a generally hollow holder for receiving and containing a battery . . . [which] is generally cylindrical in shape having an opening at one end and a generally closed base at the other end." '900 Patent col.1 1.54-58.

To adopt Perimeter's position, we would have to read the limitation from the Description into the claim construction. See Dayco Prods., 258 F.3d at 1327. Claim 9, however, merely provides that the battery holder is "shaped for containing a battery." '900 Patent col.1 1 1.32. Thus, the clear language of claim 9 does not limit the battery holder to a particular shape, and certainly does not limit it to being cup-shaped.

Perimeter also claims that the battery holder is a single-piece design, with the "closed base" and the "generally tubular sidewall" integrally connected as illustrated in the drawings. See '900 Patent figs. 8,10. However, claim 9 does not specify that the battery holder is single-piece; in fact, the written specification, including the Description, never describes the battery holder that way. Therefore, the Court will not import this limitation into claim 9. See Dayco Prods., 258 F.3d at 1327.

Furthermore, Perimeter proposes that the opening is defined as the end through which the battery is inserted and the base is defined as opposite the opening through which the battery is inserted. Any requirement, however, which limits the insertion of the battery is clearly not found in claim 9 or in the written specifications. Indeed, Perimeter points to fig. 3, "an enlarged perspective view of the battery pack," in which the battery is seemingly inserted through the opening, as the only intrinsic evidence in support of its proposed construction.

Perimeter does urge a common-sensical approach, arguing that the opening is the only possible way that the battery can be inserted into the battery holder, since the battery cannot be inserted through a closed base. This argument, however, seemingly depends upon the notion that the closed base and tubular sidewall are integrally connected-a concept we already have rejected. In addition, Invisible Fence proposes that even in a single-piece design, the battery could be inserted through the base before it is ultrasonically welded to the tubular sidewall. 6 Because generally the entire battery pack, and not just the battery, is replaced when the battery weakens, Invisible Fence's proposition is consistent with the invention's purpose-to make battery replacement simple. See '900 Patent col.11.40-46.

6 We do not suggest that the manufacturing process is limited in that way; indeed, the patent poses no requirements regarding the manufacturing process of the battery pack. Instead, Invisible Fence offered this explanation as just one example of how the claim could encompass more than just the limitation proposed by Perimeter.

Because claim 9 makes no reference to the insertion of the battery, the Court will not limit the definition of the opening to "the end . . . through which the battery is inserted." 7

7 Invisible Fence also supports its argument with intrinsic evidence from the prosecution history, specifically the Office Action dated April 5, 1994, when the Examiner stated that "the ends of the spring are recited as being in contact with the base of the battery pack, but they appear to actually be located opposite the base, at the open end closed by the retaining ring." U.S. Dep't of Commerce Patent & Trademark Office, Examiner's Action 2 (Apr. 5, 1994). Invisible Fence claims that because the Examiner made no reference to the insertion of the battery, the battery holder being cup-shaped, or the battery holder being single-piece, the Office Action reveals that claim 9 should not be narrowly construed in conformance with
Perimeter's proposed construction. However, the Court does not find the prosecution history particularly helpful here. The Office Action ostensibly has little to do with defining the opening or the closed base, since the Examiner was merely seeking clarification regarding the configuration of the "ends of the spring." Regardless, because the Court finds the language of claim 9 to be unambiguous, we need not rely on the prosecution history. See Interactive Gift Exp., 256 F.3d at 1332.

Finally, the parties dispute how the retaining ring defines the opening. Invisible Fence asserts that once the retaining ring is ultrasonically welded to the tubular sidewall, see '900 Patent col.7 1.44-47, the opening and the central aperture of the retaining ring become "one in the same." (Pl.'s Opening Br. 10.) Perimeter counters that the opening and the central aperture cannot be coincident with one another, since the central aperture is necessarily smaller than the opening in order to retain the battery within the holder. The Court agrees that the retaining ring does not define the opening. Because welding the retaining ring to the tubular sidewall is merely a preferred embodiment, it is impermissible to limit the definition of opening to coincide with the central aperture. See '900 Patent col.7 1.44-45 ("[The] retaining ring . . .may be securely attached to [the] battery holder. . . .")

For the reasons discussed above, the Court construes the term "an opening" to mean "an opening of the battery holder at an end opposite the generally closed base," and interprets the term "closed base" to mean "an end of the battery holder that is opposite the opening."
8. The term "opening for overflow" (claim 12)

The Court agrees with WIMCO that this term does not need to be construed. The words "opening for overflow" are ordinary words, and nothing in the intrinsic evidence requires those words to be given some unusual meaning.

The Court therefore rejects Lange's argument that an "opening for overflow" is necessarily the "top opening of [a] standpipe." JCCS at 4; Def. Claim Constr. Br. at 39-40. As the Court has already explained, claim 9 (from which claim 12 depends), like claim 6, is not limited to basins with standpipes. Accordingly, although an "opening for overflow" could be the top of a standpipe (as it is in the preferred embodiments disclosed in the '207 patent), it does not have to be the top of a standpipe.

The parties also disagree over the meaning of the phrase "switch housing formed with an opening therein." (052 Patent, col.7, l.66.) Specifically, the parties' interpretation diverges in relation to the word "opening." Both parties refer to the Oxford English Dictionary for the plain meaning of "opening" which defines it as "a vacant space between portions of solid matter; a gap, hole, or passage; an aperture." Oxford English Dictionary Vol X 044-045 (2d ed. 1989). However, based on this definition, the parties urge two entirely different constructions.

Transpec contends that "opening" refers to a hole or a slot located in the side of the switch housing that would allow passage from the inside to the outside of the housing. Specifically, Transpec contends that column 4, line 10 of the specification, which states: "the switch housing is formed with a large opening or slot," supports such a construction. Additionally, Transpec suggests that it is inherent in the meaning of "housing" that there is some empty space inside the housing and thus the term "opening" could be omitted without altering the meaning of the claim. 4

Ellison, however, asserts that "opening" in this sentence refers to the vacant space inside of the switch housing and not to a slot or passage from the inside of the housing to the outside of the housing. In support of its claim Ellison also relies on the plain meaning of "opening" but focuses instead on the portion which describes an opening as a "vacant space between portions of solid matter." Oxford English Dictionary Vol X, 044-045 (2d ed. 1989). Ellison also contends that Transpec's proposed construction is wrong because the claim language states that the housing has an "opening" therein and not thereon, thus suggesting that it is referring to the space within the housing and not some type of hole or slot in the side of the housing. Finally, Ellison argues that the language in the specification referring to the opening as a "slot" is not decisive because it serves only as a preferred embodiment of the invention and should not be used to limit the meaning of the claims. (Pl.'s Reply Br. 4-5.)

Although the specification is to be viewed as a preferred embodiment and not used to limit the terms of the claim language, the claim should not be interpreted in a way that renders the specification outside of the patent claim. See E-Pass Techs., Inc. v. 3COM Corp., 343 F.3d 1364, 1369 (Fed. Cir. 2003) ("The problem is to interpret claims 'in view of the specification' without unnecessarily importing limitations from the specification into the claims.") (citing Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204-05 (Fed. Cir. 2002). Transpec's proposed interpretation, although conceivably suggested by the term "slot" in the specification, would result in such an interpretation. For example, column 4 of the specification contains the following description for the beam generators and sensors' location:
A pair of beam generators 38, 38' are mounted in the switch housing on one side of the opening 34 . . . for generating and directing a linear beam across the opening 34. A pair of beam sensors 40, 40' are mounted in the switch housing 30 on the other side of the opening 34 and directly in the path of the beams generated by the beam generators 38, 38' respectively.

('052 Patent, col.4, ll.14-23 (emphasis added).) This embodiment clearly describes the beam sensors and generators being inside the switch housing and on opposite sides of the switch housing. However, if the "opening" referred to was a hole or passage to the outside of the housing, it would be impossible for the generating and sensing means to both be located on opposite sides of the opening and at the same time be in the switch housing. Thus, if Transpec's interpretation were adopted, the specification would not fall within the scope of the patent. Such interpretations are highly disfavored. See Vitronics Corp., 90 F.3d at 1583-84 ("Such an interpretation is rarely, if ever, correct and would require highly persuasive evidentiary support . . . ."); see also Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1581 (Fed. Cir. 1996) ("We share the district court's view that it is unlikely that an inventor would define the invention in a way that excluded the preferred embodiment, or that persons of skill in this field would read the specification in such a way."). Thus, the term "opening" in claim 1 will be interpreted to mean the space within the switch housing and will be construed as follows:

(c) An enclosed structure containing the three elements in subsection (i), (ii), and (iii) and also some vacant, unoccupied space.

The claims in patent 449 also require that the arcuate lower portion "opening toward the channel-shaped upper portion." The ordinary meaning of toward is "in the direction of." Webster's Third New International Dictionary of the English Language Unabridged, p. 2417 (Merriam-Webster Inc., 1986). Ameritex argues that opening toward requires the lower portion to open so that the center point of the lower portion is in a direct line with the center of the base of the upper portion.

First, the claims do not indicate a meaning different from the ordinary meaning of opening toward. Second, the preferred embodiment illustrated by figures 2 and 3 depicts a lower portion that lies along the circumference of a circle and that has a center point. 449 patent, col. 4, ll. 30-33. The angle formed by the mounting member is measured by the location of the center point. 449 patent, figures 2 and 3. The location of the center point determines which arcuately spaced opening is used to secure the lower portion to the deck. 449 patent, col. 4, ll. 65-68 and col. 5, ll. 1-16. However, figures 2 and 3 are preferred embodiments. The specification states that non-circular lower portions may be used. A non-circular lower portion does not have a center point. Moreover, the specification never refers to a requirement that the center point of the lower portion must be in a straight line with the center point of the base of the upper portion for the mounting system to function.

The prosecution history does not reveal any additional limitations placed on this claim term. Consequently, the phrase opening toward the channel shaped upper portion is provided its ordinary meaning of opening in the direction of the upper portion.

"Slots" and "Openings" are Limited to Slots and Openings Less than .254 mm Wide

The '940 patent employs the term "openings" in claims 1 and 37 and the term "slots" in claims 10, 11-14, and 39. In the specification and claims, the term "openings" is sometimes used in reference to a feature of the screening plate/medium, see id., Col. 5, Lns. 43-45; Col. 5, Lns. 55-57; Col. 13, Lns. 25-26, and sometimes used in reference to a feature of the backing plate, see, e.g., id., Col. 2-3, Lns. 66-67, 1-2; Col. 5, Lns. 55-57; Col. 13, Lns. 40-44, whereas the term "slot" is always used in reference to a feature of the screening plate/medium. 9 "Slots" is not defined in the specification, however, the term appears to be a subset of "openings," which the specification states "is intended to encompass apertures of all shapes and sizes, including holes, slots, orifices and passageways." Id., Col. 5, Lns. 38-41. One preferred embodiment of the present
invention provides "a slot width of 0.5 mm." Id., Col. 12, L. 5. Accordingly, AFT seeks to construe these terms broadly, with "openings" simply meaning, something that is open, and "slots" meaning a narrow opening or groove. Opp'n Construction Mot. at 16-18.

9 The terms "openings" and "slots" are also used in the specification in reference to a feature of traditional screens where no distinction is made as to separate screening medium and backing plate components. See, e.g., '940 patent, Col. 1 at 33, 60. Despite the apparent breadth of "openings" and "slots" provided for by the claims and specification, AFT unequivocally limited the scope of these terms during the prosecution history. Again while attempting to show that the Gillespie did not anticipate the present invention, AFT distinguished the former as inappropriate for the use towards which the latter was solely directed, namely pulp treatment. To do so, AFT emphasized, "the slot sizing of the Gillespie screen further underscores how inappropriate the device is for screening pulp fibers." Mesiti Decl., Ex. D1 (Dkt. No. 33-16) at 80. The slot size of the Gillespie is .762 mm. Id. AFT explained, "this slot size would be totally inappropriate for screening . . . pulp fibers. . . . [P]ulp fibers have diameters less than 50 microns . . . and typically slot widths of 0.2 mm would be used for aspects of the [present] invention." Id. (emphasis added). AFT continued, "[t]he slots of Gillespie are over three times the size of the slot width of the present invention." Id. (emphasis added). Based upon these statements to the Examiner, J&L seeks to narrow the definition of "slots" and "openings" to include only slots or openings with widths of 0.2 mm or less. Construction Mem. at 15-17.

The statements made by AFT during the prosecution history in order to avoid anticipation by the Gillespie constitute an unmistakable disavowal of the full scope that the claim terms and specification indicate for the terms "slots" and "openings." 10 That disavowal, however, is slightly narrower than the construction proposed by J&L. AFT, in arguing to the Patent Examiner, clearly disavowed any slot width that was not suitable for screening pulp. AFT stated that would "typically" limit slots used in the invention to 0.2 mm. That statement does indicate a clear intent to always limit the slots to 0.2 mm. AFT went on to assert a more definitive limit for slots employed in the invention when it flatly stated that the .762 mm slots found in the Gillespie "are over three times the size of the slot width of the present invention." AFT, thereby, unequivocally disavowed any slot with a width equal to or greater than 0.254 mm. Having done so during prosecution, AFT cannot now argue a broader interpretation of these terms. Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1578 (Fed. Cir. 1995) ("A patentee may not proffer an interpretation for the purposes of litigation that would alter the indisputable public record . . . and treat the claims as a 'nose of wax.'") (quoting Senmed, Inc. v. Richard-Allan Med. Indus., 888 F.2d 815, 819 n.8 (Fed Cir. 1989); see also Texas Instruments, Inc. v. Int'l Trade Comm'n, 988 F.2d 1165, 1174-75 (Fed Cir. 1993)) (prosecution history estoppel applies where unmistakable statements were made to the Patent Office in support of patentability); Cf. Haliczzer v. United States, 356 F.2d 541, 545, 174 Ct. Cl. 507 (Ct. Cl. 1966) ("Plaintiff may not here take a position inconsistent with the one he maintained before the Patent Office in the proceedings which led to the issuance of the patent"). Thus, the terms "openings" and "slots" mean openings or slots with widths less than 0.254 mm.

10 While AFT refers in this excerpted history only to "slots," it is clear that it is equally disavowing "openings" insofar as they relate to the screening plate/medium. AFT makes the above argument to show that "Gillespie does not anticipate the invention recited in claim 1." Mesiti Decl., Ex. D1 (Dkt. No. 33-16) at 80. Claim 1, however, employs the term "openings" rather than "slots." AFT later makes the same argument with regard to claim 10, which uses "slots." Id. at 81. Here, as in the specification, the terms "slots" and "openings" appear interchangeable, at least when directed to the screening plate/medium.
On September 19, 2003, the Court held a hearing in accordance with Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996), to construe the disputed terms and phrases of the asserted claims. The Court's October 7, 2003 Order Following Claims Construction Hearing construed the following disputed terms in the '415 patent which are relevant to the present findings on validity and invalidity:

"implant delivery assembly"  
"an apparatus for delivery of occlusive devices, such as embolic coils that comprises three distinct components: a pusher, a coupling, and an implant"

"pusher"  
"any device or structure intended to push another device or structure"

"selectively operable coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"coupling"  
"a connecting device that connects the implant to the pusher and that can be selectively operated by the user"

"said coupling operable by fluid pressure so that when a sufficient amount of fluid pressure is applied to the coupling, the fluid pressure causes the occlusive implant to separate from the pusher"  
"the coupling is a connecting device that can be operated by selectively applying fluid pressure to the coupling to separate the implant from the pusher, and the application of the fluid pressure by the user to the coupling causes the detachment of the implant at the coupling"

"delivering fluid pressure through the pusher such that the implant detaches from the pusher by the fluid pressure"  
Plain and ordinary meaning applies, no specific construction by the Court

(The Markman Order at 22-29, Docket Item No. 177.)

GO BACK

8. Claim 1 - "operable for flexing transversely to said longitudinal axis to relax the dunnage structure when the side walls are moved to a collapsed position such that the relaxed dunnage structure is generally positioned in the reduced size container for return"

Bradford proposes that this term means "being 'coupled to' the two 'side walls' such that folding the two 'side walls' causes bending or folding relative to said longitudinal axis to relax the 'dunnage structure' and occurs during the time that the two 'side walls' are being folded into a collapsed position such that the relaxed 'dunnage structure' is generally positioned in the reduced size container so that the container can be sent back while in the collapsed position." Defendants propose that this term means "being 'coupled to' the two 'side walls' such that moving the two 'side walls' causes bending, folding, or contracting relative to said longitudinal axis to relax the 'dunnage structure' and occurs during the time that the two 'side walls' are being moved into a collapsed position such that the relaxed 'dunnage structure' is generally positioned in the reduced size container so that the container can be sent back while in the collapsed position." Again the difference between the parties' proposed definitions is that Bradford limits the term to "fold" or "folding". In contrast, Defendants maintain the limitation "move" or "moving", albeit they do add that moving the side walls causes "contracting".

For the reasons stated in Part IV. A.3, supra, "moved to" should not be limited to folding operations. Accordingly, Bradford's
definition is rejected to the extent it limits this term to "fold" or "folding".

With respect to "contracting", Bradford argues that "contracting" is akin to "flexing", as in flexing a muscle. Bradford argues that flexing is not the same as the collapsing operation this invention performs. On the other hand, Defendants rely on the dictionary definition of "flex" in arguing that "flexing transversely" includes contracting. They note that flex means "to bend (something pliant or elastic). To bend (a joint). To bend a joint repeatedly. To contract."). Tr. at 67.

Defendants' dictionary indicates that "contracting" is encompassed within the term "bending." Bradford's proposed definition is an admission that the "upper edge" bends when the side walls are moved to a collapsed position. Therefore, the Court finds that adding the limitation of "contracting" to this term would be redundant. Accordingly, to that extent Defendants' definition is rejected.

The Court holds that "operable for flexing transversely to said longitudinal axis to relax the dunnage structure when the side walls are moved to a collapsed position such that the relaxed dunnage structure is generally positioned in the reduced size container for return" means "being 'coupled to' the two 'side walls' such that moving the two 'side walls' causes bending or folding relative to said longitudinal axis to relax the 'dunnage structure' and occurs during the time that the two 'side walls' are being moved into a collapsed position such that the relaxed 'dunnage structure' is generally positioned in the reduced size container so that the container can be sent back while in the collapsed position."

II

On appeal, On Serts argues that the district court's claim construction was erroneous, and no infringement can be found under On Serts's proffered construction. Because the parties dispute the meaning of terms in the claims of the patent, this court reviews the district court's order under Markman v. Westview Instruments, Inc., 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The claim language, of course, defines the bounds of claim scope. Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995) ("First, and most importantly, the language of the claim defines the scope of the protected invention."). "To determine the meaning of disputed claim terms, however, a construing court may consider other sources, including the patent specification and the administrative record leading to patent issuance. These additional sources may provide context and clarification about the meaning of claim terms." York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996) (citation omitted); see also Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561, 19 U.S.P.Q.2D (BNA) 1500, 1503 (Fed. Cir. 1991). While extrinsic evidence may also be considered in claim construction, no such evidence was considered here.

Claim 1 of the '080 patent, the only claim at issue, states:

Apparatus for producing a succession of self-adhesive labels carried on a backing of release material, the apparatus comprising:

[1] means for conveying along a pathway a laminar material comprising a succession of label base portions, each of which is coated on its reverse side with a pressure sensitive adhesive, and having a backing of release material;

[2] detecting means situated along the pathway for detecting a succession of particular locations which are spaced along the length of the laminar material;

[3] an adhesive applying station situated along the pathway and including an adhesive applicator, which is operable in response to the means for detecting, for applying a layer of adhesive to a particular area on each label base portion;

[4] a label applying station situated along the pathway downstream of the adhesive applying station, the label applying station including label applying means, which are operable in response to the means for detecting, for successively applying individual pre-printed labels to respective successive layers of adhesive so that a pre-printed label covers each area of each label base portion to which adhesive has been applied.
This appeal focuses on the meaning of elements [3] and [4]. The parties offer conflicting interpretations of "operable in response to," the pertinent phrase in the relevant elements. Instance favors the construction of the district court.

The district court, in the form of jury instructions, determined that the words 'operable in response to', as they are used in claim 1 of the '080 Patent, do not imply that a specific control means is being claimed. In other words, if the web sensor in [On Serts's] label system causes a response in the operation of the adhesive applicator, that adhesive applicator may be found to be operable in response to the web sensor.

On Serts, on the other hand, suggests a different and narrower construction. On Serts argues that the adhesive applicator is only "operable in response to" the detector when the sensor initiates the operation of the adhesive applicator either "immediately or after a predetermined delay of time." Because the accused device does not contain a web sensor that initiates the operation of the glue applicator immediately or after a predetermined delay of time, On Serts argues that this fact precludes literal infringement.

III

On Serts's claim construction rests on an importation into the claims of limitations from the embodiments in the specification. See Intervet America, Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053, 12 U.S.P.Q.2D (BNA) 1474, 1476 (Fed. Cir. 1989) (stating that limitations from the specification should not be read into the claims); Sjolund v. Musland, 847 F.2d 1573, 1581, 6 U.S.P.Q.2D (BNA) 2020, 2027 (Fed. Cir. 1988) ("While . . . claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims . . . ."). In this case, "operable in response to" has a definite meaning without recourse to the specification for clarification. This claim term is not so amorphous a term that the court can only reconcile the claim language with the inventor's disclosure by recourse to the specification. See E.I. Du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, 7 U.S.P.Q.2D (BNA) 1129, 1131 (Fed. Cir. 1988) (stating that the specification can supply understanding of unclear claim terms, but should never trump the clear meaning of claim terms).

Thus, the claim terms define the bounds of the patentee's property right. Stiftung v. Renishaw PLC, 945 F.2d 1173, 1177, 20 U.S.P.Q.2D (BNA) 1094, 1098 (Fed. Cir. 1991) ("Claim interpretation must begin with the language of the claim itself.") (citing Smithkline Diagnostics, Inc. v. Helena Laboratories Corp., 859 F.2d 878, 882, 8 U.S.P.Q.2D (BNA) 1468, 1472 (Fed. Cir. 1988)). In this case, the term "operable in response to" defines broadly the relationship between the various components of the claimed device. Broad terms, however, are not necessarily indefinite. Contrary to On Sets's assertion, this drafter did not choose either of the more limiting phrases "directly operable in response to" or "immediately operable in response to." Instead, as the district court correctly determined, "if the web sensor in [On Serts's] off-line system causes a response in the operation of the adhesive application, that adhesive applicator may be found to be operable in response to the web sensor." (Emphasis added.) The district court's instruction thus comports with the meaning of the claim language.

IV

The specification of the '080 patent also supports the district court's claim construction. In the preferred embodiment, for example, a START sensor detects the leading edge of the label. The specification then describes the action of the adhesive applicator in relation to the sensors: "When the START sensor 24 detects the said given point, an electrical signal is sent therefrom to initiate the operation of the adhesive applicator 30, either immediately or after a predetermined delay of time." This description is repeated for the STOP sensor. Reinforcing this reading, the specification continues:

It will be apparent to those skilled in the art that the separation of the START sensor 24, STOP sensor 26 and adhesive applicator 30, as well as any time delays in initiating and terminating the operation of the adhesive applicator 30, can be varied as desired.

(Emphasis added.) Clearly, in this embodiment, the sensor causes a response in the operation of the adhesive applicator. This response can vary according to the desires of the operator.
The specification offers an additional embodiment:

Instead of employing a START sensor 24 and a STOP sensor 26, the apparatus can employ a START sensor 24 which is coupled to an encoder . . . . When the START sensor 24 detects the given point on a respective label base portion 16, an electrical signal is sent to the encoder which acts to measure the distance travelled [sic] by the moving web from a given start position. After the web has travelled [sic] a prescribed distance, the encoder activates the adhesive applicator 30 for a given period.

In this embodiment, the distance traveled by the web determines the length of the glue application. In this embodiment, the response is measured in terms of distance traveled by the web instead of in terms of time elapse. This difference, however, is mostly semantics. At a constant rate of speed, a predetermined distance is equivalent to a predetermined period of time. Still another embodiment explicitly states that the START sensor 24 and the STOP sensor 26 may detect printed marks which activate initiation or termination responses in the application of adhesive. Each of these embodiments describe relationships between the adhesive applicator and the sensor properly described by the concept of "operable in response to."

The specification sheds similar light on the words "operable in response to" with respect to the application of the booklet to the label. The fourth element of the claim requires that the label applying means is "operable in response to" the sensors. Once again, the specification provides numerous references to the operation of that particular element. For example, like the activation of the adhesive applicator, the sensor "initiates the operation of the adhesive applicator 30, either immediately or after a predetermined delay of time." These statements from the specification reinforce the district court's interpretation of the claims.

F. "Lock spindle being operable to rotate between a lock position and a release position"

Pedicraft asserts that this claim language in Claims 10 and 18 should be construed to mean "in response to operation of the handle, portions of the lock spindle are rotated from a position that precludes unwanted side rail travel to a position that permits desired side rail travel." Dkt. 65, pg. 24. Once again, however, Stryker's construction is more specific as to the meaning of this language. Stryker argues that this language means that "the lock spindle turns about its longitudinal axis from a lock position whereby the lock pin is resting on a catch to a release position whereby the lock pin slides through a clearance groove without obstruction."

Pedicraft centers its argument around its broader construction of "vertical lock spindle" (i.e., as potentially an assembly) as well as its claim that the spindle does not necessarily have to rotate around a vertical axis. It contends that Claim 10 expressly provides for the rotation between lock and release positions using the locking pins, and it is the release that permits movement of the associated side rails between their uppermost and lowermost positions. Dkt. 65, pp. 24-25; '855 Patent, Col. 9., Claim 10. According to Pedicraft, Stryker's specific and limited construction is not contained in Claim 10, and as such there is no support in the '855 Patent itself for importing the "specific catch and clearance groove arrangement" proposed by Stryker. Dkt. 65, pg. 25. Instead, Claim 10 only requires that in response to the actuation of the handle component, the lock spindle rotates relative to the side rail such that it is either held in a vertical position or allowed to move. Id.

Stryker again disputes Pedicraft's broader and more vague construction and offers a more specific one it contends is supported by the specification and figures embodied in the '855 Patent. See '855 Patent, Col. 6. The Court agrees that there is no support for the contention that only "portions" of the lock spindle will rotate relative to the side rail, and as explained above, there is no evidence to suggest that a "spindle" could possibly be a multi-part assembly. Instead, the '855 Patent describes the entire vertical lock spindle as being rotatably attached, and the ordinary meaning of "spindle" in the context of the '855 Patent clearly suggests a longitudinal axis of rotation. The Court further agrees that Pedicraft's use of terms such as "unwanted" and "desired" side rail movement in its proposed construction does improperly introduce vagueness and confusion into the patent, particularly when the term "spindle" has an ordinary meaning and its vertical attachment, movement and rotation are made clear from the express language of the '855 Patent itself. See, e.g., Wang Labs, 197 F.3d at 1384.
Stryker's construction that "the lock spindle turns about its longitudinal axis from a lock position whereby the lock pin is resting on a catch to a release position whereby the lock pin slides through a clearance groove without obstruction" is once again based on common sense. The language "lock spindle being operable to rotate between a lock position and a release position" therefore simply means that it rotates about its axis in such a way that its lock pins are either resting on a catch to prevent movement of the side rails, or the pins are in a release position to allow clearance (and thus movement) of the side rails. Such construction comports with both logic and the specific language of the '855 Patent itself.

D. "Arranged for Operative Engagement" and "Operably Arranged"

"Arranged for operative engagement" is found in claim 1 of the '486 patent and claim 7 of the '677 patent and "operably arranged" is found in claim 1 of the '677 patent. Hysitron asserts that both of these terms are easily understood and do not require clarification by the Court. Joint Claim Construction Statement at 11, 47. MTS asserts the same construction for both terms: "where the sample is moved in the x, y, and z directions when in contact with a probe, or a probe is moved in the x, y, and z directions when in contact with a sample, and where said movement of the sample or said movement of the probe in the z direction is controlled by feedback from a force sensor." Id. at 11-12, 48.

MTS's construction of these terms follows from its proposed unitary construction of "scanning head." Adopting that construction would eliminate the possibility that components of the scanning head be "operably arranged" or "arranged for operative engagement." The Court has rejected MTS's construction of "scanning head" and accordingly rejects MTS's construction of "operably arranged" and "arranged for operative engagement." Webster's New Collegiate Dictionary (1977) defines "operative" as "producing an appropriate effect." Supra at 804. It defines "arrange" as "to put into a proper order or into a correct or suitable sequence, relationship, or adjustment." Id. at 62. It defines "engage" as "to interlock with." Id. at 378. Therefore, the Court defines "operably arranged" to mean "placed in a suitable relationship so as to produce the appropriate effect" and "arranged for operative engagement" to mean "placed in a suitable relationship so as to interlock appropriately."

b. Operably Connected

Claim 1 of the '662 Patent describes several components that are "operably connected" to other components of the invention. Plaintiff asserts that "operably connected" should be defined uniformly throughout the patent to mean that one component is connected to another component, either directly or indirectly, so that the components may interact with each other. Defendant, on the other hand, contends that the term "operably connected" is indefinite and not supported by structure and, thus, that the drawing and specification must be used to determine the structure and meaning of the term "operably connected" as to each connected set of components.

The Court agrees with Plaintiff that the common meaning of the term "operably connected" is that one component is connected to another component in such a manner that the components may interact with each other. In construing the term in that manner, the Court notes the principle that claim terms should be construed consistently. See Phonometrics, Inc. v. Northern Telecom, Inc., 133 F.3d 1459, 1465 (Fed. Cir. 1998) ("A word or phrase used consistently throughout a patent claim should be interpreted consistently."). Here, the language is used consistently throughout the patent to generically mean that the specified components interact with each other. Nothing in the language of the claims or specifications, or the prosecution history, urges the Court to reach a different result. Furthermore, Defendant's own witness has testified that this term means "that the interface between two components will serve the function causing one component to interact with respect to one another." See Plaintiff's Claim Construction and Brief Regarding '263 and '662 Patents at 14, citing Deposition Testimony of Paul Cross. The Court finds no reason to further narrow the term as the claims, not the specifications, should limit the scope of the patent.
Thus, the Court construes the language "operably connected" to mean that one component is connected to another component in such a manner that the components may interact with each other.

4. "Operably Connected"

Bradley also argues that the word operably in the phrase operably connected means directly because that is the only connection described in the specification. Defs.' Opp'n to Claim Constr. at 14-18. Bradley relies upon two cases for the proposition that operably in the '960 Patent can only mean directly, Toro Co. v. White Consolidated Indus., Inc., 199 F.3d 1295 (Fed. Cir. 1999) and Gentry Gallery, Inc. v. Berkline Corp., 134 F.3d 1473 (Fed. Cir. 1998). In those cases, the Federal Circuit found that the meaning of the disputed claim terms were limited by the disclosure in the patent specifications at issue. See Toro, 199 F.3d at 1301-02; Gentry Gallery, 134 F.3d at 1480. Bradley argues that the '960 Patent specification only discloses a multiple response thermostat that has a second, faster thermostat portion directly connected to the flow control valve means. Therefore, because no broader disclosure is made in the '960 Patent, operably must mean directly. Bradley specifically points to the following language in the '960 Patent:

2. "Yet another object of the present invention is to provide a thermostatic control valve assembly which quickly responds to changes in fluid temperature at low flow conditions." Id. col. 2, ll. 43-46.

3. "Thermostat portion 143 has a faster response rate but smaller travel than portion 142 to provide immediate, accurate control nearest the discharge of flow control valve 114, where at low flows the hot and cold fluids may not be fully mixed. Conversely, thermostat portion 142 has a slower response but greater travel than portion 143 to provide subsequent control way [sic] from the discharge of flow control valve 114, where the hot and cold fluids are more fully mixed." Id. col. 6, ll. 48-55.

See Defs.' Opp'n to Claim Constr. at 15-16.

However, Lawler argues that there is no means-plus-function language in this part of the claim that would limit the invention described in claim 1 to one with the second thermostat portion directly connected to the flow control valve means. Pl.'s Reply to Claim Constr. at 5-7. Lawler argues that the plain meaning of operably is broader than directly. Id. at 6. Moreover, limiting the definition of operably to directly imports a limitation from the preferred embodiment into the claims, which is improper. See id. (citing Virginia Panel Corp. v. MAC Panel Corp., 133 F.3d 860, 866 (Fed. Cir. 1997); Continental Paper Bag Co. v. Eastern Paper Bag Co., 210 U.S. 405, 418, 52 L. Ed. 1122, 28 S. Ct. 748 (1908)); see also id. at 6-7 (discussing Northern Telecom. Ltd. v. Samsung Elecs. Co., Ltd., 215 F.3d 1281, 1293 (Fed. Cir. 2000)). Furthermore, the '960 Patent specification discloses a multiple response thermostat where the second portion with the faster response rate is connected to the flow control valve means through the first thermostat portion. Id. at 8 (citing '960 Patent, col. 7, ll. 14-29). Thus, Lawler argues that the plain meaning of operably is "either directly or indirectly."

The Court finds that in the context of the '960 Patent, operably connected to means capable of performing work on or capable of effecting the movement of. The '960 Patent describes an assembly that performs a function -- quick regulation of the outlet temperature of water at low to high flow rates. '960 Patent, col. 1, ll. 46-60. The multiple response thermostat portion of the assembly is the key to performing the regulating function. Changes in the thermostat operate or work to move the parts that control the flow of hot and cold fluids through the valve assembly. See id. col. 2, ll. 5-14; id. Abstract (stating that the assembly has "an improved multiple response thermostat having a fast response rate adjacent to the entrance of the mixing dome for responding quickly to the temperature of fluid entering the mixing dome"). This is the basic principle upon which thermostatic mixing valves work and is well known to ones skilled in the art. See id. col. 1, ll. 13-23; id. col. 1, ll. 51-60; id. col.; id. Abstract. In the case of the '960 Patent invention, the specification provides that the thermostat works to move the push rod, which in turn works to make changes in the orientation of the liner and piston, or the flow control valve means, which in turn changes the amount of hot and cold fluid entering the valve assembly. Id. col. 4, ll. 3-24. Correspondingly, the change in the amount of hot and cold fluid flowing into the valve, changes the temperature of the
mixed fluid at the outlet. See id. col. 2, ll. 1-5 ("Flow control valve means is fluidly coupled with the hot and cold inlets and the mixing chamber for controllably mixing hot and cold fluid received through the hot fluid inlet and the cold fluid inlet, respectively, and supplying the mixed fluid to the mixing chamber."); id. col. 4, ll. 11-24. According to the '960 Patent, this chain of events is triggered by the action of the thermostat upon the push rod. See id. col.4, ll. 11-24. Therefore, in the '960 Patent, the term operably in the phrase operably connected cannot be limited to directly because the thermostat is actually directly connected to the push rod, not to the flow control valve means, or the liner and piston. The '960 Patent contemplates that the action of the thermostat on the flow control valve means will be indirect. Specifically, the patent discloses that "adjustment screw 27 acts against spring 23 and thus allows the vertical position of the thermostat 26 and ultimately of the piston 19 to be adjusted, which in turn alters the relative proportions of hot and cold fluid passing through the openings 20." Id. col. 4, ll. 20-24 (emphasis added). Clearly, the word ultimately implies something other than directly.

The language that Bradley pointed out does not alter this analysis. First, the object of the invention "to provide a thermostatic control valve assembly which quickly responds to changes in fluid temperature at low flow conditions" provides no limitation on the means for accomplishing that task. Id. col. 2, ll. 43-46. As described in the discussion above, the multiple response thermostat as a whole is one of the features intended to fulfill that objective. See id. col. 1, ll. 51-60; id. col. 7, ll. 1-13.

Second, the '960 Patent Abstract states that the thermostatic mixing valve assembly of the invention "also include[s] . . . an improved multiple response thermostat having a fast response rate adjacent to the entrance of the mixing dome for responding quickly to the temperature of fluid entering the mixing dome." Id. Abstract. Again, this language does not limit the invention to multiple response thermostats that have a second, faster portion directly connected to the flow control valve means. It does imply that the multiple response thermostat have a portion that has a fast response rate close to the entrance to the mixing dome. However, the remainder of the patent teaches that the entire thermostat assembly is attached to the piston by the push rod. In fact, as Lawler points out, the patent teaches that in an alternative embodiment

coiled tubing 144 is filled with a temperature sensitive fluid and is sealed at one end 151 and is fluidly coupled at its other end 153 with an internal control piston . . . contained within the hollow bore of cylindrical portion 145 of first thermostat portion 148. The temperature sensitive fluid expands with heat addition to advance the internal control piston which in turn acts on connecting rod 156 to advance piston 158.

Id. at col. 7, ll. 21-29. Clearly, this embodiment teaches that the second thermostat portion need not be directly connected to the flow control valve means; but, indeed, it need only be able to effect the movement of the flow control valve means.

For the same reason, Bradley's third argument fails. Bradley argues that the only arrangement of thermostat portions disclosed by the patent is one where the portion with the faster response rate is closest to or adjacent to the discharge of the flow control valve, therefore, the second thermostat portion must be directly connected to the flow control valve means. 2 As just discussed, the patent discloses an arrangement of thermostat portions where the second thermostat portion with the faster response rate is not directly connected to the flow control valve means, but must cause a change that effects the first thermostat portion that in turn effects the flow control valve means through movement of the push rod. Id. at col. 7, ll. 21-29.

--- Footnotes ---

2 At the Markman hearing Dr. Ovens testified that according to his experience and tests the arrangement of thermostat portions in the preferred embodiment pictured at figure 6 and described in the '960 Patent at column 6, lines 48-55 is backward. Thermostat response rate, as both experts testified at the preliminary injunction hearing, seems to be related to surface area exposed to the fluid. See Prelim. Inj. Hr'g Tr. at 164-65, 182, Ovens-Direct; id. at 219-20, Ovens-Cross; id. 547-48, 549-51, 553-54, Ballanco-Direct. The thermostat portions pictured in figure 6 indicate that the thermostat with the larger surface area is further away from the discharge of the flow control valve. See '960 Patent, Fig. 6; id. col. 6, ll. 48-55. Thus, Dr. Ovens testified that the faster thermostat portion is in fact further away from the discharge of the flow control valve. However, this revelation has no bearing on whether the second thermostat portion must be directly rather than operably connected to the flow control valve means. Claim 1, as interpreted by the Court in this order, supports either configuration.

--- End Footnotes ---
In accordance with the analysis above, Lawler's proffered definition for the phrase operably connected, "directly or indirectly connected," does not adequately define the term either. The '960 Patent makes clear that the thermostat of the valve assembly described must act or work upon the flow control valve means for the assembly to perform as desired. Id. col. 2, ll. 1-14. This fact is not changed by the requirement in claim 1 that the second thermostat portion of the multiple response thermostat be operably connected to the flow control valve means. The second thermostat portion is part of the whole thermostat that acts to control the flow of hot and cold fluids through the assembly. So long as the second thermostat portion is connected such that it can effect the movement of the flow control valve means, this element of claim 1 is met.

Reading the plain meaning of claim 1 in light of the specification, the Court finds that operably connected to means capable of performing work on or capable of effecting the movement of.

C. Construction of Clause (c): "air-permeable secondary wall means above said chamber upper wall portion and operably coupled with said chamber-defining means."

The '767 patent claims an air flotation, ventilated mattress apparatus comprising, among other things, "air-permeable secondary wall means above said chamber upper wall portion and operably coupled with said chamber-defining means." The parties disagree about the meaning of "operably coupled." According to plaintiff, the term means that "the two elements are in mutual relation so that the operation of one works with the other to achieve a common result." Plaintiff's Ex. 401. More specifically, plaintiff argues,

this limitation means that there is at least one air-permeable cover sheet (or secondary wall) that overlies the upper wall of the chamber. This secondary wall is connected, linked, or attached in some way to the chamber described in clause (a). This would include any operable method of coupling a cover sheet with a mattress, and specifically includes attaching a cover sheet to a mattress with straps or elastic bands.

Defendants disagree, arguing that under the patent language the secondary wall means and the upper wall portion must be "chamber-defining" in order to be "operably coupled." Defendants' Ex. 414. More specifically, according to defendants,

this limitation speaks of a "secondary wall means" that is "operably coupled" with the lower chamber. Defendants move this Court to interpret "operably coupled" so that it requires a device which (1) possesses a compartment "defined between" the upper wall and secondary wall, and (2) is assembled so as to allow the inflation of that compartment and the flow of air through "substantially the entire plan surface area" of the secondary wall.

Plaintiff contends that "operably coupled" means simply that those elements "be in such a mutual relation that the operation of one interacts with the operation of the other to achieve a common result -- not that they are mechanically joined to provide a particular function described elsewhere in the claim." 8 Plaintiff's Claim Construction Brief at 14. Plaintiff asserts that defendants' interpretation seeks to limit the claims to the preferred embodiment described in the specification or to the features of prototypes of the invention. Plaintiff asserts that it is improper to read into the claim limitations from the specification. Electro Medical Sys., S.A. v. Cooper Life Sciences, Inc, 34 F.3d 1048, 1054 (Fed. Cir. 1994).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

8 According to plaintiff, the coupling could be accomplished by snaps, zippers, buttons, velcro straps, elastic bands or other means.

At the Markman hearing plaintiff's expert testified that the term "operably coupled" should be read to mean two things that are mutually related so that the work of one thing is coupled with the work of the other. Plaintiff's expert testified that the term did not require that the items be physically attached. This opinion is not consistent with the meaning proffered in plaintiff's briefs.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
Defendants first rely upon the claim language that the upper wall of the lower chamber should combine with the secondary wall to "cooperatively define[] therebetween an inflatable compartment above said chamber." '767 patent, col. 6, 1.23-25. The secondary wall must allow "substantially uniform passage of air therethrough over substantially the entire plan surface area of the secondary wall means." Id., 1.20-22. Defendants argue that to serve the goals of the operable coupling the device must have a compartment "defined [] between" the upper wall and secondary wall and must be assembled to allow inflation of that compartment and the flow of air through "substantially the entire plan surface area" of the secondary wall.

Defendants also rely upon the specification that the upper compartment "inflate" and that the operable coupling should "define" the compartment "[]between" the upper wall of the lower chamber and the secondary wall. Defendants then point to the description of drawings that "the secondary wall 36 is detachably secured by means of a conventional zipper 38 at a point proximal to the joinder between the sidewall 24 and top wall 26. As seen in Fig. 3, an inflatable compartment 40 is defined between the top wall 26 and the secondary wall 36."

In the '767 patent, the function of the secondary wall means is to define, in cooperation with the upper wall portion, an inflatable compartment above the lower chamber. '767 Patent, Col. 6, 1.21-23. The Court believes that the phrase "operably coupled with said chamber defining means" has a plain meaning in light of the '767 claims, the '767 specification, and the '767 prosecution history. A person of ordinary skill in the art of air bed engineering would read "operably coupled" to mean that two elements work in concert to create an inflatable chamber, e.g. one which is not air tight but can receive and hold air. Thus, whatever means is used to operably couple must create an inflatable chamber between the top wall and the secondary wall.

Claim 3

Claim 3 provides as follows: "The system of Claim 1 in which the actuating mechanism is operated remotely by sending signals from a communication device." Graham-White contends that the italicized phrase should be construed as "the actuating mechanism receives signals from a communication device that is not in contact with the actuating mechanism." Ellcon argues that Claim 3 is limited to wireless remote control. This court agrees with Graham-White's construction and therefore construes the phrase as follows: the actuating mechanism receives signals from a communication device that is not in contact with the actuating mechanism.

C. Claim Construction

Medtronic asserts that the district court erred in construing the claim term "operative engagement." Claim construction is a matter of law, and we review the court's claim construction without deference. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1451 (Fed. Cir. 1998) (en banc). In doing so, we are mindful of the principle that "the claims of a patent define the invention to which the patentee is entitled the right to exclude." Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). We read the claims "in view of the specification," which is "the single best guide to the meaning of a
disputed term." Id. at 1315.

Claim 1 recites the limitation of "a lower part having a lower surface for engaging a vertebrae and an upper surface portion in operative engagement with the rounded portion of the upper part." '071 patent col.6 ll.60-62 (emphasis added). At claim construction, Medtronic proposed construing "operative engagement" to mean "the interaction between the pivot insert and the rounded portion of the upper part." Claim Construction Order, 2008 U.S. Dist. LEXIS 116648, at *18. The court observed that although the preferred embodiment of the '071 patent has a pivot, claim 1 does not recite such a limitation: rather, claim 1 recites only an upper and a lower part that are "in operative engagement" with each other. The court also found that claim differentiation weighed against reading a pivot limitation into claim 1, because various dependent claims add limitations relating to a two-piece lower part with a pivot insert. Therefore, the court adopted SSI's proposed construction, construing "operative engagement" as "permitting movement (for example pivotability)." Id. at *23.

Medtronic asserts that the court erred in construing "operative engagement" as not incorporating a pivot insert. According to Medtronic, the only "engagement" disclosed by the specification occurs between the upper part and the pivot insert, not between the upper and lower parts. SSI asserts that the court's construction is correct because the plain language of the claim does not limit the invention to the preferred three-piece embodiment.

We agree with SSI that the court correctly construed "operative engagement." The language of the limitation is straightforward: the lower part of the implant engages "operatively" with the rounded portion of the upper part. Given that the claimed invention is an intervertebral implant designed to replace a disc in a spinal column, "operative engagement" must be engagement such that the upper and lower parts of the implant can move relative to each other; otherwise, the implant would be rigid and would inhibit movement of the adjacent vertebrae. Thus, the court correctly determined that "operative engagement" relates to permitting movement. The court also did not err in identifying pivotability as an example type of movement; the '071 patent specifically discloses pivotability in association with the preferred embodiment. However, nothing in the claim suggests that the upper part of the implant must be specifically engaged with a pivot insert, as opposed to the lower part of the implant. To the contrary, the claim indicates that the upper and lower parts are engaged with each other directly. '071 patent col.6 ll.60-62 ("a lower part having . . . an upper surface portion in operative engagement with the rounded portion of the upper part"). Therefore, the court did not err in construing "operative engagement" as "permitting movement (for example pivotability)."

Medtronic asserts, in the alternative, that under the court's construction claim 1 is invalid for failure to comply with the written description requirement. Therefore, Medtronic argues, the court erred in granting summary judgment that the '071 patent contains adequate written description to support the limitation "lower part having . . . an upper surface portion in operative engagement with the rounded portion of the upper part." Medtronic argues that the '071 patent only describes a three-piece device with a separate pivot insert, not a two-piece device that permits movement between the top and bottom parts. However, Figures 3 and 6 of the '071 patent illustrate the implant outside the intervertebral space (i.e., prior to insertion) and show the pivot insert as embedded in the lower part. Additionally, the evidence at summary judgment included deposition testimony from Medtronic's expert that a person of skill in the art would have known that an implant having a lower plate with an embeddable pivot insert--such as that disclosed by the '071 patent--could have been assembled prior to insertion and inserted into the patient as a two-piece device. Medtronic does not point to any evidence rebutting this testimony. Therefore, we agree with the district court that a person of skill in the art would have understood the '071 patent to describe an implant that could be pre-assembled prior to insertion, such that the upper surface of the lower part is "operatively engaged" with the lower surface of the upper part.

Medtronic contends that the '071 patent does not describe a two-piece implant because the '071 patent actively disparages the two-piece design of the '477 patent. In discussing the two-piece design of the '477 patent, the '071 patent notes that it is "particularly difficult" to achieve a minimum structural height for an implant if the pivot is embedded prior to insertion. Id. col.1 ll.11-19. However, this does not rise to the level of an express disclaimer sufficient to limit the scope of the claims; ". . . disavowal requires expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Epistar Corp. v. ITC, 566 F.3d 1321, 1335 (Fed. Cir. 2009). Further, claim 1 is not directed to the height-minimizing embodiment. The originally-filed claims recited limitations directed to "protrusions and recesses . . . which are offset laterally from one another in such a way that . . . [the upper and lower parts] mesh with one another," see J.A. 17167; claim 1 as issued recites no such limitation.
4. "inoperative and operative positions"

This portion of claim 54 deals with the manner in which the hospital bed guard rails must be mounted to the sides of the bed frame. The guard rails must be moveable from one position that would allow access to the patient or bedding, to another position that would prevent the patient from falling off the patient support assembly. The patent describes the possible positions of the guard rails as "inoperative" and "operative," and the parties disagree as to the meaning of those terms.

**Safe Bed:**
"Inoperative position" means any position of the guard rail at which the guard rail adjustment prevention means is activated to stop movement of the patient support assembly relative to the bed frame. (Safe Bed's Mem., at 9; Safe Bed's Reply, at 9).

"Operative position" means any position of the guard rail at which the guard rail adjustment prevention means is not activated and the patient support assembly is allowed to continue movement relative to the bed frame relative to the bed frame. (Id.).

The parties essentially agree that the ordinary and customary meaning of "operative" is "producing an appropriate or designed effect," whereas "inoperative" means not producing such an effect. WEBSTER'S, at 1166, 1581. (Safe Bed's Mem., at 9; KCI Mem., at 12, 17). As such, it would seem clear enough that a guard rail is an "operative" position when it is producing its designed effect of preventing the patient from rolling off the bed. Conversely, a guard rail would be in an "inoperative" position when it would be ineffective at preventing a patient from rolling off the bed. According to Safe Bed, however, this is an instance where the ordinary and customary meaning is inapplicable. (Safe Bed's Mem., at 9). As noted earlier, a patent applicant may overcome the "heavy presumption" that a claim term carries its ordinary and customary meaning by clearly using the words in the specification, prosecution history, or both "in a manner inconsistent with its ordinary meaning." Schering-Plough Corp., 320 F.3d at 1347 (citing Teleflex, 299 F.3d at 1325-26). Here, however, there is nothing that evinces an intention to depart from the ordinary and customary meaning.

Rather than define "operative" and "inoperative" positions for guard rails in terms of the guard rails' effect on patient restraint, Safe Bed defines them in terms of the guard rails' effect on the mobility of the patient support assembly. Thus, as Safe Bed would have it:

In the context of the '939 patent, an operative guard rail position is defined as one which allows adjustable movement of the patient support assembly relative to the frame, while an inoperative position of one or both guard rails is defined as a position of the guard rail that initiates a guard rail activated safety apparatus to prevent translational movement of the bed. [939 patent], 3:18-21.

* * *

The '939 specification teaches that the guard rail position at which the patient support assembly adjustment prevention means are initiated is adjustable. [939 patent], 5:60-63; 12:12-13. Accordingly, an "inoperative guard rail position" is any position at which the patient support assembly adjustment prevention means is activated. Conversely, an "operative guard rail position" is any guard rail position at which the patient support assembly adjustment prevention means are not actuated and the patient support assembly is allowed to continue movement relative to the frame.
According to Safe Bed, then, an "operative" position for the guard rail does not refer to the guard rail being operative, or even the "guard rail safety apparatus" or "patient support assembly adjustment prevention means" being operative or activated. It is Safe Bed's position that the guard rail is in an "operative" position when the patient support assembly is in motion. This seems a somewhat tortured interpretation of the claim language, as well as an unnecessary abandonment of the ordinary and customary meaning of the words.

5 The Court is not unmindful of Safe Bed's inspiration for its unconvincing interpretation. The '939 patent specification teaches that the guard rail position at which the "guard rail safety apparatus" or "patient support assembly adjustment prevention means" is activated is adjustable. ("939 patent, 5:60-63; 12:12-13). That means the "designer, manufacturer, or user" determines the operative position of the guard rail by adjusting the trigger or activation point. (Safe Bed Mem., at 9). The "designer, manufacturer, or user" might, perhaps through poor judgment, establish a trigger point below the level where the guard rail is still effective in restraining the patient. While judgment might vary, the effectiveness of the guard rail at restraining the patient is absolute: either it will restrain the patient or it will not.

That being said, the Court is not convinced of KCI's construction either, because it, too, departs from the ordinary and customary meaning of "operative" and "inoperative." According to KCI, the guard rails are in their "operative position" when they are at their highest elevation, and in their "inoperative position" when they are at their lowest elevation, below the top edge of the patient support assembly. (KCI's Mem., at 12-13; 17-18). While there is little doubt that these positions would meet the respective requirements of being "operative" or "inoperative" in terms of restraining the patient, there is also little doubt that there are intermediate positions in which the guard rails would still have, or not have, their designed effect. In this instance, the Court rejects both parties' constructions and adheres to the ordinary and customary meaning of the terms: a guard rail is an "operative" position when it is producing its designed effect of preventing the patient from rolling off the bed; and a guard rail is in an "inoperative" position when it would be ineffective at preventing a patient from rolling off the bed.

The claim term "operatively connected" appears in both the '946 and '685 patents. Before discussing the parties' proposed construction of the term, the Court will address defendant's contention that the term is a means-plus-function limitation under 35 U.S.C. § 112, ¶ 6. As discussed above, a presumption arises that § 112, ¶ 6 does not apply when the disputed claim language omits the word "means." See Lighting World, 382 F.3d at 1358. However, "[t]he presumption . . . can be overcome if it is demonstrated that 'the claim term fails to 'recite sufficiently definite structure' or else recites 'function without reciting sufficient structure for performing that function.'" Id.

The claim term "operatively connected" standing alone does not invoke the application of § 112, ¶ 6. In Mas-Hamilton Group v. LaGard, Inc., the parties disagreed as to whether the claim term "movable" was a means-plus-function limitation under 35 U.S.C. § 112, ¶ 6. As discussed above, a presumption arises that § 112, ¶ 6 does not apply when the disputed claim language omits the word "means." See Lighting World, 382 F.3d at 1358. However, "[t]he presumption . . . can be overcome if it is demonstrated that 'the claim term fails to 'recite sufficiently definite structure' or else recites 'function without reciting sufficient structure for performing that function.'" Id.

In the instant case, the parties differ as to whether the claim term "operatively connected" is a means-plus-function limitation. 4 Similar to subsequent, functional language to the claim term "movable" in Mas-Hamilton, here the subsequent functional language to the term "operatively connected" recites: (1) "for moving the hinge plates between the closed and open positions;" (Doc. # 1-2, '946 patent, col. 9, lines 64-65); (2) "such that pivoting motion of the lever produces movement of the travel bar generally lengthwise of the elongate plate;" (Doc. # 1-2, '946 patent, col. 12, lines 25-27); and
"such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the first position in which the control structure locks the hinge plates . . . ." (Doc. # 51-2, '685 patent, col. 16, lines 45-51). However, like the term "movable" in Mas-Hamilton Group, the term "operatively connected" standing alone does not invoke § 112, P 6. Therefore, the Court does not construe the term "operatively connected" as a means-plus-function limitation.

4 Defendant repeatedly identifies the entire, three phrases that contain the term "operatively connected" as the disputed claim language that requires construction by the Court. See (Doc. # 26-2, at 12-16; # 29, at 24 n.6; # 51, at 28; # 79, at 16-18). However, in the "List of Disputed and Non-disputed Claim Terms (the List)," the parties inform the Court that "operatively connected" is one of the disputed terms that requires construction, not the phrases that contain the term. (Doc. # 78). Therefore, the Court will only construe the term "operatively connected" as noted in the List within the context of the phrases.

The claim term "operatively connected" appears in both the '946 and '685 patents. Before discussing the parties' proposed construction of the term, the Court will address defendant's contention that the term is a means-plus-function limitation under 35 U.S.C. § 112, P 6. As discussed above, a presumption arises that § 112, P 6 does not apply when the disputed claim language omits the word "means." See Lighting World, 382 F.3d at 1358. However, "[t]he presumption . . . can be overcome if it is demonstrated that 'the claim term fails to recite sufficiently definite structure' or else recites 'function without reciting sufficient structure for performing that function.'" Id.

In the instant case, the parties differ as to whether the claim term "operatively connected" is a means-plus-function limitation. 3 Similar to subsequent, functional language to the claim term "movable" in Mas-Hamilton, here the subsequent functional language to the term "operatively connected" recites: (1) "for moving the hinge plates between the closed and open positions," (Doc. # 1-2, '946 patent, col. 9, lines 64-65); (2) "such that pivoting motion of the lever produces movement of the travel bar generally lengthwise of the elongate plate," (Doc. # 1-2, '946 patent, col. 12, lines 25-27); and (3) "such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the first position in which the control structure locks the hinge plates . . . ." (Doc. # 51-2, '685 patent, col. 16, lines 45-51). However, like the term "movable" in Mas-Hamilton Group, the term "operatively connected" standing alone does not invoke § 112, P 6. Therefore, the Court does not construe the term "operatively connected" as a means-plus-function limitation.

3 Defendant repeatedly identifies the entire, three phrases that contain the term "operatively connected" as the disputed claim language that requires construction by the Court. See (Doc. # 26-2, at 12-16; # 29, at 24 n.6; # 51, at 28; # 79, at 16-18). However, in the "List of Disputed and Non-disputed Claim Terms (the List)," the parties inform the Court that "operatively connected" is one of the disputed terms that requires construction, not the phrases that contain the term. (Doc. #
Therefore, the Court will only construe the term "operatively connected" as noted in the List within the context of the phrases.

The parties agree that the claim language "operatively connected" requires construction within the context of the three phrases: (1) "a travel bar operatively connected to the hinge plates" in claim 1 of the '946 patent; (2) "the lever being operatively connected to the travel bar" in claim 26 of the '946 patent; and (3) "a travel bar operatively connected to the lever" in claim 1 of the '685 patent. (Doc. # 78). The Court will discuss each in turn.

1. "a travel bar operatively connected to the hinge plates" in claim 1 of the '946 patent

Plaintiff proposes that, in the context of the phrase "a travel bar operatively connected to the hinge plates," the term "operatively connected" means "mechanically associated so as to be capable of applying mechanical force to." (Doc. # 26-2, at 11). Plaintiff argues that the term should be given its common and ordinary meaning and relies on dictionary definitions to support its proposed construction. (Doc. # 26-2, at 12).

Plaintiff refers the Court to Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1117 (Fed. Cir. 2004), whereby the Federal Circuit analyzed the construction of the term "operatively connected" in the context of a water bottle filter assembly patent. After noting that "[n]either party assert[ed] that the term 'operatively connected' [was] a technical term having a special meaning in the art of water filtration," the Federal Circuit stated that the term was "a general descriptive term frequently used in patent drafting to reflect a functional relationship between claimed components." Id. at 1118. The Federal Circuit held that, "[g]enerally speaking, . . . [operatively connected] means the claimed components must be connected in a way to perform a designated function." Innova/Pure Water, 381 F.3d at 1118. The Federal Circuit then stated that "operatively connected' takes full breadth of its ordinary meaning, i.e., 'said tube [is] operatively connected to said cap' when the tube and cap are arranged in a manner capable of performing the function of filtering." Id. Plaintiff also notes that the District of Oregon construed the term "operatively connected" in the phrase "a spring operatively connected between the handle and the blade to assist in the opening of the blade" to mean "the spring, handle, and blade are arranged such that the spring operates to assist in opening the blade." (Doc. # 31, at 28) (citing Kai U.S.A., Ltd. v. Buck Knives, Inc., No. CV 05-446-HA, 2006 U.S. Dist. LEXIS 24924, 2006 WL 314456, at *4 (D. Ore. Feb. 9, 2006)).

Defendant requests that, if the Court does not construe the term as a means-plus-function limitation, the Court adopt its alternative, proposed construction:

"A travel bar operatively connected to the hinge plates . . . . A travel bar operatively connected to the hinge plates means the hinge plates are connected to the travel bar by placing at least one pivotally movable connecting link between the hinge plates and the travel bar such that the motion of the bar produces pivotal motion of the hinge plates.

(Doc. # 26-2, at 11-12, 14-15). Defendant refers the Court to a description of a preferred embodiment in the '946 patent specification, which recites: (1) "[a]n intermediate connector 76 is pivotally connected to the lever 68 and to the travel bar 70 for pivoting motion relative to both the lever and the travel bar," and (2) "[t]he hinge plates 56 are operatively connected with the travel bar 70 by placing at least one pivotally movable connecting link 72 between the hinge plates and the bar such that motion of the bar produces pivotal motion of the hinge plates." (Doc. # 1-2, '946 patent, col. 4, lines 30-32, col. 7, lines 23-27). Defendant maintains that the Court should adopt its proposed construction, which incorporates the description of the preferred embodiment of the phrase "a travel bar operatively connected to the hinge plates." (Doc. # 26-2, at 15). Based on the description of the preferred embodiment, defendant contends that "connecting links" are necessary structures. (Doc. # 79, at 17). Defendant asserts that its proposed construction is "consistent with the maxim that claims should be construed to maintain their validity and the Federal Circuit's interpretation of the written description and enablement requirements of 35 U.S.C. § 112, P 1." (Doc. # 26-2, at 15). Finally, defendant argues that "[p]laintiff's reliance on Innova is misplaced." (Doc. # 79, at 15).

The Federal Circuit, in Abbott Laboratories v. Sandoz, Inc., holds that:

When the specification describes a single embodiment to enable the invention, this court will not limit broader claim language to that single application "unless the patentee has demonstrated a clear intention to limit the claim scope using
words or expressions of manifest exclusion or restriction."

566 F.3d 1282, 1288 (Fed. Cir. 2009) (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002))). The Court, therefore, will not import the description of the preferred embodiment into the '946 patent claim language. The claim language, specification, and prosecution history also do not make clear the definition of the term "operatively connected." Therefore, the Court adopts the Federal Circuit's ordinary and customary meaning of the disputed term, and concludes that "operatively connected" in the context of the phrase "a travel bar operatively connected to the hinge plates" in the '946 patent means "arranged in a manner capable of performing a designated function."

2. "the lever operatively connected to the travel bar" in claim 26 of the '946 patent

Federal Circuit law holds that, "[u]nless otherwise compelled, when different claims of a patent use the same language, we give that language the same effect in each claim." Innova/Pure Water, 381 F.3d at 1119. In the instant case, the term "operatively connected" appears in both claims 1 and 26 of the '946 patent, and the Court finds that "[o]peratively connected' carries the same meaning in both claims." Innova/Pure Water, 381 F.3d at 1119. Thus, the Court finds that "operatively connected" in the context of the phrase "the lever operatively connected to the travel bar" in claim 26 of the '946 patent also means "arranged in a manner capable of performing a designated function."

3. "a travel bar operatively connected to the lever" in the '685 patent

Defendant contends that the term "operatively connected" in the '685 patent is a means-plus-function limitation. However, as discussed above, the Court does not construe the term "operatively connected" as a means-plus-function limitation, and will only consider defendant's alternative, proposed construction.

Plaintiff argues that the term "operatively connected" in the '685 patent means "mechanically associated so as to be capable of applying mechanical force to." (Doc. # 51, at 27). Plaintiff relies on dictionary definitions and Innova/Pure Water and Kai to support its proposed construction. Defendant urges the Court to adopt its alternative, proposed construction:

[A] travel bar operatively connected to the lever such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the first position in which the control structure locks the hinge plates in the closed position to the second position in which the hinge plates are free to pivot to the open position. A travel bar operatively connected to the lever means the travel bar is connected to the lever by an intermediate connector.

(Doc. # 51, at 28). Defendant also provides the same arguments that it asserted with respect to the construction of the term in the '946 patent claims. Additionally, defendant contends that the construction of the term within the context of claim 1 of the '685 patent requires the inclusion of "an intermediate connector" because the structure "is the only enabling disclosure in the '685 patent specification." (Doc. # 51, at 31).

The description of the preferred embodiments in the '685 patent specification state that:

The intermediate connector 39 is located between the lever 15 and travel bar 41 and is elongate and beam shaped. . . .

As also seen, the travel bar 41 is disposed behind the plateau 17 of the housing 11 and is connected to the lever 15 by the intermediate connector 39. . . .

Pivoting the lever 15 pulls the intermediate connector 39 and travel bar 41 toward the lever. . . .

As also seen in FIG. 14, the intermediate connector 339 is located between the lever 315 and travel bar 341 and is illustrated as a wire bent into an elongate, rectangular form.

(Doc. # 51-2, '685 patent, col. 5, lines 33-35, col. 6, lines 36-39, col. 8, lines 54-55, col. 10, lines 61-63). As stated above, the Federal Circuit holds that:

When the specification describes a single embodiment to enable the invention, this court will not limit broader claim
language to that single application "unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'"

Abbott Laboratories, 566 F.3d at 1288. Upon review of the '685 patent specification, there is no clear indication that the patentee intended for the connection between the travel bar and the lever to include an intermediate connector. In fact, the patentee states that "[a] mechanism in which a pivoting lever is directly connected to a travel bar does not depart from the scope of the invention." (Doc. # 51-2, '685 patent, col. 6, lines 65-67). Additionally, the patentee states that, "[a]s various changes could be made in the above [preferred embodiments] without departing from the scope of the invention, it is intended that all matter combined in the . . . description and shown in the accompanying drawings shall be interpreted as illustrative and not in a limiting sense." (Doc. # 51-2, '685 patent, col. 16, lines 8-12). The Court, therefore, believes that the connection between the travel bar and lever in the '685 patent does not require an intermediate connector.

Furthermore, the claim language, specification, and prosecution history do not make clear the meaning of "operatively connected" in the '685 patent, and the Court adopts the Federal Circuit's ordinary and customary meaning of the disputed term. As such, the Court finds that "operatively connected" in the '685 patent means "arranged in a manner capable of performing a designated function." See Innova/Pure Water, 381 F.3d at 1118, 1120.

I. Plaintiff's Eighth Motion In Limine

In its eighth motion in limine, plaintiff requests an order barring defendant "from arguing that the Insta-Clik does not infringe Claims 1, 2, 3, 5, 9, 10, or 11 of U.S. Patent No. 7,404, 685." (Doc. # 224). In a Memorandum and Order dated July 21, 2009, the Court denied defendant's motion for summary judgment of non-infringement of the '946 patent, and granted plaintiff's motion for partial summary judgment of infringement of the '685 patent. (Doc. # 162). In response to defendant's emergency motion for reconsideration, the Court issued an Amended Memorandum and Order dated August 5, 2009, wherein the Court denied both parties' motions for summary judgment. (Doc. # 173). With respect to plaintiff's motion for partial summary judgment, the Court "conclude[d] that defendant . . . failed to provide sufficient evidence to create a genuine issue of material fact as to whether the Insta-Clik literally infringes dependent claims 2, 3, 5, 9, 10, and 10 of the '685 patent, whose meaning depends on independent claim 1." (Doc. # 173, at 5). Section B.1. of the Court's Amended Memorandum and Order only addressed the claim language "housing, hinge plates, and rings" and "control structure" as used in claim 1 of the '685 patent. Then, on September 14, 2009, the Court issued an amended claims construction order and reconstrued the term "operatively connected" in the '685 and '946 patents to mean "arranged in a manner capable of performing a designated function." (Doc. # 187, at 21-23, 32).

"A determination of infringement requires a two-step analysis. First, the court construes the asserted claims in order to determine their proper meaning and scope." Union Carbide Chemicals & Plastics Tech. Corp. v. Shell Oil Co., 308 F.3d 1167, 1176-77 (Fed. Cir. 2002), citing Markman v. Westview Instruments, Inc., 517 U.S. 370, 391, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). "After the court construes the claims, these claims are compared to the accused device." Union Carbide, 308 F.3d at 1177 (citing Bell Atl. Network Services v. Covad Communications Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001); Biovail Corp. Int'l v. Andrx Pharmas., Inc., 239 F.3d 1297, 1301 (Fed. Cir. 2001)). In light of the Court's new construction of the term "operatively connected," which appears in claim 1 of the '685 patent, (Doc. # 51-2, '685 patent, col. 16, line 45), the Court will permit defendant to compare such construction to the Insta-Clik, and to argue that the Insta-Clik does not infringe claims 1, 2, 3, 5, 9, 10, or 11 of the '685 patent.

Plaintiff proposes the construction of

the spring, handle, and blade are arranged such that the spring operates to assist in opening the blade. An outside motive force, such as from a user's hand, must manually move the blade some initial distance toward the open position, after which
the spring assists to complete the movement of the blade to the open position.

Defendant proposes the construction of "a spring connected between the handle and the blade which, in operation, imparts a rotational force onto the blade as it moves from a closed position to an open position." The court finds this phrase is clear on its face, except for the term "operatively connected." This term is addressed below.

A. "operatively connected"

The term "operatively connected" has a meaning that is broader than the term "connected." Innova/Pure Water, Inc. v. Safari Water Filtration Systems, 381 F.3d 1111, 1118 (2004). To be "operatively connected" requires "some tenacious means of physical engagement that results in a unitary structure." Id. It is a general descriptive term used in patents, and means the claimed components must be connected in a way to perform a designated function." Id. Items are operatively connected when they are. "arranged in a manner capable of performing the function." Id: at 1120.

Defendant argues that for the spring and blade to be "operatively connected" the spring must be physically connected to the blade. Defendant relies on Cross Medical Products, Inc. v. Medtronic Sofamor Danek, Inc., 424 F.3d 1293 (Fed. Cir. 2005). Cross Medical construed the term "operatively joined" and held that it meant "connected and in contact such that the device is effective to perform [its function]." Id. at 1306. Defendant asserts this construction requires the items be "in contact" to be operatively connected.

The Cross Medical court construed "joined" as requiring contact, and distinguished "joined" from the term "connected," reasoning that it "would be improper to construe joined' more broadly to mean connected' without requiring contact." Id. The phrase at issue here, however, is "operatively connected," not "operatively joined." As noted by the Cross Medical court, the term "connected" is broader than "joined." Id. As used in the 476 patent, the term "operatively connected" does not require the spring and the blade be in contact. The spring and blade need only be arranged so that they perform the designated function of assisting in opening the blade.

Defendant also argues that the term "rotational force" must be included in the construction. The prosecution history includes a statement by the patentee, in differentiating a prior art, that the spring of the prior art did not "impart any rotational force onto the blade of the knife as the knife moves from a closed position to an open position, and therefore, cannot assist in the opening of the blade' as required by [this patent]." See Def's Ex. E at 6. However, the term "rotational force" never appears in the 476 patent itself. The context in which the phrase appears in the prosecution history fails to establish that "rotational force" must be construed as part of this patent.

Defendant seeks to insert the limitation of "rotational force" into a broader claim. To disavow claim scope, the prosecution history must show a "clear and unambiguous disclaimer." Middleton, Inc. v. Minn. Min'g & Mfg. Co., 311 F.3d 1384, 1389 (Fed. Cir. 2002). The written description of the patent does not limit the force to "rotational force." The single statement made in the prosecution history in reference to a prior art does not clearly and unambiguously surrender the subject matter. The court concludes that there are insufficient grounds presented for rendering "rotational force" into the 476 patent. Accordingly, the court accepts the first sentence of plaintiff's proposed construction of this term; "the spring, handle, and blade are arranged such that the spring operates to assist in opening the blade."

2773

A. "Said Tube Operatively Connected to Said Cap"

Safari contends that "operatively connected" requires a welded, adhesive, or similar connection for creating a "unitary device" and for enabling removal of the tube and the cap from the bottle simultaneously (Doc. 45). Based on the "common broad terminology," the dictionary, and the specification of an irrelevant patent for a faucet mounted water filter, Innova urges a broader construction of "operatively connected" to include "any type of joining or linking of [the tube and the cap] so that they operate to perform a designed function." However, Innova attempts to limit the broader construction to require the "joining or linking" of the tube and the cap only during operation of the filter assembly (Doc. 44). In other words, according to Innova, "operatively connected" "generically describes some sort of joining or linking between components when they are functioning together" (emphasis added). 7
7 Innova adds that "it is clear that the term 'operatively connected' simply means that during operation the cap and the tube of filtering material are functionally joined or linked" and that "when the components of the Safari product are assembled for operation (so that they are operatively connected, i.e. so that they function together) the cap and tube are connected to each other" (Doc. 49) (emphasis added).

Claims 1 and 15 (and claim 22) describe the tube as "operatively connected" to the cap. Because no special definition inconsistent with the ordinary and customary meaning of "operatively connected" appears in the intrinsic evidence, the ordinary and customary meaning of the terms controls. See Wolverine World Wide, 38 F.3d at 1197. Here, consultation with a dictionary is proper because the dictionary definition contradicts no "definition found in or ascertained by a reading of the patent documents." Vitronics, 90 F.3d at 1584 n.6. The Oxford English Dictionary defines (1) "operative" as "productive of the intended or proper effect" and "operatively" as "in an operative manner," VII The Oxford English Dictionary 145 (1970), and (2) "connected" as "conjoined; fastened or linked together." II The Oxford English Dictionary 837 (1970). In other words, the ordinary and customary meaning of "operatively connected" requires the conjoining or the fastening or linking together of the tube and the cap to produce the intended or proper effect.

In the context of the '759 patent, "operatively connected" requires conjoining, fastening, or linking the tube to the cap, by welding, adhesive, or other means, to create a filter assembly that seals the bottle and filters the contents as the contents are poured. 8 In other words, "operatively connected" requires not merely adjoining or abutting, but affixing the tube to the cap by some tenacious means of physical engagement that results in a unitary structure. Affixing the tube to the cap fixes the tube in position for its intended purpose (i.e., in a position that, upon inversion of the bottle, enables the contents of the bottle to flow through the tube). Affixing the tube to the cap also enables removal of the tube and the cap from the bottle simultaneously. Despite Innova's contention, no intrinsic (or other) evidence limits the conjoining or fastening or linking together of the tube and the cap to "when [the tube and the cap] are functioning together." Innova's construction ignores the limits of "operatively connected" and seeks impermissibly to inject an unsupported temporal limitation into the claims. 9

8 Examples of means for connecting the tube to the cap disclosed in the '759 patent include adhesive, such as ultraviolet cured adhesive; welding, such as ultrasonic, thermal, or spin welding; and mechanical connections, such as with the use of an O-ring with corresponding engaging grooves, a flange with corresponding engaging projections, or a friction fit with mating cylindrical suction.

9 As evident below, construction of the disputed claim element requires no reference to the extrinsic evidence submitted by the parties. See Vitronics, 90 F.3d at 1585; Markman, 52 F.3d at 983.

The other '759 patent claims that address the relationship between the tube and the cap, claims 2, 3, 10 through 14, 20, and 21, all of which depend from claims 1 or 15, support the construction of "operatively connected" meaning to affix the tube to the cap by some tenacious means of physical engagement that results in a unitary structure. 10 These claims describe means of affixing or connecting the tube to the cap for creating a filter assembly that seals the bottle and, upon inversion of the bottle, filters the contents. Claim 2 claims an adhesive connection; claim 3 claims a welded connection; and claims 11 and 20 claim a mechanical connection. Claims 12, 13, 14, and 21 claim types of mechanical connections and claim 10 claims an adhesive, mechanical, or welded connection. 11 Each of the claimed means of connecting the tube to the cap affixes the tube to the cap, creates a filter assembly that is removable as one piece from the bottle (or creates a unitary structure), and results in more than merely abutting or adjoining the tube to the cap only during operation. 12

10 Claims 2, 3, 10, and 11 depend from claim 1; claims 12, 13, and 14 depend from claim 11, which depends from claim 1;
which relationship fixes the tube in position for its intended purpose by (1) positioning the flange of the tube between the projections. This "associated" relationship is identical to the relationship between the tube and the cap in the Safari product, valve support between a tube and a cap and (2) connecting the tube to the cap by engaging the tube's flange with the cap's claim a relationship between a valve and a cap that fixes the valve in position for its intended purpose by (1) positioning the flange 45 abuts the bottom of the support 50. In other words, the patentees chose "associated" instead of "connected" to encompass a valve affixed or connected to a cap, as demonstrated, for example, by figures 1 and 2 of the '759 patent, "operatively associated," which encompasses broader subject matter than "operatively connected," to describe the relationship between the valve and the cap in claims 1 and 15 supports a construction of "operatively connected" in both claims 1 and 15 that requires affixing the tube to the cap. See Southwall Techs., 54 F.3d at 1579 (Noting that the same claim terms "cannot be interpreted differently in different claims because claim terms must be interpreted consistently."). 13 The "filter assembly" of claim 1 has a tube and a cap (as well as a "manual valve"), but nothing else. Construing "operatively connected" as affixing the tube to the cap is consistent with the claim language, "[a] filter assembly . . . comprising: a tube . . .; a cap . . .; [and] a manual valve," supports a construction of "operatively connected" in both claims 1 and 15 that requires affixing the tube to the cap. See Southwall Techs., 54 F.3d at 1579 (Noting that the same claim terms "cannot be interpreted differently in different claims because claim terms must be interpreted consistently."). 13 The "filter assembly" of claim 1 has a tube and a cap (as well as a "manual valve"), but nothing else. Construing "operatively connected" as affixing the tube to the cap is consistent with the "filter assembly" described in claim 1.

12 Under the doctrine of claim differentiation, "where some claims are broad and others narrow, the narrow claim limitations cannot be read into the broad whether to avoid invalidity or to escape infringement." United States of America v. Telecontrols, Inc., 857 F.2d 778, 784 (Fed. Cir. 1988) (quotations omitted). Accordingly, Innova argues, the claims describing means of connecting the tube to the cap cannot limit the claims from which they depend. In other words, Innova asserts the impermissibility of construing the broader language of claims 1 and 15 to cover only means of connecting the tube and the cap disclosed in the dependent claims. The construction adopted here does not so limit claims 1 and 15. For example, claims 1 and 15 read upon a magnetic connection between the tube and the cap, even though no dependent or other claim describes a means of connecting the tube to the cap by magnetic force. Cf. Tate Access Floors, Inc. v. Maxcess Techs., Inc., 222 F.3d 958, 967-68 (Fed. Cir. 2000) ("While two claims of a patent are presumptively of different scope, the doctrine of claim differentiation cannot broaden claims beyond their permissible scope.").

13 Southwall Techs. requires the construction of "operatively connected" of claims 1 and 15 to apply in claim 22 as well, the only other independent claim of the '759 patent. 54 F.3d at 1579.

In addition, the selection by the patentees of "operatively associated," which encompasses broader subject matter than "operatively connected," to describe the relationship between the valve and the cap in claims 1 and 15 supports a construction of "operatively connected" that requires not merely adjoining or abutting, but affixing the tube to the cap. The patentees emphasize (presumably unintentionally) the distinction between "operatively connected" and "operatively associated" by placing the phrases in the same claims and in adjoining sentences of the specification. Although "associated" encompasses a valve affixed or connected to a cap, as demonstrated, for example, by figures 1 and 2 of the '759 patent, "associated" also encompasses mere adjoining or abutting, as demonstrated by figure 10. 14 In the embodiment depicted in figure 10, the valve "operatively associated" with the cap is fixed in position for its intended purpose by resting the valve's support (or the valve's flange-like bottom end) on a mounting flange that forms the top end of a filter tube, which mounting flange is designed for engaging projections emanating from the interior wall of the cap. The cap has an "open top 51 perpendicular to . . . [the] hollow interior [of the tube of filtering material], and . . . [the] cap comprises one or more projections for engaging said flange, said flange and one or more projections providing mechanical connection between . . . [the] cap and . . . [the] tube."
In figure 1, the "valve element 24" is "integral with the cap 15," and in figure 2, the "valve 120 simply comprises a baby bottle nipple which is bonded to the cap 115."

The specification of the '759 patent contains examples only of embodiments of the invention that feature a tube affixed to a cap. The embodiments disclosed in the specification use adhesive, welded, or mechanical means of affixing or connecting the tube to the cap. The patent's abstract notes that the "tube is operatively connected to the cap . . . by sonic welding, a mechanical connection, or adhesively." The specification explains that "there is a great deal of versatility associated with the filter assemblies and containers according to the present invention, the actual filter element being connected to the other components either adhesively, mechanically, or by welding (e.g. sonic welding)." The specification adds:

the tube may be adhesively connected to the cap second surface, but preferably is welded (e.g. sonically welded) to it, or is mechanically connected to it. For example a mechanical connection may comprise an O-ring received by cooperating grooves formed in the tube and the cap second surface, or the tube may include a flange extending substantially perpendicularly to the hollow interior [of the tube], the so cap comprising one or more projections for engaging the flange, and the flange and one or more projections providing the mechanical connection, or a locking taper slip fit between the cap closure and filter assembly.

Similarly, the drawings of the '759 patent depict only welded, adhesive, or mechanical connections between the tube and the cap. See, e.g., Wolverine World Wide, 38 F.3d at 1197 (noting that the drawings of the patent-in-suit support the district court's claim construction). In short, a reading of the claims in view of the specification supports a construction of "operatively connected" that requires affixing the tube to the cap. See Vitronics, 90 F.3d at 1582 ("Claims must be read in view of the specification . . . .")

The prosecution history supports a construction that requires affixing the tube to the cap. See Watts v. XL Sys., Inc., 232 F.3d 877, 883 (Fed. Cir. 2000) (barring the plaintiff from advancing a construction that controverts the plaintiff's statements to the Patent and Trademark Office contained in the prosecution history). On November 6, 1995, the Patent and Trademark Office (the "PTO") rejected original dependent claims 2 through 6, 9, 17, and 18, among others, all of which depended from a claim requiring a tube "operatively connected" to a cap and all of which claimed means of connecting the tube to the cap (Doc. 45, Ex. B-2). 18 Innova distinguished the prior art of Daniels, United States Patent 5,431,813 ("Daniels"), cited by the PTO, and explained that "the dependent claims even more clearly and unequivocally distinguish from the art" because the claimed means of connecting the tube to the cap are taught neither in Daniels nor in other prior art cited by the PTO (Doc. 45, Ex. B-3). 19 On May 1, 1996, the PTO again rejected the claims disclosing the specific means of connecting the tube to the cap (original claims 2, 3, 5, 6, 9, 17, and 18), except claim 4, which the PTO cancelled (Doc. 45, Ex. B-4). The PTO found the mechanical connection claimed in original claim 17 20 obvious under section 103 of title 35, United States Code, in light of the flange and projections disclosed in Parker, United States Patent 647,580 ("Parker 580")
and United States Patent 690,457 ("Parker '457"). The PTO noted that "it would have been obvious to utilize the flange/projections of Parker '580 . . . to provide a means of securing the placement of the tube within the cap 3 of Parker '457." The PTO rejected original claim 17 also as obvious in light of the combination of Dehn, United States Patent 2,055,096 ("Dehn"), 22 and McDevitt, United States Patent 2,869,724 ("McDevitt"). 23 The PTO noted that "McDevitt is considered to disclose a flange, the use of projections to ensure proper attachment is considered to be conventional, and, in any event, the threads of McDevitt are considered to provide this feature. It would have been obvious to utilize the flange/projections of McDevitt in the device of Dehn . . . to provide an alternate but equivalent connection means." In response to the rejection of original claim 17, the patentees distinguished McDevitt as "using the flange to suspend the filter," compared to original claim 17's use of the flange to form a mechanical connection to the cap (Doc. 45, Ex. B-5). By arguing this distinction, the patentees conceded that McDevitt disclosed the suspension of a filter element in the neck of a bottle by resting a flange on the bottle mouth, the method employed in Safari's product. Notably, the patentees concluded "this is contrary to Dehn [(which discloses a filter "affixed" to a cap)] . . . and the claimed invention" (emphasis added).

18 Original claim 2 disclosed an adhesive connection; original claims 3 and 4 disclosed a welded connection; original claims 5, 6, 9, and 17 disclosed a mechanical connection; and original claim 18 disclosed an adhesive, mechanical, and welded connection (Doc. 45, Ex. B-1). The PTO rejected these claims and explained that "regarding the various means of attaching the tube to the cap, such as welding, adhesion, etc., these features are considered to be conventional and would have been obvious in the device of Nohren, Jr. [United States Patent 4,769,144] to provide alternative conventional attachment means" (Doc. 45, Ex. B-2).

19 Daniels discloses a water filtering bottle and a removable water filtering apparatus "snuggly mounted" in the neck of the bottle.

20 In relevant part, original claim 17 read as follows: "[the] tube includes a flange extending substantially perpendicular to . . . [the] hollow interior [of the tube], and . . . the cap comprises one or more projections for engaging said flange, said flange and one or more projections providing mechanical connection between said cap and said tube."

21 Parker '580 and Parker '457 disclose means for securing a filter tube in the mouth of the canteen, so that, upon inversion of the canteen for pouring the contents, the contents flow through the filter tube.

22 Dehn teaches an infusion apparatus for beverages, such as coffee or tea, which apparatus comprises a strainer that functions as a filter and as an "air interchanging device" that is "affixed" to a cap and is intended for a vacuum-type receptacle.

23 McDevitt teaches a device for demineralizing and filtering water that comprises a cartridge with a wider top, or annular flange, designed for resting on the mouth of a bottle and for suspending the cartridge in the bottle neck. The cartridge is "sealed in position by the cap" when the cap, which has internal threads, is screwed onto the corresponding threads on the exterior of the bottle neck.

The PTO rejected original claims 2, 3, 5, and 6 because the "use of adhesive, welds, or o-rings . . . are all considered to be conventional and would have been obvious in the device of Dehn . . . to provide a suitable connecting means" (Doc. 45, Ex. B-4). The PTO also rejected original claim 9 in light of figure 5 of Dehn, which disclosed a mechanical friction fit. The PTO also rejected original claims 10, 13 through 15, and 18 through 21 as obvious because, in part, "Parker '457 is considered to disclose a tubular filter block attached to a cap as instantly claimed" (emphasis added). 24 The PTO's use of "a tubular filter attached to a cap" in its response revealed the PTO's belief that the claims of the '759 patent require affixing the tube to the cap. See Phillips Petroleum Co. v. Huntsman Polymers Corp., 157 F.3d 866, 872-73 (Fed. Cir. 1998) ("Examiner's understanding of a term -- as evidenced in the file history -- is highly probative of what the term means.").

24 Original claims 10, 13 through 15, and 18 through 21 either claimed or depended from a claim that claimed a "tube
operatively connected to . . . [a] cap." Original claim 10 depended from original claim 1 (now claim 22); original claim 13 constituted the original filing of asserted claim 1; original claims 14 and 15 depended from original claim 13; original claim 19 constituted the original filing of asserted claim 15; and original claims 20 and 21 depended from original claim 19.

In the September 13, 1996, supplemental amendment, the patentees submitted a new claim (original claim 24) that claimed a "filter assembly mounted in a plastic bottle as recited in claim 22" (Doc. 45, Ex. B-6). Original claim 22 depended from original claim 1, which claimed a "tube [of filtering material] operatively connected" to the cap. In the amendment, the patentees explained:

filter assemblies, and plastic bottles with filter assemblies, according to the claimed invention have obtained substantial commercial recognition and acceptance in the trade. Also the general concepts of the invention have apparently been copied in bottles constructed by competitors, such bottles having tubes or other elements of activated carbon filtering material mounted in caps for plastic bottles.

(Emphasis added). In essence, the patentees conceded that the general concept of the invention of the '759 patent included "mounting" the tube in the cap.

Innova's appeal with respect to the asserted claims of the '759 patent turns on the correct interpretation of the disputed claim term, "operatively connected." According to the district court, the ordinary meaning of "said tube operatively connected to said cap" requires that the two components be "affixed . . . by some tenacious means of physical engagement that results in a unitary structure." Innova challenges this construction as improperly importing a tenacious physical engagement limitation into claim language that does not require any such thing. Safari concurs with the district court. The district court erred. The asserted claims do not require that the filter tube and cap be affixed to one another in a manner that results in the two components forming a unitary structure. Neither party asserts that the term "operatively connected" is a technical term having a special meaning in the art of water filtration. Rather, it is a general descriptive term frequently used in patent drafting to reflect a functional relationship between claimed components. Generally speaking, and as used in the '759 patent, it means the claimed components must be connected in a way to perform a designated function. In the absence of modifiers, general descriptive terms are typically construed as having their full meaning. See Johnson Worldwide, 175 F.3d at 992 (refusing to import a modifier for the term "coupled"); Va. Panel Corp. v. MAC Panel Co., 133 F.3d 860, 865-66 (Fed. Cir. 1997) (refusing to import a modifier for the term "reciprocating"). Thus, the district court was correct to look to the ordinary meaning of the terms "operatively" and "connected" and we discern no error in the district court's initial understanding that "the ordinary and customary meaning of 'operatively connected' requires the . . . linking together of the tube and the cap to produce the intended or proper effect." But the district court erred when it proceeded beyond this plain meaning based on the "examples of means for connecting the tube to the cap disclosed in the '759 patent," all of which reflect a "physical engagement [between the tube and the cap] that results in a unitary structure." See Teleflex, 299 F.3d at 1328.

The district court also erred in interpreting the "intended or proper effect," i.e., the designated function, to be the operation of "creating a filter assembly" with a unitary structure. Instead, as Innova contends, the proper designated function is the operation of the assembly, i.e., filtering. Thus, "said tube [is] operatively connected to said cap" when the tube and cap are arranged in a manner that affects filtering. Safari contends that the district court was correct because for a connection to be operative for filtering, the structure performing the filtering must also be associated with a bottle, a limitation not found in claim 1 of the '759 patent. We disagree because the claims, and also the written description, reflect that an intended purpose for the claimed invention is for use with a bottle to filter water.

Focusing first on the claims, we observe that the preamble of claim 1 recites: "A filter assembly for use with a bottle . . . to simultaneously cap the neck or open end and filter liquid poured out of the bottle . . . ")'759 patent, col. 6, ll. 45-49 (emphasis added). Language in a preamble limits a claim where it breathes life and meaning into the claim, see In re Paulsen, 30 F.3d at 1479, but not where it merely recites a "purpose or intended use of the invention." Id. In this case, we
need not decide whether the preamble adds a limitation to the claim because we hold that it recites a purpose or intended use of the claimed "filter assembly" as, inter alia, "filtering liquid poured out of the bottle." Other parts of claim 1 also show that the intended function of the claimed structure is filtering. Beyond stating that the "tube is operatively connected to said cap," the claim also states that a "valve" is "operatively associated with said cap, in fluid communication with said tube of filtering material." '759 patent, col. 6, ll. 58-59. The claim further explains that the "valve" controls the flow of liquid through the "tube of filtering material" as the valve is "manually movable between a position defining means for allowing liquid flow through said tube and a position defining means not allowing liquid flow through said tube." Id., ll. 59-63. In sum, we think the operation defined by controlling the flow of liquid through the "tube of filtering material" is the operation of filtering.

As Safari acknowledges, Innova's argument that "operatively" refers to the function of filtering, has even "more traction" when applied to claim 15. Claim 15 is directed to "[a] container for dispensing filtered water." '759 patent, col. 7, l. 55. It expressly claims a bottle as an element of the disclosed structure. Id., ll. 56-58. It contains the "in fluid communication" limitation present in claim 1. Id., col. 8, ll. 4-9. And, it contains additional language explaining the position of the tube of filtering material relative to the cap, the bottle, and the liquid flow:

sai, Id., ll. 10-17.

Not only do both claims evidence that an intended function or operation of the claimed structure is filtering, such a function is also evident from the written description, e.g., "there is a significant demand for filtered drinking water . . .," '759 patent, col. 1, l. 6; "a filter assembly is provided . . . capable of effectively treating drinking water to remove chlorine and organic taste contaminants therefrom and reduces a variety of chemical contaminants." Id., ll. 25-29. Unless otherwise compelled, when different claims of a patent use the same language, we give that language the same effect in each claim. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003). Here, we are not otherwise compelled. "Operatively connected" carries the same meaning in both claims.

Furthermore, we observe that Safari's interpretation largely reads the term "operatively" out of the phrase "operatively connected." While not an absolute rule, all claim terms are presumed to have meaning in a claim. Cf. Pickholtz v. Rainbow Techs., Inc., 284 F.3d 1365, 1373 (Fed. Cir. 2002). If, as Safari proposes, the claim refers in the abstract to the creation of a filter assembly structure, without any grounding to an intended use, the term "operatively" is unnecessary and superfluous as the patentee could have as easily used the term "connected" alone.

Safari also proposes that the district court's construction can be supported by the patentee's use, in claim 15, of "operatively connected" and "operatively associated." The argument is that the patentee's use of the term "connected" to claim the tube-cap relationship stands in such stark contrast to the patentee's choice of "associated" to define the valve-cap relationship, that the patentee could only have intended that "connected" and "associated" were of different scope. Despite Innova's assertion to the contrary, when an applicant uses different terms in a claim it is permissible to infer that he intended his choice of different terms to reflect a differentiation in the meaning of those terms. See Bancorp Servs., L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1373 (Fed. Cir. 2004); Ethicon Endo-Surgery, Inc. v. U.S. Surgical Corp., 93 F.3d 1572, 1579 (Fed. Cir. 1996). For this argument to be dispositive of a particular claim construction, however, one must accept that "connected" and "associated" can be discerned along the lines Safari urges. In particular, one must accept the argument that although both terms can, by their plain meaning, include nonphysical attachment, "associated" was meant to define both nonphysical and physical attachment while "connected" was used in a narrower sense, incorporating only a physical attachment definition. Safari urges that we can make the distinction based on the disclosed embodiments. We disagree.

While an inference that "connected" and "associated" have different meanings in this case may be particularly appropriate because the words here define the relationship between two objects, the terms "connected" and "associated" are very similar in meaning. The context does not make clear to us that Innova's use of both terms means that "connected" should be limited to tenacious physical engagement. Moreover, we observe that in at least one circumstance, Innova described the filter as "associated" with the cap. '759 patent, col. 1, ll. 41-43 ("a cap with which the filter is associated being adaptable to fit any type of closure mechanism on a conventional plastic bottle"). Finally, as we discuss in further detail, infra, we decline to
limit the claims based only on the embodiments in the written description. Thus, the context does not show that "connected" and "associated" should be differentiated into the definitions proposed by Safari, and we must conclude that this is simply a case where the patentee used different words to express similar concepts, even though it may be confusing drafting practice. Bancorp Servs., 359 F.3d at 1373.

In sum, subject to any clear and unmistakable disavowal of claim scope, the term "operatively connected" takes the full breadth of its ordinary meaning, i.e., "said tube [is] operatively connected to said cap" when the tube and cap are arranged in a manner capable of performing the function of filtering.

A

Safari contends that in the written description and prosecution history the patentee clearly and unmistakably disavowed the full breadth of meaning of "operatively connected" and put the public on clear notice that the claims should be limited to cover only embodiments where the filter tube and cap are tenaciously physically engaged. Concerning the written description, Safari relies most heavily on the argument that at "every point" in the written description where "operatively connected" is discussed, it is discussed as having the "common denominator" of tenacious physical engagement. However, at argument, Safari's counsel had difficulty pointing to a statement in the written description that clearly and unmistakably shows the applicant's intent to limit the scope of the claims to tenacious physical engagement. Undaunted, Safari contends that even if we disagree that the written description contains specific language clearly showing disavowal, the applicant's clear and unmistakable disavowal of all embodiments in which the tube is not tenaciously engaged to the cap is evident from reading the written description as a whole. According to Safari, when one reads the written description from beginning to end, there is no disclosure of a tube and cap arrangement where the tube and cap are not, in the words of the district court, "affixed . . . by some tenacious means of physical engagement that results in a unitary structure." Safari also relies heavily on the observation that not a single drawing in the written description depicts an arrangement of tube and cap in other than tenacious engagement. 1 Thus, contends Safari, because courts do not construe claims beyond what is disclosed in the written description, the written description demands a finding by this court that "operatively connected" is limited to tenacious physical engagement. Making the same argument, although in different terms, Safari argues that, acting as his own lexicographer, the patentee in this case defined "operatively connected" as requiring tenacious physical engagement. Again, we disagree.

--- Footnotes ---

1 Innova unsuccessfully disputes this aspect of the disclosure.

--- End Footnotes ---

1

The abstract of the written description contains the statement: "The tube is operatively connected to the cap second surface at the tube second open end by sonic welding, a mechanical connection, or adhesively." '759 patent, Abstract. While a statement in the Abstract may operate as a clear expression of manifest exclusion, for several reasons, this statement does not. Nor does this statement weigh heavily when considering whether the applicant has acted as his own lexicographer. To begin, this statement is in the Abstract of the patent. This section of a patent speaks generally to the invention and, much like the syllabus of an opinion, sets forth general information about the document's content, which is described in more detail in the remainder of the document. Second, in our view, this statement reflects the applicant's attempt to disclose the broad array of means by which the tube can be connected to the cap. This observation begs a third point. Safari, and it seems the district court, appear to believe the term "mechanical connection" requires tenacious physical engagement, and accordingly, cannot include within its scope Safari's product, which suspends the tube of filtering material in the bottle mouth by means of an annular flange sealed in place by a cap screwed over the mouth of the bottle. We simply do not agree. By a twist of the wrist, the bottle cap is screwed tight, thus mechanically locking the filter to the lip of the bottle.

The connection of the filter and cap is addressed in other portions of the written description. The paragraph beginning: "According to the present invention . . .," '759 patent, col. 1, l. 23, describes the "filter assemblies and containers according to the present invention," id., ll. 38-39, as having "the actual filter element being connected to the other components either adhesively, mechanically, or by welding (e.g. sonic welding), a cap with which the filter is associated being adaptable to fit
any type of closure mechanism on a conventional plastic bottle . . . " Id., ll. 38-44. Although at first glance one might think that the use of the word "associated" creates a requirement that the filter and cap be affixed in tenacious physical engagement, it does not. Without doubt, a structural element "associated" with a separate structural element can be tenaciously physically engaged. However, there is no requirement that this be so because the word "associated" merely reflects that the recited elements be joined in some kind of relationship. Thus, in contrast to, for example, Scimed, this language is less direct, clear, and defining than the phrase "[the] structure . . . is the basic . . . structure for all embodiments." 242 F.3d at 1344.

The kernel of Safari's position is that the embodiment, or embodiments, depicted in the figures and written description show "not merely adjoining or abutting, but affixing the tube to the cap by some tenacious means of physical engagement that results in a unitary structure." Perhaps the most straightforward answer to Safari's argument is that the law does not require the court, where an applicant describes only a single embodiment, to construe the claims as limited to that one embodiment. See, e.g., Liebel-Flarsheim, 358 F.3d 898, 906-09. Indeed, such a construction is not encouraged or presumed. Id. From another level of abstraction, of course, the patentee's disclosures in this case could be viewed as the disclosure of many embodiments. So viewed, the patentee presented several examples of the types of connections between the filter tube and cap useful for the invention and in all examples depicted the connection as a tenacious physical engagement. Here, this is a difference without substance. As noted earlier, the specification as a whole reflects the patentee's efforts to describe and claim all operative connections. Also, the written description discloses that the operative connection can be "mechanical," a feature we conclude is present in the arrangement of the filter tube and cap in Safari's product as presented to this court. Finally, and most importantly, Safari's argument flies into the sun that is the plain import of the claim language "operatively connected." We thus decline to apply Safari's reasoning.

According to Safari, the prosecution history is "consistent with" their proposed definition of "operatively connected," and, based on "representations made to secure the '759 patent," "Innova is estopped" from arguing that any other construction is possible. We conclude that the prosecution history does not preclude the construction advanced by Innova and adopted in this opinion.

Safari first refers to a section 103 rejection made by the examiner to pending claims 1-18. In that rejection, the examiner stated:

Regarding the various means of attaching the tube to the cap, such as welding, adhesion, etc., these features are considered to be conventional and would have been obvious in the device of [the prior art] to provide alternative conventional attachment means.

We note here, that claim 13 ultimately issued as claim 1. At the time of the rejection however, claim 13 was merely a claim depending from then claim 1 and recited a type of filtering material. Claim 1, from this point in the prosecution history later issued as claim 22. 2 Even so, this claim contained the relevant "said tube operatively connected to said cap" language, and the cited portion of the examiner's rejection is properly read as referring to this connection.

2 At this stage in the prosecution, the claim that would issue as claim 15 in the '759 patent was claim 19. Although it contained, "said tube operatively connected to said cap," the examiner did not include it in this rejection.

Responding, the patentee made a number of arguments concerning pending claim 1, of which the district court and appellee make no issue. Then, addressing dependent claims 2-18, the applicant made the statement:

In fact, it is believed that the dependent claims even more clearly and unequivocally distinguish from the art. For example, no place in either [prior art reference] are the mutually exclusive adhesive connection of claim 2, welding, (e.g., ultrasonic welding) of claim 3, or mechanical connection of claim 5 pointed out in the previous action or seen in the references, let alone the particular O ring connection recited in claim 6, or the particular mechanical connection flanges of
Although asserting that the "significance placed on this feature by Innova estops Innova from disclaiming that the filter tube is affixed to the cap," Safari fails to explain how this statement demands such a conclusion. After careful consideration of the content of the statement, we conclude that it does not clearly and unambiguously disavow mechanical connections where the filter tube is not tenaciously physically engaged to the cap. See Omega Eng'g, 334 F.3d at 1323-24. In particular, we note that dependent claims are typically narrower and, by so being, are more likely to clearly distinguish the prior art. Generally speaking, this is, in part, their function. In addition, it is of little moment that the dependent claims mentioned in the response refer to connections that result in a unitary structure. This is so for at least two reasons. First, the language of the response refers to claims that specifically claim embodiments in which the filter tube and cap are tenaciously physically engaged. By the patentee's selection of language, which the examiner allowed, claims 1 and 15 are not facially limited to such embodiments. Second, to accommodate Safari's argument now, we would have to conclude that it would be appropriate to limit an independent claim by the additional limitations of claims depending from that claim. Although, in some cases this might be possible, the doctrine of claim differentiation "normally means that limitations stated in dependent claims are not to be read into the independent claim from which they depend." Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999) (stating that this interpretative tool stems from "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope"). In sum, the argument that dependent claims, which require tenacious engagement, "more clearly . . . distinguish from the art" does not mean that claims from which those claims depend are equally limited.

Next, Safari points to a dialog between the examiner and patentee where the examiner rejected then-pending claim 17 because "it would have been obvious to utilize the flange/projections of [the prior art] . . . to provide an alternative but equivalent connection means." The claim addressed by this rejection literally claims a connection between the tube and cap that uses a flange extending from the filter tube to engage the cap. The applicant responded to the rejection thus:

For example, [the prior art] shows an axial filter that is sealed at the top and employs a mixture of anion and cation resins, using the flange to suspend the filter of ion exchange resins which operate in axial flow mode . . . . This is contrary to [other prior art] and the claimed invention.

Safari contends that this statement disavows the use of a flange to suspend the filter tube. Innova contends that this statement was directed to the distinction of radial as opposed to axial filtering. Careful inspection of the prosecution history indicates that Innova has the better argument. Beginning with the statement itself, we cannot distinguish whether it is referring to the filter or the flange. Examining the following Office Action, we observe that the examiner understood Innova's statement to be referring to the filter: "The applicants also argue that [the prior art] discloses an axial filter; referring to the filter or the flange. Examining the following Office Action, we observe that the examiner understood Innova's statement to be referring to the filter: "The applicants also argue that [the prior art] discloses an axial filter; however [the prior art] was cited solely for the feature of a conventional flange on the rim of the tubular filter." Following this discourse, a telephone interview occurred, after which the examiner allowed the claim, unamended, and still directed to the use of a flange to make the tube-cap connection. 3 This series of communications does not reflect the clear and unambiguous disavowal of caps and filters connected by mechanical means short of tenacious physical engagement. Rather, it reflects first, the examiner and applicant talking past one another. It reflects second, that the applicant was able to convince the examiner, by off the record communications, to retreat from her position. However unfortunate it is that the public and this court are prevented from knowing what arguments caused the examiner to abandon her position, the record finally reflects the examiner's acquiescence to the claim language chosen by the applicant. This is not clear evidence of the patentee's disavowal of claim scope.

3 It issued as claim 14 of the '759 patent.

Safari also points to a rejection entered by the examiner, where the examiner describes a piece of asserted prior art as "considered to disclose a tubular filter attached to a cap as instantly claimed." It is well settled, however, that it is the applicant, not the examiner, who must give up or disclaim subject matter that would otherwise fall within the scope of the claims.
V

Innova argues the district court erred by denying the motion to amend the complaint to add the '362 patent because there was no delay on Innova's part, and no unfair prejudice to Safari would result from granting the motion. At the outset, this is a nonpatent matter where we apply the law of the circuit in which the district court sits. See Cultor Corp. v. A.E. Staley Mfg. Co., 224 F.3d 1328, 1332-33 (Fed. Cir. 2000). This appeal is from the middle district of Florida, within the eleventh circuit, which reviews the refusal of leave to amend for abuse of discretion. Lowe's Home Ctrs., Inc. v. Olin Corp., 313 F.3d 1307, 1314-15 (11th Cir. 2002). On this deferential standard of review, we detect no abuse of discretion.

In the eleventh circuit, the court freely grants leave to amend when justice so requires. Carruthers v. BSA Adver., Inc., 357 F.3d 1213, 1217-18 (11th Cir. 2004). However, a motion to amend may be denied on "numerous grounds, such as undue delay, undue prejudice to the defendants, and futility of the amendment." Maynard v. Bd. of Regents of Div. of Univs. of Fla. Dep't. of Educ., 342 F.3d 1281, 1287 (11th Cir. 2003) (citation and internal quotation marks omitted). In addition, "it is not an abuse of discretion for a district court to deny a motion for leave to amend following the close of discovery, past the deadline for amendments, and past the deadline for filing dispositive motions." Lowe's, 313 F.3d at 1315.

A number of these considerations are present in this case. In particular, Innova sought to amend the complaint approximately six months after the '362 patent issued, ten months after discovery closed, and nine months after the filing of summary judgment motions. Accordingly, the district court did not abuse its discretion when it denied Innova's motion to amend.

VI

In conclusion, the correct claim construction does not limit claims 1 and 15 to only embodiments where "said tube [is] operatively connected to said cap" by mechanical means that result in tenacious physical engagement. Accordingly, the district court erred when it granted Safari's motion for summary judgment of no literal infringement based on the fact that in Safari's accused product the filter tube is "never affixed to the cap by some tenacious means of physical engagement as required by claims 1 and 15." For the same reasons, the district court erred in granting summary judgment of no infringement under the doctrine of equivalents based on its factual conclusion that "merely adjoining or abutting . . . is not the equivalent of affixing the tube to the cap." And, finally, as discussed, we disagree with the district court that the applicant, in the course of prosecution, surrendered the method employed in the Safari product of using a flange to position the filter element.

On the record before us, however, we cannot be certain that reversing and entering summary judgment in favor of Innova is the proper course of action. We leave that decision, in the first instance, to the district court. Thus, we vacate the district court's grant of summary judgment of noninfringement in favor of Safari and remand for further proceedings in light of the correct claim interpretation. Because we detect no abuse of discretion, we affirm the district court's denial of Innova’s motion to amend the complaint to add the '362 patent.

2775

1. "a travel bar operatively connected to the hinge plates" in claim 1 of the '946 patent

Plaintiff proposes that, in the context of the phrase "a travel bar operatively connected to the hinge plates," the term "operatively connected" means "mechanically associated so as to be capable of applying mechanical force to." (Doc. # 26-2, at 11). Plaintiff argues that the term should be given its common and ordinary meaning and relies on dictionary definitions to support its proposed construction. (Doc. # 26-2, at 12).

Plaintiff refers the Court to Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1117 (Fed. Cir. 2004), whereby the Federal Circuit analyzed the construction of the term "operatively connected" in the context of a water bottle filter assembly patent. After noting that "[t]he term 'operatively connected' [was] a technical term having a special meaning in the art of water filtration," the Federal Circuit stated that the term was "a general descriptive term frequently used in patent drafting to reflect a functional relationship between claimed components." Id. at 1118. The Federal Circuit held that, "[g]enerally speaking, . . . [operatively connected] means the claimed components must
be connected in a way to perform a designated function." Innova/Pure Water, 381 F.3d at 1118. The Federal Circuit then stated that "operatively connected" takes full breadth of its ordinary meaning, i.e., 'said tube [is] operatively connected to said cap' when the tube and cap are arranged in a manner capable of performing the function of filtering." Id. Plaintiff also notes that the District of Oregon construed the term "operatively connected" in the phrase "a spring operatively connected between the handle and the blade to assist in the opening of the blade" to mean "the spring, handle, and blade are arranged such that the spring operates to assist in opening the blade." (Doc. # 31, at 28) (citing Kai U.S.A., Ltd. v. Buck Knives, Inc., No. CV 05-446-HA, 2006 U.S. Dist. LEXIS 24924, 2006 WL 314456, at *4 (D. Ore. Feb. 9, 2006)).

Defendant requests that, if the Court does not construe the term as a means-plus-function limitation, the Court adopt its alternative, proposed construction:

[Comprising a travel bar operatively connected to the hinge plates . . . . A travel bar operatively connected to the hinge plates means the hinge plates are connected to the travel bar by placing at least one pivotally movable connecting link between the hinge plates and the travel bar such that the motion of the bar produces pivotal motion of the hinge plates.

(Doc. # 26-2, at 11-12, 14-15). Defendant refers the Court to the '946 patent specification, which recites: (1) "[a]internmediate connector 76 is pivotally connected to the lever 68 and to the travel bar 70 for pivoting motion relative to both the lever and the travel bar," and (2) "[t]he hinge plates 56 are operatively connected with the travel bar 70 by placing at least one pivotally movable connecting link 72 between the hinge plates and the bar such that motion of the bar produces pivotal motion of the hinge plates." (Doc. # 1-2, '946 patent, col. 4, lines 30-32, col. 7, lines 23-27). Defendant maintains that the Court should adopt its proposed construction, which incorporates the specification's definition of the phrase "a travel bar operatively connected to the hinge plates." (Doc. # 26-2, at 15). Based on the specification, defendant contends that "connecting links" are necessary structures. (Doc. # 79, at 17). Defendant asserts that its proposed construction is "consistent with the maxim that claims should be construed to maintain their validity and the Federal Circuit's interpretation of the written description and enablement requirements of 35 U.S.C. § 112, P 1." (Doc. # 26-2, at 15). Finally, defendant argues that "[p]laintiff's reliance on Innova is misplaced." (Doc. # 79, at 15).

The claim language, specification, or prosecution do not make clear the definition of the term "operatively connected," and the Court adopts the Federal Circuit's ordinary and customary meaning of the disputed term. As such, the Court finds that the ordinary meaning of the disputed term is "arranged in a manner capable of performing a designated function." See Innova/Pure Water, 381 F.3d at 1118, 1120. The stated function in claim 1 of the '946 patent is "for moving the hinge plates between the closed and open positions . . . ." (Doc. # 1-2, '946 patent, col. 9, lines 63-64). The specification states that "[t]he hinge plates 56 are operatively connected with the travel bar 70 by placing at least one pivotally movable connecting link 72 between the hinge plates and the bar such that motion of the bar produces pivotal motion of the hinge plates." (Doc. # 1-2, '946 patent, col. 7, lines 23-27) (emphasis added). Therefore, a the travel bar and hinge plates, without at least one connecting link, could not perform the function recited in claim 1 of the '946 patent. "[I]t is entirely proper to consider the functions of the invention in seeking to determine the meaning of particular claim language." ICU Med., No. 2008-1077, 2009 U.S. App. LEXIS 5271, 2009 WL 635630, at *4, citing Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1319 (Fed. Cir. 2005).

The Court finds that the reference to the travel bar and hinge plates in claim 1 of the '946 patent contemplates the inclusion of at least one connecting link. The intended function described in the specification supports this conclusion. As such, the Court finds that "operatively connected" in the context of the phrase "a travel bar operatively connected to the hinge plates" of the '946 patent means "the travel bar and hinge plates are arranged in a manner such that at least one connecting link operates to assist in moving the hinge plates between the closed and opened positions."
Plaintiff argues that the term "operatively connected" in the '685 patent means "mechanically associated so as to be capable of applying mechanical force to." (Doc. # 51, at 27). Plaintiff relies on dictionary definitions and Innova/Pure Water and Kai to support its proposed construction. Defendant urges the Court to adopt its alternative, proposed construction:

[A] travel bar operatively connected to the lever such that pivoting movement of the lever causes movement of the travel bar in translation relative to the housing from the first position in which the control structure locks the hinge plates in the closed position to the second position in which the hinge plates are free to pivot to the open position. A travel bar operatively connected to the lever means the travel bar is connected to the lever by an intermediate connector. (Doc. # 51, at 28).

Defendant also provides the same arguments that it asserted with respect to the construction of the term in the '946 patent claims. Additionally, defendant contends that the construction of the term within the context of claim 1 of the '685 patent requires the inclusion of "an intermediate connector" because the structure "is the only enabling disclosure in the '685 patent specification." (Doc. # 51, at 31).

The claim language, specification, or prosecution history do not make clear the meaning of "operatively connected" in the '685 patent, and the Court adopts the Federal Circuit's ordinary and customary meaning of the disputed term. As such, the Court finds that the ordinary meaning of the disputed term is "arranged in a manner capable of performing a designated function." See Innova/Pure Water, 381 F.3d at 1118, 1120. The '685 patent specification states that:

As also seen, the travel bar 41 is disposed behind the plateau 17 of the housing 11 and is connected to the lever 15 by the intermediate connector 39. . . . Force is therefore transmitted from the lever 15, around the post 21a, and to the travel bar 41 while keeping direction of the force along a centerline of the connector 39. Thus, the connector is able to transmit force from the lever 15 to the travel bar 41 such that application of force to the lever produces the translational movement of the travel bar.

(Doc. # 51-2, '685 patent, col. 6, lines 36-39, 54-60). The travel bar and lever, without the intermediate connector, could not perform the function recited in both claim 1 and the specification. As stated above, "it is 'entirely proper to consider the functions of the invention in seeking to determine the meaning of particular claim language." ICU Med., No. 2008-1077, 2009 U.S. App. LEXIS 5271, 2009 WL 635630, at *4. Therefore, the Court finds that the reference to the travel bar and lever in claim 1 in the '685 patent contemplates the inclusion of an intermediate connector. The intended function described in the specification supports this conclusion. Accordingly, the Court finds that "operatively connected" in claim 1 of the '685 patent means "the travel bar and the lever are arranged such that the intermediate connector operates to assist the pivoting movement of the lever that causes movement of the travel bar in translation relative to the housing from the first position in which the control structure locks the hinge plates in the closed position to the second position in which the hinge plates are free to pivot to the open position."

Federal Circuit law holds that, "[u]nless otherwise compelled, when different claims of a patent use the same language, we give that language the same effect in each claim." Innova/Pure Water, 381 F.3d at 1119. In the instant case, the term "operatively connected" appears in both claims 1 and 26 of the '946 patent, and the Court finds that "operatively connected" carries the same meaning in both claims. Id. Claim 26 recites that "the lever is being operatively connected to the travel bar such that pivoting motion of the lever produces movement of the travel bar generally lengthwise of the elongate plate . . . ." (Doc. # 1-2, '946 patent, col. 12, lines 23-26). The specification states:

The lever 68 is operatively connected to the travel bar 70 such that application of force to the lever produces movement of the travel bar generally lengthwise of the elongate plate 32. . . . An intermediate connector 76 is pivotally connected to the lever 68 and to the travel bar 70 for pivoting motion relative to both the lever and travel bar. Force is transmitted from the lever 68 to the travel bar 70 through the intermediate connector 76.

(Doc. # 1-2, '946 patent, col. 4, lines 20-24, 30-34). A lever and travel bar, without the intermediate connector, could not perform the function recited in both claim 26 and the specification. As stated above, "it is 'entirely proper to consider the
functions of the invention in seeking to determine the meaning of particular claim language.” ICU Med., No. 2008-1077, 2009 U.S. App. LEXIS 5271, 2009 WL 635630, at *4. The Court finds that the reference to the lever and travel bar in claim 26 contemplates the inclusion of an intermediate connector. The intended function described in the specification supports this conclusion. Accordingly, the Court finds that “operatively connected” in claim 26 of the ‘946 patent means “the lever and travel bar are arranged such that the intermediate connector operates to assist the pivoting motion of the lever to produce movement of the travel bar generally lengthwise of the elongate plate.”

"impeller assembly operatively coupled to said motor"

Claims 1 and 11 of the ‘437 Patent contain the term "impeller assembly operatively coupled to said motor." SHURflo contends the term means "a rotating impeller apparatus coupled directly or indirectly to the pump motor so that they are operable together." Defendants contend that the term means "a rotating impeller apparatus coupled directly to the pump motor so that they are operable together when the impeller apparatus is not locked." The parties dispute centers around whether the phrase "operatively coupled" should be limited to "indirect" coupling.

Both parties agree that "magnetic" coupling is a type of "indirect" coupling. Defendants assert that the only embodiment disclosed in the specification is an impeller assembly coupled to a motor through a magnetic coupling. The magnetic coupling allows the motor to slip if the impeller locks. This means the motor is free to disengage from turning the impeller when the impeller locks and the impeller and motor stop turning together. In a "direct" coupling, the motor locks when the impeller locks. Defendants argue that the specification does not disclose a motor that is "directly" coupled and that "[d]irect coupling does not 'naturally align' with the specification's disclosure of indirect coupling because the motor circuit would not function as described by the patent if the impeller and motor were directly coupled." Defendants' Responsive Brief, at 28. SHURflo counters that claims cannot be limited to embodiments disclosed in the patent, even if the patent discloses only one embodiment. In addition, SHURflo argues that Claims 4 and 10 of the ‘437 Patent depend from Claim 1 and specifically require a "magnetic coupling." Thus, SHURflo argues that under the doctrine of claim differentiation, Claims 1 and 11 are broader than Claims 4 and 10.

There is nothing in the claim language or the specification that limits "operatively coupled" to "indirect" coupling. Although the specification only discloses "magnetic" coupling, the patentee chose to claim the coupling more broadly by using the term "operatively coupled." In addition, because courts presume a difference in meaning and scope when a patentee uses different phrases in separate claims, the doctrine of claim differentiation applies in this case and "operatively coupled" must be read to include both "direct" and "indirect" coupling. See Phillips, 415 F.3d at 1314-15. Accordingly, the Court adopts SHURflo's construction and construes the term "impeller assembly operatively coupled to said motor" to mean "a rotating impeller apparatus coupled directly or indirectly to the pump motor so that they are operable together."

1. Claim 1 ("the clamp including a camming member which operatively engages the actuation member such that movement of the actuation member pivots the clamp between the open and clamped positions")

Claim 1 (and all dependent claims) of the ‘544 Patent uses the above claim term in the following context:

[A] clamp pivotally mounted adjacent the distal end of the outer tube, the clamp being movable in relation to the jaw member between open and clamped positions, the clamp including a camming member which operatively engages the actuation member such that movement of the actuation member pivots the clamp between the open and clamped positions.

‘544 Patent, Claim 1 (emphasis added). Plaintiff proposes the following construction: "The camming member of the clamp (follower) and the actuation member constitute a camming mechanism to pivot the clamp." Defendant proposes: "A protrusion (follower) the motion of which is controlled by movement of the 'slot' with which it is engaged." n13

n13 Defendant originally argued that the means-plus-function limitation in 35 U.S.C. § 112 applied to this claim term, but
has since withdrawn that argument. See Markman Tr. at 6.

The Court adopts plaintiff's construction and construes the claim as follows: "The camming member of the clamp (follower) and the actuation member constitute a camming mechanism to pivot the clamp." First, the parties agree that the "camming member" is the follower part of the camming mechanism. Moreover, this construction is consistent with the claim language itself and the specifications. See '544 Claim 1, 4:26-30, 6:15-24, Figure 13. Lastly, as addressed above, there is no basis for importing the words "protrusions" or "controlled" into the claim construction.

1. "Anchor Seat Means" for Operative Joinder

Claim 5 requires "an anchor seat means which has a lower bone interface operatively joined to said bone segment ...."

Defendants argue "operative joinder" requires the screw be secured into the bone so the bottom surface of the anchor seat is joined to the bone, or to washers that sit above the bone. They assert the anchor seat must be joined to the bone to add stability to the rod, and, if the anchor seat were not joined as such, the anchor seat would move freely. Defendants claim their devices rigidly link the rod, the anchor seat, and the screw to the bone segment without joining the anchor seat to the bone segment.

Defendants argue the term "operatively" should be interpreted to mean "to produce an appropriate effect." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY at 827 (1991). They further argue the effect of providing limited motion and stability between the anchor seat and the bone segment can be found in the patent specification. The Court cannot accept Defendants' proposed definition, which would require incorporation of an additional limitation into the claim.

Plaintiff argues the word "operatively" means "involving surgical operations." WEBSTER'S COLLEGE DICTIONARY at 948 (1991). Since the claim language concerns a surgical procedure, this definition is logical. Thus, "operative joinder" in this claim means to "connect during a surgical procedure." 2

--- Footnotes ---

1 "Particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." Rhine v. Casio, Inc., 183 F.3d 1342, 1346 (Fed. Cir. 1999).

2 "Joined" means "to bring together or in contact; connect," WEBSTER'S COLLEGE DICTIONARY at 728 (1991), or "a surface forming a common boundary of two bodies." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY at 631 (1991).

--- End Footnotes ---

Defendants' contentions its products are not designed for stabilization by connecting to the bone are irrelevant because the claim does not refer to the purpose of the connection, and the Court will not read this limitation into the claim. Further, "the accused device, to be infringing, need only be capable of operating in the [infringing] mode … actual [infringing] mode operation in the accused device is not required." Intel Corp. v. U.S. Intern. Trade Com'n, 946 F.2d 821, 832 (Fed. Cir. 1991); see also Hilgraeve Corp. v. Symantec Corp., 265 F.3d 1336, 1343 (Fed. Cir. 2001) ("an accused device may be found to infringe if it is reasonably capable of satisfying the claim limitations, even though it may also be capable of non-infringing modes of operation."). Defendants' devices are capable of operative joinder to the bone segment, 3 and are sometimes used in this way. 4 Defendants' products meet the "operative joinder" limitation of Claim 5.

--- Footnotes ---

3 Defendants correctly point out "a device does not infringe simply because it is possible to alter it in a way that would satisfy all the limitations of a patent claim." High Tech Medical Instrumentation, Inc. v. New Image Industries, Inc., 49 F.3d 1551, 1555 (Fed. Cir. 1995). However, the rule does not apply in this case because Defendants' products do not need to be altered to connect to the bone segment.
4 Plaintiff moved for leave to file a surreply to respond to Defendants' evidence on this issue. Since this evidence was not controlling, Plaintiff's arguments are moot.

2781

d. "Operatively positioned at the surgeon's operating station"

Claims 1 and 10 teach that the "surgeon's control panel" is "operatively positioned at the surgeon's operating station." '688 Pat. col.19 ll.51-52; id. at col.20 ll.66-67. KSEA asserts that "operatively positioned at the surgeon's operating station" should be construed as "operable from the surgeon's operating station." (Proposed Constructions Chart 2.) S&N contends that the term should be construed as "positioned at the surgeon's operating station within reach and view of the surgeon to allow control and monitoring of the pieces of surgical equipment." (Id.)

The Court adopts S&N's proposed construction. The '688 Patent teaches that a primary advantage of the surgeon's command and control system is that it allows a surgeon to directly monitor and control the operation of surgical equipment, an improvement over the prior art, which required a surgeon to indirectly monitor and control surgical equipment through verbal interaction with surgical staff members. See '688 Pat. col.2 ll.29-50. S&N's proposed construction recognizes this improvement over the prior art, while KSEA's proposed construction does not indicate that the surgeon may directly use the control panel. "The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Phillips, 415 F.3d at 1316 (citation omitted).

S&N's proposed construction does not read "operatively" out of the claim as KSEA contends. The proposed construction explains that "operatively positioned" means positioned so that the surgeon may directly operate it.

The Court construes "operatively positioned at the surgeon's operating station" as "positioned at the surgeon's operating station within reach and view of the surgeon to allow control and monitoring of the pieces of surgical equipment."

2782

The next element of Claim 1 to which construction must be applied is:

[A]n engine control to control a parameter of said engine, said engine control including an operator input to allow an operator to signal a desire to eliminate torque between said engine output shaft and said transmission output shaft[.]\n
Exhibit A, col.7 ll.48-52 (emphasis added). Again, the Court looks first to the decision of the Board which noted:

The subject matter [of this invention] concerns . . . a vehicle drive having an engine control which in response to an operator signal determines a zero torque parameter value for the engine and which is operable to control the engine to achieve the zero torque parameter value[.] The significance of the zero torque parameter value is that when it is achieved, the transmission of the motor vehicle is free to be shifted to neutral without engagement of a clutch.

Exhibit D, supra, at 3 (emphasis added). The Board clearly stated that the operator signal resulted in the engine achieving zero torque parameter value. The Board did not go further and find that the operator signal also caused the shifting of gears after that zero torque parameter value had been met. In fact, the Board was quite specific: (1) the invention caused the transmission to achieve zero torque parameter in response to an operator signal; and (2) that torque elimination allowed the vehicle to be shifted to neutral without use of a clutch.

Despite the Board's conclusion, Meritor argues that the patent is not so limited, that is, there is nothing in the patent which excludes the signal from also accomplishing the gear shift. Eaton claims there is a distinction between eliminating torque and moving the gear into neutral versus selecting a gear and an automatic shift into that gear without further operator input.
For the same reasons as discussed above, the Court finds that Eaton's position is well taken.

Moreover, Meritor's expert, Dr. Hoff, opined that "[t]here are two distinct steps in shifting to another gear in a manual gearbox. The first step is to move the transmission from in-gear to neutral. The second step is to synchronize the speeds of the two halves of the transmission . . . so that the transmission can be engaged in a new gear." Exhibit Q, at 9. "The ['477] patent describes an apparatus to move transmission from in-gear to neutral without using the clutch, so the portion of shift . . . which is of primary interest occurs between the start of the shift . . . and the point when neutral is achieved[.]" Id. at 15.

By contrast, Eaton's expert, Mr. Speranza, opined:

Eaton's AutoShift and UltraShift transmissions are automated mechanical transmissions used on medium and heavy trucks. . . . Both AutoShift and UltraShift operate with a control console ("console"), which is the principal driver interface for these products.

The function of the consoles used in AutoShift and UltraShift is similar to that of the selector in a car having an automatic transmission. . . . In AutoShift and UltraShift, pressing the "D" button or moving the selector to "D" causes actuators in the transmission to put the truck transmission into drive mode and the transmission will shift to an appropriate starting gear[,] depending upon the start gear selected by the driver. The same is true for the other modes of operation: pushing the buttons or moving the selector to "R", "N" or "L" will cause actuators in the transmission to put the truck transmission into reverse, neutral or the selected starting gear, respectively. Pressing the "Manual" button or moving the selector to "Manual" on the AutoShift and UltraShift console permits the driver to hold the current gear. Provided the engine speed is not outside of defined limits, and other conditions related to the ability to perform the requested shift, the driver then may select the appropriate gear for road conditions using the up/down buttons. . . . Pressing the up/down button on the console while in "Manual" mode causes electronics in the console, transmission, and engine to evaluate whether a shift requested by the driver is allowable under the conditions.

The transmissions have an electric motor controlled by a computer that moves the dog clutch when disengaging from the currently engaged gear. . . . The net engine torque is a value that is continuously computed every 10 ms based on values broadcast over the J1939 data link - irrespective of any input from the driver or whether the driver has requested an upshift or downshift in Manual mode. . . . When the driver has requested a shift, the software routine will set a flag to true or false depending on whether the net engine torque is less than the "full on" torque thresholds. If net engine torque is less than the "full on" torque threshold during a software cycle after a shift request has been made, the flag will be set to "true" and the electric motor turned to "full on" power.

Exhibit E, at 2, 4-6 (emphasis added).

Despite the conclusion argued for by Meritor, its expert did not describe the '477 patent as including (1) torque elimination; (2) disengagement of the gear into neutral; and also (3) shifting by the transmission into a new gear. Indeed, the patent, both in the specification and claim language, refers to elimination of torque, followed by moving the gear into neutral with no description of a further shifting into gear except through the driver's use of the manual stick shift. See, e.g., Exhibit A, col.8 II.17-19 (Claim 9 - "A vehicle drive as recited in claim 1, wherein a manual stick shift allows an operator to manually shift said transmission speed ratios." (emphasis added)); id. col.8 II. 23-39 (Claim 11 - "A method of operating a vehicle drive comprising the steps of: . . . allow[ing] the operator to move said transmission to begin a speed ratio shift; . . . indicating a desire to eliminate torque by actuating said input switch; . . . manually moving said transmission out of engagement to a neutral position."). id. col.7 II. 5-14. 18

18 Lest Meritor argue that the Court is importing definitions from other claims, the Court notes that it is appropriate to consult "[o]ther claims of the patent in question, both asserted and unasserted, [which] can also be valuable sources of
enlightenment as to the meaning of a claim term." Phillips, 415 F.3d at 1314.

Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims. Differences among claims can also be a useful guide in understanding the meaning of particular claim terms.

Id. at 1314-15 (internal citations omitted).

Referring again to the specification,

an operator requests the torque elimination feature through button 48. The ECU [electronic control unit] varies the engine fueling as shown.[.] The operator applies force to the manual stick shift, attempting to move the collar and disengage the gear. As the actual engine fueling saw tooth profile crosses the actual zero torque value, the operator will be able to disengage the collar. A signal is sent to the ECU that the transmission is in neutral. Once a signal is received that the transmission is in neutral, control is either returned to the operator or an engine synchronization system as described generally in this application is then actuated to synchronize the speed to that which will be necessary at the next expected gear.

. . .

[A]fter the transmission is in the position shown[,] the operator must now engage a new selected gear. The present invention is preferably utilized with a system that then synchronizes engine speed with the speed necessary fo a smooth transition to the new transmission speed.

Exhibit A, col.6 II. 41-53; col.7 II. 3-8 (emphasis added). The patent does not claim the engine synchronization system, only the invention which allows the gear to be moved into neutral without a clutch. Cook Biotech, 460 F.3d at 1373. The Court concludes that Meritor's invention claims only the operator input to signal torque elimination without use of a clutch. Vitronics, 90 F.3d at 1582; Phillips, supra. It does not claim the further effecting of gear shift stemming from the initial operator signal. Id. Once the torque is eliminated, the transmission may be shifted into neutral and thereafter, into a new gear. Id. But, this requires further operator input. Thus, "operator input to allow an operator to signal a desire to eliminate torque" is so construed.

2783

The parties' first dispute concerns the construction of the phrase "side members which include opposing surfaces." Id. at col.6 I.22. The central issue in construing this phrase is the scope of the term "opposing surfaces." CPT argues "opposing surfaces" should be construed as "side members, each having a surface that faces or looks toward the corresponding surface of the other side members." Def.'s Claim Constr. Br. at 10. According to CPT, the "opposing surfaces" are restricted exclusively to the inner surfaces of the side members. IKN, on the other hand, contends the term "opposing surfaces" should not be so limited, but instead should be construed to mean "surfaces positioned across from each other." Pl.'s Claim Constr. Br. at 7. This construction would include, as IKN argues, the upper edges of the side members in addition to the inner surfaces.

Beginning with an evaluation of the claim language itself, the repeated use of the word "said opposing surfaces," which appears in relation to three limitations in the claim, reveals the patentee intended to use this term uniformly in defining the invention. According to Claim 1, the plate members must be "supported on," "extend[] transversely between," and be "releasably connectable" to "said opposing surfaces of said side members." The construction of this phrase must practically satisfy each of these conditions and remain logically consistent in defining the scope of the property right. More precisely, the term cannot be construed as the inner surfaces of the side members that oppose one another as applied to one limitation while, with respect to another limitation, given a broader construction to include additional surfaces.

The language in two of the dependent claims also informs the construction of independent Claim 1. My review of the
CPT advances the same prosecution history argument with respect to the construction of two of the limitations in Claim 1. Evidence.

Therefore, based on the logical relationship of the claim terms reveals construing the phrase "said opposing surfaces of said side members" as limited to the inner surfaces of the elongated side members ensures consistency and uniformity in defining the invention. For example, it would be inconsistent to construe the term "said opposing surfaces" in Claim 1 to include, as IKN contends, the surfaces positioned across from one another and to simultaneously impose this construction on dependent Claims 5 and 7, wherein the patentee distinguished the inner opposing surfaces from the upper edges of the longitudinally extending side members. Thus, the claim language, standing alone, does not permit a logically consistent construction of the term "opposing surfaces" that could include the upper, outer, and bottom surfaces of side members.

The specification in the '555 Patent also provides substantial support for construing the term "said opposing surfaces of said side members" as limited to the inner surfaces that oppose one another. Two preferred embodiments of the invention, which are depicted in Figures 2 and 6 of the '555 Patent, reveal the limitations associated with "opposing surfaces" can only be satisfied if the term is construed to exclusively include the inner surfaces of the frames that oppose one another. Stated conversely, upon consideration of these figures, it is impracticable to adhere to any of the limitations if "said opposing surfaces" were construed to broadly include the upper edge, outer surface, and lower edge of the side members. In the "Summary of the Invention," the patentee explained "the longitudinal guide profiles are . . . provided on the inner surfaces of the sidewalls above said upper edge of the front wall, which inner surfaces face one another . . . ." Id. at col.2 1.48-51 (emphasis added). Three paragraphs later, the patentee again distinguished the surfaces of the side members by stating "the plate members have on each of their lateral edges a longitudinal flange designed to cover the upper edge of an associated side member." Id. at col.3 1.9-11. The sentence from the specification that most informs the proper construction of the phrase "said opposing surfaces" is contained in the "Description of the Invention," wherein it states: "FIGS. 2 and 3 show that the longitudinally extending grooves 18, 20 are provided on the opposing inner surfaces of the sidewalls 12, 14." Id. at col.4 1.33-35 (emphasis added). When the patentee wished to refer to more than just the "opposing inner surfaces" of the three-dimensional side members, the patentee used the term "sidewalls" or "side members" to describe this structure. Id. at col.2 1.42-44 ("The side members are, in a preferred development of the invention, formed by sidewalls which are parallel to one another . . . ."). Simply put, the patentee, in describing the invention to a person of ordinary skill in the art, chose terms that plainly distinguish the opposing inner surfaces of the elongated side members from the other surfaces of the frame. Therefore, based on the logical relationship of the claim terms, the need for consistency in defining the invention, and the information from the specification, I will construe the term "side members which include opposing surfaces" as "side members, each having an inner surface that faces or looks toward the corresponding surface of the other side member." 9

9 CPT also argues that, during the prosecution of the '555 Patent, the patentee surrendered all other surfaces of the side members except the inner opposing surfaces. As originally submitted, the claim contained only one limitation: the plate members were required to be releasably connectable to the opposing surfaces. CPT contends a comparison of the claim as originally submitted and as eventually approved by the PTO reveals the claimed invention was narrowed to include only the inner opposing surfaces of the side members.

Although there is merit to CPT's argument, the claim language itself and the specification provide ample guidance in construing the phrase "said opposing surfaces of said side members." Therefore, the role of the prosecution history here is limited, at most, to confirming the scope of the property right as adequately revealed by the primary forms of intrinsic evidence.

CPT advances the same prosecution history argument with respect to the construction of two of the limitations in Claim 1.

- 3318 -
K. "an object attached to said connecting device opposite and directly below the free end of said member;"

The Court finds that the words used in describing the placement of the object do not require any definition. The Court construes the phrase "opposite and directly below the free end of said member" to simply mean "on the opposite side of the connecting device from the elongate member, and also directly below the free end of said member."

2. Claim Eight

Claim 8, clause 2 reads as follows: "wherein resilient gripping structures are mounted to extend along opposite sides of said housing." SCM argues that to remove any ambiguities, this claim should be interpreted to require that gripping structures appear on all opposite sides of the housing.

The term "opposite sides" is not defined in either the claims or the specifications. SCM's construction is unduly restrictive and not ordinary or usual. Its construction requiring gripping structures on all sides of the invention would essentially cover the calculator with rubber. This is at least unreasonable, if not absurd.

SCM also argues that if its construction is not accepted, the claim is too indefinite. Once again, SCM does not offer clear and convincing evidence that one skilled in the art would not be able to ascertain which "opposite sides" are at issue. We decline to invalidate the claim for indefiniteness.

The gripping structures function to aid someone in handling the calculator. This is illustrated by the definition of gripping, the claims and the specification. Gripping is defined as "having the ability to grip." Webster's Third New International Dictionary. In turn, "grip" is defined as "to seize or lay hold on tightly" or to "grasp firmly." Gripping, therefore, implies that the structures are intended to help someone, presumably the user, hold onto the calculator. Claim 9, clause 2 is consistent with this interpretation because it explains that the gripping structures are to "facilitate manual handling of the calculator."

Moreover, the preferred embodiment is also consistent with this interpretation, as it indicates that the gripping structures will prevent the calculator from slipping out of the hand of the user. Col. 6:32-36.

In light of the foregoing, we conclude that putting gripping structures on the front and rear sides would interfere with the use of the calculator and does not aid in its handling. While gripping on the back might prevent the calculator from slipping out of someone's hand, it is unnecessary and counterproductive to have gripping structures on the front where the actuator buttons are located.

Also, putting gripping structures on the top and bottom sides of the calculator would not facilitate handling because those
sides are unlikely to make contact with someone's hand if the calculator is being held when in use. Moreover, gripping on the top would most likely, if not invariably, inhibit the proper function of the lid. Thus, logically it appears that the only opposite sides that would facilitate the handling of the calculator are those on the right and left sides of the calculator.

One skilled in the art would understand "opposite sides" in Claim 8, clause 2 to be the pair of sides that facilitates the grasping of the hand-held calculator. Accordingly, we construe "opposite sides" to be the right and left sides of the calculator.

**2786**

B. Claim 2 of the '715 Patent

The Magistrate Judge recommends that the Court grant Defendants' Motion for Summary Judgment on claim 2 of the '715 patent. Plaintiffs object to the R&R, arguing that the Magistrate Judge improperly interpreted the "deflector plate" element of claim 2 and, thus, erroneously concluded that the accused devices lack that element. Specifically, Plaintiffs object to the conclusion that the accused devices do not equivalently infringe on the patented devices.

Claim 2 of the '715 patent includes the following limitation:

> a deflector plate mounted on the axial shaft opposite the passages for preventing straight line impingement of gas therefrom on the bag.

The Magistrate Judge rejected Plaintiffs' contention that "the extended area around the perimeter of the diffuser and the upper corner around the circumference" serves as the deflector plate in the accused devices. First, the Magistrate Judge interpreted the phrase "opposite the passages" as mandating that the deflector plate is not part of the element containing the gas passages. In doing so, the Magistrate Judge rejected Plaintiffs' argument that the phrase means "in opposition to the passages," reasoning that Plaintiffs' "definition twists the plain and common meaning of 'opposite' and finds no support in the claim, the patent specification, or the prosecution history." (R&R at 25). Accordingly, the Magistrate Judge found that the accused devices do not literally infringe on the patented device since the accused devices' diffuser contains the gas passages and "if the deflector plate is the diffuser, then it must be opposite itself to meet this claim limitation." Id. Defendants' Response corroborates this interpretation by emphasizing that the plain meaning of the claim requires such an interpretation by virtue of the term "therefrom"; in other words, "the deflector plate must deflect gas exiting 'therefrom' -- that is, gas exiting the gas passages." (Def.'s Resp. at 7 n.4). Defendants further point out that the specification corroborates the Magistrate Judge's interpretation, namely, in its discussion of Figure 3, which does not have a deflector plate separate and apart from the inflator housing, the specification states: "By angling the holes [gas passages] outwardly, the need for a deflector plate may be avoided." ( '715 patent, col. 7, ln. 3-4).

The Court construes Plaintiffs' objection, which conflates the claim interpretation, literal infringement, and doctrine of equivalents analyses, as objecting to the equivalency determination, because the gist of Plaintiffs' argument is that "the Report fails to fully analyze the functionality of the deflector plate which failure results in the Report's erroneous claim interpretation." (Pl.'s Obj. at 7)(emphasis added). The R&R explains that "the functionality of the deflector plate is for preventing straight line impingement of gas therefrom on the bag. Since the accused devices are all radial-flow (rather than axial-flow) designs, there is no need for the deflector plate to block gases from traveling into the front of the bag and thus toward the vehicle occupant."

Plaintiffs argue that the deflector plate "turn[s] the gas generated from an axial (toward the driver) direction to a radial (toward the sides of the bag and away from the driver) direction," and that the accused devices have structure designed to achieve the same function in substantially the same way to obtain substantially the same result as the deflector plate element of claim 2. Id. at 8. In support, Plaintiffs point to evidence that the gas generated within the accused devices flows in an axial direction and the area around the perimeter of the diffuser and the upper quarter around the circumference turn the gas to a radial direction.

However, as Defendants explain in their Response, Plaintiffs' argument is unavailing. Rather, the Magistrate Judge was referring to the gas exiting the inflator, whereas Plaintiffs' argument that the accused devices have an axial flow refers only
to the gas when it is within the inflator. This distinction is crucial to the equivalency determination, as it is an undisputed fact that the gas exiting an inflator determines whether that inflator has purely radial flow and, hence, thrust-neutrality. (SOF P 211). In contrast, gas exits the ’715 inflator with an axial flow. Because the purely radial flow achieved by the accused devices renders the differences in the allegedly equivalent structure substantial, Plaintiffs’ objections are overruled. Accordingly, the Court adopts the R&R as to claim 2 of the ’715 Patent and GRANTS Defendants’ Motion for Summary Judgment as to Noninfringement of claim 2 of the ’715 patent.

A. Court's Review of the Special Master's Report and Recommendation Regarding Definition of "Optical Arrangement."

In reviewing the Special Master's Report, this Court reviews de novo the findings of fact and conclusions of law objected to by the parties. Fed.R.Civ.P. 53(g)(3)&(4). All other findings of fact and conclusions of law may be reviewed de novo. See Fed.R.Civ.P. 53 advisory committee note on 2003 amendment.

The construction of patent terms is a question of law determined by the court. Markman v. Westview Instruments, Inc., 52 F.3d 967 (Fed.Cir. 1995). The Court must first look to the intrinsic evidence of the patent to determine the scope of the claims. Id. at 979. The intrinsic evidence includes the words of the claims themselves, the specification, and the prosecution history, if in evidence. Id. Where the use of intrinsic evidence alone will resolve the ambiguity in a disputed term consideration of extrinsic evidence is improper. Hockerson-Halberstadt, Inc., v. Avia Group, Int'l, Inc., 222 F.3d 951, 955 (Fed.Cir. 2000). However, the court may in its discretion receive extrinsic evidence to aid the court in coming to a correct conclusion as to the true meaning of language employed in the patent. Markman, 52 F.3d at 980. "Extrinsic evidence consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises." Id.

B. Erchonia's Objections to Special Master's Final Report and Recommendation.

Erchonia has set forth multiple bases in opposition to the Special Master's Final Report and Recommendation regarding his interpretation of the term "optical arrangement." Erchonia contends that Special Master's final recommendation is flawed because "optical arrangement" does not necessitate that there be two or more optical devices but rather that it can consist of a single lens or other optical device. However, in reviewing these objections it is clear that the Special Master properly considered the record before him and evidence presented to come to a logical conclusion regarding the meaning of "optical arrangement."

(1) The Parties Discussed The Definition of "Optical Arrangement" That is Proposed by the Special Master.

First, Erchonia argues that the modifications added by the Special Master to the definition of "optical arrangement" were improperly raised by REM in its Response to the Special Master's Draft Report and Recommendation. (Erchonia Objection, p. 5). However, a review of the record simply does not support that argument. Rather, a review of the Markman Hearing transcript reveals that these modifications to the definition of "optical arrangement" were discussed by both parties and, at the very least, the parties were able to come to a common understanding of the meaning of "optical arrangement" at the Markman hearing. At the Markman hearing the following discussion took place:

Special Master Peterson: Okay, I am going to dictate slowly the definition for "optical system" taken from the McGraw-Hill Dictionary of Scientific and Technical Terms, and it is in the field of optics. It is, quote: A collection comprising mirrors, lenses, prism and other devices placed in some specified configuration which reflect, refract, disperse, absorb, polarize or otherwise act on light period, close quote. Now, my question, Mr. Brunelli, is what, if anything, in the specification or prosecution history would indicate that would incorrectly describe "optical arrangement"?

Mr. Brunelli: Okay. I've got two points. One, I read the definition as requiring at least -- Because of the word "collection," I read that as requiring at least two of these things. Is that how you're reading it, as well?

Special Master: Well, I hadn't gotten to that point yet, but all right.
Mr. Brunelli: So if there is -- I suppose you could read "collection" as requiring only one or more of these, as well, so there is an ambiguity there. If it's -- If it's not at least two, I think neither the Specification nor the file history support -- would support the reading. Second, I believe that a -- "other devices" is broad in that it may include things that are not optics such as mechanical elements, a mechanical mask, or an electromechanical element such as a motorized mirror. Those are clearly -- Those type of things are clearly not encompassed by the specification.

Special Master: Well, just a second. Let me -- We can solve that issue easily by changing "other devices" to "other optical devices."

Mr. Brunelli: Okay.

Special Master: And if we just make it clear, we say "a collection comprising two or more . . ."

Mr. Brunelli: If we went with "a collection comprising two or more mirrors, lenses, prisms or other optical devices placed in some specified configuration which reflect, refract, disperse, absorb, polarize, or otherwise act upon light" and you're asking me if that would be a acceptable definition for "optical system," and clearly I think that would because it came out of the dictionary, as you just stated, and the next question becomes does "optical system" -- can optical system" be changed for "optical arrangement"? Am I following you?

Special Master: Well, no, you're changing the second question slightly. Is that an accurate definition of the term "optical arrangement" as it is used in the context of the patent and prosecution history of the case?

Mr. Brunelli: Well, I really think that the -- because of the way this patent was drafted, I really think that the patentee defined "optical arrangement" as being a particular thing.

Special Master: I understand.

Mr. Brunelli: But let's -- let's assume that argument is falling -- is falling short, in your opinion, and so I will argue in the alternative. If, in the alternative, "optical arrangement" is -- is not -- has not been defined, then I think the proposed definition that we've just run through would work in understanding what is meant by "optical arrangement" as used in the claims of the 096 Patent.

Special Master: All right. Mr. Schwartz, did you have anything to say in closing?

Mr. Schwarz: Well, I think those are good questions then. I will tell you that I think that -- seeing the file history, that there is -- that the examiner, at least, had the opinion that optical -- Well, he had a discussion about other optical arrangements as taught in Oshiro and Blum, kind of my interpretation of his -- what you stated, he had a long discussion about other optical arrangements that could be used, including light generating prisms and lenses and those things, and discussed that they were well-known in the art. So I would support your -- I support the contention that "optical arrangement" is broader than just a line generating prism and a collimating lens. And I also, as I said earlier, believe "optical system" and "optical arrangement" are equivalent.

Special Master: All right. Let me -- Let me ask you, Mr. Schwartz, from that definition that we just discussed with Mr. Brunelli would that be acceptable from your standpoint?

Mr. Schwartz: I think that the definition you just read out of the McGraw-Hill Dictionary was extremely accurate. I don't have any concern what you've proposed as alternative language here other than making clear two things. When you say -- you had -- At one point in your discussion Mr. Brunelli said "comprising two or more." I'd like to make clear that it can be in combination. You could obviously have a lens and a prism, it doesn't have to be two lenses or two prisms, although I think that's what you intended anyway. (Emphasis added).

Special Master: Yes.

Mr. Schwarz: The only point where I disagree with Mr. Brunelli was he made a point of saying that a motorized mirror, he believed, would be a mechanical device. I think that a mirror, whether it's motorized or not, is an optical device, but I'm
not sure we need to go that far for purposes of this discussion.

Special Master: All right. All right. Anything else, Mr. Schwartz?

Mr. Schwartz: No sir. I think that gives you a good flavor. I would just refer you, as I know you're fully familiar, to the briefs or anything that we didn't address during oral argument.

The above discussion demonstrates that both parties were given an opportunity to discuss and dispute the meaning of "optical arrangement" wholly consistent with the construction the Special Master recommends now. Additionally, a plain reading reveals that the parties seemed to be in general agreement that the proposed definition by the Special Master in his Final Report and Recommendation was appropriate.

(2) The Prosecution History and Prior Art Support the Special Master's Recommendation.

Second, the Special Master's Final Report and Recommendation soundly describes his determination that an "optical arrangement" calls for two or more optical devices. Despite Erchonia's argument to the contrary, the prosecution history and prior art supports the Special Master's recommendation that "optical arrangement" consist of two or more optical devices rather than just a single optical device as Erchonia contends.

Specifically, Erchonia contends that the Special Master failed to appreciate that the Patent Examiner of the 096 patent considered the possibility that "optical arrangement" could be made up of a single prism. Erchonia cites the Patent Examiner's statement in rejecting claim 5 of the 096 Patent that it would have been obvious "to modify the combined device of Ohshiro et al and Blum et al, with Itzkan to provide a line generating prism as an alternative, equivalent means for focusing the light onto the tissue in a line." (Draft Report and Recommendation p. 82, citing Office Action at 4). Erchonia contends that this statement shows that the Patent Examiner considered the possibility of a single prism acting as an optical arrangement on the 096 Patent, thus supporting its position that "optical arrangement" does not necessitate two or more such devices. However, as noted by REM, this argument has been addressed by the Special Master with sound reasoning. Most significantly, the Patent Examiner's statement, cited above, was made in the context of rejecting claim 5 of the original 096 application on the basis of obviousness in light of the prior art. Specifically, application claim 5 (ultimately patent claim 4) specified in pertinent part:

5. The device of claim 1 wherein said optical arrangement includes:

   a. collimating lens; and

   b. line generating prism, said collimating lens and line generating prism disposed in a serial relation to said generating means.

(Final Report and Recommendation, p. 118).

The Patent Examiner's rejection was based upon two optical devices, a "collimating lens" and "a line generating prism." Thus, it cannot be said that the Patent Examiner contemplated only one optical device.

Additionally, Erchonia's reliance Ohshiro et al., patent # 4,905,690, a prior art reference to the 096 Patent, for the proposition that "optical arrangement" may consist of only one optical device is not persuasive. As noted by the Special Master, the Ohshiro patent consists of a "series of lenses." (Final Report and Recommendation, p. 49, Exhibit 1 to REM's Response, abstract of Ohshiro et al.). Obviously, a "series of lenses" would suggest more than one lens or optical device.

Lastly, Erchonia's reliance on the Sousa et al, patent # 5,822,345, to lend support to its argument that "optical arrangement" does not necessitate "two or more" optical devices is not persuasive. As Erchonia points out, the Special Master noted that the Sousa et al specification relates that "optical system 13, . . . can be a focusing lens or other suitable optical arrangement . . . " (Draft Report and Recommendation, p. 89, Exhibit 2 to REM's Response, 345 patent, col. 7, ll. 19-22). However, the Sousa patent specification also possesses language suggesting that "optical arrangement" calls for two or more
optical devices, or lenses. Specifically, in the same specification, the patent calls for a "series of lenses." (Exhibit 2, to REM's Response, 345 patent, col. 5-6, ll. 62-8).

Thus, the prosecution history of the 096 patent and the prior art addressing "optical arrangement" reasonably suggest that an "optical arrangement" would likely require at least two or more lenses or devices. At the very least, contrary to Erchonia's position, the prosecution history and prior art of the 096 Patent do not evidence that an ordinary person skilled in the art would equate "optical arrangement" with only one such device.

(3) The Special Master Did Not Improperly Apply The Preferred Embodiment Into The Claims.

Erchonia also argues that the Special Master improperly read claim limitations from the preferred embodiment when interpreting "optical arrangement" in the independent claims. Specifically, Erchonia relies on the Special Master's reference in the Final Report and Recommendation that the specific embodiment disclosed in the specification of the 096 Patent has at least two optical elements or devices; specifically the "collimating lens" and "line generating prism." (Final Report and Recommendation, p. 120). However, Erchonia's argument is not well taken as it even acknowledges that the Special Master did not relate that specific limitation from the preferred embodiment of a "collimating lens" and a "line generating prism" into the definition of "optical arrangement." (Erchonia's Objection to Final Report, p. 7-8). Rather, the definition of "optical arrangement" is broader in that it only requires "two or more . . . optical devices." Therefore, it is difficult to see how the Special Master improperly read the limitations of the preferred embodiment of the 096 into the definition of "optical arrangement."

This same line of reasoning also rebuts Erchonia's argument that the Special Master ran afoul of the doctrine of claim differentiation, which prohibits dependent claim limitations from being read into independent claims. See Curtiss-Wright Flow Control Corp. v. Velan, Inc. 438 F.3d 1374, 1380 (Fed. Cir. 2006). As discussed above, the Special Master's definition of "optical arrangement" requires only a collection of "two or more . . . optical devices." (Final Report and Recommendation, p. 123). Whereas, the limitations of the preferred embodiment, such as in dependent claim four, relate that the dependent claims involve a "collimating lens" and "a line generating prism" which are distinct types of "optical devices." (Final Report and Recommendation, p. 120). Therefore, because the independent claim is based upon the broad category of "optical devices" and the dependent claims involve specific types of "optical devices" it cannot be said the Special Master read the claim limitations into the independent claims.

(4) The Special Master Did Not Improperly Assign A Burden of Proof.

Lastly, Erchonia argues that the Special Master improperly assessed it a burden of proof in determining the meaning of "optical arrangement." Specifically, Erchonia cites the Special Master's determination that neither party had provided proof of the question of how one of ordinary skill in the art would interpret "optical arrangement." However, Erchonia's argument is not persuasive because the fact that the Special Master noted that both parties provided inadequate evidence in support of their purported interpretations of "optical arrangement" does not mean he assigned a burden of proof to either party. It simply demonstrates that the evidence presented by both parties was not helpful in making the ultimate determination. Rather, the Special Master turned to other reliable means of interpretation such as other intrinsic and extrinsic evidence.

C. The Definition of "Optical Arrangement"

The Special Master followed proper procedure in formulating his final recommendation regarding the term "optical arrangement." He looked first to the intrinsic record to determine the proper definition of "optical arrangement." However, after reviewing the intrinsic record, including the claim language, prosecution history and specification it is unclear if one of ordinary skill in the art would determine if an "optical arrangement" can be made up of just one "optical device" or calls for at least two. (Final Report and Recommendation, pp. 120, 121).

Because, of this uncertainty, it was appropriate for the Special Master and is appropriate for this Court to turn to available extrinsic evidence available. Here, the Special Master with the parties consent turned to the dictionary, to resolve any ambiguity. Phillips, 415 F.3d 1303 at 1318-19 (2005). Both parties generally agreed to the persuasiveness of the McGraw-Hill Dictionary of Scientific and Technical Terms (5th Ed. 1994) with its definition of "optical system."

First, as noted by the Special Master, the plain meaning of term "arrangement" connotes multiple parts. See Merriam-
Webster's Collegiate Dictionary (10th Ed. 1999) at 64 (defining "arrangement" as "something made by arranging parts or other things together"). Thus, the term itself would call for at least two devices, not a single device as Erchonia contends.

Second, the technical definition of "optical system" as defined in the McGraw-Hill Dictionary of Scientific and Technical Terms (5th Ed. 1994) is, "a collection comprising mirrors, lens, prisms, and other devices, placed in some specified configuration, which reflect, dispense, absorb, polarize, or otherwise act on light." (emphasis added). This definition speaks in terms of multiples and again indicates that "optical arrangement" would call for at least two or more devices.

Thus, when turning to plain language of the dictionary terms of "arrangement" and "optical system" it is apparent that the term itself indicates that more than one "optical device" is necessary. The Court in performing a review of the intrinsic record and extrinsic record agrees with the Special Master's final recommendation that "optical arrangement" as listed in independent claims 1 and 10 means:

A collection comprising two or more mirrors, lens, prisms, or other optical devices, placed in some specified configuration, which reflect, refract, dispense, absorb, polarize, or otherwise act on light. That definition allows for a combination of two or more different optical devices. Also, a mirror whether it is motorized or not, is an optical device.

Therefore, the Court adopts the Special Master's Final Report and Recommendation.

5. Optical Axis

The term "optical axis" is found in Claims 10(a), 14(a) and 14(b) of the '461 patent. Vision Advancement initially advanced a construction of the term "optical axis" as "A straight line perpendicular to the front of the lens and extending through the center of the pupil." Vistakon first proposed, "The straight line normal to both faces of a lens along whose path a ray will pass without being deflected."

At the Markman hearing, the parties agreed with the Court's proposed construction. Thus, the Court construes "optical axis" to be "A straight line perpendicular to the front of the lens and extending straight through the lens without being deflected."

1. An optical bench mounted in said compact housing and extending along a central reference axis

As for the above term, the parties agree on what constitutes a compact housing, see Pl.'s '852 Markman Br. at 9, as well as what constitutes an optical bench. See id.; see also Palmer Rebuttal, at 23. The issue in dispute is whether the optical components must be mounted on a separate structure that is attached to the housing by some fastening means, as defendant asserts, or whether the optical bench can be a rigid structure within the housing of the scanner to which the optical components are mounted on the housing itself to prevent movement of the individual optical components relative to each other, as plaintiff argues. Plaintiff construes the term "optical bench" as requiring that "the device have a rigid fixed structure to which the optical components are mounted. An optical bench is generally understood to be one of ordinary skill in the art as a rigid structure to which optical components are mounted." Pl.'s '852 Markman Br. at 9. Plaintiff argues that the limitation simply requires that "there be a rigid structure within the housing of the scanner to which the optical components are mounted to prevent movement of the individual optical components relative to each other." Id. at 10. Plaintiff further identifies the back wall of the housing as a rigid structure to which the optical components can be mounted.

Defendant PSC construes this term as requiring two structures: an optical bench and a housing that are interconnected in a particular way. Def.'s '852 Br. Mot. Partial Sum. J. at 32. Defendant construes the claim as specifying a further structural relationship between these two elements, namely, that the optical bench must be mounted in a specific way to the housing.
See id. Specifically, defendant provides the following definition of "optical bench mounted in a compact housing":

There are two distinct structures -- an optical bench and a compact housing -- that are interconnected in particular manner, through mounting. The optical bench is mounted in the compact housing. The optical bench itself is a flat, rigid piece of metal (or similarly dimensionally-stable material) to which optical components are mounted.

PSC Markman Presentation, Ex. 65. Defendant maintains that the optical components must be mounted on a separate structure that is attached to the housing by some fastening means, citing the specification, which provides that "optical bench 74 [is] mounted via fasteners 76, on the inside surface of the rear wall 50 of the housing section 64 (see FIG. 3.)" '852 Patent, col. 7, 11. 13-14.

Plaintiff argues that those of ordinary skill in the art recognize that an optical bench is any rigid structure for mounting optical components. In response to defendant's argument with respect to the specification language, plaintiff asserts that the embodiment depicted in the patent simply represents one way of fixing optical components within the housing, and thus the embodiment shown in the '852 patent should not be read into the claims as requiring that the optical bench be a separate structure attached to the housing using fasteners.

The claim language of Limitation 2 provides for "an optical bench mounted in said compact housing and extending along a central reference axis[]." '852 Patent, col. 11, 11. 43-45. The specification language regarding the optical bench provides:

The optical bench 74 as clearly seen in FIGS. 2-4 is a generally rectangular, plate-like member which includes a flange extending along its two side edges and along its bottom edge.

'852 Patent, col. 7, 11. 36-39 (emphasis added). The specification also refers to the optical bench in discussing the method by which a laser beam is produced and swept across the optical components in the housing:

The means for producing the beam, focusing it, sweeping it through the housing, folding it and directing it out of the housing window are all mounted on an optical bench mounted via fasteners 76 on the inside surface of the rear wall 60 of housing section 64 (see FIG. 3).

See id. at col. 7, 11. 11-16 (emphasis added). This language raises a question as to whether the optical bench is attached to the housing via fasteners, or whether the "means for producing the beam" are mounted to the optical bench via fasteners, due to the positioning of the words in the specification. Additional specification language provides the following:

All of the mirrors are of generally planar and are mounted on the optical bench 74 adjacent the polygon 42 and under the window 30. In particular the mirrors 82-90 are mounted via a spider member 116 having five angled brackets 118, one for each mirror. The spider 116 secured to the optical bench 74 via the fasteners 76. Preferably the mirrors 82-90 are glued in place on the spider's brackets 118.

'852 Patent, col. 8, 11. 21-29 (emphasis added). This language creates the implication that the mirrors 82-90 are included within the "means for producing the beam, focusing it, sweeping it through the housing, folding it and directing it out of the housing window." The specification language indicating that the fasteners 76 fasten these mirrors to the optical bench 74 necessarily implies that the fasteners 76 in the earlier passage of the specification functioned to fasten the "means for producing the beam" to the optical bench, not to fasten the optical bench to the housing.

As defendant pointed out at the Markman hearing, the specification further describes that certain components are mounted or fixedly mounted onto the optical bench:

The details of the reflecting means made up of mirrors 82-90 will now be described. All of the mirrors are of generally planar and are mounted on the optical bench 74 adjacent the polygon 42 and under the window 30.

'852 Patent, col. 8, ll. 20-24 (emphasis added).

The laser diode 78 is fixedly mounted on the optical bench adjacent the bottom edge flange and is oriented parallel to the bench so that it projects a laser beam 48 parallel to the optic bench and in a transverse direction, that is parallel to the
transverse axis 34 of the window 30.

Id. col. 7, ll. 40-44 (emphasis added).

The polygon is mounted on the rotary output shaft of a motor 112 which is fixedly mounted on the optical bench so that its rotation axis 44 intersects an axis 114.

Id. col. 7, ll. 55-57 (emphasis added).

The focusing lens 96, as can be seen in FIGS. 2-4 is mounted opposite the collecting mirror along central longitudinal axis 114 and above the polygon 42. The means for mounting the focusing lens at that position comprises a bracket 124 fixedly secured to the front portion of the optical bench 74.

Id. col. 9, ll. 38-44 (emphasis added). The specification language referring to optical components being mounted, fixedly mounted, or fixedly mounted to the optical bench by use of a bracket, supports the conclusion that the preferred embodiment of the patent clearly envisioned the use of brackets or fasteners to mount certain components to the optical bench. This language in no way, however, refers to the mounting of the optical bench to the compact housing. Contrary to defendant's argument, the specification language further supports the reference of fasteners or brackets in the patent to mounting the components involved in producing and focusing the beam onto the optical bench, not for mounting the optical bench inside the compact housing.

In considering the claim language and specification language, there being no relevant prosecution history either raised by the parties or found in the parties' submissions, the term "optical bench mounted in said compact housing" is construed as a rigid structure within the housing of the scanner to which optical components are mounted to prevent movement of the individual optical components relative to each other. There is no requirement that the optical bench be mounted to the compact housing by fasteners or brackets.

2790

C. Optical disk.

The plaintiffs propose that the term be defined as "an optical storage medium." The defendants argue that the term should be defined as "a disk shaped storage device that is read by a laser, or other form of light." In the context of this patent, the court is persuaded that one of skill in the art would agree that the defendants' construction is correct. Indeed, the plaintiffs note that the defendants' construction "does not substantively vary from their proposed construction." (Plaintiffs' Brief at 15).

"Optical disk" is defined as "a disk shaped storage device that is read by a laser, or other form of light."

2791

3. "an optical element collecting light scattered"

Unlike the previous disputed terms or phrases in the '325 patent, the phrase "an optical element collecting light scattered" appears only in claim 36. ADE does not assert any specific meaning for the phrase. KLA, however, maintains that the phrase means that a plurality of optical elements collect scattered light from the surface of a silicon wafer during scanning and distribute said light to two or more PMT type detectors. D.I. 338 at 18. This court agrees, in part, with KLA's argument.

Claim 36 recites "an optical element." '325 at 18:31-37. The indefinite articles "a" or "an" can carry the meaning of "one or more" given an open claim format (a claim using the word comprising, including, or similar terminology). North Am. Vaccine, Inc. v. Am. Cyanamid Co., 7 F.3d 1571 (Fed. Cir. 1993). To the extent that KLA construes this phrase to mean that a "plurality" of optical elements is an affirmative element of claim 36, this court disagrees. The '325 disclosure teaches that more than one optical elements can collect scattered light from the surface during a scan. '325 at 6: 39-41. Claim 36 claims "an optical element." '325 at 18:31-37. It does not claim a "plurality" of optical elements to the exclusion of a single optical
In terms of defining the scope of a patented invention there may exist a contrast between an invention that reads upon a device containing "an optical element" (meaning one or more) and an invention that requires as an element a "plurality" of optical elements. For example, a claim preceded by the transitional word "comprising" and containing as an element "an optical element" may read on a device with "one" or a "plurality" of optical elements. A claim preceded by the transitional word "comprising" and containing as an element a "plurality" of optical elements would not necessarily read upon a device with only "one" optical element. Infringement in this later scenario would depend upon whether a patentable distinction exists between an invention with "an optical element" and an invention with a "plurality" of optical elements.

Without making any ruling as to whether a patentable distinction does or does not exist in the present litigation with respect to "an optical element" or a "plurality" of optical elements, this court holds that the phrase "an optical element collecting light scattered" means that one or more optical elements collects light. It does not mean that a "plurality" of optical elements collects light to the exclusion of collection of scattered light by a single optical element. Although this may be a splitting of the proverbial hair, inventors are entitled only to what is claimed, not what the claim language is later asserted to subsume for the purposes of litigation. Bell & Howell DMP Co. v. Altek Sys., 132 F.3d 701 (Fed. Cir. 1997); see also Roton Barrier, Inc. v. Stanley Works, 79 F.3d 1112 (Fed. Cir. 1996).

2. "Optical Element in a Telescope"

The term "optical element" appears, in either singular or plural form, in claims 1, 10, 15, 18 and 20. As used in the '908 Patent, the term "optical element(s)" includes mirrors, lenses, or prisms.

Plaintiff argues that "optical element in a telescope" should be restricted to "mirrors." (Pl.'s Reply Br. at 2.) In contrast, defendant contends that the phrase "optical element" is much broader, and includes "lenses," "mirrors," and "prisms," thus comporting with its dictionary definition. (Pl.'s Reply Br. at 3, P2.)

As a threshold matter, the term "optical element" must include both lenses and mirrors because this Court's construction of the term "telescope" includes both reflecting and refracting telescopes. However, "optical element" includes both mirrors and lenses based on other intrinsic evidence as well.

Looking to the patent claims, there are several places in which the doctrine of claim differentiation indicates that the term "optical element(s)" is not limited to mirror(s). The clearest example of this point is a comparison of claims 15 and 16. Claim 15 is an independent claim that is nearly identical to claim 1. See '908 Patent at 7:3-8. It describes "[a] method of aligning an optical element in a telescope, comprising: (a) projecting a holographic image onto at least a portion of an optical element to be aligned; and (b) aligning the optical element in response to the projected holographic image." Id. Claim 16 is "the method of claim 15, further comprising employing a mirror as the optical element." Id. at 7:9-10. Since claim 16 is a dependent claim, which, by definition, must add a limitation, and the limitation it adds is that the optical element be a mirror, the doctrine of claim differentiation instructs that the term "optical element" is not limited to a mirror.

Claims 10 and 11 have a similar relationship. Claim 10, like claims 1 and 15, describes "[a] method of aligning an optical element in a telescope." Id. at 6:55 (emphasis added). Claim 11, which is dependent upon claim 10, is "the method of claim 10, further comprising employing a plurality of mirrors as the optical elements." Id. at 6:61-62 (emphasis added). If the only "optical element" in a "telescope" could be a "mirror," then claim 11 would be redundant in requiring a "plurality of mirrors as the optical elements," since the only optical elements in a telescope would be "mirrors." Based on the doctrine of claim differentiation, the claim language evinces an intent that "optical elements in a telescope" should include more than "mirrors."

Next, looking to the specification, the introduction states that "the present invention generally relates to the alignment of optical elements, and more specifically to the alignment of mirrors in a telescope." Id. at 1:6-8, 11. If the term "optical elements" were restricted to "mirrors" then the introduction to the specification would be redundant by using the phrase "the alignment of mirrors in a telescope." The presence of the second clause of the sentence indicates that the term "optical
elements," alone, is not sufficient to specify mirrors. Moreover, as discussed supra, the specification asserts that the invention can be used with a "refracting telescope." See id. at 6:11, 19-21. Refracting telescopes contain lenses rather than mirrors. (See Markman Hearing, Def. Ex. A.) Accordingly, the meaning of "optical elements in a telescope" should at the very least, include both "mirrors" and "lenses."

Plaintiff might argue that the introduction to the specification is a disclaimer limiting "the present invention . . . more specifically to the alignment of mirrors in a telescope." Id. at 1:6-8, 11 (emphasis added). According to Phillips, "the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor. In that instance . . . the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive." 2005 U.S. App. LEXIS 13954, 2005 WL 1620331, at *8. However, as previously discussed, the plain language of the claims, as well as other parts of the specification, do not evince any attempt to limit the scope of the term "optical element." Given Phillips' insistence on maintaining the line "between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim," 2005 U.S. App. LEXIS 13954, [WL] at *15, language in the specification will not be used to limit claim scope unless that language conveys a clear intent to use the term narrowly. Given the amount of intrinsic evidence in this case demonstrating a broader definition, the introduction to the specification cannot be given such a preclusive effect. The term "optical elements" must be construed to include both "mirrors" and "lenses."

What is less clear is whether the phrase "optical elements in a telescope" should include "prisms." As discussed supra, the claims may be interpreted such that the disputed term includes other "optical elements" besides a "plurality of mirrors;" however, the specification neither mentions, nor provides a diagram demonstrating the invention's use with a telescope containing a prism. Phillips specifically warns against confining claims to specific embodiments of the invention described within the specification. See id. Therefore, a lack of intrinsic evidence is not dispositive. The issue is whether a person of ordinary skill in the art would interpret the phrase "optical element in a telescope" to include "prisms." In ascertaining how a person of ordinary skill in the art understands a claim term, a court may look at extrinsic evidence where the intrinsic evidence is ambiguous. See 2005 U.S. App. LEXIS 13954, [WL] at *16. Both the prior art as well as technical dictionaries make it clear that a prism may be used as an "optical instrument" within a "telescope." (See Markman Hearing, Def. Exs. B, C; Def ’s Opp. Br. at 3, P2.) Therefore, this Court will not exclude "prisms" from the definition of "optical elements in a telescope." In sum, this Court rejects plaintiff's definition limiting the term "optical elements in a telescope" to "mirrors," in favor of a broader definition which includes "mirrors," "lenses," and "prisms."

GO BACK

2793

III. Optical Measuring Device.

Defendants object to the Magistrate Judge's recommendation as to the construction of the phrase "optical measuring device" on the ground that Defendant's proposed construction of "a device that measures the length of an optical path" is the only construction supported by the specification.

The Magistrate Judge recommended the Court construe the phrase "optical measuring device" as "a device that can measure at least one property of electromagnetic radiation in the wavelength range including only infrared, visible, ultraviolet, and X rays." The Magistrate Judge noted Defendant's proposed definition "improperly renders subsequent claim language superfluous." Thus, to give meaning to all of the words of the claim, the Magistrate Judge found the phrase "optical measuring device" should not be construed as restricted to a device that inputs data regarding the location of defects. The Magistrate Judge also found Defendant's proposed interpretation would improperly read embodiments appearing in the specification into the claim because the claim language is broader than those embodiments.

The Court has reviewed the pertinent portions of the record de novo and does not find any error in the Magistrate Judge's Findings and Recommendation as to the construction of the phrase "optical measuring device."

GO BACK

2794
One of the primary issues before the court is whether the term "an optically absorptive refractory transition metal," as claimed in the second element of claim 1, includes alloys. The court has determined that the term "metal," as used in the context of the metal interconnect layer, includes alloys. EMI urges that the court should construe the term "metal" similarly in this instance.

To interpret the meaning of this claim limitation, the court looks to the intrinsic evidence of the patent, which comprises the claims, the specification, and the prosecution history. See Pitney Bowes, 182 F.3d at 1309. Upon arriving at a claim construction based upon this intrinsic evidence, the court consults extrinsic evidence to verify that the claim construction under consideration is not inconsistent with widely held understandings in the pertinent technical field. Id.

A term appearing repeatedly in the same claim should be interpreted consistently. See Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1345 (Fed. Cir. 1998). The word "metal," however, is not a discrete claim term. In claim 1, the word "metal" has two different usages. The "metal interconnect layer" is distinct from the "optically absorptive refractory transition metal." These "metals" have different elemental compositions--the metal interconnect is made of an aluminum-based compound, while the metal absorptive layer comprises a transition metal. The "metals" also have different functions in the claimed method--the metal interconnect conducts electricity, while the metal absorptive layer absorbs laser light and transmits heat to the interconnect. Thus, the operative claim limitations are "a metal interconnect layer" and "an optically absorptive refractory transition metal," and the court is not bound by Digital Biometrics to interpret them consistently.

The specification does not provide grounds for finding that the term "an optically absorptive refractory transition metal" refers to alloys. The specification repeatedly distinguishes elemental metals from alloys. The specification recites that the interconnect may comprise "aluminum or aluminum alloys," and states that a diffusion barrier underneath the interconnect may comprise a "transition metal layer." In the context of the absorptive layer, however, the specification only discusses the use of "a transition metal." Although the specification does not recite the use of a transition metal alloy in the absorptive layer, this alone is not fatal to EMI's proposed construction, as an applicant need not disclose every possible embodiment of his invention. See SRI International v. Matsushita Electric Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985).

The prosecution history, however, indicates that the scope of the claimed absorptive layer is limited to pure elemental metals. As originally submitted by the applicants, the claim recites a method for "forming a layer of optically absorptive material." When the PTO examiner rejected the claim in light of prior art references that employ blackened aluminum or silicon oxides for absorptive layers, the applicants amended their claims to recite "forming a layer of optically absorptive metal." In a second rejection, the examiner noted that the prior art already disclosed the use of molybdenum in a laser cutting process and stated that "even the use of a novel starting material would not necessarily render the process patentable." The applicants finally changed their claim by emphasizing the function of the absorptive layer in transferring laser energy to the interconnect, and as such amended their claim to read "using an optically absorptive refractory transition metal having a higher boiling point than the interconnect beneath it." Notably, the introduction of the word "an" to qualify the metal in the final amendment shows that the scope of the claims progressively narrowed from the use of any suitable material to the use of "an optically absorptive . . . metal."

The applicants clearly contemplated that pure elemental metals are sufficient to enable the invention. In his first rejection letter, the examiner rejected the claims under § 112 for failure to enable the invention, as he asserted that pure elemental transition metals were insufficiently absorptive to induce the claimed explosion. In reply the applicants stated that "titanium, tungsten, tantalum and molybdenum are optically absorptive metals, especially in relation to aluminum." The applicants discussed the physical properties of pure titanium that render it sufficiently absorptive to enable the claimed invention. They stated that "no further processing steps need be taken to prepare the materials optically absorptive." In this exchange with the examiner, the applicants relied on the physical properties of pure elemental metals to enable the device.

Having found no support in the intrinsic evidence to suggest that the claim limitation "an optically absorptive refractory transition metal" covers alloys, the court looks to extrinsic evidence to determine if a person of reasonable skill in the art would interpret the term "an optically absorptive refractory transition metal" to include alloys. Hawley'sCondensed Chemical Dictionary defines the term "transition metal" equivalently as "transition element," and lists pure elements as
fulfilling this definition. The dictionary clearly distinguishes between alloys and elemental metals, as the definition of "alloy" states that "the properties of alloys are often greatly different from those of the components." Because the dictionary definition of the term "transition metal" does not indicate that this term refers to alloys, and because nothing in the intrinsic evidence suggests otherwise, the court concludes that the term "an optically absorptive refractory transition metal" refers only to pure elemental metals, and does not include alloys. The court reserves the question as to whether the claim may cover alloys under the doctrine of equivalents.

ii. the relative absorptivity

The parties dispute the extent to which the transition metal layer must be optically absorptive with respect to the interconnect. Based on language in the specification, EMI asserts that the transition metal layer is "more absorptive of optical energy than the metal interconnect layer." Cypress advocates that no such limitation should be read into the claim, and that the claim should simply mean that the upper layer be "optically absorptive." Since the plain language of the claim suggests no limitation on the degree of absorptivity of the transition metal layer, the court declines to construe the specification's description of the high relative absorptivity of this layer as a claim limitation. See Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571 (Fed. Cir. 1988). No judicial interpretation is necessary for this limitation.

Claim 1 of the '750 patent reads as follows (with added emphasis on the disputed terms): 1

[1] A bar code scanner which comprises a housing having a port through which a beam of light for illuminating the bar code passes out of said housing and light reflected from said code passes into said housing,

[2] a laser diode and optics for forming said beam from the light from said laser diode,

[3] a photodetector for receiving said reflecting light,

[4] means supporting said photodetector in said housing,

[5] a printed circuit board having circuits thereon connected to said diode and said photodetector, and

[6] means assembling said laser diode and optics in supported relationship upon said printed circuit board and together with each other as a unitary structure located in said housing.

The crux of the dispute over claim construction is whether the "optics for forming said beam" include only the collimating lenses necessary to reduce the diverging fan of laser light into a ray, or whether the term includes other optics involved in the propagation of the laser beam, including the beamsplitters which shape and direct the beam after it is created. According to the claim, the "optics for forming said beam" must be together with the laser diode as a unitary structure. PSC has argued consistently that the only optics encompassed in the patent claims are the optics that create the beam, the collimating lenses. Under PSC's construction, optics which shape or direct the beam after its creation are not "optics" within the meaning of the patent claim. Therefore, the claim requires, according to PSC, only that the collimating lenses be together with the laser diode as a unitary structure.

The district court disagreed with PSC. The district court held that the term optics as used in [6] is defined by [2] as the "optics for forming said beam." After consulting a dictionary, the court held that the "optics for forming" could include optics which shape and direct the beam, including the beamsplitters. More importantly, the district court found PSC's
construction inconsistent with the specification, which states that the laser beam producing means and the beamsplitters are both part of the unitary structure. Thus, the court construed the claim as requiring the beamsplitters, which direct the beam and integrate the marker beam with the laser beam, to be part of the optics for forming said beam and concluded that they must be assembled together with the laser diode and the other optics as part of the unitary structure in [6]. The district court also found that its more limited construction was also supported by the fact that the invention claimed by the '750 patent is not a pioneering invention.

According to this construction, the district court held that Accu-Sort did not infringe because its Model 20 and 22 scanners both use mirrors which direct the laser beam after it is created. The court found that the mirrors were equivalent to the beamsplitters of the '750 patent (because both components change the direction of the beam) and concluded that there was no infringement because it was undisputed that Accu-Sort's mirrors were not integrated with the rest of the optics in a unitary structure.

II.

The district court correctly referred to the specification to define the means-plus-function language in claim 1. To literally infringe a means-plus-function claim, an accused device must employ a means that is identical to or the equivalent of the structures described in the specification. Valmont Indus. v. Reinke Mfg. Co., 983 F.2d 1039, 1042, 25 U.S.P.Q.2D (BNA) 1451, 1454 (Fed. Cir. 1993). The final inquiry as to whether an accused element is an "equivalent" is a question of fact. D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1575, 225 U.S.P.Q. (BNA) 236, 239 (Fed. Cir. 1985). The specification contains language which corresponds directly to the means-plus-function limitation in [6] and describes the means for accomplishing the function described in limitation [6] as follows: "The laser beam producing means 20, the marker beam producing means 54 together with the beam splitters 62 and 70, are mounted to each other and to a printed circuit board 68 . . . ." We agree with the district court that this language directly tracks the disputed claim language which provides: "means assembling said laser diode and optics [for forming] in supported relationship upon said printed circuit board and together with each other as a unitary structure located in said housing." Therefore, the proper construction of the terms "optics for forming" includes the collimating lenses and the beamsplitters or their equivalents.

During oral argument, PSC argued that the district court improperly found that all optics which change the shape or direction of the laser beam must be mounted together in a unitary structure. PSC argues that this claim construction is flawed because the collection lens, as described in the preferred embodiment for the '750 patent, is not part of the unitary structure. Therefore, PSC contends that the district court erred in construing the '750 patent claim in a manner which excludes the disclosed preferred embodiment. If PSC were accurately characterizing the district court's claim construction, this would be a persuasive argument. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1578 (Fed. Cir. 1996) (an interpretation of a patent claim which renders the disclosed preferred embodiment outside the scope of the claim is "rarely, if ever, correct and would require highly persuasive evidentiary support"); Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1581, 38 U.S.P.Q.2D (BNA) 1126, 1130 (Fed. Cir. 1996) ("We share the district court's view that it is unlikely that an inventor would define the invention in a way that excluded the preferred embodiment, or that persons of skill in this field would read the specification in such a way.").

However, no such situation arises in this case. PSC has mischaracterized the district court's claim construction. The district court did not, nor do we, construe the patent claim as requiring all optics which direct or shape the laser beam to be part of...
the optics for forming. The specification defines this means-plus-function limitation as including the beamsplitters, but not the collection lens. The specification states:

The laser beam producing means 20, the marker beam producing means 54 together with the beam splitters 62 and 70, are mounted to each other and to a printed circuit board 68 which contains a tone generator 78 and other analog circuitry for operating and controlling the laser diode 42 (the power control circuitry) and energizing lamp . . . . The board 68 is located in the bottom of the upper housing 14 which is substantially flat as is shown in FIGS. 2 and 3. The board is located by one of the mountings which supports the collection lens 32. . . . The entire unitary assembly 20 may then be inserted into the upper housing portion 14 and clipped in place.

The specification also explains that the "collection lens 32 is mounted against shoulders 36 and 38 of the housing in the beam port 28." Figure 1 of the patent also shows that the collection lens is not a part of the unitary structure. The specification and the figures support the conclusion that the optics for forming, which are ultimately a part of the unitary structure, include the collimating lenses and the beamsplitters, but do not include the collection lens. PSC would like us to construe the claims in a manner that is much broader than the specification permits. This, we cannot do. Therefore, we affirm the district court's construction of the '750 patent claims.

3 To the extent that PSC argues that the "together with each other" language in [6] does not require that the components be integrated as a unitary structure, but merely connected via the printed circuit board, we disagree. We agree with the district court's interpretation of these terms as requiring some integration of the components beyond their mere placement on the printed circuit board. The district court correctly refused to allow PSC to render this additional claim limitation meaningless. This construction is supported by the specification which states that the optics "are mounted to each other and to a printed circuit board."

GO BACK

Claim 30 recites a dental endoscopic device comprising six separate elements:

(1) a rigid elongated handpiece having a proximal end and a distal end;

(2) a flexible cable having one end coupled to said proximal end and another end adapted for coupling to video imaging equipment;

(3) a housing removably coupled to said distal end of said rigid elongated handpiece;
(4) a sensor for sensing an image of a selected target, said sensor being coupled to said rigid elongated handpiece and said flexible cable, said sensor extending into said housing;

(5) opto-electric componentry extending from said sensor through said handpiece to said cable; and

(6) an objective element positioned in said housing and arranged to focus an image of a selected target upon said sensor when said housing is coupled to said rigid elongated handpiece.

The parties are now before the Court on cross-motions for partial summary judgment as to Claim 30, along with claim 32, which is based on Claim 30. The salient issue presented by the parties' motions is whether the AcuCam contains "opto-electric componentry extending from said sensor through said handpiece to said cable," as stated in Claim 30. The Court discusses this matter below.

Because the Court concludes that the AcuCam lacks the limitation regarding opto-electric componentry, the Court does not reach the issue of whether the AcuCam contains a "housing" as specified in Claim 30.

DISCUSSION

A. Legal Standard

Under Federal Rule of Civil Procedure 56, a court may properly grant a motion for summary judgment if the pleadings and materials demonstrate that there is "no genuine issue as to any material fact and the moving party is entitled to judgment as a matter of law." Celotex Corp. v. Catrett, 477 U.S. 317, 322, 91 L. Ed. 2d 265, 106 S. Ct. 2548 (1986). A dispute about a material fact is genuine "if the evidence is such that a reasonable jury could return a verdict for the nonmoving party." Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 248, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986). A court may grant a summary judgment motion in a patent infringement case, as in any other case. Avia Group Int'l, Inc. v. L.A. Gear Cal., Inc., 853 F.2d 1557, 1561 (Fed. Cir. 1988).

There is a two-step analytical process to determine whether an accused device literally infringes on an existing patent. First, the Court must construe or interpret the scope of the patent claims; this determination is a matter of law. Markman v. Westview Instruments, Inc., 52 F.3d 967, 1995 WL 146983 at *11 (Fed. Cir., filed April 5, 1995). Second, the Court must then determine "whether the properly interpreted claims encompass" the accused product. ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988).

B. New Image's Definition of Opto-Electric Componentry is Correct

1. Overview of The Parties' Respective Positions

The threshold issue presented by the parties' motions is the proper construction of "opto-electric componentry extending from said sensor through said handpiece to said cable," as recited in Claim 30 of the '001 patent.

New Image argues that because the '001 patent and its prosecution history are silent as to the meaning of "opto-electric
componentry," the Court should employ the ordinary meaning of the term as it is used by those persons skilled in the art. The ordinary meaning of "opto-electric componentry," argues New Image, is a device which converts optical power (photons) to electrical signals (electrons) or vice versa. In contrast, HTMI asserts that any wiring or circuitry between the sensor and the cables constitutes the opto-electric componentry. (Pl.'s Opp'n at 11.)

2. The Specification Provides No Guidance on the Meaning of Opto-Electric Componentry

In construing the meaning of a patent claim, the court should consider the claim itself, the specification, and the prosecution history. Markham, 1995 WL 146983 at *11. The Court, in its discretion, may also consider extrinsic evidence including "all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises." Id. However, "extrinsic evidence is to be used for the court's understanding of the patent, not for the purpose of varying or contradicting the terms of the claims." Id.

In the instant case, HTMI asserts that the specification of the '001 patent demonstrates that the term "opto-electrical componentry" should necessarily be equated with the interconnections between the sensor and the cable. (Pl.'s Opp'n at 11.) HTMI contends that this fact is "obvious" from the drawings and supported by the deposition testimony of New Image's own expert, Robert Fischer. These contentions are without merit.

First, the mere reference to drawings in the '001 patent is insufficient to construe the meaning of "opto-electric componentry." As the Federal Circuit explained in Markham, "any special definition given to a word must be clearly defined in the specification." 1995 WL 146983 at *11 (emphasis added). Even assuming that the definition ascribed by HTMI is present in the specification, such meaning is far from "clearly defined." Id. In short, the conclusion advocated by HTMI is not "obvious" to the Court.

Second, HTMI misconstrues Mr. Fischer's testimony. Although Mr. Fischer did state that the wires extending between the sensor and the cable correlated to opto-electrical componentry, (Sobon Decl. Ex. I at 141), he later clarified that he misunderstood plaintiff's counsel's, previous questions and that his prior response was incorrect. (Barone Reply Decl. Ex. 2 at 152). Thus, the deposition testimony cited by HTMI is of dubious value as support for its argument.

3. HTMI's Reliance on The File History is Misplaced

HTMI next argues that the file history of the '001 patent establishes the proper meaning of opto-electrical componentry, as it is used in Claim 30. Specifically, HTMI highlights certain passages in the amendment filed by HTMI's attorneys in connection with the patent reexamination proceedings. (See Pl.'s Opp'n at 11; Sobon Decl. Ex. J.) This text states:

The interior of the handle also remains sealed, for example, through the provision of the O-Rings. In this way, the endoscopic apparatus can be immersed in a sterilizing solution without affecting the electro-optical componentry or interconnections that extend through the handpiece to couple the camera to video imaging equipment.

(Sobon Decl. Ex. J at 9-10.) HTMI contends that this demonstrates that it intended the terms "electro-optical componentry" and "interconnections" to be used interchangeably.

The Court disagrees with HTMI's assertion that the file history explicitly equates opto-electrical componentry with the interconnections between the CCD sensor and the extension cables. The above passage cited by HTMI clearly uses the terms "electro-optical componentry" and "interconnections" in the disjunctive. While the word "or" can be used to signify words that are synonymous, it can also be used to indicate alternative choices. (See Black's Law Dictionary 1095 (6th ed. 1990).) However, it is unclear from the file history which interpretation of the word "or" was intended. Moreover, there is nothing explicit in the above file history statement which suggests that HTMI intended to equate "electro-optical componentry" with either the "interconnections" or the term "opto-electrical componentry." Thus, contrary to HTMI argument, the file history simply does not clearly define the meaning opto-electric componentry in the manner so construed by HTMI. 5

5 The term used in Claim 30 is opto-electrical, not electro-optical. This distinction is noteworthy because the terms...
technically are not synonymous. The Photonics Dictionary specifically states that "Electro-optic is often erroneously used as a synonym [for optoelectronic]." (See Fischer Decl. Ex. 4.

--- End Footnotes ---

C. The Dictionary Definitions Provide the Ordinary Meaning of Opto-Electric

Because the specification and file history provide no decisive guidance in defining the term "opto-electronic componentry," this Court must determine the "ordinary meaning" of the claim at issue. Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 951 (9th Cir. 1994) ("Although a patentee can be his own lexicographer, . . . the words of a claim 'will be given their ordinary meaning, unless it appears that the inventor used them differently.'" (citations omitted).

The Court finds compelling the several definitions provided by New Image which were culled from various technical dictionaries. For example, The New IEEE Standard Dictionary of Electrical and Electronics Terms, (5th Ed. 1993), defines "optoelectronic" as:

Pertaining to a device that responds to optical power, emits or modifies optical radiation, or utilizes optical radiation for its internal operation. Any device that functions as an electrical-to-optical or optical-to-electrical transducer . . . .

(Fischer Decl. Ex. 4.; see also The Photonics Dictionary, (37th Ed. 1991) (identical definition).) From these definitions, it is evident that "opto-electric" components must, in some manner, convert optical power (photons) to electronic signal (electrons). See id. P 15 and Ex. 4 (copies of excerpts from technical dictionaries which define "optoelectronic.").

--- Footnotes ---

6 The term "optoelectronic" is synonymous with "opto-electrical." (Fischer Decl. P 16.)

--- End Footnotes ---

HTMI does not controvert New Image's dictionary definitions. 7 Instead, HTMI asserts that these definitions are sufficiently broad such that "all the components that extend from the CCD sensor to the cable connector 'pertain to' the CCD sensor." (Pl.'s Opp'n at 15.) in essence, HTMI has defined opto-electric componentry as any device or part connected to an opto-electric device. However, such a construction would result in a definition of "opto-electric" based solely on the physical proximity of the component, as opposed to its actual function. Such a definition is so vague that it would effectively render the term "opto-electric componentry" meaningless. It is precisely for this reason that the Court, in its preliminary injunction order, seriously questioned whether HTMI would succeed on the merits on infringement based on Claim 30. 8

--- Footnotes ---

7 Tellingly, HTMI does not attempt to explain its interpretation of the "ordinary meaning" of opto-electric. Instead, HTMI ignores the applicable rules of infringement analysis and argues that New Image's own evidence and testimony demonstrate that the AcuCam possesses opto-electric componentry within the meaning of Claim 30. 8 In the Court's preliminary injunction Order, this Court explained that:

HTMI, . . . assert[s] that the terms "opto-electric componentry" also encompass components which carry optical images in an electrical format, and as the AcuCam possesses such components between the CCD and the cable, it possesses this element of claim 30.

HTMI's description of opto-electrical componentry, however, overly stretches the ordinary meaning of the term as defined above. The CCD is the only component which the AcuCam possesses which fits within the plain meaning of the term opto-electric." Furthermore, HTMI conceded at oral argument that the CCD in the AcuCam corresponds to the sensor of claim 30, and not to the optoelectric componentry.

(Order Granting Pl.'s Mot. for Prelim. Inj. at 16 (emphasis added).)
Moreover, the dictionary definitions proffered by New Image clearly specify that "optoelectronic" relates to a device which "responds to optical power, emits or modifies optical radiation, or utilizes optical radiation for its internal operation." (Fischer Decl. Ex. 4 (emphasis added)). This definition is corroborated by the expert testimony adduced by New Image as well as by the technical articles authored by those skilled in the art. (E.g., Fischer Decl. P 15; Magen Decl. Ex. 1 (excerpts from deposition of Dominick Danna, an electrical engineer and endoscope designer) 9; Magen Decl. Ex. 2 (article by Hugo Vifian published in the Microwave Journal).) 10

9 In response to HTMI's attorney's questions, Mr. Danna testified at his deposition that an optoelectronic device is one which converts "photoenergy into electronic signals." (Sobon Decl. Ex. O at 124.) This is consistent with the various dictionary definitions discussed above and appended to the Fischer declaration.

10 In this article, Mr. Vifian writes:

The final group is the optoelectrical components. This group includes lightwave detectors or receivers, and demodulator sensors. These components have optical input and electrical output ports, and are O/E [optical/electrical] components.

(Magen Decl. Ex. 2 at 68.) HTMI does not address the significance of this article in its opposition. Although HTMI raises an evidentiary objection to this article in its inappropriate and unauthorized surreply (see n.1), said objection is untimely, and therefore, is deemed waived.

HTMI does not proffer its own definition of opto-electric, other than to state that opto-electric componentry essentially means anything between the sensor and the cable. Instead, HTMI attempts--unsuccessfully--to attack the evidence offered by New Image. For example, HTMI attempts to undermine the significance of Mr. Danna's testimony by noting that he stated that there "possibly" were other definitions to "optoelectronic" other than that which he had previously given. Unfortunately, HTMI, for reasons not evident from the record, did not query Mr. Danna any further concerning the nature of those other possible definitions.

HTMI's citation to the deposition testimony of George Sutton, one of New Image's experts, is equally misplaced. (Pl.'s Opp'n at 15.) In his deposition, Mr. Sutton testified that the wires in the AcuCam "carried" images taken by the CCD. (Sobon Decl. Ex. E. at 47.) This testimony does not--as argued by HTMI--establish that Mr. Sutton "thinks that all the components that extend from the CCD sensor to the cable connector pertain to' the CCD sensor." (Pl.'s Opp'n at 15.) Rather, Mr. Sutton simply acknowledged that the wires leading from the CCD act as a conduit for electrical signals produced by the CCD.

At bottom, the Court rejects HTMI's contention that either Claim 30 or its file history explicitly equate "opto-electric componentry" with the interconnections between the CCD sensor and the external cable. The Court agrees with New Image that the ordinary meaning of the term "opto-electric componentry," as it is used in Claim 30, relates to an optical-to-electrical or an electrical-to-optical transducer extending from the sensor to the cable. If the drafters of the '001 patent had envisioned something different, they "could have prevented this result through clearer drafting." Hoganas AB, 9 F.3d at 951. Therefore, the Court concludes that Claim 30 of the '001 patent (with the disputed claim language emphasized) reads as follows:

Claim 30 of the '001 patent (with the disputed claim language emphasized) reads as follows:

A dental endoscopic apparatus comprising:

- a rigid elongated handpiece having a proximal end and a distal end;
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

a flexible cable having one end coupled to said proximal end and another end adapted for coupling to video imaging equipment;

a housing removably coupled to said distal end of said rigid elongated handpiece;

a sensor for sensing an image of a selected target, said sensor being coupled to said rigid elongated handpiece and said flexible cable, said sensor extending into said housing;

opto-electrical componentry extending from said sensor through said handpiece to said cable; and an objective element positioned in said housing and arranged to focus an image of a selected target upon said sensor when said housing is coupled to said rigid elongated handpiece.

The district court construed the term "opto-electrical componentry" to mean "an optical-to-electrical or an electrical-to-optical transducer." High Tech, 1995 WL 381502, at *6. The court then determined that the AcuCam device did not meet the limitation of "opto-electrical componentry extending from said sensor through said handpiece to said cable" because it did not contain a transducer connecting the CCD sensor to the cable. See id. The court therefore granted New Image's motion for partial summary judgment. The district court did not construe any of the other limitations in claim 30.

II.

On appeal, HTMI argues that the district court erred in construing the term "opto-electrical componentry." HTMI contends that the term should be construed to mean an electrical component that conveys optical images in an electrical form. HTMI also argues that we should construe on appeal other claim terms such as "objective element" and "housing," which the district court did not address. In light of its proposed claim construction, HTMI urges us to hold that the AcuCam device infringes claim 30 of the '001 patent.

When interpreting a claim, the court should look first to intrinsic evidence: the claim itself, the specification, and the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996). If an ambiguity remains after considering intrinsic evidence, then the court may refer to extrinsic evidence, such as expert and inventor testimony. Id. at 1584, 39 USPQ2d at 1577. In addition, although technically considered extrinsic evidence, the court is free to consult technical dictionaries at any time in order to determine the ordinary meaning of claim terms. Id. at 1584 n.6, 39 USPQ2d at 1578 n.3.

In construing the term "opto-electrical componentry," the district court concluded that neither the claims, the specification, nor the prosecution history provided clear guidance for defining the term. Accordingly, the court looked to various dictionaries and technical articles, and to expert testimony for the ordinary meaning of the term. As noted, the court concluded that the ordinary meaning of the term "opto-electrical componentry" was an "optical-to-electrical or an electrical-to-optical transducer," and it adopted this meaning in its claim construction. The court then determined that the only component in the AcuCam device which had an opto-electrical function was the CCD camera, which corresponded to the "sensor" in claim 30. The court found that the components connecting the CCD sensor to the cable in the AcuCam device were resistors, capacitors, logic gates, transistors, diodes, voltage regulators, and wires. The court further found that none of these components were "opto-electrical" within the ordinary meaning of the term. The court therefore concluded that the AcuCam device did not possess "opto-electric [sic] componentry extending from said sensor through said handpiece to said cable," as recited in Claim 30. High Tech, 1995 WL 381502, at *6.

When construing a patent claim, terms should generally be given their ordinary and customary meaning. See Vitronics, 90 F.3d at 1581, 39 USPQ2d at 1576. However, we have stated that: "[a] technical term used in a patent document is interpreted as having the meaning that it would be given by persons experienced in the field of the invention, unless it is apparent from the patent and the prosecution history that the inventor used the term with a different meaning." Hoescht Celanese Corp. v. BP Chem. Ltd., 78 F.3d 1575, 1578, 38 USPQ2d 1126, 1129 (Fed. Cir.) (emphasis added), cert. denied,
136 L. Ed. 2d 198, 117 S. Ct. 275 (1996). We also have stated that courts may refer to technical dictionaries in construing claims, as the district court did in this case, "so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents." Vitronics, 90 F.3d at 1584 n.6, 39 USPQ2d at 1578 n.3 (emphasis added). Although the term "opto-electrical componentry" does not appear anywhere in the written description, it is apparent that the patentee used the term "opto-electrical componentry" to refer to electrical components that carry an optical image in an electrical form. The written description states: "Camera 56 will have connected to it a number of lead wires 64 which travel through hollow regions 62 and 48, exit handpiece 12, and are ultimately connected to an image processing system 14." '001 patent, col. 6, ll. 6-10. These wires are the only structure disclosed that connects the sensor to the cable as required by claim 30 ("opto-electrical componentry extending from said sensor through said handpiece to said cable"). We therefore conclude that a person skilled in the art reading the patent document would understand that the term "opto-electrical componentry" referred to the indicated wires.

It also should be noted, we believe, that the claim construction we have adopted is appropriate because the ordinary meaning of the term "opto-electrical componentry" would not cover any of the disclosed embodiments of the invention claimed in the '001 patent. The Supreme Court has stated that the terms in a claim must be defined in a manner that fully comports with the instrument as a whole and that preserves the patent's internal coherence. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 1395, 38 USPQ2d 1461, 1470, 134 L. Ed. 2d 577 (1996). Furthermore, a claim interpretation that does not cover a disclosed embodiment is "rarely, if ever, correct." Vitronics, 90 F.3d at 1583, 39 USPQ2d at 1578; see also Hoechst, 78 F.3d at 1581, 38 USPQ2d at 1130 ("it is unlikely that an inventor would define the invention in a way that excluded the preferred embodiment"); Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1550, 37 USPQ2d 1609, 1612 (Fed. Cir.) ("a claim interpretation that would exclude the inventor's device is rarely the correct interpretation"), cert. denied, 116 S. Ct. 2523 (1996). The ordinary meaning of "opto-electrical componentry," which forms the basis for the district court's claim construction, would require the presence of a second transducer in the device. However, there is no support for a second transducer in the specification or in the prosecution history because the only transducer described in the specification is the CCD camera.

For the foregoing reasons, we conclude that the term "opto-electrical componentry," as used in Claim 30, means electrical components that convey optical images in an electrical form. However, we are not prepared on the basis of the record before us to say that the AcuCam device contains "opto-electrical componentry extending from said sensor through said handpiece to said cable." We believe that the district court should make the appropriate factual determination as to whether this limitation of claim 30 is met in the accused device. In addition, we leave construction of the terms "objective element" and "housing" and determination of whether these limitations of claim 30 are met in the accused device to the district court in the first instance.

The decision of the district court is vacated, and the case is remanded for further proceedings consistent with this opinion.

Each party shall bear its own costs.

MAYER, Circuit Judge, dissents.

2. "Organic Material"

Both Claim 1 and Claim 67 also use the phrase "organic material." HISI requests that "organic material" be interpreted to mean "carbon containing materials (including wood, wood sawdust, and charcoal)." (HISI Brief 18). TPI, on the other hand, argues that "organic" should be limited to things that are "of, relating to, or derived from living organisms," such as wood, wood sawdust, leaves, bagasse from sugar cane, pineapple husks, and rice hulls. 2 (TPI Brief 14-15.)

2 TPI also requests that "organic" be limited to materials which can burn at temperatures of 510 [degrees] C or less. TPI argues that charcoal should be excluded because it burns above 510 [degrees] centrigade. TPI's temperature arguments, however, have already been addressed above.
Both the broad definition of "organic" proposed by HISI and the narrower definition of "organic" advanced by TPI appear equally valid and equally plausible. The claims themselves provide no insight into the intended meaning of "organic." The specifications, however, do describe the types of burning material utilized in this process, albeit without explicitly defining the term "organic." The patent states that "[t]ypical wood fuels for smoking contain primarily a hydrocarbon composition of hydrogen and carbon along with other elements . . . ." (Kowalski Patent, Col. 7, at 4-5 (emphasis added).) This language, focusing on the chemical component of smoking materials, and in particular, the presence of carbon, as opposed to focusing on the materials' relation to living organisms, indicates that Kowalski did not intend to limit his patent to the narrower definition of "organic." The Court therefore finds that "organic material," as used in the Kowalski Patent, means carbon containing materials, including wood, wood sawdust, and charcoal.

1. The "multiple orientation" limitation

Lamson argues that the district court erred in construing the "multiple orientation" limitation in claims 1 and 12 to cover one hundred eighty degree rotations of the insert. Lamson contends that the language of the claims and the specification make clear that the "multiple orientation" limitation requires an outlet cover that can encompass both horizontal and vertical electrical outlets by using a single, symmetrical insert that can be rotated ninety degrees. Intermatic responds that the plain language of the relevant claims and the specification allow one hundred eighty degree rotations of the insert to be included within the construction of the "multiple orientation" limitation. Intermatic further argues that claim 3, which depends from claim 1, claims the precise construction advocated by Lamson, and that therefore the doctrine of claim differentiation requires that the "multiple orientation" limitation not be restricted to outlet covers that accommodate both horizontal and vertical electrical outlets.

We agree with Intermatic that the district court properly construed the "multiple orientation" limitation to include one hundred eighty degree rotations of the insert. Absent an express intent to impart a novel meaning, "terms in a claim are to be given their ordinary and accustomed meaning." Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249, 48 U.S.P.Q.2d (BNA) 1117, 1121 (Fed. Cir. 1998). The relevant claims at issue require that the aperture be large enough to enable the insert to fit within the aperture "in a first orientation and a second orientation." 135 patent, col. 8, II. 48-49, col. 9, II. 38-39. The ordinary meanings of the terms "first" and "second" do not require that the orientations be separated by any specific degree of rotation, such as the ninety degree difference argued by Lamson. Rather, such language broadly claims an outlet cover with an aperture large enough to accommodate an insert placed in any two orientations, whether those orientations be separated by one hundred eighty degrees, ninety degrees, or any other degree of rotation.

The specification supports this construction of the "multiple orientation" limitation. The "Summary of the Invention" states that "the insert may be fitted within the aperture of the base plate in a plurality of orientations in order to encompass electrical outlets of either a horizontal orientation or a vertical orientation." Id. at col. 2, II. 30-33 (emphasis added). That language suggests that, in addition to being able to rotate the insert ninety degrees to accommodate both a vertical and horizontal outlet with the same outlet cover, the insert may be rotated one hundred eighty degrees, i.e., turned upside down, to accommodate only a horizontally oriented outlet or only a vertically oriented outlet. Such a degree of rotation may be necessary, for example, to accommodate outlets in which the plug receptacles are not arranged in a symmetrical fashion. Indeed, the examiner recognized this very use of the claimed outlet cover, stating that "an insert . . . could be placed in two different orientations . . . each 180 degrees apart." The ninety degree rotation construction proffered by Lamson is therefore merely a preferred embodiment of the invention. See id., col. 3, II. 49-59 ("In this embodiment . . . the aperture and the insert are such that the insert can be positioned in the aperture in two separate orientations . . . 90 degrees apart.").

Moreover, claim 3 of the 135 patent, which is dependent on claim 1, differs from the latter only in that the aperture must be "of sufficient size to enclose an electrical outlet positioned in a first substantially vertical position and a second substantially horizontal position . . . ." Id. at col. 8, II. 65-67 (emphasis added). Under the doctrine of claim differentiation, each claim in a patent is presumptively different in scope. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2d (BNA) 1001, 1005 (Fed. Cir. 1998). This presumption can be strengthened under certain circumstances. One of
those circumstances was espoused in Wenger Manufacturing, Inc. v. Coating Machinery Systems, Inc., wherein this court stated that "claim differentiation, while often argued to be controlling when it does not apply, is clearly applicable when there is a dispute over whether a limitation found in a dependent claim should be read into an independent claim, and that limitation is the only meaningful difference between the two claims." 239 F.3d 1225, 1233, 57 U.S.P.Q.2d (BNA) 1679, 1685 (Fed. Cir. 2001). Because the only meaningful difference between claim 1 and claim 3 involves the potential orientations of the insert, the doctrine of claim differentiation provides additional support for not limiting the "multiple orientation" limitation to the construction proposed by Lamson. We therefore conclude that the district court did not err in interpreting the "multiple orientation" limitation to include one hundred-eighty degree rotations of the insert.

2801

A. "Oriented" and "Oriented Coextruded Film"

1. The Parties' Proposed Constructions

Cryovac asserts that the term "oriented" should be construed as a part of the term "oriented coextruded film" to mean "a film formed by coextrusion that is then heated to its orientation temperature range and stretched to realign the molecular configuration, this stretching accomplished by a racking or blown bubble process." (D.I. 203 at 11.) Cryovac contends that this construction is supported by the definition given for the term "oriented" in the specification, and that broader constructions were disclaimed during prosecution. (Id. at 11-16.) Pechiney, on the other hand, claims that the term "oriented" should be construed to mean "a polymeric material which has been heated and stretched to realign the molecular configuration." (D.I. 204 at 20.) Pechiney asserts that the language "this stretching accomplished by a racking or blown bubble process" should not be included in the construction of the term oriented, as this language would improperly import a product-by-process limitation into the claim. (Id. at 21-22.) Pechiney further argues that the term "oriented coextruded film" should simply be a combination of the definitions of "oriented" and "coextruded", not a separate claim term, and should be defined to mean "an oriented film formed by coextrusion." (D.I. 204 at 20.)

2. The Court's Construction

The specification of the '419 patent states that "the term 'oriented' and the like is used herein to define a polymeric material which has been heated and stretched to realign the molecular configuration, this stretching accomplished by a racking or blown bubble process." U.S. Patent No. 4,755,419 at col. 3, Ins. 45-49. The parties agree that where a patent applicant provides "an explicit definition in the specification for a claim term[,...] the definition selected by the patent applicant controls." Renishaw PLC, 158 F.3d at 1249.

The dispute between the parties over the construction of the term "oriented" centers on whether the phrase "this stretching accomplished by a racking or blown bubble process" should be included in the construction of the term. (See D.I. 204 at 21.) While Pechiney asserts that the inclusion of this phrase improperly imports a product-by-process limitation into the claim (id.), Cryovac argues that this final phrase is part of the definition intended by the patentee, and that to define the term differently is inconsistent with the specification of the patent (D.I. 203 at 16-18).

Phillips teaches that claim construction is a practical exercise, in which a claim term is defined to reflect what one of ordinary skill in the art reading the patent would understand. 415 F.3d at 1324 ("There is no magic formula or catechism for conducting claim construction. Nor is the court barred from considering any particular sources or required to analyze sources in any specific sequence..."). However, as earlier noted, the language of the specification "usually ... is dispositive, it is the single best guide to the meaning of a disputed term." Id. at 1315 (quoting Vitronics, 90 F.3d at 1582).

Federal Circuit precedent, is seemingly in conflict regarding whether a product-by-process claim is limited by the process disclosed in the claim. In Scripps Clinic & Research Found. v. Genentech, Inc., 927 F.2d 1565, (Fed. Cir. 1991), the court stated that "the correct reading of product-by-process claims is that they are not limited to product prepared by the process set forth in the claims." Scripps Clinic & Research Found., 927 F.2d at 1583. However, just over one year later, the Federal Circuit relied on "a line of [Supreme Court] cases that [stated] the infringement inquiry for product claims with process limitations focuses on whether the accused product was made by the claimed process or its equivalent." Atlantic Thermoplastics Co. v. Faytex Corp., 970 F.2d 834, 842 (Fed. Cir. 1992). Thus, the court in Atlantic Thermoplastics held that
"process terms in product-by-process claims serve as limitations in determining infringement." Id. at 846-47. In light of the decisions in Scripps, Atlantic Thermoplastics, and the Supreme Court cases cited by the Federal Circuit in Atlantic Thermoplastics, 2 it appears that the determination of whether the process is properly viewed as a limitation is a context-specific inquiry. 3 Thus, in keeping with the en banc decision of the Federal Circuit in Phillips, each claim, whether it contains a product-by-process limitation or not, must be construed in light of the specification.

3 Indeed, in the Federal Circuit's most recent statement on this issue, SmithKline Beecham Corp. v. Apotex Corp., 439 F.3d 1312, 2006 WL 435838 (Fed. Cir. 2006), although the majority stated that it "need not address this controversy here" ( 439 F.3d 1312 at 1316-17, [WL] at *4), Judge Newman filed a dissenting opinion which clearly sets out the debate between Scripps and Atlantic Thermoplastics. 439 F.3d 1312, [WL] at *8-11. In her dissent, Judge Newman stated that the rule emphasized in Phillips, that "claims are construed in light of the specification … is not suspended when product and process limitations appear in the same claim." Smithkline Beecham Corp., 439 F.3d 1312 at 1322, 2006 WL at *9. Judge Newman goes on to state that Scripps and Atlantic Thermoplastics are "not in conflict; they simply deal with different situations." 439 F.3d 1312 at 1323, [WL] at *10.

Here, the patentee specifically defined the term "oriented" in the specification to include the language "accomplished by a racking or blown bubble process." U.S. Patent No. 4,755,419 at col. 3, Ins. 48-49 Additionally, the examples provided by the patentee in the specification strongly suggest that this limitation was intended to be a part of the claim. See id. at col. 4, Ins. 52-55 (stating that the film was "produced by … cast coextrusion methods, and subsequently oriented … typically by means of a blown bubble process"); id. at col. 8, Ins. 60-64 ("the coextruded and cooled tube is heated to its orientation temperature range to orient the film in e.g. a blown bubble process"). Under the guidance given by Phillips, the language in the specification of the '419 patent "is the single best guide" to the meaning of the term oriented. Phillips, 415 F.3d at 1315. Under Federal Circuit and Supreme Court case law, this is not changed simply because the definition given by the patentee contains a limitation that describes a process. Thus, I will use the definition given by the patentee in the specification, and will construe the term "oriented" to mean, with reference to a polymeric material, "heated and stretched to realign the molecular configuration, this stretching accomplished by a racking or blown bubble process.

4 Cryovac asserts that I should construe the phrase "oriented coextruded film" rather than just "oriented." (D.I. 203 at 11-16.) However, the construction of this phrase is simply a combination of the construction of "oriented" given here, and the meaning of "coextruded," on which the parties fundamentally agree (see supra note 1). Thus, the term "oriented coextruded film" needs no further definition here.

The 253 patent includes claim language stating as follows: "each hypotenuse is oriented at least one of towards and away from the centrally positioned long axis." ('253 patent, 7:15-18, 44-46.) 6 Plaintiff contends that the court should construe this claim as follows "each hypotenuse may face either toward or away from the centrally positioned axis." (Pl.'s Opp'n 30.)
6 The words "at least one of" are not here construed; plaintiff conceded at oral argument that this phrase is superfluous.

7 The figure located on page 16 depicts the orientations of the hypotenuses of the teeth of two embodiments of the patents-in-suit and of the allegedly infringing product.

Plaintiff's proposed construction would prevent the claim language from limiting or modifying the claims in any way, and would therefore render the language unnecessary. Plaintiff discusses the orientation of the hypotenuse as being either towards or away from the center line, but discusses no other possible orientation for hypotenuses. (Pl's Opp'n to Mot. for Summ. J. 33.) A limitation within a claim should not be construed in a manner that would cause it to be "meaninglessly empty." See Ethicon Endo-Surgery v. U.S. Surgical Corp., 93 F.3d 1572, 1578 (Fed. Cir. 1996). Because there are only two possible orientations for each hypotenuse, plaintiff's proposed claim construction that each individual hypotenuse may face either toward or away from the centrally positioned axis, without regard to the positions of the other hypotenuses, does not limit the claim in any way. Such a statement would be true of the bone saw claimed by the patent even if that claim language had been omitted. Furthermore, the term "each" means "all considered one by one," according to Webster's Third New International Dictionary 713 (4th ed. 1976). Therefore, the court construes the phrase "each hypotenuse is oriented at least one of towards and away from the centrally positioned long axis" to mean "either all of the individual hypotenuses are oriented towards the centrally positioned long axis, or all of the individual hypotenuses are oriented away from the centrally positioned long axis." 8

8 Plaintiff argues that under this proposed definition, the dependent claims would become superfluous because they are subsumed within the definition. (Pl.'s Opp'n 33.) However, patentees have an obligation to include broader and narrower claims to retain coverage of the invention. See Johnson & Johnston Assoc's. Inc. v. R.E. Serv. Co., Inc., 285 F.3d 1046, 1057 (Fed. Cir. 2002) (explaining that "the patentee has an obligation to draft claims that capture all reasonably foreseeable ways to practice the invention"). Such construction additionally protects a patentee in the event that the broader claims are rejected by the patent office or invalidated in the course of litigation. Of concern is when a claim limitation becomes "meaninglessly empty," in that it contributes nothing to the understanding of the claim. It is not concerning when a claim is dependent upon another; that type of superfluousness is common to any well-drafted patent.

II. First Light Fixture: "oriented to direct light downwardly to a selected reading area under said body." 5

A. Words of the Claim

In accordance with the standard set out in Phillips and reiterated in Nystrom, when construing a claim the Court first considers the words of the claim, which "themselves provide substantial guidance as to the meaning of particular claim terms." Pfizer, Inc. v. Teva Pharm., USA, Inc., 429 F.3d 1364, 1373 (Fed. Cir. 2005) (quoting Phillips, 415 F.3d at 1314). "In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Phillips, 415 F.3d at 1314. In most cases, however, courts must dig deeper into the meaning of the claim language.

Although in the Joint Statement, the parties ask the Court to construe the phrase, "selected reading area under said body," neither party addressed this issue in their briefs. (R. 23, Joint Statement at 2.)

With regard to the first light fixture, Kenall claims that the phrase "oriented to direct light" requires that "the fixture in question be designed to emanate more light toward the designated target than in any other direction." (R. 26, Kenall Markman at 3.) Genlyte counters that "oriented to direct light" simply means "to set or arrange to direct light." (R. 27,
Genlyte Markman at 22.) However, when considering the entire disputed, "oriented to direct light downwardly," very little difference between the parties' proposed constructions remains. To set or arrange to direct light downwardly has the same meaning as to emanate more light in a downward direction. This construction is clear on the face of claims 1 and 3. Claim 1 states that the first light fixture is oriented to direct light "downwardly," while the second light fixture is oriented to direct light "downwardly and outwardly." Thus, the first light fixture in claim I must direct more light downwardly than outwardly; otherwise, the words "and outwardly" would be meaningless. "An interpretation of one claim that renders another claim meaningless is disfavored." CytoLogix Corp. v. Ventana Med. Sys., Inc., 424 F.3d 1168, 1173 (Fed. Cir. 2005).

Genlyte admits that light from lamps of a light fixture can go downwardly, outwardly, and/or upwardly, and the '254 Patent specifies the direction or directions the light goes. (R. 31, Genlyte Surreply at 3.) It follows that a light fixture oriented to direct light downwardly is not oriented to direct light outwardly or upwardly. This distinction would be meaningless without an understanding that "more" light must go downwardly than outwardly or upwardly. Far from reading a quantitative term into the claim or limiting the '254 Patent to its preferred embodiment (R. 27, Genlyte Markman at 15), the modifier "more" follows from the language of the '254 Patent itself. Accordingly, the Court finds the correct construction of the phrase, "oriented to direct light downwardly" to be: "to set or arrange to direct more light in a downward direction than in an upward or outward direction."

B. Intrinsic Record

"The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Phillips, 415 F.3d at 1316; Nystrom, 424 F.3d at 1142. The intrinsic record consists of the patent specification -- the claims and the written description of the patent -- and the prosecution history. 6 Nystrom, 424 F.3d at 1142. "The specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315 (citations omitted).

6 As explained above, the absence of prosecution history for the '254 Patent does not aid the Court in claim construction.

The '254 Patent's specification supports the construction that "oriented to direct light downwardly" means that more light is directed in the downward direction than in an upward or outward direction. The same language is used in the undisputed portion of claim 3, which states: "third light fixture within said body oriented to direct light downwardly under said body to a selected patient examination area." (254 Patent at col.4, 11.1-3.) The light from the third light fixture arranged to direct more light downwardly than upwardly or outwardly so that a selected patient examination area may be highlighted. The written description supports this interpretation, as the "Abstract" states that the reading light -- a.k.a., the "first light fixture" - is "directed toward a selected reading area on a hospital bed directly below the medical lighting system." (254 Patent.) The first light fixture must be set or arranged to direct more light downwardly to this "selected reading area" like the "selected patient examination area," to avoid rendering this language meaningless. Likewise, this meaning is bolstered by the "Background of the Invention" section, which states that the reading light "provides direct light to a portion of the patient's bed" (254 Patent at col. 1, 11.14-16), and the "Objects and Summary of the Invention" section of the '254 Patent, which states that the first light fixture is "designed to direct light toward the forward portion of the patient's bed so as to allow the patient to read comfortably." (254 Patent at col.2, 11.3-6.)

C. Extrinsic Evidence

Extrinsic evidence is all evidence outside the patent and its prosecution history. Markman, 52 F.3d at 980. Extrinsic evidence is less significant and less reliable than the intrinsic record in determining the legally operative meaning of claim language. Phillips, 415 F.3d at 1317-18. Sources of extrinsic evidence, such as expert testimony, dictionary definitions, technical treatises, and articles may not be used to vary or contradict a claim's meaning that is unambiguous in light of the intrinsic evidence. Phillips, 415 F.3d at 1324 (adhering to and reaffirming the Federal Circuit's approach to claim construction outlined in Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 (Fed. Cir. 1996)). Accordingly, the Federal Circuit has found it unnecessary to consider extrinsic evidence where the intrinsic evidence was unambiguous and sufficient to support the claim construction. See Koepnick Med. & Educ. Research Found., L.L.C. v. Alcon Labs., Inc., 162 Fed. Appx. 967, 2005 U.S. App. LEXIS 28880, No. 05-1215, 2005 WL 3543012, at *6 (Fed. Cir. 2005); Vitronics, 90 F.3d at 1584 ("Where the patent documents are unambiguous, expert testimony regarding the meaning of a claim is entitled to no
A. Brackett Statement

opinions rather than the other way around." Solaia Tech. LLC v. ArvinMeritor, Inc., 361 F. Supp. 2d 797, 805 (N.D. Ill. 2005). The "relevant art is defined by the nature of the problem confronting the would-be inventor." Id. Genlyte argues that the relevant art is lighting design, or even more specifically, medical lighting design. (R. 32, Genlyte Mot. to Strike at 12-15.) Kenall, on the other hand, claims that the relevant art is light distribution and measurement or lighting design. (R. 40, Resp. to Mot. to Strike at 10.) Contrary to Genlyte's contention, the relevant art is not limited to medical lighting systems, or even lighting fixture design. Although the inventor of the '254 Patent sought to improve medical lighting systems over patients' beds, the "nature of the problem confronting the would-be inventor" is broader than Genlyte contends: the problem is how to appropriately distribute light from the light fixtures to serve certain stated purposes. Expertise in lighting design, measurement, or distribution would be important to solve this problem. Thus, the relevant art is lighting design, measurement, or distribution. See Ryko, 950 F.2d at 718-19.

"The level of ordinary skill in the art" is determined by considering factors such as the educational level of the inventor and those who work in the industry, and the sophistication of the technology involved. Id. at 718. Genlyte contends that Brackett does not have the level of ordinary skill in the art when the relevant art is defined as lighting design. (R. 32, Genlyte Mot. to Strike at 12-15.) While it is true that Brackett only has limited experience in the field of lighting design, he has extensive technical experience in the art of lighting measurement and distribution, as this Court has defined the relevant art. Brackett has thirty years experience in the application, testing and analysis of a wide variety of light fixtures. (R. 28, Kenall Reply, Ex. 1 ("Brackett Statement") at 1-2.) In addition, he has published six papers in the Journal of the Illuminating Engineering Society dealing with lighting measurements and he served as chair of the Illuminating Engineering Society of North American ("IESNA") Technical Knowledge Exam Committee. (Id.) Thus, Brackett qualifies as one of ordinary skill in the art.

Genlyte also argues that Brackett's Statement should be stricken on the grounds that it was largely ghost-written by Kenall counsel. (R. 32, Motion to Strike at 1.) Federal Rule of Civil Procedure 26 requires an expert's report to be "prepared and signed by the witness." Fed. R. Civ. P. 26. Although Rule 26 does not prohibit a party's attorney from providing assistance to the expert, "preparation implies [an expert's] involvement other than perusing a report drafted by someone else and signing one's name at the bottom to signify agreement." Manning v. Crockett, 1999 U.S. Dist. LEXIS 7966, No. 95 C 3117, 1999 WL 342715, at *3 (N.D. Ill. May 18, 1999). Genlyte points primarily to Brackett's October 11, 2005 deposition testimony to show that Kenall counsel in essence drafted the Brackett Statement. (R. 32, Mot. to Strike at 3-8.) At his deposition, Brackett did not remember and showed some uncertainty about the details of the preparation of his Statement. (R. 32, Mot. to Strike at 3-8; R. 44, Reply to Mot. to Strike at 5-7). In response to Genlyte's motion to strike, Kenall provided evidence that Brackett's statement was indeed drawn from Brackett's opinion and not from Kenall's attorney. Kenall attached to its response: (1) eight pages of Brackett's notes about the '254 Patent (R. 40, Resp. to Mot. to Strike, Ex. 1); (2) a declaration by Brackett stating that (a) Kenall's attorney, Matthew Fannin, spoke with Brackett for one and a half hours before Fannin drafted a report of Brackett's opinion, (b) Brackett spent three hours reviewing and editing this draft "to ensure it was a complete representation of my opinion," and (c) the next day Brackett requested further changes be made until "the Statement represented the opinion [he] wanted to put forth" (R. 40, Resp. to Mot. to Strike, Ex. 2); and (3) e-mail correspondence with attachments of various forms of the Brackett Statement after edits by Brackett and Fannin (R. 40, Resp. to Mot. to Strike, Exs. 3-4). After considering Brackett's deposition testimony, the drafts of Brackett's Statement, Brackett's declaration, and the e-mails, "the Court cannot exclude the possibility that the [brief] was drawn from [Brackett's] opinions rather than the other way around." Solaia Tech. LLC v. ArvinMeritor, Inc., 361 F. Supp. 2d 797, 805 (N.D. Ill. 2005). Therefore, Genlyte's motion to strike is denied. (R. 32.)

a. Brackett Statement
Although the Court declines to strike Brackett's Statement, it nevertheless has very little probative value. "Conclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court." Phillips, 415 F.3d at 1318 (citations and quotations omitted); see also Invitrogen Corp. v. Clontech Labs., Inc., 429 F.3d 1052, 1068 (Fed. Cir. 2005). Brackett's Statement consists almost entirely of conclusory, unsupported assertions. Although Brackett states that he reviewed several patents, the IESNA Handbook, and the parties' Markman statements, he does not once reference any of these or other materials in support of his seven-page opinion of the correct construction of claims 1 and 3 of the '254 Patent. (See Brackett Statement.) Rather, Brackett sets forth his opinion without any support for it. Therefore, this Court accords very little value to Brackett's Statement.

b. Lemons

In contrast, the conclusions of Genlyte's expert, Thomas Lemons, are generally well-supported by lighting handbooks and other primary materials, 7 and, in fact, support the Court's construction of the phrase "oriented to direct light downwardly." Lemons defined this phrase as "to set or arrange to direct illumination to an area below the product." (Lemons Statement at 2.) Lemons' response to Brackett's Statement shows that he believes more illumination must be directed below the product than above. In his surreply, Lemons states that Brackett does not identify the "certain direction" where the fixture "emanates more light." (R. 31, Genlyte Surreply, Ex. F ("Lemons Surreply") at 4.) However, Lemons agreed that "if the 'certain direction' is down and the other direction is up then I can accept that [Brackett] understands the use of these terms." (Id.)

7 Kenall does not dispute that Lemons is a person of ordinary skill in the art.

2. Dictionaries and Treatises

"Within the class of extrinsic evidence, the court has observed that dictionaries, especially technical ones, and treatises can be useful in claim construction." Phillips, 415 F.3d at 1318. They may not, however, be used to construe a claim "divorced from the context of the written description and prosecution history." Nystrom, 424 F.3d at 1144-45. Both parties have attached excerpts from the IESNA Lighting Handbook, the Hospital Lighting Data Book, and Webster's Ninth New Collegiate Dictionary; however, most of these excerpts do not shed light on the disputed claims in this case. This evidence primarily goes to the issue of whether a certain construction of the '254 Patent claims would render the '254 Patent invalid in light of the prior art. 8 Only the definition of "orient" in Webster's Ninth New Collegiate Dictionary 832 (1987), relates directly to claim construction in this case. Webster's defines "orient" as "to set or arrange in any determinate position esp. in relation to the points of the compass." (R. 27, Genlyte Markman, Ex. D). This definition, referring to a "determinate position" in relation to points of the compass, supports this Court's construction that the first light fixture sets or arranges more light in a downward direction than in any other direction. Another construction would render the term "determinate" pointless.

8 The issue of invalidity is generally not relevant when construing unambiguous claims. See infra, section 4, "Invalidity."

Kenall argues that the '254 patent is the "parent application" for two continuation-in-part patent applications, Patent No. 5,086,375 ("the '375 Patent") and Patent No. 5,160,193 ("the '193 Patent"), and that these patents should be considered relevant intrinsic evidence in construing the '254 Patent claims. (R. 26, Kenall Markman at 8, Exs. 2 and 3.) A separate patent, however, even if it is a continuation-in-part patent application, does not constitute relevant intrinsic evidence for the '254 Patent. See Goldenberg v. Cytogen, Inc., 373 F.3d 1158, 1167 (Fed. Cir. 2004) (while first patent cited in the prosecution history was part of intrinsic record, second patent created as a continuation-in-part of the original patent was new matter that at most constituted extrinsic evidence). In addition, the '375 and '193 Patents have little value as extrinsic evidence, as there is no proof that use of the phrase "oriented to direct light" in the '375 and '193 Patents has the same construction as in the '254 Patent, where the '375 and '193 Patents deal with a "light fixture module" rather than a "light fixture." (R. 26, Kenall Markman at 8, Exs. 2 and 3.)

Kenall also argues that Patent No. 3,928,757 ("the '757 Patent") is relevant extrinsic evidence, and Kenall asks the Court to determine that the word "directs" in the '254 Patent has the same meaning as in the '757 Patent. (R. 26, Kenall Markman at 11.) The '757 Patent, unlike the '254 Patent, however, deals with a spotlight, and there is no evidence that the term "directs" is used in the same way in both patents. (R. 26, Kenall Markman, Ex. 4.)
4. Invalidity

Kenall also claims that the Court should not adopt the claim construction proposed by Genlyte because if such a construction were adopted the claims would be invalid. 9 (R. 28, Kenall Reply at 5.) While claims should be construed to preserve their validity, validity analysis is not a regular component of claim construction. Phillips, 415 F.3d at 1327 (citations and quotations omitted). Instead, this maxim is limited to cases in which "the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous." Id. (citations and quotations omitted). See also Free Motion Fitness, Inc. v. Cybex Intern., Inc., 423 F.3d 1343, 1349 (Fed. Cir. 2005) (rejecting party's request to construe claims to preserve their validity because claim was not ambiguous). As this Court has already ruled, the claims are not ambiguous in light of the words of the claims themselves and the intrinsic record.

9 Kenall also claims that Genlyte's proposed construction would exclude Genlyte's commercial embodiment of the '254 Patent, specifically the MD*4 lighting systems. (R. 28, Kenall Reply at 12-13.) A commercial embodiment, like the preferred embodiment, should not limit the claims of a patent. Callicrate v. Wadsworth Mfg., Inc., 427 F.3d 1361, 1368 (Fed. Cir. 2005). Moreover, the MD*4 information sheets' statement that direct glare is eliminated does not mean that no light shines directly beneath the light. (See R. 31, Genlyte Surreply at 6-7.)

I. Claim Construction

Despite this Court's prior claim construction ruling following extensive briefing by the parties, Kenall and Genlyte continue to dispute the meaning of the claim terms "downwardly" and "outwardly," as well as the meaning of the words "upwardly" and "more," as used by this Court in construing the disputed claim terms. It is well-settled that "[d]istrict courts may engage in a rolling claim construction, in which the court revisits and alters its interpretation of the claim terms as its understanding of the technology evolves." Network Commerce, Inc. v. Microsoft Corp., 422 F.3d 1353, 1364 (Fed. Cir. 2005). Claim 1 of the '254 Patent reads, in relevant part: "a second light fixture within said body oriented to direct light downwardly and outwardly to a vertical wall surface outwardly adjacent from said body whereby light is reflected back to a broad area under said body." (R. 63, Kenall Mem. Supp. Summ. J., Ex. 1, '254 Patent at col.3, ll.37-48.) In the previous claim construction ruling, this Court construed this phrase to mean: "set or arranged to direct more light in a downward and outward direction than in an upward direction to a vertical wall surface next to or near either end of said body whereby light is reflected back to a broad area under said body." 5 Kenall, 413 F. Supp. 2d at 949. While this interpretation is correct, this Court will clarify and elaborate on the meaning of the "second light fixture" so as to eliminate further confusion-or manipulation-of its meaning by the parties.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 The parties agree that the relevant "vertical wall surface" is the headwall, the wall located at the head of the hospital patient's bed. (R. 63, Kenall Mem. Supp. Summ. J. at 8-9; R. 74, Genlyte Opp'n Mot. at 5.)

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

In arguing for their proposed interpretations of the second light fixture, the parties continue to read terms within claim 1 of the '254 Patent in isolation, thus eliciting conflicting definitions. "Proper claim construction, however, demands interpretation of the entire claim in context, not a single element in isolation." ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1090 (Fed. Cir. 2003) (quoting Hockerson-Halberstadt, Inc. v. Converse Inc., 183 F.3d 1369, 1374 (Fed. Cir. 1999)). Genlyte completely ignores the phrase "to a vertical wall surface" to support its argument that while more light must be directed in a downward and outward direction than upwardly, it is irrelevant whether the ambient light directs more light toward the vertical headwall than toward the sides. 6 (R. 74, Genlyte Opp'n Mem. at 5, 10-11.) In addition, Genlyte's expert, Thomas Lemons, constructs a chart matching precise angles of light with "directional zones" of light-up, upward, out, outward, down, and downward-providing only conclusory reasons for this construction. (R. 74, Genlyte Opp'n Mem., Ex. 1, Lemons Rebuttal Decl. at 5.)
By contrast, Kenall argues that its products do not infringe the ambient light fixture in claim 1 of the '254 Patent because its products directs more light downward and to the sides of the light fixtures than to a vertical wall surface. (R. 75, Kenall Resp. at 5.) Furthermore, Kenall's expert, Ian Lewin, PhD., uses the Illuminating Engineering Society of North American ("IESNA") Handbook's Glossary to define "downward" as all light below the horizontal and "upward" as all light above the horizontal. (R. 75, Kenall Resp., Lewin Resp. at 1-2.) Lewin, however, ignores the term "outward," even though the Federal Circuit discourages construing terms in a way that would render other parts of the claim superfluous. Merck & Co., Inc. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005).

Neither expert has it right. "][A] court should discount any expert testimony that is clearly at odds with the claim construction mandated by the claims themselves, the written description, and the prosecution history, in other words with the written record of the patent." Pause Tech., 419 F.3d at 1333 (quoting Phillips v. AWH Corp., 415 F.3d 1303, 1318 (Fed. Cir. 2005)). As such, Lemons' disregard of the phrase "to a vertical wall" cannot be right, and Lewin's disregard of the term "outward" cannot be right either. Furthermore, the '254 Patent is a ceiling mounted medical lighting system, which necessarily directs almost no light above the horizontal; in fact, the ambient light fixture of the MPC24 provides 0 lumens of light to the area between 90 and 180 degrees (the area above the horizontal, with 0[Degree] going directly down to the patient's hospital bed), and the MPC22 provides only 7 lumens, or 3% of light to that same area. (R. 56, Genlyte Facts PP at 51, 65-66.) Thus, Genlyte's definition of upward as including area below the horizontal does not make sense.

Given the parties' continued disagreement over-or manipulation of-the meaning of the second light fixture, this Court's prior claim construction warrants elaboration. District courts begin their claim construction analysis with the words of the claim, as they define the invention, and "][t]he construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Nystrom v. TREX Co., Inc., 424 F.3d 1136, 1142 (Fed. Cir. 2005). The '254 Patent does not include any specific angular measurements, and indeed, the '254 Patent's specification indicates that the "downwardly and outwardly" oriented light is not meant to be interpreted according to strict angular measurements and is not conducive to such measurements. Lewin's and the IESNA's definition of downwardly, however, is incomplete, as it ignores the term "outwardly." That term, however, is not rendered superfluous because as the experts agree, light is emitted on multiple planes. (R. 79, Genlyte Reply, Ex. 3, Lemons Reply Decl. at 3; R. 63, Kenall Mem. Supp. Summ. J., Lewin Decl. at 5.) While upward light is indeed light above the horizontal and downward light is light below the horizontal (as defined by the IESNA and in accordance with the '254 Patent), "outwardly" here identifies the direction of light in a different plane: specifically, "to a vertical wall," as specified in claim 1 of the '254 Patent.

Furthermore, while some ambient light travels directly downward toward the hospital bed-hence the term "downwardly,"-the patent specification of the '254 Patent demonstrates that the majority, or "more," of the downwardly and outwardly directed light goes "outwardly to a vertical wall surface." See Kenall, 413 F. Supp. 2d at 948; R. 63, Kenall Mem. Supp. Summ. J., Ex. 1, '254 Patent at col.3, ll.44-45. The Abstract of the '254 Patent states that: "[t]he ambient light directs light to a wall abutting the head of the hospital bed thereby providing reflected light to the vicinity of the hospital bed." (R. 63, Kenall Mem. Supp. Summ. J., Ex. 1, '254 Patent at Abstract (emphasis added).) Similarly, the Patent Object and Summary of the Invention section of the '254 Patent states that: "[a] second light fixture includes a fluorescent bulb and a reflector designed to direct light toward a vertical wall surface abutting the head of the patient's bed so as to provide a reflected light over a large area around the patient's bed." (Id. at col. 2, ll.6-10 (emphasis added).) This is in contrast to the reading light, which "is directed toward a selected reading area on a hospital bed directly below the medical lighting system." (Id. at Abstract.) Claim 1 states this difference as "oriented to direct light downwardly to a selected reading area under said body" versus "oriented to direct light downwardly and outwardly to a vertical wall surface . . . whereas light is reflected back to a broad area under said body." (Id. at col.3, ll.43-47.) This distinction shows that "downwardly" means directly below the medical system, while "outwardly" means toward the wall, specifically, the identified "vertical wall. Accordingly, not only is the ambient light fixture set or arranged to direct light both downwardly and outwardly to a vertical wall as opposed to
upwardly, but more of this light is directed outwardly to the vertical wall than downwardly, so that the light can be reflected off the vertical wall onto the patient's bed.

In addition, the parties now specifically agree that the "vertical wall surface outwardly adjacent from said body" is the wall located at the head of the hospital patient's bed. (R. 63, Kenall Mem. Supp. Summ. J. at 8-9; R. 74, Genlyte Opp'n Mot. at 5.) As such, this Court clarifies its previous construction of the second light fixture in claim 1 of the '254 Patent as follows:

"a second light fixture within said body set or arranged to direct some light in a downward direction toward the hospital bed and the majority of light in an outward direction toward the wall located at the head of the hospital patient's bed, whereby light is reflected back to a broad area under said body." 7

7 As both the parties and their experts spent significant time debating the construction of these phrases in claim 1 of the '254 Patent in their summary judgment briefs, the Court will not entertain further briefing on claim construction in this case.

1. "The rearward regions of the top and bottom walls being oriented toward a back of the shoe"

adidas argues that the term "oriented toward a back of the shoe" should be construed as "placed at or near the side or surface of the shoe that is opposite the front (toe) of the shoe." It reaches this definition through the dictionary definitions of "back" ("the side or surface of something that is opposite to the side regarded as its front or face"), "orient" ("place in relation to"), and "toward" ("near" or "at a point in the direction of"). adidas claims that this is consistent with the specification's use of the term because in every disclosed embodiment, the rearward regions of the U-shaped member are placed at the back of the shoe. Akeva, in opposition, argues that the referenced rearward regions in the claim need not be physically located at or near the back of the shoe. Plaintiff proposes that the term's construction should stem from the plain and ordinary meaning of "oriented toward": "directed towards or placed in the direction of a location at or near the back of the shoe."

The dictionary definition of "oriented" is "directed toward" or "placed in relation to." Webster's Third New Int'l Dictionary 1591 (1986). The definition of "toward" as a preposition is "in the direction of." Webster's Third New Int'l Dictionary 2417 (1986). adidas has pointed to no compelling evidence suggesting that the plain and ordinary meaning should be rebutted or limited. The plain meaning of the phrase "oriented toward" does not include the requirement that an object that is "oriented toward" something must be placed physically near the thing. It encompasses only the notion that the object be facing a particular direction.

Therefore, the proper construction of "oriented toward a back of the shoe" should be construed as "directed toward or placed in the direction of a location at or near a back of the shoe."

2. "orifice" is a hole or opening through which something (axle and sleeve) may pass. Although it need not be completely enclosed, it must be sufficiently enclosed to "substantially surround" that which it holds, an axle (col. 10, ll. 32-34; col. 11, l. 67) or sleeve (col. 12, l. 2-3);
not appear to be in dispute among the parties, however, the Court agrees with Plaintiff that the term should be construed so as to avoid confusion as to the meaning of the term. According to the Academic Press Dictionary of Science and Technology, "orthogonal" is defined, among other things, as "perpendicular." Academic Dictionary of Science and Technology at 1534 (Christopher Morris, ed.) (1992). The Court sees no reason to diverge from this dictionary definition, as it is consistent with the patent specifications. Thus, the term "orthogonal" should be construed to mean perpendicular.

GO BACK

2808

BACKGROUND

Plaintiff's invention improves upon prior methods for removing earwax from a person's ear canal using water. Previously syringes, capable of delivering only limited amounts of water, had been used to flush out the ear. Patients whose ears were being thus irrigated had had to rely on a waterproof apron for protection from the likely splatter each time the syringe was removed to permit drainage and begin a fresh flushing.

Inventor Daniel J. Pender recognized the benefit of a method that would involve a continuous flow of water in and out of the ear, via a tightly fitted device, until irrigation was completed, thereby avoiding splattering of the patient. He filed the application resulting in the '711 patent in December 1997. An office action rejecting the application's single claim issued in November 1998. The applicant successfully responded the next month, and the application was allowed in May 1999.

The final '711 patent contains only one claim, Claim 1, which covers:

A method of irrigating a patient's ear using an otoscope of a type having an operating mode of flushing cerumen therefrom with body temperature water, said method comprising the steps of [providing an otoscope,] 1 configuring a tip of said otoscope in a cylindrical shape in cross section and of a selected outside diameter, selecting a tip outside diameter that is slightly oversized with respect to a diameter of an anatomical opening of said patient's ear canal, inserting said tip into said ear canal, establishing at a site of engagement of said different diameters of said tip and said ear canal opening a friction fit obviating fluid leakage externally of said site, providing a source of body temperature water and a return sump therefore, and continuously flowing said body temperature water from said source into and removing water and cerumen from said ear of said patient for return to said sump through said tip until the removal of cerumen is completed, whereby a maintained said fluid leakage seal during said continuous flowing of said body temperature water obviates a splattering of said patient.

(Weiss Decl., Ex. A, '711 Patent, col. 4.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 The parties agree that this bracketed phrase should appear in the claim and that it was erroneously omitted by the U.S. Patent and Trademark Office ("PTO") from the printed version of the Patent.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

This motion concerns the meaning of the term "otoscope" as used in this claim. Defendants would define an otoscope to be "an instrument fitted with lighting and magnifying lens systems and used to facilitate visual examination of the auditory canal and eardrum." (D. Mem. at 4.) It is undisputed that defendants' accused product does not include an otoscope fitting this description. Plaintiff, however, would define the term as "a medical device which provides access to the ear canal via a tip (or speculum) for the purposes of examination, diagnosis, and/or treatment of the ear canal and/or eardrum." (P. Opp. at 1-2.) The key conceptual difference between the two definitions is that defendants style the otoscope as a viewing device, while plaintiff casts it as an access device (that does not necessarily facilitate viewing).

To support their respective definitions, the parties have submitted the record of the patent itself, comprising the specification, the single claim, and the prosecution history, in addition to other documentary evidence and the opinions of certain witnesses. This record will be described as appropriate during discussion of the issues.
DISCUSSION

I. Summary Judgment Standard

Summary judgment shall be granted "if the pleadings, depositions, answers to interrogatories, and admissions on file, together with the affidavits . . . show that there is no genuine issue as to any material fact and that the moving party is entitled to judgment as a matter of law." Fed. R. Civ. P. 56(c). A "genuine issue of material fact" exists if the evidence is such that a reasonable jury could find in favor of the non-moving party. Holtz v. Rockefeller & Co., 258 F.3d 62, 69 (2d Cir. 2001). The moving party bears the burden of establishing the absence of any genuine issue of material fact. Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 256, 106 S. Ct. 2505, 91 L. Ed. 2d 202 (1986). In deciding a summary judgment motion, the court must "resolve all ambiguities and draw all reasonable references in the light most favorable to the party opposing the motion." Cifarelli v. Vill. Of Babylon, 93 F.3d 47, 51 (2d Cir. 1996). The nonmoving party, however, may not rely on "conclusory allegations or unsubstantiated speculation," Scotto v. Almenas, 143 F.3d 105, 114 (2d Cir. 1998), and "must do more than simply show that there is some metaphysical doubt as to the material facts," Matsushita Elec. Indus. Co., Ltd., v. Zenith Radio Corp., 475 U.S. 574, 586, 106 S. Ct. 1348, 89 L. Ed. 2d 538 (1986).

II. Literal Infringement

A. Legal Standards

To determine whether a patent has been infringed, it is necessary first to resolve any dispute about the meaning or scope of the invention claimed in the patent. U.S. Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997). Interpretation of a patent claim, which defines a patentee's rights, is a matter of law reserved entirely for the court. Markman v. Westview Instruments, Inc., 517 U.S. 370, 372, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). Whether an accused method or product infringes a properly construed claim is a question of fact. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).

Summary judgment of no literal infringement may be granted only "when no reasonable jury could find that every limitation recited in the properly construed claim . . . is . . . found in the accused device." Gart v. Logitech, Inc., 254 F.3d 1334, 1339 (Fed Cir. 2001). On this summary judgment motion, the only limitation with respect to which literal infringement is disputed involves the use of an otoscope. Construing the definition of "otoscope" as used in the '711 patent, the parties agree, will determine whether defendants are entitled to a judgment of no literal infringement as a matter of law.

The Court has not yet been asked, nor is it necessary to the instant decision, to construe all of the limitations of the '711 patent's claim. While the parties essentially agree that construction of the claim term "otoscope" will dispose of any literal-infringement issue, because the claim is clearly limited to require use of an otoscope, they have not stipulated to a specific understanding of all the limitations of the claim. Plaintiff, for instance, proposes that, "for purposes of claim construction, the critical inventive elements of Dr. Pender's invention are: (a) use of an ear-irrigating instrument having a tip of defined dimensions which creates a watertight seal between the ear wall and the tip, and (b) a continuous flow of warm water in and out of the ear to remove cerumen." (P. Opp. at 3.) Defendants differently describe the claim as "allow[ing] the doctor to: (a) clean the ear canal by delivering and then removing a flow of warm water to the inside of the ear; and (b) look deep into the ear to determine if it is clean without removing the modified otoscope from the ear." (D. Mem. at 2.)

As the equivalence-infringement claim survives, and may ultimately require resolution on a "limitation-by-limitation basis," Texas Instruments Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558, 1566 (Fed. Cir. 1996); see also Warner-Jenkinson Co., Inc. v. Hilton Davis Chemical Co., 520 U.S. 17, 29, 117 S. Ct. 1040, 137 L. Ed. 2d 146 (1997) ("Each element contained in a patent claim is deemed material to defining the scope of the patented invention, and thus the doctrine of equivalents must be applied to individual elements of the claim, not to the invention as a whole.")., the parties may require a further opportunity to argue in detail the construction of other aspects of the claim. See also Sofamor Danek Group, Inc. v. Depuy-Motech, Inc., 74 F.3d 1216, 1221 (Fed. Cir. 1996) (trial court need not conclusively interpret claims at an early stage in a case). For now, it is sufficient to address the otoscope issue.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
In construing a patent claim, courts are to look first to the intrinsic evidence of record: the claim, specification, and prosecution history. Vitronics Corp., 90 F.3d 1576 at 1582. "Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language," because the court's task is to construe the meaning of a disputed term "as it is used in the claim" Id. at 1580, 1582 (emphasis added). Intrinsic coherence is also emphasized by statute -- the specification must describe an invention in "full, clear, concise, and exact terms;" 35 U.S.C. § 112, P1 -- and thus "the inventor's intention, as expressed in the specification, is regarded as dispositive." Phillips v. AWH Corp., 415 F.3d 1303, 1316 (Fed. Cir. 2005) (en banc) (citation omitted).

Courts may also consider evidence extrinsic to the patent in issue, including expert and inventor testimony, dictionaries, and treatises. Phillips, 415 F.3d at 1317. Such extrinsic evidence is "less significant than the intrinsic record in determining the legally operative meaning of claim language." Id. Indeed, where "an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term," it is not merely inadvisable but also "improper" to rely on extrinsic evidence. Vitronics Corp., 90 F.3d at 1583. The primacy of the patent evidence rests on the premise that "competitors are entitled to review the public [patent] record, . . . ascertain the scope of the . . . claimed invention and, thus, design around [it] . . . . [Neither a] patentee [nor an alleged infringer] may . . . proffer an interpretation for the purposes of litigation that would alter the indisputable public record." Id. For this reason extrinsic evidence that is publicly accessible in advance of litigation, such as prior-art documents and dictionaries, is preferable for the purpose of claim construction to such extrinsic evidence as expert testimony. Id. at 1585.

A claim term should be afforded its "ordinary and customary meaning," which is "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention" reading the patent. 3 Phillips, 415 F.3d at 1312-13. The "ordinary and customary meaning" standard is consistent with the emphasis on intrinsic evidence: The inventor, whose explanations constitute the intrinsic record, may be presumed to be, if anyone is, a person of ordinary skill in the art relevant to the invention. See Phillips, 415 F.3d at 1313 ("That starting point is based on the well-settled understanding that inventors are typically persons skilled in the field of the invention and that patents are addressed to and intended to be read by others of skill in the pertinent art."). The question is not the inventor's private or subjective intention, but the meaning that would be given his words by a person skilled in the art in the context of the patent.

3 Neither party offers, let alone attempts to support, a description of the person of ordinary skill in the art in this case. In briefing this motion, the parties address the nature of the person of ordinary skill in the art only in the context of the credibility of expert witnesses. However, nothing in this decision depends on crediting either one of the proffered witnesses as such a person. In the absence of any argument or showing to the contrary, the Court adopts for purposes of resolving this motion the vantage point of a person of ordinary skill in the "field of invention." Phillips, 415 F.3d at 1313, that is named in the '711 patent itself: the field of "ear irrigation procedure" (Weiss Decl., Ex. A, '711 Patent, col. 1).

B. Construction of "Otoscope"

In this case, the intrinsic evidence dictates an interpretation of the disputed claim term, "otoscope," in accordance with defendants' proposed construction. Consideration of extrinsic evidence thus is not necessary to the decision; the extrinsic evidence submitted by plaintiff, even though considered, does nothing to negate such a construction.

1. Intrinsic Evidence

Plaintiff argues that "[t]here is nothing in the language of Claim 1 of the '711 patent that limits the term 'otoscope' to a device including a light and a lens that is used for visualizing the ear canal" (P. Opp. at 6) -- in other words, to defendants' proposed definition. Yet the claim describes a method involving "us[e of] an otoscope of a type having an operating mode of flushing cerumen" from the ear with water, and the insertion of a specially configured tip of the otoscope tightly into the ear canal for flushing "until the removal of cerumen is completed." (Weiss Decl., Ex. A, '711 Patent, col. 4, emphasis added.) The reference to a point of completion implies the necessity of incorporating into the claimed method a means for observing the progress of earwax removal. Plaintiff points to nothing in the claim that explains how such observation could be effected
other than by use of a device such as that which defendants have defined the claim's "otoscope" to be. It is true that, as plaintiff contends, the method claimed does not "[explicitly] include visualization of the ear canal." (P. Opp. at 7.) Yet the method clearly if implicitly contemplates visualization of some aspect of the earwax-removal process. Because defendants' definition of "otoscope" would satisfy that visualization aspect of the claimed method, while plaintiff's definition would leave mysterious how such visualization could occur, the language of the claim supports acceptance of defendants' definition.

For the same reason, the specification, which "is the single best guide to the meaning of a disputed term," Vitronics Corp., 90 F.3d at 1582, supports accepting defendants' definition of "otoscope" rather than plaintiff's. Plaintiff correctly points out that the portions of the specification distinguishing the prior art do not "include any reference to visualization of the ear." (P. Opp. at 8.) However, as with the claim, the lack of explicit mention of visualization in the specification does not establish that "the key elements of Dr. Pender's invention . . . have nothing to do with visualization." (Id.) Rather, the specification's focus on "maintaining the patient splatter-free" (Weiss Decl., Ex. A, 711 Patent, col. 1), via a flushing mechanism that does not "ha[ve] to be removed from time to time during the ear canal irrigation procedure" (id.), would plainly teach a person of ordinary skill in the art reading the patent that some means would be required for observing the progress of that procedure without removing the flushing device. A careful reading of the specification supports this view. The specification states that "[u]nderlying the present invention is the recognition that an operating mode which contemplates the use of a continuous warm water supply under pressure is one which obviates the removal of the ear-irrigating instrument prior to an observed completion of cerumen removal." (Weiss Decl., Ex. A, 711 Patent, col. 2, emphasis added.)

Moreover, the specification describes a preferred embodiment as involving an "otoscope [with] . . . a flushing water delivery and removal head[,] . . . a view port lens telescoped, . . . [and] a fiber optic light source," permitting "observation through the lens [to see if] removal of cerumen is completed." (Id., cols. 2-3.) While it is well established that descriptions of possible embodiments do not by themselves limit a claim, see Phillips, 415 F.3d at 1323, the description in this case is relied upon not to limit the claim to the particular embodiment described, but rather to help determine what a term of the claim would mean to an ordinary skilled person in the field reading the claim in the context of the specification. See Phillips, 415 F.3d at 1313 ("Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification."). As with the claim, adoption of plaintiff's definition of "otoscope" would leave mysterious how the visualization of earwax-removal as clearly contemplated -- and instructively, if not dispositively, described -- in the specification would occur. The language of the specification, therefore, in conjunction with the language of the claim itself, supports acceptance of defendants' definition, to satisfy the visualization aspect of the claimed method. 4

--- Footnotes ---

4 The preferred embodiment specifies a particular lens type and light source. These preferences are particular to the embodiment described, but they illustrate the point that the "otoscope" in question has some capacity for visualization -- as surely as it has a capacity for "flushing water delivery and removal" (Weiss Decl., Ex. A, 711 Patent, col. 2), which plaintiff concedes is central to the invention.

--- End Footnotes ---

Finally, the prosecution history also supports acceptance of defendants' definition. "[B]ecause the prosecution history represents an ongoing negotiation between the PTO and the applicant, rather than the final product of that negotiation, it often lacks the clarity of the specification and thus is less useful for claim construction purposes [than the language of the claims and specification themselves]." Phillips, 415 F.3d at 1317. Even allowing for such ambiguity and construing it in plaintiff's favor, the '711 patent's prosecution history at best provides no reason to doubt that defendants' definition of "otoscope" is the most consistent with the claim and specification; at worst for plaintiff, it affirmatively supports defendant's definition.

In her only rejection of the '711 patent application, on November 20, 1998, the PTO examiner wrote that "Claim 1 is confusing because it is unclear if an otoscope is used or not. The preamble suggests using the otoscope, while the body of the claim is merely directed to the tip of the otoscope. It is suggested that applicant add a step of 'providing an otoscope' to clarify that an otoscope is used." (Weiss Decl., Ex. C, Prosecution History of '711 Patent, Office Action P 8.) The patentee subsequently amended the claim to add precisely the suggested language (see id., Response to Office Action), as reflected in
what the parties agree should be treated as the final version of the claim.

That the patentee complied with a PTO directive to modify the claim language to clarify that "an otoscope is used" -- as opposed to merely the tip of an otoscope -- without more does not do anything to define what the term "otoscope" means in this context. At most, this aspect of the prosecution history only cements that the '711 patent claim "requires the use of an otoscope" (D. Mem. at 6), a proposition that is not contested on this motion.

In her rejection of the '711 patent application, however, the PTO examiner went on to evince an understanding of "otoscope" that accords more closely with defendants' proposed definition than with plaintiff's. Rejecting the claim as obvious in light of certain prior art, she wrote:

Goldenberg discloses the use of an otoscope in combination with a middle ear fluid sampling device for the purpose of removing a specimen from the ear. The purpose of the otoscope is to provide visual control of the Goldenberg device . . . . [Prior art] Grossan is cited to exemplify that irrigating the ear canal with a friction fitting end portion . . . is well known. Accordingly, it would be obvious to one of ordinary skill in the art to use the Goldenberg device with an otoscope to irrigate and clear the ear canal as taught by Grossan, for the purpose of having an ear cleaning device which is fitted with an otoscope for greater visual control of ear irrigation.

(Weiss Decl., Ex. C, Prosecution History of '711 Patent, Office Action P 10, emphases added.) The prosecution history may serve as evidence of how the patent examiner and the inventor understood an aspect of a claim and of whether their understandings excluded any particular interpretation. See Phillips, 415 F.3d at 1317; Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). The language of her rejection makes clear that the examiner regarded the otoscope in the context of this patent application to mean a device for viewing inside the ear canal.

Plaintiff does not address this particular passage of the rejection at all. However, the submitted evidence of the inventor's response to that rejection could be taken at least as rendering ambiguous whether the inventor shared the examiner's apparent understanding of "otoscope." The patentee sought "[r]econsideration of the rejection . . . on the basis of Goldenberg in view of Grossan," arguing that Goldenberg was "non-analogous art" and that "Grossan clearly does not disclose or suggest establishing a site of a friction fit by selection of the outside diameter of the otoscope tip so it is slightly oversized in relation to the patient's ear canal." (Weiss Decl., Ex. C, Prosecution History of '711 Patent, Response to Office Action at 4-5.) This response evidently sufficed, as the examiner thereafter approved the application for issuance of a patent. The response statements do not directly counter the examiner's apparent understanding of "otoscope" - indeed, they could be taken to accept that understanding without objection. However, it could also be argued that the response succeeded in negating any applicability of Goldenberg, and thus Goldenberg's version of an "otoscope," as irrelevant, and that it expressed the patentee's understanding of "otoscope tip," not of an entire otoscope, leaving the examiner's understanding uncorroborated.

None of this prosecution history, however, affirmatively supports adoption of plaintiff's definition of "otoscope" as a non-viewing device over defendant's definition. At best, construed in plaintiff's favor, it leaves construction of the term to hang, as already discussed, on the claim and specification. The fairest analysis of the prosecution history, though, is that, because the examiner clearly understood "otoscope" in the context of the application to mean a device for viewing inside the ear canal, it is likely that a person of ordinary skill in the art viewing the patent evidence would similarly understand the term.

2. Extrinsic Evidence

While it is not necessary to do so, as the intrinsic evidence suffices for choosing between the two proffered constructions of the disputed claim term, the Court has reviewed the extrinsic evidence submitted by plaintiff and determined that none of it counsels against adopting defendants' definition, and indeed, that resort to dictionaries supports defendants' interpretation.

Plaintiff first points to the primary definition of "otoscope" found in the online Oxford English Dictionary ("OED"): "Originally: an instrument resembling a stethoscope, used to listen for the sound of air in the middle ear or Eustachian tube (now rare or disused). Later (in full acoustic otoscope): an instrument that measures sound reflected from the tympanic membrane, used chiefly to detect fluid in the middle ear." OED Online, www.oed.com (search for "otoscope") (emphases in original). The first use of the term "acoustic otoscope" noted in the explanatory examples following that definition is dated 1984. See id. The secondary definition provided is: "An instrument used for visual inspection of the ear." Id.
Courts may consult and even rely on dictionary definitions when construing claim terms, "so long as the dictionary definition does not contradict any definition found in or ascertained by a reading of the patent documents." Phillips, 415 F.3d at 1322-23. The primary source for defining a disputed term must remain the intrinsic evidence of the patent itself, because "elevating the dictionary to such prominence" problematically "focuses the inquiry on the abstract meaning of words rather than on the meaning of claim terms within the context of the patent." Id. at 1321. Such a focus is undesirable, because "[t]he patent system is based on the proposition that claims cover only the invented subject matter . . . . The use of a dictionary definition can conflict with that directive because the patent applicant did not create the dictionary to describe the invention." Id.

Here, plaintiff's proffered dictionary entry, defining an otoscope as an acoustic device, not only contradicts the definition ascertainable, as discussed, on a reading of the patent's intrinsic evidence, but also fails to support plaintiff's interpretation of "otoscope" as an access device. The online OED's primary definition does not describe the referenced otoscope as providing access to the ear canal.

Moreover, the dictionary's acoustic definition suggests that its relevance as the principal meaning of "otoscope" is historic. Currently, the acoustic reference is "rare or disused," and at least as early as 1984, the OED suggests, this meaning required express specification by the term "acoustic otoscope." In contrast, the secondary definition, referencing "visual inspection," is not described as archaic or outdated. The "ordinary and customary meaning of a claim term" is to be gauged as of "the time of the invention, i.e., as of the effective filing date of the patent application," Phillips, 415 F.3d at 1313, and the '711 patent application was filed in December 1997. Thus, the primary dictionary definition advanced by plaintiff does nothing to persuade against adopting defendants' construction of "otoscope" as supported by the intrinsic patent evidence.

For similar reasons, plaintiff's evidence that "the earliest otoscopes" lacked lights and lenses and were used to "provide access to the ear canal" (P. Opp. at 12, citing C. Keith Wilbur, M.D., Antique Medical Instruments (4th Ed. 2000)), cannot be taken to counter defendants' suggested construction. As the title of the reference makes clear, it relates to "antique," rather than contemporary, understandings. In any case, the treatise's need to remind readers that "the earliest otoscopes" lacked lights and lenses strongly suggests, by negative implication, that the understanding of the device by those familiar with its use at the time of this invention would include such means of visual inspection.

Defendants' construction, in contrast, is supported by a definition provided in a leading online medical dictionary: "an instrument fitted with lighting and magnifying lens systems and used to facilitate visual examination of the auditory canal and eardrum." (See Nash. Decl., Ex. 3, printout of Medline Plus: Medical Dictionary by Merriam-Webster, definition of "otoscope;" also at www.nlm.nih.gov/medlineplus/mplusdictionary.html, search for "otoscope.") Other dictionaries similarly support defendants' proposed understanding. Supporting the OED's conclusion that the use of the term to reference primarily an acoustic device was long outdated by the time the instant patent application was filed, Funk and Wagnalls Standard College Dictionary (1966) already promotes "[a]n instrument for viewing or examining the interior of the ear" to pride of place as the principal definition, noting that the term can "also" refer to an "instrument for auscultation [in turn defined as "a listening"] of the ear." Webster's New Universal Unabridged Dictionary Deluxe Second Edition (1983) provides the same two meanings, in the same order. Like the OED, these sources make no reference to plaintiff's preferred definition of the term as a means of introducing other instruments into the ear.

The very derivation of the word, moreover, provides further support for defendants' construction. The American Heritage Dictionary of the English Language (4th ed. 2000) defines the suffix "-scope" as "[a]n instrument for viewing or observing," for example, a bronchoscope, derived from the Greek "skopein," to see. Though some words containing this suffix may involve only metaphorical "seeing" (as with the stethoscope and acoustic otoscope), all appear to involve methods of enhancing perception, and none suggests a usage that involves a means of introducing instruments to inaccessible locations without some sense - most often, literal - of "seeing."

The other extrinsic evidence submitted by plaintiff is similarly unpersuasive. Plaintiff cites Welch Allyn's U.S. Patent No. 4,380,998 ("998 patent"), as referencing different kinds of otoscopes, but it fails to explain how that patent, for a "soft tip speculum" (Dep. of Stephen Burnett, Ex. 10), may be considered within the same field of invention ("ear irrigation procedure") as the subject patent. (See P. Opp. at 13.) Moreover, even assuming that the reference can properly be considered, it at best supports a conclusion that the term "otoscope" may sometimes be understood in the sense plaintiff advocates: "Two types of otoscopes are used by physicians in examining and/or treating the ear. One is an operative
instrument through which other smaller instruments are passed to gain access to various parts of the inner ear . . . . The other is a diagnostic instrument which is used to visually observe the functional activity of the ear." (See P. Opp. at 13, citing '998 Patent, col. 1.) Plaintiff does not claim that its invention entails any operation-type procedure, 5 and it provides no other rationale explaining why, if the word may have two different senses, the claim in issue should be construed in accordance with one rather than the other of the two understandings of "otoscope" identified in the '998 patent.

Finally, plaintiff offers the testimony of a purported expert against adoption of defendants' construction. However, this testimony largely recites the extrinsic documentary evidence about "the earliest otoscopes" and operating otoscopes, which, as already discussed, does nothing for plaintiff's case. (See Decl. of Jack J. Wazen, M.D. PP 6, 7.) All it offers in addition is the witness's endorsement of plaintiff's proposed construction of "otoscope," apparently based on his 30 years' experience using otoscopes in the field of otolaryngology. (See id. PP 1, 4, 5.) As claim construction presents a question of document interpretation, and the standard interpretation rule requires that a term should be defined in a way that comports with the document as a whole, the adoption of an expert's testimony about a definition will depend on whether the definition "fully comports with the specification and claims and so will preserve the patent's internal coherence." Markman, 517 U.S. at 390. Because "[a]ny other rule would be unfair to competitors who must be able to rely on the patent documents themselves," "expert testimony . . . may not be used to vary or contradict the claim language." Vitronics Corp., 90 F.3d at 1584. Even where there is intrinsic ambiguity that credible expert testimony purports to clarify, courts are not compelled to rely on such testimony. Markman, 517 U.S. at 387 (Courts may "avail themselves" of expert testimony but "are not . . . obliged to blindly follow" it.) (citation omitted). Therefore, even if the Court were to deem the intrinsic evidence insufficient to support adopting defendants' construction of otoscope, which it does not, and even if plaintiff's witness were to be credited as a qualified expert, the testimony would be rejected as advancing a definition that contradicts the internal coherence of a patent that requires a means for visualizing earwax removal. 6

Because the intrinsic evidence dictates an interpretation of the disputed claim term in accordance with the defendants' proposed construction, because, even if it were properly considered, the extrinsic evidence suggests no reason to adopt plaintiff's proposed construction instead; and because understanding the otoscope to be an instrument fitted with a light and lens and used for visual examination of the inner ear means defendants' device, which undisputedly lacks such features, cannot literally have infringed the otoscope-requiring '711 patent, judgment of no literal infringement is granted to defendants.

2809

I. Term 11: Outer bezel disposed over said antenna (as used in claim 23).

Lutron contends that Term 11 means "A structure which frames or surrounds a manual actuator or display element, physically arranged to cover or surround the antenna." Control4 contends the term means "A structure, attached to the front of the support yoke, disposed over the antenna."
The bezel is the outer component of the remote control device, which means it must have spaces or holes so that the buttons or other controls on the manual actuator may be accessible. In this sense, the bezel frames or surrounds a manual actuator or display element. The claim itself states, however, that the outer bezel is "disposed over" the antenna. This implies that it covers or at least partly covers the antenna as opposed to merely surrounding it. "Partly covers" allows for the outer bezel to be disposed over the antenna, but also captures that the outer bezel has spaces or holes in it for access to the actuator.

Control4 asks the Court to specify that the outer bezel is attached to the front of the yoke. While the "outer" bezel is an exterior component, it is not required to attach to the yoke. Figure 3 provides an example where multiple components are between the outer bezel and the yoke. Consequently, it is possible for the outer bezel not to touch the yoke. Based on these factors, the Court concludes the term means "An exterior structure that covers, at least in part, the antenna."

62 '103 Patent, Fig. 3 (showing multiple components in between the bezel (330) and the yoke (318).)
a removable cushion disposed within the outer covering to form a cushioned bottom portion; and a bolster removably disposed within the interior of the outer covering and substantially all of said bolster disposed exteriorly about at least a portion of the perimeter of the bottom portion without being secured to the removable cushion.

'502 patent at col. 3, ll. 37-46 (emphasis added).

Beginning with the claim language itself, the term "outer covering" is singular and the articles "the" and "an," which are used in connection with "outer covering" in the claim and throughout the specification, are also singular. This suggests that the patentee intended there to be only one cover enclosing both the cushion and the bolster. This language alone does not preclude the possibility that the single cover contains interior pockets or compartments providing some separation between the two pillows.

The other claims and the specification, however, indicate that the term "outer covering" does not include coverings that completely seal off the bolster from the pillow. Claim 2 claims "a reclosable access opening." 502 patent at col. 3, ll. 49-50. Claim 7 states: "the removable cushion and bolster are separately removable from the outer covering interior through the reclosable access opening." Id. at col. 4, ll. 20-22. The use of the singular here again indicates that the covering has only one opening. Figures 3, 4, and 5, although arguably representing only preferred embodiments, clearly depict a single opening.

The specification explains that the invention was designed to allow removal of both the cushion and the bolster through a single opening:

the bolster is easily removable by the simple expedient of unzipping the zipper 7 on the bottom of the pet bed 1, disengaging the straps 8, and withdrawing the bolster through the reclosable access opening. . . . The bottom cushion 4 can also be withdrawn in the same way.

Id. at col. 3, ll. 9-14. If the covering contained an internal partition completely sealing off the cushion from the bolster, removal of the two pillows through a single opening in the bottom of the covering would be impossible.

The same issue arises from claims 4, 7, 9, and 11. They describe a bolster that is "removably affixed" or "removably secured" to the interior of the outer covering. The specification contemplates no other mode of access to the affixed bolster other than through the single opening in the covering. If the bolster were completely walled off from the compartment containing the opening, the user would be unable to detach it from the interior of the covering and remove it for cleaning.

In anticipation of this problem, the specification teaches that the pocket of the covering containing the bottom cushion must "communicate" with the bolster pocket. Id. at col. 2, ll. 12-14. In other words, the spaces containing the bolster and the bottom cushion must open into each other. Figure 5, which clearly illustrates the insertion of both the bolster and the cushion through a single opening, further supports the conclusion that the two pillows must communicate.

Although the claims and specification present a strong case for a narrow construction of "outer covering," the parties debate extensively whether the patentee disavowed such a construction during prosecution. Arguments made by the applicant during patent prosecution may serve to refine the scope of claim coverage. Omega Engineering, Inc. v. Raytek Corp., 334 F.3d 1314, 1323-24 (Fed. Cir. 2003). In order for the doctrine of prosecution disclaimer to apply, the patentee must make "clear and unmistakable" actions or statements disavowing claim scope. Id. at 1325-26. In determining the scope of disavowal, the test is "whether a competitor would reasonably believe that the applicant had surrendered the relevant subject matter." Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1457 (Fed. Cir. 1998).

The patent examiner initially rejected claims 1-3 of the 502 patent as anticipated by U.S. Patent No. 5,010,843 ("Henry patent" or "'843 patent"). Docket No. 86, Ex. 2 at DMC000034-36. The Henry patent discloses a pet bed having a pair of top cushions that rest on a base cushion. '843 patent at Abstract. The top cushions are joined to the base cushion by stitching or other means. Id. at col. 2, ll. 19-28. One embodiment of Henry's invention consists of a circular base cushion with two semi-circular top cushions, or bolsters, that leave a circular space in the middle for a pet. Id. at Fig. 5. The patent examiner found that this embodiment of the Henry patent anticipated the 502 patent. Docket No. 86, Ex. 2 at DMC000034.

In response, claim 1 was amended to read that the bolster is located within the outer covering "without being secured to the
removable cushion." Docket No. 86, Ex. 2 at DMC000039. In accompanying remarks, the inventor attempted to distinguish his invention from Henry by arguing that Henry teaches "separate covers" for each cushion with the potential for exposed connections that a pet could tear apart. In contrast, the present invention avoids the problem of exposed connections because "a single cover encompasses both cushions." Id. at DMC000042; 843 patent at col. 2, ll.56-60. at DMC000042. He further argued that "Henry does not suggest a single cover for all of the cushions, and it would be difficult to design such a cover and assemble such a bed using the interconnected cushions of Henry." Id.

The patent examiner did not comment further on the issue of separate covers. He merely proposed two additional amendments to claim 1: adding the phrase "substantially all of said bolster" and the word "exteriorly" to describe the position of the bolster relative to the bottom cushion. Id. at DMC000046. After a telephone interview with the examiner confirming that the 502 patent as amended read over the prior art, the patentee accepted the amendments and the patent issued. Id. at DMC000044.

Defendants contend that in distinguishing Henry on the basis of separate covers, the patentee limited the scope of his claims to a single cover with one interior compartment for both the bottom cushion and the bolster. Flexi-Mat argues that the examiner's response and suggested amendment indicate that the examiner rejected the patentee's attempt to distinguish Henry, and because the patentee accepted the examiner's proposals without further comment, any disavowal of claim scope is ambiguous.

I find that the patentee's comments during prosecution "clearly and unmistakably" disavow separate covers. Flexi-Mat effectively concedes this point. What is not clear from the record is the patent examiner's interpretation of the scope of the disavowal and his reasons for ultimately allowing the claims. Although the applicant and examiner discussed the issue of separate covers, Docket No. 86, Ex. 2 at DMC000034, 42, the examiner's final communication offers only two amendments unrelated to the nature of the covering and no further explanation of his reasoning. Id. at DMC000046.

Flexi-Mat argues that this silence on the part of the examiner suggests that examiner rejected the patentee's expressed claim limitation. Flexi-Mat, however, misconstrues the law: the examiner's silence does not discount the value of the patentee's comments. The fact that "the prosecution shifted to a different focus does not blunt the impact of those remarks made to overcome the prior rejection." Springs Window Fashions LP v. Novo Industries, LP, 323 F.3d 989, 995 (Fed. Cir. 2003). See also Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1462 (Fed. Cir. 1998) ("Regardless of the examiner's motives, arguments made during prosecution shed light on what the applicant meant by its various terms. The fact that an examiner placed no reliance on an applicant's statement distinguishing prior art does not mean that the statement is inconsequential for claim construction.") (internal citation omitted). Thus, although I can draw no conclusion directly from the examiner's silence, the clarity of the patentee's disavowal is sufficient to cause a competitor, after reviewing the specification and the prosecution history, reasonably to conclude that the claimed invention consisted of a single covering, not multiple separate coverings. 2

--- Footnotes ---

2 Flexi-Mat distinguishes Springs Window Fashions LP v. Novo Industries, LP, 323 F.3d 989, 995 (Fed. Cir. 2003) from this case on the grounds that the examiner here rejected the patentee's attempt to distinguish Henry on the basis of separate coverings. As discussed above, the examiner's proposal for two further amendments sheds no light on his acceptance or rejection of the separate covers argument. Thus, Spring Windows, which addresses the situation in which an examiner's motivations are unclear, is on point.

Flexi-Mat analogizes this case to Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 953 (Fed. Cir. 1993), in which an applicant attempted to distinguish his invention for making light-weight bricks over the prior art by arguing during prosecution that the fibers had to be thicker than capillaries. The district court found that the patentee disavowed coverage of capillary-sized fibers. Id. The Federal Circuit affirmed this conclusion, explaining that a "reasonable competitor could have concluded, from a reading of the prosecution history, that the examiner relied on this distinction in allowing the claim, and thus, that Hoganas had given up coverage" of that subject matter. Id.

Flexi-Mat ignores this central holding. Instead, it mistakenly focuses on the Court's rejection of Hoganas' argument that the scope of the disavowal encompassed all of the distinctions that the patentee made between his invention and the prior art. Id. The Court refused to apply prosecution history estoppel to arguments that the examiner could not reasonably have relied
on in allowing the claims. Id. In this case, the separateness of the coverings was clearly a meaningful way to distinguish over Henry, and there is no question that the examiner would have relied upon it. Thus, Flexi-Mat’s reliance on Hoganas is misplaced.

The prosecution history clarifies that the “outer covering” must be a single covering, but it is of little use in resolving the main point of contention between the parties: whether that single covering includes compartments in which the bolster and cushion are entirely sealed off from each other. That point of contention reduces the dispute to the definition of “separate.”

“Separate” in this context is not a technical term, and its meaning is readily apparent: to set or keep apart. Webster’s Third New International Dictionary (1986). The 502 patent refines this definition in that it teaches that the pillows may be “separate” in the sense that they are located in different parts of the interior, but they cannot be entirely sealed off from each other; the spaces containing each pillow must “communicate.” 502 patent, col. 2, ll. 12-13.

Flexi-Mat contends that the definition of “separate” turns on the way the covering was manufactured. Specifically, it argues that the distinction between the “separate” covers in Henry and those at issue here is that each Henry cover is manufactured individually and completely and then connected together; the 502 cover, in contrast, is a unitary structure. Thus, Flexi-Mat argues, the 502 patent covers a bolster and pillow enclosed in a single covering sewn to create entirely sealed off pockets for each, but does not cover a bed made from pillows enclosed in individually made coverings, then connected together. Id.

This argument makes little sense in light of the claims and the specification. The patentee distinguished his invention over Henry because the Henry pillows were physically isolated in individual coverings and his were not; the method of manufacture was not at issue. 3

In sum, relying primarily on the claim terms, the claims, and the specification in accordance with Phillips, I construe the term “outer covering” as an article for receiving and enclosing both the removable bottom cushion and the removable bolster within an interior space such that the two pillows communicate with each other. 4

Flexi-Mat suggests that a construction of “outer covering” that excludes coverings with walled off compartments would exclude the preferred embodiment. Docket No. 107 at 2, n.1. This is not the case. The preferred embodiment describes a covering with two “pockets” -- one for each pillow -- and no suggestion of a barrier between them. 502 patent at col. 2, ll. 45-46, 51-52, 65-67, and col. 3, ll. 1-2. This design fits comfortably within the construction that I have given to the term “outer covering.”

Next, the district court construed the term “outer housing” to require an outer housing that “functions as a handle for the use of the swab,” and is “not designed to be removed and thrown away.” Hemphill, 134 F. Supp. 2d at 727. Specifically, the
district court found that during prosecution of the 720 patent, Hemphill distinguished her invention from U.S. Patent No. 2,393,677 (the 677 patent), noting that her "outer housing" transformed into a "handle structure," a metamorphosis absent from the invention of the 677 patent. We find that the district court properly construed the term "outer housing."

2813
"Outer spatial volume"

Cytyc's proposed construction  Xoft's proposed construction
(no construction required)  Balloon or cage.

or
A region of space defined by an expandable surface element and surrounding an inner spatial volume.

The phrase "outer spatial volume" in the '204 patent is analogous to the "outer, closed, inflatable chamber" of the '813 patent. The "outer spatial volume" is also explained in a similar manner; it is "defined by an expandable surface element disposed proximate to the distal end of the body member in a surrounding relation to the inner spatial volume." '204 patent, col. 8, ll. 22-25. Xoft again confuses the concepts of a volume with the boundary of a volume. Cytyc's proposed construction is congruent with the language of claim 1 of the '204 patent, so the court will construe "outer spatial volume" as "a region of space defined by an expandable surface element and surrounding an inner spatial volume."

2814
2. '589 Patent, Claims 1 and 9; and '703 Patent, Claim 15: "(c) . . . having an outer surface defining a drive head that accepts a driving mechanism for rotating and linearly translating said bolt."

Gillespie asks the court to construe "having an outer surface defining a drive head that accepts a driving mechanism for rotating and linearly translating said bolt," as used within Claims 1 and 9 of the '589 patent and Claim 15 in the '703 patent, to mean that the drive collar has a surface, separate from the frusto-conical inner surface of the drive collar, for defining a drive head capable of accepting a mine roof bolt driver mechanism that can rotate and linearly translate the mine roof bolt; the drive head may be of any shape or configuration that accepts a mine roof bolt driver mechanism. (See Pl.'s Brief, at 12.)

DSI asserts that Gillespie should be estopped from asserting a scope under the doctrine of equivalents of the term "outer surface defining a drive head" that would encompass a mine roof bold with a collar having a cylindrical outer surface (see Defs Brief, at 23) because during the prosecution in support of patentability to the United States Patent and Trademark Office ("USPTO"), and in response to rejection over the Spies patent, Gillespie specifically argued that Spies (attached as Exhibit E to Def.'s Brief) did not disclose his hexagonal collar because the Spies collar was "cylindrical on the outside" surface. Thus, DSI argues that Gillespie cannot rebut the presumption of prosecution history estoppel nor assert that the '589 patent claims a cylindrical collar. (See Def.'s Brief, at 17-23.)

It does not appear to this court that the prosecution history should be read in such a limited way. Although it is true that during the prosecution of the '589 patent, Gillespie stated to the USPTO:

- There is nothing in the Spies patent to suggest that the collar 17 should be used for this purpose. In fact, Spies teaches away from such an interpretation of the drawings. Collar 17 appears to be cylindrical on the outside, thus impractical for being rotated by a mine roof bolting machine. * * *
Applicant's invention comprises essentially a solid, effectively single-piece bolt head comprising the tapered plug 20 and the hexagonal head collar 26, that when pressed tightly together, define the bolt head as set forth in amended claims 1 and 10.

(Def.'s Brief Exh. F, at 6-7), this argument must be read into context. The central point of Gillespie's argument was that the Spies bolt has a fundamentally different construction which would prevent it from being driven by the collar, no matter its shape. And although the patent specification consistently describes a mine roof bolt having a drive collar with a hexagonal outer surface defining a drive head (see, e.g., Pl.'s Brief Exh. A, col. 3, In. 54-55; col. 4, In. 52-53; col. 5, In. 6), the surrender of other-shaped outer surfaces defining the drive head must be clear and unmistakable, which it is not. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-26 (Fed. Cir. 2003). Rather, the patent specifications of the '589 and '703 patents state

"[a]lthough the collar 26 is shown as a hexagonal head, obviously a square head or any other shaped head that accepts a mine roof bolt driver mechanism and boom should function adequately for the intended purpose"

('589 Patent, col. 3 In. 54-58; '703 Patent, col. 5, In. 10-14.)

Moreover, although DSI argues that the plain meaning of the term "outer" means "exterior," the court must determine the ordinary meaning that would be attributed to those words by persons skilled in the relevant art. See SuperGuide Corp. v. DirecTV Enters., Inc., 358 F.3d 870, 874-75 (Fed. Cir. 2004) (emphasis added). In which case, the meaning of the word "outer" is not limited to merely the "exterior" surface. This claim term clarifies that a surface of the drive collar that is "outer" (relative to the frusto-conical "inner" surface portion thereof) provides a drive head.

Thus, the ordinary meaning of the claim, the written descriptions, the context of the prosecution of the patent, and the described embodiments persuade the court to construe claims 1(c), 9(c) and 15(c) to mean the drive collar has a surface outside and separate from the frusto-conical inner surface of the drive collar for defining a drive head capable of accepting a driving mechanism that can rotate and linearly translate the mine roof bolt. The drive head may be of any shape or configuration that accepts such a driving mechanism.

Claim Construction

The claims of a patent define what is protected, i.e., what a patentee has the right to exclude the public from making, using, importing, offering for sale, or selling. See Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) ("It is a 'bedrock principle' of patent law that 'the claims of a patent define the invention to which the patentee is entitled the right to exclude.'"). The meaning and scope of patent claims are reviewed as a matter of law. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). Precedent establishes that no deference is owed to the district court's claim construction or to any underlying factual findings predicate to construing the meaning and scope of the claims. Id. at 1451.

Dywidag states that the prosecution history negates the district court's claim construction. During prosecution Gillespie distinguished his invention from a cited reference, U.S. Patent No. 4,798,501 (the Spies patent), that shows a bolt-like rock anchor having a head with a recess in the end whereby a tool can rotate the bolt. When the examiner rejected Gillespie's application on the ground of obviousness in view of Spies, Gillespie argued that the collar at the end of the Spies bolt was cylindrical on the outside and was impractical for engagement by a mine roof bolting machine:

There is nothing in the Spies patent to suggest that the collar 17 should be used for this purpose. In fact, Spies teaches away from such an interpretation of the drawings. Collar 17 appears to be cylindrical on the outside, thus impractical for being rotated by a mine roof bolting machine.

'589 Patent Application (Paper No. 3).

However, Gillespie stresses that his claims should not be limited in a way that excludes the Spies structure, because the Reasons for Allowance did not depend on how the drive collar is rotated:
The following is an Examiner's Statement of Reasons for Allowance: The prior art does not teach a tapered plug and a tapered drive collar, as recited in the claims, wherein the tapered plug is placed over the end of a cable and inserted into a recess of the internally tapered drive collar and wherein the drive collar is rotated.

Mr. Gillespie also argues that the term "outer surface" in the specification and claims means the surface outer of the mine roof, not the outside of a hexagonal collar. He argues that the "outer" surface is thereby distinguished from the usage of "inner" for the conical surface that wedges the cable into the bolt head. The district court accepted this construction, stating:

"It does not appear to this court that the prosecution history should be read in such a limited way."

The central point of Gillespie's argument was that the Spies bolt has a fundamentally different construction which would prevent it from being driven by the collar, no matter its shape. And although the patent specification consistently describes a mine roof bolt having a drive collar with a hexagonal outer surface defining a drive head, the surrender of other-shaped outer surfaces defining the drive head must be clear and unmistakable, which it is not. Rather, the patent specifications of the 589 and 703 patents state "[a]lthough the collar 26 is shown as a hexagonal head, obviously a square head or any other shaped head that accepts a mine roof bolt driver mechanism and boom should function adequately for the intended purpose" of the word "outer" is not limited to merely the "exterior" surface. This claim term clarifies that a surface of the drive collar that is "outer" (relative to the frusto-conical "inner" surface portion thereof) provides a drive head. . . .

Moreover, although DSI argues that the plain meaning of the term "outer" means "exterior," the court must determine the ordinary meaning that would be attributed to those words by persons skilled in the relevant art. In which case, the meaning of the word "outer" is not limited to merely the "exterior" surface. This claim term clarifies that a surface of the drive collar that is "outer" (relative to the frusto-conical "inner" surface portion thereof) provides a drive head. . . .

The drive head may be of any shape or configuration that accepts such a driving mechanism.

437 F. Supp. 2d at 1266-67.

We agree with the district court to the extent that the mechanism by which the bolt is grasped by a tool and rotated is not the only difference from the Spies bolt. However, we do not agree that a person of ordinary mechanical skill would read the specification, the drawings, and the claims to construe "outer surface" of the drive collar to include a collar whose interior, not exterior, accepts the drive tool. The specification and drawings describe and illustrate a drive collar whose inner (interior) surface engages the tapered plug, and whose outer (exterior) surface accepts the drive tool. Although we agree that the surface need not be hexagonal, it must be outer with respect to the collar. This is the meaning that Gillespie used when he argued during prosecution that the Spies reference was distinguished by its smooth outer surface, as contrasted with Gillespie's angular outer surface. In this argument, Mr. Gillespie clearly used "outer" to refer to the outside surface of the bolt head, and pointed out that the cylindrical outside surface of the Spies bolt head rendered it incapable of being driven by a mine roof bolting machine. Although Gillespie argues that this distinction was not material to the grant of his patent, citing the examiner's Reasons for Allowance, supra, he nonetheless argued this distinction from the Spies mine roof bolt. The words of a claim are generally given the ordinary meaning that they would have to a person of ordinary skill in the field of the invention, see Phillips, 415 F.3d at 1312, and are read in view of the specification, of which they are a part. Phillips, 415 F.3d at 1315. In addition, "claim terms are normally used consistently throughout the patent," Phillips, 415 F.3d at 1314, the words "inner" and "outer" appearing several times in each claim.

Gillespie's specification and argument are directed to an exterior surface of the drive collar, shaped to accept the drive tool. This is the meaning that Gillespie used when he argued the difference from Spies. A cylindrical outer surface that is not adapted to be grasped by a drive tool characterizes the Spies and the Dywidag bolt heads. Such construction was negated during prosecution. The patentee is held to what he declares during the prosecution of his patent. North American Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1345-46 (Fed. Cir. 2005). See also Springs Window Fashions L.P. v. Novo Indus., L.P., 323 F.3d 989, 995 (Fed. Cir. 2003) ("The public notice function of a patent and its prosecution history requires that a patentee be held to what he declares during the prosecution of his patent.")

On this construction, the judgment of literal infringement cannot stand. See Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1326 (Fed. Cir. 2006) ("in reviewing claim construction in the context of infringement, the
The legal function of giving meaning to claim terms always takes place in the context of a specific accused infringing device or process"). The judgment of infringement is

REVERSED.

2816

16. "an outer surface of one of said members"

This phrase is found in Claim 16. Plaintiff proposes the following construction: "a surface on the outside of the U-shaped terminal." Defendants assert that the phrase need not be construed, and the Court agrees. Because the Court see no ambiguity as to the meaning of the phrase "an outer surface of one of said members" and because its ordinary and customary meaning is clear to one skilled in the art, the Court declines to construe the phrase as it is used in the '015 Patent.

2817

G. Claim language to be construed from Claims 3 and 6 -- "the outer surface of said sheathing being tapered towards the immersion end of said tube such that a minimum thickness of said sheathing is directly adjacent to and exposing said immersion end of said tube for minimizing trapped gases adjacent to the measuring head when immersed in a metal bath" --

col. 4, ll. 53-58; col. 6, ll. 54 60

HEN contends that no construction of these terms is required and that they should be given their plain and ordinary meaning. (HEN CC Br. at 27.) Minco, however, proposes the following construction: "the outer surface of said sheathing is continuously and substantially tapered, and the minimum thickness of the sheath at the immersion end does not taper to a flat, radially outwardly extending annular shoulder (like that described in Russian/Soviet reference 144620 or German patent 1928845)." (Minco CC Br. at 40.) We agree with HEN that no construction of this claim language is required, and we reject Minco's proposed construction.

Minco argues that the specification and the prosecution history support its proposed construction. Minco argues that the specification language calls for a sheathing that has a minimum thickness at the immersion end in order, inter alia, to reduce the trapping of liberated oxygen and other gases in the area of the oxygen sensor. Minco contends that to conform to this requirement, the sheathing cannot taper to a "flat, radially outwardly extending annular shoulder." (Minco CC Br. at 40.) We disagree. A sheathing that tapers towards the immersion end of the probe and comes to a flat, radially and outwardly extending annular shoulder adjacent to the immersion end would still have its minimum thickness adjacent to the immersion end. Additionally, although the figure included in the specification does not contain a flat, radially and outwardly extending annular shoulder, but rather continuously tapers towards the immersion end, it would be improper to import this limitation appearing solely in the specification into the patent claims.

We also disagree with Minco's argument based on the prosecution history. Minco argues that during the prosecution of the '736 patent, HEN distinguished its probe from Russian/Soviet Patent No. 144,620 ("the Russian patent") and German Patent No. 1,928,845 ("the German patent") because they both had flat, radially and outwardly extending annular shoulders proximate to the measuring area that would serve to trap gases near the measuring unit and negatively affect the accuracy of the readings. Therefore, according to Minco, a taper that comes to a generally annular flat shoulder near the measuring area is not covered by the '736 patent. However, when distinguishing the Russian patent, HEN stated:

[i]t appears as though the outer sheath (5) of the Russian probe does not taper down to a minimum cross-sectional thickness. Instead, while it does slightly taper, a radially outwardly extending annular shoulder of approximately one-half of the overall wall thickness of the outer sheath remains proximate the measuring element. A shoulder of this type could disrupt the flow of gases away from the measuring element.

(Minco App. 4L at HEN000164.) The distinction identified by HEN is not simply that the Russian probe has a radially and outwardly extending annular shoulder while its probe does not. Rather, HEN stated that the Russian probe's radially and
outwardly extending annular shoulder was approximately one-half of the overall wall thickness of the outer sheath. HEN stated the following with respect to the German patent:

[j]it appears as though the [German patent] relates to a probe which includes an outer sheath (7) which is tapered toward the immersion end. The manner in which the sheath is tapered is different from that of the applicants' sheath in that both the inner diameter and the outer diameter are tapered toward a generally flat annular shoulder which extends outwardly from the probe body. An additional annular member (6) extends beyond the outer sheath towards the immersion end and forms an additional radially outwardly extending annular shoulder closer to the measuring element (5). Thus, neither the outer sheath (7) nor the additional element (6) tapers down to a minimum thickness proximate the measuring element to avoid trapping the gases proximate to the measuring element.

(Minco App. 4L at HEN000163-164.) Again, HEN did not distinguish the German patent based on the fact that the German patent has a radially and outwardly extending annular shoulder and its probe does not. Rather, HEN distinguished the German patent because the German probe's sheath tapered both towards and away from the probe's body, and the German probe included an additional annular member that extended beyond the sheath. We conclude that the arguments HEN made to distinguish the Russian and German patents do not amount to a clear disavowal of claim coverage over any sheath that tapers to a radially outwardly extending annular shoulder as proposed by Minco.

Finally, Minco argues that HEN submitted a drawing to the PTO attached to its application that showed a flat, outwardly extending annular shoulder, and that later, during the prosecution of the patent, HEN submitted a revised drawing omitting the flat, outwardly extending annular shoulder and showing instead a rounded shoulder like that depicted in the figure in the '736 patent specification. Minco argues that HEN revised the drawing of its probe in order to distinguish it from the German and Russian patents, which included flat, outwardly extending annular shoulders, and that, therefore, we should construe the patent claim to exclude coverage of probes with such shoulders. We find that Minco's argument is not supported by the record. The drawing submitted by HEN to the patent office showing a flat, outwardly extending annular shoulder is from the Belgian patent application No. 2/59866 from which the '736 patent claims priority. (Minco App. 4B at HEN000034, 000042.) HEN argued during the Markman hearing that it submitted the drawing as part of its Claim of Foreign Priority and Transmittal of Priority Document. Additionally, the parties have submitted into evidence the original patent application. (See Minco App. 4A at HEN000020-29.) However, while the original patent application in the record before us does not include a drawing of the applicant's probe, there is evidence which leads us to conclude that the original drawing of the applicant's probe is not the drawing with a flat, annular shoulder as Minco asserts. First, HEN argues that the original patent application was stamped with the number "513532." (See Minco App. 4A at HEN00022.) The first time a drawing depicting a probe with a rounded shoulder appears in the record before us is in a document titled "Request for File Wrapper Transmittal of Priority Document. Additionally, the parties have submitted into evidence the original patent application. (Id. at HEN000082.) HEN argues that this shows that the figure with the rounded shoulders was how the probe was depicted in the original patent application because it was stamped with the same number by the PTO. Finally, the original patent application contains references to a drawing containing elements marked 6A and 8A. (Minco App. 4A at HEN00024025.) The drawing alleged by Minco to have been the original depiction of the probe, and which shows a probe with a flat annular shoulder, does not contain any elements marked 6A or 8A, whereas the drawing that contains rounded shoulders does have elements marked 6A and 8A. (See Minco App. 4B at HEN000042 and Minco App. 4F at HEN000082.) During the Markman hearing Minco did not present any evidence or make any arguments countering this evidence. We therefore reject Minco's claim that HEN limited the scope of its patent by allegedly modifying the depiction of its probe during the patent prosecution in order to distinguish it from the German and Russian prior art.

GO BACK

2818

84. The court construes the fourth additional limitation in claim 24, "an outlet line interconnecting a compressor outlet to said compressed [nitrox] storage assembly," as follows: a line which connects the outlet end of the compressor to the nitrox storage assembly.

GO BACK
III. Second Light Fixture: "oriented to direct light downwardly and outwardly to a vertical wall surface outwardly adjacent from said body whereby light is reflected back to a broad area under said body."

A. "Vertical wall surface outwardly adjacent from said body whereby light is reflected back to a broad area under said body"

10 Kenall claims that with regard to the second light fixture, "outwardly adjacent" refers to "the vertical wall surface closest to the body of the lighting system." (R. 26, Kenall Markman at 3.) Genlyte argues, however, that "outwardly adjacent" merely means "next to or near." (R. 27, Genlyte Markman at 2.) While Kenall's proposed construction goes too far, Genlyte's does not go far enough.

10 Although in the Joint Statement, the parties ask the Court to construe the phrase, "whereby light is reflected back to a broad area under said body," neither party addressed this issue in their briefs. (R. 23, Joint Statement at 1.)

1. Intrinsic Record

"Outwardly adjacent" must mean more than "next to or near," because to decide otherwise would render the term "outwardly" meaningless. "When different words or phrases are used in separate claims, a difference in meaning is presumed." Nystrom, 424 F.3d at 1143; see also Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 1999) ("Unless the patent otherwise provides, a claim term cannot be given a different meaning in the various claims of the same patent"). The term "adjacent" is found several times within the claims of the '254 Patent, in addition to claims 1 and 3. Dependent claim 9 states that:

The medical lighting system of claim 5 11 . . . wherein said second fluorescent light fixture is inwardly adjacent to said first fluorescent light fixture and said second fluorescent light fixture is parallel to first shorter end; and wherein said third fluorescent light fixture is outwardly adjacent from said second fluorescent light fixture and abuts a second shorter end of said body . . .

('254 Patent, col. 4, 11.24-37) (emphasis added). In contrast to claim 9, claim 14 refers to the term "adjacent" on its own: "The medical lighting system of claim 3 wherein a distribution of light from said first and second light fixtures excludes glare from areas adjacent to a standard hospital bed placed below the medical lighting system." (254 Patent, col.4, 11.60-64) (emphasis added).

11 Claim 5 involves "the medical lighting system of claim 4," which involves "the medical lighting system of claim 3."

Claim 9 provides valuable insight into the meaning of the phrase "outwardly adjacent," as it is used together with the phrase "inwardly adjacent." The second light fixture is "inwardly adjacent to" the first light fixture, and the third light fixture is "outwardly adjacent from" the second light fixture and "abuts a second shorter end of said body." (254 Patent, col. 4, 11.24-37.) Claim 9 further explains that "said body is rectangular and a first shorter end [sic] of said body is designed to abut the vertical wall surface," and the first light fixture abuts this first shorter end. (254 Patent, col.4, 11.25-28.) This language plainly states that the first light fixture (the reading light) is closest to the vertical wall surface, as it "abuts" the wall surface. Therefore, the second light fixture (the ambient light), which is "inwardly adjacent" to the first light fixture, must be further from the vertical wall surface. It follows that the third light fixture, which is "outwardly adjacent from" the second light fixture, is even further away from the vertical wall surface, since the first light fixture abuts the wall.

The written description of Figure 1, which is described as a "Preferred Embodiment" of the '254 Patent (254 Patent, col.2, 11.27-28), supports the Court's construction of the terms in claim 9. 12 Figure 1 is a diagram of the ceiling mounted structure. The description of Figure 1 states that: "ambient light reflector 24 is inwardly adjacent to reading light reflector 20" (254 Patent col.2, 1.50); and "examination light reflector 28 is outwardly adjacent to ambient light reflector 24, includes short side 18 and is opposite from reading light reflector 20." (254 Patent col.2, 11.66-67.) In the preferred embodiment figure, reading light reflector 20 is at the end of the ceiling mounted body that is closest to the wall. (254 Patent, Fig. 1.) Ambient light reflector 24 is close to the center of the ceiling mounted body, further away from the wall. (254 Patent, Fig. 1.) Examination light reflector 28 is even further away from the wall, and thus further from the center of the ceiling mounted body. (254 Patent, Fig. 1.)
12 While Figure 1 is described as a "side plan view of lighting fixture 10" (‘254 Patent, col.2, 1.32), the ‘254 Patent only contains claims for a light fixtures 1, 2, and 3. As Figure 1 is the preferred embodiment of the '254 Patent, "lighting fixture 10" must be the ceiling mounted body of the preferred embodiment of the medical lighting system at issue.

The language in claim 9 and the written description of Figure 1 shows that "a vertical wall surface outwardly adjacent from said body" does not necessarily mean "the vertical wall surface closest to the body of the lighting system," as in both cases, the "outwardly adjacent" light fixture or reflector was the furthest from the vertical wall surface abutting the body of the lighting system. In addition, the "inwardly adjacent" light fixture or reflector in both cases is closest to the center of the ceiling mounted body. It follows that "inwardly adjacent" to a vertical wall would be the vertical wall closest to the center of the ceiling mounted body; that is, any vertical wall that is adjacent to the horizontal side of the ceiling mounted body, but not the ends of said body.

Moreover, claim 9 shows that the '254 Patent refers to the vertical wall surface closest to the body of the lighting system as "designed to abut the vertical wall surface" (‘254 Patent, col.4, 1.26) (emphasis added) or in claim 12 as "substantially abutting the vertical wall surface." (‘254 Patent, col.4, 11.53-54) (emphasis added). Thus, the Court finds that the '254 Patent's claims and written description show that the meaning of the phrase, "a vertical wall surface outwardly adjacent from said body," is "a vertical wall surface next to or near either end of said body."

2. Extrinsic Record
   a. Expert Reports
   This Court's construction of the phrase "a vertical wall surface outwardly adjacent from said body" aligns with Lemons' original opinion that the phrase means "the wall is next to or near one end of the housing." (R. 27, Genlyte Markman, Ex. C at 2.) Interestingly, in stating its proposed construction, Genlyte dropped the second part of the phrase, "one end of the housing," arguing that "outwardly adjacent" should simply mean "next to or near." (R. 27, Genlyte Markman at 20-22.)

   b. Dictionary Definitions
   Genlyte points to the Webster's Dictionary definition of "adjacent," which is "not distant: nearby." (R. 27, Genlyte Markman at 21, Ex. D at 56). As explained above, the Court agrees with this construction of "adjacent;" however, Genlyte omits any definition or discussion of "outwardly," which is a key modifier in this phrase. See also Free Motion, 423 F.3d at 1349 (upholding district court's construction of "adjacent" as meaning "near").

   B. "Oriented to direct light downwardly and outwardly"
   In their Joint Statement, the parties originally agreed that the phrase "oriented to direct light downwardly," as used twice in claim 1 and 3, was the only phrase in dispute. (R. 23, Joint Statement at 1-2.) In their briefs, however, the parties realized that the phrase, "oriented to direct light downwardly" (‘254 Patent, col.3, 11.40-41), was only used once in the claims, to describe the first light fixture, and a different phrase, "oriented to direct light downwardly and outwardly," was used to describe the second light fixture. (‘254 Patent, col.3, 11.43-44.) The parties dispute the construction of both of these phrases. Thus, the Court separately addresses construction of the phrase "oriented to direct light downwardly and outwardly" below.

1. Intrinsic Record
   Kenall asks the Court to construe the phrase "downwardly and outwardly" to mean a single intended directionality of light from the second light fixture, specifically, "the single direction of the focus of the light toward the wall." (R. 28, Kenall Reply at 14.) By contrast, Genlyte argues that the phrase "downwardly and outwardly" means "below and away from center (of the light fixture)." This Court agrees with Genlyte that the plain language of the claim shows that the light is oriented in more than one direction - both downwardly and outwardly, but this Court declines Genlyte's invitation to deviate from this Court's previous claim constructions.

   There is no support in the '254 Patent, the extrinsic evidence, or common sense for Kenall's argument that downwardly and outwardly means only one direction: outwardly, toward the wall. The words of the claim plainly state that the light has more than one intended directionality: downwardly and outwardly. To hold otherwise would render the terms "and outwardly" meaningless. In the first section of claim 1, the '254 Patent describes a light that is oriented only "downwardly," as opposed to both "downwardly and outwardly." (‘254 Patent, col.3, 11, 40-44.) Contrary to Kenall's claims, the fact that the second light fixture is directed to a vertical wall and reflected from there to a broad area under the body, does not mean that "all" of the light goes toward the vertical wall and no light travels directly downward. The phrase "oriented to direct light downwardly and outwardly" means "to set or arrange to direct more light in a downward and outward direction than in an upward direction."
2. Extrinsic Record

a. Expert Report

In his initial statement, Lemons broke apart the phrase "oriented to direct light downwardly and outwardly," defining "oriented to direct light downwardly" as "to set or arrange to direct illumination to an area below the product." (Lemons Statement at 2.) Lemons then defined "and outwardly to a vertical wall surface" as "also aims illumination towards the wall." (Id.) In his surreply statement, Lemons slightly altered this definition to: "(oriented to direct light) below and away from center [of fixture] (to a vertical wall surface)." (Lemons Surreply at 6.) Lemons explains that "downwardly and outwardly" does not mean the light is separated in two separate directions, but that light will also travel below the lighting system without first being reflected off the vertical wall. (R. 31, Genlyte Surreply at 3; Lemons Surreply at 2-6.) This explanation accords with this Court's construction.

b. Other extrinsic evidence

In its reply, Kenall attached a copy of technical information sheets for MD*4 lighting systems sold by Genlyte. (R. 28, Kenall Reply, Ex. 4). Not only is this evidence of very little probative value, but it does not show that the second light fixture directs all light toward a vertical wall. (R. 28, Kenall Reply at 13.)

2. Extrinsic Record

a. Expert Report

In his initial statement, Lemons broke apart the phrase "oriented to direct light downwardly and outwardly," defining "oriented to direct light downwardly" as "to set or arrange to direct illumination to an area below the product." (Lemons Statement at 2.) Lemons then defined "and outwardly to a vertical wall surface" as "also aims illumination towards the wall." (Id.) In his surreply statement, Lemons slightly altered this definition to: "(oriented to direct light) below and away from center [of fixture] (to a vertical wall surface)." (Lemons Surreply at 6.) Lemons explains that "downwardly and outwardly" does not mean the light is separated in two separate directions, but that light will also travel below the lighting system without first being reflected off the vertical wall. (R. 31, Genlyte Surreply at 3; Lemons Surreply at 2-6.) This explanation accords with this Court's construction.

b. Other extrinsic evidence

In its reply, Kenall attached a copy of technical information sheets for MD*4 lighting systems sold by Genlyte. (R. 28, Kenall Reply, Ex. 4). Not only is this evidence of very little probative value, but it does not show that the second light fixture directs all light toward a vertical wall. (R. 28, Kenall Reply at 13.)

A. "Outwardly Angled Traction Surface"

</table>

The '047 Patent describes the covered golf cleats as having a traction surface that is "outwardly angled." '047 Patent, col. 5 l.50; see also id. col.5, 11.66-67, col.7, 11.1, 14-15, 30-32, & col. 8, l.1. The parties agree as to the first part of the definition, that being, "a surface facing away from the axis AL that provides traction, having an outward angle relative to the axis AL," but disagree as to the second part respecting whether the angle can change in use.

1. The Parties' Contentions

Greenkeepers contend that the '047 Patent's intrinsic evidence indicates that the outward angle "is predetermined," which means that the angle is settled in advance and "maintain[s] the desired angle . . . throughout the life of the cleat," '047 Patent, col.2, 11. 12-14, not that the angle will not change in use. (Pls.' Resp. 2-3, Softspikes, Docket No. 70, Taylor Made, Docket No. 68.) Greenkeepers aver that the claim language and patent specification provide that the cleats are made of "resilient and flexible material," '047 Patent, col.6, l.28; see also id. col.1, 11.56-57, that is, polyurethane material that may have the hardness of a tire and may flex slightly under load. (Pls.' Opening 8-11, Softspikes, Docket No. 61, Taylor Made, Docket No. 56.)

Defendants respond that the patent specification shows that the cleats were designed to not flex. (Defs.' Opening 11-12, Softspikes, Docket No. 57.) 1 According to Defendants, Greenkeepers expressly disavowed claim coverage of flexible cleats during the patent's prosecution history, 2 by characterizing their cleats as having the "hardness of a bowling ball," and by distinguishing cleats covered by a prior Dassler patent that had outwardly angled teeth, on the basis that because such the angle of such teeth change under load, the teeth are not suitable for golf cleats because any bending may interfere with a
golfer's swing. (Defs.' Opening 12-14 (internal quotation marks omitted).) Defendants aver that Greenkeepers have not presented extrinsic evidence showing that virtually all golf cleats bend or flex under load. (Defs.' Reply 3-6, Softspikes, Docket No. 77, Taylor Made, Docket No. 79.)

1 Taylor Made, Callaway, and ECCO joined onto Softspikes's construction briefs. (Taylor Made, Docket Nos. 54, 67, & 69; see also Oral Arg. Tr. 71:25-72:8, Jan. 21, 2010.) At the January 21, 2010 oral argument, counsel for Defendants confirmed that Pride shares Softspikes's constructions and supporting arguments. (Oral Arg. Tr. 4:19-23.)

2 The "prosecution history" includes the prosecution of United States Patent Number 5,794,367 (filed Feb. 20, 1997), the first of '047 Patent inventor Francis C. Carroll's patent applications for outwardly angled golf cleats, United States Patent Number 6,530,162 (filed Feb. 28, 1998), a continuation-in-part application of the then-pending '0367 Patent, and of which the '047 Patent is a reissue. Carroll's prosecution efforts are attributed to Greenkeepers, to whom the patents have been assigned.

Greenkeepers reply that even the hardness of a bowling ball permits some flexing, and that they differentiated Dassler cleats on the basis that such cleats had an angle that changed greatly under load, not that the cleats' angle changed at all. (Pls.' Reply 3-6, Softspikes Docket No. 78, Taylor Made, Docket No. 89.)

2. Analysis

The primary question for the Court is whether Greenkeepers disclaimed coverage of cleats for which the outward angle changes under load. "The doctrine of prosecution disclaimer is well established in Supreme Court precedent, precluding patentees from recapturing through claim interpretation specific meanings disclaimed during prosecution." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003). "Where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Id. at 1325. The Federal Circuit, however, requires statements to be "both so clear as to show reasonable and deliberateness" and "so unmistakable as to be unambiguous evidence of disclaimer" before applying the doctrine. Id. at 1325; see also id. at 1324-25 (describing and comparing cases involving an ambiguous claim disavowal with those involving a clear disavowal). Such a requirement aims "to balance the importance of public notice with the right of patentees to seek broad patent coverage." Id. at 1325.

The prosecution history indicates that Greenkeepers differentiated prior art Dassler cleats whose angle changed greatly under load: Greenkeepers stated that because the Dassler cleats' angle "change[s] because of the great flexibility thereof" and "varies on load application," they are not "adaptable to use in golf cleats," since bending, "minute that it may be, may interfere with the golfer's swing." (Defs.' Resp., Ex. J at SS_00006013, SS_00006015-16, Ex. I, at SS_00006033.) As a result, Greenkeepers "expressly disclaimed" coverage of golf cleats whose outward angle substantially changes under load, and prosecution disclaimer applies. Omega Eng'g, 334 F.3d at 1323.

On the other hand, the Court is not convinced that Plaintiff's disavowal is so broad as to cover golf cleats with an outward angle that does not change at all under load, because the patent language repeatedly emphasizes that the cleats are to be made of a "flexible" material, '047 Patent, col.6, 1:28; see also id. col.1, 11:56-57. Moreover, examination of a sample of the '047 Patent at the January 21, 2010 oral argument confirmed that the cleats can bend, however slightly, when pressure is applied. (Oral Arg. Tr. 44:7-22, Jan. 21, 2010, Softspikes, Docket No. 88, Taylor Made, Docket No. 83.) Rather than accepting either of the parties' proposed constructions, the Court, therefore, finds that the intrinsic evidence indicates that the outward angle referenced in the patent may permit some bending under load, albeit not significant bending, which Greenkeepers previously disclaimed. The parties, in their post-argument supplemental briefing, did not expressly object to the Court's construction. (Pls.' Supp. Br. 1-2, Softspikes, Docket No. 92, Taylor Made, Docket No. 86; Defs.' Supp. Br. 1-2, Softspikes, Docket No. 93, Taylor Made, Docket No. 87.) Accordingly, the Court construes "outwardly angled traction surface," "outer traction surface having an outward angulation," and "outer traction surface extending from said main body in a direction away from and at an angle to said axis AL," as "a surface facing away from the axis AL that provides traction, having an outward angle relative to the axis AL that is predetermined, such that it does not change significantly in use."
Next Avon asserts that the phrases "outwardly extending blade disposed on a first side of said barrier" in claim one and "a second and third spaced apart outwardly extending blade disposed on a second side of said barrier" in claim nine require a direct connection between the blade and the vertical barrier. Suncast disputes this interpretation, asserting that "outwardly extending" does not require a direct connection. Suncast does not provide an alternative definition of the terms. The claim language does not state "extending from" the barrier. Rather it states, more generally, "outwardly extending" and "disposed on a . . . side" of the barrier. "Dispose" means "to arrange" or "to place." Webster's, at 365. Thus, the blade is arranged on a side of the barrier, but this does not necessarily mean directly attached. The phrase "outwardly extending" does not imply a connection. "Extend" merely means "reach" or "to stretch out in distance." Id. at 439. So the phrase suggests that the blades project away from the barrier. But they do not necessarily originate from the barrier.

Avon looks to the figures in the patent, which show the blades as being in direct contact with the barrier, and the prosecution history, in which Suncast told the PTO that the "blades are integrated into a lower portion of the barrier," to support its interpretation. Def. Memo. Non-Infringement, Ex. I. However, Avon seeks to add an extraneous limitation that is not necessary for the claim language by requiring the blade to extend from the barrier. The prosecution history and the specification cannot be used to read limitations into a claim. See Intervet America, Inc., 887 F.2d at 1053. Accordingly, the claim language does not require the blade to extend directly from the barrier.

11. "outwardly facing surface"

The parties propose the following constructions for "outwardly facing surface," which is present in claims 24 and 36. Dkt. No. 114.

RTI
A surface that faces toward the outside of the syringe

BD
A surface that faces away from the center of the syringe and is parallel to the direction of the plunger motion

The parties present arguments similar to those presented in connection to the term "inwardly facing surface." For the same reasons as stated above in connection with inwardly facing surfaces, the Court finds that the claimed outwardly facing surfaces should not be limited to a direction parallel to the plunger motion.

Accordingly, this Court finds that the term "outwardly facing surface" means "a surface that faces away from the center of the syringe."

8. "Outwardly projecting edges," and "projecting edges." Consistent with the patents at issue 14 and their prosecution history, 15 the court construes "outwardly projecting edges" to mean "portions of the U-shaped, Y-shaped or W-shaped members that tip outwardly during expansion, resulting in projections on the outer surface of the expanded stent."

14 See, e.g., '154 patent, col. 2, ll. 46-51; col. 4, ll. 10-12; col. 6, ll. 17-26; col. 8, ll. 14-23.

15 D.I. 438 at 1537.
C. Over A Substantial Portion Of The Height/Over Substantially The Entire height Of A Pleat Leg 4

4 The parties have agreed that the phrase "substantial portion of the height," which appears in several claims of the '765 patent, shall have the same meaning that is ascribed to the phrase "substantially the entire height."

This Court finds that the term "over a substantial portion of the height" means largely but not necessarily wholly the height of a pleat leg including at least 50% of the leg height. This construction, which Pall has argued for, is intrinsically supported. Cuno's proposed construction - to include as much of the pleat height as is practically possible - is not supported intrinsically. Furthermore, the Court declines, once again, to impose limits on the claims that do not appear in the claim language or the other intrinsic evidence other than preferred embodiments.

The claims and the specification of the asserted patents support a claim construction that "over a substantial portion of the height" means largely but not necessarily wholly the height of the filter including at least 50% of the height. The relevant part of claims 1 and 54 of the '047 patent provide that there is intimate contact "over substantially the entire height of each leg and over a continuous region extending for at least approximately 50% of the" length of the filter element. '047 patent, col. 26, lines 26-28; '047 patent, col. 30, lines 14-16. Claim 92 of the '047 patent states that there is intimate contact "over substantially the entire height of each leg and over a continuous region extending for at least approximately 95% of the longitudinal length of the pleated filter element." '047 patent, col. 32, lines 45-48. Similarly, claims 1, 8, and 40-41 of the '765 patent contain almost identical language to the language in claims 1 and 54 of the '047 patent, and claim 39 of the '765 patent tracks the language in claim 92 of the '765 patent.

Cuno argues that, although "substantially" and "at least 50%" appear in the same claim, "at least 50%" modifies the length of the filter element and not the pleat height. (Def.'s Opp'n 28.) While the Court takes note of Cuno's point, the specification, albeit in the description of preferred embodiments, seems to use the terms substantial, significant, entire, portion, and at least 50% interchangeably when describing the pleat heights and the axial length of the filter element. See, e.g., '047 patent, col. 4, lines 5-10 ("the opposing inner surfaces 11d of the legs 11a of each pleat 11 are in intimate contact with one another over substantially the entire height h of the legs extending for a significant portion of the axial length of the filter length.") (emphasis added). Moreover, there is nothing in the intrinsic evidence that supports Cuno's proposed construction - as much as practically possible.

Cuno's argument that the prosecution history does not support Pall's position is untenable. The examiner stated that "over substantially the entire height of the legs of the pleats and a continuous region existing for at least 50% of the axial length of the element, the pleats are in intimate contact." (Korniczky Decl., Ex. 5 p. 188.) Accordingly, the prosecution history supports Pall's position and this Court's finding. To support a finding that the intended meaning was as much as possible, the
examiner's writings would have been different. For instance, if the examiner was concerned that the claim be limited to "as much as possible," there would have been a more careful use of the terms.

Finally, this Court considered this language when it construed the term "intimate contact" in the 1997 Action. The Court held that the

meaning of the term 'intimate contact' and the examples set forth in the specifications require a layering of drainage and filter materials and laid-over pleating such that contact between the adjacent pleat legs would be substantially continuous; that is, over at least 50 percent of the axial length of the filter element.

Pall Corp. v. Cuno Inc., No. 95-CV-7599, 2001 U.S. Dist. LEXIS 16778, at *24-45 (E.D.N.Y. Sept. 7, 2001) ("Pall I"). Based on the intrinsic evidence, the Court declines to assign any other meaning to "over substantially the entire height" than as set forth in this Order. That is, "over substantially the entire height" means largely but not necessarily wholly the height of a pleat leg, including at least 50% of the height.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 To be clear, the Court did not construe the language "over substantially the entire height" in the 1997 Action, but it did consider the language and use it in its construction of intimate contact.

2825

overall size of the binder

Plaintiff argues that the term also requires no definition. Defendants propose that the term be defined as: "overall longitudinal length including shield and levers."

The language of the Claim relates the length of the paper to the overall size of the binder; therefore, Defendants are on the right track. The size of the binder as used in this Claim relates to its length and the length of a sheet of paper. Accordingly, the Court construes the term "overall size of the binder" as:

The overall size of the binder means the overall length of the binder.

2826

B. "over-center spring"

The parties also request the Court to construe the meaning of "over-center spring". As Claim 1 explains, the over-center spring is "coupled to the activating lever and bias[es] it to a first position in which the arm moves the actuator pawl to the automatic locking position and also bias[es] it to a second position out of engagement with the actuator pawl." '912 patent, col. 8, ll. 29-33.

The parties agree "over-center spring" is not "a newly coined term with no definite meaning," D.I. 91 at 19, but rather is "a particular type of spring the characteristics of which are recognized by those skilled in the art," D.I. 94 at 9. Indeed, the proposed definitions to which the parties have stipulated are not far apart. Takata proposes an over-center spring is "a spring that biases a member toward a first stable position under a first set of mechanical conditions and toward a second stable position under a second set of mechanical conditions, with the member passing through an intermediate meta-stable position." D.I. 98, P 3(b). Defendants urge that an over-center spring is "[a] spring that biases a member in one direction until the member passes a transition point, and then biases the member in another direction." D.I. 98, P 3(c). Thus, the primary dispute between Takata and Defendants is whether the over-center spring biases a member toward a position or in a
direction. 24

Although the competing definitions also differ regarding the language of the "transition point" or the "meta-stable" position of the member, the language of each definition encompasses the same notion and the difference is not significant.

Interestingly, although Takata uses "intermediate" in its proposed definition, it is not a point of dispute between the parties here.

Both definitions are consistent with the usage of the term "over-center" in technical treatises. See Mechanical Design and Systems Handbook § 4.2.9, at 4.7 (Harold A. Rothbart, ed., 2d ed. 1985); Mechanisms & Mechanical Devises Sourcebook 214-17 (Nicholas P. Chironis, ed. 1991). Because the common usage of the term is unclear with regard to whether an over-center device biases a member in a direction or to a position, the Court turns to language of the claim itself. The claim, which is of primary importance in claim construction, Smiths Indus., 1999 WL 498219, at *9; Johnson Worldwide, 175 F.3d at 989-90, describes the action of the over-center spring in the patented invention as follows: "an over-center spring coupled to the activating lever and biasing it to a first position in which the arm moves the actuator pawl to the automatic locking position and also biasing it to a second position out of engagement with the actuator pawl . . . " 912 patent, col. 8, ll. 30-33 (emphases added). In writing the claim, the inventor envisioned the over-center spring not in terms of direction, but in terms of position. Indeed, as described in the claim, the activating lever is either engaged with the actuator pawl or out of engagement with the actuator pawl: the importance of the motion of the activating lever described in the claim is the position at which it arrives. Nothing in the claim language suggests that the bias of the activating lever toward either the first or second position occurs in a particular direction. It follows the claim itself indicates that the inventor used "over-center spring" to mean "a spring that biases a member [the activating lever] to a first stable position under a first set of mechanical conditions and to a second stable position under a second set of mechanical conditions, with the member passing through an intermediate meta-stable position."

The discussion of the over-center spring in the specification confirms this interpretation of the claim language. For example, the over-center spring "holds the [activating] lever in the position . . . ." 912 patent, col. 6, ll. 30-31 (reference number omitted). While the definition of over-center spring urged by Defendants encompasses an over-center spring which biases the activating lever in a direction, connoting motion, Defendants' proposed construction does not encompass an over-center spring which holds the activating lever. On the other hand, defining an over-center spring as a spring that biases a member to a position does connote a spring which can hold the activating lever.

One portion of the specification does describe the bias of the over-center spring in directional terms. In describing the way in which the preferred embodiment achieves engagement between the activating lever and the actuator pawl, the specification states, "The bias of the over-center spring on the lever is transferred to counter-clockwise . . . ." 912 patent, col. 7, ll. 6-8. This use of direction does not, however, contradict the Court's conclusions. First, as a general rule, the preferred embodiment cannot serve to limit the terms of a claim. Karlin Technology Inc., 177 F.3d at 973; Laitram Corp. v. NEC Corp., 163 F.3d at 1348; Enercon v. International Trade Commission, 151 F.3d at 1384; CVI/Beta, 112 F.3d at 1158. To import this configuration of the preferred embodiment, which has an over-center spring which biases to the first and second positions in two different directions, would be an impermissible importation of the preferred embodiment into the claim. Secondly, even if the over-center spring described in the preferred embodiment does bias the activating lever to each position in a direction, interpreting "over-center spring" based only on this statement would ignore those portions of the specification which describe the over-center spring as holding the activating lever.

The Court adopts the "construction that stays true to the claim language and most naturally aligns with the patent's description of the invention," Renishaw, 158 F.3d at 1250, and construes "over-center spring" to mean "a spring that biases a member toward a first stable position under a first set of mechanical conditions and toward a second stable position under a second set of mechanical conditions, with the member passing through an intermediate meta-stable position."
4. "Overhang" or "Overhang Portion"

The parties dispute the meaning of the term "overhang" and the following related phrases: "defines an overhang portion that extends beyond an edge of said backer" (claim 1 of '018 Patent); "overhang portion" (claims 1, 3, and 18 of '018 Patent and claims 6, 7, 8, 12, and 22 of '493 Patent); and "defines an overhang portion" (claims 6 and 17 of '493 Patent). Specifically, Defendants argue that the overhang portion must be long enough to fold over the backer or serve to attach the facer to a post and proposes that the term "overhang portion" be defined as "a segment of the facer that is long enough to fold over the backer." Plaintiff contends that the overhang portion must simply extend "beyond an edge of the backer." Defendants appear concerned that under Plaintiff's construction, infringement would exist in a panel where the backer and facer were designed to be the same size but where manufacturing issues resulted in a de minimis overhang.

The patents at issue in this action use the term "overhang portion" in a number of claims that do specify whether the "overhang portion" is to be folded over the backer or folded away from the backer so that it may be used to attach the liner panel to a vertical post. (See, e.g., claim 4 of '018 Patent (claiming overhang portion that wraps around the edge surface so that the facer covers at least a portion of the back side of the backer); claim 24 of '018 Patent (claiming overhang portion that folds out to form an edge surface for attaching the liner panel to a vertical post).) In the claims central to this dispute, however, there is no indication of how far the overhang portion extends beyond the edge of the backer. The specification states that "more or less than" one inch of facer can be left to overhang the backer. (‘018 Patent, col. 6:22-24.) Defendants contend that the overhang portion must be long enough to serve a purpose, such as attaching the facer to a post or folding over the edge of the backer to prevent fraying of the facer.

There is no support in the claim language or the specification for Defendants' proposed limitation on the term "overhang portion"; nothing requires that it be long enough to fold over the backer. Therefore, the Court is thus inclined to adopt Plaintiff's proposed definition. The Court notes, however, that the claim language and the specification suggest that the overhang portion must be long enough to serve some purpose. Instead of simply specifying that a facer extends beyond the edge of the backer, the claims define "overhang portion" as a specific structure. The specification recites several functions for the overhang portion. For example, the overhang portion may fold over the backer to protect against fraying-whether or not it wraps around to the backer's opposite side (id. col. 7:5-12), or it may be used to attach the liner panel to a vertical post (id. col. 7:22-27). Accordingly, it is clear to the Court that a de minimis extension of the facer beyond the edge of the backer would not be an "overhang portion." For this reason, the Court construes "overhang portion" to mean "a portion of the facer that extends more than a trifling amount beyond an edge of the backer."

As to the '122 patent, "overlapping edges" means two edges of a continuous piece of copper foil aligned to completely encircle a layer of dielectric material where there is no discontinuity of copper along the equatorial direction or circumferenc of the copper, and there is only discontinuity of copper in the axial direction of the cable. See Column 3, lines 5-12. The final configuration being one that the beginning edge of the continuous piece of copper is completely covered by the body of the copper on top and the bottom of the beginning edge of copper is resting on the dielectric material, while the terminating edge of the copper is covered on its top by a metallic braid and the bottom of the terminating edge of copper is resting upon the continuous piece of copper. See Figures 2, 3.

D. "Overlying" ('715 patent, claims 1 and 23; '419 patent, claims 1 and 11)

The parties' contentions regarding this claim language mirror their arguments over "on and in contact with" above. However, "overlying" is used in four different claims in two patents and in relation to at least three different pairings of materials: aluminum is overlying polysilicon in claims 1 and 23 of the '715 patent and claim 11 of the '419 patent, while a
metallization layer is overlying an insulating layer in claim 1 of the '419 patent and polysilicon is overlying a semiconductor substrate in claim 1 of the '715 patent. Although APT proposes only the vague sentence described above by way of addendum to Ixys' proffered construction, its brief seems to suggest that this court read into the claim the requirement that "overlying" require electrical contact when used to reference certain pairings of materials.

Not only does the claim language itself not hint at the necessity of reading in such limitations, the specifications provide no further support for APT's assertions. The sections APT cites do not themselves require such connection. See '715 patent, 5:66-6:11. Even if the specifications had indicated the necessity of electrical contact between polysilicon and the first metallization layer, "absent a clear disclaimer of particular subject matter, the fact that the inventor anticipated that the invention may be used in a particular manner does not limit the scope to that narrow context." Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003).

The court construes this claim language (in all locations) to mean: "In a layered device formed on a substrate, a relationship between first and second layers wherein the second layer is above or over the first layer."

--- Footnotes ---
27 Motorola's proposed construction is: "Molding by transferring or injecting an encapsulating material under pressure into a mold cavity covering one side of a substrate."

--- End Footnotes ---

C. "overprinting layer"

The specification does not expressly define the term "overprinting layer." However, the language of the specification suggests that an overprinting layer is a design that is printed over an area that has previously been printed. This construction is supported by several dictionaries specific to the field of graphic arts and printing, which define "overprinting" as "printing that is done on top of a previously printed area," The GATF Encyclopedia of Graphic Communications 567 (1998) ("GATF Encyclopedia"), and "double printing; printing over an area that already has been printed," Pocket Pal: A Graphic Arts Production Handbook 199 (16th ed. 1995). Additionally, even the Defendant's expert witness stated that "[o]ne of ordinary skill in the art of security (lottery) printing would understand an overprint layer to be a design printed over the scratch-off layer," and that "[i]n the lottery industry, the term overprint' or overprint layer' is the design printed on the scratch off layer." (Summary of Expert Opinion of Gordon E. Pickett PP 59, 69.) Thus, the meaning of the term "overprinting layer" to a person of ordinary skill in the relevant art is "a design printed on top of a previously printed area." In the context of the claims at issue, the previously printed area is the scratch-off layer.

However, the Defendant contends that the specification refers to a particular type of overprinting layer. It argues that the patentee acted as his own lexicographer by expressly limiting the ordinary meaning of overprinting layer in the claim itself. For example, claim 1(c) of the 647 patent states:
applying an overprinting layer over the scratch-off layer, said overprinting layer comprising an image obtained from a design in which at least two colors in the design have been separated into screened half tone images of each color and then said images are superimposed in separate printing steps to form said overprinting layer.

(‘647 patent, claim 1(c)) (emphasis added). Similar language appears in the specification. (See 647 patent, col. 3, 11. 50-54; 504 patent, col. 3, 11. 32-36.) The Defendant argues that the claim and specification language clearly give a special meaning to overprinting layer. The Court disagrees.

The Defendant's proposed definition of "overprinting layer" is preceded by the term "comprising." Comprising is a term of art used in patent claims that is open-ended, meaning that the named elements are essential but that other unrecited elements may be added and still fall within the scope of the claim. Mars, Inc., 377 F.3d at 1375-76 (citing Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997)); Manual of Patent Examining Procedure § 2111.03 (8th ed., rev. 1 2003)). "A drafter uses the term comprising' to mean I claim at least what follows and potentially more." CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005) (quoting Vehicular Techs. Corp. v. Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383-84 (Fed. Cir. 2000)). Therefore, by using the term comprising in the claim, the patentee did not clearly and unambiguously limit or redefine "overprinting layer." See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Although the cited language still has the practical effect of limiting the scope of the invention to require a particular type of overprinting layer that includes at least the recited elements, the language does not redefine the term itself. Moreover, claim terms are to be construed in relation to the context in which they appear. Phillips, 415 F.3d at 1315. The fact that the claim describes the specific elements that must be part of the particular overprinting layer indicates that the patentee did not contemplate that "overprinting layer" inherently includes those limitations. See id. Thus, consistent with the ordinary meaning of the term, "overprinting layer" means "a design printed on top of the scratch-off layer."

F. Term 9: "overrunning clutch means"

The Court construes the term "overrunning clutch means" in claim 24 of the ’325 patent and claim 9 of the ’664 patent to be a means-plus-function limitation under 35 U.S.C. § 112 P 6. The claimed function and corresponding structure are those identified above in connection with disputed Term 8.

The use of the word "means" in the term "overrunning clutch means" raises a presumption that this is a means-plus-function limitation. Micro Chem., 194 F.3d at 1257. The presumption can be overcome "if the claim itself recites sufficient structure, material, or acts to perform the claimed function." Id.

Toro argues that the presumption is overcome because "overrunning clutch" is a sufficiently definite structure. Toro Opening Br. at 37. The Court disagrees. As noted above, the adjective "overrunning" describes only function, not structure. And the noun "clutch" denotes a large class of devices for creating an interruptible connection between a driving element and something being driven. See generally BorgWarner, Inc. v. New Venture Gear, Inc., 237 F. Supp. 2d 919 (N.D. Ill. 2002) (discussing various types of clutches in construing patent claims related to an all-wheel-drive system). Thus the term "overrunning clutch" does not describe sufficient structure to take the term "overrunning clutch means" outside of § 112, P 6.

Claim 27:

1. "an oversized tang portion of the blade that is sized to extend through the opening in the handle when the blade is stored in the handle so that the oversized tang portion is exposed for manipulation from the back of the handle"

Plaintiff proposes

the oversized tang portion has a size such that, when the blade is closed, the oversized tang portion extends only out of the back of the handle opposite the side of the blade receiving opening. This permits a user's finger to press on the oversized
tang portion to move the blade from the closed position. The oversized tang portion does not extend out of the pivot end of
the handle opposite the blade tip end when the blade is in the closed position.

Defendant contends that the term is clear on its face.

The court finds that the term is clear on its face and does not require construction.

4. "Overturned Rim Extending From the Periphery of the Side Wall"

a. Construction

This limitation is present only in the ‘500 patent. The construction favored by Hallmark is "a rim which is curved from the
periphery of the sidewall and which has an edge portion extending downward for a length sufficient to contain compressed
pleats and provides increased rigidity to the claimed container." This is based on a modification made during prosecution, in
which the PTO required amendment from an "outwardly extending rim" to an "overturned rim extending from the periphery
of the sidewall." PX-11. pp. 71, 73-74. Moreover, the specification describes the "overturned rim" as being "found to
particularly enhance the rigidity of the container structure." DX-2. col. 3, lines 12-14. In addition, the specification refers to
the rim having "a downturned edge portion, compressed and densified" and the rim being seen to "curve over and down
about a smaller radius to form the overturned rim." DX-2, col. 3, lines 12-12; DX-2, col. 4, lines 64-68.

James River favors the meaning of "a rim that is a termination and outward extension of the sidewall and that serves to add
geometric stability to the plate and to provide an area for grasping the plate."

Any uncertainty about the natural meaning of "overturned rim" is eliminated by the specification. The rim of the invention
clearly must turn over, i.e. curve downward. Moreover, the specification indicates the rim must curve about a smaller radius.
One can easily imagine a rim that would remain flat and not curve down, or angle upward at a shallower angle than the side
wall. These would not be overturned rims. Moreover, the specification clearly indicates that the overturned rim's
downturned edge portion must be compressed and densified so as to add strength and rigidity.

6. Construction of "Oxidation Index"

Howmedica argues that the Court should construe this term to mean "a relative measurement of the amount of oxidized
material present in the UHMWPE." Defendants propose that oxidation index should be read to mean "the area of the IR
absorption peaks in the frequency range of between 1660 and 1800/cm divided by the area of the 1463/cm peak."

"020 Patent, claim 3: "the polyethylene has an FTIR ... oxidation index which does not increase with oven aging in
air . . ."

"020 Patent, claims 6, 10: "polyethylene having ... an oxidation index which does not increase during oven aging in air"

"020 Patent, claim 7: "polyethylene having ... a non-increasing FTIR oxidation index during oven aging in air"

"020 Patent, claim 11: "polyethylene ... irradiated and annealed ... for a sufficient time to have an non-increasing FTIR
oxidation index of .01 during oven aging in air"

"020 Patent, claim 12: "polyethylene ... irradiated and annealed ... for a sufficient time to have an non-increasing FTIR
oxidation index of .01 or less during oven aging in air"

The meaning of this term is impossible to derive from the language of the claim itself, nor is the ordinary meaning of this
In contrast, to support their construction, defendants point to the sole occasion in which the term "oxidation index" appears in the '020 Patent specification. The term appears in the context of an involved description of how the oxidation index for a particular set of materials was obtained:

Two sets of 1-mm-thick UHMWPE sheets prepared by Methods A through D above were oven aged in air at 80 [degree] C for 11 and 23 days respectively. After these sheets were cooled in room temperature, a thin film specimen of about 100 microns in thickness was cut from each of the 1-mm-thick aged UHMWPE sheets and placed in an IR window for a standard FTIR (A Nicolet 710 FTIR system was used) transmission run. A total of 32 spectra (scans) was collected and averaged. To determine the extent of oxidation, the IR absorption peaks in the frequency range of between 1660 and 1800 cm<-1>, corresponding to carbonyl (C--O) functional groups, were integrated for the peak area. The peak area is proportional to the amount of oxidized UHMWPE in the specimen. To correct for difference in specimen thickness, the integrated peak area was then normalized to the specimen thickness, by dividing by the area of the 1463 cm<-1> (methyl) peak which is proportional to the specimen thickness. The obtained ratio was defined as oxidation index.

'020 Patent 7:63-8:13 (emphasis added). This portion of the specification expressly defines the term "oxidation index" to mean a ratio which is derived from the spectroscopic measurements described by the specification. When the specification gives a special definition to a term, that definition trumps the ordinary meaning of that term. See Phillips, 415 F.3d at 1316; CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002); Markman, 52 F.3d at 979-80. Accordingly, the Court adopts the definition of "oxidation index" expressed by the specification.

To the extent that defendants' proposed definition accurately conveys the process for obtaining an oxidation index for UHMWPE material, the Court adopts that definition. If the parties further contest the construction of this term, additional briefing and/or arguments may be required.

B. Package

The parties' dispute centers on the meaning of the word "package." Webster's defines package as: "(1) the act or process of packing; (2) (a) a small or moderate-sized pack (b) a commodity or a unit of a product uniformly wrapped or sealed (c) a preassembled unit; (3) a covering, wrapper or container; (4) something that suggests a package as (a) package deal … ." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY 845 (1990) [hereinafter WEBSTER'S]. Blank proposes that "package" should be construed to mean "an independently created bundle or container into or onto which items are subsequently encased or attached." (Def.'s Markman Brief at 12.) Fiala would interpret "package" to mean "a small or moderate-sized pack, something that suggests a package, a preassembled unit, for merchandising and display of the product prior to purchase." (Pl.'s Markman Brief at 20.) Either construction is consistent with the dictionary definition.

Considering first the language of the claim itself, the court must eliminate part of Fiala's proposed definition. "Package" cannot mean a "preassembled unit," because the claim language makes clear that the package is something distinct from the first card. Preassembled unit, in the context of the patent, means a unit consisting of the first card and the package together. Thus, it would make no sense to read the claim language "in combination a first card … and a [preassembled unit]." The claim language does not further require, however, that either party's construction be accepted or rejected.

The specification repeatedly refers to the package holding a card. See e.g., U.S. Patent No. 5,918,909, Column 4;5, 5:6-7, 9:65-66. The specification also refers at several points to cards "in" or "within" a package. See id. at Column 20:37, 49, 63. The court notes that these stated functions of a package comport with the ordinary and customary meaning of "package." The specification, however, indicates that the "independently created" part of Blank's proposed definition should be
rejected. The specification states that "the package can be separately manufactured," thus implying that the package could also be manufactured simultaneously with the product itself. Id. at Column 5:11-12 (emphasis added). Nothing in the ordinary and customary meaning of "package" requires that a package be created independently of the product or that the product be inserted or attached to it after creation. Those aspects of Blank's definition, therefore, must be rejected.

The court also has reviewed the file wrapper for this patent. Nothing in the prosecution history, however, aids in interpreting the meaning of package.

Having considered the claim language, specification and prosecution history, the court construes "package" to mean: a covering, wrapper or container capable of holding a product for the purposes of merchandising and display prior to purchase. This definition is consistent with the ordinary and customary meaning of the word. The evidence before the court also indicates that a person of ordinary skill in the art would have so defined "package" at the time the patent was prosecuted.

Webster's defines package as: "(1) the act or process of packing; (2) (a) a small or moderate-sized pack (b) a commodity or a unit of a product uniformly wrapped or sealed (c) a preassembled unit; (3) a covering, wrapper or container; (4) something that suggests a package as (a) package deal … ". WEBSTER'S at 889. Plaintiff seeks to define package as "a small or moderate-sized pack, something that suggests a package, a preassembled unit, for merchandising and display of the product prior to purchase." (Pl. Brief at 21.) SVS asks the court to define package as "a preassembled unit ready for use, unaltered from the time of manufacture." (Def. Brief at 7.)

Considering first the language of the claim itself, the court must eliminate part of each party's proposed definition. "Package" cannot mean a "preassembled unit," because the claim language requires that the package be something distinct from the first card. Preassembled unit, in the context of the patent, means a unit consisting of the first card and the package together. Thus, it would make no sense to read the claim language "in combination a first card … and a [first card and package]."

The remaining issue is whether the claim language can be construed so that the "package" must be "unaltered from the time of manufacture." It is well established that "the prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995); see also Spectrum Intl, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998) ("Explicit statements made by a patent applicant during prosecution to distinguish a claimed invention over prior art may serve to narrow the scope of the claim"). SVS argues that Fiala offered this narrower definition to the patent examiner as a basis for distinguishing the patent from prior art. (Def. Resp. at 1-2.) SVS relies on the portion of the prosecution history in which the plaintiff states:

" … the lateral displacement of the data-encoded strip from the package enables the data-encoded strip to be read by an appropriate "point of purchase" reader so that the card can be "activated" without removing the card from the package and without tampering with the package. By lateral displacement of the data-encoded strip from the package, the activation of the card does not harm or alter the package during activation.

In contrast, the magnetic strip of the card disclosed in the Hill reference cannot be read by a standard "point of purchase" (e.g., at the cash register) reading device without removing the card from the package, precisely because the Hill reference does not disclose laterally displacing the magnetic strip remote from the package in a direction substantially parallel to the plane of the card.

(Id. at 2 (quoting Prelim. Am. Prior to First Exam. at 8)(emphasis in original.)) SVS argues that the magnetic strip disclosed in the Hill reference (the prior art) could only be activated by opening its packaging, whereas the invention claimed in the '909 patent is distinguished by its ability to be activated without opening its package. SVS claims that this distinction was necessary to procure the '909 patent, and that it is therefore a definitional element of the invention which Fiala cannot now disclaim.
There are two flaws in this argument. The first is the misidentification of precisely what was claimed and disclaimed to distinguish the '909 patent from the Hill reference. The distinguishing feature of the invention claimed in the '909 patent was "the lateral displacement of the data-encoded strip from the package." In other words, the magnetic strip of the card claimed in the Hill reference did not "stick out" in a direction parallel to its packaging panel; the magnetic strip of the card at issue here does stick out in such a way from its packaging. It is clear from a review of the patent documents that this spatial feature is what distinguished the '909 patent from the prior art. The specific language added to gain acceptance for the '909 patent refers to the packaging having an "outer perimeter" and requires that "at least a portion of the data-encoded strip is exposed and displaced externally remote from a portion of said outer perimeter . . ." (Pl. Brief Ex. B, '909 Prosecution History at FH 186 (Applicant's Remarks Supporting Consideration of Amendment, filed Jan. 12, 1999.))

No part of the magnetic strip of the card disclosed in the Hill and McIntire references, on the other hand, was "displaced externally remote from a portion of the outer perimeter of the panel." (Id.) The added language refers only to the arrangement of the card in relation to its packaging. One functional advantage of such a spatial arrangement is, of course, that the magnetic strip disclosed in the '909 patent can be activated without removing the card from its packaging. There is no reason, however, that this functional advantage should be read into the requirements of the patent, when the amended claim language refers only to the physical structure of the invention. See Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003) ("the fact that the inventor anticipated that the invention may be used in a particular manner does not limit the scope to that narrow context").

The second flaw is that, even if the patent required that the card be activated without altering the package, it is not clear why such a requirement should be read specifically into the word "package." "Package" was not one of the terms amended to distinguish the claimed invention from the prior art. Furthermore, an ordinary reading of the defendant's proposed definition suggests that the phrase "unaltered from the time of manufacture" refers to a particular kind or class of "package," and is not meant to expand or clarify the meaning of the term itself. The defendant has offered similar constructions -- suggesting that the package must be intact at the time the card is activated -- to at least two other claim terms, each of which refers more specifically to the relationship between the card and the packaging panel. (See Def. Brief at 8, 11.) These suggestions demonstrate further that such a construction is not easily attached to the word "package" itself.

Nothing in the ordinary and customary meaning of the word requires that a package be "unaltered from the time of manufacture." Nothing else in the specification or prosecution history aids in further interpreting the meaning of the term. Considering the '909 patent previously, this court construed "package" to mean: a covering, wrapper or container capable of holding a product for the purposes of merchandising and display prior to purchase. See Barry Fiala, Inc. v. Arthur Blank & Co., No. 02-2282 Ma, 2004 U.S. Dist. LEXIS 28624 (August 24, 2004). This definition is consistent with the ordinary and customary meaning of the word. The evidence before the court also indicates that a person of ordinary skill in the art would have so defined "package" at the time the patent was prosecuted. The court accordingly construes "package" in this case to mean: "a covering, wrapper, or container capable of holding a product for the purposes of merchandising and display prior to purchase."
single package, and statements made by Destron/IDI on appeal to the Federal Circuit in the Infopet case.

In the "Background of the Invention" section of the specification, the packaging is described as follows:

In particular, it is an object of one aspect of the invention to provide a conveniently prepackaged, sterile cannula and identification transponder combination, such that the individual implanting the transponders into animal can be provided with all the equipment needed in a single sterile package which is used on a one-time basis; the cannula then being simply disposed of. In this way, sterility is ensured and operator convenience is optimized.

'129 patent, col. 3:48-56. In the "Summary of the Invention" section, the specification states "[the transponder] may be supplied together with a disposable cannula for convenient syringe implantation into an animal." Id. at col. 4:16-18. The "preferred packaging" of the invention is depicted in Figure 2, and is described as follows:

In order to reduce the expense of implanting transponders, operator convenience should be maximized, without compromising the goals of sterility and minimization of trauma to the animal. Figure 2 shows a combination of a sterile cannula 30 with a sterilizable transponder 32 according to the invention, and as discussed in detail below, supplied already located within the tubular portion of the cannula. As shown, the cannula 30 with the transponder 32 packaged therein can both be supplied together in a sterile package 34; this clearly will maximize the convenience of the operator, who needs merely to open the package 34, attach the ferrule of the cannula to a syringe, inject the transponder and throw the cannula away.

Id. at col. 6:36-49.

The preferred packaging of the invention depicted in Figure 2 accomplishes the primary packaging goals of sterility, convenience, and low-cost. Even though separate packaging would detract from the primary packaging goals, the specification reveals, by its use of words such as "can" and "may," that the inventors contemplated packaging in which the cannula and transponder would not be packaged together in a single package. Id. at cols. 4:16, 6:44. However, separate packaging is not contemplated by claim 6, which claims "said transponder and said cannula being packaged together in sterile packaging means." Id. at col. 14:14-16. The claim language as well as the teaching of the specification show that claim 6 is directed toward a combination in which a cannula and transponder are packaged together in a single sterile package. See Phillips, 415 F.3d at 1323-24 (describing the sometimes "difficult task" of determining when the embodiments define the outer limits of the claim term or are merely exemplary in nature, and stating that "the manner in which the patentee uses a term within the specification and claims usually will make the distinction apparent."). The term "packaged together in sterile packaging means" is construed to mean "packaged as a combination in a single sterile package."

The parties also dispute the construction of the term "packaging" and "packaged." Michael Foods contends that the terms means placed or placing in a container, (Michael Foods' Initial Markman Br. at 43), while Sunny Fresh argues that the term means aseptically packaged or packaging (Sunny Fresh's Resp. at 25-26).

Some claims terms use "aseptically packaged," (see,e.g., Kempf Aff., Ex. 1, Col. 15, l. 65; Claim 4, Col. 16, l. 21), and some use just "packaged," (see, e.g., Id., Col. 16, l. 3; Col. 16, l. 33). Interpreting the terms identically erroneously would read the additional limitation of "aseptic" into the claim element "packaging." See Texas Co. v. Globe Oil & Ref. Co., 112 F. Supp. 455, 467 (7th Cir. 1955)("the presence of an express limitation in one claim negatives an intent similarly to limit by implication a claim in which the limitation is not expressed...."). It also would render the term "aseptic" redundant and thus the phrase "aseptic packaging" nonsensical. 16 See, e.g., Binargo Western Sales v. Helena Chemical Co., 160 F. Supp. 2d 1112, 2001 WL 980961 (E.D. Cal. 2001)(stating that a patent claim should not be construed to render language in patent meaningless). Thus, the court construes the terms "packaging" and "packaged" to mean placed or placing in a container.
Based upon Sunny Fresh's interpretation of "packaging" as "aseptic packaging," the term "aseptic packaging" when written in the claim literally would be interpreted to mean "aseptic packaging packaging." The court cannot adopt such a meaningless interpretation of the claim language. See Biagro Western Sales v. Helena Chemical Co., 160 F. Supp. 2d 1112, 2001 WL 980961 (E.D. Cal. 2001).

--- End Footnotes ---

2840

1. Pad assembly

- Plaintiff's proposed construction: One or more pads attached to the helmet.
- Defendant's proposed construction: Two or more ear flap or jaw pads attached or releaseably secured together.

The parties dispute 1) what pads are included in a pad assembly and 2) whether the individual pads of the pad assembly are secured together or merely secured to the inside of the helmet. Claims 1 and 20 claim "a pad assembly attached to each ear flap, each pad assembly having an ear flap pad and a jaw pad." However, claim 25 merely claims "a pad assembly attached to an inner surface of the shell." Although the specification does not mention "pad assembly," it teaches that a "shock absorbing liner" preferably "is releaseably connected to the inner wall surface" and "generally includes a plurality of resilient members." '376 patent, col. 10, lns. 51-55 and 61-66. The specification further teaches that although a "resilient pad member" could be "integral with" all of the other pads, it is preferable for resilient pad members to be releaseably attached to each other, forming a shock absorbing liner. Id., col. 11, lns. 9-18.

Neither the claims language nor the specification supports defendant's construction that a pad assembly must always include both an ear flap pad and a jaw pad and that the individual pads have to be secured together or secured "releaseably" to a liner in every instance. These appear to be only embodiments.

Defendant argues that plaintiff used the term pad assembly in prosecuting the patent to refer to jaw and ear flap pads, that although claims 25-29 do not use the terms "ear flap pads" and "jaw pads," plaintiff added these claims late in the prosecution and that because plaintiff represented that claims 25-29 did not introduce new matter, the use of the term "pad assembly" in these claims must include ear flap and jaw pads, as specified in the other claims. This is not a persuasive argument. Nothing in the patent prosecution history shows that the examiner required a pad assembly to be limited to ear and jaw pads. Further, any statements plaintiff made about the pad assembly being limited to those areas was directed to a particular claim (number 34 at that time). Although the later-added claim 25 is broader, the examiner apparently had no problem issuing a notice of acceptability following its addition to the patent.

I conclude that the term "pad assembly" as used in claims 1-6, 9-19 and 20-28 of the '376 patent means one or more pads.

2841

1. Painted surface of a vehicle

--- Footnotes ---

1 This appears to be a typo. The word in the amended claims, which were allowed without amendment by the Examiner, was "comprising."

--- End Footnotes ---

The term "painted surface of a vehicle" appears in claim 1 and claim 12. In the joint claims construction statement and in the papers filed in connection with the hearing on claims construction, Chip-Mender argues that "painted surface of a
vehicle" means "painted surface of an automobile," while Sherwin-Williams asserts that "painted surface of a vehicle" means "any vehicle surface with paint, regardless of whether the surface is metal, plastic, or otherwise, including any self-painted surface of a self-propelled land vehicle such as a car or a motorcycle."

Chip-Mender proposes no construction for "painted surface," presumably intending that the phrase have its ordinary meaning, 2 while Sherwin-Williams contends that "painted surface" means "any… surface with paint," which simply rephrases the term "painted surface." Sherwin-Williams adds that the "surface" can be metal, plastic, or "otherwise," while Chip-Mender does not specify the composition of the "surface." Sherwin-Williams provides no support for its proposed limitation regarding the type of surface, simply asserting that because there are vehicles made of materials other than metal--such as the 1950s Corvettes, made of fiberglass--the correct construction must specify that the "surface" can be any material, so long as it is "painted."

2 In its proposed construction for disputed term No. 8, below, Chip-Mender defines "painted surface" as "painted body."

Nevertheless, there appears to be no real dispute regarding the construction of "painted surface." Moreover, the court finds nothing in the patent claims or specification which requires that the construction include a limitation as to the composition of the "surface" that is "painted."

The only real dispute reflected in the papers involves the meaning of "vehicle." Sherwin-Williams asserts that "vehicle" is not limited to passenger cars, but also includes any "self-propelled land vehicle" that has a "surface" with paint, such as motorcycles, trucks, vans, sport utility vehicles (SUVs), farm equipment, trailers, and trains. The court interprets this as an argument that "vehicle" not be construed as "automobile." Although Chip-Mender argues in its moving papers that "vehicle" means "automobile," counsel for Chip-Mender stated at the hearing that he would be "happy" to construe "vehicle" as "vehicle" instead of "automobile." Moreover, Chip-Mender asserts in its reply brief that the invention of the '299 patent is not limited to application of automotive touch-up paint to "passenger cars," and argues that the term "automobile" includes all modes of transportation normally associated with that term, including pick-up trucks and SUVs.

Based on the claim language and the specification, the court finds that the term "vehicle" is not a "technical term[] of art, and do[es] not require elaborate interpretation," see Brown v. 3M, 265 F.3d 1349, 1352 (Fed. Cir. 2001), as the parties agree that "vehicle" is a commonly understood word with a widely accepted meaning. See Phillips, 415 F.3d at 1314. Thus, in light of the parties' arguments, the court finds that "painted surface of a vehicle" means "any vehicle surface with paint."
argues that the reference to "trouser grafts" demonstrates that the term "pair" must mean something of equal length, because trousers have legs that are the same length. Cook supports that definition by reference to a dictionary definition in which "pair" is defined as "two things equal." (See Cook Ex. 14.)

The word "pair" also means "two corresponding things designed for use together" or "something made up of two corresponding pieces (a - of trousers)." These definitions of the word, however, do not necessarily require a pair to be "equal" in all respects. See Webster's Ninth New Collegiate Dictionary at 847 (1987); id. at 293 (definition of corresponding: "having or participating in the same relationship (as kind, degree, position, correspondence, or function)). Thus, apart from the reference to "trouser grafts," neither the specification nor the prosecution history provide clear support for Defendants' proposed construction.

Gore also argues that the construction of the term should also include the requirement that each of the connector legs "has an opening for connecting to a graft adapted to be anchored within the branch." (Gore Br. at 14:21-23.) The Court agrees with Gore on this point. The word "connector" is an adjective for the verb "connect," which means "to become joined," or "to join or fasten together … by something intervening" or "to place or establish in relationship." See, e.g., Webster's Ninth New Collegiate Dictionary at 278. Support for incorporating a connection function in the construction of the term "a pair of connector legs," also is supported by the specification. The inventors state therein that supplemental grafts can be introduced to overlap or dock, i.e. connect to or with, the ends of a bifurcated device. ('458 Patent, col. 4, ll. 18-32.)

Accordingly, the Court construes the term "a pair of connector legs" to mean: "The two branches at the downstream end of the bifurcated base [graft] structure, each of which has an opening to which an additional graft may be connected."

(c) Claim One, Clause Four

Claim 1, clause 4 reads as follows: "said housing including a pair of flanges extending from opposite side edges of said housing in parallel spaced relationship[]." The parties' only dispute is whether the prepositional phrase "in parallel spaced relationship" modifies the noun "flanges" or the noun phrase "extending from opposite side edges." In other words, the parties dispute whether "parallel spaced relationship" refers to the flanges or the opposite side edges.

SCM asserts that the claim is indefinite because this language is capable of two meanings. However, it has not demonstrated that someone skilled in the art would find the language ambiguous. SCM has not shown indefiniteness by clear and convincing evidence.

We conclude that, in ordinary English, the "parallel spaced relationship" modifies the noun (flanges), not the noun phrase (extending from opposite side edges). This construction is supported by the shape of the invention which has a generally flat rectangular housing. Claim 1(a). If the housing is rectangular, then by definition, all of the opposite sides would be parallel to one another. See Webster's Third International Dictionary (defining rectangle as "a parallelogram all of whose angles are right angles"). Since the opposite sides are parallel by definition, they would be in parallel spaced relationship to one another. As such, it would be superfluous to have the phrase "parallel spaced relationship" modify "opposite side edges." On the other hand, the flanges would not necessarily be in a "parallel spaced relationship" to one another absent this language in the claim. Accordingly, we conclude that the phrase "parallel spaced relationship" modifies the "flanges," not the "opposite side edges."

Budde argues that the district court erred in construing the "pair of fuel injectors mounted in a fuel injector and throttle body" limitation in claim 1 of the '348 patent. This claim limitation states in pertinent part: "a pair of fuel injectors mounted in a fuel injector and throttle body secured to said intake manifold." '348 patent, col. 12, ll. 33-34. The district court initially construed this term to require "that two fuel injectors be mounted in a fuel injector and throttle body." Budde I, slip op. at 8. The parties did not appeal the construction of this claim term, and this court did not decide issues related to this claim.
construction in the prior Budde II appeal. On remand, the district court clarified its claim construction, stating that this limitation required that the fuel injectors be mounted in the throttle body. Budde III, 2003 U.S. Dist. LEXIS 25990, *24.

We discern no error in the district court's claim construction. The express language of the claim distinguishes between a "fuel injector and throttle body" and an "intake manifold" and recites that the fuel injectors are mounted to the "fuel injector and throttle body," which is secured to the "intake manifold." See '348 patent, col. 12, ll. 33-34. Under the ordinary and customary meaning of the words of the claim, the pair of fuel injectors must be mounted in the "fuel injector and throttle body" and not the "intake manifold." Thus, the district court was correct in concluding that mounting the pair of fuel injectors in the intake manifold does not literally infringe the claim.

The district court found undisputed evidence that in Harley-Davidson's "old" EFI system, the parts corresponding to the throttle body and intake manifold claim limitations were combined into an integral "induction module." Budde III, 2003 U.S. Dist. LEXIS 25990, *26. Because the pair of fuel injectors are mounted in the induction manifold portion of the induction module rather than the throttle body portion, the "old" EFI system did not literally meet the claim limitation. Id. Concerning Harley-Davidson's "new" EFI system, the district court found it was undisputed that the throttle body and intake manifold are separate parts bolted together and that the fuel injectors are mounted in the intake manifold. Id. We agree and, thus, concur in the district court's conclusion that no reasonable juror could find that either of Harley-Davidson's "old" or "new" EFI systems literally met the "pair of fuel injectors" limitation of claim 1 of the '348 patent. Claim 1 is therefore not literally infringed by these systems.

1. The Pair of Actuators in Claim 1

a. The Language of the Claims

The crucial clause of claim 1 requires "a pair of linear actuators mounted on said frame and connected to said levers for swinging said levers and thus tilting said cradle . . . from said first position through a second position . . . to a third position . . . ." 2 The claims provide for no other actuators in the carrier to perform this lifting and dumping function. Claim 2 requires struts be mounted to the frame to support the cradle in its second, or carrying, position. Claim 3 requires that these struts be linear actuators that support the cradle in the second position. Thus, it appears that the claims set forth a carrier with two pairs of linear actuators and each performs a specific function: one pair has the function of lifting the cradle through its three positions and the other pair has the function of supporting the cradle in its second position.

Kress argues unpersuasively that the plain meaning of the claim language can include an additional pair of actuators to perform the lifting and dumping function. For example, Kress urges us to ignore the functional limitation in claim 1, which provides that one pair of actuators lift the cradle through its three positions. Kress does not cite to any controlling authority for this proposition that would require us to ignore the clear language of the claims. To the contrary, we have consistently held that all limitations of claims must be considered meaningful. See Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1562, 19 U.S.P.Q.2D (BNA) 1500, 1504 (Fed. Cir. 1991); see also Perkin-Elmer Corp. v. Westinghouse Elec. Corp., 822 F.2d 1528, 1532-33, 3 U.S.P.Q.2D (BNA) 1321, 1324-25 (Fed. Cir. 1987). We decline Kress' invitation to ignore clear limitations in the claims.

b. The Written Description

The language used in the specification preceding the claims also supports this construction of the claims. For example, the written description explains that "it is an object of the invention to provide a carrier . . . that utilizes only two major primary working linear hydraulic actuators and two small simple secondary holding cylinders." (emphasis added). The specification...
Further states that:

a pair of linear actuators, acting through lifting levers, are operable for tilting the cradle from its first position to a second position wherein the pot is raised from the ground but held substantially level and then to a third position wherein the pot is at least partially inverted to a dumping position.

(emphasis added and numerical references omitted). The specification further reinforces the concept that one pair of actuators performs the lifting and dumping function by stating "the lifting levers are swung by the actuators through less than 90 degrees to produce tilting of the cradle through approximately 140 degrees. In this way, just two main actuators can both lift the pot to travel position as well as swing the cradle to its third dumping position." (emphasis added and numerical references omitted). The specification reinforces this point by stating that "those skilled in the art will appreciate that the slag pot carrier is of relatively simple design so as to be economical to manufacture and maintain, particularly in that only two primary linear actuators are utilized for lifting and dumping." (emphasis added and numerical references omitted).

There are other references in the specification to the effect that one pair of actuators independently performs the lifting and dumping function.

However, there is one section of the specification that reads:

to eliminate the load on the main actuator hydraulic system and its links during travel of the carrier while carrying a loaded pot, as well as to assist the main linear actuator in picking the pot off the ground, a pair of struts in the form of simple two-position linear actuators are [sic] mounted on the frame in box-like guides and are [sic] adapted to be positioned for supporting the cradle in its second, traveling position.

(emphasis added and numerical references omitted). Kress argues that this sentence should overcome the clear meaning of claims as well as the other statements in the specification. The Appellees argue that this language describes an alternative system not covered in the claims. We agree that this portion of the specification describes a use for the second pair of actuators that is not described elsewhere in the claims or in the written description. This sentence merely describes an alternative use for the second pair of actuators; it does not define the function of the second pair of actuators as the structural and functional limitations in the claims are not ambiguous from the claim language and the remainder of the specification. Indeed, any possible confusion that this sentence may have injected into the claim construction process is vitiated by the analysis of the prosecution history below.

c. The Prosecution History

Finally, the prosecution history supports our understanding that claim 1 of the '658 patent sets forth one pair of actuators performing the lifting and dumping function and claims 2 and 3 set forth the other pair performing the support function. During prosecution of the '658 patent, the patent examiner rejected claims 1 and 2 of the application as obvious in light of three other patents, the Freedy patent, the British patent, and the Livingston patent. Kress specifically emphasized to the examiner that:

Claim 1, the main independent claim, stands rejected on a combination of three references (one of which, the patent to Freedy et. al., being somewhat far afield), but even if these three disclosures could be assembled in the manner suggested by the Examiner, the resulting structure still does not meet the terms of claim 1. In the British patent, two sets of actuators are required, one to initially lift the pot and a second set to perform the tilting function. The patent to Livingston does not use actuators at all. The patent to Freedy et al., if at all relevant, also shows multiple actuators and levers for producing the desired front end loader bucket movement.

In contrast, the structure claimed includes only a pair of linear actuators which, as the last six lines of the claims state, produces three different positions of the cradle and hence of the pot carried by the cradle. That is not in the art.

(emphasis added).

Eventually, claim 1 issued. Kress argues that because no amendment to incorporate this statement into the claim was made, this statement should not be used to limit the scope of its claim. In addition, Kress argues that the statement was not related to the examiner's patentability concerns, which Kress argues regarded the linkage structure and not the number of actuators.
for lifting, and therefore Kress' statement should not limit its claims.

Although an amendment was not made to the claimed language to incorporate specifically Kress' statement during prosecution, Kress' clear disavowal of claim coverage is relevant in interpreting the meaning of its claims. See York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1575, 40 U.S.P.Q.2D (BNA) 1619, 1624 (Fed. Cir. 1996). By Kress' own clarification to the patent examiner, its claim was for an invention in which only one pair of actuators could independently perform the lifting and dumping function. This functional limitation is clearly set forth in the claim language as well as the written description and the prosecution history, and cannot be ignored. The prosecution history supports our understanding that claim 1 of the '658 patent requires one pair of linear actuators independently perform the lifting and dumping function and claims 2 and 3 require an auxiliary pair of actuators to provide independently the support function.

Kress argues that such a construction of claims 1 through 3 ignores the legal doctrine of claim differentiation. The doctrine of claim differentiation "presumes that there is a difference in scope among the claims of a patent." Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1479, 45 U.S.P.Q.2D (BNA) 1429, 1434 (Fed. Cir. 1998). This interpretation does not ignore this doctrine, but rather follows it - no claim is rendered identical to another claim. This construction renders claims 1, 2, and 3 as claiming different subject matter: claim 1 claims a pair of linear actuators to move the cradle through its three positions; claim 2 claims an additional pair of struts to support the cradle; and claim 3 requires these struts to be in the form of actuators. Thus, such an interpretation does not render any two claims identical.

Our independent review of the claim language thus reveals that the district court's construction of the '658 patent was supported by the language of the claim itself, the written description, and the prosecution history. We have considered all of Kress' arguments in support of its proposed claim construction and find them to be without merit. We hold that claim 1 of the '658 patent requires one pair of actuators to perform independently the lifting and dumping function.

14. "pair of spaced members"

This phrase is found in Claim 16. Plaintiff proposes the following construction: "two parts separated by a distance that form the sides of the U-shaped terminal." Defendants assert that the phrase need not be construed, and the Court agrees. Because the Court see no ambiguity as to the meaning of the phrase "pair of spaced members" and because its ordinary and customary meaning is clear to one skilled in the art, the Court declines to construe the phrase as it is used in the '015 Patent.

III. "Panel"

Plaintiffs' proposed construction: none, or, "a large unitary piece of construction material that forms a trailer wall when coupled to other large unitary pieces of construction material" 4

4 In its reply brief, plaintiff argues that "panel" means "a discrete piece of construction material capable of being coupled to another discrete piece of construction material" although it does not explicitly advocate this as a proposed construction. See dkt. 33 at 6.

Defendant's proposed construction: "a distinctive part of a construction surface or material"

The term "panel" is used in all claims of the patents-in-suit. Claim 1 of both patents recites a wall joint comprising a first
panel and a second panel. Claim 15 of the '564 patent and claim 16 of the '902 patent recite a cargo body comprising a plurality of panels. The parties' dispute over the meaning of this term centers on whether a panel is a discrete structure (plaintiff's position) or merely a part of a construction surface or material (defendant's position).

Defendant's contention that a "panel" must be part of a construction surface or material as opposed to a discrete structure is not supported by the claims or the specification. All of the references to "panel" in the claims are consistent with a panel being a discrete structure. The patent is titled "Wall Joint Configuration," the invention "relates generally to devices and configurations for joining panels" ('564 Patent, 1:1-2), and it teaches a configuration for joining "a pair of adjacent first and second panels" with "each joint being at least partially defined by an edge of the first panel and an edge of the second panel adjacent to the first panel." '564 Patent, Claim 15. Claim 10 refers to a wall joint comprising first and second panels located substantially in the same plane, coupled together by a splicer plate. Claim 13 claims a joint composed of panels "having a first core material sandwiched between layers of a second material, different from the first core material."

All of these references suggest that the term "panel," as used in the patents-in-suit, is a unitary structure and not merely a "part" of a structure. Further, the preferred embodiment depicted in Figure 1 shows 13 separate sidewall "panels" joined together using the patented invention to create a sidewall. If the panels were merely a portion of a construction surface or material, as defendant proposes, there would be nothing to join.

Court's construction: "panel" means "a discrete structure capable of being coupled to another discrete structure."

Delta's non-infringement argument centers on the claim language requiring "at least one print receiving layer consisting of a paper, a synthetic paper or a coated film." U.S. Patent Nos. 5,418,026, col. 7:12-14; 5,543,191, cols. 6:66-7:1.

Delta first argues that its baggage tags cannot infringe because they do not possess "at least one print receiving layer." Delta's baggage tags are designed for use in direct thermal printing. Direct thermal printing uses neither ink nor toner to produce an image, but instead creates an image by causing a chemical reaction to occur within the top layer of the print stock. Delta argues that because direct thermal printing, for which its baggage tags are designed, transfers neither ink nor toner to the printed sheet, its baggage tags do not have a "print receiving layer." This argument is without merit. The top layer of Delta's baggage tags bear the words "Delta Air Lines." These words are printed in ink. Thus, whatever else it may be, the top layer of Delta's baggage tags is a print receiving layer. Moreover, the image that appears on the top layer as a result of the heat-induced chemical reaction is print and is received as a result of the printing process. That layer is thus accurately described as the "print receiving layer."

Delta also argues that its baggage tags do not infringe because, so Delta argues, the top layer of its tags does not "consist of" "a paper, a synthetic paper or a coated film." The phrase "consisting of" is a term of art in patent law. The phrase is a restrictive one, "closing the claim to the inclusion of materials other than those recited except for impurities ordinarily associated therewith." Ex parte Davis and Tuukkanen, 80 U.S. P.Q. 448, 450 (Pat. & Tr. Off. Bd. App. 1948). See also PPG Industries v. Guardian Industries Corp., 156 F.3d 1351, 1354 (Fed. Cir. 1998) (describing claims written in "consisting of" format as "closed"). In light of the claim language, the claim encompasses a baggage tag only if the top layer of the tag is made from "a paper, a synthetic paper or a coated film" and nothing else.

Delta asserts that its baggage tag does not infringe because its top layer, which is designed for use in direct thermal printing, is not "a paper, a synthetic paper or a coated film." Delta maintains that the top layer of its baggage tag is a coated paper, and that coated paper is not included within the meaning of "paper" as that term is used in the asserted claims. Relying heavily on the fact that the adjective "coated" is specifically used elsewhere in the asserted claims to modify the term film, Delta argues that the claims' failure to use "coated" in connection with paper precludes construing the claim to include coated paper.

Delta's argument, however, is contrary to well-established principles of patent construction. Patent claims are to be read in light of the patent specification. See Markman, 52 F.3d at 979; ACS Hosp. Systems, 732 F.2d at 1577. Here, the specification of each patent-in-suit states that a "laser or thermal transfer printing enhancing coating . . . can be spread on the print receiving face of the top sheet." U.S. Patent Nos. 5,418,026, col. 6:43-47; 5,543,191, col. 6:33-36. Thus, because
the patent specification of each patent-in-suit clearly contemplates the use of a coated paper for the top layer, the term "paper" is properly construed to include coated paper. This result is strengthened by the principle that a court should not "add a narrowing modifier before an otherwise general term that stands unmodified in a claim." Johnson Worldwide Assocs., 175 F.3d at 989. See also Renishaw, 158 F.3d at 1249. Here, the term "paper" stands unmodified. It would be improper for this Court to impute a limiting modifier that would exclude coated paper from the scope of the general term "paper."

--- Footnotes ---

3 The patent prosecution history does not dictate otherwise. While it is true that the patent examiner required the plaintiff Mr. Dronzek to change the claim language from the open phrasing "comprising a paper, synthetic paper or a coated film" to the closed phrasing "consisting of a paper, synthetic paper or a coated film," see Hardy Decl., Ex. II, that says nothing about the scope of the term "paper."

--- End Footnotes ---
1. Parties' positions

Tulip proposes that "parallel" be given its ordinary and accustomed meaning, "extending in the same direction." 77 Dell's proposes that "parallel" be construed according to its ordinary meaning, "extending in the same direction … everywhere equidistant … and not meeting," 78 but that the phrase "substantially parallel" must be given a different meaning than when "parallel" is used without that modifier.

Dell notes that Claims 1 and 2, as originally filed, contained the phrase "substantially parallel" in reference both to the location of the mating connector on the motherboard and to the orientation of expansion boards to the motherboard when inserted into the riser card. 79 After those claims were rejected by the examiner, the substituted claims removed the modifier "substantially" from before "parallel" in reference to the location of the mating connector on the motherboard, but "substantially" was not removed from before "parallel" in reference to the expansion boards being "substantially parallel" to the motherboard. Dell cites Jeneric/ Pentron, Inc. v. Dillon Co., Inc. for the proposition that when flexible language ("about" in that case) is included in a claim, the court must strictly construe terms without flexible language. 80 Dell argues that by removing the word "substantially" during prosecution, Tulip surrendered an interpretation of the claims that would allow the mating connector to be anything but exactly "parallel" to "a peripheral side edge." Therefore, Dell insists that the court apply its proposed construction, "extending in the same direction, everywhere equidistant and not meeting," with mathematical precision.

79 Claims 1 and 2 as filed on June 13, 1996 in the original patent application recited: "said riser card having a predetermined number of positions for expansion cards and comprising a number of connectors, substantially arranged in a row parallel above each other, for such expansion cards, while the plane of an expansion card, when it is arranged in a connector of the riser card, extends substantially parallel to the plane of the motherboard, characterized in that the connector for the riser card is arranged adjacent a side edge of the motherboard and substantially parallel thereto." D.I. 324, Ex. 2 at TLP2 117060-61 (emphasis added).

80 See 205 F.3d 1377, 1381 (Fed. Cir. 2000).

Tulip asserts that Dell's proposed construction, which includes the limitation of being "everywhere equidistant," is impracticable as it is beyond the ordinary tolerances of circuit board manufacturing and, therefore, that definition could not be consistent with the ordinary and accustomed meaning of "parallel" to one of ordinary skill in the art. Tulip argues that Jeneric/ Pentron is inapplicable here as that case concerned precise numeric limitations in chemical composition claims where the precise numeric limitations were required to distinguish over the prior art, circumstances different from those of this case. Finally, Tulip contends that the '621 patent specification supports its proposed construction which explicitly discloses a riser connector that is substantially parallel to a side edge of the motherboard. 81
81 See '621 at 2:65-3:1 ("To that end, the invention provides a motherboard of the above-mentioned type, characterized in that the connector for the riser card is arranged adjacent to a side edge of the motherboard and substantially parallel thereto, …"); Id. at 4:1-4 ("characterized in that the connector for the riser card is arranged adjacent a side edge of the motherboard and substantially parallel thereto, ….").

2. Court's construction

Although Tulip suggests defining "parallel" according to its ordinary and accustomed meaning, Tulip only cites part of the definition put forth to define that term. The dictionary Tulip cites as reciting the ordinary and accustomed meaning of "parallel" defines that term as: "extending in the same direction and at the same distance apart at every point, so as never to meet," 82 a definition no different than that recited by Dell as the ordinary and accustomed meaning of "parallel."

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Tulip is correct, however, in arguing that the facts of Jeneric/ Pentron are distinguishable from those presented in this case. The patent at issue in Jeneric/ Pentron was directed to a porcelain composition used in dental restoration products. Within one of the claims at issue in that case, the patent recited both precise ranges the for chemical components of its claimed composition and imprecise language, "about," to qualify the values of other elements of that claim. 83 The Jeneric/ Pentron court also noted that those precise ranges had to be written narrowly to avoid being found anticipated or obvious in light of a prior art patent incorporated by reference into the patent at issue in that case. 84 Based on those facts, the Federal Circuit agreed with the trial court's determination that the scope of the asserted claim was limited to the precise ranges recited stating, "Jeneric may not rely on the precise ranges of the claims to distinguish itself from prior art during prosecution and then later construe the ranges more broadly during an infringement action." 85

In this case, Tulip amended the '621 patent application to avoid the examiner's initial determination of obviousness in light of two prior art references. Tulip did not, however, rely on its substitution of a claims reciting that the mating connector was "parallel" to the side edge of the motherboard for cancelled original claim which recited a mating connector that was "substantially parallel" in order to avoid a prior art reference. Instead, Tulip argued that the two references cited by the examiner would not have made its claimed invention obvious to one of ordinary skill in the relevant art. The Harwer patent (U.S. Patent No. 5,440,755) teaches a riser card with a plurality of expansion connectors. The Harwer patent teaches form factor wherein the riser card is centrally located on the motherboard with expansion connectors for PCI boards at the top of the riser card and expansion connectors for ISA boards on the lower part of the riser card. The Lam patent teaches, in the context of a notebook computer, placing a riser card on the edge of the motherboard with only one expansion connector thereon. As discussed in the section concerning the term "personal computer," Tulip argued that the physical environment of a notebook computer would not accommodate its claimed invention and, therefore, no one in skilled in the art would have looked to the Lam patent to remedy the disadvantages of a centrally located riser board having a plurality of expansion connectors. This court determined, above, that these representations narrowed the scope of Tulip's invention so as not to encompass notebook computers. Tulip's successful attempts to distinguish the prior art referenced by the examiner did not, however, depend on, or even mention, whether the claimed mating connector was "parallel" or "substantially parallel" to the
side edge of the motherboard. The fact remains, though, that Tulip did delete the word "substantially" from before "parallel" in describing the orientation of the mating connector to the side edge of the motherboard and may have, inadvertently or not, narrowed the scope of the claims in suit.

Perhaps in realization of this fact, Tulip seems to contradictorily argue that the term "parallel" should be given its ordinary and accustomed meaning but proposing a truncated version of the definition contained in its cited dictionary because the full definition would purportedly be impracticable as beyond standard circuit board manufacturing tolerances. Such manufacturing tolerances are extrinsic evidence not necessary to the court's understanding of the commonly understood term "parallel." That extrinsic evidence might be relevant to the finder of fact at a later stage of this litigation should the issue of infringement, either literal or by the doctrine of equivalence, depend on whether a mating connector is "parallel" or "substantially parallel" to the side edge of the motherboard. For the purposes of construing the word "parallel," however, the court need look no further than the intrinsic record.

Nothing in the claims, specification, or prosecution history leads this court to accept the truncated definition of "parallel" suggested by Tulip. Based on each party's assertion that "parallel" be given its ordinary and accustomed meaning, and finding no need to examine extrinsic evidence, the court construes the term "parallel" to mean extending in the same direction with every point the same distance apart and never meeting. 86

86 The parties have not submitted "substantially" as a disputed term this court needs to construe. As the definition of parallel is to the same each time it is recited in the claims, "substantially" parallel provides deviation from the precise meaning of "parallel" to the extent a future finder of fact may determine. Although the court need not address Dell's contention that the definition be applied with "mathematical precision," it is noted that the relevant reference for a determination of whether the mating connector is parallel is no greater than the length of the side edge of the motherboard adjacent to which the connector is mounted and would not be determined by an infinite extension of imaginary lines coextensive with the mating connector and the side edge of the motherboard.

2851

C. "Parallel to a Major Surface of Said Conductive Layer"

The parties also disagree about the proper construction of the word "parallel" as it is used to describe the position of the emission face of a diode with respect to a "major surface" of the conductive layer. LDAI takes the position that this language covers curved surfaces as well as flat ones. LDAI contends that where a major surface extends along an axis, and an emission face of a diode bar follows that same axis along the length of the bar, the major surface and the diode bar are both parallel to the axis, and hence to each other. To put it another way, using Paradigm's array as an example, an imaginary line (the "z axis," in Paradigm's words) runs through the center of the cylinder. Any line that runs through the conductive surface, i.e. through corresponding points at either end of the cylinder, is parallel to the z axis. Likewise, the emission faces also run parallel to that axis, i.e. they remain equidistant from the axis throughout their length. In LDAI's view, that makes the emission faces and the surface of the conductive layer parallel to each other as well.

Paradigm disagrees. Paradigm asserts that under the laws of geometry, a flat surface can never be parallel to a curved surface. According to Paradigm, the whole concept of parallelism is based on linear or planar geometry. Paradigm's expert, Dr. Richard W. Dixon, who testified at the Markman hearing stated that, a "curved surface cannot be parallel to a plane." Transcript ("Tr.") at 149. He added that "parallel is defined to be a term that applies to straight lines and planes. So two planes can be parallel. … But you can't have a spherical surface or a cylindrical surface parallel to a plane." Tr. at 153.

I find Paradigm's position more persuasive. I credit Dr. Dixon's statements that as a simple matter of geometry, a curved surface cannot be parallel to a curved surface. The concept of parallelism implies that two parallel objects are everywhere equidistant. See, e.g., Webster's Third New International Dictionary (Unabridged) (1981) at 1637 (defining "parallel" as, inter alia, "extending in the same direction and everywhere equidistant," and "everywhere equally distant"). At different
points on a curved surface, however, a neighboring flat surface will be different distances away, even if it runs in the same
direction. Even if parallelism does not completely exclude all curved surfaces (e.g. arguably two concentric cylinders might
be considered parallel to each other), I do not see how that concept can be applied to both a curved surface and a planar
surface.

True, the planar and curved surfaces at issue here--the emission faces and surface of the conductive layer in Paradigm's
arrays--run in the same direction. As stated, however, parallelism requires more than that. If a cylinder of infinite length
shared a line in common with a plane, one would not describe them as parallel, but as tangent to each other. Id. at 2337
(defining "tangent" as "having a common tangent line at a point -- used of two curves in a plane, two space curves, or a
surface and a space curve"). In fact, in his testimony at the hearing, LDAI's own expert, Dr. J. Stanley Whiteley, conceded
that in a diagram in his expert report, which uses tangent lines to demonstrate the relative positions of the emission faces
and the major surface of the conductive layer, see POB Ex. A at 22 (Fig. 4), the major curved surface was not parallel to
surface of the emission face. Tr. at 115.

LDAI's attempt to reduce this concept to geometric lines running through the respective surfaces distorts the fact that we are
not in fact dealing with lines, i.e. with one-dimensional objects, but with two- and three-dimensional objects: planes and
cylinders, or at least planar and cylindrical objects. To focus on the fact that any given line running the length of the cylinder
is parallel to any line running the length of the emission face, then, is to sidestep the real question, which is whether the
cylinder itself can be considered parallel to the emission faces. After considering all the evidence, including the expert
reports and testimony, I do not believe that a person of ordinary skill in the art would understand the word "parallel," as used
in the '951 patent, to cover both curved and flat surfaces. I conclude, then, that this claim language requires that the surface
of the conductive layer be substantially planar and that the plane of the emission face of the diodes be parallel to that
surface.

As used in claim 1 of the '112 patent, the phrase "to partially block the extrusion of said molten thermoplastic material from
said first side passage" means that the plug prevents the extrusion of molten thermoplastic material through the first side
passage only at the location on the circumference of the first side passage where the plug is disposed. As used in claim 2 of
the '112 patent, the phrase "to partially block the extrusion of said molten thermoplastic material from said second side
passage" means that the plug prevents the extrusion of molten thermoplastic material through the second side passage only
at the location on the circumference of the second side passage where the plug is disposed.

Plaintiff proposes that the phrase "an intake passageway . . . at least partially defined by said runner filler" does not need to
be construed because its meaning is clear. Defendant proposes that the phrase be construed to mean that the runner filler
must enclose at least a segment of the intake passageway. I conclude that the runner filler may "at least partially define" the
intake passageway without enclosing it.

Defendant argues that the preferred embodiments shown in the '502 patent disclose two types of runner fillers. Some
completely enclose the intake passageway when inserted into the runner filler. Defendant calls these "closed" runner fillers.
Others are only semi-circular and, when inserted into the runner filler, cooperate with the intake runner to form the intake
passageway. Defendant calls these "open" runner fillers. Defendant contends that independent claims 15 and 22 equate the
claim term "defined" with the word "enclosed." Therefore, defendant argues, claims 15 and 22 require the use of closed
runner fillers.

In support of its position, defendant relies solely on the embodiments shown in the patent specification. The embodiments
that correspond to claims 15 and 22 show closed runner fillers. However, the court will "not import limitations into claims
from examples or embodiments appearing only in a patent's written description, even when a specification describes very
specific embodiments of the invention . . . unless the specification makes clear that the patentee intends for the claims and the embodiments in the specification to be strictly coextensive." JVW Enterprises, Inc. v. Interact Accessories, Inc., 424 F.3d 1324 (Fed. Cir. 2005). The '502 patent does not indicate that the invention taught by claims 15 and 22 is limited to those in which a closed runner filler is used to completely enclose the intake passageway. In order to "at least partially define" the intake passageway, the runner filler must form only a portion of the intake passageway. It may do so by completely forming a segment of the intake passageway or by partially forming a segment of the intake passageway. Therefore, the rejection should be withdrawn.

B. "Partially Overlapping Said First Gelatinous Coating And Forming A Seam"

The parties are essentially in agreement about the meaning of the phrase "partially overlapping said first gelatinous coating"; their proffered definitions differ only in choice of words, not in any substantive sense. With regard to the meaning of "seam", however, defendant argues that the patentee disavowed coverage of any surface feature other than "a visible transition" consisting of "a thickened portion and a non-uniformity in the surface".

Defendant argues that the specification in the '524 patent assigns this narrow definition to the term "seam," but the specification simply does not disclose any such definition. Rather, the specification uses "seam" simply to refer to a surface feature of the medicament, without clearly setting out any particular description of the physical appearance of that feature. The specification does note that several drawings set out in the accompanying sheets of illustrations display a "seam", but the indicated drawings simply display a region on the medicament where the seam is located. Defendant argues that the drawings display a visible raised portion in the region of the seam, but any such elevation in the surface area is extremely slight, possibly an accidental by-product of the drafter's effort to set off the seam in order to indicate its location on the surface. Nothing in the language of the specification mentions a "visible raised portion" as a surface feature, or mentions such a feature as something worth noting in the drawings.

Defendant also argues that the prosecution history reveals that the patentee disclaimed any meaning of "seam" other than "a visible transition in the thickness of the coating material... [consisting of] a thickened portion and a non-uniformity in the surface." (Defendant's Markman Brief at 30) Plaintiff responds that "seam" does not refer to thickness, but rather means a "line of junction formed by the abutment (touching) of edges between the two gelatinous coatings." Plaintiff argues that the patentee "did not amend the language of the claims to include a limitation relating to gelcaps having different gelatin thicknesses." (Plaintiff McNeil's Responsive Pre-Markman Hearing Brief at 25) The remarks accompanying the amended claims in the prosecution history of the '524 patent make plain, however, that the patentee was revising the language of the claims to emphasize the seam in order to distinguish the claimed medicament from the older patent, by Richards, and thereby escape rejection by the PTO, and that plaintiff's revised language did indeed define "seam" to refer to a transition in the thickness of the coating material.

The original patent application had been rejected because the claimed structure was too similar to an invention patented earlier by Richards. The original '524 patent application had described "first and second gelatinous coatings substantially covering said caplet to form a simulated capsule-like medicament with a seam." This original description did not indicate that that seam resulted from the overlap of the coatings; rather, it simply stated that the medicament featured a "seam" which might have been a gap, an abutment, an overlap, or something else. In the amended claim, the patentee specifically altered this language to describe "[a] second gelatinous coating... partially overlapping said first gelatinous coating and forming a seam." The patentee stated that he had "amended the claims to more clearly state the structure of the coated caplet as having an overlapping seam of gelatin. Therefore, the... rejection should be withdrawn."

The remarks consistently emphasize two features that set the claimed invention apart from the medicament described by Richards: different colors on either end of the medicament, and a "thickened portion" formed by the overlap of the two gelatin coatings at the midsection of the medicament. The remarks declare that the separate colors provide an illusion that the medicament is, in fact, a capsule. The remarks go on to stress that further enhancing the illusion, is the specifically claimed structure... calling for a seam... provided by the overlapping of the two gelatinous coatings which form a thickened portion at the overlap. The change in thickness accompanied by the changing color makes it appear that... the medicament is actually a... capsule. These features and structural limitations...
are clearly not disclosed by, or inherent in Richards.

These comments leave no doubt that the "seam" is a "thickened portion" of the surface at the location of the transition in color, i.e. the point where the two differently colored gelatinous coatings meet. The comments make it clear that, for the purpose of escaping rejection and distinguishing the claimed invention from Richards, the patentee disavowed any type of seam other than an overlap of two coatings resulting in a 'change in thickness.'

This interpretation is confirmed by the comment later in the remarks that "what Richards is attempting to provide is a smooth continuous coating about the entire pill…. [The '524 a]pplicant's claimed structure, however, actually… requires non-uniformity in its surface. The transition of color, the transition of thickness, the clear demarcation between the two gelatinous coatings are not disclosed or inherent from Richards." From the repetition of this point, and the explicit insistence that the "transition in thickness" is one of the crucial elements entitling the patentee to escape rejection, any competitors reading the prosecution history would reasonably believe that the patentee had surrendered any claim to a "seam" other than one consisting of a "transition in thickness." Contrary to plaintiff's arguments, the patentee did indeed amend the language of the claim and place the word "seam" in a different context for the specific purpose of escaping rejection. Having done so, the patentee went on, in remarks which are recorded in the prosecution history, to emphasize that "seam" had a specific definition: a feature consisting of a transition in thickness at the location of the transition in color. Plaintiff is therefore barred from asserting an inconsistent position on claim construction, and the Court will apply the definition of "seam" that the patentee assigned in the prosecution history.

Plaintiff attempts to argue that the definition of "seam" suggested by defendant would constitute a 'limitation' on that claim term, and that courts are prohibited from reading limitations from prosecution history into claims which do not contain those limitations, citing Intervet America, Inc. v. Kee-Vet Labs, Inc., 887 F.2d 1050, 1054 (Fed.Cir. 1989). Intervet can be distinguished from the present case, however. There, the prosecution history included a statement by the attorney that all seven claims under consideration would, in the future, prior to issuance of the patent, be amended specifically to include a numerical limitation on the frequency of administration of an action. In fact, only four of the seven claims were actually amended to include the limitation that the attorney had described, and the court held that it was erroneous to read that specific, discrete, numerical limitation into the three claims which did not contain it. When an attorney's erroneous remark tending to ascribe a limitation to the claims which is not present there, the court held, the claim language controls. See id. at 1053 - 1054. In the present case, there was no erroneous remark in the prosecution history. The term "seam" appears in the claim, and the prosecution history allows the public to understand the meaning of that term as it is used in the '524 patent. See Markman, 52 F.3d at 980 ("The court has broad power to look as a matter of law to the prosecution history of the patent in order to ascertain the true meaning of language used in the patent claims."). The explanation in the prosecution history of what is meant by a seam is properly read, not as a diminishment or variation of the limitations in the claims, but rather as a definition of the term "seam." The Federal Circuit has made it clear that the prosecution history cannot be used to enlarge, diminish, or vary the limitations in the claims, so that when the claims contain limitations, the prosecution history cannot contradict those limitations. See id. The prosecution history can, however, serve effectively to limit the meaning of terms used in the claims by providing a definition of terms as they are used in that patent, as the amendment remarks do here.

Plaintiff's contention that "it is impossible to specially define a claim term in the file history" (Plaintiff's Responsive Brief at 24) is broadly correct as a statement of law, but is irrelevant to the present case. The Federal Circuit has held that when the patentee wishes to serve as his or her own lexicographer and provide an 'uncommon' definition, one which "differs from the conventional definition," that special definition must be clearly set out in the specification. See Beachcombers Intl', Inc. v. Wildewood Creative Products, Inc., 31 F.3d 1154, 1158 (Fed.Cir. 1994); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed.Cir. 1992). 2 In the present case, the prosecution history does not provide a special, novel, unconventional definition for the word "seam," but simply one particular understanding of a word which could have numerous potential meanings in the context of a medicament. Both in the claims and in the prosecution history, the "seam" is the feature of the medicament where the edges of the two gelatinous coatings are in proximity, just as a seam on a garment is the feature where two pieces of fabric are connected. The '524 patent's prosecution history does not provide a novel definition in contradiction of the common understanding, but rather limits the definition to a particular type of seam, in accordance with the claimed structure that is described and the possible alternatives, such as a line of abutment, which are disavowed. The definition in the prosecution history is thus not a "special" definition, which can only appear in the specification, but is rather an explanation of "the true meaning of language used in the patent claims," which is a proper purpose for it to serve under Markman, 52 F.3d at 980.
Defendant has also argued that the prosecution history limits plaintiff to a definition of "seam" which provides that the transition in thickness is "visible." The patentee asserted at one point in the amendment remarks that the amended claims call for "a visible seam, something which is unwanted in the Richards process." The claim language was not amended to add any mention of visibility of the seam, however, and the remarks do not consistently and specifically emphasize visibility as an element of the seam which separates the claimed invention from the medicament described in Richards. Where the remarks do discuss visibility, they generally describe it as a function of the seam generally, and not as a specific result of the transition in thickness.

The remarks, such as the sentence quoted by defendant regarding a "visible seam", place great stress on the fact that the claimed medicament has a bifurcated color structure, which Richards does not, and that the seam is the feature that occurs at the location of the transition in color, i.e. the juncture of the two gelatinous coatings. The remarks do suggest that the seam is visible, but since they do not describe visibility as a specific result of the transition in thickness, it is doubtful from the remarks that the 'visibility' of the seam results from the transition in thickness. Reading the remarks in context, they suggest that the seam's visibility is due to the transition in color which occurs at the point of the seam. The sentence quoted by defendant, referring to a "visible seam", appears in the context of a discussion of the process for drying the gelatinous coatings. The patentee states that in Richards, the coatings might be blurred, which is adequate for Richards because in that patent "no color difference is disclosed." In the '524 patent, by contrast, the patentee explains, the gelatin sets quickly, which "prevents undesirable blurring between the colors. It is clear [the remarks continue] that Applicant's structure calls for a visible seam." In that context, the reference to the visibility of the seam appears to refer to the transition in color and not the transition in thickness.

In addition, one aspect of the remarks suggests that the change in thickness is not itself visible at all. The remarks state that the contrast of the colors gives "the illusion of different sizes to the two ends" of the medicament. The fact that the appearance that the two ends of the medicament are of different sizes is only an illusion strongly suggests that any appearance of a 'change in thickness' is also an illusion, and that, even though there may in fact be a change in thickness, no such change is actually visible to the ordinary viewer. The remarks do not establish with any certainty that the change in thickness is not, in fact, visible, but the failure of the remarks to address this point consistently and directly, and the ambiguity of the references to the visibility of features on the surface of the medicament, prevent the prosecution history from serving to clarify whether the "change in thickness" is to be understood as visible or non-visible. The amendment remarks therefore do not limit the construction of the claim term "seam" to a transition of thickness which is actually visible.

*   *   *

IV. CONCLUSION

The Court concludes that the disputed terms have the following meanings:

1. "Simulated capsule-like medicament" shall mean "a medicinal form that imitates, resembles, or suggests in form or appearance a gelatin shell enclosing medicine."

2. "Partially overlapping said first gelatinous coating and forming a seam" shall mean "extending over and covering part of, but not all of, the first gelatinous coating in a manner such that there is a transition of color and a transition of thickness."
The disputed claim in this case is the "first mirror being partially reflecting" as mentioned in claims one and seven. This mirror is referred to multiple times in the remainder of the patent by three different names: "partially transparent," "two-way mirror," and "partially reflecting." The mirror is also described as "appear[ing] to be fully reflecting" to an adjacent observer. Plaintiff interprets his claim broadly, to cover any surface made of any material that reflects more than a de minimis amount of light and is at all transparent. Defendant takes issue with this broad interpretation for two reasons. First, Defendant contends that the descriptions of the partially reflecting mirror in Plaintiff's actual patent show an intent to cover only partially reflecting mirrors that appear to be fully reflecting to an adjacent observer. Second, Defendant asserts that Plaintiff disavowed transparent covers in the patent prosecution process when he distinguished his patent from the Giboney patent. For the reasons stated below, the court finds the first argument dispositive, and therefore does not reach the prosecution history issues.

Defendant's argument regarding the language in the patent description is well taken. Plaintiff's broad interpretation of the term "partially reflecting mirror" runs counter to the patent description language. Plaintiff's position is that anything that reflects some light, but not all light, is a partially reflective mirror:

THE COURT: Because anything that reflects, I mean is a mirror anything that reflects?

MR. LINDON: Are you talking about a mirror or a partially reflective mirror?

THE COURT: Any mirror.

MR. LINDON: Yes. I mean as I'm standing here, I can see a reflection of that light in that window. It's reflecting it.

THE COURT: So anything that --

MR. LINDON: I can see my reflection in it. I can see the image that is reflecting off of it. That's a mirror. It doesn't even have to be a piece of glass.

It could be a highly polished piece of metal. That's a mirror.

THE COURT: That's a partially reflecting mirror.

MR. LINDON: That window right there, yes, it is. You can turn the light off behind it and in front of it and vary the amount of light and you will get a completely different effect.

* * *

THE COURT: But you're saying almost anything can be a partially reflecting mirror under the right light and circumstance?

MR. LINDON: Well, it has to have at least some transparent property to it or it won't, you know, it's a functional consideration as you are pointing out. It's functional. Does this thing function as a mirror. If it does, it's what my client is going after, regardless of the methods or the materials, if it functions as a mirror and allows -- reflects some of the light and allows the rest of the light to go through it, it's a partially reflective mirror. Okay?

(Hearing Tr. 64-66.) However, the patent language does not support such a broad interpretation. The patent claims a "partially reflective mirror," but there is no definition of the term in the actual claim. Rather, the description section regarding the patent clarifies that the "partially reflective mirror" must appear fully reflecting to an adjacent observer. This is inconsistent with Hargabus' current position that a partially reflective mirror is any mirror that reflects more than a de minimis amount of light.

In claim construction, "the specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Phillips v. AWH Corp., 415 F.3d 1303, 2005 U.S. App. LEXIS 13954, *29 (Fed. Cir. July 12, 2005) (quoting Markman, 90 F.3d at 1582). The Federal Circuit went on to
clarify the proper use of patent specifications or descriptions:

[T]he specification may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs. In other cases, the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor. In that instance as well, the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive.

Phillips, 415 F.3d 1303, 2005 U.S. App. LEXIS 13954 at *33-34. In the instant case, Hargabus offers a specific description of what he means by "partially reflective mirror" in the "Detailed Description of the Invention." Under the applicable case law, this specification is highly relevant, usually dispositive, and evidence of the inventor's intent. Therefore, since Hargabus asserts that the "partially reflective mirror" should appear fully reflective to the adjacent observer, this court construes the claim as such. There is no literal infringement unless the partially reflective mirror appears fully reflective to an adjacent observer.

Having reached this conclusion, it is unnecessary for the court to further address the patent prosecution history and Defendant's position that there was prosecution history estoppel. 1

--- Footnotes ---

1 The court notes that any alleged subject matter disclaimer is not as simple as Defendants contend. At a minimum, Plaintiff's argument that the Giboney patent had a different purpose and function than the Hargabus infinity mirror display, and that as such, there was no clear and unmistakable surrender of subject matter, is not frivolous.

--- End Footnotes ---

II. "Particles"

For the claim construction hearing, Claims 2-4 of the ’358 Patent were at issue. The parties agree that the only claim term that is in dispute is the word "particles" as it appears in independent Claim 2. Thus, the purpose of the Markman hearing was to determine the meaning of the word "particles." Independent Claim 2 of the ’358 Patent, in its entirety, reads as follows: (See Column 6, Lines 5-20).

--- Footnotes ---

2 The term "particles" is also found in Claims 1 and 8 of the ’342 Patent and Claim 1 of the ’358 Patent.

--- End Footnotes ---

2. A semi-resilient exercise grip comprising:

a core containing a deformable mixture of tightly packed individual dry particles that are in continuous contact with each other; and

a resilient covering surrounding said core, wherein said covering is in the form of a plurality of nested sacks, wherein each sack is made of a resilient material and includes an opening, and wherein the sacks are located about the core, the openings of adjacent sacks are spaced apart from each other, and wherein each sack applies its own inward force on the core and the total inward force on the core is the combined total of the individual inward forces exerted on the core by each of the sacks making up the covering.

Claims 3 and 4 of the ’358 Patent further limit the coverings of the exercise grip. Dependent Claims 2 and 3, in their entirety, read as follows: (See Column 6, Lines 21-25).
3. The grip of claim 2 wherein each of the sacks that make up the covering are substantially ball-shaped when in a non-stressed state.

4. The grip of claim 2 wherein each of the sacks are made of a latex rubber material.

Sport Squeeze contends that the term "particles" is limited to particles that are similar in size and shape to millet (roughly the size of bird seed), which is one of the examples of particles disclosed in the Scatterday patents. The allegedly infringing Ad Squeeze product uses silicon beads which are much smaller in size than millet. Accordingly, Sport-Squeeze contends that the term "particles" is limited to larger, millet-sized particles, which, under its proffered construction, would result in the Ad Squeeze product not infringing the asserted claims.

In opposition, Pro-Innovative contends that the term "particles" should be given its broad and ordinary meaning which includes particles not limited in size and shape to millet. Specifically, Pro-Innovative requests the court to construe the term "particles" to mean "small specks of matter which include starch particles, microsphere particles, hard plastic or silicon beads and millet."

IV. Discussion

A. Legal Standards

a. Construing the Term "Particles" in the '342 and '358 Patents is a Question of Law for the Court

Construing a claim to determine its scope and meaning, also known as "claim construction," is a pure question of law for the court. Markman, 52 F.3d 967, 970-71. The language of the claim defines the scope of the protected invention. Bell Communications Research v. Vitalink Communications Corp., 55 F.3d 615, 619-620 (Fed. Cir. 1995). "Words in a patent claim are construed as they would be understood by a reader skilled in the relevant art unless it appears that the inventor used the words differently." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1997).

When interpreting disputed claim language, the court must first look to "intrinsic" evidence, including "the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (citing Markman, 52 F.3d at 979). The parties agree that the disputed claim language can be construed with reference to intrinsic evidence only. Thus, it would be improper to look to extrinsic evidence. Id. at 1583.

b. The Doctrine of "Claim Differentiation"

"There is presumed to be a difference in meaning and scope when different words or phrases are used in separate [patent] claims. To the extent that the absence of such [a] difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). The doctrine of claim differentiation has its greatest force when an interpretation of a dependent and independent claim would render the dependent claim superfluous. Beachcombers v. WildeWood Creative Products, Inc., 31 F.3d 1154, 1162 (Fed. Cir. 1994) (interpretation that renders dependent claim superfluous is "presumptively unreasonable" under doctrine of claim differentiation); United States v. Teletronics, Inc., 857 F.2d 778, 783 (Fed. Cir. 1988) (where some claims are broad and others narrow, the narrow claim limitations cannot be read into the broad claims). The doctrine may also be used to interpret an independent claim in light of another independent claim. See, e.g., Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044, 1055 (Fed. Cir. 1988); Caterpillar Tractor Co. v. Berco, SPA, 714 F.2d 1110, 1116 (Fed. Cir. 1983).

"Although the doctrine of claim differentiation may at times be controlling, construction of claims is not based solely upon the language of other claims; the doctrine cannot alter a definition that is otherwise clear from the claim language, description, and prosecution history." O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1582 (Fed. Cir. 1997); see also Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) ("While we recognize that the doctrine of claim differentiation is not a hard and fast rule of construction, it does create a presumption that each claim in a patent has a different scope.").

B. Claim Differentiation Supports Pro-Innovative's Construction
Pro-Innovative argues that its three exercise grip patents contain a wide spectrum of language regarding certain "particles," describing them in narrow and broad terms. It argues that the claims of the '342 Patent use the term "particles" both with and without qualifying language, and that the '358 Patent includes no language limiting "particles" based on size and shape. Upon review of the three patents, the court finds that the doctrine of claim differentiation supports Pro-Innovative's position.

1. The '504 Patent

Claim 1 of the first patent issued to Scatterday, the '504 Patent issued in 1993, limited the "particles" used to fill the exercise ball to millet-sized particles. (See Column 5, Lines 23-26).

1. A semi-resilient exercise grip comprising a nonresilient core containing a deformable mixture of individual particles identical in size and shape to millet

Claim 7 of the '504 Patent is also limited to "millet-sized" particles. (See Column 6, Lines 15-19). The parties do not dispute that the plain language of Claim 1 of the '504 Patent and the patent's prosecution history confirm that Claim 1 is limited to millet-sized particles.

2. The '342 Patent

However, the term "particles" in the subsequently issued '342 Patent is not expressly limited to "millet-sized" particles. Specifically, Claims 1-3 of the '342 Patent read: (See Column 5, Lines 27-43; Column 6, Line 1).

1. A semi resilient exercise grip comprising a non-resilient dry core containing a deformable mixture of tightly packed individual particles that are in continuous contact with each other.

2. The grip of claim 1 wherein the particles are hard and are similar in size and shape to millet.

3. The grip of claim 2 wherein the particles are millet.

Applying the doctrine of claim differentiation, the term "particles" in Claim 1 cannot be limited to particles "similar in size and shape to millet." Under such a construction, Claim 2 would have the same scope as Claim 1, rendering Claim 2 superfluous—a construction that is "presumptively unreasonable." Beachcombers, 31 F.3d at 1162. Sport Squeeze presented no evidence during the hearing or in its papers rebutting the strong presumption that the "millet-sized" limitations in dependent Claim 2 should not be incorporated into Claim 1.

Sport Squeeze argues that the prosecution history of the '342 Patent supports a narrow reading of the term "particles." Specifically, Sport Squeeze emphasizes that the Patent Office rejected the initial Claim 7 as obvious under U.S. Patent No. 3,601,923 issued to Rosenberg. (See Sport Squeeze Exhibit G). To overcome the Patent Office's rejection, Scatterday limited the "particles" in initial Claim 7 to "substantially millet-sized" particles and explained to the Patent Examiner that the "millet-sized" particles in the revised claim distinguished the claim from Rosenberg, which used considerably smaller starch particles. (See Sport Squeeze Exhibit B, at 6-7 (Stamp no. 122-123) (stating that "the tiny particles used by Rosenberg form a crucial component of his invention.")).

--- Footnotes ---

3 The claim which became Claim 7 of the '342 Patent was originally designated as Claim 15 in Scatterday's earlier applications. For purposes of this Order, the court will refer to Claim 15 as the "initial Claim 7," and the claim issued by the patent office as "issued Claim 7."

4 The Patent Office also rejected various claims of the '342 Patent under the doctrine of "double-patenting." Scatterday subsequently filed a terminal disclaimer to cure the rejection so that all three patents ('504, '342, and '358) would expire on the date of the first patent. See In re Goodman, 11 F.3d 1046, 1052 (Fed. Cir. 1993) (filing of terminal disclaimer cures double patenting rejection).
In essence, Sport-Squeeze argues that the prosecution history of Claim 7 (which resulted in a claim dependent upon "millet-sized" particles) supports its contention that the "millet-sized" limitation should be implied into claims that do not contain this limitation. This argument is unpersuasive. The fact that Scatterday limited "particles" in initial Claim 7 to "millet-sized" particles while leaving "particles" in Claim 1 without such a limitation supports Pro-Innovative's contention that the term "particles," standing alone, is not limited to particles that are millet-sized. Moreover, the difference between the "particles" in Claim 1 and issued Claim 7 provides additional support for Pro-Innovative's arguments that claim differentiation forecloses a construction of the term "particles" limited to particles that are millet-sized. 5

Sport-Squeeze argues that Scatterday represented to the Patent Office during prosecution of the '342 Patent that millet-sized particles were essential to the semi-resilient nature of the exercise grip. (See Sport-Squeeze's Opening Brief at 9-10 (quoting Sport-Squeeze's Exhibit I, at 6)). However, those comments were made in reference to a claim which explicitly contained a "millet-sized" limitation. Thus, Sport-Squeeze's "file wrapper estoppel" arguments concerning the other claims are without merit as this explanation was not offered to obtain allowance on any other claim. Moreover, Sport-Squeeze presented no evidence during the Markman hearing that the invention's semi-resilient characteristics depend upon millet-sized particles. In any event, this statement does not overcome the presumption raised by the doctrine of claim differentiation.

Sport-Squeeze argues that this language discloses that the "particles" in the '358 Patent are limited to millet-sized particles. However, while "the specification may aid the court in interpreting the meaning of disputed claim language, particular embodiments and examples appearing in the specification will not generally be read into the claims." Comark Communications, Inc., 156 F.3d 1182 at 1187; see also Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."). Sport-Squeeze has provided no basis for reading the specification's illustrative use of "millet-sized" into the claims of the patent. The court has found nothing in the long and somewhat confusing prosecution history of the '358 Patent which would warrant a narrow reading of "particles" inconsistent with its plain meaning and the construction of that term in the '342 Patent.

With all three patents, when Pro-Innovative sought to limit the "particles" in its claims to a particular size or shape, it qualified that term by including the limitation that the particles be the size or shape of "millet." When Pro-Innovative did not wish to limit the size or shape of the "particles," it did not include any size or shape limitation.

i. Application of Claim Differentiation to the '358 Patent

Sport-Squeeze contends that the doctrine of claim differentiation cannot be applied to the '358 Patent because the doctrine is "inapplicable to continuation patents." The sole case Sport Squeeze relies upon, Jonsson v. Stanley Works, 903 F.2d 812 (Fed. Cir. 1990), held that the prosecution history of one patent can be used to determine the scope and to interpret the meaning of another patent where both patents stem from a common parent application. 903 F.2d at 818. The court found it unnecessary to apply the doctrine of claim differentiation because the court's finding that the claim contained a limitation existing in a separate dependent claim was supported by the prosecution history, the patent, the specifications, and
deposition testimony. Id. at 820 ("Hence, since it is apparent that the court had ample evidence to determine the scope of the '912 patent, Jonsson's reliance on claim differentiation requires no discussion."). Thus, Jonsson merely reinforces the rule that the doctrine of claim differentiation can be overcome by a patent's prosecution history. 6

6 Most of the sections of Jonsson quoted in Sport-Squeeze's Opening Brief were not the opinion of the court, but rather arguments asserted by the parties.

In this case, however, the court need not necessarily rely upon the doctrine of claim differentiation to conclude that the "particles" in the '358 Patent are not limited to "millet-sized" particles. As discussed in the preceding section of this order, nothing in the prosecution history or specifications justifies departing from the plain meaning of the term "particles." Rather, the prosecution history of all three patents reveals that both Scatterday and the patent examiner understood that differing particle sizes were significant in light of Tarnoff and Rosenberg.

Although not necessary to the court's conclusion, it notes that the doctrine of claim construction may provide additional support for Pro-Innovative's position. All three patents (1) involved the deformable exercise grip, (2) were issued over a relatively short period (three years), (3) involved the same patent examiner (Stephen Crow), and (4) made reference to the same prior art references. These facts support the court's conclusion that the term "particles" in the '358 Patent should be construed consistently with that term in the '342 Patent.

V. Sport-Squeeze's Arguments in Opposition

Sport-Squeeze presents two main arguments to support its contrary position that the "particles" in the '358 Patent must be millet-sized. First, Sport-Squeeze argues that the term "particles" should be narrowly construed to avoid conflict with prior art patents. Second, Sport-Squeeze argues that Judge Moskowitz previously ruled that the "particles" in the '342 and '358 Patents are millet-sized and that this determination is "law of the case."

a. Sport-Squeeze's Argument that a Narrow Reading of "Particles" is Necessary to Avoid Invalidation in light of Tarnoff is Logically Flawed

Sport-Squeeze argues that a broad construction of "particles" should be avoided because such a construction would read back on the Tarnoff prior art. According to Sport-Squeeze, a broad reading of the term "particles" would render the '342 and '358 Patents invalid under Tarnoff and Rosenberg because both of these patents use microspheres that are substantially smaller than millet.

Sport-Squeeze's argument is logically flawed because it assumes the term "particles" must be analyzed as an isolated term, construed outside the context of the claim it limits. In fact, it is of little consequence that a single term in a patent claim reads back on a term in a prior art patent so long as the claim as a whole does not read back on a claim in the prior art. Here, particle size is only one of many possible limitations contained in the claims of the '342 and '358 Patents. (See, e.g., Pro-Innovative's Exhibit 369). Claim 2 of the '358 Patent, for example, contains numerous limitations not found in Tarnoff or Rosenberg, including: (1) a plurality of nested sacks, (2) openings of adjacent sacks that are spaced far apart from one another, (3) each sack applies inward force on the core, and (4) the total inward force is the combined total of the individual inward forces. Id. These limitations, rather than an implied limitation on particle size, likely formed the basis for patentability of Claim 2. 7

7 In its Reply brief, Sport-Squeeze contends that "to have any differentiation between the claimed squeeze ball and the prior art, the term 'particle' must be defined as including particles approximately millet-like, but excluding microspheres ranging from 0.0001 inches to 0.06 inches." (See Sport Squeeze's Reply at 6:17-19). A similar argument appears in its Opening brief, where Sport-Squeeze argues that a narrow reading of the term "particle" is necessary to avoid conflict with Tarnoff. (See Sport-Squeeze's Opening Brief at 5:11-15). This arguments are rejected for the reasons stated in the text.
Thus, the court rejects Sport-Squeeze's argument that the term "particles" must be construed narrowly because the term may read back on the microspheres of Tarnoff. Moreover, Sport-Squeeze made no arguments during the Markman hearing or in its briefs that the broad construction of "particle" urged by Pro-Innovative would cause any of the claims of the '342 or '358 Patents to read back on Nichols, Rosenberg, Cherl, or Tarnoff.

b. Judge Moskowitz's Previous Ruling is not "Law of the Case"

Sport-Squeeze relies heavily upon the language of two orders from Judge Moskowitz, both dated August 10, 1998. (See Sport-Squeeze Exh. D, E). Sport-Squeeze relies particularly on page 5 of Judge Moskowitz's August 10, 1998 order denying Pro-Innovative's motion for summary judgment. (See Order Denying Motion for Summary Judgment on Patent Infringement (Doc # 106)). In that order, Judge Moskowitz rejected Pro-Innovative's contention that the term "particles" in the '358 Patent consisted of particles of any shape and size. He noted that this construction was "incredibly broad" and "unsupported by the record." (See id. at 5:15-23). Sport-Squeeze contends that Judge Moskowitz's ruling is "law of the case" and is binding on this court. The court finds this argument unpersuasive for two reasons.

First, the sole issue before Judge Moskowitz was whether Pro-Innovative was entitled to summary judgment on the issue of Sport-Squeeze's alleged infringement of the '358 patent. Since a Markman hearing had not been conducted, the question of claim construction was not before the court. In fact, in a footnote Judge Moskowitz observed that the parties had failed to lodge the Rosenberg and Tarnoff patents, and that without those references, "the Court cannot at this time determine whether 'particles' should be construed to include the 'size and shape of millet' limitation urged." (See id. at 6 n.2). At the conclusion of his order, Judge Moskowitz scheduled a Markman hearing and set a briefing schedule, negating any inference that he intended his previous order to serve as the final word on the construction of the three Scatterday patents.

Second, the court notes that, to the extent "law of the case" is applicable, it "merely expresses the practice of [a] court generally to refuse to reopen what has been decided." Christianson v. Colt Industries Operating Corp., 486 U.S. 800, 817, 100 L. Ed. 2d 811, 108 S. Ct. 2166 (1988) (quoting Messenger v. Anderson, 225 U.S. 436, 444, 56 L. Ed. 1152, 32 S. Ct. 739 (1912)) (Holmes, J.). It is not a limit to the court's power. Id.; Capital Investors Co. v. Executors of Morrison's Estate, 584 F.2d 652, 654 (4th Cir. 1978) ("The principle [of law of the case] is not absolute nor inflexible."). The court retains inherent authority to revise interim or interlocutory orders any time before judgment, including orders denying motions for summary judgment. See, e.g., FED. R. CIV. P. 54(b) (any order not certified under Rule 54(b) and which adjudicates fewer than all the claims as to all the parties "is subject to revision at any time before the entry of [final] judgment"); Balla v. Idaho State Bd. of Corrections, 869 F.2d 461, 465 (9th Cir. 1989) ("Courts have inherent power to modify their interlocutory orders before entering a final judgment."); Curran v. Kwon, 153 F.3d 481, 487 (7th Cir. 1998) ("When a district judge is presented with additional evidence, therefore, he is free to revisit a denial of summary judgment."). Thus, even assuming the issue of claim construction was addressed in the court's August 10, 1998 Order, the doctrine of "law of the case" would not preclude this court from revisiting the issue, especially where, as here, the parties presented evidence and argument they did not present at the time the court issued its previous order.

VI. Conclusion

For the foregoing reasons, the court concludes that the term "particles" in the claims of United States Patent Nos. 5,350,342 and 5,556,358 means particles in its ordinary sense without limitation based on the size or shape of millet. Specifically, the court finds that the term "particles" contemplates small specks of matter, including but not limited to, starch particles, microsphere particles, hard plastic or silicon beads and millet.
9 This order resolves only the issue of claim construction. The court expresses no opinion on the determination of infringement, the applicability of any defenses Sport-Squeeze may wish to assert, or the viability of the non-patent claims.

The dispute here centers on the phrase "particles that pass through a screen" (emphasis added). The Court agrees with Plaintiff's reading. Plaintiff claims that the verb "pass" refers to particles and that particles does not mean briquettes alone.

Defendant argues that this claim refers to the additive -- something that is added either as a granular, mixture or briquette -- and that is made up of particles (Tr. 42-43). The Court agrees that this claim further refines the metallurgy addition referenced in Claim 1. However, Defendant's explanation that "pass" refers to "addition" is strained. The verb "pass" describes the closest preceding noun: "particles" (Tr. 46). To paraphrase the meaning of this claim, the additive is made up of particles which are of a size small enough to pass through a screen with four inch square openings.

HEN contends that "particulate material which is loosely packed such that it is gas permeable" should be construed to mean "particles/particulate-matter arranged such that gas may pass through it." (HEN CC Br. at 22.) Minco, on the other hand, argues that this claim language should be construed to mean "particulate material which is unrestrained, not bonded together into a solid or rigid form, but rather free to move." (Minco CC Br. at 31.)

Minco argues that the specification supports its proposed construction. First, Minco notes that the figure in the specification depicts the sheathing and the particulate matter inside the tube differently and in a manner consistent with the PTO guidelines for how to indicate loose particulate matter versus packed particulate matter. Minco asserts that the area showing the particulate matter inside the conductive tube (see Minco Ex. A at Figure 1, number 10) is depicted by dots, indicating that it is loose, whereas the sheathing (see id. at Figure 1, number 2) is depicted with dots and hash lines indicating that it is packed. Additionally, Minco asserts that the specification states that both the sheathing and the particulate material inside the tube can be resin coated molding sand. Minco asserts that the sheathing must be physically solid and rigid because it is not otherwise contained by any structure, but that since the particulate matter in the conductive tube is contained by the tube, it does not need to be solid and rigid. Minco concludes that because the sheathing and the particulate matter are depicted differently and the sheathing is solid and rigid, the logical consequence is that the particulate material must be loose, unbonded, and free to move. We find this reasoning to be an insufficient basis for us to conclude that the particulate matter cannot bonded together and must be free to move because, by depicting the two areas differently, the applicant could simply be conveying that the two areas are different elements, not that one element must necessarily be solid and the other loose. Moreover, even if we were to accept Minco's arguments that the specification shows the particulate matter inside the conductive tube as being loose, unbonded, and free to move, construing the claim language to require the particulate material to be in such a state would result in the importation a limitation that only appears in the specification, and not in the claim language.
Minco also relies on the prosecution history to support its proposed construction. First, Minco claims that, in order to overcome the prior art contained in German Patent No. 2207307 to Kunzer ("the Kunzer patent"), HEN stated, "Note that the resin coated molding sand of the present invention is utilized for the refractory sheath 2 while molding sand is provided within the support tube 1." (Minco App. 4D at HEN000058.) Minco claims that this statement supports the conclusion that the sheath must be physically hard baked, but that the interior of the tube is filled with loose particles of sand, since molding sand contains no resin and cannot be baked hard or rigid. Regardless of whether molding sand can or cannot be baked into a solid form, we find that this statement by HEN does not amount to a clear disavowal of claim coverage over particulate matter that is bonded together. Minco also asserts that the patent examiner clearly understood the particulate matter to be loose sand, not baked hard rigid sand. However, what the patent examiner thought is not a clear disavowal of claim coverage by HEN.

Consequently, Minco's arguments that HEN limited the allowable construction of these claims terms during the prosecution history are without merit and we construe the claim language "particulate material which is loosely packed such that it is gas permeable" to mean "particles/particulate-material arranged such that gas may pass through it."

Honda argues that this phrase should be construed as "two crankcase portions connected together at a separation surface that crosses, at a slant, an axis of said first and second bearing portions". Coast argues that the phrase should be construed as "first and second parts of the crankcase are coupled together at a seam that defines a plane that is neither parallel nor perpendicular to the center axis of first and second portions for accommodating bearings, each portions completely encircling the entire periphery of one end of a crankshaft." As an alternative, Coast argues that the phrase should be construed as "two crankcase portions connected together at a planar separation surface that crosses, at a slant, the axis of rotation of the crankshaft."

The parties' dispute centers primarily around the proper construction of the term "parting plane." Honda argues that the plain meaning of term "parting plane," to one of ordinary skill in the art, is a "separation surface." (Shariati Decl., Ex. F ("Stern Decl., P 64").) Honda further argues that, because the parting plane is the point at which the first and second crankcases are coupled to one another, this separation surface need not limited to a flat surface. The Court begins with the claim language. Although the term "plane" implies a flat or level surface, see, e.g., Webster's at 899, in the context of the claim, it is clear that the "plane" claimed relates to the point where the two crank cases are coupled to one another.

Coast argues that, because the claim also requires that the parting plane "obliquely intersect[s] an axis of said first and second bearing portions," the term plane must be construed to mean a level or flat surface. Otherwise, according to Coast, "it would be impossible to determine at which angle it intersects an axis of the bearing portions." (Opp. Br. at 16.) However, as Coast itself argues, the term "obliquely," implies that the parting plane intersect the axis "as slant."

Accordingly, the Court construes the term "first and second case halves which are coupled to each other at a parting plane extending to obliquely intersect an axis of said first and second bearing portion" to mean: "two crankcase portions connected together at a separation surface that crosses, at a slant, an axis for the supports for opposite ends of a crankshaft, the axis for the supports being a line coincident with the axis of rotation of the crankshaft."

Turn-Key argues that this limitation must be construed as referring to the surfaces of the two mold parts between the two mold parts that either touch or lie adjacent to the other mold part before the mold parts separate, excluding the product
molding cavity(ies) that is situated internally to the parting surfaces. In so arguing, Turn-Key specifically objects to the "additional limitations" of Defendants' interpretation. Pl's Opening Brief at 7-8. Defendants argue that a parting surface consists of those faces of each of the two mold parts that touch each other when the mold is closed and that oppose each other when the mold is open. They, however, note that portions of these faces may be slightly relieved so that they do not touch each other when the mold is closed but face each other in close proximity and with no intervening structure. Crest's Responsive Brief at 11-13; KM, MC & Concord's Brief at 5. The dispute over the interpretation of "parting surface" thus centers around (1) whether the faces of the mold parts must touch each other, (2) whether the faces must oppose each other when the mold is "open," and whether (3) there can be no intervening structure. 2

2 Here, Defendants utilize the term "open" to refer to the position of the mold parts during the "separating" process described in Element (b). See IV.A.3.

The Court construes "parting surface" to signify the faces of the two mold parts that either touch or lie adjacent when the mold parts are brought together in the "combining" process described in Element (a). See supra at Section IV.A.2. In applying the ordinary and customary meaning of "combining" as the act of bringing into or joining in a close union or whole, the Court finds that not all of the faces of the two mold parts are required to actually touch each other; they need to be only in some proximity to each other. Random House Webster's College Dictionary at 261. Having said that, however, the Court notes that there must be at least some point at which the faces of the two mold parts touch other, thus preventing the fluid from leaking out of the cavity before it is molded into the plastic product. The Court declines to construe the mold parts as "opposing" each other when they are being kept apart in the "separating" process described in the first portion of Element (d) on the grounds that it adds an extra limitation not present in the claim language. See supra Section IV.A.5.a. 3 In addition, the Court further declines to construe this claim as requiring an absence of an intervening structure on the grounds that it adds an extra limitation not present in the claim language.

3 The Court agrees with Turn-Key that with a "claim" model mold, the parting surfaces would not "oppose" each other like paired opposites upon opening their book-like hinges. Pl's Reply Brief at 19.

The parties disagree on the meaning of the terms "air plenum" and "partition" in Claim 15. Claim 15 calls for:

a partition disposed in said interior chamber for defining an air plenum on one side of said partition and a rack receiving chamber on the opposing side of said partition, said air plenum and said rack-receiving chamber being in fluid communication with each other such that cooled air can be channeled through said air plenum and into said rack-receiving chamber.

See '569 Patent at column 8, lines 6-33.

The words of the claim itself make clear that an "air plenum" refers to an air flow passage through which cooled air travels to an adjacent dispensing rack. Because the patent specification and prosecution history do not give the term "air plenum" any special meaning, it must be given its ordinary meaning. The best place to look for that meaning is a technical dictionary. See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002) (acknowledging that dictionaries "may be the most meaningful sources of information to aid judges in better understanding . . . the terminology used by those skilled in the art"). The ordinary meaning of the word "plenum" used in the heating, ventilating, and air-conditioning ("HVAC") field is an "air flow passage". Home Energy Magazine Online DUCTIONARY, Ex. H to Thompson Dec. (defining "plenum" as an "air flow passage made of duct board, metal, drywall, or wood" that "joins supply and return ducts . . .").
with HVAC equipment"; see also WordNet 1.6 (1997), available at http://dictionary.reference.com/search?q=plenum (defining "plenum" as "an enclosed space in which the air pressure is higher than outside"). This definition is consistent with the use of the term in Claim 15. However, the claim language includes one limitation -- that cooled air be able to travel through the air plenum to an adjacent rack-receiving chamber. Thus, the definition of the term "air plenum" in Claim 15 of the '569 Patent must include this limitation.

The meaning of "partition" in Claim 15 is an interior wall that forms an air plenum on one side and a rack-receiving chamber on the other. The ordinary meaning of "partition" is "an interior wall dividing one part of a structure (as a house, room, or enclosure) from another." Webster's Third New Int'l Dictionary of the English Language Unabridged at 1647 (2002), Ex. N to Thompson Dec. This meaning is consistent with the use of the term "partition" in the patent, specification, and prosecution history. However, Claim 15 further specifies that the "partition" must "define" the space inside the interior chamber into an air plenum on one side and a rack-receiving chamber on the other side. Thus, it is necessary to construe the term "define" (or "defining") as well.

In this case, the Court must look first to the patent specification because it assigns a particular meaning to the term "defining" in Claim 15. The specification states that the air plenum is "formed" by the rear wall and the partition, 13 see '569 Patent at column 4, lines 53-54, thereby using "formed" as a synonym for the term "defined" in Claim 15. This definition, with slight variations, is found in many dictionaries. See, e.g., The American Heritage Dictionary of the English Language (4th ed. 2000), Ex. A to 3/5/03 Third Declaration of Roger Thompson ("Thompson Third Dec.") (indicating that one meaning of the term "define" is "to delineate the outline or form of"); Random House College Dictionary at 348 (rev. ed. 1975), Ex. A to Thompson Third Dec. (stating that one meaning of the term "define" is "to make clear the outline of form of"). Thus, in order to infringe Claim 15, the partition must "form" an air plenum on one side and a rack-receiving chamber on the other.

13 If the air plenum is "formed" by the partition, then the rack-receiving chamber must also be "formed" by the partition because the claim recites that the partition "defines" both the air plenum and the rack-receiving chamber.

14 Although the diagram in the patent shows the partition extending from one side wall of the merchandiser to the opposite side, nothing in the patent, specification, or prosecution history suggests that the partition must extend from one side wall of the merchandiser to the opposite side wall. Likewise, the existence of vent holes in the partition is a preferred embodiment, not a requirement. See '569 Patent at column 4, lines 34-36 ("The merchandiser may include ventilation openings, such as lower vent holes and upper vent holes in the . . . partition."). Thus, contrary to TPI's suggestions, see Def. Mem. at 11-13, these limitations are merely preferences, which cannot be read into the claim.

2862 Parts

Defendants argue this term should be construed to mean "sub-components of equipment." Orion contends "parts" does not require construction, and the Court agrees. Defendants have not demonstrated that this term is used in a manner inconsistent with its ordinary lay meaning. Further, Defendants' construction overly complicates the term. "In the preferred embodiment, the types of parts under the cross-referencing/parts selection procedure include batteries, filters, remanufactured electric parts, lubrication and bearings." Col. 9:4-8. While a lay jury would likely consider batteries or lubrication to be "parts," it is less certain that they would consider them to be "sub-components of equipment.

2863 A. Apparatus Claim 17
Although a threaded configuration is shown for the second section, other non-smooth geometries may be used to remove geometries and a conical shape:

1576-77 (Fed. Cir. 1996). Here, the written description states that the structure for the passage includes non-smooth necessary, extrinsic evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1580 (Fed. Cir. 1996). In construing a claim limitation, we look to the claim language, the written description, the prosecution history and, if necessary, extrinsic evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996). Here, the written description states that the structure for the passage includes non-smooth geometries and a conical shape:

Although a threaded configuration is shown for the second section, other non-smooth geometries may be used to remove
water vapor and cause that water vapor to be trapped in the second section of the bore. For example, a series of ridges may be included in the interior surface of the second section. Alternatively, the second section of the bore may be conical in configuration. As with the threaded or ridged configuration, the conical shape causes a swirling effect on the water vapor to remove that vapor from the analyte slug.

'557 patent, col. 7, lines 13-22 (emphasis added). The written description also distinguishes over prior art geometries as follows:

A number of different geometries for the second section are contemplated, including those having an irregular shaped surface or noncylindrical shape. In contrast, the prior art has generally specified that the pneumatic tubing and passageways between the trap and GC are smooth-walled.

'557 patent, col. 7, lines 45-50 (emphasis added).

All of the "passage" structures contemplated by the written description are thus either non-smooth or conical. In addition, the description expressly distinguishes over prior art passages by stating that those passages are generally smooth-walled. OI has not identified anything in the prosecution history contrary to those statements. Therefore, we conclude that one skilled in the art reading the claims, description, and prosecution history would conclude that the term "passage" in claim 17 does not encompass a smooth-walled, completely cylindrical structure. Because the description adequately explains the meaning of "passage" as used in this patent, we need not consider extrinsic evidence. See Vitronics, 90 F.3d at 1582-83, 39 U.S.P.Q.2d (BNA) at 1577. It is undisputed that the accused device contains a smooth-walled, completely cylindrical passage. Thus, even though the district court erred in construing the claim term "passage" to be subject to the interpretation required by section 112, P 6, it did not err in concluding that there is no genuine issue of material fact that the accused device does not meet the terms of claim 17 of the '380 patent and that Tekmar is entitled to a judgment as a matter of law that it does not infringe that claim. The court's error thus was harmless. See Fed. R. Civ. P. 61.

OI argues nonetheless that construing the word "passage" to exclude smooth-walled geometries violates the doctrine of claim differentiation, noting that dependent claims further limit the meaning of the word "passage" to a structure that produces swirling or spiraling of the analyte slug. OI argues that the independent claim, being broader in scope than the claim that depends from it, should not be limited to structures that swirl the analyte slug. We do not agree. Although the doctrine of claim differentiation may at times be controlling, construction of claims is not based solely upon the language of other claims; the doctrine cannot alter a definition that is otherwise clear from the claim language, description, and prosecution history. See Hormone Research Found., Inc. v. Genentech, Inc., 904 F.2d 1558, 1567 n.15, 15 U.S.P.Q.2d (BNA) 1039, 1047 n.15 (Fed. Cir. 1990) (stating that the doctrine of claim differentiation "cannot overshadow the express and contrary intentions of the patent draftsman"). We conclude that the description provides a clear meaning for the language of the claim in this case and that it trumps the doctrine of claim differentiation.

B. Method Claim 9

We next address method claim 9 of the '557 patent. OI argues that the district court erred in applying section 112, P 6, to the asserted method claims. In particular, it argues that the court erred in relying upon the broad recital of a purpose in a claim preamble as a function that requires application of section 112, P 6, to a series of process steps. It asserts that section 112, P 6, only applies to steps having an individually associated function, and to steps without recited acts in support thereof. Tekmar responds that the "passing" clauses of claim 9 of the '557 patent are step-plus-function clauses subject to the limitations of section 112, P 6, and that, when so construed, the claims are not infringed.

We first address the application of section 112, P 6, generally to method claims. Appellant asserts, as have other parties, that we have not done so previously. Section 112, P 6, provides that:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112, P 6 (1994) (emphasis added). This statutory provision clearly applies to claims for a combination. It is well-established of course that, in combinations that are apparatus claims, means for performing a specified function are
subject to this paragraph when they lack recital of definite structure or material. Logically, structure and material make up
the various means of apparatus. However, "the word 'combination' in this paragraph includes 'not only a combination of
mechanical elements, but also a combination of substances in a composition claim, or steps in a process claim." In re
186 (Mar. 1993)) (emphasis added).

The statute of course uses terms that might be viewed as having a similar meaning, namely, steps and acts. It refers to means
and steps, which must be supported by structure, material, or acts. It does not state which goes with which. The word
"means" clearly refers to the generic description of an apparatus element, and the implementation of such a concept is
obviously by structure or material. We interpret the term "steps" to refer to the generic description of elements of a process,
and the term "acts" to refer to the implementation of such steps. This interpretation is consistent with the established
correlation between means and structure. In this paragraph, structure and material go with means, acts go with steps. Of
course, as we have indicated, section 112, P 6, is implicated only when means plus function without definite structure are
present, and that is similarly true with respect to steps, that the paragraph is implicated only when steps plus function
without acts are present. The statute thus in effect provides that an element in a combination method or process claim may
be recited as a step for performing a specified function without the recital of acts in support of the function. Being drafted
with the permissive "may," the statute does not require that steps in a method claim be drafted in step-plus-function form but
rather allows for that form.

Here, the language in question is "the steps of . . . passing the analyte slug through a passage." The district court considered
the statement which appears in the preamble, "removing water vapor from an analyte slug," as a function which invokes
application of section 112, P 6. We do not agree. The preamble statement of the purpose of the overall process does not
constitute an associated function for the two "passing" steps of claim 9. Performing a series of steps inherently produces a
result, in this case the removal of water vapor from the analyte slug, but a statement in a preamble of a result that
necessarily follows from performing a series of steps does not convert each of those steps into step-plus-function clauses.
The steps of "passing" are not individually associated in the claim with functions performed by the steps of passing.

Section 112, P 6, as is well-documented, was intended to permit use of means expressions without recitation of all the possible
means that might be used in a claimed apparatus. See Federico, supra, at 25 (stating that the statute authorizes
greater liberality in the use of functional expressions in combination claims than had been permitted by some court
decisions such as Halliburton Oil Well Cementing Co. v. Walker, 329 U.S. 1, 91 L. Ed. 3, 67 S. Ct. 6 (1946)). The price that
must be paid for use of that convenience is limitation of the claim to the means specified in the written description and
equivalents thereof. Similarly, a step for accomplishing a particular function in a process claim may also be claimed without
specificity subject to the same price. But claiming a step by itself, or even a series of steps, does not implicate section 112, P
6. Merely claiming a step without recital of a function is not analogous to a means plus a function. We note that the
Halliburton case concerned an apparatus claim, not a process claim, and we must be careful not to extend the language of
this provision to situations not contemplated by Congress. If we were to construe every process claim containing steps
described by an "ing" verb, such as passing, heating, reacting, transferring, etc. into a step-plus-function limitation, we
would be limiting process claims in a manner never intended by Congress. Accordingly, we conclude that the "passing"
limitations of claim 9 are not step-plus-function limitations subject to the requirements of section 112, P 6.

Tekmar argues that, because the method claims "parallel" the apparatus claims, they must be construed consistently with the
apparatus claims. Assuming that the limitations of the apparatus claim are subject to the limitations of section 112, P 6,
Tekmar thus reasons that the steps of the method claim must likewise be subject to those limitations. Moreover, it argues
that OI made no distinction between the method and apparatus claims during the prosecution of the patents and that,
accordingly, they must be construed consistently with each other. We understand that the steps in the method claim are
essentially in the same language as the limitations in the apparatus claim, albeit without the "means for" qualification.
However, even if we were to hold that the word "passage" in the apparatus claims meets the section 112, P 6, tests, we
would not agree with Tekmar that the "parallelism" of the claims means that the method claims should be subject to the
requirements of section 112, P 6. Each claim must be independently reviewed in order to determine if it is subject to the
requirements of section 112, P 6. Interpretation of claims would be confusing indeed if claims that are not means- or step-
plus-function claims were to be interpreted as if they were, only because they use language similar to that used in other
claims that are subject to this provision. As discussed above, the method claim is not drafted in step-plus-function form and
is thus not subject to this provision.
We will therefore construe the meaning of the word "passage" in claim 9, freed from the strictures of section 112, P 6. OI argues that the word "passage" should be given its ordinary and accustomed meaning and that the district court erred in limiting the passage to its preferred embodiment. We do not agree. The textual language describing the passages in the '380 written description are also present in the '557 patent. Therefore, for the reasons explained above, we conclude that the word "passage" in claim 9 does not encompass a completely cylindrical, smooth-walled structure. There is no dispute that the accused device contains such a structure. Tekmar is therefore entitled to a judgment as a matter of law that it does not infringe claim 9. Although the district court erred in concluding that the method claims are subject to the requirements of section 112, P 6, it did not err in concluding that the accused device did not contain a passage as required by those claims. The district court's error thus was harmless. See Fed. R. Civ. P. 61.

CONCLUSION

The word "passage" in the asserted claims, properly construed, does not encompass a completely cylindrical, smooth-walled structure. There is no genuine issue of material fact concerning whether the accused device contains such a passage, and Tekmar thus is entitled to judgment as a matter of law that it does not infringe the asserted claims. Accordingly, the district court's judgment is affirmed.

iii. "Passageway"

180s construes "passageway" as "a long, narrow way, typically having walls on either side, that allows access." (180s seemed to abandon its request for "long" and "narrow" at oral arguments.) Gordini defines "passageway" as "a loop, like a belt loop, having a perimeter fully enclosing an opening and is topologically genus one."

I construe "passageway" as a "way, typically having barriers at least on either side, that allows access." This parallels 180s' proposed construction, with two exceptions. First, "at least" is added to clarify that a "passageway" may have barriers on more than just two sides. For example, the "passageway" in Figure 17 has, in addition to barriers on two walls, a barrier on what looks like, depending on how the ear warmer is positioned, the roof. Figure 17, therefore, has barriers on three sides of the "passageway." Second, "narrow" and "long" are omitted because the passageways referenced in the specification are neither "long" nor "narrow." (See, e.g., id., Ex. A at col. 7, ll. 57-60.) Nor am I convinced, despite some dictionary evidence to the contrary, that "long" and "narrow" are a part of the ordinary meaning of "passageway." Regardless, the meaning supported by the specification--that a "passageway" need not be "long" or "narrow" (although it may be)--trumps any extrinsic dictionary definition. (See Def.'s Mem. at 7-8 (citing Phillips, 415 F.3d at 1317).)

Gordini's assertion that a "passageway" must be "fully enclosed" is contrary to the plain meaning of "passageway," and Gordini does not present any evidence that "passageway" is understood differently to someone of skill in the art. Although the specification only refers to figures showing "passageways" that are in fact fully enclosed (see Pls.' Mem., Ex. A at col. 7, ll. 57-60, Fig. 17), "a court should not read a limitation from the specification into the claim." See Tate, 185 F. Supp. 2d at 595. "Similarly, the mere fact that the patent drawings depict a particular embodiment of the patent does not operate to limit the claims to that specific configuration," Anchor Wall Sys., 340 F.3d at 1306-07. Further, the '483 patent noted its relation to the application for U.S. Patent No. 6,502,248 ("'248 patent") (Pls.' Mem., Ex. A at col. 1, ll. 10-12.), and the '248 patent includes an illustrative figure showing a passageway that is not "fully enclosed" on all four sides. (Id., Ex. H at col. 8, ll. 50, Fig. 14.) All of these points highlight the fact that a passageway may be fully enclosed, but it need not be. If 180s intended to for "passageway" to mean a "fully enclosed passageway," the claim should have read "fully enclosed passageway" or "tunnel."

2865

2. Passageway
The intrinsic record reveals that the term "passageway" was never used in the '130 application by itself. Instead, the foundational term that is found in the summary of the invention and in numerous claims is "central passageway." See '130 application summary at 7 and claim 1 at 35 ("a housing which defines a central passageway having fluid inlet and fluid outlet openings"). The patents that followed contain the additional term "internal passageway" along with "central passageway." See '609 patent summary 4:2-4 ("a housing which defines a central passageway having fluid inlet and fluid outlet openings"); '958 patent claim 1 at 17:62-64 ("a housing defining an internal passageway having a gas inlet opening near an upstream end of said housing, and a gas outlet opening spaced from said gas inlet opening"); see also '674 patent claim 13 at 27:31-35.

Two Forty acknowledges that there is different terminology used in the patents such as "central passageway" and "internal passageway." Two Forty proposes that the Court define "passageway" by itself, as it is the structural element, and any adjective placed before it can be dealt with by the jury. The jury, for example, can plug in the definition of "passageway" regardless of whether it is preceded by "internal" or "central." The Court agrees, and therefore, will only define the major structural portion.

Aqua-Lung proposes that "passageway" be defined as "a conduit formed in the housing that leads gas through the housing and which is filled with pressurized gas when the housing is connected to a source of gas." Two Forty proposes that it be construed as "a path in the device."

Aqua-Lung's proposed definition attempts to add in extraneous limitations, which are found nowhere in the representative claims set forth above or the illustrative embodiments. Neither the identified claim language nor any of the claims appear to include any limitation regarding the "passageway" being filled with pressurized gas, or the passageway leading gas through the housing. The intrinsic record reveals that the conduit is a fixed thing, which cannot actively lead anything. That is, it is a fixed structure and gas may or may not flow through it. Said another way, the claim is directed at a defined structure, and not any contents that may or may not be in the passageway at any given time. Any resulting construction, therefore, cannot include any extraneous portion of Aqua-Lung's proposed definition detailing: (1) any leading of "gas through the housing"; and (2) the conduit being "filled with pressurized gas when the housing is connected to a source of gas."

This leaves the Court with Two Forty's self-styled simplistic proposed definition and the first portion of Aqua-Lung's proposed definition of the term "passageway." In some cases, the ordinary meaning of a claim by one of ordinary skill in the art may be readily apparent even to lay judges. Phillips, 415 F.3d at 1314. In such a case, claim construction involves nothing more than the application of the widely accepted meaning of the commonly understood words through the use of a general purpose dictionary used in conjunction with the intrinsic evidence. Id. In Brown v. 3M, 265 F.3d 1349, 1352 (Fed. Cir. 2001), for example, the word "or" was construed to mean that the apparatus was capable of converting "only two-digit, only three-digit, only four-digit, or any combination of two-, three-, and four-digit date-data." The Federal Circuit held that was a correct plain reading of the claim text and it did not constitute a technical term of art requiring elaborate interpretation. Id.

At the hearing, Two Forty acknowledged that its proposed definition, while comporting with the plain meaning of a simple term, might be overbroad. Accordingly, they proposed a modified definition of "passageway" as "a conduit formed in the housing that allows gas through it." This definition incorporates the remaining first part of Aqua-Lung's proposed definition and excludes the extraneous second part described above. In light of this amended definition, and based on the foregoing, the Court adopts Two Forty's amended construction of "passageway" as "a conduit formed in the housing that allows gas to pass through it."

C. "Passing an amount . . . in excess of that necessary to saturate the wash load"

In the second step recited of Claim 13 the parties also dispute the meaning of the term "passing an amount . . . in excess of that necessary to saturate the wash load." Whirlpool contends that if this term has to be construed at all, it should be construed as "an amount that is just more than that which is needed to saturate the wash load." Defendants contend that it should be construed to require that "the total amount of wash liquid continuously passing through the clothes, exceeds the amount of liquid required to saturate the clothes." According to Whirlpool, Defendants' insertion of the word "continuously"
has no basis in the claim term or anywhere in the intrinsic evidence, and its insertion causes a fundamental and improper change to the claim term.

The patent specification describes the quantity of detergent solution as follows:

> It has been found that an amount of detergent solution only slightly in excess of that required to saturate the clothes load is sufficient for the concentrated washing operation.

'666 Patent, col. 2 ll. 34-37 (emphasis added).

The concentrated detergent solution is preferably a volume which is slightly in excess of the saturation level for the clothes load. For the purposes of this specification, saturation is defined as the point at which a load of clothes contains all the liquid it can hold. Adding additional liquid at this point merely causes a like amount of liquid to be discharged from the load.

'666 Patent, col. 5 ll. 49-55 (emphasis added).

Defendants contend that their addition of the concept of "continuously" passing through to the construction of the term comes from the prosecution history, and that it was a limitation agreed to by Whirlpool in order to gain allowance of the claim.

The Examiner's Interview Summary record reveals that the attorney "proposes to amend the claims to include "continuously passing a concentrated detergent solution so that the total amount passed through would be greater than the amount necessary to saturate the wash load." Def. Ex. L., LGE 257 (emphasis added). Thereafter, on April 11, 1988, Whirlpool filed Amendment "B," in which it summarized the agreement reached during the interview with the Examiner as follows:

> It was agreed that if each of the claims were clarified, where necessary, to specify the method feature capturing the essence of "continuously passing a concentrated detergent solution so that the total amount passed through would be greater than the amount necessary to saturate the wash load", then the claims would be allowable and the case would be in condition for allowance.

Def. Ex. L, Amendment "B" at 4, LGE 266 (emphasis added). Whirlpool then represented that it had amended the claims "to more clearly set forth the specifics of the step just identified along the lines agreed to during the interview." Def. Ex. L., Amendment "B" at 4, LGE 266.

In construing this term Whirlpool has relied solely on the specifications and dictionary definitions. Whirlpool has not responded to Defendants' citation to the discussion of "continuously" in the prosecution history. It is not clear to the Court what the insertion of this limitation adds to the meaning of the claim, but the Court cannot ignore what appears to be a concession in the prosecution history. Having agreed to one meaning during the prosecution of the patent, Whirlpool cannot now avoid this concession. See Lemelson v. General Mills, Inc., 968 F.2d 1202, 1208 (Fed. Cir. 1992). Accordingly, the Court will construe the term "passing an amount . . . in excess of that necessary to saturate the wash load" consistent with the prosecution history as "continuously passing a concentrated detergent solution so that the total amount passed through would be greater than the amount necessary to saturate the wash load."
of the pulley. Pulleys, by virtue of their function, have a certain direction; if the cables are pointed upward, the tension is going up, and the cable is “over” the pulley even if, from an earth-centered perspective, the cable is “under” the pulley. In other words, the cable is "over" the pulley relative to whether the tension is going upward or downward.

Having thus construed the claim, there is no question that this limitation reads on the accused product. The WeiderPro 9930 includes first and second cables that "pass over" their respective floating pulleys.

Step 5. Micro-Waste contends that step 5, “passing particulate articles from said microwave field to a temperature maintenance zone,” must be construed as a passing of said articles between two distinct physical areas.

A "field" is "a region or space in which a given effect (as magnetism) exists ...." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY 460. Thus, a microwave field, according to its ordinary meaning, is an area in which there is microwave radiation.

A "zone" is "a region or area set off as distinct from surrounding or adjoining parts ...." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY 1372. Thus, the temperature maintenance zone, according to its ordinary meaning, is a distinct area in which the temperature is maintained.

It is erroneous to adopt a construction "that ... eliminates the distinction between ... terms that is set forth in the written description of the patent itself." AFG Indus., Inc. v. Cardinal IG Co., 239 F.3d 1239, 1249 (Fed. Cir. 2001).

The distinction in the terms, "field" and "zone" implies that the microwave irradiation and maintenance of temperature occur in two distinct areas.

The Court construes Step 5 as the passing of the particulate articles from one area where microwave radiation exists to another area described as "the temperature maintenance zone."

The court adopts Rexam's proposed construction as modified, below.

Claim 13 of the '230 patent recites: "a curvilinear anti-fracture score formed in the frangible panel generally parallel to said score groove, said anti-fracture score having a tail portion passing through the hinge segment."
Claim 7 of the ’728 patent recites: "[t]he end member of claim 1, wherein, at least a portion of the second score groove passes through the hinge line generally transverse to a hinge line passing between the first end and second end of the primary score groove." 120

Here, the claim language does not clearly define what the inventors meant by "passing through." Examining the specification, Crown argues that the patent illustrates four embodiments depicting the anti-fracture, or second, score groove: figures 2, 4, 6, and 7. Crown maintains that figures 2, 4 and 7, each illustrate the second score "passing through the hinge segment 26 from one end to the other." 121 Crown then cites the specification's description of figure 4 wherein the can end "includes a score gro[o]ve 62 that passes through the hinge segment 26." 122 Crown acknowledges that the embodiment shown in figure 6 "appears to penetrate into but does not pass through the hinge segment 26," but contrasts the description of figure 6 with that of figure 4. 123 Figure 6, Crown points out, is described differently: "[i]n the alternative embodiment of FIG. 6, the tail portion 25 terminates in the end wall 12 beyond the score 22, and at least slightly transecting the line defining the hinge segment 26." 124 Crown argues that this difference in language indicates that in the embodiment illustrated in figure 6, the second score does not "pass through" the hinge segment and that "there is no reason why a claim term should be construed to encompass every embodiment described in the patent . . . ." 125 Crown also cites a dictionary definition of "through" which purportedly supports its position. The court is not convinced by Crown's arguments.

First, although Crown accurately cites the specification's description relating to figures 4 and 6, the contrasts in those descriptions do not compel acceptance of Crown's proposed construction.

Describing figure 2, the specification states that "the anti-fracture score 24 has a tail portion 25 that intersects the hinge segment 26." 126 The specification describes the preferred embodiment as having a "the tail portion 25 that transects the line defining the hinge segment 26." 127 The inventors used various words (e.g., "intersects," "transects," "at least lightly transects," and "passes through") in describing various embodiments of the claimed invention and, arguably, a differing extent to which the anti-fracture score enters or crosses the hinge segment. The disputed phrase "passes through" in these claims encompasses penetrating into as proposed by Rexam and, as so construed, does not exclude an embodiment described in the specification.
Furthermore, when the inventors intended to claim a second score line "pass[ing] through the entire hinge, not merely penetrate into a portion of the hinge," as Crown argues, 128 they were specific in their intent, as with claim 1 of the '230 patent: "a second score groove having a tail portion passing from the frangible panel into said adjacent area of the central panel and transecting said hinge segment." 129 Finally, although not relied upon in construing these terms, the court notes that both parties cited dictionary definitions of the word "through" which would not require acceptance of Crown's proposed construction. Each cited a definition that included "penetration or passage within, along or across an object." 130

Therefore, the court adopts a modified version of Rexam's proposed construction: "at least penetrating into." 131

It is not clear whether any part of this claim language is in dispute. Perouse provided constructions of "cord," "holds," and "edges" in its opening brief. (Perouse Opening Br. 32-33.) Gore did not address this claim language in either its opening or reply brief. However, in the proposed order accompanying its reply brief, Gore construed this phrase to mean "a single cord extends through a conduit formed by all of the 'gussets' and holds the opposing edges of the housing part in contact with one another." (Gore Proposed Order 3.). Neither party addressed this claim language during the Markman hearing.

There appears to be no dispute regarding the claim terms "cord" and "edges." Therefore, the Court will not construe these terms.
Finally, Gore's proposed construction apparently construes "holds said edges together" to require that the opposing edges of the housing part contact one another. Figure 8 depicts the two edges of the housing part in contact with one another. Again, however, this is a limitation from the specification that should not be imported into the claim. See Phillips, 415 F.3d at 1323. Furthermore, this limitation is not consistent with the ordinary meaning of the non-technical term, "holds together," and is rejected. "Holds said edges together," in ordinary usage, means "holds said edges near or in contact with one another." See, e.g., The Oxford English Dictionary (2d Ed.), vol.18 p. 189 ("Of two persons or things: Into companionship, union, proximity, contact, or collision"). Nothing in the intrinsic evidence warrants departure from this ordinary meaning.

The Court construes the phrase "said cord passing through each of said gussets along each of said edges such that said cord holds said edges together" to mean "said cord extending through each of said gussets along each of said edges such that said cord holds said edges near or in contact with one another."

2871

1. "a patient support assembly"

The parties' dispute of the construction of this claim element focuses on what "a patient support assembly" includes.

Safe Bed:

"A patient support assembly" is a conventional mattress or other assembly for supporting a patient directly or indirectly. (Safe Bed's Memorandum in Support of its Claim Construction ("Safe Bed's Mem."), at 7).

KCI:

"A patient support assembly" must include at least one conventional mattress and an underlying patient support frame. (KCI's Memorandum in Support of its Claim Construction ("KCI's Mem."), at 6).

While the parties disagree over the construction of this claim element, both sides support their proposed construction by reference to the same language in the patent specification. (Safe Bed's Mem., at 7; KCI's Mem., at 7). The pertinent portion of the specification reads:

Supported by the frame 10 is a patient support assembly 12 including one or more conventional mattresses 12A, possibly, an optional overlying pressurizable member 12A' and an underlying patient support frame 12B. ('939 patent, 5:15-18). While Safe Bed submits that "a patient support assembly" could be interpreted as nothing more than "one conventional mattress," KCI argues that the use of the word "assembly" dictates that the term require more. According to KCI, it must, at a minimum, include not only one conventional mattress, but an underlying patient support frame as well. The Court agrees with KCI's construction of this claim.

Claim interpretation begins with the ordinary and customary meaning of the words. "Assembly" is defined as "a collection of parts [fit together] as to form a complete machine, structure, or unit." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY, at 131 (1986). 1 From this standpoint, then, a "patient support assembly" cannot be a single item, such as one conventional mattress, but must be a collection of more than one part. To accept Safe Bed's interpretation that the "patient support assembly" could be one mattress or other assembly would render the term "assembly" superfluous, which would violate a cannon of patent claim construction. Elekta Instrument S.A. v. O.U.R. Scientific Intern., Inc., 214 F.3d 1302, 1307 (Fed. Cir. 2000) (rejecting claim interpretation that would term superfluous).

--- Footnotes ---

1 Throughout its submissions in this case, Safe Bed repeatedly faults KCI for relying on a dictionary published in 1993, two years after the March 12, 1991 issue of the '939 patent. (Safe Bed's Reply Memorandum on Claim Construction Issues, at 2). Because it is true that the court should consult a dictionary that was "publicly available at the time the patent is issued" to determine the ordinary and customary meaning of a disputed term, Telegenix, Inc., 308 F.3d at 1202-03, the court employs a dictionary that predates the issue of the '939 patent. Nevertheless, the passage of a few years has not had the dramatic effect on the language that Safe Bed suspects.
Safe Bed also argues that the specification cannot be grammatically read in the manner KCI suggests. According to Safe Bed:

the plain English meaning of the quoted specification language is that a patient support assembly is comprised of one or more conventional mattresses. The sentence continues that the patient support assembly could "possibly" include an optional overlying pressurizable member and an underlying patient support frame. . . . This refers to the pressurizable member and an underlying support frame as optional, not required elements.

(Safe Bed's Reply Memorandum on Claim Construction Issues ("Safe Bed's Reply"), at 4). To the contrary, the sentence construction suggests that only "overlying pressurizable member" is modified by "an optional." The support assembly is said to include, "possibly, an optional overlying pressurizable member and an underlying patient support frame" as opposed to "possibly, an optional overlying pressurizable member and underlying patient support frame." The second version would more readily indicate both were optional, but that is not the version in the specification. To be sure, the specification language evinces a battle with grammar, but it is more amenable to KCI's interpretation than to Safe Bed's.

Safe Bed also points out that claim 52, which is dependent on claim 50, specifies that "said patient support assembly has an articulated frame mounted for adjustable movement." (Safe Bed's Reply, at 6 (quoting ’939 patent, 20:12-14)). According to Safe Bed, KCI's claim construction would import the "articulated frame" of claim 52 into claim 50, thus violating the doctrine of claim differentiation. (Safe Bed's Reply, at 6). While not a hard and fast rule of claim construction, the doctrine of claim differentiation does create a presumption that each claim in a patent has a different scope. Sunrace Roots Enterprise Co., Ltd. v. SRAM Corp., 336 F.3d 1298, 1302 (Fed. Cir. 2003). That presumption is especially strong when the limitation in dispute is the only meaningful difference between an independent and dependent claim, and one party is urging that the limitation in the dependent claim should be read into the independent claim. Ecolab Inc. v. Paraclipse, Inc., 285 F.3d 1362, 1375 (Fed. Cir. 2002). This is not the case here, however. KCI is not arguing that the limitation of an articulated frame be read into claim 50, but merely an underlying support frame. The two phrases are not identical. The term "articulated" adds a meaningful difference between claim 50 and dependent claim 52: the difference between an ordinary frame and one "consisting of segments united by joints." WEBSTER'S, at 124. The specification, for example, indicates that a patient support frame might be mounted to the hospital bed frame in one fashion, while an articulated frame -- which would have interconnected segments -- would be mounted in another. (’939 patent, 5:19-24). Accordingly, the Court construes "patient support assembly" to include at least one conventional mattress and an underlying patient support frame.

Tanita's first argument is that in order to infringe on the '163 or '000 patents, the accused device must measure patients in a prone position. Tanita points to various statements throughout the specification that the patient must be prone and asks this court to construe the term "patient's body" in the claim to mean "patient's prone body." Tanita then argues that because none of its devices measure a patient in a prone position, it does not infringe on either of the patents-in-suit. Healthport argues that the statements relied upon by Tanita come from the preferred embodiment and other portions of the specification, and that it is improper to read a limitation from the preferred embodiment or specification onto the claim.

Neither of the patents-in-suit use the term "prone" in their claims. Both of the patents-in-suit do, however, specifically state in the section titled "Test Procedure" that the patient must be measured prone: "Position the patient prone on a non-conductive surfaced table. . . . The patient must be prone to minimize interference from muscle contractions. (Antagonist muscle contractions in standing or sitting patients create inaccurate Impedance results.)" The instruction to place the patient prone also appears in the sections titled "Operation" and "Operation Checklist."

The general rule in patent law is that the specification may aid in claim interpretation but particular limitations or embodiments appearing in the specification will not be read into the claims. E.I. DuPont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988). Tanita, however, directs the court to a line of cases, beginning with
In SciMed, the asserted patent claimed a catheter with two passageways, or "lumens." 242 F.3d at 1339. Although the claims did not on their face specify that the two lumens were coaxial (one inside of the other), the trial court found the discussion in the specification criticizing catheters with dual (side by side) lumens to control. The court held that the claims were limited to coaxial lumens and could not be construed to cover dual lumens. The Federal Circuit affirmed. In its opinion, the Federal Circuit court addressed the argument that the trial court had committed one of the "cardinal sins of patent law -- reading a limitation from the written description into the claims." Id. at 1340. The court explained that the district court properly read the claims in view of the specification, of which they are a part. Id. The court noted that "one purpose for examining the specification is to determine if the patentee has limited the scope of the claims." 242 F.3d at 1341 (quoting Watts v. XL Sys., Inc., 232 F.3d 877, 882 (Fed. Cir. 2000)). The court continued, "[w]here the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." Id.

In AstraZeneca v. Mutual Pharmaceutical Company, Inc., 384 F.3d 1333 (Fed. Cir. 2004), the asserted patents claimed new pharmaceutical preparations related to extended-release felodipine tablets for use in treating hypertension. The claim construction dispute centered around the term "solubilizer." The parties agreed that an ordinary and customary meaning as understood by one of ordinary skill in the art of the term solubilizer would include surface active agents, known as surfactants, co-solvents, and complexation agents. The defendant argued, however, that in the context of the specification and prosecution history, the term solubilizer encompasses only surfactants. The Federal Circuit agreed, holding that "the intrinsic evidence . . . clearly binds AstraZeneca to a narrower definition of 'solubilizer' than the extrinsic evidence would support." Id. at 1338. The court based it's holding on, inter alia, the fact that the specification clearly disavowed nonsurfactant solubilizers in two ways. Id. at 1340-41. First, the inventors implicitly disavowed nonsurfactant solubilizers by stating in the specification that "[t]he solubilizers suitable according to the invention are defined below," and then two paragraphs later, stating "[t]he solubilizers suitable for the preparations according to the invention are semi-solid or liquid non-ionic surface active agents" Id. at 1339; 1341 (emphasis in original). And second, the "Description of the Invention" described "micelle structures" as a feature of the invention and surfactants were the only solubilizers believed to form micelle structures in watery environments. Id. at 1341.

AstraZeneca argued that those statements simply addressed features of the preferred embodiments and should not be read to limit the claims. The court disagreed, stating,

AstraZeneca seems to suggest that clear disavowal requires an 'expression of manifest exclusion or restriction' in the form of 'my invention does not include . .' But again, such rigid formalism is not required: Where the general summary or description of the invention describes a feature of the invention (here, micelles formed by the solubilizer) and criticizes other products (here, other solubilizers, including co-solvents) that lack that same feature, this operates as a clear disavowal of these other products (and processes using these products).

Id. at 1341 (citing SciMed, 242 F.3d at 1340-45).

In Phillips, the Federal Circuit's most recent seminal case on claim construction, the court affirmed the importance of the specification in construing patents:

The claims, of course, do not stand alone. Rather, they are part of "a fully integrated written instrument," Markman, 52 F.3d at 978, consisting principally of a specification that concludes with the claims. For that reason, claims "must be read in view of the specification, of which they are a part." Id. at 979. As we stated in Vitronics, the specification "is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." 90 F.3d at 1582.
Here, the patents-in-suit emphasize that the key aspect of the "present invention" is to generate more accurate, valid measurements of human body composition. As a result, the public is on notice that any statements in the patents concerning how that invention achieves accurate results limit the scope of the claims. See e.g. Aguayo v. Universal Instruments Corp., 356 F. Supp. 2d 699, 727 (S.D. Tex. 2005) (Where the "specification calls an embodiment the 'invention' or the 'present invention,' it is appropriate to limit the claims to that embodiment.") (citations omitted). The patents-in-suit then go on to specify that the "patient must be prone to minimize interference from muscle contractions," and warn that the device will not measure accurately if the patient is standing or sitting. I find that the specification expressly disavows measurements taken of a standing or sitting patient, and that limitation must be read onto the claim. Accordingly, I construe the term "patient's body" in the claims of the patents-in-suit to mean "patient's prone body."

This case is slightly different from SciMed in that SciMed addressed what the invention itself looked like and this case involves how the invention is applied. Nonetheless, I find that the language in the patents-in-suit discussed above constitutes a sufficient disavowal such that it falls under the umbrella of SciMed and its progeny.

A. Pattern

A variable color display device includes a plurality of variable color display areas arranged in a pattern.

Plaintiff, Texas Digital Systems, Inc., alleges that the proper interpretation of the word pattern encompasses not only a seven segment display and matrix array, but any type of systematic arrangement of pixels. The Defendant alleges that the term pattern is limited to the seven segment font. The starting point for any claim construction must be the claims themselves. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999). Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed. Cir. 1984). In looking at the strict words of the claim, the claim states as follows:

In the patent language description of the prior art, Havel states in his 619 Patent:

A display device that can change color and selectively exhibit characters as described in my U.S. Patent No. 4,086,514 entitled "Variable Color Display Device" and issued on April 25, 1978. This display device includes display areas arranged in a suitable display font, such as well-known seven segment font, which may be selectively energized in groups to exhibit all known characters.

This language specifically informs the public and a person of ordinary skill in the art, at the time of the filing of the patent application, this was not a limiting term, but rather an expansive term giving an example, as opposed to a limitation on the patent. Further, Mr. Cooper, who was admitted as a person of ordinary skill in the art at the time of the invention, has defined the word pattern in his testimony and in his chart exhibit, Exhibit 81, as having a systematic arrangement. The defendant in its argument relies upon the 514 Patent as well as the file wrapper on the 619 Patent. However, the reliance upon the examiner's refusal to accept original Claims One through Eight and Claims Nine through Fourteen is misplaced. The Court finds that pattern is defined as having a systematic arrangement.

E. "display areas arranged in a pattern"

The limitation "display areas arranged in a pattern" appears in the asserted claims of the '481 and '619 patents, as well as claim 4 of the '890 patent. The district court construed "pattern" to mean "having a systematic arrangement." Telegenix argues that this construction is too general, and the limitation should be limited to a seven-segment display pattern, for
example, that shown in Figures 1a-c of the '890 patent. TDS responds that this limitation is not limited to a seven-segment display or any other fixed pattern, and that the scope of the claims is broad enough to encompass a matrix display.

Where "pattern" is described in the specifications of the patents in suit, the seven-segment display is listed as an example of the preferred font. The '481 patent specification describes "seven elongated display segments a, b, c, d, e, f, g, arranged in a conventional pattern." '481 patent, col. 2, ll. 24-25. The preferred embodiment of the '890 patent is described as including "a variable color display area consisting of seven segments 31 arranged in a well known 7-segment font." '890 patent, col. 2, ll. 16-18. Nowhere in the specification is the limitation "display areas arranged in a pattern" restricted, explicitly or implicitly, to the seven-segment arrangement of the preferred embodiment.

Telegenix does not dispute that the patents in suit describe the seven-segment pattern in exemplary language. Instead, Telegenix argues that U.S. Patent No. 4,086,514 ("'514 patent") establishes that the same inventor represented matrix displays and seven-segment displays as two separate embodiments of the same invention. We fail to understand the relevance of Telegenix's argument. Whether or not the claims in an unrelated patent are broad enough to encompass both a matrix and the familiar seven-segment pattern, this proposition sheds no light on whether the claims of the patents in suit are limited to the seven-segment pattern. See Abbott Labs. v. Dey, L.P., 287 F.3d 1097, 1104, 62 USPQ2d 1545, 1550 (Fed. Cir. 2002) (finding the relationship between two unrelated patents, although having common subject matter, a common inventor, and the same assignee, "insufficient to render particular arguments made during prosecution of [one of the patents] equally applicable to the claims of [the other patent]").

Referring to the prosecution history, the Examiner's Statement of Reasons for Allowance for the '619 patent stated, "In this manner, multicolored arrays (i.e., color cathode ray tube displays such as Takeda, of record) in which there is no physical distinction between a foreground or background pixel (display area), are distinguished from by the claimed subject matter." Although the prosecution history may help define the scope of a term if relevant, see Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 USPQ2d 1673, 1676 (Fed. Cir. 1995), this Examiner's statement has no bearing on the meaning of the term "pattern." Nor does this statement limit the scope of "pattern" to the familiar seven-segment font.

Accordingly, because there is nothing in the claims or the intrinsic evidence of record to indicate otherwise, we conclude that this limitation was correctly construed by the district court according to the ordinary meaning of "pattern." The district court's construction, "having a systematic arrangement," is not in error.

2. Pattern, Design, Logo or Other Marking

Even if Thilmany's coating is a recurring one, Thilmany asserts that its coating does not constitute a "pattern," much less a "design," "logo" or "other marking." These are terms, Thilmany argues, which suggest the coating must have some sort of visible effect, whereas Thilmany's coating is not intended to be seen, and in fact is essentially invisible. CEI argues that the coating need not have any visible decorative properties; it is enough that the varnish layer is "discontinuous;" in other words, the coating does not completely cover the film. CEI finds support for its position in the specification, which describes the coating as being in a "recurring pattern or design, such as a logo or other marking, rather than flood-coated over the entire surface of the film." (Id. col. 6, 58-61; col. 7, 7-9.) Similarly, it describes the invention being coated "with a varnish or other material in a recurring pattern, design, logo, or other marking (rather than flood-coated across the entire surface)." (Id., col. 7, 21-23.) Thus, the distinction CEI draws is between a fully coated surface and one where the surface is incompletely coated with a pattern or other marking.

The distinction also finds support in the prosecution history. The examiner had objected that the claims were obvious in light of a patent to Balloni. In response, CEI amended the claims and argued that:

Amended Claim 1 requires that the first or second layer of the solid film ream wrapper be coating [sic] in a recurring pattern, design, logo or other marking on one side with a material that alters that static COF by at least .02. Balloni does not coat the film in any manner and transfers the silicon oil to both layers of film. Therefore, amended claim 1 is not obvious over Balloni.
When the examiner ultimately accepted the amended claims, he noted: "[t]he applicants have … amended the claims to require a repeating pattern or image (i.e. discontinuous layer) wherein the pattern alters the COF measurement. … the coating in Balloni et al. was applied as a continuous coating and there is no obvious reason to apply it discontinuously (i.e. in the form of a pattern)." (Franzini Aff., Ex. G at 2) (italics added).

Thus, both the prosecution history and the patent itself support CEI's argument that the importance of the term is that it describes a discontinuous coating instead of a complete one. There is nothing in the evidence indicating that the coating must have a decorative effect in order to be a "pattern, design, logo, or other marking." Nothing in the specification suggests any additional usefulness arising from the fact that the pattern might be visible or have a decorative effect; in fact, the only advantage the patent mentions is that the coating will make the wrap less prone to slipping and easier to open. Neither of these advantages has anything to do with decoration. And, although the terms "logo" or "other marking" would imply that the coating must be visible, there is nothing so limiting about a pattern or design. To return to the earlier example, the dollar bill contains several designs or patterns that, for security reasons, are invisible to the untrained eye. Accordingly, I will decline to interpret the claim in the fashion Thilmany suggests.

The phrase "pattern, design, logo, or other marking" needs no further elaboration apart from the clarification that the coating need not be visible or have a decorative effect.

--- Footnotes ---

3 My ruling at this stage does not address the validity of the patent in suit. As Thilmany seems to anticipate, the potential for validity problems increases as the claims are construed more broadly.

--- End Footnotes ---

11. "Patterning the continuous layer of transparent conductive material" ('682 Patent, claims 22, 25, 26, 29) (Claim Element 10)

a. The Parties' Positions

The '682 and '711 Patents provide for a method of fabricating a liquid crystal display that involves arranging two different substrates. Claim 22 of the '682 Patent can be used as an example of this fabrication process. According to Claim 22 of the '682 Patent, the fabrication of a liquid crystal display is comprised of different steps. Specifically, this Claim provides as follows:

A method of fabricating a liquid crystal display, said method comprising the steps of:

providing a substantially transparent first substrate member;

disposing a layer of substantially opaque material upon one side of said first substrate;

forming at least one opening through said layer of substantially opaque material;

disposing a light influencing material in said at least one opening;

disposing a continuous layer of a transparent, passivating material atop said layer of opaque material and said light influencing material;

disposing a layer of transparent, conductive material atop said passivating layer;

providing a second substantially transparent substrate member having a continuous layer of a transparent conductive material disposed on one surface thereof, said second substrate being spacedly disposed from said first substrate and arranged so that the layer of transparent conductive material of the second substrate faces the layer of transparent conductive material of the first substrate;
patterning the continuous layer of transparent conductive material; and

disposing a layer of liquid crystal material between said first and said second substrates

(1) "Patterning" the Conductive Layer

The Parties do not dispute that Claim Element 9 relates to the method of fabricating the second substrate and finally completing the liquid crystal display. Dkt. No. 113 at 7-8. The Parties do, however, dispute whether Claim Element 10 relates to patterning the conductive layer on the first or the second substrate, as each substrate includes a separate conductive layer. ATI argues that this "patterning" is of the conductive layer on the second substrate. Dkt. No. 81 at 23-26. ATI argues that such a construction is supported by the specification. Id.

Sharp argues that the "patterning" must be of the conductive layer on the first substrate. Dkt. No. 113 at 8-9. Sharp argues that the conductive layer on the second substrate cannot be patterned because it is a continuous conductive layer. Dkt. No. 113 at 7-8. Specifically, Sharp argues that a continuous conductive layer is first placed on the "second substrate." Id. Then, later in the claim element, the phrase "said second substrate" is used to refer back to this second substrate. Id. When the inventor refers back to the second substrate by saying "said second substrate," Sharp argues that he was referring also referring back to the continuous conductive layer placed on the second substrate. Id. Sharp argues that if this construction is not adopted, this Court will be ignoring the importance of the word "said" and the fact that this word should be used to refer back to the previous use of the word. Id.; Hearing Transcript at 146-148.

In its response, DNP focuses more on the timing of the patterning and does not specifically argue as to which conductive layer is patterned. Dkt. No. 84 at 28-29. Instead, DNP merely argues that the "transparent electrically conductive material" is patterned. Id.

(2) Timing of the "Patterning"

The Parties also dispute whether this patterning step must be completed before or after the substrates are arranged so as to face each other. ATI argues that the patterning step is completed before the substrates are so arranged. Dkt. No. 81 at 23-26. ATI argues that nothing in the intrinsic record precludes the patterning of conductive material before the substrates are arranged. Id.

Sharp does not provide any specific argument regarding the timing of this patterning. Dkt. No. 113 at 8-9. However, Sharp does propose that the "patterning" cannot be of the conductive layer on the second substrate because then the patterning would have to occur after the substrates were arranged. Id. Sharp argues that if the "patterning" were found to be of the conductive layer on the second substrate then this phrase violates 35 U.S.C. § 112 as ambiguous. Id. DNP argues that the "patterning" must occur after the substrates are arranged. Id. DNP argues that if this construction is not adopted, then this claim element is insolubly ambiguous and the corresponding claims would be invalid as indefinite under 35 U.S.C. § 112.

b. Construction

(1) "Patterning" the Conductive Layer

The claim language establishes that Claim Element 10 requires the patterning of the conductive layer on the second substrate. Specifically, Claim Element 10 requires the patterning of "the continuous layer of transparent conductive material." (emphasis added). The only other reference to the continuous layer of transparent conductive material is in Claim Element 9 (referring to the second substrate). Accordingly, the "patterning" must be of the conductive layer on the second substrate, not of the conductive layer on the first substrate.

Furthermore, Sharp's argument that the patterning must be of the conductive layer on the first substrate is not persuasive. As noted above, Sharp argues that Claim Element 9 uses the phrase "said second substrate" to refer back to the second substrate with the continuous conductive layer. While Sharp is correct in its argument that "said second substrate" refers back to the second substrate, nothing in this claim element requires that this "said second substrate" must also include a continuous (as opposed to patterned) conductive layer. 19
19 However, this Court does find that Sharp's argument that a layer cannot be both "continuous" and "patterned" at the same
time is persuasive. Such a construction is supported by the specification. See, e.g., Col. 7, Lines 44-52 (stating that the
conductive layer may be patterned or "[a]lternatively" may be left unpatterned). ATI also does not dispute this proposed
construction. Hearing Transcript at 134-135, 138. Therefore, this proposed construction is adopted.

(2) Timing of the "Patterning"

DNP's proposed construction that the "patterning" must occur after the substrates are arranged to face each other cannot be
adopted. Under the general rule, method steps need not be performed in the order written. Baldwin Graphic Systems, Inc. v.
Siebert, Inc., 512 F.3d 1338, 1345 (Fed. Cir. 2008). Defendants have not established that an exception to this general rule
should be applied. Also, the claim language itself does not explicitly or implicitly require a specific order. Id. (holding that
"although a method claim necessarily recites the steps of the method in a particular order, as a general rule the claim is not
limited to performance of the steps in a particular order, unless the claim explicitly or implicitly requires a specific order.")
(internal citation omitted). Therefore, these method steps need not be performed in the order written.

Moreover, the specification does not require that these method steps be performed in a specific order. See, e.g., Col. 8, Lines
10-24. DNP even recognizes that the specification does not require these method steps to be performed in the order written:

A second plate is then prepared by first depositing a layer of conductive material upon one surface of a second transparent
substrate. (Id. at Fig. 4, ref. No. 42; id. at 8:10-12). The layer of conductive material may be left as a continuous layer or
may be patterned by photolithography to form display electrodes. (Id. at Fig. 4, ref. No. 42; id. At 8:14-17). The two plates
are then arranged so that the different layers of material disposed on the two substrates face each other. (Id. at Fig. 4; id. At
8:21-24).

Dkt. No. 84 at 3 (emphasis added).

Additionally, DNP's proposed construction--which would require the patterning after the substrates are arranged--would
render this invention inoperable. Even a rudimentary understanding of the technology behind the fabrication of a liquid
crystal display would dictate against requiring such a construction. Namely, after the two substrates are arranged so as to
face each other, it would be unreasonable to then pattern the conductive layer. Even DNP recognized that such a
construction would be impractical:

THE COURT: . . ."That is, from DNP's briefing it seemed to me that you seem to require or are wanting to require Claim
22 to be done in sequence. In other words you're--the way you interpret that is once the assemblies are put together, the
subassemblies are put together, then if there is going to be any patterning on the second substrate, it has to happen then. Is
that the way you're--is my reading of your position correct?

MR. CHALSEN: Yes, that's our argument, Your Honor. And actually this is another one of our indefinite--it's really an
indefinite in that this claim really is inoperable or it's invalid. It can't be--it's not practical--

Hearing Transcript at 136.

Accordingly, this Court adopts the following construction for Claim Element 9: "Providing a second substrate having a
continuous layer of transparent conductive material placed on one surface. The substrates are assembled so that the first and
second substrates are spaced apart from each other and the layer of conductive material of the first substrate and the layer of
conductive material of the second substrate face each other." This Court adopts the following construction for Claim
Element 10: "Patterning the continuous layer of transparent conductive material on the second substrate. This patterning
step may be done before or after the substrates are arranged such that they face each other."

Furthermore, DNP's proposal that the transparent conductive material be placed "directly onto the second substrate" should
not be adopted. As noted repeatedly in this opinion, these claims use the open-ended word "comprising" when detailing their steps. Such a word indicates there could be additional steps included in the invention with the potential for intervening layers between the second substrate and the continuous layer of transparent conductive material. CollegeNet, Inc., 418 F.3d at 1235.

C. Pavement Construction Material Mixture

This term is found in claims one and thirteen. The Plaintiff proposes "a mixture of materials for use in constructing pavement, including without limitation soils, aggregates, asphalt, cement asphalt and concrete mixes." The Defendants propose "a construction pavement mixture of constituent raw materials that includes one or more aggregates, soils, asphalt, cement asphalt, and cement." The parties agree that the term is limited to construction pavement and that it includes aggregates, asphalt, cement asphalt, and concrete/cement.

This disputed term appears only in the claims of the patent, so the specification does not provide an explicit definition. The patentee does state in the background of the invention, "to ensure that the materials conform to the specification, various tests have been developed for standard test methods for Quality Assurance/Quality Control of soils, aggregates, asphalt, cement asphalt, and concrete mixes." Col 1: 34-37. The patentees also listed various types of tests that can be performed, including soil test methodologies (col. 2:12), asphalt test methodologies (col. 2:18-19), asphalt mix test methodologies (col. 2:23), concrete mix test methodologies (col. 2:28), and aggregate test methodologies (col. 4:27). The patentees also specified that the server allows the consumer to use software packages for standardized tests for "soils, aggregates, asphalt, cement asphalt and concrete mixes." Col. 3:63-64.

The dispute in this term is whether the disputed phrase is a mixture of constituent raw materials. The Defendants argue that the mixture must be made of "constituent raw materials." The Defendants argue that this is the definition of a mixture, but they do not offer any evidence for that argument. The Defendants also point to a statement in the prosecution history where the patentees distinguished their invention over two Harbuda references because those references related to manufacturing raw material and lacked the construction material mixture required by the claims. See ATSER_R_0000806. This prosecution history evidence does not, however, limit the disputed term or the claimed invention to a mixture of constituent raw materials. In fact, the Defendants' own expert testified that the disputed term could be a blend of raw and pre-processed materials. Adding a limitation that the mixture be made up of constituent raw materials is unhelpful to a jury and inconsistent with the evidence presented.

Construction: A mixture of materials used to construct pavement. Such materials include soils, aggregates, asphalt, asphalt mix, cement asphalt, and concrete mix.

Payload Platform

Payload Platform

Each parties' claim construction of the relevant term in the '662 patent is listed as follows:

<table>
<thead>
<tr>
<th>Disputed Term</th>
<th>Defendants' Proposed Const.</th>
<th>Plaintiffs' Proposed Const.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Payload Platform</td>
<td>The platform on which the payload (e.g., a camera) is directly mounted and not any other element of the device</td>
<td>Of rigid construction, either as a solid manufactured piece or as a rigid construction of pieces which together form the payload platform, and to which payloads can be attached. It comprises the structure of the '662 device that is stabilized from the motion</td>
</tr>
</tbody>
</table>
impacted by the vehicle or moving
object upon which the '662 device
is mounted, and it is the structure
that is moved by the 'means
of moving.'

Neither parties' formulation is very illuminating, but for different reasons: Defendants' construction is not specific or precise, but is all too self-referential (a payload platform is the platform where the payload is affixed); plaintiff's formulation is simply indecipherable and unintelligible as it gives no meaning to the term (a payload platform is something which forms a "payload platform structure"). That said, it does seem apparent from the parties' accompanying arguments that defendants' seek to limit the payload platform to the horizontal surface or plate upon which the device in question is directly mounted or affixed, while plaintiff seeks to include within the term not only the horizontal surface or plate but also the supporting structure thereto, namely struts, legs, etc., that is, then attached to and moves in conjunction with the motors or other means of moving. (Compare Defs' Reply at 8 ("the definition proposed by Defendants ... limits the structure to the horizontal piece that holds the camera") with Pls' Reply Br. at 6 ("the payload platform ... is the entirety of the platform that is stabilized by the device' or stated another way "a single machined element that attaches to the motors or means for moving and includes the horizontal attachment plate"). With this understanding and refinement of the parties' respective proposed constructions, the Court now turns to determining which most aptly captures what is meant by the term as used in the '662 patent.

Turning to the language contained in the patent, both sides make much of the fact that the '662 patent alternately speaks of the payload platform as the "camera support platform 22" or a "platform for supporting an article to be stabilized" (see Col 4, lines 39-40 ("sensor package B [(the second sensor package)] is mounted on the camera support platform") and Col. 2, lines 1-3 ("In accordance with one aspect of the present invention, a stabilized platform includes a payload platform for supporting an article to be stabilized")). Defendants argue that, by specifically linking the concept of the payload platform to the device in question (the camera), the patent plainly directed that it was only that portion of the invention upon which the device was affixed or mounted, and not the remainder, that was covered. Plaintiff counters by focusing on the use of the word "support" as indicating that the "platform" extended beyond the area where the device was affixed or mounted to the length of the structure that attached the device to the means of moving (e.g., motors).

The Court is not persuaded by either sides' argument, as each proposed definition suffers from the same imprecision as that of the term it is being used to substitute. That the word "camera" is mentioned does not necessarily mean that the platform in question is limited to just the top of the tripod/structure. Nor is the fact that the '662 patent provides that the payload "platform ... support[s] an article to be stabilized" necessarily mean that such support must include not only the immediate area providing such support (that is, the horizontal attachment plate) but also the metal legs or struts coming off of the horizontal plate that affixes that plate to the rest of the device. Simply put, it is not clear to the Court that the different linguistic formulations of the relevant aspect of the device was intended to serve, or indeed does serve, as a means to delimit or otherwise define the precise scope of how far down the device a payload platform is considered to extend.

Rather, it appears these alternative formulations for the part of the device in question are as unilluminating on the precise question at issue in this case -- what is the extent of the platform? -- as the original formulation of "payload platform." The reformulations do not specifically point, one way or the other, to how far down the support structure the word "payload platform" extends, whether that be just to the mounting plate or further down to the support structure holding/attaching the mounting plate area to the rest of the invention's structure. Instead, they speak in broad terms that could be read to support either proposed definition.

Telling in this regard is the fact that, when using the alternative phrasing "camera support platform," the '662 patent makes references to item 22 in FIGS 1 and 2 of the preferred embodiments. As made apparent during the Markman hearing, it is not entirely clear (especially in connection with FIG 2) whether item 22 is simply the horizontal plate, or if it also includes the hatched lines forming a triangular shape revealing the support structure connected to the horizontal plate (that is, those hatched lines which appear to connect the horizontal plate to the invention's motorized apparatus).

The parties' reference to the dictionary is equally unilluminating, as it too is subject to supporting either party's construction. The dictionary defines a "platform" as "a device or structure incorporating or providing a platform especially such a structure on legs used for offshore drilling (as for oil)." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 891 (10th
ed. 1999). Such a definition could support, although does not require, the notion that the part of the device performing the function of a platform (or at least being encompassed within it) extends beyond the flat horizontal attachment plate to the support structure. The Court emphasizes the word "could" because the definition speaks of a "structure on legs." Thus, it is equally possible that the definition seeks to separate the relevant "structure" from the "legs" that support it; the "structure" being the horizontal platform. Another dictionary definition emphasizes the horizontal attachment plate as being the relevant part of the invention performing the function required by the term "platform": "A raised horizontal surface especially a raised flooring." Id.

As can be discerned from these competing dictionary definitions, a platform can either be viewed as the horizontal surface upon which a person or device stands or rests, or it can extend to the supporting struts or legs holding the horizontal surface aloft.

In the end, the Court finds that what is key to deciphering the meaning of this term is the comparable structures mentioned in prior art concerning gimbal-based devices, and how that prior art was discussed and distinguished by both Grober and the PTO during the re-examination of the '662 patent. Specifically, an understanding of what specific structural aspect of the prior art Grober and the PTO re-examiner were talking about in relation to the "payload platform" provides meaningful insight into what part of the '662 patent is sought to be captured through use of that term in the '662 patent itself. Notably, in Howes v. Medical Components, Inc., 814 F.2d 638 (Fed. Cir. 1987), the Federal Circuit held that the prosecution history of a reissue application must be considered in interpreting a claim even when the claim appeared in the original patent and was not altered or amended during the reissue proceedings. Similarly, in Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448 (Fed. Cir. 1985), the Federal Circuit held that a disclaimer or concession made by a patent owner during reissue proceedings is binding as to the interpretation of the claim. As one district court noted: "The arguments and amendments made by the patent owner during the prosecution are pertinent to claim interpretation. . . . They also limit the allowable equivalents under the doctrine of equivalents. . . . This prevents the patent owner from construing the claims narrowly before the PTO and broadly before the courts." Total Containment, Inc. v. Environ Prods, Inc., 921 F. Supp. 1355, 1389-90 (E.D. Pa 1995).

3 Although not recited in the body of this Order, the Court is mindful of and has employed the standards set forth in Phillips v. AWH Corp, 415 F.3d 1303, 1312-17 (Fed. Cir. 2005), that in executing the Markman mandate the Court must follow certain rules ranking in importance various sources of evidence (i.e., intrinsic and extrinsic evidence, and that within those broad categories there is a hierarchical ranking of subcategories of such evidence) to elucidating the meaning of claim terms.

This principle applies with equal force to a patent owner's construction of claims made during reexamination proceedings in order to avoid prior art. "[A]rguments made to distinguish prior art during reexamination proceedings are retroactively applied to limit the scope of a claim limitation as of the issue date of the patent, not the date those arguments were made." Intermatic Inc. v. Lamson & Sessions & Co., 273 F.3d 1355, 1367 (Fed. Cir. 2001), vacated on other grounds, 535 U.S. 722, 122 S. Ct. 1831, 152 L. Ed. 2d 944 (2002).

PTO Re-examination Proceedings

It is clear to the Court that, through arguments advanced by Grober during the reexamination proceedings, amendments to the patent he submitted in connection therewith, as well as the PTO's subsequent adoption of at least one of those arguments, the defining characteristic of the '662 patent which distinguish it from a long line of prior art concerning two-axis gimbal based devices (most notably the Welch and Duckworth patents) was the fact that the '662 patent "requires 'the second sensor package [be] fixed to the payload platform.'"

This distinguishing feature of the '662 patent is central to defendants' most persuasive argument: If the payload platform is more than just the horizontal plate or surface upon which the camera is directly affixed, then the '662 patent runs up against the prior art should it be demonstrated that sensors from the second sensor package in the prior art similarly showed them affixed to the metal support.struts/legs to the horizontal plate. If that is the case, then the PTO's finding (and Grober's
similar representation to that effect to the PTO re-examiner) that the prior art did not teach that there were sensors from the second sensor package on the "payload platform" must mean, logically, that such supporting legs/struts are not and cannot be considered part of the payload platform in the '662 patent. To hold otherwise would be to render large parts of the claims in the '662 patent invalid as being anticipated or rendered obvious by the prior art in Welch and Duckworth. To understand whether there is anything to this argument, it is important to understand the particulars of the Welch and Duckworth's devices, the arguments advanced before the PTO re-examiner in regards to the prior art, and the PTO re-examiner's resolution of those arguments.

Welch device

Welch described the critical part of his invention in the '039 patent as follows: "FIG. 1 illustrates the active stabilized platform system in one embodiment of the present invention. FIG. 2 is an enlarged view of the stabilized structure of the first embodiment of the present invention." With respect to the "stabilized platform system," Welch made clear that there were three subparts comprising it:

The principle mechanical design will be discussed first. There are three major mechanical subassemblies of the stabilized platform: (1) the protective enclosure or radome 12, (2) the base structure 14, and (3) the stabilized structure 16, which further includes a platform structure 18 and a counterbalance structure 21. FIGS. 1 and 2 show the stabilized structure 16 and these subassemblies. Each of the three (3) subassemblies serves a specific purpose in the overall active stabilized platform system 10.

It is this last subassembly, the stabilized structure and its accompanying subassemblies, that was the focus of the re-examination proceedings related to Grober's '662 patent and the present Markman hearing. As best the Court can tell, Welch further divided his stabilized structure as including within it a platform structure and a counterbalance structure. The stabilized structure was the equivalent of the '662 patent's flat horizontal plate, as it was the part of the Welch invention upon which the antenna was directly mounted and touching the plate. The question remains -- what to make of the platform structure? On FIG 1 to the Welch patent it shows that a sensor, the pitch potentiometer item 27, is affixed to the "platform structure" which appears to include both horizontal surface as well as the vertical legs or support structures.

Duckworth device

Duckworth described the critical part of his invention in the '312 patent as follows:

FIG. 1 is a schematic view of a conventional stabilized platform. . . . Referring to FIG. 1, a radar antenna 1 is mounted to be rotated about the azimuth axis 2 upon a stabilized platform 3. The stabilized platform 3 is carried from the deck of a ship represented at 4 by a two axis gimbal system, consisting of a frame 5 carried from two supports 6 and 7 fixed to the deck of the ship 4. The frame 5 is mounted between the two supports 6 and 7 so as to be capable of rotation about a horizontal roll axis 8. The stabilized platform 3 is mounted within the frame 5 so as to be rotatable about a horizontal pitch axis 9, the axes 8 and 9 being orthogonal.

So item 3 in the Duckworth device is the equivalent of the horizontal plate in the Grober '662 patent. It would appear that item 5 is the most equivalent to the metal legs or support to the horizontal plate on the Grober '662 patent.

This raises the question of where Duckworth calls for his sensors to be placed. And herein lies the problem: It is not at all clear that the Duckworth patent calls for a specific location for the sensor to be placed; instead it emphasizes that wherever the sensor is placed it must be able to measure certain movement along the two axis. As Duckworth explains:

Referring to FIG. 2, this is a schematic diagram of the error signal detection and control system provided in respect of one of the axes 8 and 9 of FIG. 1. . . . Again the antenna is represented at 1. The synchro transmitted 10 is arranged to detect movement of the aerial 1 about the roll axis 8, i.e., movement of the frame 5 relative to the supports 6 and 7 about axis 8.

From reading this, and then looking at the schematic in question, it is hard to decipher were, if anywhere, the synchro item 10 is attached or affixed to the device.

Resolution by the PTO
Among the twenty-nine grounds proffered in its re-examination of the '662 patent, defendants argued in grounds one, two, and eleven that claim 1 and certain other dependent claims in the patent were anticipated or rendered obvious by Welch (grounds one and two) or Duckworth (ground eleven). Ultimately, the PTO re-examiner agreed with Grober and did not adopt grounds one, two, or eleven. However, in doing so, the PTO re-examiner drew a distinction -- advocated by Grober -- between the '662 patent and the Welch and Duckworth patents that served to place a limit on the claim terms contained in the '662 patent. Specifically, the PTO re-examiner noted that it was the failure in the Welch or Duckworth prior art to fix sensors from the second sensor package to the payload platform that made the '662 patent device distinguishable and thus patentable:

Claims 1-13 are confirmed because the prior art of record fails to teach or make obvious a stabilized platform having a second sensor package that is fixed to the payload platform as recited in claim 1. The inclusion of a second sensor package being fixed to the payload platform defines patentability over the prior art of record because it defines a distinguished structure of a stabilized platform which is not taught or made obvious by the prior art of record alone or in combination.

However, as to what parts of the prior art were considered to be analogous to the '662 patent's "payload platform" (and by extension what was meant by use of that term in the '662 patent) differed from those advanced by Grober during the re-examination proceedings (as detailed below); it is this interplay between the position advocated by Grober and defendants, and the PTO re-examiner's resolution of the same, that is highly probative of the central claim term at issue here.

In articulating why the grounds put forward by defendants were mistaken, Grober emphasized the importance of the payload platform in his device, especially in relation to the positioning of the second sensor package. First, Grober sought to amend the claims in the '662 patent in several places to emphasize the point that, in the '662 patent, the "second sensor package . . . is wholly fixed to the payload platform." (Defs' Am. Opening Br., Ex. E at 10, 13, & 15 ("patent owner, in the amendment filed on 12/20/05 . . . explained the fundamental difference between Welch and the '662 patent 'by point[ing] out that claim 1 . . . requires "the second sensor package is fixed to the payload platform," and argued that Welch does not teach this limitation").). As explained by Grober to the PTO re-examiner, "the wording 'Fixed to' found in claim 1 . . . especially within the context of Grober's patent specifications and drawings show that no part of the second sensor is fixed to anything other than the payload platform. Therefore by definition it is 'wholly fixed to'. Grober FIG 2 item B, and FIG 3 item B, and FIG 13 item 38, clearly show the sensor as 'wholly fixed to' the payload platform." (Defs' Am. Opening Br., Ex. E at 23-24).

Next, Grober argued that neither the Welch nor the Duckworth patents taught this requirement for their devices to work. "The amendment precludes any possible terminology confusion when comparing with Welch and Duckworth's potentiometers, encoders, synchros or resolvers which are clearly identified in their specifications and figures as not wholly on the payload platform. Welch never uses the words 'fixed to' or 'mounted on' to describe his potentiometers 27 and 29. They are clearly not 'fixed to', and most definitely not 'wholly fixed to' Platform Structure 18. Welch and Duckworth would not work if they were." (Defs' Am. Opening Br., Ex. E at 24).

Grober also commented on the location of the payload platform in the preferred embodiments to the '662 patent. Grober thus remarked that, unlike the prior art, the '662 patent taught that, using "the wording 'fixed to' found in claim 1, and the wording 'mounted on' in claim 4 especially within the context of Grober's patent specifications and drawings show that no part of the second sensor is fixed to anything other than the payload platform. Grober FIG. 2 item B, and FIG. 3 item B, and FIG 13 item 38, clearly show the sensor as 'wholly fixed to' the payload platform." 4 (Defs' Am. Opening Br., Ex. E at 23-24). Interestingly, in those figures (see FIGs 2 and 3, whose depictions are illustrated above) mentioned by Grober, the sensor (item B in FIGs 2 and 3) is shown attaching to the horizontal plate upon which the camera is directly fastened, not to the supporting structure or struts to the plate. At oral argument during the Markman hearing, however, Grober correctly noted that in FIG 2 to the '662 patent there is a hatched line that could indicate that the area encompassed by item 22 extended beyond the horizontal surface to what appears to be legs supporting that horizontal surface. However, it is also equally clear that the relevant sensor depicted in FIG 2 to the '662 patent, that is, item B, is also clearly shown as being affixed to the flat horizontal portion of item 22 and not the hatched line area pointed to by Grober (assuming Grober is correct and item 22 extends beyond the flat horizontal plate to the supporting legs thereto).

--- Footnotes ---

4 Claim four in the '662 patent referenced by Grober in his pleadings before the PTO stated: "The stabilized platform of
Nevertheless, in the PTO reexamination proceedings, Grober also went on to specifically describe what parts of the devices in the prior art he viewed as being a comparable to the '662's "payload platform." In speaking of the Welch invention before the PTO, Grober wrote "Welch never uses the word 'fixed to' or 'mounted on' to describe his potentiometers [sensors] 27 and 29. They are clearly not 'fixed to,' and most definitely not 'wholly fixed to' Platform Structure 18." 5 (Defs' Am. Opening Br., Ex. E at 24). Later, in the same response submitted to the PTO, Grober made the following observation about the Welch patent: "Are potentiometers and encoders [in the Welch patent] 'fixed to the payload platform'? Grober submits they are not. If they were, they would not work. Grober submits that his terminology in view of his claim 1 wording 'fixed to the payload platform' is clearly shown in Grober's drawings and specifications as well as dictated by the sensor type to be wholly 'fixed to the payload platform.' Welch and Duckworth's potentiometers are not wholly fixed to the payload platform, nor are they even 'fixed to the payload platform' because they would not work if they were." (Defs' Am. Opening Br., Ex. E at 40-41). As explained by Grober: "[Defendant] proposes that Welch's position sensor(s) 27 and/or 29 are fixed to platform 18, the equivalent of Grober's payload platform. This is not supported by Welch's claims, specification or figures. Welch's second sensor package is two distinctly separate sensors located in two separate positions at the gimbal between the framework parts. The parts are not attached or fixed to the payload platform. . . . Pitch Potentiometer 27 is shown fixed to the frame structure of which Platform Structure 18 rocks within." (Defs' Am. Opening Br., Ex. E at 42-43).

5 Grober similarly distinguished Duckworth device on the grounds that the sensors were not fixed to the payload platform on that device. (Id. at 58).

Notable from this discussion is that Grober argues that the structure on the Welch gimbal-based device that is comparable to his payload platform was FIG 1 item 18 (the Platform Structure) in the Welch patent. What is remarkable about this assertion is that the Platform Structure identified in the Welch patent was not just the horizontal surface upon which the device in question (an antenna) was mounted, that item being item 16 the Stabilized Structure. Instead, FIG 1 item 18 to the Welch patent was comprised of the struts and supports upon which the Stabilized Structure was affixed and which were themselves connected to the motor used to maintain the stability of the antenna. Even more remarkable is that, despite Grober's assertion that no part of the potentiometers (again defined by Grober as being items 27 and 29 in the Welch patent) were "even fixed to the payload platform" (which again he defined as item 18 to the Welch patent), it is not entirely clear that is the case. From a review of FIG 1 to the Welch patent, it is not clear whether or not sensor 27 is affixed to item 18 Platform Structure or is affixed to something else. Sensor 27 is depicted as being affixed to a raised squarish object that is itself either attached to or is part of the Platform Structure. Nowhere does the preferred embodiment in FIG 1 or in the Welch patent identify whether or not this raised squarish part is considered part and parcel of the Platform Structure.

Nonetheless, Grober sought to reinforce this point in his response to the re-examination: "Requestor proposes that Welch's position sensor(s) 27 and/or 29 are fixed to platform 18, the equivalent of Grober's payload platform." (Defs' Am. Opening Br., Ex. E at 42). Grober thus again points to the "framework parts" as being part and parcel of the payload platform, and then goes on to rebut the argument that in the Welch patent the sensors are affixed to platform item 18, noting instead that the sensors were taught in Welch's device as one being affixed to "the frame structure of which Platform Structure 18 rocks within" and the other sensor "fixed to the Base Structure 14." (Id. at 43). That the support structure to the flat mounting plate were all considered part of the payload platform by Grober was made plain by his statement to the PTO re-examiner that the sensors used on the Welch device are not described as "fixed to the payload platform' or Welch's Stabilized structure 16, or its attached Platform Structure 18." (Id. at 46-47). Again Grober lobbed the mounting plate (the Stabilized Structure item 16 in FIG 1 to Welch's invention) and the support to that plate (the attached Platform Structure item 18 in FIG 1 to Welch's invention) as part and parcel of the "payload platform."

The PTO examiner was not convinced by Grober's argument over whether item 27 was or was not affixed to item 18. "[The] examiner notes that neither the patent owner's argument nor the requester's argument is found persuasive because figure 1 of Welch does not clearly show whether sensors 27 or 29 are fixed to the payload platform or not. Frankly, one can not say
with certainty] by looking only at the figure." (Defs' Am. Opening Br., Ex. B at 16).

Instead it was another argument that would convince the PTO examiner that the '662 patent was distinguishable from the prior art, an alternative argument that Grober directed to the claim language found in the Welch patent.

Grober noted to the PTO that claim 30, column 12, lines 18 to 22, to the Welch patent provided that "said first sensor; a first drive motor for rotating said stabilized structure about a first axis, and said dual-axis gimbal, being mounted between said stabilized structure and said base structure." From this it was argued that the Welch patent implied that the portion of the device that the second package of sensors were fixed to was not the payload platform but an area between the base and the stabilized structure. The obvious implication being that the stabilized structure (i.e., item 16 in FIG 1 to the Welch patent) was considered the payload platform, it being the only area left that could fill such a role without having a sensor attached to it. Thus Grober, in this alternative argument, asserted by implication that the horizontal plate/surface in the Welch patent, upon which the antenna was directly affixed, was considered the payload platform. The PTO examiner accepted this argument and found that item 16 in FIG 1 to the Welch patent, the Stabilized Structure, was the equivalent of the payload platform found on the '662 patent. "Examiner agrees with the patent owner's argument. Claim 30 of Welch clearly teaches the second sensor package (sensors 27 and 29) being mounted between the stabilized structure (16) and the base structure (14). Thus, Welch does not teach the second sensor package is fixed to the payload platform 16. . . . because Welch does not teach a second sensor package being fixed to the payload platform, Welch cannot anticipate claims 1, and 34-36 of the '662 patent." (Defs' Am. Opening Br., Ex. B at 17). Grober did not challenge this finding by the examiner in the responses he later tendered to the PTO re-examiner's action closing the prosecution of the reexamination. (Pls' Reply Br., Ex. 2 at 10("In the responses, patent owner and requester did not comment on the reasons set forth by the examiner").

The same process played itself out with respect to the Duckworth patent. It was argued by Grober that "the fundamental difference between Duckworth and the '662 patent" was that "Duckworth does not teach the limitation that the second sensor package being fixed to the payload platform as required" by claim 1 in the '662 patent. (Defs' Am. Opening Br., Ex. B at 30). Defendants responded that the Duckworth patent teaches that "the synchros [that is, sensors] are fixed to the gimbals of stabilized platform 3." In other words, defendants pushed what was considered the equivalent payload platform in the Duckworth patent to extend beyond the horizontal surface upon which the device (the antenna) was directly affixed (item 3 in FIG 1) to include the "gimbals" or support structure holding item 3 in place. The PTO examiner was not persuaded by defendants' argument, finding that it conflated the gimbal system itself with the payload platform on the Duckworth patent, item 3 the Stabilized Platform. "Duckworth teaches a payload platform 3, a base 4, a stabilizing system which includes a gimbal system (frame 5 and supports 6 and 7) and motors 16, a first sensor package 12 and a second sensor package (synchro 10). As it is clear . . . payload platform 3 and gimbal system are distinct elements and cannot be lumped together. Thus, Duckworth teaches the second sensor package is mounted on the gimbal system, not the payload platform." (Defs' Am. Opening Br., Ex. B at 30). From this it is apparent that the PTO re-examiner classified (and Grober advocated for) item 3 on the Duckworth patent as being the equivalent to the payload platform in the '662 patent. This is important because item 3 again is simply the horizontal surface or plate upon which the device (an antenna) is mounted, implying again that it is this mounting surface upon which a device (such as an antenna or a camera) in question is directly affixed, not the supporting brackets or struts that constitutes the payload platform for purposes of the '662 patent.

Now Grober argues that item 3 in the Duckworth patent is comprised of more than just the "rigid platform" or "box" to which a line is drawn toward in FIG 1 to the patent's preferred embodiment, but also the "shaft attachment points" connecting the box to both the gimbal to the side as well as the antenna above. Instead, Grober argues that the payload platform in the Duckworth patent is akin to an inverted platform, with the legs, struts, going upwards from the flat horizontal surface. As explained in his papers, "Duckworth's payload platform 3 is the rigid platform which comprises both the vertical box uprights to which the axis shafts indicated along the axis 9 are attached, as well as the horizontal top plate to which is then mounted the radar antenna 1, attached to another vertical axis." (Pl's Reply at 4). The problem for Grober is there is no indication in the Duckworth patent that these "attachment points" are in any sense of any substance (other than their connectivity of the various parts of the particular embodiment of the device) as being considered part and parcel of item 3, which is clearly identified in the patent and the identification line drawn in FIG 1 of the preferred embodiment as the "rigid platform" or "box." Grober's argument on this point thus suffers for much of the same reasons as his argument over the sensor placement of item 27 in the preferred embodiment to the Welch patent.

Given the admissions and representations made by Grober during the re-examination proceedings, and giving context to the prior art, it is apparent that the payload platform is the flat horizontal metal plate to which the camera is attached and
nothing else, be it the metal arms or legs immediately supporting that plate, which are in turn connected to the motors continuously moving about to keep the camera stabilize by correcting the movement of the base. Those other parts of the "structure" (the motors, support struts, legs, etc.,) do not comprise the payload platform. Thus, the motors and support structures beyond the ones directly attached to the horizontal mounting plate would not be part of the payload platform.

Given the parts of the relevant FIGS in the Welch and Duckworth patents that the PTO reexaminer concluded were considered the "payload platform," it is evident that, Grober's present argument notwithstanding, the term as used in the '662 patent was meant to refer to the horizontal plate or surface upon which the relevant device is affixed or mounted. If the Court were to hold otherwise and include the supporting struts, legs, etc., as advocated by Grober, then not only would this be inconsistent with the position advocated by him and then adopted by the PTO during the re-examination proceedings, but it would render claim 1 in the '662 patent invalid as it would have been rendered obvious or anticipated by the prior art. And it is in this respect that the Court finds defendants' proposed construction is correct because, as their Markman brief makes clear: "The definition proposed by Defendants . . . limits the structure to the horizontal piece that holds the camera." (Defs Reply at 8).

Accordingly, as the re-examination proceedings make plain and a review of the prior art discloses, the Court finds that a "payload platform" is nothing more than just a raised flat horizontal surface upon which a device (be it an antenna or a camera) is directly mounted and touching, it does not include the support structure to that horizontal surface from which it is attached to the rest of the device or to any other part of the device.

The Court accordingly construes the claim term "payload platform" to mean "the horizontal plate, piece or surface upon which the device (e.g., a camera) is directly mounted upon or affixed to."

The next disputed term, "payment mechanism," first appears in claim 1 and occurs in several subsequent, dependent claims, including the disputed claim 49. Plaintiffs define "payment" as "paying money in some form," and "mechanism" as "machinery or process for achieving a result." (Pls.' Mem. On Claim Construction 13). Defendant interprets "payment mechanism" to mean "an arrangement of connected parts for payment that is part of the vending machine," as based on its understanding of the specification and the dictionary definition of mechanism. (Def.'s Rebuttal Claim Construction Br. 19). Defendant properly disputes plaintiffs' construction of mechanism as a process or method, since the Patents disclose an apparatus, not a method or process. The specification language cited by plaintiffs in support of its proposed definition allows payment by currency or "in electronic form," referring to contemporaneous payment by an electronically-read or magnetically-read card (e.g., credit card, debit card, hotel key card) or other such device. ('400 Patent 2:50-56). The specification also suggests that payment may be "carried out through software that is present in the user's laptop or other device," and that "no physical method need be included in the vending machine." ('400 Patent 2:55-56, 3:23). Contrary to plaintiffs' claim, this does not mean that the vending machine's payment mechanism is located external to the vending machine, especially in light of the specification and claim language that clearly defines a vending machine as comprised of, in part, a payment mechanism. Rather, instead of being made by a credit card, the payment may be made by electronic currency, e.g., "e-money," or an online service that issues credit to the user and separately bills the user. These are examples of forms of payment, and while these may be dictated by the type of payment mechanism located in the vending machine (for example, if the vending machine does not contain a mechanism for accepting currency but only for processing e-money), they do not dictate the location of the vending machine's payment mechanism.

Accordingly, I construe the disputed claim language as follows:

<table>

B. Payment Mechanism

Claim 1(a) discloses "a payment mechanism for obtaining information from the customer to initiate a vending transaction." '400 patent col. 16, 11. 5-6. The parties' dispute concerns the meaning of the term "mechanism." T-Mobile argues that a mechanism is "an arrangement of connected parts," T-Mobile Br. at 19, while PowerOasis contends that "'mechanism' means machinery or process for achieving a result." PowerOasis Br. at 13.

T-Mobile offers two unconvincing arguments to support its interpretation. First, T-Mobile notes that the dictionary definition of "mechanism" is "an arrangement of interconnected parts." T-Mobile Br. at 19 (citing American Heritage College Dictionary). In fact, "mechanism" has several dictionary definitions, including ones that comport with PowerOasis' proposed construction of "payment mechanism." See Compact Oxford English Dictionary of Current English (defining "mechanism" as "the way in which something works or is brought about"). Thus, dictionaries are unhelpful.

Second, T-Mobile argues that the patentees' earlier patents used "mechanism" in terms such as "cover mechanism," '643 patent col. 9, 1. 22, "steam supply mechanism," '169 patent col. 18, 11. 25-26, "hydrocarbon supply mechanism," id. col. 18, 11. 28-29, and "electric supply mechanism," id. col. 18, 1. 34, "to describe items that are made of connected parts." T-Mobile Br. at 19. These references do not support T-Mobile's argument because they use "mechanism" in the same way as it is used in the phrase "payment mechanism" without providing any additional guidance as to the term's intended meaning.

In contrast to the other "mechanisms," the patentees explained that a "cover mechanism" is a protective enclosure for the customer's electronic device. '643 patent col. 9, 11. 17-23. While I agree with T-Mobile that a "cover mechanism" is a physical structure, my conclusion derives from the patentees' explication of how the "cover mechanism" functions as a cover for the customer's device rather than their use of the term "mechanism." Accordingly, "cover mechanism" sheds no light on the meaning of "mechanism" in "payment mechanism."

T-Mobile's argument also falters in light of the specification's statement that "no physical payment method is required [in which case] payment is carried out through software that is present in the user's laptop or other device." '400 patent col. 2, 11. 54-56; see also '400 patent col. 3, 11. 22-23. I agree with PowerOasis that this language refutes T-Mobile's contention that a "mechanism" must be "an arrangement of connected parts." As this statement demonstrates, the patentees clearly envisioned an embodiment in which the "payment mechanism" consists of software on the customer's laptop rather than a coin acceptor, card reader, or other "arrangement of connected parts."

Although I agree with PowerOasis that "payment mechanism" includes software loaded on the customer's computer, I decline to adopt its proposed definition without qualification. As T-Mobile has correctly pointed out, the '658 and '400 patents are apparatus claims rather than method claims. PowerOasis' definition of "mechanism" as "a process for achieving a result" improperly attempts to convert disclosed structure into a method for achieving the result. In order to clarify that the term "payment mechanism" does not encompass all possible methods for obtaining payment from the customer, I construe "payment mechanism" to mean "a mechanical, electrical, or electronic (i.e., software) means for achieving payment."

2. "peaks and valleys"

The phrase "peaks and valleys" is found in claims 1, 8-9, 12-13, 16-17, 20, 22, 29-30, 33-34, 40-41, 43, 45-48, 52-53, and 55-75 of the '037 patent, and in claims 11-25 of the '255 patent. See Joint Statement, '037 and '255 Patents. Plaintiffs contend the phrase should be construed to mean "[w]hen viewed in two dimensions, the upper surface of the crest of the wave is the peak, the upper surface of the trough of the wave is the valley." Defendants contend that the phrase should be construed to mean "when two slopes or curves meet, the furthest projecting point or surface on the outside of that intersection is a 'peak' and the furthest recessed point or surface on the inside of that intersection is a 'valley.'" The intervenor, for its part, contends that the phrase should be construed as "the inside of an apex is a 'valley' and the outside of
The phrase "peaks and valleys" is not described in either the claim language or the specification, although there is -- as defendants point out -- a limited mention of the term "peak" in the specification. Specifically, in connection with a description of illustrated Figure 12c, which is discussed as a type of flexure means disposed in the "longitudinal struts" of the claimed stent design, the specification states that Figure 12c may be considered "to be an in line symmetric double peak." See Joint Statement, '037 Patent at 11:47-49. Turning to the illustration at issue, the "peak" looks to be the point at which two sloped lines meet or, as defendants propose, the "furthest projecting point" at the place where two slopes meet. This would-be support for defendants' proposed construction falters, however, because a closer look at the specification language discloses that the description of Figure 12c as "an in line symmetric double peak" is made in the context of the specification's general description of differing types of longitudinal struts -- e.g., connectors -- that form a part of the claimed stent design. Yet the actual claim language makes clear that "peak," when construed in connection with the phrase "peaks and valleys," is to be construed with reference to circumferential members, not longitudinal struts. See id. at 14:39-41 (Claim 1 covers stents having a "circumferential portion comprising alternating peaks and valleys"). Accordingly, the specification's description of "peak" in connection with Figure 12c of the patent is not all that relevant to the proper construction to be given the phrase "peak" as used in the disputed phrase at issue. And defendants' corresponding argument that Figure 12c therefore supports a construction of "peak" as "the furthest projecting point or surface" on the outside of the intersection where "two slopes or curves meet," is also unpersuasive.

Since neither the claim language nor the specification therefore shed any light on the ordinary meaning of the phrase "peaks and valleys," the court turns to the prosecution history, which both parties rely on in support of their differing proposed constructions. Plaintiffs note that the prosecution history of the '037 Patent indicates that the applicants understood Figure 5 of the patent to depict "peaks and valleys," as illustrated by the undulating patterns of circumferential members in Figure 5. They also note that the '255 prosecution history indicates the same understanding of "peaks and valleys," as depicted by the figure drawing included by the applicants in their submissions to the examiner, and Figures 2D and 3 of the prior art Orth Patent, which the applicants also relied on in prosecution the '255 Patent. See Declaration of Kadie M. Jelenchick ("Jelenchick Decl."), Ex. E at AB0732124-25. According to plaintiffs, both Figure 5 of the '037 Patent and, all the figure drawings relied on by the applicants in prosecution the '255 Patent all depict undulations, or "waves," in which the entire upper surface of the crest is a "peak," and the entire upper surface of the trough is a "valley."

Defendants, for their part, also rely on Figure 5 of the '037 Patent, and the same figure drawing disclosed by the applicants in the prosecution history of the '255 Patent, to support their differing construction for "peaks and valleys." Defendants contend that, as disclosed therein, a "peak" is the "furthest projecting point" on the outside of the intersection of two slopes, while the "valley" is the "furthest recessed point" on the inside of same.

In the court's view, however, neither of these arguments is especially compelling. The court could find no support for plaintiffs' proposed construction, which essentially adds, without defining, new elements to the claim language -- i.e., "crest" and "wave" -- that are nowhere found in the prosecution history, or in the claim language or specification, for that matter. Moreover, Figure 5 of the patent, which defendants assert depicts "peaks and valleys," does not, in the court's view, actually depict any shapes that would necessarily qualify as "crests," "troughs," or "waves." See, e.g., Merriam-Webster's Collegiate Dictionary 295, 1342, 1415 (11th Ed.). As for defendants' proposed construction, the court is not convinced that "peaks" and "valleys" must be construed as limited solely to the furthest projecting or furthest recessed points on the outside and inside surfaces of the claimed intersections. For as plaintiffs point out, Figure 10 of the '037 patent depicts "valleys" that include a slightly raised point of connection where a connector meets the valley. See Joint Statement, '037 Patent at Fig. 10. In other words, the valley appears similar to a "w" shape, with the connector rising out of the valley to form that "w." Defendants' proposed construction, however, is inconsistent with this depicted "valley," since there is no single furthest recessed point that can be located in the valley. Rather, there are at least two furthest recessed points. Yet the prosecution history and claim language indicates that even the "w" shaped valley is still a "valley."
Forced to conclude, therefore, that neither of the parties' proposed constructions is accurate, the court must nonetheless construe the disputed phrase at issue. On balance, the court finds that the construction of "peaks and valleys" that is most consistent with the intrinsic evidence is as follows: "the surface outside the point at which two slopes or curves meet is the peak, and the surface inside the point at which two slopes or curves meet is the valley." The court hereby adopts this construction.

In so doing, the court notes that it is reluctant to construe any disputed term in a manner not proposed by either side. For that reason, the court will be amenable to accepting a revised construction, jointly agreed upon by the parties, in place of the one herein adopted. Should the parties wish to submit a jointly revised construction in place of the present one adopted by the court, they are instructed to do so, via joint letter brief, within 2 weeks of the date of this order.

---

2. "Material, peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor." Used in Claim 1.

Flashmark suggests that no construction is necessary. In the alternative, Flashmark proposes "a material that responds distinctively to an intensity of light in a range of wavelengths, or of heat, which is not normally encountered in ordinary use in amounts sufficient to cause said material to discolor." GTECH has suggested:

a material, including an infra-red absorbing dye, formulated to dramatically enhance sensitivity to radiant energy and to reduce the amount of time and energy required to cause the material to become visible in response to radiant energy in infrared wavelengths, in comparison to dry silver materials. 5

A construction of this term requires a definition of "radiant energy," which is addressed above. The court must also construe the "ambient light" in which the "radiant energy" is not normally present.

---

5 In the responsive brief, GTECH suggested: "a material including an infra-red absorbing dye, formulated to dramatically enhance sensitivity to radiant energy and to reduce the amount of time and energy required to cause the material to become visible in response to wavelengths of radiant energy outside the visible spectrum in the range of about 750-950 nm, and at intensity levels not normally encountered in ordinary use, namely about 50 ergs per square centimeter."

---

a. Use of Term in Claims and Specification

Claim 1 describes the material as being responsive to radiant energy that is "not normally present in ambient light in amounts sufficient to cause said material to discolor." '153 patent, col. 7, 11. 22-23. It does not place any further restrictions on the type of material that can make up the article.

The specification states that the "material" is normally invisible, which means that the "material is only slightly visible or visible as background, and does not interfere with the genuinely visible markings on the coupon." '153 patent, col. 3, 11.25-30. "The material 13 may be responsive to radiant energy such as heat or light. Upon being exposed to heat or light energy not normally encountered in ordinary use, the material 13 will become visible." '153 patent, col. 3, 11. 33-37.

In a preferred embodiment, the specification states that the "presently preferred material 13 is a photosensitive material formed by a mixture of a dry silver material and an infrared absorbing dye." '153 patent, col. 3, 11. 42-44. "The preferred materials exhibit high absorption of light wavelengths in the approximate range of about 750 nanometers to 950 nanometers." '153 patent, col. 3, 11. 61-63.

This preferred embodiment is seen in Claims 5 and 6, which are dependent on Claim 1. Claim 5 states: "The article of claim
4 wherein said range of light wavelengths covers about 750 nanometers to about 950 nanometers." Claim 6 states: "The article of claim 5 wherein said material comprises a mixture of dry silver and infra-red absorbing dye."

GTECH's proposal, therefore, is based upon limitations in a preferred embodiment and the dependent claims. In general, an independent claim is presumed to be broader in scope and to encompass the dependent claim. See Phillips, 415 F.3d at 1315 ("[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.")

Flashmark argues that in defining this term, the words "ambient light" be changed to "ordinary use," relying upon a single appearance of that phrase in the specification at Col. 3, l. 36. If "ambient light" could just be changed to "ordinary use" then "radiant energy" would be more likely to refer to "heat" in forms other than electromagnetic wavelengths. The patentee could have picked any words he wanted for the claims, but he chose to add "ambient light," not "ordinary use," to Claim 1 to overcome the Examiner's initial rejection. Amendment, 6/25/1991 p. 2, FLASH 0000078 in GTECH's Ex. E [Doc. # 107, Attach. # 11, p. 18 of 76]. And, in distinguishing prior art while trying to overcome that rejection, the patentee stressed that prior inventions discolored in ambient light. Amendment, 6/25/1991, pp. 4-5, FLASH 0000080-81 in GTECH's Ex. E [Doc. # 107, Attach. # 11, p. 20-21].

A further indication of what the patentee intended by the use of "ambient light" is found in the same amendment: "As stated in the description, color formation is caused in DYLUX by UV found in daylight or artificial light which contains UV. To prevent discoloration in ambient light the DYLUX paper must be deactivated . . . ." Amendment 6/25/1991, p. 8, FLASH 0000084 in GTECH's Ex. E [Doc. # 107, Attach. 11, p. 24] (emphasis added). The court need not consider at this point whether the "ordinary use" term is a disclosure of an invention in the specification which was not claimed, and so is donated to the public. Johnson & Johnston Assoc. V. R.E. Serv. Co., 285 F.3d 1046, 1054 (Fed. Cir. 2002) ("[W]hen a patent drafter discloses but declines to claim subject matter, . . . this action dedicates that unclaimed subject matter to the public.").

At the hearing the court discussed a proposed definition, together with numerous changes suggested by the parties. In the end, Flashmark would not agree to a construction that defined "ambient light" as anything but "ordinary use." For the reasons noted above there is no basis to adopt "ordinary use," especially when the patentee chose not to use the phrase in amending the claim.

Flashmark's expert stated that while "direct" light would be "focused," ambient light would include "normal lighting" in a room and direct sunlight outdoors, or "conditions of the environment without that presence of the directed light." This is a more expansive definition of ambient light than that suggested by the court, and agreed to by GTECH. However, it is not outside the ambit of the use of the term in the specification and in the prosecution history references set out above, and it comports with its use in some dictionaries.

The court was concerned about imposing a limitation requiring that the "material" of the invention not discolor even in direct sunlight, as will a newspaper and many other papers. However, Flashmark insisted that "ambient light" included direct sunlight, perhaps because their idea of "ordinary use" includes using the articles in direct sunlight. The court is not adverse to adopting this concept as it is reasonable and narrows, rather than expands, the scope of the claim. This term will be construed as follows:

- Material peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor means "a substance which darkens or changes color when exposed to radiant energy (as previously defined by the court) of a type or intensity (or both) that is not ordinarily present in sunlight or normal indoor lighting."

The court was concerned about imposing a limitation requiring that the "material" of the invention not discolor even in direct sunlight, as will a newspaper and many other papers. However, Flashmark insisted that "ambient light" included direct sunlight, perhaps because their idea of "ordinary use" includes using the articles in direct sunlight. The court is not adverse to adopting this concept as it is reasonable and narrows, rather than expands, the scope of the claim. This term will be construed as follows:

- Material peculiarly responsive to a particular form of radiant energy not normally present in ambient light in amounts sufficient to cause said material to discolor means "a substance which darkens or changes color when exposed to radiant energy (as previously defined by the court) of a type or intensity (or both) that is not ordinarily present in sunlight or normal indoor lighting."

Both parties agree that a pen-light laser is "about as small and slender as a fountain pen." Irwin, though, contends that this limitation applies to the whole device, while Orosz argues that the limitation only requires that a pen-light laser be included in the device.

According to Irwin, the specification consistently uses the terms "pen-light sized laser" and "portable laser unit"
interchangeably. Moreover, some figures included in the specification point to the whole device as being the pen-light laser. Thus, to Irwin, the consistent use of the term pen-light laser in this manner impliedly defines the term as the whole device. See Bell Atlantic Network Servs., Inc. v. Covad Communication Group, Inc., 262 F.3d 1258, 1273 (Fed. Cir. 2001) ("The patentees defined the term . . . by implication, through the term's consistent use throughout the . . . patent specification.").

However, the specification does not reveal that Orosz consistently used the term pen-light laser in this fashion to implicitly define the term as applying to the whole device. In column 1, lines 33-35 of the patent, Orosz refers to the pen-light sized laser as an exemplification of the compact, pocket-sized light beam device. The specification further explains that other components may be affixed to the device and that the portable laser unit may include more components than just a pen-sized laser. 

"[A] flat surface member . . . might be provided at the bottom of the pen-like housing incorporating the beam circuitry and power source." (Column 4, lines 54-56). Furthermore, the specification and figure 5 also explain that in another embodiment of the invention, a second pen-light laser can be used in the device; the specification specifically states that "a unit assembly of two portable pen-light lasers . . . can be aligned side-by-side in an assembly." (Column 5, lines 32-34). If a second pen-light laser or other components can be added to the portable laser unit, then the pen-light laser cannot, in and of itself, constitute the whole device.

Irwin further argues that the claimed pen-light laser itself must be fully functional by including a power source. Otherwise, the device would be rendered inoperable; and, therefore, the patent would not contain an enabling disclosure. According to Irwin, the specification reference stating the pen-light housing incorporates the beam circuitry and electric power source demonstrates that the device is an independently functioning laser that is pen-light sized, while Orosz's construction leaves the device inoperable because the claim would not include a power source.

Adopting Irwin's construction, however, would improperly add a claim limitation from the specification. See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204-05 (Fed Cir. 2002). Moreover, the specification, and not just the claim, may enable those skilled in the art to make the claimed invention. See, e.g., Johns Hopkins Univ. v. CellPro, Inc., 152 F.3d 1342, 1359 (Fed. Cir. 1998). Whether the specification makes an enabling disclosure is not proper to resolve in a claim construction proceeding.

The prosecution history of the '081 patent also fails to expressly state that the pen-light laser is the whole device. A patentee may not state that the claims of a patent do not cover a particular device during prosecution and then change that position during an infringement suit. Springs Window Fashions LP v. Novo Industries, L.P., 323 F.3d 989, 995 (Fed. Cir. 2003).

Irwin argues that Orosz distinguished the patented invention over the prior art by including a leveling means with a pen-light-sized laser, instead of using a multiple combination of elements in a case housing a level and a laser disclosed in the prior art. However, Orosz distinguished the invention over the prior art by being the first to use a leveling means with a pen-light-sized laser that, significantly, used a line-forming lens instead of a diffuser. (Pl.'s App. at A0064-A0065).

Lastly, the patent claims demonstrate that the pen-light laser is not the whole device. Initially, the unit is described as a portable laser unit which is comprised of a pen-light laser. Other claims of the '081 patent that are dependent on claim 1 also explain that the portable laser unit may incorporate a second laser. For example, claim 4 states "[a] portable laser unit as set forth in claim 1 in which a second laser is incorporated in said unit . . . ."

Therefore, Orosz did not consistently use the term pen-light laser in the specification and prosecution history to implicitly define it as being the whole device. Instead, a pen-light laser is defined as a laser that is about as small and slender as a fountain pen; and the pen-light laser, consistent with the claim, may be part of a larger, portable laser unit.

Penetrate

Claims in the '930 and '631 Patents require the cutters to "penetrate" the formation or "penetration" of the formation. Baker Hughes contends "penetrate" means "cut into." ReedHycalog contends "penetrate" means "shear." Baker Hughes uses the term "penetrate," and ReedHycalog uses the term "shear" to construe related terms in dispute.
The Court agrees with Baker Hughes. All of the patents-in-suit use the term "depth of cut" and refer to "cutters" that penetrate the formation. Thus, "penetrate" means "cut into," and "penetration" means "cutting into." 25

--- Footnotes ---

25 Ref. No. 27 of Appendix B contains the disputed terms and their constructions.

--- End Footnotes ---

Per revolution of the drill bit

The Court next must determine whether the term "per revolution of the drill bit" found in Claims 6 and 8 measures only by complete drill bit revolutions. The relevant language from Claim 6 is "calculating the volume of formation cut by each cutting structure per revolution of the drill bit," and from Claim 8 is "calculating the axial force acting on each cutting structure per revolution of the drill bit." Relying on the American Heritage College Dictionary, Smith claims that the word "per" means "to, for, or by each; for every." Thus, Smith argues that the word "complete" is implicit in Claims 6 and 8, and "per revolution of the drill bit" means "for each complete 360 degree turn."

The Court finds that a person of skill in the engineering field would read the word "per" in Claims 6 and 8 as the English word for the mathematical function "divide." There is no question but that Claims 6 and 8 describe calculations because they begin with the word "calculating." When performing a calculation, a person of ordinary skill would convert English words into mathematical symbols whenever possible, and in math the English word "per" directly translates into "divide." Thus, "per revolution of the drill bit" means "divided by the drill bit revolutions."

Because the denominator in any mathematical formula may be a whole number or a fractional number, the Court finds that a person of skill in the relevant field would not limit the denominator in Claims 6 and 8 to a whole number. Haliburton's analogy to calculating an automobile's speed is appropriate. Miles per hour simply means the number of miles traveled divided by hours. Even though a car may have only driven for half of an hour, one may calculate the speed by dividing the miles traveled by .5 hours. Indeed, for every instant that a car moves, or does not move, one may calculate miles per hour, and no one would argue that the term "miles per hour" means "miles per complete hour." Therefore, the Court adopts Haliburton's construction and finds that "per revolution of the drill bit" in Claims 6 and 8 means: "as a function of the number of revolutions of the drill bit."

---

4. "Perforated" Means Pierced or Punctured with Holes

In oral arguments, AFT raised "perforated" as a term requiring construction. Tr. (Dkt. No. 106) at 53-56. AFT suggests the term means "having holes or perforations." AFT's Post-Hearing Br. at 8. J&L agrees that the term requires holes, but asserts that they must be made by piercing or puncturing. J&L Post-Hearing Br. at 10. The Court adopts J&L's construction.

The claims and specification do not define "perforated," however, extrinsic evidence makes clear that its construction requires puncturing or piercing; that conclusion in no way contradicts the claims. J&L's construction comes from the McGraw Hill Dictionary of Scientific and Technical Terms' definition of the verb, perforate, and the noun perforation. See Cross Decl., Ex. C (Dkt. No 39-5). Both forms of the term note a hole resulting from piercing or puncturing. Id. Similarly, the general use dictionary supplied by AFT defines "perforation" to mean "a hole or pattern made by or as if by piercing or boring." O'Brien Decl., Ex. G (Dkt. No. 113-8). Thus, both the technical and general use dictionaries supplied by the parties strongly suggest that "perforated" should be construed to mean characterized by holes made by piercing or puncturing. That construction fits easily with the specification. The sole exception is a one-sentence mention that "a wedgewire screening plate may be used." '940 patent, Col. 11, Lns. 64-65. "Wedgewire" is not recited in any of the claims. Its singular mention in
the specification, particularly in light of AFT's representation to the Patent Office in which it defined the screening element as "a perforated barrier" or "perforated metal plate," does not change the Court's conclusion that the ordinary meaning and the meaning given to "perforated" in the '940 patent is pierced or punctured with holes.

7. '181 Patent, Claim 37: "perforated plate"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Dyson Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>'181/37. The vacuum cleaner according to claim 36 and further comprising a perforated plate in a flow path between the upstream and downstream cyclones.</td>
<td>A flat disc which is annular or circular and which has holes through it. (Jt. State.)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Bissell Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>'181/37. The vacuum cleaner according to claim 36 and further comprising a perforated plate in a flow path between the upstream and downstream cyclones.</td>
<td>A thin sheet with holes in it. (Jt. State.)</td>
</tr>
</tbody>
</table>

Dyson's proposed construction would require that the perforated plate be annular or circular, while Bissell's proposed construction would not limit the perforated plate to a particular shape. The patent language does not support, and indeed explicitly departs from, Dyson's proposed construction. The patent states, for example, that "[i]n another embodiment, the outlet of the first cyclonic airflow chamber if [sic] formed by a perforated wall . . . . Typically, the perforated wall is substantially cylindrically shaped but other shapes of the perforated wall can be used." (4:47-55.) (emphasis added.) Figure 15 depicts the perforated plate as a thin cylinder, not a flat disc. Claim 36 itself does not impose any limitations on the shape of the perforated plate. Unlike Dyson's proposed construction, which would exclude embodiments the patent describes explicitly, Bissell's proposed construction is consistent with the language of the patent itself. The Court adopts Bissell's proposed construction of "perforated plate," as a "thin sheet with holes in it."

2888

3. Perforating

The next claim term at issue is "perforating." AVI construes perforating to mean using any device that creates "channels" in the foam, which channels may be any cross-sectional shape, including rectangular. Dow does not disagree with that definition insofar as it goes; however, it seeks to add a functional limitation that the channels formed must "allow accelerated release of the blowing agent so that the cure time is substantially reduced."

As I have already noted, accelerated release is to be read into the claim to the extent stated above. Accordingly, I construe "perforating" to mean using any device that creates "channels" in the foam, which channels may be any cross-sectional shape, including rectangular, that allow for the accelerated release of a blowing agent.
4. Construction of "Perforation Means"

For purposes of this appeal, we focus our attention on the fifth element of claim 1, which reads,

perforation means extending from the leg band means to the waist band means through the outer impermeable layer means for tearing the outer impermeable layer means for removing the training brief in case of an accident by the user.

The district court correctly ruled that the claimed "perforation means . . . for tearing" is not a means-plus-function element under § 112, P 6, which reads as follows:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112, P 6 (1994). To invoke this statute, the alleged means-plus-function claim element must not recite a definite structure which performs the described function. Patent drafters conventionally achieved this by using only the words "means for" followed by a recitation of the function performed. Merely because a named element of a patent claim is followed by the word "means," however, does not automatically make that element a "means-plus-function" element under 35 U.S.C. § 112, P 6. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 19 U.S.P.Q.2D (BNA) 1367 (Fed. Cir. 1991), cited in the dissenting opinion, creates no presumption to the contrary. The converse is also true; merely because an element does not include the word "means" does not automatically prevent that element from being construed as a means-plus-function element. See, e.g., Raytheon Co. v. Roper Corp., 724 F.2d 951, 957, 220 U.S.P.Q. (BNA) 592, 597 (Fed. Cir. 1983) (construing functional language introduced by "so that" to be equivalent to "means for" claim language), cert. denied, 469 U.S. 835, 83 L. Ed. 2d 69, 105 S. Ct. 127 (1984); 1162 O.G. 59, 59 (17 May 1994) (examination guidelines stating that the term "means" is not required to invoke § 112, P 6). We decide on an element-by-element basis, based upon the patent and its prosecution history, whether § 112, P 6 applies. See Palumbo, 762 F.2d at 975, 226 U.S.P.Q. (BNA) at 8 (Fed. Cir. 1985) (courts should consider prosecution history when construing "means-plus-function" claims).

The drafter of claim 1 in the '239 patent was clearly enamored of the word "means": six of seven elements in that claim include the word "means," which occurs in the claim fourteen times. We find, however, no reason to construe any of the claim language in claim 1 as reciting means-plus-function elements within the meaning of § 112, P 6. For example, the "perforation means . . . for tearing" element of Cole's claim fails to satisfy the statute because it describes the structure supporting the tearing function (i.e., perforations). The claim describes not only the structure that supports the tearing function, but also its location (extending from the leg band to the waist band) and extent (extending through the outer impermeable layer). An element with such a detailed recitation of its structure, as opposed to its function, cannot meet the requirements of the statute. Here, the claim drafter's perfunctory addition of the word "means" did nothing to diminish the precise structural character of this element. It definitely did not somehow magically transform this element into a § 112, P 6, "means-plus-function" element. The district court correctly recognized that words in a patent claim are construed as they would be understood by a reader skilled in the relevant art unless it appears that the inventor used the words differently. Since there is no evidence to suggest that "perforation" has any meaning other than the dictionary definition accepted by the court, we look to that definition, which reads as follows:

a hole, or one of a number of holes, bored or punched through something, as those between individual postage stamps of a sheet to facilitate separation.

Webster's Encyclopedic Unabridged Dictionary (1989). We construe the "perforation means . . . for tearing" to mean "perforations" as did the district court. We further construe "perforations" in view of the above dictionary definition.

Cole is also bound by her representations to the PTO during the prosecution of the '239 patent. Therefore, we next consider what effect the prosecution history of the '239 patent has, if any, on our construction of "perforation means."

Subsection II(A)(1) above discusses how Cole distinguished the Roberts patent. We believe Cole erred in her response to
the first office action when she stated that "the stitched seams can not be readily torn apart in the Roberts patent . . . ." The stitched seams in Roberts are designed to be readily torn apart by "grabbing the chain stitch and pulling same which disassociates edges 18 and 19." Further, Roberts' preferred embodiment uses a perforate seam rather than a chain stitch seam. We do not, however, agree with the district court's interpretation of what Cole surrendered when distinguishing the Roberts patent in her first office action. The only thing Cole expressly surrendered when distinguishing the Roberts patent was stitched seams when she argued that perforations are not stitched seams.

As noted above in subsection II(A)(2), in Cole's first request for reexamination, she stated, "The side seams of the [Strohbeen] patent are substantially different from the side seams of the instant [Cole] patent." The Strohbeen patent notes, however, that ultrasonic sealing is a "particularly preferred system for the [Strohbeen] invention." Cole made similar arguments regarding the significance of the Repke patent. The district court found that an estoppel arose from Cole's distinction of the Strohbeen and Repke patent. We agree. When Cole distinguished these references, she thereby surrendered any argument that her "perforation means" encompasses ultrasonic bonded seams.

This estoppel was bolstered when Cole distinguished the Heran patent in her second request for reexamination. As noted above in subsection II(A)(3), Cole stated that the Heran patent was not pertinent structurally, except possibly for having tearable side seams. Heran, however, discloses ultrasonic bonding to make its seams. See subsection II(A)(2). In summary, we believe the district court correctly concluded that the "perforation means" element is not a means-plus-function element under § 112, P 6. We also believe the district court correctly interpreted the prosecution history to require that the "perforation means" limitation cannot be construed to include ultrasonic bonded seams. Cole surrendered ultrasonic bonded seams in her requests for reexamination.

My divergence on literal infringement focuses on the term "perforation means" in the fifth element of claim one. Under the statutory regime of 35 U.S.C. § 112, P 6, a means-plus-function format has significant implications. Because the "perforation means . . . for tearing" claim also recites some structure, this court avoided addressing those implications. The recitation of some structure, however, does not remove a claim from the scope of section 112, P 6. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536, 19 U.S.P.Q.2D (BNA) 1367, 1369 (Fed. Cir. 1991). Mere invocation of the word "means" also does not magically conjure all the implications of means-plus-function claiming, but Laitram suggests that the use of "means" creates at least a presumption in favor of section 112, P 6. See id.; see also York Prods. Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 40 U.S.P.Q.2D (BNA) 1619, 1623 (Fed. Cir. 1996) ("The use of the word 'means' triggers a presumption that the inventor used the term advisedly to invoke the statutory mandates for means-plus-function clauses.") (citing Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584, 39 U.S.P.Q.2D (BNA) 1783, 1787 (Fed. Cir. 1996)). Some claim language describing the location of the structure should not be sufficient to over-come this presumption. Nor does the word "perforation" provide enough structure to negate the import of the very next word - "means." I would honor the presumption and construe this claim under the statutory guidance of section 112.

The parties also dispute the meaning of the term "perimeter." Jennmar contends that no claim construction is needed because this is a common mathematical term, but proposes the following definition: "boundary or outer limit around a piece or product." Excel argues that when there is a three-dimensional shape, such as where one or more of the edges is folded, the perimeter must reflect all of the edges in all of the dimensions. Thus, Excel proposes the definition: "Edge or outer limit or free end around a piece or product." There is no dispute about that which constitutes the "perimeter" with respect to the three preferred embodiments of the '933 Patent. Because plates with rolled, looped and folded edges do not have a "free end" in that the "edge" is joined to the major surface, Excel agrees with Jennmar that the perimeter would be the outer limit. Excel's definitional dispute arises only when a product (such as the Spider Plate) has a "free end."

After careful and deliberate consideration, the Court finds that Plaintiff's proposed definition of "perimeter" is the correct
construction. The language of the Patent appears to use the terms "perimeter" and "periphery" as synonyms. Compare, e.g., '933 Patent Column 4 ("safety edge 32 is formed around the peripheral section") with '933 Patent Column 7 ("safety edge formed around the perimeter"). It is apparent that Jennmar did not intend to re-define the common, ordinary meaning of "perimeter" as a two-dimensional measurement. See Merriam-Webster Online Dictionary (which defines "perimeter" as "the boundary of a closed plane figure").

The theoretical concerns of defense counsel about which two dimensions of a three-dimensional object should be measured need not be resolved in the context of this case. The plates described in the Patent are basically flat, square objects. If a plate were placed on a surface and a line was drawn around the outer limit of it, that would commonly be understood to be the "perimeter." Indeed, the Court takes judicial notice from Excel's website that it markets a Spider Plate with the dimensions 17" x 17". 2 Jennmar's Roof and Rib Plate is 18" x 18". It is a simple matter to determine which two dimensions will constitute the "perimeter" of the products at issue and the objections of defense counsel appear to be a "red herring."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Interestingly, these dimensions do not change based on whether the Spider Plate has a standard, flat edge or a "curled edge." It appears that, in the marketplace, Excel defines the term "perimeter" as Jennmar suggests, as opposed to the definition it proposes in this litigation.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The proposed definition of Excel is fraught with difficulty, complexity and unnecessary ambiguity. Excel suggests three alternative definitions ("edge or outer limit or free end") with no rule to determine how to choose among the alternatives. There is no principled way to determine when the "edge" becomes flush with or joined to the major surface such that it is no longer a "free end" and the "outer limit" becomes determinative. Similarly, as to objects in which all of the edges or free ends lean inward (for example, a pyramid shape), the definition of Excel would lead to the non-sensical result that the "perimeter" might be far smaller than the outer boundary. The common understanding is that the "perimeter" of a pyramid is measured around its base - the widest part. There is no indication that the '933 Patent intended to depart from this ordinary meaning. Moreover, Excel's language is difficult to reconcile with the language of the '933 Patent Column 5, which describes an "end" that is "spaced from the perimeter," a condition that could not occur under Excel's definition if the "end" were the same as the "perimeter." In summary, the Court agrees with Plaintiff that the term "perimeter" simply means the "boundary or outer limit around a piece or product." The Court rejects the efforts of Excel to unduly complicate this term.

2892

(iii). Claim 20

What is claimed in claim 20 is the following:

A tray kit comprising:

a first tray having a body portion and a perimeter portion extending around said body portion, said body portion having a plurality of pockets formed therein, said perimeter portion including a latch disposed on a lower surface thereof; and

a second tray, said second tray having an upper surface with a cavity formed therein and defined by a rim extending around said cavity, said rim including a recess formed therein, said latch of said first tray being selectively coupleable with said recess to retain said first tray in said cavity.

Fisher-Price alleges infringement of claim 20 by Evenflo's Simplicity tray set only, and points to two protrusions integrally molded on the rear lower surface of the body portion of the tray insert. Pl. Reply, p. 10; Pl. No. Demo 1 (Tab 5), Figs. S-20B, S-20C and S-20D. Fisher-Price advocates for a construction that includes the "perimeter portion" (as well as the "outer portion") of the tray insert on the "body portion." Pl. Reply, p. 10, citing '830 patent, Figs. 5 and 6.

Evenflo, consistent with its position on claim 1, argues that the "perimeter portion" of the claimed tray insert is completely
separate and distinct from the "body portion" of the insert. Def. Memo, pp. 14-15. It urges that, because the rear latches are located on the body portion, rather than the perimeter portion, its Simplicity insert tray does not infringe claim 20.

This Court notes that the phrase "perimeter portion" does not appear anywhere in the patent except claim 20. However, the claim is worded in such a way that one assumes the body and perimeter portions are discrete parts of the insert tray, with the "perimeter portion extending around [the] body portion."

The specification does not provide further guidance; the phrase "perimeter portion" is not used at all and the word "perimeter," standing alone, appears only once relative to the insert tray:

[T]he tray insert 200 includes a perimeter 218 that defines a contour for tray insert 200 that conforms to the contour of the cavity 114 formed in the base tray 100. Col. 4, lines 14-17; see also, Figs. 5 and 7.

When perimeter 218 is shown on Figure 5, supra, it appears as the outer boundary of outer portion 210. However, the use of the term "portion" in claim 20, along with a reference to a lower surface thereof, indicates to this Court that the "perimeter portion" is a substantial element, rather than a boundary line.

In claim 20, the body portion is described as having pockets formed therein and the perimeter portion as including a latch on its lower surface. Were the perimeter portion part of the body portion, as Fisher-Price contends, this claim could more clearly and simply read "body portion having a plurality of pockets formed therein (or in its upper surface) and a latch disposed on its outer (or lower) surface." However, that is not how the claim reads. Rather, the "perimeter portion" reads as a distinct element of the insert tray that extends around its "body portion."

--- Footnotes ---

20 The terms "latch" and "coupler" are not defined in the patent documents, but do not appear to be interchangeable. Couplers are described as being "releasably engageable" whereas the latch is "selectively coupleable."

--- End Footnotes ---

Considering the patent language in its entirety, this Court concludes that the claimed "perimeter portion" of claim 20 and the "outer portion" 21 of claims 12 and 27 are one and the same. "[C]laim drafters can . . . use different terms to define the exact same subject matter. Indeed [the Federal Circuit] has acknowledged that two claims with different terminology can define the exact same subject matter." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380-81 (Fed. Cir. 2006) (citations omitted).

--- Footnotes ---

21 As with the "perimeter portion," the patent describes and shows the "outer portion" extending around the "body portion." Col. 3, lines 41-43, Fig. 5.

22 Ascribing the same construction to "perimeter portion" in claim 20 and "outer portion" in claims 12 and 27 is not prevented by the doctrine of claim differentiation because other distinguishing limitations remain.

--- End Footnotes ---

c) "Period Of Time"

The last to be interpreted is "period of time." There is no specific definition, but the specification indicates that Ricci used a period of "approximately 5 minutes" to achieve one of his desired looks. ( '213 patent, col. 3, l. 14-15.) None of the claims that depend from claim 6 mention the length of the period. However, because claim 1 also uses those words, we can use limitations of that claim to try to define "period of time." Claim 4 tells us that the period of time may vary "commensurate

- 3443 -

PUBPAT
with the strength and the desired appearance of the faded cloth or garment," thus allowing longer tumbling for more fading, lesser tumbling for less fading. Just as the exact ratios of bleach to fabric or granules to fabric were left to the skilled artisan to determine what is needed "to achieve the desired effect," the amount of time necessary to produce the desired effect itself must be "within the skill of the person of ordinary skill in the art." (Amendment of Nov. 16, 1987 at 7, in Pros. Hist., Tab I.) Since the "desired effect" is a "random faded effect," the length of time is such to produce that effect.

2894

2. a peripheral cover hook, said peripheral cover hook comprising ('826 patent, claim 13);

a circumferentially extending peripheral cover hook ('875 patent, claims 32 and 50)

Crown's proposed construction is a "[c]urved portion of the can end that is to be formed into a portion of a double seam." 16 Rexam's proposed construction is "[w]hen looking at a cross section of the can end, the outermost portion of the can end that is curved or conforms to one or more radii, which engages a can body flange to form at least a part of a double seam, and ends where the curved or radiused portion(s) stops." 17

--- Footnotes ---

16 D.I. 325 at 2.
17 Id.

The court adopts Crown's proposed construction.

Claim 13 of the '826 patent recites a "can end comprising: a peripheral cover hook, said peripheral cover hook comprising a seaming panel adapted to be formed into a portion of said double seam during said seaming operation." 18 Claim 13 also recites "a wall extending inwardly and downwardly from said cover hook." 19 The common specification uses the term "cover hook" and the term "curl" synonymously. 20 The common specification also describes the peripheral cover hook as a "flange." 21

--- Footnotes ---

18 '826 patent, claim 13, 10:43-47 (emphasis added). Similarly, claims 32 and 50 of the '875 patent recite "providing a can end having (i) a circumferentially extending peripheral cover hook, said peripheral cover hook comprising a seaming panel to be formed into a portion of said double seam during a seaming operation." '875 patent, claim 32, 13:4-7 (emphasis added); '875 patent, claim 50, 15:11-15 (emphasis added).
19 '826 patent, claim 13, 10:50-51 (emphasis added).
20 See '826 patent, 3:23-24 (describing a prior art can end, "FIG. 2 shows on an enlarged scale the chuck 5 and can end 10. The can end comprises a peripheral curl 13, a chuck wall 14 dependent from the interior of the curl . . . ") (emphasis added); '826 patent, 3:54-57. (describing a can end according to the invention, "FIG. 4 shows a can end, according to the invention, comprising a peripheral cover hook 23, a chuck wall 24 extending axially and inwardly from the interior of the peripheral cover hook . . . ") (emphasis added).
21 See '826 patent 4:39-42 (describing a can end according to the invention, "FIG. 5 shows the peripheral flange 23 of can end 22 of FIG. 4 resting on the flange 11 of a can body 12 before formation of a double seam as discussed with reference to FIG. 1") (emphasis added).

--- End Footnotes ---
At the Markman hearing, Crown noted that it did not disagree with the first part of Rexam's proposed construction ("the outermost portion of the can end that is curved or conforms to one or more radii, which engages a can body flange to form at least a part of the double seam") but disagreed with the last portion of that construction ("and ends where the curved or radiused portion(s)"). 22 Rexam argues that its proposed construction identifies the location of the cover hook and where the cover hook should begin and end--the end being where the curved portion ends. Rexam contends that Crown's proposed construction purportedly fails to identify the location at which the cover hook ends and the wall begins. Citing figures 4, 5, and 6 of the patents, Rexam argues that the only way to identify where the cover hook ends and the wall begins is that cover hook 23 is curved and wall 24 is not curved.

--- Footnotes

22 See D.I. 322 at 28 (transcript of March 16, 2006 Markman hearing).

--- End Footnotes

The court declines to accept Rexam's additional limitations. To the extent that the can ends illustrated in the cited figures support Rexam's position, the Federal Circuit has cautioned against importing limitations contained in preferred embodiments into a patent's claims. 23 Also, claim 32 of the '875 recites that the can end has a "first wall portion extending from said seaming panel to a first location on said wall and comprising a radiused portion extending from said seaming panel." 24 Moreover, the description of figure 4 includes radius r[1], identified as "seaming panel/chuck wall radius," indicating that the chuck wall is not necessarily flat as Rexam contends.

--- Footnotes

23 See Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005) (en banc) ("[A]lthough the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments."); see also id. ("[W]e have expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment.").

24 '875 patent, claim 32, 13:11-14 (emphasis added).

--- End Footnotes

It is clear from the patents' common specification and claim language that Rexam's proposed construction must be rejected as it relies on the assertion that the chuck wall extending from the cover hook necessarily must be flat. Therefore, the court adopts Crown's proposed construction: "curved portion of the can end that is to be formed into a portion of a double seam."
Defendants' Response Brief, Docket No. 46, at 10).

At the very least, one skilled in the art of swimming pool skimmer assemblies would understand that the claimed device must have an edge extending entirely around the central opening so that a cover element may be sealingly engaged to prevent pool water from entering the skimmer. Nevertheless, the question remains: must the location of that edge be limited to the outer edge of the face plate? The intrinsic evidence, namely the claim language itself, the language in the written description, and the file history must be examined to answer this question. See Phillips, 415 F.3d at 1313.

A. The Language of Claim 1

Defendants contend that the context of the claim itself as well as language from the specification limit the term "peripheral edge" to only the outer edge of the face plate. In support they note that introduction of a claim term "provides antecedent basis" for further reference to that term. See Energizer Holdings, Inc. v. ITC, 435 F.3d 1366, 1370-71 (Fed.Cir. 2006). They argue that in the second full paragraph of Claim 1, the use of the definite article "the" prior to "peripheral edge around the face plate" indicates that the claim term "peripheral edge around said face plate" has been previously introduced in the claim. (Docket No. 46 at 9-10). Accordingly, the only way the term "peripheral edge around said face plate" could have been previously introduced is if the term "peripheral edge extending therearound" in the first full paragraph refers to the face plate. (Id.).

Plaintiff posits that as used in the clause in question, the word "therearound" is parallel to and means the same thing as the use of the words "around said central opening." (Reply Brief, Docket No. 47, at 6). She reiterates that in the context of Claim 1, the word "around" is always used to refer to the area around the central opening in order to emphasize that the primary purpose of the invention is to cover the central opening. (Id. at 6). Therefore, the only limitation on the term "peripheral edge" is that the "edge" be located "peripheral" to the central opening. (Id. at 7). Thus, according to Plaintiff, the "peripheral edge" can be either the "outer peripheral edge" or the "inner peripheral edge" of the frame-like face plate, which in any event is still peripheral to the central opening. (Id. at 7).

The language of claim 1 does not support defendants' position. The term "peripheral edge around said face plate" on column 4, lines 41-42 of the '538 Patent, refers back to the term "peripheral edge" on column 4, line 34. Thus, as used in the first instance, the term "peripheral edge" is not clearly limited to the outer edge of the face plate.

Moreover, in the '538 Patent plaintiff did not attach any special meaning to the terms "peripheral" or "edge" as they are used in Claim 1. (Docket No. 47 at 8). Accordingly, the terms must be given their ordinary and plain meaning as understood by one skilled in the art.

Generally, the term "peripheral" refers to a positional relationship, something located outside of a bounded or central area. The Oxford Dictionary and Thesaurus defines peripheral to mean "of the periphery; on the fringe." The Oxford Dictionary and Thesaurus, American Edition (1996). Periphery in turn means "the boundary of an area or surface" or "an outer or surrounding surface." Id. Synonyms include circumferential, external, perimetric, outside, outer and border. Id. And as used in general parlance is not restricted to the outer-most part of a thing or device. For example, the phrase "peripheral vision" indicates the part of vision located on either side of the central gaze. Or in computer parlance, the word "peripherals" means devices outside of the Central Processing Unit, including the keyboard, mouse, monitor, printer, etc. Therefore, to one skilled in the art of swimming pool skimmer assemblies, something peripheral to the central opening may reasonably be anywhere beyond the central opening, and not necessarily limited to the outer-most edge of the faceplate.

Furthermore, the language of claim 1 does not explicitly limit the location of the "edge" to the outer border of the face plate. The only clear limitation as to the location of the "edge" is that it must be "carried by the face plate" beyond the central opening such that it can sealingly engage the cover element and seal the entire opening. (the '538 Patent, col. 4, Ins. 29-45). The patentee could have used language in the claim that explicitly limited the location of the peripheral edge to the outermost edge of the face plate but elected instead to use broader language. See Acumed, 483 F.3d at 807.

Even though the claim language itself does not explicitly limit the term "peripheral edge" to mean the outer edge of the face plate, the language of the claim must be further evaluated in light of the specification before reaching a definitive conclusion as to its proper construction. See Vitronics, 90 F.3d at 1582.
B. The Specification

The specification describes the face plate as having a "substantially flat border surface surrounding the opening and laterally extending from the opening to a peripheral edge of the face plate." (the '538 Patent, col. 2, lns. 64-67). Defendants cite to numerous passages in the specification to support their contention that the location of this edge must be the outer perimeter of the face plate:

The face plate has a flat border area 30 surrounding opening 28 and laterally extending from sidewall 32 of opening 28 to a peripheral edge of the face plate, see FIGS. 2, 3, and 4. (‘538 Patent, col.2, lns. 64-67).

The cover element is square or rectangular in shape, sized in plain view to fit snugly around the peripheral edges 26 of the face plate. (‘538 Patent, col.3, lns. 10-12).

The skimmer face plate 22' has an upstanding or raised flange 40 outwardly extending from the flat border surface 30' around the outer peripheral edge 26' thereof. As seen in FIG. 3, the flange 40 is substantially perpendicular to a plane defined by the flat border surface 30' of the face plate. (‘538 Patent, col. 3, lns. 45-51) (emphasis added).

The U-Shaped sides of the lip portion 27' are adapted to snugly engage opposed sides of the raised flange 40 of the face plate completely around the outer peripheral edge 26'. Additionally, the planar portion on 25' preferably engages the flat border surface 30' to provide secondary sealing when the cover element is in place. (‘538 Patent, col. 3, lns. 54-60) (emphasis added).

The face plate may carry a raised bead 36 or similar looking means formed around the outer peripheral edge 26. (‘538 Patent, col. 3, lns. 65-67) (emphasis added).

Defendants assert that these are further evidence that the patent teaches only the art of securing a corner around the outer edge of the face plate.

The Federal Circuit has repeatedly warned against importing limitations from the specification into the claim and limiting claims only to the preferred embodiments. See Phillips, 415 F.3d at 1316; Voda, 536 F.3d at 1320. The only exceptions are where the specification contains words of "manifest exclusion or restriction" or the patentee intentionally disavows the scope of its invention. See Liebel-Flarsheim Co., 358 F.3d at 905-06: Phillips, 415 F.3d at 1316.

The above-referenced language describes the preferred embodiments of Plaintiff's invention, namely a skimmer assembly that includes a face plate that carries the sealing means along the outer perimeter of the face plate. But this language only identifies the preferred design of the invention; the specification contains no words of "manifest exclusion or restriction" that limit the invention to the preferred embodiments. Consequently, the language in the specification does not provide a basis for restricting the scope of the claim language. See Liebel-Flarsheim, 358 F.3d at 905 (noting that even where the specification describes only one embodiment, the claim should not be read restrictively unless the specification contains words of manifest exclusion or restriction); Innova, 381 F.3d at 1120 (same).

Furthermore, the specification makes clear that

[t]he … preferred embodiments described herein are meant to be illustrative only and not limiting as to the scope of the invention which is to be given the full breadth of the appended claims and any and all equivalents thereof.

(the '538 Patent, col. 4, lns. 17-21). Plaintiff has not, therefore, "intentionally disavowed" the scope of its invention in the specification. Phillips, 415 F.3d at 1316.

While the embodiments describe a device in which the cover element engages the sealing means along the outer perimeter of the face plate, the claim covers more than the specification. Plaintiff claims in the '538 patent a device that includes a frame-like face plate that surrounds the central opening to the swimming pool skimmer and also carries a means to completely seal that opening. The sealing means are located on an edge peripheral to the central opening. The embodiments describe the preferred design that does have the sealing means located along the outer perimeter of the face plate. However, the claim language does not make or implicitly require such a limitation. (the '538 Patent, col. 5, lns. 26-43).
Further, if the Court were to adopt Defendant's proposed claim construction, corresponding language in the specification would be rendered redundant and thus superfluous. The term "outer peripheral edge" (the '538 Patent, col. 3, lns. 46-47, 55-56) would then read "outer outer edge of the face plate." In other words, the use of the word "outer" would be rendered redundant because the concept already would be included through the use of the term peripheral. The patentee likely did not intend to include such redundant and thus superfluous language when describing its claimed invention. The term "outer peripheral edge" itself contemplates the existence of an "inner peripheral edge." And as Plaintiff notes, the face plate resembles a picture frame in appearance, and a typical picture frame has both an outer and inner edge. (See Plaintiff's Reply Brief, Docket No. 47, at 3 n.1). Given the logical force of this analogy, we decline defendants' invitation to read the claim in a manner that produces an inconsistency in the provisions of the specification.

While the patent only discloses embodiments that describe a skimmer assembly with the sealing means located at the outer edge, the claim itself uses language that provides a broader effect, calling for a peripheral edge extending around the central opening. Given that (1) the claim language is of a broader scope than the language in the specification, (2) the specification does not contain words of manifest exclusion or restriction, (3) the patentee did not intentionally disavow the scope of the claim language, and (4) that reading the claim in the manner pressed by defendants would attribute the use of superfluous language without justification for doing so, the claim cannot be limited to the embodiment set forth in the specification. Compare Acumed, 483 F.3d at 807 (refusing to limit the particular claims to the preferred embodiments, even where the embodiments were the only description of the invention, because the claim language had a broader scope than the embodiments); Ventana, 473 F.3d at 1181 (same); Innova, 381 F.3d at 1120 (same).

The file history is considered part of the intrinsic evidence. Therefore, the file history of the '538 patent must be reviewed to examine the intrinsic evidence fully.

C. The File History

The prosecution history of the patent is part of the intrinsic evidence. See Medrad, 401 F.3d at 1319. The patent examiner rejected Plaintiff's initial application because the term "associated with the face plate" was vague and indefinite and because the claim was obvious in light of two previous patents. (Plaintiff's Reply Brief at 10-11). Defendants contend that because Plaintiff argued during the application process that the prior art did not permit sealable engagement "around a peripheral edge of the face plate", the term "peripheral edge" is limited to the outer edge of the face plate. (Defendants' Response Brief, Docket No. 46, at 15). Defendants accuse Plaintiff of trying to characterize the claims and the art in a manner different than she did during the patent prosecution. (Id.).

Plaintiff counters that she only amended the patent to include the term "carried by" in response to an examiner's rejection that the corresponding term "associated with" was vague and indefinite. (Docket No. 47 at 11). Further, by distinguishing its invention from the prior art, Plaintiff assertedly was arguing that the examiner's obviousness rejection was improper, and her current characterization is quite consistent with the patent prosecution. (Id.).

The pertinent language from the prosecution history is:

Applicant takes issue with the Examiner's position and respectfully requests reconsideration in light of the following remarks.

The device of Dengel et al. includes a rigid cover plate 30 and gasket 32 having a plurality of aligned holes formed therein to permit the insertion of threaded screws 34 therein for subsequent attachment to the faceplate 20 of the skimmer. Applicant has obtained a snap-on faceplate cover from Hayward Pool Products, Inc., Catalog No. SPX-1094R, and photographs of the part, along with its container, are enclosed herewith for the Examiner's information.

The Hayward part depicted in the photograph is a square faceplate cover having an open interior. The part is adapted to be fitted over an existing screw-fitted faceplate in spas/hot tubs in order to cover the screw heads for cosmetic purposes. The inner throat portion of the faceplate cover surrounding the water opening carries a plurality of protrusions which apparently mechanically engage the interior walls of the pre-installed screw-fitted faceplate. It would appear that a mechanical, interface-type fit is established between the protrusions of the cover and the walls of the faceplate to hold the parts together. Thus, the Hayward part in no way seals the water opening in the preinstalled faceplate. As such, it is difficult to ascertain
how or why the "snap-on" feature of the Hayward could be adapted to modify Dengal at al. [sic] The Dengal et al. cover has no open throat area to modify in the manner suggested by Hayward.

In addition, neither of the cover elements of Dengel, et al. or Hayward are constructed of a flexible material to permit sealable engagement around a peripheral edge of the faceplate, as required by the claims. Dengel et al. has no peripheral lip, as claimed, to sealably engage the peripheral edge of the faceplate. In this regard, not that the plate 30 and gasket 32 of Dengel et al. are flat...Hayward has a peripheral lip, but it is rigid and inflexible and could not function to sealably engage the peripheral edge of the faceplate. It is, therefore, not seen how Dengel et al. could or would be modified by resort to the Hayward part to arrive at the claimed structure, other than by improper hindsight reconstruction. Clearly, the modified structure of Dengel, et al. (if it could be modified) would not perform in the same way as Applicant's claimed device since the rigid peripheral lip could not perform the necessary "sealable engaging" function as required in the claims(emphasis added).

The various embodiments set forth in claims 2-9 are, likewise, not rendered obvious by the applied references. As stated above, these claimed features are not fairly suggested by Hayward since Hayward includes a rigid peripheral lip. Taken with Dengel et al.'s structure, which contains no peripheral lip, it is difficult to understand how the references can be combined to arrive at Applicant's claimed structure which all require...a flexible, peripheral lip.

(Letter of July 9, 1993, Defendants' Response Brief, Docket No. 46, Ex. 6).

In these remarks to the examiner, Plaintiff distinguishes her device from the Hayward and Dengel patents by highlighting the fact that her claimed invention uses a flexible cover element with a peripheral lip to sealably engage a peripheral edge of the faceplate, while the prior art uses a rigid peripheral lip or lacks a peripheral lip altogether. In doing so, plaintiff does not disavow the scope of the claim in any way, much less in one that limits the term "peripheral edge" to the outer edge of the faceplate. See Purdue Pharma L.P. v. Endo Pharms, Inc., 438 F.3d 1123, 1136 (Fed.Cir. 2006). To the contrary, throughout the specification and the above-referenced letter to the examiner, plaintiff was careful to signify that the flexible material forming the sealable engagement need only attach "around a peripheral edge of the faceplate." The use of such language clearly indicates that there could be multiple peripheral edges available for sealability, and undermines defendants' attempt to restrict the construction of the claim language to only one possible location of the edge on the face plate. Absent such a clear and unmistakable disavowal, it cannot be said that Plaintiff is or was so limiting her claim. Id.; see also Liebel-Flarsheim, 358 F.3d at 905.

Moreover, Plaintiff did not rely on having a peripheral edge around the outer edge of the face plate to distinguish its invention from the prior art. Instead, it was argued in the application that the difference was in the cover elements: Plaintiff's invention utilized a cover element with a flexible peripheral lip that would sealingly engage the peripheral edge while the prior art cover elements had either a rigid peripheral lip or no peripheral lip to sealingly engage a peripheral edge. (Docket No. 46, Ex. 6) ("[N]either of the cover elements of Dengel, et al., or Hayward are constructed of flexible material to permit sealable engagement around a peripheral edge of the faceplate, as required by the claims."). It follows that Plaintiff is not presently characterizing the claims and art in a materially different manner. Because there was no clear and manifest disavowal of claim scope and because Plaintiff did not rely on the peripheral edge being located along the outer-most edge of the face plate to distinguish her device from the prior art, it is apparent that Plaintiff did not limit her claim during the patent prosecution process to encompass a peripheral edge only around the outer edge of the face plate.

V. CONCLUSION

Based on the above, the disputed claim terms will be construed as follows:

"Peripheral Edge" - any edge of the face plate that is peripheral to the central opening of the face plate;

"Peripheral Edge Extending Therearound" - a peripheral edge that extends entirely around the central opening;

2896

a. The first disputed term in Claim 7: "A base wall including a peripheral portion from which extends an annular sidewall
that diverges radially outwardly to a terminal edge"

i. Claim language. The first term in the '809 patent that the court must construe is found in Claim 7. The disputed term in this claim is "a base wall including a peripheral portion from which extends an annular sidewall that diverges radially outwardly to a terminal edge." Claim 7, with the disputed term italicized, states the following:

7. A method of making an integral, smooth and uniformly constructed plastic washing machine basket having a base wall including a peripheral portion from which extends an annular sidewall that diverges radially outwardly to a terminal edge in an apparatus including a mold core, cavity sidewall members spaced about the mold core which carry core pins each having a beveled tip portion adapted to abut the mold core during a molding operation and a cavity cover member spaced about an end of the mold core and abutting the cavity sidewall members so as to define a cavity between the mold core and both the cavity cover member and the cavity sidewall members comprising:

injecting a plastic material to fill the cavity while flowing around the beveled tip portion of each of the core pins to form a plastic washing machine basket having sidewalls provided with a plurality of spaced beveled apertures; and ejecting the washing machine basket from the apparatus by separating the mold core and cavity cover member and shifting the cavity sidewall members away from the mold core.

The '809 patent, Claim 7 (emphasis added).

ii. The parties' definitions and arguments. The parties' proffered definitions of this term are shown below, with bold font indicating differences between their definitions. Also, the authority on which each party relies for its definition is shown just below that party's definition.

"A BASE WALL INCLUDING A PERIPHERAL PORTION FROM WHICH EXTENDS AN ANNULAR SIDEWALL THAT DIVERGES RADially OUTWARDLY TO A TERMINAL EDGE"

Maytag's Definition
"A base wall including a peripheral portion from which extends an annular sidewall having a radius measured from the vertical center axis to the sidewall that increases from the base wall to the terminal edge"

Electrolux's Definition
"the bottom wall of the washing machine basket is the base wall; the peripheral portion of the base wall is the outside edge of the bottom wall of the washing machine basket; the sidewall of the washing machine basket is disposed from a central axis a greater degree at the top edge than at the bottom; the terminal edge is the top edge of the sidewall"

Maytag's Authority
'809 patent, Fig. 2; col. 2, ll. 8-15; col. 4, ll. 22-25; col. 6, ll. 3-44; claims 24, 29 and 34; '909 patent claims 11, 12, and 18; dictionary definitions of "diverge" and "radial"

Electrolux's Authority
'809 Patent at Fig. No. 2, No. 5 (base wall); Fig. 2, No. 10 (peripheral portion); Fig. 2, No. 8 (sidewall); Fig. 2 (radially outwardly); Fig. 1, No. 36 and Fig. 2, No. 36 (terminal edge); col. 2, lines 9-15 and lines 48-50; col. 3, lines 8-9, lines; col. 6, lines 36-42; dictionary definitions of "radial"
The parties agree that the "heavy lifting" on this claim term has already been done, because the parties have already argued, and at this point, the court has already construed "annular sidewall that diverges radially outwardly to a terminal edge." See supra, beginning on page 62. The parties also argued the proper construction of other parts of this claim term, but in reference to claim terms that the court has held are not "in dispute" at this time. Therefore, while the parties' work was done with briefing of other claim terms, the court must still consider for the first time the parties' constructions of the constituent terms "base wall," "peripheral portion [of the base wall]," and "terminal edge."

Maytag did not address these remaining constituent terms in its initial brief, because it took the position that they were not "in dispute" for purposes of infringement. In its opening brief, however, Electrolux construes "base wall" as "the bottom of the washing machine basket," albeit in reference to Claims 23 and 25 of the '909 patent. Electrolux's primary argument is that the drawings in both the '909 patent and the '809 patent depict the "base wall" as the bottom of the washing machine basket. Also in reference to Claims 23 and 25 of the '909 patent, Electrolux argues that "peripheral portion [of the base wall]" means the "outside edge of the bottom wall of the washing machine basket." Again, Electrolux contends that the drawings with the patents support its construction. On the other hand, Electrolux contends that Maytag's construction of this term (as "a portion of the base wall located away from the center of the base wall") is overly complicated. Finally, in its opening brief, again in reference to Claim 25 of the '909 patent, Electrolux argues that "terminal edge" means the "top edge of the sidewall." Electrolux again asserts that the illustrations in the patents support its construction, while Maytag's definition (which refers to the "access opening") is overly complicated.

In its rebuttal brief, Maytag takes issue with Electrolux's definition of "base wall," because Maytag argues that the pertinent patent claims and parts of the specification do not teach a "top" and "bottom" orientation of the washing machine basket. As to "peripheral portion [of the base wall]," Maytag contends that Electrolux is improperly construing "portion" to mean "edge." While Maytag concedes that the peripheral portion includes the base wall's edge, Maytag contends that it includes more than just the edge, indeed, the rest of the outside portion of the base wall--apparently meaning by "outside" any portion not in the center of the base wall. Thus, Maytag contends that Electrolux's construction is too narrow. Maytag also contends that use of "edge" in other patent claims means that the patentee knew how to claim an "edge" when one was intended. Finally, Maytag asserts that "terminal edge" does not mean merely "top edge," again because there is no "top" and "bottom" orientation to the washing machine basket to be drawn from the patent claims; rather, Maytag contends that "terminal edge" simply means what it plainly states, a "terminal edge."

In its surrebuttal brief, Electrolux contends that "base wall" and "terminal edge" are as depicted in the patent illustrations, regardless of their orientation as "bottom" or "top." As to "peripheral portion [of the base wall]," Electrolux contends that Maytag's definition is hopelessly vague, because it includes any and all portions of the base wall that are not in the center of the base wall. Thus, Electrolux contends that Maytag's construction is broader than the claim language.

iii. Analysis. In its construction of the disputed term in Claim 25 of the '909 patent above, the court concluded, inter alia, that the two ends of the washing machine basket are properly defined as the "base wall" and the "open end," respectively. See supra, page 66. Implicit in that conclusion was a finding that the court now confirms explicitly: "base wall" is unambiguously the "closed end" of the washing machine basket and no further construction of the term--for example, to indicate "up" or "down" orientation of the basket by referring to the "closed end" as the "bottom"--is required. In the same discussion leading to that conclusion, the court also found that the "terminal edge" is not the "top edge of the sidewall," but the "edge of the sidewall at the open end of the washing machine basket."

These prior conclusions leave for resolution here only the proper construction of the term "peripheral portion [of the base wall]." Unfortunately, neither the plain language of the claims in which "peripheral portion [of the base wall]" appears, see Nystrom, 424 F.3d at 1142 (construction begins with the words of the patent); Biagro, 423 F.3d at 1302 (same), nor the portions of the specification cited by the parties, see Phillips, 415 F.3d at 1314-16 (the specification remains of "central importance" to determining the proper construction of the term and may even be "dispositive"), provide any real illumination for the meaning of this term, because all of the cited portions merely repeat the term.

Consequently, the court turns, once again, to standard dictionary definitions for assistance. See Free Motion Fitness, Inc., 423 F.3d at 1348 ("Phillips confirms that courts may "rely on dictionary definitions when construing claim terms" and that 'dictionaries are often useful to assist in understanding the commonly understood meaning of words.'") (quoting Phillips, 415 F.3d at 1322, in turn quoting Vitronics Corp., 90 F.3d at 1584 n.6). Indeed, the court again finds that it is possible to
Finally, the parties disagree as to the meaning of "peripheral region," as that term is used in claim I of the '253 patent. Fujinon does not believe this term needs to be construed by the Court. See Tr. at 55, 58. If, however, the Court is to construe "peripheral region," Fujinon proposes the "outer" region or the area "located away from the center." See id. at 58. Motorola, on the other hand, contends that "peripheral region" is "an ambiguous term by ... itself," making construction necessary. Id. at 68. Motorola proposes that "peripheral region" be construed as "the region outside 70% of the radius of the third lens."

I agree with Motorola that "peripheral region" is ambiguous and that the jury would be left confused without a construction of this term. Fujinon's proposed constructions do little to reduce either the ambiguity or risk of confusion. I also agree with Motorola that the '253 patent indicates where the "peripheral region" is to be found: "outside 70% of the radius" of the lens. The Abstract states that "the peripheral region of the third lens component, outside 70% of its radius, has positive refractive power." '253 patent Abstract (JCCC at M00016); see also Netcraft v. eBay, 549 F.3d 1394, 1398 (Fed. Cir. 2008) (affirming district court's construction after finding support for it in patent's Abstract).

I do not agree, however, with Motorola's suggestion that the "peripheral region" must include the entirety of the area outside 70% of the radius. See Tr. at 71-72. According to Motorola, only the area from 71-100% is the "peripheral region;" subparts of that area are not, in Motorola's view, part of the "peripheral region." In other words, Motorola contends that if something happens in just the 91-100% area, for example, then that something is not happening in the "peripheral region." This is inconsistent with the specification, which explains that in the "peripheral region" the third lens component will have "positive refractive power," and adds that "the lens region that has positive refractive power is set at a relatively distant position from the optical axis X." '253 patent, col. 3 lines 58-60 & col. 4 lines 35-44 (emphasis added)(JCCC at M00007)

These statements indicate that something happening in the positive refractive region "at a relatively distant position" from the optical axis X is happening in the peripheral region. Accordingly, I conclude that there is no basis to exclude from "peripheral region" any portion or subpart of the entire peripheral region.

Therefore, I recommend that the Court construe the "peripheral region" as "any portion of the region that begins outside 70% of the radius of the third lens."
E. The side edge and peripheral side edge

The terms "peripheral side edge" and "the side edge" refer to the position on the motherboard of the mating connector for the riser card ("a mating connector for a riser card, said mating connector situated on the motherboard and adjacent and parallel to a peripheral side edge thereof") 87 and the location and orientation of the riser card and any attached expansion boards when the riser card is plugged into the mating connector ("said riser card being oriented with respect to the motherboard such that each one of the plurality of expansion boards inserted into a corresponding one of said expansion connectors is oriented in a direction substantially parallel to a horizontal plane of the motherboard and extends inward from a vicinity of the side edge towards a central portion of the motherboard"). 88

1. Parties' positions

As with the disputed term "riser card," Tulip has offered several definitions for the term "peripheral side edge. In its final Markman brief, Tulip proposes giving the words of the phrase "peripheral side edge" their ordinary and accustomed meanings and construing the disputed phrase to mean "an edge on a side at the periphery of the motherboard, as contrasted to an edge on the front or back of the motherboard." 89 Dell contends that the phrase has no clear meaning and is indefinite. If any meaning can be ascribed to the phrase, Dell suggests that, "edge" means a line where the motherboard ends, "side edge" means a long edge, rather than a short edge or end, of a rectangular motherboard, and "peripheral side edge" means a side edge on the periphery of the motherboard.

--- Footnotes ---

89 D.I. 368 at 14. In the parties' joint submission of disputed terms, Tulip suggested "peripheral side edge" be defined as: "a side on the periphery of the motherboard." D.I. 308 at 6. In its initial Markman brief, Tulip defines "peripheral side edge" as: "one of the sides at the periphery of the motherboard, as contrasted to the front or back edge of the motherboard." D.I. 326 at 13.
--- End Footnotes ---

Tulip contends that "peripheral" has an ordinary and accustomed meaning of "pertaining to, constituting, or of the nature of a periphery." 90 Tulip suggests the ordinary and accustomed meaning of "side" is "(a) any of the lines or surfaces that bound or limit something; as, a square has four sides, a cube six; (b) any bounding line or surface of an object other than the ends or top and bottom; (c) either of the two bounding surfaces of an object that are distinguished from the front, back, top, and bottom." 91 Tulip states that the ordinary meaning of "edge," is "the abrupt border or margin of anything; the brink, as the edge of the table; the edge of a precipice." 92 These ordinary meanings, Tulip contends, support a construction of the phrase "peripheral side edge" as a border on the periphery of a motherboard which is not the front, back, top, or bottom. Tulip argues further that its use of the indefinite article "a" ("a peripheral side edge thereof"), indicates that the claimed peripheral side edge of a motherboard is not limited to a single peripheral side edge running the entire length of the motherboard but also encompasses a side edge on the periphery of the motherboard that may extend across a portion of that length if, for example, a motherboard was not rectangular or had an irregular side edge. Tulip contends that its proposed construction is consistent with the disclosure of a preferred embodiment recited in the '621 patent's specification reciting, "FIG. 2 shows how, in accordance with the invention, by moving the connector 22 for the riser card 23 to the side of the motherboard 21, the above-outlined problems are obviated and additional advantages are obtained." 93
Tulip suggests that the phrase "the side edge" be construed to mean the "peripheral side edge" (according to Tulip's proposed construction) of the motherboard adjacent to the connector for the riser card. Tulip argues that the antecedent basis for "the side edge" is "a peripheral side edge," introduced earlier in the claims. Tulip also points out that there is no language in the specification which refers to the relative lengths of the sides of the motherboard, as is included in Dell's proposed construction.

Dell contends that the meaning of the term "the side edge" is clear from the language of the claims. Dell states that the term "edge" should be given its ordinary meaning of a line where the motherboard ends and that "side edge" should be construed to mean the longer edge, rather than a shorter edge or end, of a rectangular motherboard. Dell insists that the terms "side" and "edge" must be given different meanings or those terms would be redundant. Dell argues that its construction is also consistent with the specifications of the '621 patent and points to Figure 4 where the motherboard 41 includes four edges: two sides (or longer edges) and two ends (or shorter edges). The riser card 43 is located along one of the two sides or longer edges. Dell also directs the court's attention to Figure 2 which shows that the expansion boards inserted into the riser card 23 extend inwardly from one of the two side edges toward a central portion of the motherboard 21.

Dell argues that because the phrase "peripheral side edge" is not clearly defined within the language of claims 1 and 2, and since "peripheral side edge" is not referenced in the written description or prosecution history, this court should determine that the phrase is indefinite. Dell contends that if the court disagrees with its argument that the term is indefinite, since "peripheral" is qualified by the term "thereof," the only proper reference point is the motherboard and the phrase must be construed to mean either of the side edges on the periphery of the rectangular motherboard. Although Dell argues this construction is proper, it contends that the word "periphery" in this construction is surplusage.

Dell maintains that Tulip improperly suggests a construction where "the side edge" and "peripheral side edge" be given the same meaning. Such a construction, Dell argues, is contrary to the principal of claim construction that different terms used in a claim should be construed differently. Dell also urges the court to reject Tulip's antecedent basis argument for construing the two phrases identically. Dell points out that the phrase "a peripheral side edge" is properly the antecedent "the peripheral side edge" not "the side edge." Dell notes that original claims 1 and 2 referred had a single reference to a "side edge" but did not include the word "peripheral." 94 Claims 1 and 2 of the '621 patent as issued contain the two references to "side edge" contained in the disputed phrases. The word "peripheral" precedes the first reference to "side edge" but not the second reference to "side edge." Dell argues that if Tulip intended the phrase "a peripheral side edge" to serve as the antecedent for the phrase "the side edge," the word "peripheral" would have been included before both references to "side edge."

2. Court's construction

The parties agree that "peripheral side edge" and "side edge" refer to the motherboard. The parties' proposed definitions of
"edge" are consistent with the definition of that word as "the line or point where a material object or area begins or ends: BORDER." 95 The parties disagree as to how "side" is to be defined so as to give that word a different meaning from "edge." The court disagrees with Dell's suggestion that "side" means the long, as opposed to the short, edges of a rectangular motherboard. There is no claim element referencing the relative lengths of the edges of the motherboard. In fact, there is no evidence in the specification or prosecution history that necessitates narrowing the scope of Tulip's invention to a rectangular motherboard. That being the case, the '621 patent could cover a square motherboard whose edges are, by definition, all the same length; a shape to which Dell's proposed construction could not be applied. The court also disagrees with Dell's argument that Figures 2 and 4, showing a rectangular motherboard having the mating connector for the riser card along one of the longer edges of that motherboard, support its proposed construction. Accepting Dell's argument would improperly narrow the claims at issue to a preferred embodiment illustrated by those figures.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

The court agrees with Tulip's suggestion that the "side" the motherboard referred to in the disputed term is an edge of the motherboard which is not a front edge or a rear edge of the motherboard. 96 This construction gives a different meaning to the words "side" and "edge" and can be applied to motherboards of differing shapes (whether rectangular, square, or as Tulip posits, having an irregular shape). Therefore, the court construes "side edge" to be the border of the motherboard which is not the front or rear of the motherboard.

96 See WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 2111 (1993) (defining "side" as "one of the surfaces or surface parts of an object which are distinguished … from the front or back as being more or less perpendicular to the observer").
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

The addition of the modifier "peripheral" to "side edge" is somewhat perplexing. Peripheral is an adjective referring to the periphery of something, here a "side edge." Periphery is defined as "the outward bonds of something as distinguished from its internal regions or center." 97 Periphery and edge (when referring to a border, as here) are synonyms 98 so it is unclear what, if anything, the word "peripheral" adds to the phrase "side edge." Tulip's proposed construction of the phrase "peripheral side edge" ("an edge on a side at the periphery of the motherboard, as contrasted to an edge on the front or back of the motherboard") attempts to define the disputed phrase using "periphery" without suggesting how "periphery" adds meaning to the phrase. Indeed at oral argument, Tulip appeared to concede that the word "peripheral" does not add additional meaning to the phrase "side edge." When asked to distinguish "peripheral side edge" from "side edge" Tulip responded that "peripheral side edge and side edge are mutually reinforcing terms. They're saying the same thing. They are not trying to define different terms." 99 Like Tulip's proposed construction, Dell's definition of "peripheral side edge" as "a side edge on the periphery of the motherboard" is no different in scope than the court's construction of the phrase "side edge." For the reasons that follow, the court determines that the word "peripheral" and "edge" are redundant and construes the disputed phrase "peripheral side edge" to have the same meaning as the disputed phrase "side edge."

There is no evidence, and neither party argues, that the disputed phrases are referring to different locations on the motherboard or that "peripheral side edge" is intended to refer to a more limited area than "side edge." 100 As Dell points out, the single reference to a "side edge" was not modified by the word "peripheral" in claims 1 and 2 as originally filed. During prosecution, original claims 1 and 2 were cancelled and the claims that ultimately issued as claims 1 and 2 in the '621 patent were added by amendment and included two references to the phrase "side edge," the first of which included the modifier "peripheral." As explained above, however, the cancellation of original claims 1 and 2 was in response to an obviousness rejection which had nothing to do with the definition of the phrase "side edge." The modifier "peripheral" was not added to avoid the referenced prior art and the applicant's comments with regard to the claims in the amendment did not discuss the phrase. 101

100 Tulip did argue that, in order to give some meaning to the word "peripheral," the court could construe the disputed phrase "to refer to the side edge of the motherboard that is closest to an outer side wall (i.e., a periphery) of the computer housing." D.I. 383 at 9. This would not be a reasonable construction as ascribing such meaning to the term requires reference to the computer housing. A computer housing is not mentioned in either claim 1 or 2. Additionally, the claim language recites, "said mating connector situated on the motherboard and adjacent and parallel to a peripheral side edge thereof." '621 at 5:66-6:1 (claim 1); Id. at 6:38-40 (claim 2) (emphasis added). That language unambiguously refers to the peripheral side edge of the motherboard. Moreover, the parties are in agreement that the disputed term is directed to a location on the motherboard. The court will not adopt Tulip's tortured alternative construction by interpreting two words of the disputed phrase, "side" and "edge," as referencing the motherboard and the third word, the adjective "peripheral," as referring to a structure not mentioned in either claim at issue, the computer's housing.

101 The fact that "peripheral" was not added during prosecution to narrow the scope of coverage of "side edge" distinguishes this case from CAE Screenplates Inc. v. Heinrich Fiedler GMBH & Co. KG, 224 F.3d 1308 (Fed. Cir. 2000), which Dell cites for the uncontroversial proposition that different claim terms should be construed differently. There, the court determined from the language of substituted claims, and the applicant's arguments to the examiner contained in the prosecution history, that the applicant had narrowed the scope of its claim to avoid prior art referenced in an anticipation rejection. Id. at 1317-18. Significantly, and contrary to the facts of this case, the changes that further defined and narrowed the applicant's claims in CAE Screenplates were made to the claim term whose meaning was in dispute. Similarly in Jack Guttman, Inc. v. Kopykake Enterprises, Inc., 302 F.3d 1352 (Fed. Cir. 2002), the court determined, when construing the term "tortuous bend" that the dictionary definition of "tortuous," ("marked by repeated twists, bends, or turn") could not be used to define the disputed phrase "because [that definition] simply makes the phrase 'tortuous bend' redundant, without providing any insight into the crucial issue of how curved a bend may be before it becomes 'tortuous' within the meaning of claim 11." Id. at 1357 (emphasis added). There, the construction of the disputed phrase "tortuous bend" was crucial to the court's determination of whether the plaintiff in that case had a reasonable likelihood of success on its infringement claim. Here, the plaintiff is not basing its infringement allegations on a distinction between the phrase "peripheral side edge" and "side edge" and the defendant is not proposing a more narrow definition of the phrase "peripheral side edge" which would avoid its products alleged infringement of the '621 patent. In fact, Dell responded to the court's question at oral argument, "is there any example of edge that's not also in the periphery?" by stating, "no. I think they're redundant with each other." D.I. 396 at 78. The effect, if any, of that redundancy will be addressed in this court's opinion on Tulip's motion for summary judgement of validity under 35 U.S.C. § 112 (D.I. 336) in which Tulip challenges Dell's argument that the phrase "peripheral side edge" is so ambiguous so as to make the '621 patent invalid.

Next, this is not a case where considerations of claim differentiation come into play. Both claims 1 and 2 have identical bodies, each reciting both disputed phrases. Neither claim is rendered surplusage if the court construes "peripheral side edge" and "side edge" to have the same meaning. Furthermore, none of the other claims of the '621 patent, those not at issue in this case, are rendered surplusage by that determination.

Finally, Tulip suggests that "a peripheral side edge" provides the antecedent basis for "the side edge" and contends that this further supports its position that both phrases refer to the same area of the motherboard. Although Dell is correct in pointing out that according to standard claim drafting "a peripheral side edge" is the proper antecedent for "the peripheral side edge," there is no other antecedent basis in the claims for the phrase "the side edge" other than the disputed phrase "a peripheral

- 3456 -
side edge." A review of the intrinsic record convinces the court that, despite an apparent sloppiness in claim drafting, the two references to "side edge" are do have the same meaning.

Nothing in the intrinsic evidence has been cited to, or discovered by, the court which indicates that the adjective "peripheral" changes, or adds to, the meaning of the phrase "side edge." 102 Because the court finds that word "peripheral" is synonymous with the word "edge" as a reference to the border of the motherboard, the court construes "peripheral side edge" as having the same meaning as "side edge," the border of the motherboard which is not the front or rear of the motherboard.

--- Footnotes ---

102 The extrinsic record before the court also fails to suggest a meaning for the phrase "peripheral side edge" that is different from the meaning of the phrase "side edge." During his deposition, Tulip's expert Ronald S. Bader, was asked, "in 1994 or prior thereto, had you personally ever used the term peripheral side edge in connection with your work as an engineer?" Bader answered, "no. I have not. That's an interesting term." D.I. 370, Ex. 14 at 197. Nevertheless, Bader stated in his expert report that a person of ordinary skill in the art would understand the phrase "peripheral side edge" to have an ordinary and accustomed meaning of "border or margin." D.I. 326, Ex. D at 8. That meaning is merely a definition of the word "edge" and fails to give the words "peripheral" and "side" any effect at all.

--- End Footnotes ---

2899

1. ":[A] peripheral zone being defined adjacent the peripheral edge of the anterior face that is tapered thinner toward the peripheral edge of the lens." Used in '740 patent, claim 1.

"[A] peripheral zone being defined adjacent the peripheral edge of the lens that tapers thinner toward the peripheral edge of the lens." Used in '903 patent, claim 29, 34, 38.

"[A] peripheral zone adjacent the peripheral edge of the anterior lens." Used in '746 patent, claim 1.

CooperVision proposes "a portion of the lens with a decreasing thickness to provide a ramp from a ballast periphery to the lens edge, to create a comfort zone around the edge of the lens." CIBA contends that this term should mean "a zone or region on the anterior face of the lens that is tapered thinner toward the peripheral edge of the lens, is located adjacent to the peripheral edge, and that circumscribes and is separated from the INNER ZONE by either a curved or rounded transition (i.e., an area of the lens that creates a smooth junction between adjacent curvatures) or by a discrete boundary, discontinuity or corner (collectively, 'boundary'). The boundary separating the zones is the only such identifiable boundary between the peripheral edge and the boundary of the optic zone."

The parties do not dispute that a peripheral zone can be construed similarly among the Toric patents. The claim language describes a contact lens comprising a contact lens body with an anterior face, a posterior face, and "a peripheral edge there between with a peripheral zone being defined adjacent the peripheral edge of the anterior face that is tapered thinner toward the peripheral edge of the lens body." '740 patent, col. 11, ll. 42-46.

The present invention includes three zones on the anterior face of the lens: an optic zone, an inner zone, and a peripheral zone circumscribing the inner zone. '903 patent, col. 4, ll. 5-7; col. 5, ll. 50-55. Although smooth, rounded transitions between the different zones are preferred, discrete boundaries or corners are not excluded. '903 patent, col. 10, ll. 15-17. The peripheral zone is adjacent to the peripheral edge of the lens and tapers so as to be thinner at the lens edge than at the inner zone. '903 patent, col. 3, ll. 65-67; col. 6, ll. 6-7. This taper within the peripheral zone provides a "so-called" comfort zone around the edge of the lens. '903 patent, col. 9, ll. 5-7. Because of the reduced thickness, movement of the eyelids across the contact lens is facilitated, and there is less irritation. Id.

CooperVision's assertion that the peripheral zone extends to a ballast periphery is unsupported by the specification. The specification provides that the inner zone has a circular ballast periphery that is slightly offset toward the top of the lens.
along a vertical meridian. '903 patent, col. 6, ll. 3-5 (emphasis added). The ballast surface may be contained wholly within
the inferior portion of the inner zone. '903 patent, col. 6, ll. 59-61; col. 10, ll. 39-44. If CooperVision's construction is
adopted, then the peripheral zone would encompass a large portion of the lens, rather than around the edge of the lens, when
the ballast surface is contained wholly within the inferior portion. This would contradict what is required by the patents. See
'903 patent, col. 9, ll. 5-6. Although in one "exemplary embodiment" discussed in '903 patent, col. 7, ll. 48-50, the lens
tapers downward within the peripheral zone between the ballast periphery to the inferior edge, the court will not import
limitations from a preferred embodiment into the construction of claims. Electro Med. Sys. S.A. v. Cooper Life Sciences,
Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994).

In its proposed construction, CIBA places the limitation that there can only be one transition between the optic zone and the
peripheral edge of the lens. CIBA also states that there must be distinct boundaries between each zones. The court rejects
this construction based on Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1374 (Fed. Cir. 2005). There, the Federal
Circuit followed the maxim that claims will not be read restrictively unless the patentee has demonstrated a clear intention
to limit the claim scope using words or expressions of manifest exclusion or restriction. In that case, the patent-in-suit
claimed a wet-shave safety razor with multiple blades. Id. at 1369. Specifically, the patent claimed a "safety razor
comprising . . . a group of first, second, and third blades," but the defendant manufactured a four-blade safety razor. Id. After
reviewing the patent specification, the Federal Circuit determined that the invention relates to safety razors having blade
units with a plurality of blades and despite numerous cites to three-bladed razors, "no statement in the patent surrenders or
excludes a four-bladed razor." Id.

The written description of the Toric Patents is similar to the written description in Gillette in that the written description
defines a claim term but nonetheless provides a disclosure of examples of limited scope. The specification states that the
anterior face defines a "plurality of zones thereon . . . ." In fact, the patentee stressed that "although the present application
describes distinct zones or portions in contact lenses, those zones are shown for clarity of description of the invention
only. . . . [T]here are no sharp distinctions between-these different zones of the lens, but that, they are instead smoothly
blended into one another." '903 patent, col. 8, ll. 62-67.

Moreover, the specification teaches:

the clear delineations in the drawings between the optic zone 22 peripheral zone 24 and inner zone 26 should not be taken
to imply that there is a discontinuity or corner at those locations, and in fact the exemplary lens of the present invention
possesses gradually curved transitions between the zones. '903 patent, col. 8, ll. 62-67.

Analogously, between the different portions (i.e., superior, intermediate, and inferior) the present invention may have either
smooth, rounded transitions or discrete boundaries or corners. '903 patent, col. 10, ll. 15-17.

There is no authority for the addition of superfluous limitations in claim construction, and certainly not from description of
the preferred embodiment, even if they may later be useful to the infringement analysis of a party. The claim language at
issue involves only the peripheral zone, and the court will not include additional language involving the number of zones or
transitions. That is a matter for another time.

The court defines these terms as follows:

"[A] peripheral zone being defined adjacent the peripheral edge of the anterior face that is tapered thinner toward the
peripheral edge of the lens" and "a peripheral zone being defined adjacent the peripheral edge of the lens that tapers thinner
toward the peripheral edge of the lens" and "a peripheral zone adjacent the peripheral edge of the anterior lens" means: A
zone or region on the anterior face of the lens located adjacent to the peripheral edge, and that circumscribes and is
separated from the inner zone by either a curved or rounded transition or by a discrete boundary, discontinuity or corner.
The zone has a decreasing thickness toward the peripheral edge of the lens to provide comfort to the wearer.

11. Permanently
Defendants' Proposed Construction: "Permanently" means affixed to an "object" or "container" such that a placard permanently attached or affixed to the substrate cannot be removed without damaging the placard or the "object" or "container."

Plaintiff's Proposed Construction: "Permanently" means capable of continuing or enduring through multiple cycles of labeling and relabeling of the container.

The Court's Claim Construction: "Permanently" means affixed to an "object" or "container" such that a placard permanently attached or affixed to the substrate cannot be removed without damaging the placard or the "object" or "container."

Defendants first note that all of the claims at issue involve "substantially permanently attaching" or "substantially permanently affixing" a placard to a container or an object, yet none of those claims mention the removal of the placard after it is attached or affixed. Similarly, the patent specification does not discuss the possibility of removing the placard once it has been attached to a the container. This supports Defendants' definition of permanently.

MPT counters that there is no reason that removal of a placard from a container must cause damage to one of these items. MPT draws support for its definition from the patent specification, which generally describes multiple applications of pressure sensitive adhesive labels on the release coated face of the placard. (‘790 patent, col. 1, ln. 49-54, col. 2, ln. 47-57). The implication is that the only requirement for a permanently attached placard is that it is attached in a manner that allows for the repeated application of labels. MPT also draws support from a lay dictionary definition of permanent as "continuing or enduring (as in the same state, status, place) without fundamental or marked change . . . ."

Defendants also rely on the specification. One of the advantages of the invention is the ability to release a label even if it has a "so called permanent adhesive backing" such that "inexpensive permanent pressure sensitive adhesive coatings rather than more expensive removable coatings" may be used. (‘790 patent, col. 1, ln. 52-3, col. 2, ln. 65-68). During prosecution, a permanent adhesive was described as follows:

Permanent: An adhesive designed to stick to a substrate without edge lifting that cannot be removed without damaging either the label or the substrate.
Removable: An adhesive designed to stick to a substrate without edge lifting that can be removed without damage to either the label or the substrate.

(‘882 file, p. 51).

If permanent means something that "cannot be removed without damaging either the label or the substrate," it follows that a permanently attached placard could not be removed without damaging the placard or the container. Industry publications provide the following definitions:

"PERMANENCY A measure of an adhesive's ultimate holding power or bond strength. A permanent adhesive will develop a bond that makes label removal difficult or impossible without distorting the face stock." (TLM p. 43).

"PERMANENT ADHESIVE An adhesive characterized by having relatively high ultimate adhesion to a wide variety of surfaces." (TLM p. 43).

"A label is considered permanent if the bond to the substrate makes removal difficult or impossible without distorting the facestock or damaging the substrate." (Fasson p. 6).

MPT does not dispute these definitions. Instead, it argues that they are inapplicable, since the specification's reference to a permanent adhesive was with respect to the labels, not the placard. Although the Court recognizes the distinction, it does not support a different definition in the claims. For example, Claim 1 of the '790 patent describes the process of "substantially permanently attaching the placard to the object . . . using said adhesive coated face [of the placard] . . . ."

There is no indication that an adhesive used to "permanently attach" the placard to the container would be any different than the permanent adhesive of a label. Therefore, the Court adopts the definition of "permanently" proposed by Defendants. 32

Claim 6 of the ‘790 patent and Claim 1 of the ‘164 patent do not recite a placard adhesive face. However, MPT has made no argument that these claims should be treated differently with respect to their use of the term permanently. Because MPT has applied the same definition to all instances of permanently, and Claims 1 and 4 must adopt the definition supplied by Defendants, the Court applies this definition to all instances of permanently.
K-2 Corporation ("K-2") is the owner of reexamined U.S. Patent No. 5,437,466 ("the '466 patent"), issued August 1, 1995, entitled "In-Line Roller Skate." The '466 patent is generally directed to an in-line skate that has a soft, pliable inner "bootie" or "shoe" surrounded in certain areas by molded plastic or straps affixed to the base of the skate. This arrangement allows the wearer's foot to breathe and offers a substantially lighter skate while retaining structural stiffness required for performance.

Claims 1, 5, and 6 of the '466 patent are the only claims at issue in this case. Representative claim 1 recites five major claimed components, as set forth in brief form below with the key limitation underlined:

1. In an in-line roller skate having
   an upper shoe portion and a lower frame portion . . .
   a non-rigid shoe portion adapted to receive and substantially enclose the entire foot of the skater . . .
   support means positioned adjacent selected areas of said non-rigid shoe portion for providing support to aid the skater in maintaining said in-line roller skate in a substantially vertical position . . . and
   a base portion, . . .
   said non-rigid shoe portion being permanently affixed to said base portion at least at said toe area and said heel area for substantially preventing movement therebetween at least in a horizontal plane, wherein at least a portion of said non-rigid shoe portion extends continuously from said base portion to at least the top of said ankle support cuff.

Claims 5 and 6 contain what the parties agree is equivalent language with respect to the key limitation:

5. . . .
   said non-rigid shoe portion being permanently interconnected with said base portion at least at said toe area and said heel area for substantially preventing movement therebetween at least in a horizontal plane . . .

6. . . .
   said non-[rigid] upper portion being non-removably affixed to said rigid base adjacent both said heel and toe portions of said base for substantially preventing movement therebetween at least in a horizontal plane . . .

Salomon S.A. and Salomon North America (collectively, "Salomon") make and sell an in-line skate, designated as model TR, that includes a soft inner bootie surrounded by a rigid plastic structure ("the TR skate"). The TR skate's inner bootie is fastened to the lower, rigid portion of the skate by the use of rivets and a screw in the toe area and by a removable hex-head screw in the heel area. The parties agree that the dispositive issue in this case is whether the use of a removable screw in the heel area of the TR skate can meet the "permanently affixed" limitation found in claims 1, 5, and 6 of the '466 patent.

In April 1998, K-2 sued Salomon for infringement of the '466 patent. On cross-motions for summary judgment, the district court rejected K-2's arguments that the disputed "permanently affixed" claim limitation should be construed to be synonymous with "affixed," "secured," or "firmly held," and instead held that the ordinary meaning of "permanently
affixed" could not encompass the removable screw used in the heel area of the TR skate. See K-2 Corp. v. Salomon S.A., 1998 U.S. Dist. LEXIS 21869, 50 U.S.P.Q.2D (BNA) 1054, 1056 (W.D. Wash. 1998). The court determined that because the TR skate was missing an element of the '466 patent claims, it could not, as a matter of law, literally infringe those claims. See id.

The district court also held that the TR skate could not, as a matter of law, infringe under the doctrine of equivalents because of prosecution history estoppel. See 50 U.S.P.Q.2D (BNA) at 1057. The court concluded that in amending the relevant claims during prosecution and examination to add the "permanently affixed" limitation and the heel and toe locations of the fastening, K-2 had relinquished coverage of in-line skates that did not have a bootie permanently affixed at both the heel and the toe. See id. The court further noted that the relevant prosecution history suggested that K-2 amended the claim to avoid a prior art reference, U.S. Patent No. 5,331,752 to Johnson ("the Johnson reference"), that discloses an in-line skate in which the bootie is removable and affixed at the toe and mid-foot. See id. The district court concluded that K-2's relinquishment of such subject matter prevented it from now asserting that the heel screw of Salomon's TR skate was equivalent to the "permanently affixed" limitation of the '466 claims. Summary judgment of noninfringement was granted in favor of Salomon. See id.

II

We review the grant of summary judgment de novo. See Conroy v. Reebok Int'l, Ltd., 14 F.3d 1570, 1575, 29 U.S.P.Q.2D (BNA) 1373, 1377 (Fed. Cir. 1994). In doing so, we must keep in mind that summary judgment is appropriate only if there is no genuine issue of material fact. See Fed. R. Civ. P. 56(c). To this end, the court must draw all reasonable factual inferences in favor of the nonmovant. See Anderson v. Liberty Lobby, Inc., 477 U.S. 242, 255, 91 L. Ed. 2d 202, 106 S. Ct. 2505 (1986).

An infringement analysis is a two-step process in which the court first determines, as a matter of law, the correct claim scope, and then compares the properly construed claim to the accused device to determine, as a matter of fact, whether all of the claim limitations are present in the accused device, either literally or by a substantial equivalent. See Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1247-48, 48 U.S.P.Q.2D (BNA) 1117, 1120 (Fed. Cir. 1998); General Mills, Inc. v. Hunt-Wesson, Inc., 103 F.3d 978, 981, 41 U.S.P.Q.2D (BNA) 1440, 1442 (Fed. Cir. 1997); Young Dental Mfg. Co. v. Q3 Special Prods., Inc., 112 F.3d 1137, 1141, 42 U.S.P.Q.2D (BNA) 1589, 1592 (Fed. Cir. 1997). See also Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454, 46 U.S.P.Q.2D (BNA) 1169, 1172-73 (Fed. Cir. 1998) (en banc).

Because the relevant aspects of the accused device's structure and operation are undisputed in this case, the question of whether Salomon's TR skate literally infringes the asserted claims of the '466 patent turns on the interpretation of those claims. See Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1578, 37 U.S.P.Q.2D (BNA) 1365, 1370 (Fed. Cir. 1996) ("Where, as here, the parties do not dispute any relevant facts regarding the accused product but disagree over [claim interpretation], the question of literal infringement collapses to one of claim construction and is thus amenable to summary judgment.").

We begin, of course, with the language of the claims. See Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120; Abtox, Inc. v. Eexitron Corp., 122 F.3d 1019, 1023, 43 U.S.P.Q.2D (BNA) 1545, 1548 (Fed. Cir. 1997); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995). The general rule is that terms in the claim are to be given their ordinary and accustomed meaning. See Johnson Worldwide Assoc., Inc. v. Zebo Corp, 175 F.3d 985, 989, 50 U.S.P.Q.2D (BNA) 1607, 1610 (Fed. Cir. 1999); Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121; York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996). That is, the ordinary and accustomed meaning of a disputed claim term is presumed to be the correct one, see Johnson Worldwide, 175 F.3d at 989, 50 U.S.P.Q.2D (BNA) at 1610, subject to the following. First, a different meaning clearly and deliberately set forth in the intrinsic materials--the written description or the prosecution history--will control. See id.; In re Paulsen, 30 F.3d 1475, 1480, 31 U.S.P.Q.2D (BNA) 1671, 1674 (Fed. Cir. 1994); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387-88, 21 U.S.P.Q.2D (BNA) 1383, 1386 (Fed. Cir. 1992); Lear Siegler, Inc. v. Aeroquip Corp., 733 F.2d 881, 888-89, 221 U.S.P.Q. (BNA) 1025 (Fed. Cir. 1984). Second, if the ordinary and accustomed meaning of a disputed term would deprive the claim of clarity, then further reference must be made to the intrinsic--or in some cases, extrinsic--evidence to ascertain the proper meaning. See
Johnson Worldwide, 175 F.3d at 990, 50 U.S.P.Q.2D (BNA) at 1610-11. In either case, a party wishing to alter the meaning of a clear claim term must overcome the presumption that the ordinary and accustomed meaning is the proper one, demonstrating why such an alteration is required. See Johnson Worldwide, 175 F.3d at 989-90, 50 U.S.P.Q.2D (BNA) at 1610.

**Here the critical claim language is "permanently affixed."** The parties agree that the relevant language in claims 5 and 6 is equivalent, and there is no dispute about the meaning of "affixed" in this context. Thus, our analysis begins with the ordinary and accustomed meaning of the term "permanently" in the phrase "permanently affixed." The ordinary and accustomed meaning of this phrase, as the district court noted, see K-2, 50 U.S.P.Q.2D (BNA) at 1056, does not encompass affixation via removable screw. That is, the ordinary and accustomed meaning of "permanently affixed" in this context requires that the fastening be unremovable.

K-2's primary argument is that the functional language in the claim following this limitation--"for substantially preventing movement therebetweent at least in a horizontal plane"--dictates the meaning of "permanently affixed." That is, K-2 suggests that the inclusion of this functional language converts the meaning of "permanently affixed" to mean "affixed to prevent movement in at least a horizontal plane." We cannot accept this reading of the claim. The functional language is, of course, an additional limitation in the claim. See, e.g., Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1443-44, 43 U.S.P.Q.2D (BNA) 1837, 1840 (Fed. Cir. 1997) (functional language analyzed as a claim limitation). This limitation requires that the attachment between the bootie and the base "substantially prevent[]" movement of the bootie (and presumably, the user's foot when inserted in the bootie) in a horizontal plane. In other words, the functional language requires that the attachment prevent the bootie from sliding around on top of the base; it demands a structural rigidity in the horizontal dimension to the connection between the bootie and the base. It also, as K-2 correctly notes, may be accomplished with an attachment that is easily removable, or at least something less than permanent. But it is undeniable that this language is fully consistent with a permanent attachment as well. That is, the functional language tells us something about the structural requirements of the attachment between the bootie and the base; it speaks not at all, however, about whether that attachment is permanent, something less than permanent, or entirely removable. The only answer to that question, of course, is the specific claim limitation that the bootie be "permanently affixed" to the base. K-2 reads the functional language in a way that would effectively expunge the term "permanently" from the claim language. Cf. Perkin-Elmer Corp. v. Westinghouse Elec. Corp., 822 F.2d 1528, 1533 n.8, 3 U.S.P.Q.2D (BNA) 1321, 1325 n.8 (Fed. Cir. 1987) ("Specific claim limitations cannot be ignored as insignificant or immaterial in determining infringement."). A more natural construction reads the two clauses as complementary, recognizing that "permanently affixed" requires an unremovable attachment, while the functional language requires that the attachment prevent sliding. See, e.g., Renishaw, 158 F.3d at 1250, 48 U.S.P.Q.2D (BNA) at 1122 (Fed. Cir. 1998) ("The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction.").

While the claim itself provides no reason to alter the ordinary and accustomed meaning of "permanently affixed," K-2 may (and does) argue that the intrinsic evidence clearly sets forth an alternate definition. See Beachcombers v. Wildewood Creative Prods., Inc., 31 F.3d 1154, 1158, 31 U.S.P.Q.2D (BNA) 1653, 1656 (Fed. Cir. 1994) ("As we have repeatedly said, a patentee can be his own lexicographer provided the patentee's definition, to the extent it differs from the conventional definition, is clearly set forth in the specification."); Hoganas AB v. Dresser Indus. Inc., 9 F.3d 948, 951, 28 U.S.P.Q.2D (BNA) 1936, 1938 (Fed. Cir. 1993) ("Although a patentee can be his own lexicographer, as we have repeatedly said, the words of a claim will be given their ordinary meaning, unless it appears that the inventor used them differently" (internal quotations omitted)). In particular, K-2 points to amendments and arguments made in support of patentability over the prior art Johnson skate. There, the applicant stated that the addition of the term "permanently" served to distinguish the claims from the "detachable" boot disclosed in Johnson. The applicant further argued that an advantage of the permanent connection was that it avoided the sliding heel the applicant noted as a problem with the prior art. From these passages, K-2 draws a conclusion similar to that outlined above: that "permanently affixed" must mean simply "affixed to prevent sliding in a horizontal dimension." We reject this conclusion: the proposed definition of "permanently" as "preventing sliding in a horizontal dimension" does not appear with the required clarity, deliberateness, and precision to impart an unaccustomed meaning to an otherwise clear claim term. See In re Paulsen, 30 F.3d at 1480, 31 U.S.P.Q.2D (BNA) at 1674 ("Although an inventor is indeed free to define the specific terms used to describe his or her invention, this must be done with reasonable clarity, deliberateness, and precision."); Hoganas, 9 F.3d at 951, 28 U.S.P.Q.2D (BNA) at 1938-39 (finding patentee's proposed definition unsupported in the specification or prosecution history). Nowhere in the passages cited to us does the applicant squarely describe the nature of the connection (i.e., "permanently affixed") in the pending claims. Instead, the relevant language focuses on the connection in the prior art Johnson skate ("detachable") and the advantages provided by
the "permanently affixed" connection. K-2 therefore asks that we infer that the distinctions the applicant draws between the "detachable" boot in the prior art and the "permanently affixed" connection required by the claims constitute a clear explication of an unaccustomed meaning of the term "permanently." We decline, however, to adopt a proffered unaccustomed meaning with so little support in the intrinsic record. See In re Paulsen, 30 F.3d at 1480, 31 U.S.P.Q.2D (BNA) at 1674 ("The specification merely describes in a general fashion certain features and capabilities desirable in a portable computer. This description, however, is far from establishing a specialized definition [of computer].").

To be sure, the prosecution history indicates that the applicant intended to amend the claims to avoid the "detachable" connection of the Johnson skate. The same history, however, indicates that the applicant chose to add the term "permanently" to the claims in order to achieve this result. That the applicant could possibly have added terms other than "permanently" to create a patentable distinction with the asserted prior art is simply irrelevant to our claim construction task. Courts do not rewrite claims; instead, we give effect to the terms chosen by the patentee. See, e.g., Texas Instruments Inc. v. International Trade Comm'n, 988 F.2d 1165, 1171, 26 U.S.P.Q.2D (BNA) 1018, 1023 (Fed. Cir. 1993) ("To construe the claims in the manner suggested by TI would read an express limitation out of the claims. This, we will not do because 'courts do neither broaden nor narrow claims to give the patentee something different than what he has set forth'" (quoting Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 396, 155 U.S.P.Q. (BNA) 697, 701 (Ct. Cl. 1967))). Here, we hold that the district court correctly construed "permanently" according to its ordinary and accustomed meaning--that is, the phrase "permanently affixed" requires that the connection between the bootie and the base of the skate be unremovable.

K-2 argues that its proposed definition of "permanently affixed"--meaning "affixed to prevent sliding in a horizontal plane"--is the ordinary and accustomed meaning of the phrase, and that in any event, Salomon has not presented evidence to support its contention that the ordinary and accustomed meaning of the phrase is "unremovable." We, of course, recognize that the "ordinary and accustomed" meaning of a claim term will often be in dispute, irrespective of the clarity of the terms used. See Senmed, Inc. v. Richard-Allan Med. Indus., Inc., 888 F.2d 815, 819 n.8, 12 U.S.P.Q.2D (BNA) 1508, 1512 n.8 (Fed. Cir. 1989) ("Lawyers may create a 'dispute' about any word, but there is nothing ambiguous or linguistically obscure about [the disputed claim term] as used in the present claim."). But a dispute over the ordinary and accustomed meaning does not imply that such a meaning does not exist. Here, for example, we recognize that the term "permanently" has what can be said to be the flavor of infiniteness about its meaning, which might raise questions about the use of the term in this claim: even the most permanent of "permanently affixed" connections between the bootie and the base of the skate can, after all, be undone upon the total destruction of the skate itself. This, however, does not mean that because no connection between the bootie and skate can be "infinitely" permanent, there can be no ordinary and accustomed meaning for the claim term. Indeed, we would be hard pressed to describe anything as "permanent" if that term is understood to require an infinite duration. But claim construction is not philosophy; we need not wring our hands when considering the implications of a metaphysical analysis of claim terms. Instead, we need only recognize that claim construction is firmly anchored in reality by the understanding of those of ordinary skill in the art. See, e.g., Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2D (BNA) 1126, 1129 (Fed. Cir. 1996). In this case, the parties and the district court agree that the rivet and screw attachment in the toe area of the accused skate meet the "permanently affixed" claim limitations. This is so because the rivet supplies the permanent, unremovable connection. Indeed, in the written description of the '466 patent, a rivet is cited as a conventional fastening means to accomplish a permanent connection. See '466 Pat., col. 8, ll. 55-58 (describing connection between base and lower frame). The rivet-made permanent connection is of course not "infinitely" permanent, because the rivet can be broken. The same is true of an embodiment of the invention that achieved a permanent connection between the base portion and the lower frame portion of the skate by using a single injection molded unit. See id. at col. 8, ll. 58-61. Likewise, were an adhesive laminate used to provide the permanent connection, see id. at col. 13, ll. 48-55, that permanence too could be destroyed by breaking the structure apart. Screws, unlike rivets and laminates, are meant to be unscrewed, that is, to be removed. A rivet or a laminate, to the contrary, is meant to remain permanent, unremovable unless one is bent on breaking the permanent structure apart.

Here, we are convinced that the district court was correct in holding that the ordinary and accustomed meaning of "permanently affixed" requires an unremovable connection between the bootie and the base.
The third disputed phrase is "permanently affixing the resilient structure within the fallopian tube" found in claims 37 and 38. Proposed constructions are shown below:

CONCEPTUS'S PROPOSED CONSTRUCTION
"affixing the resilient structure within the fallopian tube, such that it remains (or is intended to remain) affixed in the fallopian tube for a long, indefinite period"

HOLOGIC'S PROPOSED CONSTRUCTION
"affixing the resilient structure within the fallopian tube so long as it is in the tube, e.g., is not expelled or absorbed"

At the heart of this dispute is what is meant by the word "permanently." Both parties agreed during oral argument that the term pertains to permanent contraception -- a conclusion that finds ample support in the specification (see, e.g., cols. 1:27-35, 1:57-58, 2:54-60, 7:65-67). Indeed, the specification frequently emphasized that one of the objects of the present invention was to improve upon the "unacceptably high percentage" of non-surgical intrafallopian contraceptive devices that became unintentionally dislodged (i.e., did not remain in place and were expelled) after being inserted into the fallopian tube (cols. 2:1-4, 8:46-48).

Despite this agreement, Conceptus and Hologic nevertheless propose two different constructions commensurate with their respective strategic needs. Both constructions are confusing and flawed. For example, Conceptus's proposed construction inexplicably introduces a subjective element -- "intended to remain" -- into the claim, but never explains whose subjective intent is at issue. Additionally, Conceptus would require the contraceptive device to remain "affixed in the fallopian tube for a long, indefinite period." How one would go about proving that an accused device met such a limitation is a mystery to all involved.

Hologic's proposed construction is equally confusing. Not only does it inexplicably add the limitation that the contraceptive device not be "absorbed," it equates "permanently" with simply being "within the tube." This is contrary to the plain meaning of the word "permanently" as used in the context of the claim, and would only serve to confuse the jury.

1 Hologic's last-minute argument that this phrase is indefinite is both untimely and without merit. Both parties essentially agreed at oral argument on the basic meaning of the term "permanently." The parties merely differ over the details of its construction. See Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1374 (Fed. Cir. 2001) ("If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds.").

Having considered the context of the disputed phrase within the claim language, and the fact that the specification did not impart "permanently" with a definition that was different from its plain and ordinary meaning, this order finds that no construction is required for the phrase "permanently affixing the resilient structure within the fallopian tube."

Permanently fixed to

Again, in Claim 24 of the 851 patent, the parties dispute the term "permanently fixed to" as stated in Claim 24 as follows:

"at least one protrusion permanently fixed to said first end cap…"

According to Plaintiffs, the term needs no construction, while Defendants contend it means "permanently attached and immovable relative to." The parties do not dispute the term "permanent" but do dispute whether something that is permanently fixed to something else is also necessarily immovable. Plaintiffs argue that an object - i.e an inner ring and an
outer ring may be permanently fixed together yet the inner ring may rotate inside the outer ring. Defendants argue to the contrary, contending that the general definition of fixed means "attached or placed so as to be firm and not readily moveable; stationary; rigid." Citing Expert A. Wahls Ex. 3 and Merriam Webster's College Dictionary (1999).

Court's Construction

Defendants concede there is no language in the claim or specification stating that the protrusion be immovable. In the absence of such limiting language in the claim or specification, the Court will not read such limitation onto the claim. Therefore, the Court agrees with Parker and finds "permanently fixed to" needs no construction.

5. permanently secured

Fargo affixed in such a manner as to stay in the same state or without any change that destroys form or character

Iris the pins cannot be removed without damaging the pin receiving plate

Iris contends that Fargo's definition, and specifically the phrase "stay in the same state," is vague and adds more uncertainty to the meaning of "permanently secured." Fargo contends that its definition takes into account both references in the specification, because the specification refers to the pins being prevented from falling out during shipping or use. (Fink Aff., Ex. B.) The Court agrees with Iris, however, that the second part of Fargo's definition adequately encompasses the first. If, as both parties agree, the pins are secured so as to be incapable of removal without damage, they are also secured so as not to fall out accidentally. In contrast, Fargo's definition itself would require further construction concerning the meaning of the phrase "stay in the same state." The Court accordingly adopts Iris's definition of the term.

The court construes the second limitation of claim 23, "a permeable membrane gas separation system for separating a nitrogen gas component and [a nitrox] component from said compressed air," as follows: The structure for the separation system is a standard, commercially available, permeable membrane, nitrox and nitrogen gas separation system. (‘845 patent, col. 3, lines 60-66.) The limitation is further narrowed by specifying a function for the element, namely to separate the compressed air into nitrogen and nitrox components.

C. "permitting compression"; "such that compression and rebound of said fork are permitted"

The parties again agree on part of the construction; that "permitting" means "allowing." They differ on the construction of "compression." SRAM argues that the term needs no further definition, and that to the extent that it is further construed, it should be given the term's plain meaning. Fox argues that "compression" should be construed as "the pair of inner tubes of the fork slide into the pair of outer tubes of the fork." "Compression" needs no further construction; its meaning is clear and ordinary. Fox's proposed construction states the means by which compression is accomplished within the structure described by Claim 16; it does not define the term itself. The parties also disagree on the construction of "rebound" in the second phrase. SRAM again argues for no construction or for plain meaning; Fox argues for "the pair of inner tubes of the fork slide out or the pair of outer tubes of the fork." The plain meaning here - that "rebound" means "expansion" - is appropriate. The terms are used interchangeably throughout the ’049 Patent. (1:38-39; 9:8-17) To the extent that these phrases require construction, they should be read as "allowing compression" and "such that compression and expansion of said fork are allowed."
a. "personal delivery pattern"

i. The Parties' Proposed Construction

Smiths argues that I should construe the term "personal delivery pattern" to mean "an individual pattern of multiple infusion rates." (D.I. 165 at 36.) MiniMed argues that I should construe the term to mean an "individual pattern of multiple basal rates to be infused into a user over a 24 hour period." (Id.)

Smiths argues that MiniMed's construction imports limitations, specifically the "24 hour" and "basal rate" requirements, found nowhere in Claim 10 and unsupported by the specification. (D.I. 218 at 38.) MiniMed argues that the specification and prosecution history support this construction. Specifically, one of the preferred embodiments describes a "delivery pattern" as being programmed to operate over 24 hours. (‘798 patent, col. 27:1-16.) To support its argument that the term be construed to cover only basal rates, MiniMed cites to a response to an office action. (D.I. 169 at 35.) In that response, the patentee overcame the prior art by pointing out that "the ability to switch between bolus and basal rates is not the same as the at least two personal delivery patterns . . . [and that] there is no pattern since one merely switches between two rates." (D.I. 207, Ex. J at 35.) MiniMed argues that the patentee "overcame prior art rejections specifically by distinguishing between basal delivery and bolus delivery." (D.I. 169 at 36.)

ii. The Court's Construction

"Personal delivery pattern" means "an individual pattern of multiple infusion rates." "Personal delivery pattern" contains no durational limitation nor is it restricted to only basal rates, as opposed to bolus rates. With respect to limiting "personal delivery pattern" to just basal rates, MiniMed's arguments are unconvincing. In the cited text, there is nothing singling out basal rates as being connected to "personal delivery pattern." (D.I. 207, Ex. J at 35.) The patentee merely states that "the ability to switch between bolus and basal rates is not the same as the at least two personal delivery patterns . . ." (Id.) Moreover, the specification describes a bolus that is programmed ahead of time with a variable delivery pattern. (‘798 patent, col. 10:48-62.) In describing such a bolus, the specification states that "the user may program a profiled bolus that uniquely matches the needs of the individual user (for instance it may contain square, ramp, pulse or curved portions that make up the profile to be delivered over a period of time)." (Id. at 10:53-57.) This supports the argument that a "personal delivery pattern" could be used to supply a bolus as well as a basal rate. 25

--------- Footnotes ---------

25 Because I have construed "personal delivery pattern" to include both basal and bolus rates and I have construed "basal rate profile" to be limited to basal rates, see supra, Part IV.C.2.a, I am not confronted with a problem under the doctrine of claim differentiation. See Comark Commun. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998) (stating that "there is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims"). The doctrine of claim differentiation supports this construction of "personal delivery pattern."

--------- End Footnotes ---------

The intrinsic evidence does not support adding the "24 hour" limitation. The part of the specification cited by MiniMed to support adding this limitation represents only one of the preferred embodiments of the invention. (‘798 patent, col. 6:10-12,27:1-16.) It is improper to limit the claim to one of its preferred embodiments. Thus, I construe "personal delivery pattern" to mean "an individual pattern of multiple infusion rates."
Plaintiff's Construction
Physical material that was
especially created or
adapted to allow access to
an event, including, for
example, a card provided by
the seller or event managers
or a ticket embodiment such
as a paper or cardboard
ticket, a physical token, or
a smart card containing a
physical token.

Defendant's Construction
Physical material bearing or
containing information specific
to an individual ticket holder.

The dispute between the parties is whether "personalized physical material" is limited only to items that are "especially created or adapted to allow access to an event" (Plaintiff's position) or not (Defendant's position). In essence, the parties are disputing whether the term "personalized physical material" is broad enough to encompass items such as a credit card or driver's license (Defendant's position) or not (Plaintiff's position). To be clear, the claims require that access to events be granted without the presentation of "personalized physical material." Thus, under Plaintiff's proposed construction, the presentation of credit cards or driver's licenses for admission to an event would fall within the scope of the claims, whereas under Defendant's proposed construction it would not.

In the Court's view, Plaintiff's proposed construction does not comport with the ordinary meaning of "personalized physical material." Indeed, Plaintiff's proposed construction does not in any way embody the concept of "personalization." For instance, although Plaintiff notes that a dictionary defines the term "personalized" as "custom tailoring to the individual," (D.I. 60 at 10 (citing Alan Freedman, Computer Desktop Encyclopedia (Osborne/McGraw-Hill 1981-2008))), the Court simply does not see such a concept in Plaintiff's proposed construction. Rather, Plaintiff's proposed construction is instead focused on limiting "personalized physical material" to information "especially created or adapted to allow access to an event." In these circumstances, the Court is highly reluctant to adopt Plaintiff's proposed construction.

A review of the prosecution history further confirms that Plaintiff's proposed construction is inappropriate. During prosecution, the examiner focused on two pieces of prior art: U.S. Patent No. 6,067,532 issued to Lucas Gebb ("Gebb") and U.S. Patent No. 5,724,520 issued to Joel R. Goheen ("Goheen"). Both Gebb and Goheen pertain to ticketing systems. Gebb discloses that the ticket buyer "can use a ticketless entry into the event, such as, for example, by an e-token on a smart card." (D.I. 51, Exh. B at 7:12-13.) Goheen discloses that airline passengers can access an airplane using "an identification plastic card" that has a "card number . . . encoded onto a magnetic strip at the back" and that, if the card is lost, passengers can gain access to the airplane using identification "such as a driver's license or the like." (Id., Exh. C at 2:50-60, 6:8-10, 8:13-20.) In light of this art, following an April 2002 interview with the patentee, the Examiner "indicated that the claims as currently recited don't indicate that the authentication data is provided without the use of any man-made tokens or physical material, however, an added limitation to this effect would appear to be allowable over the prior art of record." (Id., Exh. I.) In response, the patentee amended the claims "to clarify that, according to the present invention, the authentication data does not constitute a physical material." (Id., Exh. J at 6.) The Examiner, dissatisfied with the amendment, responded as follows:

Furthermore, the claims do not currently recite that the buyer presents non-physical authentication data to gain access to the event. The claims merely recite that the paperless tickets are reassociated with authentication data of the ticket buyer and that the buyer presents this authentication data to gain access to the event. Examiner submits that this language does not preclude the use of physical forms of authentication data such as an identification card. Examiner submits that Gebb discloses wherein the buyer possesses a paperless ticket in the form of an electronic token (Col. 3, lines 34-42) wherein the ticket holder can use a ticketless entry into the vent (Col. 7, lines 7-13) and further include authentication data such as identification or unique security code (Col. 8, lines 63-67).

( Id., Exh. K at 3.) After an additional Examiner Interview to discuss this issue (see id., Exh. L), the Examiner, with the patentee's authorization, amended the claims to specifically state that the ticket buyer is granted access to the event "without the buyer presenting any personalized physical material." (Id., Exh. M.) In his statement for reasons of allowance, the Examiner explained that Gebb, either individually or in combination with other prior art of record, fails to teach that "the
buyer is granted access to the event by presenting the authentication data without presenting any personalized physical material." (Id., Exh. M at 6.)

Notably, during prosecution, the Examiner expressed concern that the "specification does not provide support for a system with an access device that accepts authentication data without the use of some form of physical man-made token such as a credit card or bar code." (D.I. 63, Exh. P.) In a supplemental response to an office action, the patentee asserted that they had identified support in the specification for this particular mode of operation and thus resolved the Examiner's concerns. (D.I. 63, Exh. R at 3.) Specifically, the patentee wrote that "[a]s Applicant pointed out during the interview, neither the specification nor the claims require presentation of a physical cell phone or credit card. Instead, the Application sets forth examples of non-physical information that can constitute authentication data (i.e., a credit card number or a phone number)." (Id.) The applicant further stated that "contrary to the Examiner's contention, the present Application provides support for an access device that accepts authentication data without the use of some form of physical man-made token such as a credit card or bar code." (Id. at 4.) In the Court's view, this exchange confirms that both the Examiner and the patentee mutually understood that to make the claims allowable, they would need to be amended to exclude the use of "personalized physical information" - such as credit cards - to gain access to an event.

In view of this prosecution history, the Court concludes that the claims should not be understood to encompass granting access to an event through the presentation of a credit card or driver's license. Accordingly, the Court will construe the term "personalized physical material" to mean, as Defendant contends, "physical material bearing or containing information specific to an individual ticket holder."

Plaintiff contends that this construction will exclude a preferred embodiment from the scope of the claims, and that such constructions are "rarely, if ever, correct and . . . require highly persuasive evidentiary support . . . ." Vitronics Corp. v. Conceptronic, 90 F.3d 1576, 1583 (Fed. Cir. 1996). In the Court's view, the prosecution history discussed above constitutes "highly persuasive evidentiary support." Furthermore, the Federal Circuit has explained that where, as here, both the claim language and prosecution history support a particular claim construction, that claim construction should perhaps nevertheless be adopted even if it excludes a sole embodiment. See Lucent Techs., Inc. v. Gateway, Inc., 525 F.3d 1200, 1216-17 (Fed. Cir. 2008) (based on the claim language and prosecution history, adopting a construction that excluded the sole embodiment).
erroneously implies that there are only two shafts; but Figure 1 of the patent illustrates a preferred embodiment showing three shafts, with "Angle A" associated with two shafts that rotate in one direction, and "Angle B" associated with a third shaft that rotates in the opposite direction. (‘763 patent, Fig. 1 & col. 3 lin. 55-56.) That embodiment is consistent with claim 5's language that the first vibratory drive assembly "includ[es] a first rotatable shaft" (without excluding the possibility of additional rotatable shafts), while the second vibratory drive assembly explicitly "ha[ve] a single second rotatable shaft." (‘763 patent, col. 8 lin. 4-8) (emphasis added). Third, GK's construction is inconsistent with the specification's explanation of how a phase angle is measured: referring to Figure 1, for example, the specification explains that angle A is "measured between an outwardly directed radial line from the center of the respective rotating shafts through the midpoint of the weights (or some other selected reference point on the shaft) and a data plane" and that the weight on the third shaft "will have an angle B similarly measured." (‘763 patent col. 4, lin. 5-9) (emphasis added). 4 But GK's construction accounts neither for the radial line nor the data plane and instead implies that a phase angle inherently depends on the relationship between two shafts. That limitation is not supported by the specification and is inconsistent with DiEuliis's understanding. (R.67, Ex. 2, Markman Tr. 30.) Fourth, GK's contention that its construction is consistent with Figure 5 is unpersuasive; although that drawing shows proximity switches detecting a "flag" or reference point on each of the shafts, it does not suggest that the process of detection is inherent to the phase angle itself. (‘763 patent, Fig. 5.)

4 GK contends that these angles are not "phase angles" because, in its view of Figure 1, they "inherently vary continuously during rotation of the shafts." (R.68, GK Post-Markman Br. 4.) Although the court does not dispute that, as understood in Figure 1, angles A and B may vary during rotation of the shafts, the court finds no language in claim 5 requiring that a phase angle remain constant. Moreover, the court disagrees with GK's contention that, because the portion of the specification discussing angles A and B deals with the resultant force acting on the conveyor, angles A and B could not be phase angles; the resultant force, as explained in this same section, depends upon the relative values of angles A and B. (‘763 patent col. 4 lins. 12-35.)

In contrast, CVE's proposed construction uses the words "angular position . . . with respect to a reference plane," which better captures the specification's notion of an angle measured "between . . . [a] radial line . . . and a data plane." In defining the term "phase angle" with reference to a "phase element," moreover, CVE's construction appropriately draws a connection implicit in the use of the modifier "phase" in each of the terms. And that the angular position is "of a phase element on a rotating shaft" also is consistent with the specification: in Figure 1 the radial line extends outward from the center of the shaft through a weight on the shaft, known as a "phase element," which operates as a "reference point" for measuring the angle. (‘763 patent Fig. 1.) Finally, CVE's proposed construction is consistent with DiEuliis's understanding of this term.

In its post-Markman brief, GK relies on the description of the ‘763 patent invention contained in U.S. Patent No. 6,024,210 (‘210 patent) to contend that CVE's proposed construction, which allows for the phase angle to change during operation of the machine, is contradictory. Specifically, it cites the following language in the ‘210 patent:

"The invention in the aforementioned Patent ['763 patent] addresses the problem of maintaining a predetermined phase angle for providing the desired angle of attack throughout an operating cycle of the conveyor through use of a control system."

(‘210 patent at col. 1, lin. 31-35.) This extrinsic description implies that a single predetermined phase angle could be maintained throughout an operating cycle of the ‘763 invention. But claim 5, which controls the court's analysis, explains that the resultant vibratory force is "determined by a relative phase angle relationship between [the] first and second phase elements" (emphasis added), which strongly implies that there is a phase angle associated with each phase element. Moreover, the specification in the ‘763 patent further explains that, "[b]y varying the relative positioning or relative phase angle between the shafts, the direction or angle of attack of the resultant forces can be changed . . . ." (‘763 patent at col. 4, lin. 30-33.) This language supports CVE's construction, which defines "phase angle" based on the positioning of a phase element with respect to a data plane, thereby allowing for the "relative positioning" of phase elements on different shafts, along with a "relative phase angle relationship," as contemplated by claim 5 and the rest of the specification. GK's construction, on the other hand, would read out the words "relative" and "relationship" from the claim. Accordingly, the court adopts CVE's construction.

- 3469 -
In this case, the district court determined that the Sweda catalogue anticipated, or disclosed and enabled each and every element of, the claimed invention. The Sweda catalogue advertises three different methods of making customized watches: a "full color watch rendering" method, a "mock-up sample" method, and a "speculative sample" method. The catalogue states that the first two methods use a computer laser printer, and the "speculative samples" method uses silk-screening, hot stamping, color process/offset printing, etchograph stamping, or engraving. The catalogue then shows images of color watch faces made with each of the advertised methods. All three methods require the customer to submit "camera ready, color separated artwork," i.e., separate pieces of black and white artwork representing each color in the design.

Top concedes that the Sweda catalogue does not teach expressly all limitations of the asserted claims. Hence, the only issue for this court to determine is whether the claim limitations not taught expressly by the Sweda catalogue are nevertheless disclosed inherently. This inherent anticipation question implicates claims 3 and 8. Claim 3 recites, in relevant part:

3. A method of constructing a functional multicolor element having indicia thereon, utilizing a computer and a color photocopier, comprising the steps of:

(a) electronically creating or providing in the computer an electronic simulation of the desired functional multicolor element, with indicia thereon,

(b) under the control of the computer, transmitting electronic signals from the computer to the photocopier so that the photocopier transforms the electronic simulation of the desired functional multicolor element onto a piece of sheet material . . . .

Col. 7, ll. 16-26 (emphases added).

The district court construed the term "color photocopier" to mean a "color printer." The district court noted that the Sweda catalogue expressly advertises: "A color picture of your customers custom logo produced by our new advanced computer laser printer." Based on this, the district court determined that the Sweda catalogue inherently disclosed a color printer because "those in the graphic arts industry would have recognized that a color printing device is necessarily present in the catalogue's description of 'a full color rendering' produced from a 'computer laser printer.'" Nevertheless, a color printer is not a color photocopier.

The '717 patent specification teaches that a "major component" of the invention "is a printer, preferably a color photocopier." Col. 3, ll. 62-64. At the same time, the patent also recognizes that a color photocopier does more than print in color -- it copies. Specifically, the specification teaches "photocopying with a color photocopier, such as of the types earlier described." Col. 6, ll. 20-21. The undisputed trial testimony of Dr. Steven J. Bares underscores this point: "Digital color copiers comprise a digital color scanner and a digital color laser printer which are directly connected together so that graphics transformed into digital information through the scanner are transmitted to the digital color laser printer for printing." As a matter of correct claim construction, therefore, a "color photocopier" requires the ability both to print and photocopy subject matter with color.

The difference between a printer and a photocopier may be minimal and obvious to those of skill in this art. Nevertheless, obviousness is not inherent anticipation. Jones v. Hardy, 727 F.2d 1524, 1529, 220 U.S.P.Q. (BNA) 1021, 1025 (Fed. Cir. 1984) ("though anticipation is the epitome of obviousness, [they] are separate and distinct concepts"). Given the strict identity required of the test for novelty, on this record no reasonable jury could conclude that the Sweda catalogue discloses either expressly or inherently a color photocopier. Because claim 3 is not inherently anticipated, dependent claims 4 and 5 also are not anticipated.

GO BACK
The district court found that Guttman was unlikely to prove that the Kwik-Kopy contained the claimed "photocopy machine." Though the court did not explicitly define photocopy machine in its order denying the preliminary injunction, it is clear that the court assigned it its ordinary meaning: a standard office photocopy machine. Guttman argued to the trial court, as it does here, that the patent explicitly defines photocopy machine to include any apparatus with scanning and image reproduction (i.e., printing) capabilities that operate in tandem--regardless of whether the scanner and printer equipment are housed separately.

As Kopykake notes, the preferred embodiments described in the specification are all conventional plain paper photocopy machines that conform to the district court's understanding of the "photocopy machine" claim limitation. However, after detailing the preferred embodiments, the specification explains ways in which the invention is broader than the specific embodiments illustrated in the drawings and detailed in the text; for example, the patentee states that edible toner formulae would be covered as well as the edible ink described and shown in the drawings. With respect to the photocopy machine, the patentee states:

Similarly, while the photocopy machine is shown as an integral unit, the scanning and image reproducer aspects need not be in the same housing. As will be appreciated, a characteristic of plain paper photocopy machines is that single button operation results in scanning of an image on the copy glass and reproduction of same on the [edible] web. Thus, where the scanning and image reproduction aspects are separate (within or without the same housing), but cooperate to produce the effect of a plain paper photocopy machine with, in essence, one button operation to scan and reproduce the image, the two aspects are deemed to define a photocopy machine as that term is used herein.

"'530 Patent, col. 6, lines 39-51 (emphasis added). We agree with Guttman that the above statement explicitly defines photocopy machine to include a system with separate scanner and printing capabilities so long as the two parts function cooperatively with one-button operation to produce the effect of a plain paper photocopy machine.

It is black letter law that a patentee can "choose to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term that could differ in scope from that which would be afforded by its ordinary meaning." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342, 60 U.S.P.Q.2D (BNA) 1851, 1854 (Fed. Cir. 2001). "The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1577, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996). Where, as here, the patentee has clearly defined a claim term, that definition "usually . . . is dispositive; it is the single best guide to the meaning of a disputed term." Id. In this case, the definition of photocopy machine provided in the specification does indeed dispose of the claim construction dispute, and it was error for the district court to overlook it.

Kopykake argues that we may affirm the district court's claim construction because the language from the specification quoted above was merely meant to ensure that the patent would capture plain paper photocopy machines that happened to place the scanning and image reproduction components in separate housings. In Kopykake's view, it was not meant to include any machine with both scanning and image reproduction capabilities that work cooperatively. We disagree. Had the patentee intended to claim only conventional plain paper photocopy machines, whether composed of a single housing or not, he would not have used the phrase "cooperate to produce the effect of a plain paper photocopy machine." Such a phrase indicates that the term includes an apparatus that is not a conventional "plain paper photocopy machine," but that nonetheless possesses scanning and reproduction features that work together to produce the effect of such a photocopy machine.

Kopykake also argues that the patentee expressly disclaimed systems without conventional photocopy machines during prosecution. Kopykake focuses on a statement in the prosecution history distinguishing a Patent Cooperation Treaty (PCT) application by explaining that the PCT application "is completely silent with respect to the use of a photocopy machine in a method of decorating an iced bake [sic] good." But far from disclaiming anything other than plain paper photocopy machines, this statement simply begs the question what a photocopy machine is. The PCT application, WO95/01735 to Douglas Stewart (the same inventor as for the '530 patent), discloses making edible substrate films for bakery applications, as well as a method of decorating the edible sheets with edible ink. The application discusses many different methods of depositing an image on the edible sheets, including conventional printing presses, silk-screening, and ink-jet printing. What it does not disclose, however, is a scanner combined with an inkjet printer--or any other machine that contains both scanning...
and reproduction capabilities working together to give the effect of one-button copying. Therefore, there was no need for the patentee to disclaim all machines other than conventional photocopiers in order to distinguish the PCT application, and the claims should not be narrowed on this basis.

Because the patentee provided an explicit definition of "photocopy machine" in the specification, and because no other intrinsic evidence casts doubt on that definition, the patentee's definition controls. Thus, a photocopy machine is defined to include not only conventional plain paper photocopy machines, but also systems with separate scanner and printing capabilities so long as the two parts function cooperatively with one-button operation to produce the effect of a plain paper photocopy machine.

2913

D. "photographic quality"

a. Parties' Positions

As with the preceding terms, Plaintiff contends that the "photographic quality" does not require construction but offers a construction nonetheless. "Photographic quality" is found only in the text of claim 21. The parties' main dispute is whether the claim term is indefinite.

Plaintiff
(Having the) accuracy or representation sufficient to resemble a photograph

Defendants
Indefinite

Plaintiff argues that claim 21 sufficiently provides the public with notice of what is required of the "enlarged graphic" print. Dkt. No. 104 at 31. Plaintiff argues that "photographic quality" is a common term such that a person of ordinary skill in the art would understand its meaning. Id. at 32. As support, Plaintiff cites to Defendant 3M's patents and advertising materials using the same term. Id. at 32-33.

Defendants argue that "photographic quality" lacks an "objective anchor." Dkt. No. 110 at 25. That is, Defendants contend that "photographic quality" must fail because it relies too heavily on subjective opinion and that the intrinsic evidence does not provide an objective standard for "photographic quality." Id. at 27. For support, Defendants cite to the deposition testimony of one of Plaintiff's founders, Ed Cies, and attempt to correlate "photographic quality" to other indefinite terms like "aesthetically pleasing." Id. at 25-26.

In reply, Plaintiff argues that Mr. Cies is not one of ordinary skill in the art and that even though the term "photographic quality" could mean different things to different people, it is not indefinite. Dkt. 119 at 10-11.

b. Court's Construction

The test for indefiniteness is whether a person of ordinary skill in the art would understand all of the language in the claims -- that is, understand what is claimed -- when they are read in light of the specification. Morton Int'l Inc. v. Cardinal Chem. Co., 5 F.3d 1464, 1470 (Fed. Cir. 1993); see also, Young v. Lumenis, Inc., 492 F.3d 1336, 1346 (Fed. Cir. 2007). If the skilled artisan would understand the bounds of the claim when read in light of the specification, then the claim satisfies the definiteness requirement of 35 U.S.C. § 112 P2. The definiteness requirement does not mandate absolute clarity. The proper inquiry is whether the terms can be given any reasonable meaning, and a difficult issue of claim construction does not automatically require a finding of indefiniteness. Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). A finding of indefiniteness requires showing by clear and convincing evidence that the patent does not meet the statutory requirements and is thus invalid. Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376 (Fed. Cir. 2001). In determining whether a claim term fails for indefiniteness, general principles of claim construction apply. Young, 492 F.3d at 1346.

In this case, Defendants argue that a person of ordinary skill in the art would not understand the meaning of "photographic quality." For support, Defendants cite to Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342 (Fed. Cir. 2005). In
Datamize, the Federal Circuit affirmed the district court's finding of invalidity based on indefiniteness of the phrase "aesthetically pleasing" because none of the evidence provided any meaningful definition for the phrase. Datamize, 417 F.3d at 1349-1350. The Datamize panel examined the intrinsic and extrinsic evidence for some objective standard with which to "anchor" the subjectivity of the term "aesthetically pleasing." Id. at 1351-1355. After a similar examination of the relevant evidence, this Court finds that, unlike "aesthetically appealing," the phrase "photographic quality" is sufficiently defined so as to meet the requirements of § 112 P2.

Defendants -- who bear a heavy burden to demonstrate indefiniteness -- have failed to demonstrate that a person of ordinary skill in the art could not discern a meaningfully precise scope of "photographic quality." Defendants argue that "no portion of the intrinsic evidence … provides an 'objective anchor.'" Dkt. No. 110 at 27. This argument does not withstand a thorough examination of the claims and specification.

The claim language uses "photographic quality" in independent claim 21 to describe the "graphic print." The subsequent dependent claims describe the print as being able to create a "substantially full-size, full scale simulation" of a retail product or a "photographic simulation" of an object, floor covering, or ground terrain. '632 Patent c.6 ll. 34, 41, 43-45. Additionally, the specification repeatedly provides other situations where the claimed inventions may be used. For example, the specification discusses using the images to "create a simulated decor." Id. at c.2 l.17. The specification describes the images used in conjunction with the invention using words like of "simulation," "illusion," and life-sized decor. For example:

[P]hotographic floor tiles with life size photographs of naturally occurring objects such as sand, water, leaves, foliage, rock, or marble can be used to create a simulation of those articles without actually having to use the articles themselves in the setting. A life size photographic floor tile of a sidewalk, rocky path, or a stream or pond, or the like can be used appropriately. Similarly, a beach or water setting could be simulated using the photographic floor tiles. Also, a marble floor could be simulated using photographic tiles made from a photograph of a marble floor. In this manner the photographic tiles create the illusion that the photographed item is actually present.

Id. at c.2 ll.18-29 (emphasis added). Thus, even though the specification does not contain the phrase "photographic quality," it is within these situations that the boundaries of "photographic quality" are defined such that a person of ordinary skill would understand the scope of the asserted claims. A skilled artisan would understand that the graphic prints must be of sufficient quality to be able to "create the illusion" or simulate an environment or terrain, such as a marble facade. That is, regardless of size, the images must be of sufficient resolution, clarity, and accuracy to do so. Thus, a person of ordinary skill would know that the patent recognized the image quality generally associated with a photograph as integral to the purported invention.

Additionally, Defendants' argument that even Mr. Cies and Ms. Bisker cannot agree on "photographic quality" lacks merit. Bancorp Services, L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1371 (Fed. Cir. 2004) ("[I]f the meaning of the claim is discernible, 'even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds.'") (quoting Exxon Research and Eng'l, 265 F.3d at 1375).

In sum, the term "photographic quality" is not insolubly ambiguous so as to render it indefinite. A print or image may be of photographic quality if its resolution, clarity, and accuracy allow it to simulate or create the illusion -- at least in two dimensions -- of specific objects and things. Generally, a photograph accurately reflects its subject's attributes such as color, shape, or size. A photograph can be distinguished from other media on the basis of clarity and resolution as well. In light of the foregoing, the Court construes "photographic quality" to mean "having the qualitative properties -- for example resolution, clarity, and accuracy -- of a photograph."

**2914**

B. "photographic print"

a. Parties' Positions

The parties propose the following constructions for "photographic print," which is present in claims 1 - 4 of the '632 Patent.
The primary dispute between the parties is whether the claim term should include images generated through ink printing.

**Plaintiff**

Plain meaning

An enlarged positive image on light-sensitive material made from a film negative or plate and

Alternatively, "a reproduction resembling a photograph"

Plaintiff again argues that the ordinary meaning sufficiently defines "photographic print." Again, though, Plaintiff submits that a combination of the dictionary definitions for "photographic" and "print" would be appropriate should the Court feel a construction is warranted. Dkt. No. 104 at 25-26.

**Defendants**

Defendants' main argument is that their construction most accurately reflects "the patentee's characterization of her invention as involving traditionally developed images and her dismissal of ink printing." Dkt. No. 110 at 15. Defendants contend that the patent expressly defines "photographic printing" to exclude ink printing. Id. at 16. Defendants cite multiple portions of the specification to support their position that the patentee intended a "clear distinction" between photographic printing and ink printing:

Also, large format ink prints have been used to make large scale posters. However, ink printing is very expensive and is usually only cost-efficient where very high volumes are involved. Furthermore, ink printing does not provide the high quality images which can be achieved through photography. As a result, photographic printing is far superior to ink printing where low volume and high quality products are desired. '632 Patent at col.1, ll.43-50.

Because of its lower quality images and higher cost, ink printed images are not a viable alternative for the photographic tiles of the present invention. The photographic tiles of the present invention are typically used where a low volume of tiles is desired and a very high quality print is desired. As a result, tiles using ink printed images would be prohibitively expensive and of an inferior quality. Id. at col.2, ll.1-7.

Defendants claim that these statements represent clear expressions of manifest exclusion or restriction that disavow ink printing. Dkt. No. 110 at 17 (citing Teleflex v. Ficosa North America Corp., 299 F.3d 1313, 1328 (Fed. Cir. 2002)).

b. Court's Construction

Plaintiff argues that these statements provide "background" of the prior art or "are nothing more than general statements about advantages over the prior art, which is insufficient as a matter of law to create a disavowal of claim scope." Dkt. No. 104 at 28-29. To the contrary, the patentee's statements about the potential role of ink printing clearly and unmistakably disclaim ink printing as a means to generate images.

First, Plaintiff contends that the embodiments in the specification should not limit broader claim language. Dkt. No. 104 at 28. While this Court generally agrees, the limiting statements were made in the Background of the Invention and the Summary of the Invention portions of the specification, not in the Description of the Preferred Embodiment. A statement's location is not determinative, but the location can signal the likelihood that the statement will support a limiting definition of a claim term. Statements that describe the invention as a whole, rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term. See C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) (finding that the description of the claimed "plug" in the summary of the invention section globally required a pleated surface); see also, SciMed Lifesystems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337, 1343 (Fed. Cir. 2001) (concluding that characterization of one structure as part of the "present invention" is strong evidence against reading the claims to encompass the opposite structure).

Second, Plaintiff points to a statement in the specification as evidence that the patentee intended no disavowal. The statement that "the photographs used in the photographic tiles can be created using conventional or digital photography" demonstrates that the patentee did not disclaim ink printing. Plaintiff argues. This language, however, must be read in context with the rest of the specification. In the same portion of the specification, the patentee disparages the ink printed images as "not a viable alternative for the photographic tiles of the present invention." This latter phrase -- significantly
The Court finds that the term "image" is too broad, and the parties do not dispute the construction of "print" but rather the proposed construction, however, is too narrow. Therefore, the Court construes the term "print" to mean "a photographic print" to mean "a photograph that has been printed or a print created by conventional photographic processes rather than by ink printing." 2

In sum, Defendants have met their burden of demonstrating that the patentee has surrendered ink printing. Defendant's proposed construction, however, is too narrow. Therefore, the Court construes the term "photographic print" to mean "a print created by conventional photographic processes rather than by ink printing." 2

---

2 The Court finds that the term "image" is too broad, and the parties do not dispute the construction of "print" but rather
what constitutes a "photographic print" within the scope of the patent.

D. "Physical Indicia"

L-F moves the Court to construe the term "physical indicia" as it is used in the asserted claims of "the 612 patent" and the 197 patent. 18

Each of the asserted independent claims of the 612 patent and the 197 patent includes the term "physical indicia." 19 These "physical indicia" relate to various properties of a syringe such as the capacity of a syringe, the distance of the plunger from the end of a syringe, the amount of fluid in a syringe, the end of travel position of an injector ram, the range of travel of an injector ram, and an offset value.

18 The asserted claims of the 612 patent are 7, 8, 10, and 11 and the asserted claims of the 197 patent are 1, 2, 4, 5, 7, 8, 10, 11, 13, 14, 16, 17, 19, 20, 22, 23, 25, and 27.

19.

...a detector located proximate to a syringe . . .for detecting a physical indicia on said syringe related to the capacity of said syringe, and generating an electrical signal representative of said physical indicia,

612 patent, Claim 7,

detecting a physical indicia on a syringe . . ., said indicia being related to the capacity of said syringe, and generating an electrical signal representative of said physical indicia...

612 patent, Claim 10

...a syringe having . . . physical indicia related to the distance of the plunger from an end of said syringe ...

197 patent, Claim 1

... detecting a physical indicia on a syringe installed on said injector, said indicia being related to the distance of the plunger from an end of said syringe ...

197 patent, Claim 4

... a syringe having . . . physical indicia related to the amount of fluid in the syringe

...

197 patent, Claim 7

...detecting a physical indicia on a syringe installed on said injector, said indicia being related to amount of fluid in said syringe ...
197 patent, Claim 10

...a syringe having ... physical indicia related to the end of travel position of an injector ram coupled to the plunger when the syringe is coupled to an injector ...

197 patent, Claim 13

...detecting a physical indicia on a syringe installed on said injector, said indicia being related to the end of travel position of a ram moved by said motor when said syringe is mounted to the injector ...

197 patent, Claim 16

... a syringe having ... physical indicia related to the range of travel of an injector ram coupled to the plunger when the syringe is coupled to an injector ...

197 patent, Claim 19

... detecting a physical indicia on a syringe installed on said injector, said indicia being related to the range of travel of a ram moved by said motor when said syringe is mounted to the injector ...

197 patent, Claim 22

... wherein the control circuit is operable obtain an offset value from physical indicia detected on the syringe ...

197 patent, Claim 25

... detecting a physical indicia on a syringe . . . , said indicia being related to the capacity of said syringe, to obtain an offset value, computing a value indicative of the location of said plunger within said syringe by applying the store offset value to the tracked location of said motor, and ceasing motion of said plunger when said computed value indicates that said plunger is at an end of said syringe.

197 patent, Claim 27

(Doc. No. 30, Exhs. 3, 4).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

L-F urges this Court to give the term "physical indicia" its ordinary and customary meaning without looking beyond the claim language. Physical is defined as "of or relating to ... material things as opposed to things mental, moral, spiritual, or imaginary." Webster's Third New International Dictionary at 1706 (1971). Indicia is defined as "a distinctive mark that indicates or that is felt to indicate the nature or quality or existence or reality of something." Id. at 1150. Thus, the term "physical indicia" means a tangible marking on a syringe that relates to a specific property of the syringe. L-F proposes that these specific properties include the capacity of a syringe, the distance of the plunger from the end of a syringe, the amount of fluid in a syringe, the end of travel position of an injector ram, the range of travel of an injector ram, and an offset value that is related to the capacity of a syringe. (Doc. No. 164, p. 24).

Medrad does not appear to disagree that the term "physical indicia" means a tangible marking on a syringe that relates to a specific property of the syringe. Rather, Medrad is arguing that "physical indicia", as used in the 612 and 197 patents, is limited only to indicia that indicate the length of an extender element used in a syringe. 20 (Doc. No. 172, pp. 29-30).

- - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

20 An extender is an element in a syringe that compensates for variations in the location of the plunger in pre-filled syringes to accommodate varying syringe volumes.
It should be noted that the language of the asserted claims does not limit the term "physical indicia" to the use of an extender element. Rather, the claim language unambiguously states that "physical indicia" are related to capacity of a syringe, the distance of the plunger from the end of a syringe, the amount of fluid in a syringe, the end of travel position of an injector ram, the range of travel of an injector ram, and an offset value. Supra, fn. 19. Therefore, unlike the ambiguous language construed in Section III(B) ("syringe receiving opening"/requirement of a pressure jacket), the claim language relating to the term "physical indicia" is clear and unambiguous. This distinction is significant because it affects the manner in which this Court will view the rest of the intrinsic evidence, i.e., the specification and the prosecution history. The Federal Circuit has recently held that:

If the claim language is clear on its face, then our consideration of the rest of the intrinsic evidence is restricted to determining if a deviation from the clear language of the claims is specified. A deviation may be necessary if "a patentee [has chosen] to be his own lexicographer and use terms in manner other than their ordinary meaning." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1576. A deviation may also be necessary if a patentee has "relinquished [a] potential claim construction in an amendment to the claim or in an argument to overcome or distinguish a reference." Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 979, 52 U.S.P.Q.2D (BNA) 1109, 1113 (Fed.Cir. 1999). If however the claim language is not clear on its face, then our consideration of the rest of the intrinsic evidence is directed to resolving, if possible, the lack of clarity.

Interactive Gift Express, 256 F.3d at 1331. Therefore, when construing the term "physical indicia", the Court will rely on the rest of the intrinsic evidence to determine only if a deviation from the clear language of the claim is specified rather than to resolve the meaning of the claim language, as it did in Section III(B).

Medrad bases its argument that "physical indicia" is limited to indicating the length of an extender on the following excerpts from the specifications of the 612 and 197 patents 21:

The offset value. . . may be automatically computed by detecting physical indicia on the syringe or extender which indicate the length of the extender.

612 patent, Abstract

Alternatively, the offset value may be automatically computed by detecting physical indicia on the syringe or extender which indicate the length of the extender.

612 patent, col. 4, lines 2-3

197 patent, col. 4, lines 1-2 22

(Doc. No. 30, Exhs. 2, 3). Medrad argues that this language defines "physical indicia" as indicia related only to length of extender. Not surprisingly, L-F counters that this language is merely a preferred embodiment in which the physical indicia on the syringe indicates a specific property -- the length of an extender. 23 (Doc. No. 182, p. 15). L-F argues that this embodiment does not preclude the use of physical indicia in relation to other properties of the syringe (i.e., capacity, distance of the plunger from the end, amount of fluid, etc.).

21 As explained in detail in footnote 4, the 612 and 197 patents have the same specification.

22 Medrad also cites to unasserted Claim 3 of the 612 patents which states, in pertinent part, that the injector contains a detector used for "detecting the length of the extender which is attached to said plunger from physical indicia on the syringe or extender and generating an electrical signal representative of the detected length..." (Doc. 30, Exh. 3). In light of the law of claim differentiation discussed in section III(B), this claim language does not support Medrad's argument. Unlike the situation in section III(B), L-F is not attempting to broaden the asserted claims beyond the scope of the claim language.
23 The Court notes that the language in question falls under the heading "Summary of the Invention" as opposed to the later heading of "Description of the Preferred Embodiments."

Medrad also cites to the prosecution history of the 197 patent to support its interpretation. (Doc. No. 172, pp.30-32). Claim 7 of the 197 patent includes the element "physical indicia related to the amount of fluid in the syringe," and claim 10 of the 197 patent includes the element of a "[physical] indicia being related to amount of fluid in said syringe." During the prosecution of the 197 patent, the PTO Examiner rejected L-F's proposed claims 7 and 10 due to failure to comply with the written description requirement of 35 U.S.C. section 112. In the Detailed Action, the PTO Examiner, in rejecting claims 22-45, explained that

The specification, as originally filed on 28 August 1997, does not adequately support the embodiments set forth in claims 22-27 wherein the syringe includes physical indicia related to the position of the plunger; claims 28-33 wherein the syringe includes physical indicia related to the amount of fluid in the syringe; claims 34-39 wherein the syringe includes physical indicia related to the end of travel position of a ram moved by the motor; and claims 40-45 wherein the syringe includes physical indicia related to the range of travel of a ram moved by the motor. The only recitation in the specification regarding the indicia on the syringe is on page 6, lines 23-26:

'Alternatively, the offset value may be automatically computed by detecting physical indicia on the syringe or extender which indicate the length of the extender.'

Thus there is inadequate disclosure of such indicia being related to plunger position, fluid quantity, end of travel position of the ram, and range of travel of the ram as now claimed. The disclosure only provides support for the indicia being related to the length of the extender.

The PTO Examiner rejected claims 22-45 based on failure to comply with 35 U.S.C. section 112, first paragraph. (Id. at 3).

In response to the PTO Examiner, L-F argued that the other elements of "capacity of the syringe" and "amount of fluid in the syringe" were related to the length of the extender, and thus, those elements were supported in the specification through the references to the length of the extender:

With respect to claims 28-33, the Examiner submits that the specification does not support physical indicia on a syringe related to the amount of fluid in the syringe, and does not support computing the amount of fluid in the syringe.

In response, Applicant would note that a comparison of Fig. 1A to Fig. 1B clearly shows that the capacity of a syringe having an extender is less than the capacity of a syringe that does not have such an extender. Notably, the syringe shown in Fig. 1B is a 'pre-filled' syringe, thus the syringe is filled to its capacity when it is installed on the injector. Since the capacity of the syringe is directly related to the length of the extender in the syringe, it follows that the amount of fluid in the syringe is directly related to the length of the extender. Accordingly, the indicia recited at page 6, which indicates the length of the extender, also thereby indicates the amount of fluid in the syringe. Indeed, at page 4, line 4 it is stated that the extender 'reduces the initial volume of the pre-filled syringe'. Accordingly, Applicant submits that the specification clearly describes a syringe having indicia related to the amount of fluid in the syringe.

(Id. at 12-13). L-F made similar arguments with respect to physical indicia relating to the distance of the plunger from the end of a syringe, the end of travel position of an injector ram, and the range of travel of an injector ram. (Id. at 10-12, 13-16). The patent was subsequently issued by the PTO without any substantive amendment by L-F of the claims or specification. (Doc. No. 174, Exh. 4, Notice of Allowance on 4/1/99, p. 139).

The Court would agree with Medrad's argument that the term "physical indicia" is limited to indicia related to the length of the extender if the preceding excerpts from L-F's response to the PTO Examiner reflected the entirety of L-F's response. However, in the final paragraph of L-F's response, L-F stated that:
Applicant would further note that although the supporting specific embodiment of the invention found in the specification is disclosed in the context of compensating for the presence of a plunger extender attached to the plunger, the independent claims do not necessarily require a plunger extender, but rather are directed generally to using information from indicia on a syringe, to compensate for syringes having differing initial plunger positions, differing initial amounts of fluid, differing end-of-travel positions or ranges of travel for the ram.

(Id. at 16). Thus, L-F unequivocally stated to the PTO Examiner that the asserted claims of the 197 patent were not limited to indicia relating to the length of an extender.

In order to narrow unambiguous claim language based on the prosecution history, an accused infringer must "demonstrate that the patentee 'defined' the claim as 'excluding' a broader interpretation 'with reasonable clarity and deliberateness.'" Pall Corporation v. PTI Technologies, Inc., 259 F.3d 1383, 1392-93 (Fed.Cir. 2001)(quoting Northern Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1294-95 (Fed.Cir. 2000)). Based on the final paragraph of L-F's response, the Court cannot conclude that L-F limited the asserted claims to "physical indicia" only related to the length of an extender. L-F clearly viewed "physical indicia" as encompassing other syringe characteristics besides the length of the extender.

Thus, the Court construes the term "physical indicia" as a tangible mark on a syringe relating to various properties of the syringe. The properties may include the capacity of a syringe, the distance of the plunger from the end of a syringe, the amount of fluid in a syringe, the end of travel position of an injector ram, the range of travel of an injector ram, or an offset value.

Medrad argues that in the event the Court accepts L-F's construction of the term "physical indicia", the 612 and 197 patents are invalid pursuant to 35 U.S.C. § 112 for lack of enablement and failure to provide an adequate written description. (Doc. No. 172, pp. 32-33). This argument will be addressed in section VII(A).

Each of the asserted claims, except for claim 25 of the '197 patent, requires that the syringe possess "physical indicia related to" a property of the syringe. For example, claim 7 of the '197 patent, quoted above, recites "physical indicia related to the amount of fluid in the syringe," while other claims recite physical indicia related to "the distance of the plunger from the end of said syringe," "the end of travel position of an injector ram," "the range of travel of an injector ram," and "the capacity of the syringe."

Medrad argues that we should construe the term "physical indicia" as limited to features that indicate the length of the extender. To support its position, Medrad asserts that the only reference to the "physical indicia" limitation in the specification describes the "physical indicia" as providing information as to the length of the extender:

In preferred embodiments, the offset value may be computed by querying the operator as to the capacity of the syringe and determining therefrom the appropriate offset value. The controller may be configurable so that this query is not made (for example, if the injector will not be used with pre-filled syringes, and therefore the offset value will not change). Alternatively, the offset value may be automatically computed by detecting physical indicia on the syringe or extender which indicate the length of the extender.

The claim language itself does not limit "physical indicia" to indicia related to the length of the extender. Instead, the various claims explicitly state that the physical indicia are related to a variety of properties, such as the amount of fluid in the syringe, the distance of the plunger from the end of the syringe, the distance to the end of the plunger's travel position, and the range of travel of the ram. Medrad thus must overcome the "heavy presumption' that [the claims] mean what they say." Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002); Teleflex, 299 F.3d at 1325 ("We indulge a 'heavy presumption' that a claim term carries its ordinary and customary meaning."). As we explained above, it is improper to read limitations from a preferred embodiment described in the specification--even if it is the only embodiment--
into the claims absent a clear indication in the intrinsic record that the patentee intended the claims to be so limited. See ACTV, 346 F.3d at 1088; Brookhill-Wilk, 334 F.3d at 1301; Altiris, 318 F.3d at 1371, 1373; Teleflex, 299 F.3d at 1327. Although the passage Medrad cites describes an embodiment in which the physical indicia are related to the length of an extender, Medrad does not point to any language in the specification that expresses an intention to limit the scope of the term "physical indicia" to that embodiment.

Nor does the prosecution history support Medrad's narrow reading of the asserted claims. During the prosecution of the application that matured into the '197 patent, the examiner rejected the claims as lacking support for physical indicia related to properties other than the length of the extender. The applicants responded by explaining that various properties, such as the amount of fluid in the syringe, could be calculated from the information as to the length of the extender. The applicants went on to explain, however, that

although the supporting specific embodiment of the invention found in the specification is disclosed in the context of compensating for the presence of a plunger extender attached to the plunger, the independent claims do not necessarily require a plunger extender, but rather are directed generally to using information from indicia on a syringe, to compensate for syringes having differing initial plunger positions, differing initial amounts of fluid, differing end-of-travel positions or ranges of travel for the ram.

Far from a clear disavowal of claim scope, the quoted passage makes clear that the application contemplated that the claims of the '197 patent would encompass "physical indicia" related to properties other than the length of an extender.

Moreover, Medrad's own version of the prosecution history of the '612 and '197 patents cuts against reading the claims at issue restrictively. The original claims in the applications for the two patents limited the term "physical indicia" to features indicating the "length of the extender" and excluded features indicating other syringe properties such as "the capacity of the syringe." According to Medrad, when the applicants learned of Medrad's injectors they amended the claims at issue in an effort to encompass Medrad's injectors, as they did with respect to the "pressure jacket" issue. That characterization of the prosecution history, however, is unhelpful to Medrad's claim construction argument: By broadening the claims to cover Medrad's devices, the applicants covered physical indicia other than those indicating the length of an extender. The district court therefore correctly concluded that the term "physical indicia" is not limited to indicia related to the length of an extender.

Medrad further suggests in passing that the broad reading of "physical indicia" given by the district court would render the asserted claims of the '612 and '197 patents invalid for lack of a sufficient written description or enablement. As we discussed above, however, the canon that claims should be construed to preserve their validity, if possible, applies only if the scope of the claims is ambiguous. The asserted claims at issue in this case clearly cover more than the "indicia indicating the length of the extender." We therefore may not interpret the claims narrowly because of concerns about their possible invalidity. Rather, the issue of invalidity must be addressed head-on in the remand proceedings where the questions of priority, and the adequacy of the written description and enablement, will be directly presented.

"pin"

Claims 4, 12, and 18 of the '767 Patent contain the term "pin." SHURflo contends that "pin" means "a piece used to attach or support," while Defendants contend that "pin" means "a separate elongated fastener." The parties' dispute centers around whether a fastener must be "separate" and "elongated."

SHURflo's proposed construction is again unduly broad as the several other mechanisms disclosed in the patent would seem to fit the definition (e.g., a "hook" or "clip" is used to attach or support). Defendants argue that because the specification provides "[p]ins or screws 82 are placed into through bores 80 and into holes 24 where they are secured," a pin is necessarily a "separate elongated fastener" to attach a pump to the housing. '767 Patent, col. 6:34-36. Although Defendants are correct that a "pin," as disclosed in the cited embodiment, is not integral with the housing, the specification does not indicate that the "pin" must be completely separate. In addition, the term "pin" is a commonly understood word and there is no support in the specification to limit "pin" to an "elongated" fastener. Although "pins" are generally elongated (e.g.,
sewing pin, cotter pin, or split pin), a "pin" does not necessarily have to be elongated (e.g., pushpin or thumbtack). Rather, the essence of a "pin," as used in the specification and elsewhere, is that it works by being inserted through bores and holes to fasten or hold by insertion. See '767 Patent, col. 6:34-36. Accordingly, the Court construes the term "pin" to mean "a device not integral with the housing that assists in holding something by insertion."

Claim 8 is dependent upon claim 1 and claims: "The system of claim 1 wherein the base mounting means includes a recess therein, and wherein the stem mounting means includes an extending pin for mating with the recess." 313 patent, col. 6, 11. 1-4.

"Extending pin" and "recess"

Zimmer asserts that "extending pin" should be construed as "the male component of a Morse taper." To support this reasoning, Zimmer points to the specification, which states that the mounting structure, itself, is a Morse taper. As such, Zimmer asserts that the proper construction of "extending pin" is the pin, or the male component, of a Morse taper connection. 04/06/05 Zimmer Mem. at 16. After consulting the specification, and in coordination with the construction of "extending pin," Zimmer asserts that the proper construction of "recess" is as the "female component of a Morse taper." Id. Howmedica only responds to these arguments by way of presenting anticipation arguments.

In construing the stem mounting means of claim 1, the Federal Circuit stated that the disclosed structure for performing the mounting function is the Morse taper. The specification states that a Morse taper includes an extending pin and a recess. 313 patent, col. 3, 11. 45-50. The base mounting means must include a recess therein, and the stem mounting means must include an extending pin for mating with the recess. 313 patent, col. 3, 11. 45-48. Moreover, this Court finds that Zimmer's construction is supported by the intrinsic evidence and more clearly defines the terms' boundaries than if they were left otherwise undefined. Stmicroelectronics, Inc. v. Motorola, Inc., 327 F.Supp.2d 687, 697 (E.D. Tex. 2004). Accordingly, this Court adopts Zimmer's construction of "extending pin" as the "male component of a Morse taper" and "recess" as the "female component of a Morse taper."

The defendants have urged the court to construe this limitation to mean "a pin, displaced from the side of said shaft." The plaintiff argues that construction of this term is unnecessary, as the terms are readily understandable. The court agrees with the plaintiff that the terms used in this element are readily understandable and that no construction is necessary.

The eighth disputed claim language states:

pins attached to said storage structure for releasably engaging said bores,

Joint Statement, Table X, at 74-75. The language is clear and does not need construction. The language describes pins that engage the bores to secure the cover member. Sukup argues that the phrase must be interpreted under the means plus function method. The Court disagrees. The word "means" is not used so there is no presumption. The language also describes objects, pins that are part of a latching apparatus. The means plus function analysis therefore does not apply.
2. Claim 8(e) -- "piping network"

Limitation (e) of claim 8 claims, "piping network interconnecting said first and second containers, said filter unit and said first and second couplings". (Dkt. entry no. 1, Ex. A, '511 patent, at col. 12, lines 5-7.) Defendants argue that they stay true to the language of this limitation by interpreting it as "a network of pipelines that interconnects the various elements." (Defs. Resp. Br., at 18 (emphasis in original).) RTI argues that "Defendants have done no more than paraphrase the claim language for this claim element, which suggests that the claim does not need construction." (RTI Reply Br., at 19.) Based on the parties' submissions at this juncture, the Court believes there is no dispute with respect to limitation (e) of claim 8, and thus, we will not construe this limitation at this time, but note that it should be read in accordance with the ordinary and plain meaning of its terms.

7. Piston

Synventive proposes "a drive mechanism having a flange defining a radial clearance for self-alignment of the actuator cap with the piston." Husky proposes "a drive mechanism." The parties agree that a piston is a drive mechanism, but Synventive claims that the piston of the claim language must be read in light of the specification to include an annular flange that extends inward from the piston and creates a clearance that enables limited lateral motion as the hot runner manifold expands. See '025 Patent col.7 l.1-4; figs. 3-6.

One of the objects of the invention is "to provide an improved valve pin actuator that provides for a clearance between the actuator piston and actuator cap." '025 Patent col.2 l.24-26. The '025 Patent also describes one of the benefits of the invention as essentially a self-alignment between the actuator assembly and the valve pin assembly . . . ; the valve pin assembly is supported in such a manner that would allow some limited side-to-side motion in any direction thereof as the hot runner manifold undergoes certain expansion . . . . This is facilitated by the interaction of the ring, actuator cap and the annular flange extending inwardly of the piston. When the manifold, and valve pin assembly mounted thereto, moves, the flange and piston can move side to side within the clearance that is formed between the actuator cap and the flange.

'025 Patent col.6 l.64-col.7 l.11.

Claim 12 does not specifically recite a requirement that the piston include an annular flange, however. Other claims in the '025 patent do recite the requirement that the piston have an annular flange: for example claim 5 and claim 7 as they depend from claim 1. According to the principles of claim differentiation a piston as used in the '025 patent need not therefore include an annular flange; otherwise the language in dependent claims 5 and 7 would be superfluous, and claim 5 might well be invalid. The term is construed as "a drive mechanism that moves the valve pin."
